If ψ have other values, the expression (b) or the density of light will vanish when $R=0$, $R=\lambda$, $R=2\lambda$, &c. But the equivalent of R containing, as a multiplier, $\sin.^2 i$; (i being the incidence of a ray on the crystal after diverging from A; or the angle which, as above mentioned, a ray from A makes with the axis AB) one giving successively to R the values 0, λ, 2λ, &c., it is found that $\sin. i$ has corresponding values proportional to 0, $\sqrt{\frac{2\lambda}{T}}$, $\sqrt{\frac{4\lambda}{T}}$, $\sqrt{\frac{6\lambda}{T}}$, &c.; (T being the thickness of the plate of crystal) and since the expression (b) has the same value, and vanishes or is a maximum, for all rays whose angles i of incidence in the conical pencil diverging from A are the same, it follows that, about the axis of the field of view, there are dark rings whose radii have the proportions of $\sqrt{2}$, $\sqrt{4}$, $\sqrt{6}$, &c. The expression (b) is a maximum when $R=\frac{1}{2}\lambda$, $\frac{3}{2}\lambda$, $\frac{5}{2}\lambda$, &c., or when $\sin. i$ has values proportional to $\sqrt{\frac{\lambda}{T}}$, $\sqrt{\frac{3\lambda}{T}}$, $\sqrt{\frac{5\lambda}{T}}$, &c.; and it follows that, about the axis of the field, there is a series of bright rings whose radii have the proportions of $\sqrt{1}$, $\sqrt{3}$, $\sqrt{5}$, &c.

The expressions (b) and (c) added together produce a^2; hence the tints of the several rings formed when the planes of polarization in AB and AC are coincident are complementary to those which are formed when those planes are perpendicular to one another: and in the former case the bright rings have radii which are proportional to $\sqrt{2}$, $\sqrt{4}$, $\sqrt{6}$, &c., while the dark rings have radii proportional to $\sqrt{1}$, $\sqrt{3}$, $\sqrt{5}$, &c.

For the investigation of the phenomena of the rings seen (as in *Fig.* 4) when IK is a bi-axal crystal having its surfaces cut perpendicularly to the plane passing through the axis; and also for the phenomena presented when a plate of crystal, uni-axal or bi-axal, is so cut that the surfaces are not perpendicular to the axis, or to the plane passing through the two axes, see Airy's Tracts (Undulatory Theory). The reader is referred also to Sir David Brewster's Treatise on Optics in the Edinburgh Encyclopædia, and to Sir John Herschel's Treatise on Light in the Encyclopædia Metropolitana.

POLEMO'NIUM (πολεμώνιον of Dioscorides), a genus of plants, the type of the natural order Polemoniaceæ. It has a campanulate 5-cleft calyx, a rotate corolla, and a short tube with a 5-lobed equal erect limb: 5 equal stamens inserted in the throat of the corolla with filaments dilated at the base, bearded in a continuous ring, and nearly closing the throat, and incumbent anthers; a roundish capsule with membranous crustaceous valves, covered with the permanent calyx and many-seeded cells; the seeds oblong, trigonal, and filled with albumen; the radicle twice as long as the cotyledons. The species are erect herbaceous plants, with alternate unequally pinnate leaves; the flowers terminal, bracteated, arranged on panicled corymbs, with blue or white corollas. About twelve species have been described, most of them being cultivated and known in our gardens as Greek Valerian.

P. cæruleum, common Greek Valerian, Jacob's Ladder, or Ladder of Heaven, has a glabrous stem, pinnate leaves, ovate lanceolate acuminated leaflets, the segments of the calyx ovate or elliptic, lanceolate, pointed; the panicle downy, glandular. The stem is one or two feet high, the leaves alternate, the flowers numerous, bright blue or white, somewhat drooping. It is a native of Europe and America, and is found in Great Britain, but is a rare plant. A great number of varieties have been described. It is a favourite plant in our gardens, and will grow in any common garden soil, and may be readily propagated by dividing the root or by seed. Although deriving its generic name from the Polemonium of Dioscorides, it does not appear to agree at all with his description of that plant, and Fraas refers it to Hypericum olympicum. Great virtues were attributed to the antient Polemonium, and these were transferred to the modern plant; but neither the antient nor modern plant possesses any active medical properties. Slight astringency is the only property possessed by any of the species of Polemonium.

(Fraas, *Synopsis Plant. Floræ Classicæ*; Don, *Gardener's Dictionary*; Babington, *Manual of Brit. Bot.*)

POLICE. In Scotland the larger towns have separate police statutes, by which the management and control of the system is put into the hands of elected commissioners. The act 3 & 4 Wm. IV. c. 46, is a general police act, the provisions of which, or a portion of them, may be adopted, so as to become law, by any royal burgh, burgh of regality, or burgh of barony, at a meeting of a specified number of ten-pound householders. The act provides for the election of commissioners with power of management and control, by the same class of persons who are entitled to decide on the adoption of the act. By 2 & 3 Vict. c. 65, called the Rural Police Act, the commissioners of supply of any county are authorised, at a meeting called on requisition by ten of their number, to assess the county for maintaining a constabulary force. The act directs the commissioners to publish annual accounts of receipt and expenditure. The system is co-operative with the expenditure of an old established fund for rural police purposes, called the 'Rogue Money.'

POLLA'JUOLI, PIERO and ANTONIO, two distinguished Florentine painters and sculptors of the fifteenth century; they were the sons of Jacopo del Pollajuolo. Piero was the pupil of Andrea del Castagno; Antonio was the more distinguished, he was the pupil of Lorenzo Ghiberti, and assisted him in the celebrated gates of the baptistery of San Giovanni; he became also a famous goldsmith, and was as such without a superior in Florence; Maso Finiguerra was his contemporary. The two brothers generally executed their paintings together; the best of them, says Vasari, is the Martyrdom of St. Sebastian, painted in 1475, in the church de' Servi at Florence. St. Sebastian was painted from nature and is one of the best figures that had been painted up to that time; it is engraved in the *Etruria Pittrice* of Lastri. Antonio is said to have been the first artist who studied the dead subject for the purposes of design. Antonio Pollajuolo was invited to Rome in 1484, after the death of Sixtus IV., by Innocent VIII., and he made the monuments of Sixtus IV. and of Innocent VIII.; that of Sixtus, in 1493, is now in the chapel of the Sacrament in St. Peter's; the monument of Innocent is also in St. Peter's. Antonio was also a medalist, and he engraved three or four plates, which are extremely scarce.

(Vasari, *Vite de' Pittori*, &c., and the notes to Schorn's German translation; Rumohr, *Italienische Forschungen*; Cicognara, *Storia della Scultura*; Baldinucci, *Notizie dei Professori del Disegno*, &c.)

POLLAJUOLO, SIMONE DEL, or Simon Masi, a distinguished architect, commonly called Il Cronaca, from his ability in relating stories, was born at Florence in 1454. He was related to Antonio del Pollajuolo, and lived with him some time at Rome. He is chiefly distinguished for the Palazzo Strozzi, one of the most solid and imposing buildings of Florence; it was commenced in 1489 by Benedetto da Maiano, but was completed by Cronaca, and the great cornice or entablature and the court in the interior are from the designs of Cronaca. The ironwork and the beautiful lanterns are by Niccolo Grosso, commonly called Caparra, a nickname which was given to him by Lorenzo de' Medici on account of his always persisting in being paid before he delivered his work; Caparra signifies deposit or advance-money. Grosso was the most celebrated smith of his time.

Cronaca built also the great council-hall for the Signoria of Florence, which was afterwards enlarged and embellished by Vasari; the church of San Miniato al Monte, the convent Dei Servi, and the Sacristy of Santo Spirito. He was a follower of Savonarola: he died in 1509.

(Vasari, *Vite de' Pittori*, &c.; Gage, *Carteggio Inedito d'Artisti.*)

POLLOK, ROBERT, a poet and miscellaneous writer, was born at Muirhouse, in the parish of Eglesham, in Renfrewshire, in 1799. He studied at the university of Glasgow, and afterwards followed the course of theological education necessary to fit him for a charge in the United Secession Church, of which he became a licentiate in 1827. His principal work, which is in some respects auto-biographical, speaks of the solitude and pastoral simplicity of the scenes in which he passed his youth:—

In rural quietude, 'mong hills and streams
And melancholy deserts, where the sun
Saw, as he passed, a shepherd only here
And there, watching his little flock, or heard
The ploughman talking to his steers.

He was a hard student, and appears to have been early endowed with a strong ambition to create for himself a permanent name in literature. In his own words—

The ancient page he turned, read much, thought much,
And with old bards of honourable name
Measured his soul severely; and looked up
To fame, ambitious of no second place.

Just before he received his licence, he had finished the poem on which his literary reputation rests, 'The Course of Time.' A work so ambitious, from the hands of a country student attached to a small body of dissenters, was not likely to find a patron among publishers. It happened to be shown to Professor Wilson, of Edinburgh, as a curiosity, and he was astonished to discover in it great poetic power. In deference to his recommendation it was published by Mr. Blackwood, of Edinburgh, and speedily passed through several editions. Its flight of genius was a novelty in the class of evangelical religious literature to which it belonged, and besides pleasing those who are partial to that class of religious literature, it was a boon to many who are inclined to read religious books, but are repulsed by their general dryness and insipidity, while it was warmly admired by the literary world at large. Mr. Pollok's partial admirers expected for him a place on a level with Milton. After the novelty of such a phenomenon had however passed off, the book became neglected by purely literary readers; and at this day it may be said that it is estimated too highly by the religious, and too insignificantly by the literary world. It is a work of great power, but meagre fancy. It has a considerable amount of sentiment deeply tinged with religious asceticism. Many sentiments are spun out or repeated, and the interest frequently flags. The work exhibits a great command of the English language and a power of terse rapid melodious diction. Pollok's mind was evidently imbued with 'Paradise Lost,' and he follows Milton often to the verge of slavish imitation. Before the publication of his poem this interesting young man had undermined his constitution by excessive mental labour, and he scarcely lived to see its success. On the recommendation and through the assistance of his friends he was preparing for a journey to Italy. The simplicity in which his family was brought up, may be imagined from the circumstance that his sister, who was to accompany him, obtained a certificate of good character from the minister and elders of her parish, believing that such a testimonial was all the more necessary as they were about to proceed to 'the land of graven images.' The disease had however made too great progress to admit of his leaving Britain, and he died near Southampton on 15th September, 1827.

POLYCARPON (from πολύ, many, and καρπος, a seed or fruit: seeds numerous), a genus of plants belonging to the natural order Paronychieæ. The sepala are slightly cohering at the base, the petals 5 and emarginate. The stamens from 3 to 5; styles short and 3 in number. The fruit is 1-celled, 3-valved, and many-seeded capsule.

P. tetraphyllum has triandrous leaves, emarginate petals, the stem-leaves in fours, and the leaves on the branches opposite. In young plants the leaves are often all opposite. It is a native of the coasts of the south-west of England, of Europe, and the Canary Islands.

There are two other species of Polycarpon: *P. alsinefolium*, an inhabitant of Europe, the Cape of Good Hope, and Holland; and *P. peploides*, a native of Sicily and France. The seeds of the annual species require only to be sown in the open border in spring. The last species, being perennial, should be grown in a small pot, and placed among other alpine plants.

(Don's *Gardener's Dictionary*; Babington's *Manual of British Botany*.)

POLY'GONUM (the Greek πολύγονον, 'much-productive'), a genus of plants belonging to the natural order Polygoneæ. It has a 5-parted perianth, from 5 to 8 stamens, and from 2 to 3 styles; a 1-seeded trigonous or compressed nut, lateral incurved embryo, the cotyledons not contorted. This is a very extensive genus, containing the knotgrasses, bistorts, persicarias, and buckwheats of our own waysides, fields, and gardens. They grow in almost any soil, some being aquatic, and others flourishing in sandy sterile tracts

P. Bistorta, Snake-weed, has a dense spike, ovate subcordate leaves, the radical leaves with winged foot-stalks, the stamens half as long again as the perianth, the nut triquetrous, its faces ovate, smooth. The calyx is rose-coloured and deeply five-cleft, obtuse, and spreading. The fruit is black and shining. This plant is one of the most powerful vegetable astringents, its root contains tannin and gallic acid in abundance; a decoction of it is employed in gleet and leucorrhœa as an injection, as a gargle in sore-throats, and as a lotion to ulcers attended with excessive discharge. Internally it has been used combined with gentian in intermittents. It may also be employed in passive hæmorrhages and diarrhœa.

P. amphibium has a dense ovate cylindrical spike, stalked ovate oblong floating leaves, a compressed smooth shining nut, 5 stamens, and a creeping root. The flowers are of a bright crimson colour. It is a native of England in ponds, ditches, and wet places. It is a fine showy plant, but one of the most difficult to eradicate from lands recovered from rivers or drained lakes and marshes. The subaquatic stems root at every joint, and extend to a surprising length, rising through the soil. They bear some resemblance to sarsaparilla, and according to Coste and Willemet they are substituted for this drug by the herbalists of Nancy; these authors also report that the apothecaries and druggists of Lorraine give it the preference.

P. hydropiper, the Water-Pepper, has drooping filiform interrupted spikes, lanceolate wavy leaves, glandular perianths, a large compressed nut, its faces ovate, acute, and of a purplish black colour. It is a hot acrid plant, and is reputed to be a powerful diuretic, but it loses its activity by drying, and therefore requires to be used in a fresh state. It dyes wool of a yellow colour. The seeds, according to Bulliard, are used in some of the French provinces instead of pepper. The leaves are so acrid as to act as vesicants. It is native of England in ditches and wet places.

P. aviculare has from one to three flowers together, axillary lanceolate leaves, or elliptical plane stalked lanceolate acute ocreæ, with few distant simple nerves at length by growth becoming torn, a triquetrous nut with raised points shorter than the perianth. Its numerous seeds supply abundant food for small birds; they are said to be emetic and cathartic. Thunberg says that in Japan a blue dye is prepared from this plant. There are many other species of Polygonum, natives of Great Britain and other parts of the world, but too numerous for description here. *P. tinctorium* is cultivated in France and Flanders on account of the fine blue dye extracted from it. The seeds of *P. barbatum* are used in medicine by the Hindu practitioners, and are said to ease the pain of griping in the colic. The leaves of *P. hispidum* are said by Humboldt to be substituted in South America for tobacco; and *P. anti-hæmorrhoidale* is esteemed in Brazil on account of its astringency in baths, poultices, &c. &c. The juice, as well an infusion of the ashes when burned, is employed by the Brazilians in the clarification of syrup and the condensation of sugar.

P. Fagopyrum, the Buck-wheat, is now referred to *Fagopyrum esculentum*. [FAGOPYRUM, P. C. S.]

(Lindley's *Vegetable Kingdom*; Babington's *Manual Brit. Bot.*; Burnett's *Outlines of Botany*; Lindley's *Flora Medica*.)

POLYPO'DIUM. [FILICES, P. C. S.]

POLYPO'GON (from πολύ, and πώγων, a beard), a genus of grasses belonging to the tribe Agrostideæ. It has scarious nearly equal glumes, each furnished with a long seta from just below the emarginate summit. The pallæ are shorter than the glumes, the outer ones usually curved from below the summit.

P. monspeliensis has the setæ more than twice as long as the rather obtuse glumes. It has a fibrous root, a stem from a foot to foot and a half high, a dense lobed silky panicle often two inches long. The glumes are linear and hairy. It is a very beautiful grass, and is a native of Great Britain in salt marshes. It is the ἀλωπέκουρος ('fox-tail') of Theophrastus, *Hist. Plant.* 7, 17.

P. littoralis has its setæ equalling the acute glumes. The root is somewhat creeping, the stem about a foot high, the panicle close lobed and purplish. The glumes are linear lanceolate. It is a British species and is found in muddy salt marshes.

(Babington's *Manual of British Botany*.)

POLYTECHNIC SCHOOL. This Institution, which has produced so many men eminent for their attainments in pure and physical science, originated, at the time of the great revolution in France, with one of the representatives of the people, named Prieur (de la Côte d'Or), who being a member of the Committee of Public Safety, and charged with the duty of superintending the practice of the arts which relate to the service of the country, introduced a plan for the establishment of the school to one of the particular committees which had been appointed by the National Convention. In consequence of a report made by Fourcroy in the name of three united committees, the institution, under the designation of 'Ecole centrale des Travaux publics,' was, by a decree of the Convention, dated 21 Ventose, An II. (Feb. 13, 1794), directed to be formed; and the charge of organizing it was assigned to Monge, La Grange, Berthollet, and Guyton Morveau: the first, in particular, was appointed to determine the branches of science which were to constitute the course of study.

The school was to consist of 400 pupils, who were to be admitted on undergoing, satisfactorily, an examination respecting their knowledge of the elements of arithmetic, algebra, and geometry; and, after remaining three years at the institution, during which time they were to be instructed in the higher branches of mathematical science, they were to receive appointments for the posts of civil or military engineers. The course of instruction was divided into two principal branches: the first consisted of mathematical analysis with its applications to geometry and mechanics; and to these were added a course of descriptive geometry [MONGE, P.C.], with its application to stereotomy, architecture, and fortification: the second branch consisted of chemistry and natural philosophy. A building in the Rue Ste. Geneviève was chosen, and the students were divided into classes, each consisting of 20 youths, who carried on their studies, each class in a separate hall, during six hours of the day: at certain times, however, they attended lectures in the theatre of the institution; and on two days in every ten they were employed in performing chemical experiments in the laboratory. They were required to execute all drawings relating to the subjects of their studies, and to perform experimenta with their own hands, conformably (as is stated in the programme) to the method followed in the school formerly existing at Mézières, for military engineers, and in the school of chemistry and mining at Schemnitz in Hungary.

Such was the origin of an institution of which, with respect both to the talents of its professors and the contributions which science has received from so many of its *élèves*, France may be justly proud; and it is worthy of remark that it was formed at a time when some of the most influential men in the government of the country proposed to put all the learned men to death, and to annihilate science as being inimical to the interests of the new republic.

Outlines of the lectures delivered by the professors during the first year were published in 1795 in a volume forming the first of those which constitute the 'Journal de l'Ecole Polytechnique;' and among these are one on stereotomy, by Monge, on architecture by Baltara, on fortification by Dobenheim and D'Arçon, on drawing by Neveu, on chemistry by Fourcroy, and on analysis by Prony.

In the course of the same year, 1795, the National Convention decreed that the 'Ecole centrale des Travaux publics' should take the name of 'Ecole Polytechnique,' and some new regulations were made concerning the subjects in which the candidates for admission were to be examined. In mathematics there was required a knowledge of algebra, as far as the resolution of equations of the four first degrees, with its application to geometry; the summation of series; trigonometry and the properties of conic sections. For the convenience of persons residing in the provinces, the examinations for admission to the school were appointed to be held, at the same time, at towns situated in different parts of France; the municipal authorities of the towns were to be present, and the examinations were to be conducted by duly qualified persons who were to attend for the purpose. A youth between 16 and 20 years of age only was admissible; and before a candidate was allowed to present himself for examination, he was required to exhibit a certificate of good conduct, and of his attachment to *republican principles*; or, as the sentiment was sometimes expressed, *his love of liberty and equality, and hatred of tyrants*. A successful candidate was required to report himself to the chiefs of the institution in Paris, on an appointed day: an allowance of money equal to that which was made to a private artillery-man of the first class being assigned to him for his travelling expenses; and, during the time that he remained at the school, the pupil was to receive as pay 1200 livres (50*l.*) yearly. Three years were considered as the time necessary for the completion of the appointed course of study; and a student was not, under any circumstances, to remain at the school longer than four years. Public examinations were to take place at the end of each year; and pupils who should not be found to have attained the requisite proficiency in at least three-fourths of the subjects constituting the prescribed course of education were to be withdrawn from the institution.

In the following year (1796) the National Convention decreed the formation of eight special schools for instruction in matters concerning the different professions which relate to the public service; these were the Ecole d'artillerie at Châlons; des ingénieurs militaires at Metz; des ponts et chaussées, des mines, des géographes, des ingénieurs de vaisseaux, de navigation, and de marine, at Paris: and the students in all these institutions were to receive salaries from the state.

A student desirous of serving the country in any one of the professions for which the special schools were appointed, might, after being two years at the Polytechnic School, become a candidate for that particular profession; and if, after examination, he was found qualified, he was either admitted in the special school or was, on a vacancy occurring, appointed immediately to a post in the department to which he aspired. An unsuccessful candidate might remain at the Polytechnic School during the third year; and, at its expiration, he might again present himself as a candidate for examination. A student admitted to exercise the functions relating to any particular department of the service was also allowed to remain during the third year at the Polytechnic School, in order that he might complete the course of study at that institution. The government of the school was placed under the direction of the minister of the interior; and it was the duty of that minister, under the Executive Directory, to assure himself that the regulations were carried into effect: the number of students was, at the same time, reduced to 360.

At the end of the first year, 40 young men were taken from the school to servo as officers of engineers; and these performed duty in Paris till their services were required with the armies in the field: nine were admitted to the school for military engineers and several were appointed to posts in the other special schools.

The necessity of having teachers for the purpose of preparing the junior pupils, or such as required more detailed instruction than could be afforded by the professors, led, in 1796, to the appointment of assistant preceptors; and these were selected from among the students who, having completed their course of education, were qualified to perform that duty: at the same time, also, the students were made to wear a military uniform. It is remarked that Bonaparte, after his return from the campaigns in Italy, often visited the institution, where he took pleasure in encouraging the youths to prosecute their studies; and when he sailed on the expedition to Egypt he took with him twenty of the most advanced pupils: he was also accompanied, in that expedition, by Monge, who was the principal professor.

In the year 1800 the school was re-formed and the number of students was reduced to 300: the mathematical course was increased; and it was decreed that candidates who had served in the armies of the republic during three years should be admissible till they were 26 years of age. The pupils, in general, had then the rank of serjeants of artillery, and their daily pay was 98 centimes (9¾ pence). The military uniform was continued, and on the margin of the buttons were the words 'Ecole polytechnique:' some alterations were made in the mode of conducting the examinations; and a council was appointed for the purpose of attending to tho state of the school, and also of suggesting measures for its improvement.

When Bonaparte became emperor, in 1804, the school was again remodelled, and Monge was replaced at its head: it then acquired the title of 'Ecole polytechnique impériale,' and it received an organization completely military. While that extraordinary man governed France the institution may be said to have been in its most flourishing state: and the subjects of the course of study were then arranged under thirteen heads, as follow:—Mathematical analysis; mathematical analysis applied to geometry; descriptive geometry; mechanics; machinery; natural philosophy; chemistry; geodesy; topography; the military art; architecture; drawing of figures and landscapes; grammar and the belles-lettres. At that time also, the following were the subjects a knowledge of which was required for admission to the school:—1. Arithmetic, with an explanation of the metrical system. 2. Algebra, containing the resolution of equations of the two first degrees—indeterminate equations of the first degree—the composition of equations—demonstration of the binomial theorem—the method of commensurable divisors, and that of equal roots—the resolution of numerical equations by approximation—and the elimination of unknown quantities in equations of any degree having two unknown quantities. 3. The theory of proportion—progressions and logarithms. 4. Elementary geometry and plane trigonometry. 5. Part of the course of descriptive geometry. 6. Discussion of lines represented by equations of the first and second degrees with two unknown quantities—the principal properties of conic sections. 7. Statics demonstrated synthetically and applied to the equilibrium of simple machines, as the lever, wheel and axle, &c. 8. The candidates were also required to translate part of a Latin author in prose, and give a grammatical analysis of French phrases. 9. To construct, with scale and compasses, any geometrical figure which the examiner might indicate. And 10. To draw and shade, with pencil, a figure from a given model.

In 1814 the students of the school took a share in the defence of Paris, and even assisted in serving the guns directed against the allies. On the restoration of the Bourbon family, the school was for a time suppressed; but it was afterwards revived, and it then received the title of 'Ecole Royale Polytechnique,' which it still retains. Occasionally since, unmindful of the submission due to the government which educates them, the students have, as in 1816 and 1830, manifested dispositions to put themselves in opposition to its measures: the acts of insubordination which took place in 1845 appear to have originated merely in a dislike which, for some reason, the students entertained to a person who had been appointed one of the examiners; but those acts were so violent that the king, Louis-Philippe, entirely suppressed the institution. It has, however, again been revived, and, except a few of the most culpable, the same students have been readmitted.

The object of the Polytechnic School is still the same as at its formation; and the young men are educated for the following branches of the public service: viz., l'artillerie de terre et de mer; le génie militaire et le génie maritime; la marine royale et le corps des ingénieurs hydrographes; les ponts et chaussées et les mines; le corps royale d'état-major; les poudres et salpêtres, and l'administration des tabacs.

The number of students is now reduced to 200, and the duration of the course of instruction is two years. Each student subscribes annually 1000 francs (41*l.* 13*s.* 4*d.*), and the expense of his clothing is, in addition, about half that sum. The commander-in-chief of the French armies is the head of the institution, and all the students are subject to military law. A candidate for admission must be a native of France, or a naturalized subject of the kingdom, and he must be between sixteen and twenty years of age. Military men are, however, admitted till the age of twenty-five; but they cannot receive leave of absence, to prepare themselves for the examination, till they have been two years with their regiments.

The government does not engage itself to receive in its employ all the young men who have been educated at the school: but such as pass their final examination are allowed, according to the degree of merit which is awarded to them by the *jury* appointed to decide respecting their qualifications, to enter one of the branches of the public service as far as the vacancies will permit. In the gift of the Ministre de la Marine there are four scholarships, in that of the Ministre de l'Intérieur eight, and in that of the Ministre de la Guerre twelve; and these are for the benefit of youths whose parents or guardians are unable to pay the subscription. They are called 'places gratuites,' and each is equivalent to two 'places demi-gratuites' which the minister may grant to persons who are capable of paying half the amount of the subscription. The programme of the subjects, a knowledge of which is required preparatory to admission, is very nearly the same as that which has been given above. The students rise at 5 A.M., and breakfast at 7½: their hours of study and recreation for each day are regulated, and they dine at 2 P.M. They sup at 8, and at 9½ P.M. the lights are extinguished.

The 'Journal de l'Ecole Royale Polytechnique' continues to be published by the 'Conseil d'Instruction,' and it contains many valuable essays on subjects relating to the highest branches of mathematical science. The earlier papers were contributed by La Grange, Monge, La Place, Poisson, Prony, and other celebrated men; and those of more recent date are written by the ablest mathematicians of France, several of whom have been pupils of the institution.

PO'MEÆ, a section or sub-order of the natural order of Rosaceæ. [ROSACEÆ, P. C.] The following is a synopsis of the genera belonging to this section of plants:—

1. *Cratægus* (κράταιγος). Calyx urceolate, 5-cleft; petals orbicular; ovary 2-5-celled; styles 2-5, glabrous; the fruit fleshy, ovate, containing a bony putamen. [CRATÆGUS, P. C.]

2. *Raphiolepis* (from ῥαφις, a needle, and λεπίς, a scale). The limb of the calyx funnel-shaped, deciduous; the ovary 2-celled, 2-styled; the fruit with a thickened closed disk, and a papery putamen containing 2 gibbous seeds.

3. *Chamæmelis* (from χαμαί, the ground, and μῆλον, an apple). Calyx truncate, with 5 little teeth; the petals small, erose; the stamens 10-15; the ovary 1-celled; the style single; ovules 2, erect.

4. *Photinia* (from φωτεινός, shining). Calyx 5-toothed; petals reflexed; ovary villous, 2-celled; styles 2, glabrous; fruit 2-celled inclosed in the fleshy calyx.

5. *Eriobotrya* (from ἔριον, wool, and βότρυς, grape). Calyx woolly, 5-toothed; petals bearded; styles 5, pilose, inclosed; fruit closed, 3-5-celled.

6. *Cotoneaster*. Flowers polygamous; calyx turbinate, bluntly 5-toothed; petals short; stamens length of the calycine teeth; styles glabrous, shorter than the stamens; 2-3 carpels, parietal, inclosed in the calyx with 2 ovules. [COTONEASTER, P. C. S.]

7. *Amelanchier*. Calyx 5-cleft; petals lanceolate; stamens rather shorter than the calyx; ovary of 10 cells or 5 bipartite ones with a solitary ovule in each partition; styles 5, joined at the base; fruit 3-5-celled; seeds 3-5; the endocarp cartilaginous.

8. *Mespilus*. Calyx 5-cleft; segments foliaceous; petals nearly orbicular; disk large, filled with honey; styles 2-5, glabrous; fruit turbinate, open at the apex, 5-celled; endocarp bony. [MESPILUS, P. C. S.]

9. *Osteomelis* (from ὀστέον, a bone, and μῆλον, an apple). Calyx 5-cleft; petals oblong; styles exserted, the same length as the stamens, bearded below; ovary 5-celled; cells 1-seeded; fruit closed, woolly; endocarp bony.

10. *Pyrus*. Calyx urceolate, 5-lobed; petals roundish; styles usually 5, rarely 2 or 3; fruit closed, 5-celled; cells cartilaginous; seeds 2 in each cell. [PYRUS, P. C.]

11. *Cydonia*. Calyx 5-cleft; petals orbicular; styles 5; fruit closed, 5-celled; cells cartilaginous, many-seeded; seeds covered with pulp.

The species of the genus Raphiolepis are known by the name of Indian Hawthorns. They are natives of various parts of Hindustan and China. There are six species of this genus, four of which have been cultivated in this country, and introduced as species of Cratægus or Mespilus. These are—*R. Indica*, a native of India and China; *R. pheostemon*, a native of China; *R. rubia*, a native of Cochin-China; and *R. salicifolia*, a native of China. All the species are trees in their native climates, with evergreen crenated coriaceous reticulated leaves; flowers in terminal racemes, with white petals, and red stamens. The species will grow well in a mixture of sand, loam, and peat. *R. Indica*, in British gardens, is an evergreen shrub flowering from February to August, and in many instances has borne our winters for many years. It is probable all the species would bear our winters if planted against a south wall, and covered with mats in severe weather.

The genus *Chamæmelis* was constructed by Lindley for a single species, *C. coriacea*, which is found in the island of Madeira. It grows on the sea-cliffs to the east of Funchal, about a mile from the town on the road to Canico.

The species of the genus *Photinia* are evergreen trees with undivided coriaceous serrated or entire leaves, and flowers in terminal corymbose panicles, followed by small fruit. They require the same treatment as the species of Cratægus, and are eminently ornamental.

P. serrulata has oblong acute serrulated leaves, and is a native of Japan and China. It has been long cultivated in Great Britain as a standard in the open air, in warm situations. Where it is too cold to grow it as a standard, it may be placed against a wall. 'Fit associates for it against a wall are Photinia arbutifolia, Cratægus glauca, C. mexicana, Raphiolepis indica, and Eriobotrya japonica.' (Loudon.) Three other species of Photinia, *P. arbutifolia*, *P. integrifolia*, *P. dubia*, have been cultivated in this country. There are four or five other species described, natives of Asia, which might probably be cultivated with success.

The species of *Eriobotrya* are less hardy than those of the last genus. They are small trees with tomentose branches, broad simply serrated leaves, which are woolly beneath, with woolly compound terminal racemes of flowers, and subulate deciduous bracts. *E. japonica* is the common Loquat. It has broad elliptic serrated rather wrinkled leaves, tapering at the base and tomentose beneath; the lobes of the calyx rounded. This plant is a small tree attaining a height of from 10 to 20 feet, and is a native of China and Japan. The fruit is of a middling size, pear-shaped, yellow, downy, and disposed in large pendulous branches. The fruit of the loquat resembles the apple, and is said to be equally good with that of the mango. Lord Bagot has grown this tree at Blithfield, where it bears fruit, which is represented as having a flavour equal to that which is produced in Ceylon. It should be placed out in a warm place in the months of July, August, and September, and kept in a very warm house during the rest of the year. There are four other species of Loquat described, but none have been introduced into cultivation in this country.

Amelanchier is another genus separated by Lindley from the old genus Mespilus. The species are small trees, natives of Europe and North America, with simple serrated deciduous leaves, white racemose flowers, and linear-lanceolate deciduous bracts. They are cultivated in British gardens on account of their early white showy flowers, their fruit which ripens in June, and the deep yellow red which their vegetation assumes in autumn.

A. vulgaris, the common Amelanchier, has roundish-oval bluntish leaves, downy beneath, glabrous afterwards; the fruit dark blue. It is a native of mountainous woods among rocks in many parts of the continent of Europe. It has been in cultivation in England since the year 1596.

A. botryapium, the Grape-Pear, has oblong-elliptical cuspidate leaves, somewhat villous when young, and afterwards glabrous. It is a shrub or low tree in this country, but in its native districts in Virginia and Canada, in America, it reaches a height of 30 or 40 feet. The fruit is of a purplish colour, and ripens in June. It has an agreeable sweet taste. *A. sanguinea*, *A. ovalis*, and *A. Florida*, are other species cultivated in this country. They are all hardy, and well fitted for shrubberies: they may be propagated by laying down the branches or by cuttings, which should be placed in a sheltered situation, with a hand-glass over them; also by suckers and seeds.

The *Pyrus anthyllidifolia* of Sir J. E. Smith has been made into the genus *Osteomelis* by Lindley. At present this is the only known species. It is a shrub, native of the Sandwich Islands, with pinnate leaves and a small fruit crowned by the styles and calyx.

The species of *Cydonia* yield the fruit called the Quince. [CYDONIA VULGARIS, or QUINCE, P. C.] Independently of this recommendation, they are very useful as stocks for other species of Pomeæ, and are deserving a place in every ornamental plantation. *C. vulgaris*, the common Quince-tree, is most commonly cultivated, and several varieties are described. It has ovate leaves, obtuse at the base, entire, tomentose beneath; the calyx tomentose, its lobes serrulated, and a little leafy, the stamens in one row. The quince is a low tree with a crooked stem and tortuous rambling branches; the leaves are duskish green above and downy underneath. The flowers are large, pale red or white, succeeded by a large globular or pear-shaped bright yellow fruit. It is at the present day apparently indigenous in the south of France, Germany, and the banks of the Danube, but it has been cultivated from time immemorial. The κυδώνιον of Theophrastus, *Hist. Plant.* lib. 2, cap. 3, is the variety *Cydonia vulgaris maliformis* of modern botanists, whilst the στρουθίον mentioned in the same place is the *C. v. pyriformis*.

In cultivation the quince prefers a moist but free soil near water. The finest specimens in this country are found in orchards near ponds. The best mode of propagating it is by layers. It may also be grown from cuttings planted in the autumn in a moist sandy soil.

Two other species, *C. sinensis* and *C. Japonica*, the Chinese and Japan Quince, are often cultivated in this country. They require the same general treatment as the foregoing. The Portugal Quince is a variety of the first species. There is one other species of Cydonia, *C. Sumboshia*, a native of Nepaul, where it is called *Sumboshi-swa* or *Bhee*, but it has not been introduced into this country.

(Don, *Gardener's Dictionary*; Loudon, *Arboretum et Fruticetum Britannicum*.)

PONTEDERA'CEÆ, a natural order of plants belonging to the class of Endogens. It has a 6-parted tubular coloured perianth, more or less irregular, with a circinate æstivation. The stamens arising from the calyx 6 or 3 opposite the petals, the anthers turned inwards, opening lengthwise. The ovary is free, more or less completely, 3-celled, many-seeded; one style, the stigma simple. The capsule 3-celled, occasionally acquiring an adhesion to the perianth, 3-valved with loculicidal dehiscence; the seeds are indefinite, attached to a central axis; ascending hilum small; the embryo with its radicle rather enlarged, orthotropal in the axis of somewhat mealy albumen. The species are aquatic or marsh plants. The leaves sheathing at the base, with parallel veins in the larger species, arrow-headed, cordate, or dilated. The flowers are either solitary or in spikes or umbels, spathaceous; frequently blue, sometimes yellow. The aquatic plants comprehended in this order are distinguished by the divisions of their flowers being rolled inwards after flowering, to which may be added mealy albumen and an indefinite number of seeds. They are natives exclusively of North and South America, the East Indies and tropical Africa. Very little is known of their uses. Some of the species are employed by the native Indian practitioners in liver complaints and diseases of the stomach.

Rubbed down in butter and drank, they are said to remove redness of the eyes; powdered and mixed with sugar, to relieve asthma; and when chewed, to remove tooth-ache; brayed with milk, some are administered in fever and some eaten as pot-herbs.

(Lindley, *Vegetable Kingdom*.)

PONTIUS, PAUL, a celebrated engraver, was born at Antwerp in 1596 according to some accounts, according to others in 1603. The date of his death appears not to be known: the Slaughter of the Innocents, after Rubens, one of his principal works, is dated 1653.

Pontius was the pupil of Vorsterman, and he is chiefly distinguished for his excellent prints after Rubens, which he executed under that great painter's inspection. He engraved also a celebrated set of portraits after Vandyck, including those of many of the most distinguished Flemish painters.

PONTORMO, JA'COPO DA, or Jacopo Carrucci, a distinguished Florentine painter, was born at Pontormo, in 1493, and died at Florence in 1558. He was a short time the pupil of Leonardo da Vinci, and he studied under Albertinelli, Piero di Cosimo, and Andrea del Sarto. He painted for some time in a similar style to Andrea, and was that painter's rival; but he frequently changed his manner, and three distinct styles are ascribed to him, progressively inferior; the last imitated from the works of Albert Dürer. Towards the close of his life he spent eleven years in painting some frescoes of the Deluge and the Last Judgment in the church of San Lorenzo, in the manner of the imitators of Michael Angelo, but they have long since been whitewashed over.

(Vasari, *Vite de' Pittori*, &c.; Lanzi, *Storia Pittorica*, &c.)

POOR LAWS, SCOTLAND. The foundation of the Old Poor Law of Scotland was the act of parliament, 1579, c. 74, which in so many respects resembled the celebrated English statute of the fourteenth of Elizabeth, passed a few years earlier, as to have been considered a mere adaptation from it. The Scottish act, however, fell short of the English in the one important particular of not providing for the care of the able-bodied. By this old act, a settlement was acquired by birth, and once so established could not be changed unless by a seven years' industrial residence in another parish. By the act of 1672, c. 18, this period was shortened to three years. The method of administering the law, which arose partly out of the terms of the old acts, partly out of custom, and partly from the directions given to these sanctions by the judgments of the courts, was as follows:—In the rural parishes, the 'kirk sessions,' or lowest ecclesiastical judicatories, consisting of the parish clergyman and certain elders, shared the management with the 'heritors,' or rated landed proprietors; but it became customary for the latter body to interest themselves solely in the voting and levying of the rate, leaving its distribution and the management of the poor to the former. In those municipal corporations holding rank as royal burghs, the assessment and management lay with the corporate authorities. The funds for the relief of the poor were of two kinds. The collections at church doors, along with certain fees and eleemosynary bequests, constituted the one department; and rates assessed on the parish, or a substitute voluntarily paid instead of an assessment, the other. Of the sums collected at the church doors only a half went to the regular relief of those legally entitled to relief; the other became a fund for general charitable purposes at the command of the kirk session. In many cases there was no assessment, and the regular practice came to be, that if the miscellaneous sources were insufficient for the relief of the poor, the heritors and session in a country parish, or the magistrates in a town parish, might levy a rate. It became a common practice for the parties chiefly interested to agree to a 'voluntary assessment,' for the purpose of postponing the imposition of a fixed legal rate. When an assessment was imposed, it became a rule that one half of it should be levied on the proprietors of land, in respect of their land; the other on householders, in respect of their 'means and substance,' or their incomes so far as not derived from land. The adjustment of the rating was the ground of much dispute, and different parishes followed very distinct methods in practice.

For a considerable period, the Scottish system was very favourably received by political economists, who saw the country in a comparatively sound moral condition, with a parsimonious poor law, while the lavish system of England seemed to promote profligacy and idleness. But from the time when these doctrines were first promulgated to the completion of the great change of the English poor law, a vast internal alteration had taken place in the social economy of Scotland. The comparative low rate of wages, attracting manufacturing capital from England, had caused a more than average migration of the rural labourers to the manufacturing districts, and a peculiarly rapid increase of the city population. It was found that with these complicated materials, the simple parochial system adapted to a state of society where each man watched over the interests and the conduct of his neighbour, was incapable of grappling. It was found that even for poor country districts the system was unsuitable, because, though still far behind the English system in profusion, the administrators were compelled by the voice of public opinion to become more liberal in their dispensations, while the managers of the country parishes not subject to the same influence, kept down the allowances, and thus gave the poor an inducement to endeavour to obtain a settlement by three years' industrial residence in the cities. Dr. Chalmers was the great champion of the old system. With the assistance of some enthusiastic followers, he organised the administration of a parish in the poorer parts of Glasgow, as a demonstration of the efficiency of which the system was capable. It was a very pleasing picture, but the public soon felt that the success with which one energetic individual and his enthusiastic followers might voluntarily perform the duties generally exacted by legal compulsion, was no sufficient ground for believing that the rest of the community can be at all times and in all places depended upon for the performance of onerous public services without the coercion of law.

The public were first awakened to the imperfections of the Scottish poor law by Dr. W. P. Alison, a physician in Edinburgh, and professor of the practice of medicine in the university. Having frequently administered professional services to the poorer classes, he showed from his own experience that the utter inadequacy of the provision afforded to those who, by inability to work, or bad seasons, or revulsions in trade, were reduced to want, was an extensive cause of disease, vice, and misery. The city population speedily answered to this appeal, and associations were formed, and inquiries made in various directions. It was shown that the amount expended on the relief of the poor in Scotland amounted to little more than a sixth part of the sum distributed throughout an equal population in England by the economised poor law. In England, the expense of supporting the poor amounted to 6*s.* 10¾*d.* per head of the population; in Scotland, to 1*s.* 2¼*d.* In some of the Highland parishes, whence the most destitute objects emigrated over the rest of the country, the allowances were ludicrously small; and a Report made to the General Assembly of the Church of Scotland in 1839, enumerated instances where sums averaging from 3*s* to 1*s.* yearly were solemnly awarded to destitute people, as the provision which the poor law made for their wants. In the mean time, the discussion of these matters had a tendency gradually to increase the amount of the provision for the poor. The practice of assessments made considerable progress, and a return to parliament in 1843 shows that between 1836 and 1841 the sums raised by assessment had increased from 89,101*l.* to 128,858*l.*; while the sums raised by voluntary assessment had risen from 15,829*l.* to 22,385*l.* A commission was at last appointed to inquire into the whole state of the subject, and after hearing much evidence, they presented a Report, accompanied by a voluminous appendix, in 1843. The amendments proposed in this Report were supposed to be of a somewhat narrow nature; the country expressed dissatisfaction with them; and in 1845 a measure was passed embodying alterations considerably more extensive.

By this act, 8 & 9 Vict. c. 83, a board of supervision is appointed, consisting of persons connected with the municipal bodies and the administration of justice in Scotland, with one salaried member, who gives constant personal attendance. The office of the board is in Edinburgh. This board is endowed with ample means for ascertaining, in all parts of the country, the condition of the poor, and the method in which the system of relief is administered. The board has, however, no directory or prohibitory control over the proceedings of the local boards. These bodies are, however, re-organised by the act. In the rural parishes where there is an assessment, the local board is to consist of landowners to the extent of 20*l.* annual value, the kirk session, and certain elected representatives of the other rate-payers, according to the number fixed by the board of supervision. In city parishes, the boards are each to consist of four persons named by the magistrates, deputies not exceeding four from each kirk session in the city, and certain elected persons according to a number and qualification fixed by the board of supervision. In parishes where there is no assessment the management is to continue under the old system. There is thus in this act no machinery for levying or exacting a rate for the poor, unless in those parishes where the persons more immediately concerned agree to such a measure. It is held, however, that the facilities which the statute gives the poor for exacting from the respective parochial authorities the relief to which they are entitled, will render it necessary to put more extensive funds at the disposal of the distributors of relief, and this can only be accomplished through the system of assessment. When persons apply for relief, it is provided that, though they have no settlement, if the claim would be just in the case of their having one in the parish where it is made, subsistence must be afforded them till it is determined what parish is liable. When relief is refused, the applicant may apply to the sheriff, who may grant an order for temporary relief, and then hear parties, and decide whether the applicant is or is not entitled to relief. In this form, however, neither the sheriff nor any other judge can decide on the *adequacy* of relief. The initial step to any judicial appeal against the amount of the relief afforded, is by an application to the board of supervision, and on that body reporting its concurrence, the applicant is placed on the poor-roll of the court of session, where he has the privilege of the question being discussed gratis. By this act, provision is made for medical attendance and medicines, being part of the system of pauper relief, and for the education of pauper children. It is provided, that for the purposes of the act, parishes may be united into 'combinations.' By a special clause, nothing in the act is to be construed as entitling the able-bodied to relief, and their claim is thus left in the state of doubt in which it stood before the passing of the act. Men deserting their wives and children are made liable to punishment as vagrants, a provision which it is hoped may afford a remedy to a defect which has long characterised the law of Scotland—the absence of any means by which deserted wives can make effectual claims on their husbands for sustenance to themselves and their children, without a regular action in the court of session. By the new act, a new and more specific mode of apportioning the assessment between landed and other property has been attempted to be established, but this provision is already a fruitful source of dispute and litigation. The time necessary to acquire an industrial settlement is increased from three to five years.

POPLARS, PO'PULUS. [SALICACEÆ, P. C.]

PORCE'LLIA, a fossil genus of Heteropod Mollusca allied to Bellerophon. From the mountain limestone. (Leveillé.)

PORES OF PLANTS. [STOMATES, P. C.]

POROSITY is that condition of material bodies which consists in the discontinuity of their molecules, the intervals between these being called pores (from πόρος, a passage). Porosity is a property common to all the bodies of nature, at least we know none in which the particles are contiguous to one another. In some, as sponge and cork, the pores are visible to the eye, and in others they may be rendered so by the aid of a microscope. In bodies whose pores are not thus manifest, the existence of the intervals between the molecules is proved by various circumstances. Thus water or mercury being contained in an open vessel of wood over the exhausted receiver of an air-pump will, by the pressure of the atmosphere, be forced through the wood and fall from thence in a shower: liquids also are frequently filtered by being made to pass through the pores of paper; and in the Florentine experiment, for determining whether or not water is compressible, the fluid was by pressure forced through the pores of the vessel of gold in which it was contained. Again, the porosity of bodies is inferred from their elasticity and the sounds which are heard when the molecules are in a state of vibration: also, in transparent bodies (and the most dense metals are, when rendered sufficiently thin, found to be transparent) it is inferred from the fact that the particles of light pass through them, or that the vibrations of an ætherial fluid take place among the molecules. Finally, the porosity of bodies is proved from the fact that they suffer contraction of volume by being exposed to cold, and by mechanical compression, since such contractions can only take place in consequence of the particles being forced closer together than they are in the usual states of the bodies.

When salt is dissolved in water, the particles of the former seem to introduce themselves between those of the latter, so that the volume of the mixture is less than the sum of the volumes of the separate substances; and the like may be said of the mixture of alcohol with water; in which cases the particles of one of the kinds of substance appear to enter and occupy the spaces between the particles of the other. The intervals between the particles of gaseous substances are very great; and though, in some cases, the volume of a mixture is equal to the sum of the volumes of the separate gases, yet, in others, it is equal to not more than $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, or $\frac{1}{8}$ of the sum of the separate volumes. A body of aqueous vapour composed of a volume represented by $2v$ of hydrogen gas, and a volume v of oxygen gas, is equal in volume to $2v$ only.

All material substances being subject to attractive forces, it has been made a question whether the attractions which take place between the molecules of bodies, and which are insensible at all appreciable distances from them, are the same as that general attraction which extends indefinitely through space; modified, however, by the figures and mutual distances of the molecules, by heat, electricity, and perhaps by powers which are at present unknown to us: but, in order that this hypothesis may be admissible, the dimensions of the molecules of bodies should be extremely small compared with those of the spaces among them; and the densities of the molecules immensely greater than the densities of the bodies themselves. La Place estimates ('Système du Monde,' ch. xviii. 4th edit.) that a molecule of a spherical form, whose diameter is one millionth part of a mètre, ought to have a density more than six million times as great as the mean density of the earth in order that it might exercise an attraction equal to that of terrestrial gravity; and he observes, that the attractive forces exercised by the molecules of bodies, which are probably only the excesses of the entire attractions of the molecules over the repulsive forces of the caloric in the intervals, must be vastly greater than that of gravity, since the actions of the molecules of a body produce visible inflexions of the rays of light, which cannot be asserted concerning the attraction of gravity.

PORTER, SIR ROBERT KER, K.C.H., was born at Durham in 1780, but his early boyhood was passed in Edinburgh, whither his mother removed upon the death of her husband, who was an officer in the English army. He was the brother of Anna Maria Porter and Jane Porter. His strong natural disposition for the arts was first called into activity by the celebrated Flora Macdonald. Sir Robert, then a boy of only nine or ten years of age, was spending the evening with his family in the house of that extraordinary lady, who, perceiving his fixed attention to a certain battle-piece, explained to him that it was one of the battles of '45; and she proceeded to describe the battle in all its details in such glowing terms that the boy's blood kindled, and from that moment he became a painter of battles. He from this time was incessantly sketching battles, and his mother was induced by his evidence of talent to take him to London, in order that he might have the opportunity of instruction in the Royal Academy. His mother took him, in about 1790, to West, the president of the Royal Academy, who is said to have been so much struck with the spirit of the boy's sketches, that he procured his admission into the academy, and predicted his certain success with confidence. Sir Robert's career certainly was remarkable, and the early part of it as much so as any other. In 1793 he had already evinced such extraordinary progress as to receive a commission to paint an altar-piece for Shoreditch church. In 1794 he presented an altar-piece of Christ allaying the Storm to the Roman Catholic chapel at Portsea; and in 1798, another of St. John preaching in the Wilderness, to St. John's College, Cambridge. His most extraordinary productions, however, were his great battles. In the year 1800 he exhibited an immense picture 120 feet long, in the Lyceum Great Room, representing the storming of Seringapatam. He is said to have been only six weeks in painting the picture, and yet the execution was in no part neglected. West, after he had seen it, went to some of the academicians then occupied in preparing the exhibition, and said, 'he had just looked on what he must consider a wonder in the art: a work of such dimensions, finished throughout, in a brevity of time which any other man would demand even to sketch out his designs, done by young Ker Porter, hardly then in his twentieth year.' This picture was burnt in the fire which consumed a friend's warehouse where the painter deposited it before he left England to go to Russia; but the sketches exist, and were sold at the sale of Sir Robert's effects in 1843. Another great battle was the Siege of Acre, exhibited also in the Lyceum Room in 1801; he published at the same time a book entitled 'The Siege of Acre, chiefly intended as a companion to the great historical picture painted by Robert Ker Porter, now exhibiting at the Lyceum, 1801;' it contains spirited etchings of the picture. These were followed by a third great battle-piece, Agincourt, which he presented to the City of London, and it is still in the possession of the corporation: it was hung up in the Guildhall a few years ago. He painted also pictures of the Battle of Alexandria, and the Death of Sir Ralph Abercromby. In 1804 he went to Russia, and was appointed historical painter to the emperor. While he was in St. Petersburg he gained the affections of the Princess Mary, the daughter of the Prince Theodore de Sherbatoff, of Russia, and the marriage was arranged; but some ministerial differences caused him to leave Russia; in the year 1811, however, the marriage took place, and the princess survived him. He painted at St. Petersburg, on the walls of the Admiralty, Peter the Great planning the port of Cronstadt and St. Petersburg. After his return to England, about 1806, he published 'Travelling Sketches in Russia and Sweden.' In 1808 he accompanied Sir John Moore's expedition to the Peninsula, and attended the campaign throughout, up to the closing catastrophe of the battle of Corunna. On his return to England he published some anonymous letters from Spain and Portugal.

After his return from a second visit to Russia, after his marriage, he published, in 1813, 'An Account of the Russian Campaign,' and he was knighted by the Prince Regent in the same year. He executed many sketches of the campaign in Portugal, and some Cossack affairs. 1817 to 1820 were occupied in his extensive travels in Asia, of which he published a detailed account in 1821-22—'Travels in Georgia, Persia, Armenia, Ancient Babylonia, &c., during the years 1817-18-19-20, with numerous engravings of Portraits, Costumes, Antiquities, &c.,' 2 vols. 4to. In this work are many excellent designs in outline from the fine characteristic antient sculptures of Nakshi Roustam, Nakshi Rajab, Shiraz, and Persepolis. A comparison of Sir Robert's representations of the bassi-rilievi of the steps at Persepolis will show how extremely inaccurate and insufficient are the previous engravings given by Le Brun, Niebuhr, and Chardin. Some of the figures of these sculptures, which in Le Brun's time (1704) were mere headless trunks, are represented by Niebuhr ('Reisebeschreibung,' &c., ii. 136), half a century afterwards, with eyes and noses complete, but executed without the least skill whatever; the representations of Sir John Chardin are not much better.

In 1832 Sir Robert Ker Porter was created Knight Commander of the order of Hanover, by William IV.; he was appointed a few years before British consul at Venezuela, where he resided at Caracas until 1841, and he painted while there three sacred pictures, which were his last principal works; he also made numerous sketches of scenery in the meanwhile. The first of these three pictures was Christ at the last Supper blessing the Cup, painted as an altar-piece for the chapel of the Protestant burying-ground, of which he had procured the establishment; but he removed it afterwards on account of the heat of the sun, and put up in its stead a tablet with the ten commandments in the native language. The second was our Saviour blessing the little Child; and the third and last an 'Ecce Homo.' He painted also a portrait of General Bolivar. In 1841 he paid his last visit to St. Petersburg, and the cold winter appears to have been too much for his constitution, then inured to the warm climate of Venezuela. Sir Robert himself, in a letter dated only the 3rd of May, announced his intention to his brother, Dr. Porter, of Bristol, of embarking immediately for England; on the following day, however, a letter was written by the chaplain of the British embassy announcing his death by apoplexy. The following is an extract from the letter:—'Yesterday Sir Robert went to court to pay his respects to the emperor, and afterwards he made two or three visits to private friends: on arriving at his home about three o'clock in the afternoon the servant, on opening the door of the carriage, perceived that his master was holding himself in, and that he moved to the door with much difficulty; but before he could descend the steps he fell down from the effects of an apoplectic stroke, and was carried up stairs; he took a little water, soon after which consciousness ceased, and he expired at eight o'clock this morning (May 4, 1842), in his sixty-second year.' His effects were publicly sold in London, in March, 1843.

(*Athenæum*, 1842-43, and the Artist's Works.)

PORTFIRE is a composition consisting of saltpetre, sulphur, and mealed gunpowder, mixed together by being rubbed between the hands, and, after being passed through hair-sieves, moistened with spirits of wine: the mixture is then rammed or driven into a paper case of a cylindrical or conical form, and less than an inch in diameter. A piece of portfire sixteen inches long will burn from twelve to fifteen minutes.

It is sometimes used as a match for firing artillery, in which case the saltpetre, sulphur, and powder are in the proportion of 6, 2, and 1, respectively; but it is frequently employed in firing mines or in blasting rocks, when the proportions of the like ingredients are as 7, 2, and 8, respectively. For these last purposes the portfire is attached at the extremity of the train, or is inserted in the shaft bored in the rock or object to be blasted; and the fire is applied to it by a match.

POSIDONOMY'A. [POSIDONIA, P. C.]

POSSESSIO FRATRIS. [DESCENT, P. C.]

POST HORSES. [POSTING, P. C.]

POTAMO'GETON (from ποταμος, a river, and the termination γετον, which probably means 'produced'), a genus of plants belonging to the Endogenous class, and the natural order Potameæ. It has a perfect flower, a 4-parted perianth, 4 sessile anthers opposite to the divisions of the perianth, 4 ovaries, and 4 drupes or nuts. The species are water-plants.

P. natans is a British plant, with floating ovate stalked leaves, the petioles plano-concave above, the nuts large, rounded on the back when fresh keeled; when dry the peduncles are equal. There is a creeping rhizoma at the bottom of the water. The roots are sometimes eaten in the wilds of Siberia by men, but in more temperate regions are fed on only by swans, who devour them with avidity.

P. crispus has a compressed stem, pellucid oblong linear leaves, sessile and wavy, the nuts with long beaks, keeled on the back; when dry the peduncles are equal. It is a native of Great Britain.

P. densus has its leaves all opposite, pellucid, clasping, elliptical-lanceolate or lanceolate; the spikes shortly stalked, ultimately reflexed; the spike is 4-flowered. It is found in ditches and ponds of water in England. Ducks feed on the seeds and leaves of both these species, but they serve a more important purpose in giving out oxygen, and rendering the water respirable for fish and other aquatic animals. There are twenty British species of Potamogeton, and Haller says that in the Swiss lakes *P. serratum* grows to the length of from 10 to 20 fathoms, forming extensive subaquatic forests.

(Burnett's *Outlines of Botany*; Babington's *Manual of British Botany*.)

POTAMOMY'A, a genus of Conchifera from the freshwater strata of Headon Hill, in the Isle of Wight. (Sowerby.)

POTENTILLA (*potens*, powerful, from the supposed medical qualities of some of the species), a genus of plants belonging to the natural order Rosaceæ. It has a concave calyx from 4-to 5-parted, with 4 or 5 bractlets; there are from 4 to 5 petals, numerous stamens, a lateral or nearly terminal style. The fruit consists of numerous small nuts placed on a flattish dry receptacle; the seeds pendulous or ascending, the radicle superior; the flowers white or yellow, rarely red.

P. reptans, Creeping Cinquefoil, is a common British species: it is found likewise in other parts of Europe. The stem is filiform, procumbent, and creeping; the leaves quinate and stalked; the leaflets obovate, serrated; the peduncles solitary; carpels granulate, scabrous. The flowers are large bright yellow, and on long hairy axillary stalks. It appears to have been the officinal plant of the antients, and is the πεντάφυλλον of Theophrastus, ix. 13, and of Dioscorides, iv. 42. Pliny mentions it as Quinquefolium, 25, 9. 27, 10. It is still used as a febrifuge by some practitioners.

P. tormentilla has a procumbent or ascending stem, ternate sessile leaves, and longitudinally wrinkled carpels; the leaflets are acute and somewhat hairy. The flowers are bright yellow, small, with the parts of the calyx and corolla in fours on slender hairy stalks much longer than the leaves. It is the *Tormentilla erecta* of Linnæus. It abounds in Great Britain. The roots are very astringent, and have been used medicinally. In the Western Isles of Scotland and the Orkneys they are used for tanning leather, and are preferred even to oak-bark. They are also used for dyeing a red colour. We are told that pigs are fed on them in Killarney, and they are also thought to be serviceable in some diseases to which sheep are subject.

P. anserina has a creeping stem, interruptedly pinnate leaves; the leaflets numerous, oblong, acutely serrate, silky beneath; the peduncles solitary. The flowers are large and yellow, and the leaves form a favourite food with geese: they are sometimes used as pot-herbs. Its roots are eaten both by hogs and men; they taste like a parsnep, but are small; the common people roast or boil them for food. In the islands of Tiray and Col they answer in some measure the purposes of bread, and have been known to support the inhabitants for months together during a time of scarcity.

The leaves of *P. fruticosa* and *rupestris* are employed in Siberia as a substitute for tea.

P. hirta has a pilose erect few-flowered stem; the leaves with 5 or 7 leaflets, pilose, and cut at the apex; the stipules lanceolate, entire; the petals obcordate, longer than the calyx. It is native of the Pyrenees, South of France, Silesia, &c., and is the Πεντάφυλλον of Hippocrates ('Ulc.,' 880).

All the species of Potentilla are of easy cultivation, and some of them are handsome when in flower. They will grow in any common garden-soil and are easily propagated by dividing at the roots or by seed. The shrubby kinds are very proper for the front of shrubberies, and they grow freely from cuttings planted in the autumn in a sheltered situation.

(Don, *Gardener's Dictionary*; Lindley, *Vegetable Kingdom*; Lindley, *Flora Medica*; Babington, *Manual of British Botany*; Burnett, *Outlines of Botany*; Fraas, *Synop. Floræ Classicæ*.)

POTE'RIUM (from ποτήριον, poterium, a drinking-vessel or cup, one of the species being infused in drink), a genus of plants belonging to the natural order Rosaceæ. It has monœcious or polygamous flowers; a 4-cleft calyx, with three external scales at its base; and a quadrangular tube. The petals are wanting, the style terminal, stamens numerous, and the seed suspended.

P. sanguisorba, lesser Burnet, is an herbaceous plant, with a slightly angular stem, the calyx of the fruit quadrangular and hardened. The leaves are pinnate, with numerous small ovate coarsely serrate leaflets, glabrous or slightly hairy beneath. It is found on dry calcareous soils in Great Britain. It forms a useful fodder for cattle, and at one time was extensively cultivated for that purpose, but is now generally superseded by *sainfoin* and other artificial grasses. On the Continent, and occasionally in this country, the young leaves are eaten as salad, and it is said to form one of the ingredients of the favourite cool tankard. It is said to give the name to the species, from the custom of infusing it in liquors. The common people of Siberia eat the roots. There are about nine species of Burnet described, which are distributed over Europe, Africa, and America. The hardy herbaceous species will grow in any common garden soil, and are best propagated by seeds, as most of them are little better than biennial plants. The shrubby species thrive best in a light rich soil, and young cuttings readily take root under a hand-glass.

(Don, *Gardener's Dictionary*; Lindley, *Vegetable Kingdom*; Babington, *Manual of British Botany*; Burnett, *Outlines of Botany*.)

POTTING OF PLANTS. When plants are placed to grow in a small earthen vessel, like a garden-pot, their condition is very different from that to which they are naturally exposed. The roots have not liberty to extend themselves as they choose, and they are either obliged to grow back upon themselves or round the vessel in which they are confined; they are likewise exposed to great varieties of temperature and depend on an uncertain supply of moisture. It is therefore the object of the careful gardener to obviate as much as possible these evils, and at the same time to secure the advantages derived from the operation itself. These advantages consist mainly in the facility with which it enables the gardener to change the arrangement and position of his plants; it also, hy cramping the roots, diminishes the tendency to form leaves, and increases the disposition to flower. It secures a constant and effective drainage from the roots, and renders it more easy to expose them to a favourable amount of bottom heat. For the raising and nourishment of young seedlings it is also an advantageous process. Exhaustion of the soil is one of the inconveniences which result from this system. In order to remedy it liquid manure should be applied; or the plants placed in *pan-feeders*, shallow earthen vessels containing manure, to which the roots have access through holes in the bottom of the pot. It is however to *shifting* more particularly that recourse should be had for renovating the soil; and this, if skilfully performed without injuring the plant, is most successful. It is not alone for the purpose of improving the soil that shifting is desirable; the roots if allowed to remain long in a confined space form a hard knotted mass, which is very unfavourable to the retention of moisture and the growth of the plant. All the earth therefore which clings to the roots should be carefully separated before the plant is placed in the fresh soil. The roots of a plant are always found to be in contact with the sides of the pot, and this, being generally composed of a highly absorbent substance, is snbject to great variations of temperature. The practice of plunging greenhouse plants into the earth during the summer to obviate this is very undesirable, as when they are again taken up the roots are generally found to have taken advantage of the earth around them and to have fastened themselves in it. The best mode of counteracting the injurious effects of unequal temperature is hy the use of double pots, as recommended in the *Gardener's Mag.* ix. 576, the space between the two pots being filled with moss or some other substance retentive of moisture. The drainage of potted plants is of great importance, and in all cases a quantity of broken pieces of tiles and earthenware should be placed at the bottom of the pots to prevent the stagnation of water about the roots. To be managed perfectly a young plant should be placed in as small a pot as it will grow in, and gradually and successively transferred to large pots as it advances. Dr. Lindley says 'It is by paying constant attention to the shifting of the growing plant, by the employment of a very rich stimulating soil, and by a thorough knowledge of the kind of atmosphere which suits them hest, that have heen obtained those magnificent pelargoniums, cockscombs, and balsams, &c. that have so often and so justly excited the admiration of even the most experienced gardeners.'

(Lindley, *Theory of Horticulture.*)

POUNDAGE. [SUBSIDY, P. C.]

POWER. We find that the article ROOT, P. C., does not answer the reference made from POWER, P. C. We briefly supply the defect here, and take the opportunity of describing some important suggestions which have been recently made as to the manner of conducting algebraical operations.

In FACTORIALS, P. C. S., the manner in which the term *power* was introduced into arithmetic is seen. By definition, the fourth power of x means the product of four $x$es, or $x\times x\times x\times x$; and the same of other powers. But it is far more symmetrical to begin from unity; and to say that the fourth power of x is the result of four multiplications hy x, unity being understood as the commencement. Thus the successive powers of x, first, second, third, &c. are $1\times x$, $1\times x\times x$, $1\times x\times x\times x$, &c.: denoted by x^1, x^2, x^3, &c. And the term *root* is the inverse of power, as follows:—If A be the mth power of B, B is the mth root of A, denoted hy $\sqrt[m]{A}$. The peculiar algebraical character of the roots is explained in ROOT, P. C.

It is thus easily proved that when m and n are any two integers,

$$x^m\times x^n=x^{m+n};$$

that when m is greater than n,

$$x^m\div x^n=x^{m-n}.$$

$$\text{Also that } x^m\times y^m=(xy)^m,$$
$$(x^m)^n=x^{mn},$$
$$\text{and that } \sqrt[n]{x^m}=x^{\frac{m}{n}},$$

whenever m is divisible by n without remainder. These rules, if applied in defiance of the restrictions first mentioned, lead to such results

$$\text{as } x^0,\ x^{\frac{2}{3}},\ x^{-4},\ x^{-\frac{2}{3}},\ \&c.,$$

which are unintelligible as far as the definitions have yet been stated. Their proper interpretations [INTERPRETATION, P. C.] are as follows:—First, x^0 must be allowed to stand for unity, whatever x may be; secondly, x^{-a} must be understood to be $1\div x^a$; thirdly, $x^{\frac{m}{n}}$, m and n being positive integers, must stand for $\sqrt[n]{x^m}$. When these new definitions are added, all the rules remain true, whether m and n be positive or negative, integral or fractional: and the system of algebraic powers is complete.

An algehraic expression is said to be arranged in powers of a letter, say x, when the powers of that letter which enter are made to enter in ascending or descending order of algebraic magnitude. Thus $ax^2+bx^{-3}-x^4-x^{-1}$ is not at present arranged at all. To arrange it in ascending or descending powers of x, we must write it thus—

$$bx^{-3}-x^{-1}+ax^2-x^4,\ \text{ascending};$$
$$-x^4+ax^2-x^{-1}+bx^{-3},\ \text{descending}.$$

But even yet it is incomplete for many algebraical purposes, having no written indication of the fact that the ascent or descent is interrupted. Completely written in ascending powers, it should be

$$bx^{-3}+0x^{-2}-x^{-1}+0x^0+0x^1+ax^2+0x^3-x^4.$$

Written in this form, which may remind us of the use of a cipher in writing ordinary numbers, it is clear that we hardly read the expression less easily, and write it much more briefly, if we omit x and its powers altogether, and make some distinctive mark, analogous to the decimal point, between the parts which belong to the positive and negative powers. Thus the above might be written—

$$b+0-1+\mid 0+0+a+0-1,$$
$$\text{or}\quad -1+0+a+0+0\mid -1+0+b;$$

the mark | being on that side of the adjacent + or − which belongs to the positive powers. This mark however is not necessary in what follows.

The late Mr. Horner [INVOLUTION, &c., P. C. and P. C. S.] was the first who suggested the systematic rejection of the ascending or descending powers. An example of multiplication and division will sufficiently explain it. Suppose it required to multiply $7x^3-2x^2-3$ and $2x^4+x^2-4x-5$:—

$$\begin{array}{l}
2+0+1-4-5\\
7-2+0-3\\
\hline
14+0+7-28-35\\
\quad -4+0-\ 2+\ 8+10\\
\qquad\quad -\ 6+\ 0-\ 3+12+15\\
\hline
14-4+7-36-27+\ 7+12+15
\end{array}$$

Accordingly the answer is $14x^7-4x^6+7x^5-36x^4-27x^3+7x^2+12x+15$; and every stroke of the pen which the usual method contains, more than is in the preceding, is mere waste, and risk of error into the bargain. Now let it be proposed to divide $4x^6-3ax^5+2a^2x^4-11a^5x-a^6$ hy $x^3+2ax^2-a^3$:—

$$\begin{array}{l}
4-\ 3+\ 2+\ 0+0-11-1(1+2+0-1\\
4+\ 8+\ 0-\ 4 \qquad\qquad\quad 4-11+24-44\\
\hline
\quad -11+\ 2+\ 4+\ 0\\
\quad -11-22+\ 0+11\\
\hline
\qquad\quad 24+\ 4-11-11\\
\qquad\quad 24+48+\ 0-24\\
\hline
\qquad\qquad -44-11+13-\ 1\\
\qquad\qquad -44-88+\ 0+44\\
\hline
\qquad\qquad\quad 77+13-45
\end{array}$$

Accordingly the quotient is $4x^3-11ax^2+24a^2x-44a^3$ and the remainder is $77x^2+13ax-45a^2$.

Mr. Horner himself did not live to publish this suggestion, which, simple as it is, seems never to have been made before him. The possessor of his papers, Mr. T. S. Davies of Woolwich, published some extracts from those papers in an appendix to a reprint of the paper on the solution of equations, which reprint appeared in the 'Ladies' Diary' for 1838; having previously introduced the simplification into the 11th edition of Hutton's Course. Since that timo a paper on *Algebraical Transformation*, sent by Mr. Horner to the Royal Society, but not printed in the 'Philosophical Transactions,' has been published in the first and second volume of the *Mathematician*. Details and examples are given in Mr. Davies' 'Solutions of Questions contained in Hutton's Course,' 1840, and in the 12th edition of that course, 1841.

But the greatest improvement in the operation of division, and one which contains the principle of a class of improvements, is one which Horner called the *synthetic method*, which amounts to deferring the actual steps of subtraction until they are wanted. If we were to proceed one step farther with the preceding division, -44 in the quotient would be followed by $+77$. This $+77$, if we look at all its components from the beginning, arises from $+0-11-0+88$. In like manner -44 arises from $+0+4-0-48$. Now arrange the process as follows:—

$$\begin{array}{r|l} 1 & 4-3+2+0+0-11-1 \\ \hline -2 & \quad -8+0+4-11+24-44 \\ +0 & \qquad +22+0+0+0 \\ +1 & \qquad\quad -48+88 \\ \hline & 4-11+24-44 \mid +77+13-45 \end{array}$$

Write the coefficients of the dividend horizontally a, b, c, &c., and of the divisor vertically p, q, r, &c., taking care to change the sign of every term of the divisor *except the first*.

$$\begin{array}{r|l} p & a+b+c+d+e+f+g+h \\ \hline +q & \quad +uq+ur+us+ut+vt+wt+xt+yt \\ +r & \qquad +vq+vr+vs+ws+xs+ys \\ +s & \qquad\quad +wq+wr+xr+yr \\ +t & \qquad\qquad +xq+yq \\ \hline & u+v+w+x+y \mid +u'+v'+w'+x' \end{array}$$

Divide a by p, giving u, and then write uq, ur, us, and ut in the successive columns which follow that of u. Make up $+b+uq$, the second column, and divide by p, giving v: write vq, vr, vs, vt, in the successive columns which follow that of v. Make up $c+ur+vq$ and divide by p, giving w: write wq, wr, ws, wt, in the columns which follow that of w, and so on. Then $u+v+w+$ &c., will give the coefficients of the quotient, and $u'+v'+$ &c., made from the columns which have not been used to find quotient terms, will give the coefficieuts of the remainder. For example, we want to find some terms of the quotient of x^4+1 divided by x^3+x^2-3x:—

$$\begin{array}{r|l} 1 & 1+0+0+0+1 \\ \hline -1 & \quad -1+3+0+0+0+0+0 \\ +3 & \qquad +1-3+12-21+60 \\ +0 & \qquad\quad -4+7-20 \\ \hline & 1-1+4-7+20 \mid -41+60+0 \end{array}$$

Hence the quotient is $x-1+4x^{-1}-7x^{-2}+20x^{-3}$, and the remainder is $-41x^{-1}+60x^{-2}$.

When the first coefficient is anything but unity, fractions are introduced into the quotient. To avoid this, proceed as follows:—Let a be the coefficient of the first term of the divisor. Multiply the successive coefficients of the dividend by 1, a, a^2, a^3, &c.: turn the first coefficient of the divisor into 1, and multiply the second, third, fourth, &c. by 1, a, a^2, &c. Proceed as above with the coefficients thus altered, and suppose that in the last line the quotient terms become $u+v+w+$ &c., and those for the remainder $u'+v'+$ &c. To find the true quotient terms write

$$\frac{u}{a}+\frac{v}{a^2}+\frac{w}{a^3}+,\ \&c.$$

and for the true remainder terms write

$$\frac{u'}{a^m}+\frac{v'}{a^{m+1}}+,\ \&c.$$

where a^m is the last power used in the quotient terms, *repeated*, not the next one to it. Suppose for example, we are to divide $x^3+mx^2+m^2x+5m^3$ by $2x^4+m^2x^2-3m^4$. Here, since x descends and m ascends regularly, we throw out x and m, and the abridged dividend and divisor become

$$\begin{array}{llll} 1+1+1+5 & \text{and} & 2+0+1+0-3 \\ 1\quad 2\quad 4\quad 8 & & 1\quad 2\quad 4\quad 8 \end{array}$$

underneath which we have written the multipliers. Hence we begin with $1+2+4+40$ and $1+0-2+0+24$:

$$\begin{array}{r|l} 1 & 1+2+4+40 \\ \hline +0 & \quad +0-2+0+24+48+48+864 \\ -2 & \qquad +0-4+0+0+0 \\ +0 & \qquad\quad +0-4-72 \\ +24 & \qquad\qquad +0 \\ \hline & 1+2+2+36 \mid +20-24+48+864 \end{array}$$

Hence the quotient is

$$\frac{1}{2}\frac{1}{x}+\frac{2}{4}\frac{m}{x^2}+\frac{2}{8}\frac{m^2}{x^3}+\frac{36}{16}\frac{m^3}{x^4}$$

and the remainder is

$$\frac{20}{16}\frac{m^4}{x}-\frac{24}{32}\frac{m^5}{x^2}+\frac{48}{64}\frac{m^6}{x^3}+\frac{864}{128}\frac{m^7}{x^4}.$$

One of the easiest modifications of this rule is the division of $ax^m+bx^{m-1}+\ldots$ by $x-p$ or $x+p$, as explained in FRACTIONS, DECOMPOSITION OF, P. C. S.

POZZO DI BORGO (sometimes BARGO), CARLO ANDREA, the late distinguished diplomatist, was one of that considerable number of remarkable men produced by the island of Corsica in the earlier part and middle of the last century. His family had ranked among the nobility of the island ever since the twelfth century; and he was born on the 8th of March, 1764, at Ajaccio, also the native place of Napoleon Bonaparte. The latter was the younger by five years, but they were in early life intimate friends. After having received a careful elementary education in his own country, Pozzo di Borgo went to finish his studies at Pisa; whence he had not long returned when Corsica, now under the dominion of France, was excited and shaken, like all the rest of that kingdom, by the outbreak of the Revolution of 1789. He had attached himself to General Paoli; and, under the patronage of that venerable head of the patriots, he was appointed, along with General Gentili, to proceed to Paris with the thanks of Corsica to the Constituent Assembly for having declared the island an integral portion of the French territory. This mission led to his being nominated a member of the Legislative Assembly, which commenced its sittings in October, 1791. While occupying this position he is stated to have attracted considerable notice by the knowledge and talent he showed in the diplomatic committee. When the Legislative Assembly was dissolved, in September, 1792, he returned to Corsica, and there joined Paoli in those efforts by which he accomplished the liberation of his country for a season from France, and the restoration of a native government under the protection or supremacy of England. When the new constitution was established, in the summer of 1794, Pozzo, who had previously acted as one of the Secretaries of the General Consult held at Corte, by which the constitution was drawn up, was appointed, according to his biographer M. Capefigue, President of the Council of State, that is, we suppose, the Board of Council, nominated by the King of England to assist the Viceroy. When the English abandoned Corsica, in 1797, he came to this country with the Viceroy, Sir Gilbert Elliot, (afterwards Earl of Minto); and he remained here for about a year and a half. While in England Pozzo was considered as the principal adviser and agent of the French refugees; and it is from this period of his life that we may date the real, if not the formal, commencement of his diplomatic career. In 1799 he proceeded to Vienna, where he attempted unsuccessfully to bring about a coalition between Austria and Russia. He continued to reside at Vienna during the short peace that followed the treaty of Amiens. Soon after the recommencement of hostilities (in May, 1803), he entered the diplomatic service of Russia, in which he spent the remainder of his life. Having been made a Councillor of State, he was first sent on a mission to Vienna, whence, after a few months, he was despatched in the character of Russian commissioner to the army, composed of English, Russian, and Neapolitan forces, in the North of Italy. After the battle of Austerlitz and the peace of Presburg (December, 1805) he returned to Vienna, and thence proceeded to Petersburg. When Prussia rose against Napoleon in October of the year following, and was about to be joined by Russia, Pozzo received the military rank of colonel, and was to have accompanied the emperor as one of his suite, when the scheme of the confederates was struck to the ground and annihilated by the fatal battle of Jena (14th October, 1806). He now proceeded once more to Vienna, where he endeavoured, without success, to induce Austria again to take up arms. Meanwhile war had, at the instigation of France, been declared against Russia by the Porte (30th December, 1806); and in the beginning of the year 1807 Pozzo joined the English fleet which was sent, under Sir Thomas Duckworth, to force the passage of the Dardanelles. He was present in the battle fought between the Russian and Turkish fleets near the island of Tenedos on the 1st of July, when the Turks were signally defeated. But on the 7th of the same month Russia made peace with France by the treaty of Tilsit, one of the articles of which provided for an armistice between

Russia and the Porte, which was accordingly concluded on the 24th of August following. Pozzo, all whose feelings were vehemently anti-Gallican, now obtained Alexander's permission to travel; upon which he proceeded to Vienna, and he continued to reside in that capital till the destruction of the fifth Anglo-Austrian coalition against France by the peace of Vienna (14th October, 1809).

He now betook himself to Constantinople, whence he proceeded to London, which he reached in October, 1810. There he remained till after the expulsion of the French from Russia in the winter of 1812, when he was recalled by Alexander; and, passing through Sweden, he met the emperor, after a separation of five years, at Kalitz. Bernadotte, prince royal of Sweden, had already engaged to join the combination against France by the treaty of Petersburg (24th March, 1812); but he still hesitated to commit himself by any actual movement. Pozzo, who had had an interview with him on his way to Kalitz, was now therefore sent to urge him, at the same time that other negotiations were opened with Moreau, and with Murat and Eugene Beauharnais; and he at last succeeded in overcoming his scruples. After the Congress of Prague (July, 1813), Pozzo, now raised to the rank of major-general, was sent to Bernadotte at Berlin; and it is said to have been by his representations that the Swedish prince-royal was prevailed upon to take part in the battle of Leipzig (18th October, 1813). Meanwhile, immediately after the previous affair of Gros-beerin (23rd August), Pozzo had been despatched to Frankfort, to take part in the military conferences held there by the allies; and thence, in the beginning of January, 1814, he proceeded to London, charged with a request from the allied sovereigns that Lord Castlereagh might be sent over to join their deliberations. He soon returned to the Continent accompanied by the English minister, with whom he proceeded to Baden, where the allied sovereigns were now assembled. He continued in close attendance upon the Emperor Alexander at the Congress of Châtillon, where he strenuously opposed the reception of the offers made by Bonaparte, and throughout the rest of the campaign of the first months of 1814, till they had the satisfaction of entering Paris together on the memorable 31st of March. Pozzo, to whom is attributed great influence in keeping Alexander steady and in determining him in favour of the restoration of the Bourbons, was now nominated Russian commissioner to the provisional government, and was soon after despatched to England to bring over Louis XVIII., with whom he returned to Paris on the 3rd of May. He remained in the French capital till the meeting of the Congress of Vienna in the beginning of November. At the conferences there he advised that the dethroned emperor should be sent out of Europe; and he is said to have produced some coldness towards him for a time on the part of Alexander by the opposition he made to tho project then entertained by the Czar of restoring the old kingdom of Poland. The changed aspect of things, however, that followed the escape of Bonaparte from Elba (1st March, 1815) at once chilled Alexander's liberalism and restored Pozzo to favour. The latter immediately proceeded to Louis XVIII. at Ghent, and, having then joined the allied army as Russian commissioner, he was present in that character at the battle of Waterloo, where he received a wound. He now returned to Paris, and, declining Talleyrand's invitation to take office in the French ministry, resumed his former functions of Russian ambassador, and in that capacity he signed the Treaty of Paris of the 20th November. Soon after the Duke de Richelieu, now head of the ministry, conferred upon him the rank of a count and peer of France. He does not appear to have again left Paris till he was sent, after the Spanish campaign of the Duke of Angoulême in 1823, on a mission to Madrid, from which, however, he soon returned to the French capital. The death of the Emperor Alexander and the accession of Nicholas (31st March, 1825) did not alter his position; and he received new letters of credence to King Louis-Philippe after the Revolution of 1830; but he at last revisited St. Petersburg in 1834. Passing on his journey thither through Vienna and Berlin, he had the Order of the Red Eagle conferred upon him by the former court and that of St. Stephen by the latter. On the breaking out of the War of the East in 1835 he was sent on a mission to London; after a stay of only a few months he returned to his former post at Paris; but he was soon sent back to this country as ambassador extraordinary to the King of Great Britain. According to M. Capefigue, he felt this appointment as both a mortification and a disgrace, and it afflicted him greatly; but M. de Nesselrode consoled him with the promise that as soon as they should have turned the Duke of Wellington from his inclination to join with Austria (de se rapprocher de l'Autriche) in the Eastern question, and should have supported the Tories in an effective manner, then M. Pozzo should return to Paris to follow his tastes and accustomed pursuits. M. Capefigue, as is well known, deals largely in all his writings in information of this sort, of which no other writer has had the luck to hear, and which we must believe upon his simple assertion—if we believe it at all. Count Pozzo, however, got back to Paris ere long; and all that there is further to be told of him is that he died in that capital on the 15th of February, 1842.

(Abstracted, with the exception of the dates, most of which we have supplied, from a very elaborate article in the *Biographie Universelle*, vol. 77 (Supplement), pp. 497-507, by M. Capefigue, which has also been published separately.)

PRELATE. [Bishop, P. C.]

PRESCRIPTION has, by the law of Scotland, a much wider operation than either by the civil law or the law of England, supplying the place of the Statute of Limitations in the latter system. It not only protects individuals from adverse proceedings which other parties might have conducted if the lapse of time had not taken place, but it in some instances creates a positive title to property. The prescription by which a right of property can be established is that of forty years—a period probably borrowed from the *Praescriptio quadraginta annorum* of the Romans. Whatever adverse right is not cut off by the other special prescriptions of shorter periods, is destroyed by the *long* prescription. It may be said generally to preclude the right of exacting performance of any claim, as to which no judicial attempt has been made to exact performance for forty years from the time when it was exigible. To create a title to real property, the long prescription must be both positive and negative. The party holding the property must, by himself or those through whom he holds, have been forty years in unchallenged possession of the property on a title ostensibly valid—this is called positive prescription; and the claimant and those whom he represents must have been forty years without an ostensible title, and must, by not judicially attacking it, have tacitly acquiesced in the possessor's title—this is called negative prescription. An action raised in a competent court interrupts the long prescription. It is usually stated in the Scottish law-books that it is interrupted by the minority of any person who could challenge the opposing right; but it would be more correct to apply in this case the phraseology of the French lawyers, who say it suspends prescription, as the years of minority are merely not counted in making up the period of forty years, while, when there is a judicial interruption, a new period of forty years commences to run. When the prescription applies to a pecuniary obligation, payment of interest or an acknowledgment of the obligation will interrupt it. It may be observed that, by a sort of analogy from the system of prescription, when there is in Scotland any judicial inquiry as to the antiquity of a custom, it is usual to limit the period of the inquiry to forty years, as sufficient to establish its having existed from time immemorial. It having been the practice in the neighbourhood of Edinburgh for the proprietors of land to irrigate fields with the contents of the city sewers—the system increasing until it became offensive to the neighbourhood—these proprietors produced evidence of their having continued the practice for forty years; and although it had during that time increased from an evil felt only by the individuals immediately concerned with the practice, to the extent of a public nuisance, these proprietors have, so far as the dispute has hitherto gone, been able to defend themselves on the ground of prescription.

The other and shorter prescriptions cut off particular descriptions of claims or methods of supporting them. By the vicennial or twenty years' prescription, holograph writings, not attested with the usual solemnities of Scottish writs, cease to 'bear faith in judgment.' An obligation of cautionary or suretyship is limited to seven years. Bills of exchange and promissory notes cease to have force after six years; but the debts which they represent, if they do represent debts, may be proved by other means. The quinquennial prescription cuts off all right of action, after the lapse of five years, on bargains proveable by witnesses. It also protects agricultural tenants from a demand for rent after they have been five years removed from the land to which the demand applies. The triennial, or three years' prescription, is very important. It cuts off claims on account of goods or services, the three years running from the date of the last item of the account; and also claims for wages, each year's wages running a separate prescription, and ceasing to be exigible, if not pursued for, in the lapse of three years from the time when it became due.

PRESS, LIBERTY OF THE. [CENSORSHIP, P. C. S.]

PRESTON, THOMAS, was a master of arts of Cambridge and a fellow of King's College; and he was afterwards created a doctor of law and master of Trinity Hall. In 1564 he acted with great applause before Queen Elizabeth, in Rightwise's Latin play of Dido. About the same time, or a litle earlier, he wrote 'A Lamentable Tragedy, mixed full of pleasant mirth, containing the life of Cambises king of Persia, &c., and last of all his odious death by God's justice appointed: done in such order as followeth.' This rude and imperfect old piece is curious from its early place in the history of the English drama; but its tumidity made it a fair mark for Falstaff in proposing to be tragical 'in King Cambyses' vein.' The play is printed, from the undated black letter edition, in Hawkins's 'Origin of the English Drama,' 1773.

PRI'MULA, a genus of plants belonging to the natural order Primulaceae. It has a tubular 5-cleft calyx, a salver-shaped regular corolla, as long as the calyx, or longer; a spreading limb in 5 rather deep inversely heart-shaped obtuse segments; a free 1-celled ovary, with a free central placenta. It has a capitate stigma and 1 style. The fruit is a capsule with numerous roundish seeds.

P. vulgaris, Primrose, is one of our commonest British plants. It has oblong, ovate, wrinkled crenate leaves; single flowered scapes and a tubular calyx; linear, lanceolate, attenuated teeth very acute; the limb of the corolla flat. It is found in woods and thickets, and is one of the earliest of our spring flowers.

P. elatior, Ox-lip, has ovate leaves contracted below, wrinkled and denticulate, many-flower umbellate scapes, a tubular calyx; lanceolate acute teeth; the limb of the corolla concave, with cordate ovate segments; nodding flowers and erect fruit. It is found in woods and meadows, but rarely in England.

P. veris, Cowslip, has ovate wrinkled crenate leaves, contracted below, many-flowered umbellate scapes; a bell-shaped calyx, rather downy, with short ovate teeth; the limb of the corolla concave, or cup-shaped, of a deeper yellow on the upper side, with 5 orange spots. It is found plentifully in meadows and pastures in England. The flowers possess well-marked sedative and diaphoretic qualities, and make a pleasant soporific wine. The fresh root has also a smell resembling anise, and was formerly employed as a tonic medicine and also as a diuretic.

P. farinosa is distinguished by its mealy obovate lanceolate leaves, oblong ovate calyx, linear teeth, and obcordate segments rounded below, distant, and as long as the tube. It is found in the North of England and Scotland, and is called the Bird's-eye Primrose.

P. scotica is found only in the North of Scotland. It is known by its swollen calyx, with short ovate obtuse teeth; the limb of the corolla is flat, with broadly obcordate approximate segments half the length of the tube. The flowers are of a bluish purple colour with a yellow centre.

The leaves of *P. auricula* are used in the Alps as a remedy for coughs. Swine are the only animals that feed upon any of these species as their especial sustenance. They are valuable chiefly on account of their beautiful appearance and their early blossoming.

(Lindley, *Vegetable Kingdom*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany*; Babington, *Manual of British Botany*.)

PRINGLE, THOMAS, was born January 5, 1789, at Blaiklaw, in Tiviotdale, Scotland. His father was a respectable farmer in Roxburghshire. Pringle's right limb, when he was very young, was dislocated at the hip-joint by an accident, which the nurse imprudently concealed till reduction was no longer practicable, and he was thus obliged to use crutches for life. In his fourteenth year he was sent to the grammar-school at Kelso, and three years afterwards went to Edinburgh to complete his studies at the university; after which he became a clerk to the Commissioners on the Public Records of Scotland. His employment was merely that of copying old records, and his salary was barely sufficient for his humble wants.

In 1811 Pringle and a friend published a poem called 'The Institute,' which seems to have been satirical, and obtained them some praise but no profit. In 1816 he was a contributor to 'Albyn's Anthology,' and the author of a poem in the 'Poetic Mirror,' called 'The Autumnal Excursion,' which was praised by Scott, and was the origin of Pringle's acquaintance with him. About the same time he was busy with the project of establishing a magazine as a rival to the 'Scots' Magazine,' and when his plan was pretty well advanced he resigned his situation in the Register Office, which he could resume if his project was unsuccessful. Among his coadjutors were Lockhart, Wilson, Clegborn, Dr. Brewster, and Hogg. Early in 1817 the 'Edinburgh Monthly Magazine' appeared, of which Pringle was the editor. His most important contribution to the first number was an article on the Gipsies, the chief materials for which were furnished by Scott, unasked for and gratuitously, and which Scott had himself intended to work up into an article for the 'Quarterly Review.' About the same time Pringle became editor of the 'Edinburgh Star' newspaper. The magazine soon fell into the hands of other proprietors, and changed its title to that of 'Blackwood's Magazine,' Pringle still continuing to be the editor, at the same time that he became joint editor of 'Constable's Magazine;' but disputes between Pringle and Blackwood led in a short time to a separation. Before this untoward event took place he had married. Soon afterwards he published 'The Excursion, and other Poems,' with little or no profit. The editorship of 'The Star' newspaper was unprofitable, and he resigned it; and he probably derived little emolument from 'Constable's Magazine,' for in January, 1819, he was again on his former seat in the Register Office, performing the laborious drudgery of a copying clerk to the Record Commission.

Meantime Pringle's four brothers, all of whom were farmers, had become more or less unprosperous, and he proposed that they should avail themselves of the government scheme of colonizing the unoccupied territory at the Cape of Good Hope. One brother had previously emigrated to the United States of North America. The other brothers agreed to his proposal, though the eldest brother could not get his affairs arranged in time to accompany them; but be promised to follow them, and Pringle undertook the management of his farm till his arrival.

The party of twenty-four persons, consisting of twelve men, six women, and six children, having set sail, arrived at the Cape of Good Hope in April, 1820. On the 21st of June they reached Roodewal, on the Great Fish River, and after a toilsome march of some days arrived at their place of settlement, in the upper part of the valley of the Baavians' River, or River of Baboons, one of the smaller tributaries of the Great Fish River.

The small colony, having surmounted the first difficulties, became tolerably prosperous, and Pringle's brother having arrived in July, 1822, he resigned his farm, and went to seek employment at Cape Town, as had been his original intention. Scott, Sir John Macpherson, and others, had exerted their influence with the colonial secretary, and Pringle was offered and accepted the situation of librarian to the government library. The salary was only 75*l.* a year, but afforded a fair ground-work of income to a working literary man. He at first received pupils for private instruction, and then, in conjunction with the Rev. Mr. Faure, a Dutch clergyman of the town, made arrangements for the publication of a periodical in English and Dutch. Lord Charles Somerset, however, who was then governor, on being applied to in February, 1823, would not permit any journal to be published except the Government Gazette. Pringle was obliged to submit, and wait the arrival of commissioners, who had been sent out by the British government to examine into the state of the colony. The commissioners, when they arrived, approved of his plan; but their powers did not extend beyond that of making a report to the home government.

Meantime Pringle, in conjunction with his friend Mr. Fairbairn, who had followed him from Scotland, organized a private academy on an extensive scale, which was prosperous beyond their expectations. While occupied with this new business, he was surprised to receive a communication from the governor authorizing him to commence his periodical, the plan of which, it seems, had met with the approbation of Lord Bathurst, who was then colonial secretary.

The 'South African Journal' forthwith appeared, one edition in English and one in Dutch. Soon afterwards, Mr. Greig, a printer, commenced the 'South African Commercial Advertiser,' a weekly newspapor, of which Pringle became editor, as well as of the 'Journal.' The two works were prosperous, the pupils of the academy increased, and Pringle fancied himself about to make a rapid fortune.

A man of the name of Edwards was tried for a libel on the governor, and the trial, like others, was expected to be reported. On this occasion, however, the Fiscal was ordered to proceed to the printing-office, and assume the office of censor of the press. Pringle states that everything likely to be personally offensive to the governor had been carefully expunged; but he refused to submit to this assumption of arbitrary power, and having no legal means of resistance, threw up his editorship. Greig discontinued the publication of tho uewspaper, announcing to his readers his intention of appealing to the British government. Greig's press was immediately ordered to be sealed up, and himself commanded by warrant to leave the colony within a month. The Fiscal at the same time assumed the censorship of the Magazine also, stating that if he had been aware of certain paragraphs in the second number ho would have expunged them or suppressed the numbers. Pringle disclaimed his right of censorship, and, on the 15th of May, 1824, announced the discontinuance of the work in the Gazette. A petition to the king in council was got up by the respectable inhabitants, and the governor became alarmed. He summoned Pringle to appear before himself and Sir John Truter, the chief justice. Ho at first attempted to hully Pringle into submission, and, failing in that, tried to cajole him, and bring him over by flattery; Pringle, however, resolutely refused to recommence the Magazine unless he received a promise that the press should not be interfered with except by legal process. To this the governor would not agree, and Pringle retired, and immediately resigned his appointment as librarian. The result was that the governor's resentment pursued him till, finding himself ruined in circumstances and prospects, he deemed it prudent to leave the Cape, and in July, 1826, arrived in London. He applied to the government for compensation for his losses, which he estimated at 1000*l.*, but in vain. Meantime he was engaged as secretary to the Anti-Slavery Society, a situation which he held till slavery was abolished; he became the editor of 'Friendship's Offering,' wrote and published a 'Narrative of a Residence in South Africa,' and contributed to the chief periodical works of the day.

In June, 1834, Pringle wrote to his doctor, to say, that in taking supper a crumb of bread passed down the windpipe, and brought on a violent fit of coughing; that a little blood flowed, which however soon ceased; but that in the morning he felt a sensation as if there had been some slight abrasion of the part. This slight abrasion seems to have produced consumption, and his medical advisers informed him that removal to a warmer climate afforded the only chance of saving his life. He was preparing to return to the Cape, and had actually engaged a passage for himself, his wife, and her sister, when an attack of diarrhœa, operating upon his weak state of body, occasioned his death, December 5, 1834.

The greater part of Pringle's works probably consist of fugitive pieces written during the timo when he was secretary to the Anti-Slavery Society; but his reputation as an author depends mainly on his 'Narrative' and his 'Poems.' His 'Narrative' is very entertaining; somewhat diffuse perhaps, but simple, distinct, and effective, interspersed with passages of picturesque power and beauty, and characterized throughout by the appearance of undeviating truth. He published also an 'Account of English Settlers in Albany, South Africa,' 12mo. His poetry has great merit. It is distinguished by elegance rather than strength, but he has many forcible passages. The versification is sweet, the style simple and free from all superfluous epithets, and the descriptions are the result of his own observations. His 'African Sketches,' which consist of poetical exhibitions of the scenery, the characteristic habits of animals, and the modes of native life in South Africa, are alone sufficient to entitle him to no mean rank as a poet.

(*The Poetical Works of Thomas Pringle, with a Sketch of his Life*, hy Leitch Ritchie.)

PRINOS (πρῖνος is the Greek name of the Holly, which the present genus much resembles), a genus of plants belonging to the natural order Aquifoliaceæ. It has polygamous flowers, a permanent half 6-cleft calyx, a rotate 6-parted corolla, 6 subulate erect filaments, a short style with an obtuse stigma, and a berry with 6 stones. The species are shrubs with alternate deciduous or permanent leaves.

P. verticillatus has oval deciduous acuminated leaves, serrated, pubescent beneath; small white flowers in little imperfect axillary umbels, which are nearly sessile. The calyx is small, 6-cleft, and persistent; the corolla monopetalous, spreading, without a tube, the border divided into 6 obtuse segments. The fruit is a bright scarlet, roundish, supported by the persistent calyx and crowned with the stigma, 6-celled, containing 6 long seeds which are convex outwardly and sharp edged within. The bark is very bitter, and has been substituted for Cinchona bark in cases of fever. Dr. Meere recommends it for its antiseptic powers, and the American practitioners employ it as a lotion in cutaneous disorders and in cases of gangrene. The berries are said to be tonic, and Bigelow asserts that they are emetic.

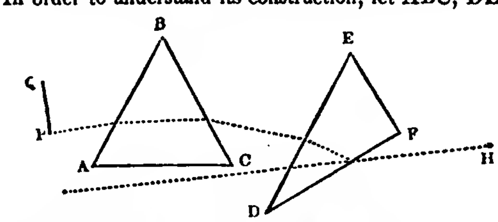
P. glaber, Glabrous Winter Berry, has rather pubescent branches, evergreen cuneate lanceolate coriaceous smooth shining leaves, a little toothed at the apex; the pedicels are axillary, usually solitary, for the most part 3-flowered. It is native of North America from Canada to Florida. The berries are black, and are called in Jersey *Ink Berries*. It is a low handsome shrub, and is said to be one of the plants the leaves of which are sometimes used instead of Paraguay Tea. The hardy species of this genus are well suited for shrubberies, and will thrive well in any common light soil, but they prefer peat. They are readily propagated by laying down the shoots or hy seeds. The stove species will grow well in a mixture of loam and peat, and ripened cuttings will root in sand under a hand-glass in moderate heat.

(Don, *Gardener's Dictionary*; Lindley, *Vegetable Kingdom*; Burnett, *Outlines of Botany*.)

PRINTS AND ENGRAVINGS. [Copyright, P. C.]

PRISMATIC TELESCOPE AND SEXTANT. Instruments bearing these names were invented by Professor Amici, at Modena, and the former is briefly described by Sir John Herschel in the Treatise on Light in the 'Encyclopædia Metropolitana.' In its simplest form it consists of two pairs of triangular prisms of glass, each pair being such that an object seen through the two shall he free from colour.

In order to understand its construction, let ABC, DEF, in

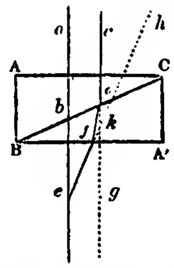


the plane of the paper, be the principal sections of the prisms, and PQ be one side of a square object having its surfaces perpendicular to the paper, so that the sides which pass through P and Q perpendicularly to the paper may be parallel to the refracting edges of the prisms; also let the eye of the spectator be situated at H: then the light proceeding from the surface of the square will, after refraction in the prisms, produce in the eye an image of a rectangular form, having the breadth in the direction of PQ greater than PQ, the length perpendicular to the paper being unaltered. If now tho rays emergent from the second prism be made to pass through two others similar to ABC and DEF, but having the plane of their principal sections perpendicular to that of the former prisms, the visible image of the square on PQ will have the length perpendicular to the paper increased as much as PQ was before increased while PQ retains the magnitude which it had acquired. Thus, after refraction through four such prisms, the image of an object is equally magnified in every direction, and is quite free from colour: and it is easy to perceive that by suffering the rays of light to pass through other systems of prisms, similarly formed and disposed, any required degree of magnifying power may be produced.

Sir John Herschel conceives that a telescope of this nature might be used with advantage for viewing bright objects, as the sun, since it would require no darkening glasses, and would be exempt from all the inconveniences which oppose the perfection of telescopes of the usual construction when applied to this particular purpose.

An optical instrument, which is also called a prismatic telescope, has been formed hy placing between the object-glass and its focus two prisms of a douhly refracting medium; thus producing two images of an object, which being, by moving the prisms, made to approach to or recede from one another, permit the instrument to be used as a micrometer. It was invented or improved by M. Rochon, and is sometimes employed for the purpose of ascertaining the magnitudes of terrestrial objects, or their distances from an observer: it has been also used in measuring small angular distances in the heavens.

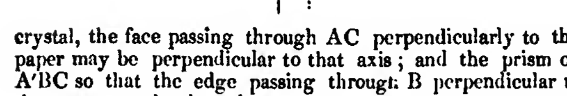
The two prisms may be of Iceland spar, or rock crystal, and each is cut in the form of a wedge whose principal section is a right angled triangle, as ABC or A′BC, and the two are applied in contact with each other as in the figure. The prism on ABC is cut so that, AB being the axis of the natural



crystal, the face passing through AC perpendicularly to the paper may be perpendicular to that axis; and the prism on A′BC so that the edge passing through B perpendicular to the paper may be the axis.

Now, if rays of light fall perpendicularly on the surface which passes through AC perpendicularly to the paper, those which, as *abe*, suffer the *ordinary* refraction, will preserve, in passing through the double prism and also on emerging from thence at the surface passing through A′B, the same directions as they had at their incidence on the opposite face; while the rays which, as *cd*, suffer the *extraordinary* refraction will, on arriving at the surface passing through BC, be turned from the original direction and take some other as *df* towards either B or A′ according as the crystal is of the kind called attractive or that which is called repulsive (suppose the former); then, on emerging from the surface standing on A′B, tho rays will proceed in some direction as *fe*, as if they came from points corresponding to *k* in the rays *cd* produced, and will cross the ordinary rays in points corresponding to *e*. An eye placed near *e* so as to receive the rays of both kinds will perceive two images of the object from whence they proceeded before they fell on the prism. The constant angle at which the rays are inclined to another is measured by *aeh*, *h* being in the direction of *ef* produced; and when the prism is of Iceland spar tho angle *aeh* may exceed 43 degrees; when of rock-crystal it may amount to 10 degrees.

Let the double prism be placed between the object-glass O of a telescope and its focus, the face standing on AC being



towards the former and perpendicular to the optical axis; and for simplicity, let the object be a straight line XY in a vertical position having one extremity X in the axis OE: then x and y being the foci of pencils diverging from X and Y, after being refracted through tho object-glass O, the line xy may represent the image of XY formed as usual by the ordinary rays in the pencil of light, and $x'y'$, in a vertical line passing through xy, the image produced by the extraordinary rays; the angle xkx' or $yk'y'$ being that which was denoted by *aeh* abovo. Therefore, if the angular deviation of the images formed by the two kinds of rays is small enough to permit the rays to enter the eye near E, after passing through the eye-glasses of the telescope (the angular deviation not being altered by the refractions in those eye-glasses) corresponding points in the two images will in general appear to subtend some angle at the eye. If the points k and k' in the prism are at the foci x and y of the object-glass, the two images of XY will evidently coincide; but, on moving the prism towards O, the images will separate gradually from one another, the angular deviations being proportional to the distance of k from x.

Now, on the exterior of the telescope in a direction parallel to its axis, there may be formed a scale which, by means of an index moveablo with the prisms, will serve to measure any subtended angles; thus:—The angle subtended at the naked eye of the observer by any object as XY, which may represent a straight line or the diameter of a circular disk, being less than the constant angle xkx', there will be found a certain position of the prisms at which one extremity Y of the line or diameter seen by the ordinarily refracted rays will appear to coincide with the opposite extremity X of the same line or diameter seen by the extraordinarily refracted rays. Then, the angle which the same object subtends at the eye in that position being determined trigonometrically or otherwise, the point at which the index stands should be numbered so as to express that angle. The like operation being performed for an object subtending a different angle at the eye, if the interval between the points at which the index stands be divided into a number of equal parts corresponding to the difference between those angles, and the divisions be continued in opposite directions, there will be constituted the required scale, by which the angle subtended when the images of any other line or disk are placed in contact, by moving the prisms, may be measured.

The *Prismatic Sextant*, invented by Professor Amici, is described in Zach's 'Correspondance Astronomique,' tom. vi. p. 554. It has no mirror, but, nearly at the place where the index-mirror is situated on a common sextant, there are two triangular prisms of glass whose parallel edges are perpendicular to the face of the instrument. One of these is fixed, and the other turns on one of its edges by the motion of the index-bar, the broadest faces being parallel to each other, and nearly in contact when the index is at the zero of the arc: the telescope also turns on a pivot near the prisms. The rays of light falling on the exterior faces of the prisms will, after two refractions and one reflexion, and after passing through the telescope, enter the eye of the observer, so that, by moving the index-bar, the images of the objects from whence the rays proceed may be made to appear in contact with each other; when the angle subtended between the objects will be rather greater than twice that which is described by the movement of the index. If the prisms are of common glass, and the broader faces of the prisms make with each other an angle of 90 degrees, the angle between the objects will be about 204 degrees.

The advantages of this sextant are that double altitudes of the sun, when on the meridian, may be observed by it, even at the equator, and that at sea the anterior and posterior horizon may be brought in contact, and thus the amount of tho horizontal refraction may be determined. It may be added that very little light is lost by reflexion, and that there is no parallax for near objects.

PRISTACANTHUS, a genus of fossil placoid fishes, from the oolite of Stonesfield. (Agassiz.)

PRISTIS. Three species of this genus of fishes are men tioned as fossil in the tertiary strata of England. (Morris's Catalogue.)

PRIVATE ACT. [PARLIAMENT, P. C.]

PRIVET. [LIGUSTRUM, P. C. S.]

PRIVY SEAL. [SIGNET, SEAL, P.C.] The Lord Keeper of the Privy Seal is a member of the Cabinet, and has a salary of 2000*l.* per annum. By an Act of 2 Wm. IV. c. 49, the Commissioners of the Treasury may abolish any of the offices of Clerks of the Signet and Privy Seal when they become vacant, and direct the duties to be performed by the remaining clerks.

PRIZE-MONEY. [PRIZE-MONEY, P. C.] Apprizements and sales of prize and capture are made by agents appointed by the commanders and other commissioned officers. A certified list of the persons entitled to share in the capture is transmitted to Chelsea Hospital by the commanding officer. There is a penalty of 500*l.* for altering names. At the end of three months from the receipt of prize-money, the treasurer of Chelsea Hospital is required to notify in the 'London Gazette' and in two London morning papers that distribution will be made at the end of one month. In this notification the share of an individual in each class must be declared. Shares of prize-money due to a non-commissioned officer or soldier, will be paid only upon personal application, or to his wife, or child, father or mother, brother or sister, or to the regimental agent of his regiment, or to any other regimental agent. If discharged, a certificate must accompany the application, signed by the clergyman and one of the churchwardens or overseers. Personating or falsely assuming the name and character of a person entitled to prize-money with fraudulent intent is punishable with transportation for life, or not less than seven years. By 3 & 4 Vict. c. 65, the Privy Council may refer to the High Court of Admiralty matters concerning booty of war (property captured by land forces). The Prize

Court of the Admiralty is the proper court for deciding on matters captured by naval forces.

PROBATE AND LEGACY DUTIES. These duties yield a sum exceeding two millions a year. The legacy duty is charged on legacies of the value of 20*l.* and upwards out of personal estate or charged upon real estate, and upon every share of residue. Legacy to a husband or wife is exempt from duty. To a child or parent, or any lineal descendant or ancestor of the deceased, the duty is 1*l.* per cent.; to a brother or sister or their descendants, 3*l.* per cent.; to an uncle or aunt or their descendants, 5*l.* per cent.; to a great uncle or great aunt or their descendants, 6*l.* per cent.; to any other relation or any stranger in blood, 10*l.* per cent. The probate duty is payable on the total sum left by the deceased. For sums above 20*l.* and not exceeding 100*l.* the duty is 10*s.* if there is a will; and if there is no will the duty of 10*s.* is chargeable on sums of 20*l.* and not exceeding 50*l.* The duties continue to increase according to a certain scale up to 1,000,000*l.* The following tables show the operation of the legacy and probate duties for nearly half a century; and in Porter's 'Progress of the Nation,' vol. iii. pp. 125-133, will be found some useful and interesting considerations on these duties as indications of the progress of national wealth :—

Duty received from 1797 to 1845 inclusive.	Legacies.	Probates, Administrations, and Testamentary Inventories.
	£.	£.
England . .	36,696,279	29,110,230

PRO'CULUS, a distinguished Roman jurist, the successor of Nerva the father. He belonged to the school of Labeo, and the followers of that school derived their name Proculiani from him. [LABEO, ANTISTIUS, P. C. S.] It is generally stated that his name was Sempronius Proculus, but Pomponius (Dig. 1, tit. 2, s. 2, § 47) calls him simply Proculus. The passage of the Digest (31, tit. 1, s. 47) which is cited to prove that his name was Sempronius does not prove that it was. In this passage Sempronius Proculus sends greeting to his grandson, and asks him his opinion about a legacy. 'Proculus respondit,' Proculus gave his opinion, and therefore the grandson and Proculus are the same person; and as Zimmern remarks, Proculus the jurist might be the son of the daughter of Sempronius Proculus the grandfather, in which case his name would not be Sempronius. It has been conjectured that Proculus the jurist is the Licinius Proculus whom Otho made Praefectus praetorio (Tacitus, *Hist.* i. 46, 82, 87, ii. 39, 40, 44, 60). Proculus is often cited in the Digest, and he is specially mentioned in a Rescript of the Divi Fratres as an eminent authority (Dig. 37, tit. 14, s. 17). There are thirty-seven excerpts in the Digest from a work of Proculus, entitled Epistolae, of which there were at least eleven books (Dig. 18, tit. 1, s. 69), though the Florentine Index mentions only eight. One of the excerpts (Dig. 33, tit. 6, s. 16) has the title 'Proculus, libro iii. ex Posterioribus Labeonis,' which appears to be a separate work or commentary on the Posteriora of Labeo. But as Javolenus wrote on the Posteriora of Labeo (Dig. 33, tit. 7, s. 4), it is conjectured that the title of s. 16 (Dig. 33 tit. 6) should be 'Javolenus.' (Grotius, *Vitae Jurisconsultorum*; Zimmern, *Geschichte des Römischen Privatrechts*, p. 316.)

PRODU'CTUS, the original name given by Sowerby to a large group of fossil Brachiopoda, most frequently found in the mountain-limestone series. Producta and, for part of the group, Leptæna, are synonyms.

PROMULGATION. Promulgation is from the Latin Promulgo, which is equivalent to Provulgo, and means 'to make public.' The modern sense of Promulgation of a Law is the making of it public or giving notice of it to all persons in some way or other. Blackstone observes (*Comm.* i. 45), 'It may be notified by universal tradition and long practice, which supposes a previous publication, and is the case of the common law of England. It may be notified *vivâ voce* by officers appointed for that purpose, as is done with regard to proclamations, and such acts of parliament as are appointed to be publicly read in churches and other assemblies. It may lastly be notified by writing, printing, or the like, which is the general course taken with all our acts of parliament.' A law is a command from a political superior to a political inferior to do or not to do something, with a penalty attached to the violation of the command, and it is assumed by Blackstone that the command is made known in some way to all who are bound to obey it; or it is presumed that it is known to all. But as to 'a universal tradition and long usage,' it is a mistake to say that it supposes a previous publication. A long usage does not of itself make law: the usage must be pronounced to be law by some competent authority, and that is the only promulgation which it has. Promulgation by proclamation is very ineffectual: it only reaches those who hear it. Further, everybody cannot hear an act of parliament which is read in churches, for the churches would not hold one-fourth of the people if they all went to hear it read; and if they heard it read, very few would understand it. Printing is at present the most efficient means of promulgating a new statute; but to all those who cannot read it is ineffectual; and also to those who cannot understand.

No remedy can be provided for these difficulties, and it is simply a positive rule of law that a new statute is binding on all persons who are under the authority of the power which makes the statute, from the moment that the statute is made and completed in due form. It is a foolish way of speaking to say that a person is presumed to know a law, when it may be very easy to show in many cases that he did not know it and could not know it. One kind of legal presumption consists in the assumption of a fact, which presumption may be disproved by evidence. But the presumption that a man knows the law is not an assumption which a man is permitted to disprove even if he can, and this presumption should be struck out of the list of presumptions and placed among positive rules of law.

If a man were allowed to urge ignorance of law as an excuse, it might be urged by a great majority in many matters of contract and in other cases too; and the trial of the fact of ignorance of law would give ample room for fraud. The positive rule that all the members of a state are bound by its laws, causes less evil than the admission of the excuse would.

Promulgation of a law among the Romans meant the placing of the bill (rogatio) in some public place where it could be read before it was voted upon in the Comitia. The Roman rule was that ignorance of law (ignorantia juris) was no excuse. (Paulus, *Dig.* 22, tit. 6. s. 9.)

PROPERTIES OF IRON, MEDICAL. Iron, in a purely metallic state, does not exert any appreciable influence over the human system. Nevertheless metallic iron is recommended as an antidote to poisoning by the salts of copper. Iron filings have been administered with a view to precipitate the copper in a metallic and therefore innocuous state. White of egg is a more prompt and generally more accessible antidote. The employment of iron filings to absorb fœtid exhalations from the feet is less beneficial than that of recently prepared and freshly powdered charcoal, put every morning into the shoes of those afflicted with this annoyance. Iron filings are sometimes prescribed, but before any marked effect can be produced by them, the metal must become an oxide or a salt; the presence of any acid in the stomach or alimentary canal promotes this change, while alkalies retard it. This form has been adopted in the treatment of worms, chiefly from the notion that the worms would be annoyed and dislodged by the mechanical irritation of particles of iron. This is an erroneous view. [ANTHELMINTICS, P. C.] Tincture of sesquichloride of iron in infusion of quassia is extremely beneficial in all cases of worms, but its efficiency depends on its tonic and astringent properties.

A few only of the preparations and uses of iron can be given here. Sesquioxide of iron (rust, or the subcarbonate of some pharmacopœias), has been given in tic douloureux, in very large doses; in some instances with success. It is likewise useful in some cases of spasmodic contractions of the joints. The very large doses in which it is required to be given is a serious impediment to its use; for not only are the patients averse to it, but it clogs the intestines, which require to be frequently cleared out by a brisk cathartic.

The black oxide is not so liable to objection, as it is more readily soluble in the fluids of the alimentary canal.

Ammonio-chloride of iron possesses no advantage over the simple chloride; the tincture of which, called tincture of sesquichloride of iron, is extremely valuable, as an emmenagogue; it likewise is very beneficial in checking menorhagia proceeding from relaxation of the uterus. It checks hæmaturia from relaxation of the tissue of the kidneys. In frequently repeated small doses it relaxes spasmodic stricture of the urethra. But the sense of nausea and sinking which it causes, render patients averse to its repetition. It acts as a potent astringent when employed externally or to mucous membranes as an injection.

Sulphate of iron can be given in small doses, in pills or otherwise. Its powers are often much heightened by combination with sulphate of quinia. In nervous debility and indigestion this form is valuable.

Ferro-tartrate of iron has less unpleasantness of taste than most of the other preparations of iron, and is therefore more acceptable to children, to whom also the vinum ferri is much prescribed. Both these are nearly superseded by the citrate or ammonio-citrate of iron, which can be given in the form of lozenge or syrup. The latter given in warm water or lemonade is relished by most children.

Iodide of iron is a preparation of great value in strumous disorders.

The same may be said of the phosphate of iron, a preparation formerly in the 'London Pharmacopœia,' and now most unjustly excluded from it. In the phosphatic diathesis of feeble subjects, with a tendency to rickets, it is invaluable. The dose for children is a very few grains, cautiously increased. The numerous preparations of iron recently introduced by chemists have not been sufficiently tried to permit them to be spoken of with certainty; but in many cases their utility is obvious. Of these the chief are citrate of iron, Potassio-citrate, Sodio-citrate, Zinco-citrate, Magnesio-citrate, Ferro-citrate, and Citrate of quinine and iron; this last is of great service in tic douloureux.

Chalybeate waters often furnish the best medium for administering iron; especially when the iron is associated with much free carbonic acid. Where no free carbonic acid is present, and in some instances even where it exists, the water of the springs should be received in and drunk out of *warm* water. This often prevents the spasm which is apt to occur when very cold water is suddenly taken into the stomach.

Besides being reputed an antidote to the poisonous salts of copper, iron is asserted to prove an antidote to other violent poisons.

Hydrate of peroxide of iron, called also hydrated peroxide of iron, is considered a trustworthy antidote against arsenic, if administered promptly, while the arsenic is yet in the stomach, and not absorbed. Prussic acid may be decomposed or combined, so as to be rendered innocuous, by giving promptly, first, solution of carbonate of potass, followed by a very diluted solution of the proto-persulphate of iron; the object being to form a ferro-prussiate of potass in the stomach. (See 'Lancet,' 5th October, 1844, or 'Pharmaceutical Journal,' vol. iv. p. 373.)

Physiological Effects and Therapeutic Employment of Iron.—Iron exists both in plants and many animals, as the mammiferæ and birds, constituting an essential part of their fluids and solids; but, incorporated as it is thoroughly with them, it gives rise to none of those phenomena which it occasions when taken into the stomach. Upon the living tissues iron has a tonic influence; and as its preparations greatly promote digestion, they excite the appetite and render more easy the elaboration of the aliment. The vitality of the digestive organs being exalted, they extract from the food more of the nutritious principles, and thereby furnish a greater quantity fit to be assimilated.

These beneficial effects are best seen when the medicine is given in small and long-continued doses, or in the greatly diluted state in which iron occurs in the mineral waters or chalybeate springs. On the other hand, chalybeates occasion at times, especially if in large doses, pain of the epigastre, nausea, fœtid eructations, and great anxiety; consequences referable to the immediate impression, a sort of constrictive action, which the preparations of iron make or exercise when they reach the stomach, upon its internal surface, and the nerves which are distributed upon it. The unpleasant effects may generally be avoided by giving it at first in very small doses, gradually increased, or by diluting it with some vegetable substance of little activity.

Iron given in large doses, when it reaches the intestines, produces in some persons obstinate constipation, accompanied with a sense of great heat in the lower belly; in others it occasions colics and frequent alvine dejections; while with a third set of persons none of these effects follow its administration.

During the use of iron the fauces invariably become blackened, which is caused by the tannin of our food acting upon the iron.

In respect to the secondary effects of iron, the amount of these depends upon the quantity absorbed, and the length of time it has been given. That it is absorbed, in most instances, and carried into the circulation, is proved both by the effects of it being felt over the whole system, and by being distinctly recognisable in the urine on the addition of an infusion of galls. When used for some time, chalybeates increase greatly the power of the heart; the pulse becomes stronger and harder—effects most observable upon persons previously enfeebled by disease. If persisted in, they cause increased arterial action, followed by febrile commotion, sense of heat, and hæmorrhagic discharges from different parts of the body. These phenomena show themselves most speedily in persons of a plethoric habit and sanguine temperament; iron also rouses the absorbent organs when sluggish.

The functions of nutrition and assimilation are greatly heightened by the use of iron; but if it be too long persevered in, diseases of over-action ensue, as inflammations, hæmorrhages, &c. These symptoms indicate the necessity of discontinuing it.

The preparations of iron are unquestionably efficacious in diseases which proceed from a relaxation of the substance of the living tissues, from an inactivity of the reparative or assimilative function, or in case of weakness proceeding from deficient supply of nervous energy.

Hence they are indicated in Anæmia, in convalescence from debilitating fevers, and other tedious diseases, as well as after some of the more acute phlegmasiæ, as pneumonia, the cough remaining after which, if not occasioned by any organic change, is sooner removed by preparations of iron or bark than any other means. Chalybeates are likewise given in defective menstruation from debility of the uterus, and sometimes in sterility. In chlorosis iron is almost our sheet-anchor, while it is also very serviceable in some forms of dyspepsia, also in worms (in which the sulph.-ferri is given in large doses), in passive hæmorrhages, and is prescribed empirically in many of the cachexiæ, as scrofula.

Chalybeates are found useful in many nervous diseases, as hysteria: the cough which is often present in these complaints may be effectually removed by preparations of iron. The indurations, too, of the mammæ (apt to be considered of a cancerous nature), and of other glands in hysterical females, are often dispersed by the use of iron. Some of the forms of tic douloureux, not dependent upon organic causes, are often cured by chalybeates. Iron has likewise been prescribed in the intervals of the paroxysms of intermittents, particularly quartans. The sulphate is given in the dose of ʒi. in a pint of water,—in which circumstances it can only act beneficially, like cinchona or bitter tonics,—iron being among minerals what bitter herbs are among vegetable remedies.

Chalybeates are *contra*-indicated in plethora and all inflammatory diseases, as well as active hæmorrhages, as also during pregnancy in females of a sanguine temperament.

PROPERTY-TAX. [Taxation, P. C.]

PROPYLÆUM (προπύλαιον: the great entrance to the Acropolis of Athens was called προπύλαια, in the plural number; Thucydides, ii. 13), signifying literally a fore-portal or one detached from and placed in advance of the building to which it gave access, is used as a distinctive term for the structures through which was the entrance into the enclosure surrounding some of the Grecian temples. Unlike the vast truncated pyramidal masses or moles that enclosed the fore-court of Egyptian temples, on the entrance side, leaving only a lofty square-headed portal for access, thereby screening the main edifice and colonnades within the court, and giving the exterior the aspect of a fortress,—the propylæa of the Greeks were detached structures placed in advance of the sacred edifice itself, so as to mark very conspicuously the approach to it through the outer enclosure or boundary. They seem to have been intended in some degree to prefigure the temple itself to which they conducted, their general appearance in front being almost identically the same as that of the frontispiece-façade or pediment end of a prostyle temple;—which repetition, by the by, and sameness of design do not say much for invention on the part on tho architects, or for the capability of the style employed by them to impress distinct character on structures of so opposite a kind as a temple and the gateway conducting to it; unless we would rather suppose that the kind of prefiguration above hinted at was aimed at directly and studiously.

The general arrangement and character of a Greek propylæum may be described as similar to those of an amphiprostyle temple [TEMPLE, P. C.], shorter however on its sides than the width in frunt, and without any *cella*, yet not entirely open to both fronts, but divided by an inner wall across it from side to side, into two portions, the outer one of which, answering to the *pronaos* of a temple, was larger than the other; so that the whole may be more briefly, if not more intelligibly explained, by comparing the plan to the *pronaos* and *opisthodomus* of an amphiprostyle temple, put together without any intervening cella, being separated only by the wall above mentioned, in which were as many open doorways as there were intercolumns in front.

Such was the disposition of the propylæa both of the Parthenon at Athens and of the temple at Eleusis, the only two examples of such structures known to us, and the latter now so only by the drawings of it in the unedited antiquities of Athens: there were, indeed, as we learn from Pausanias (ii. 3) propylæa at Corinth, but of their architectural design we know nothing. Tho Athenian structure stands on the west side of the Acropolis, as may be seen by the cut in PARTHENON, P. C. (vol. xvii. page 288, col. 2), which shows its relative position to the temple itself—an irregular one, the two buildings not being on the same axis or line. This propylæum, which was begun by the architect Mnesicles in the 4th year of the 85th olympiad, and completed in five years, is of the Doric order, and hexastyle on both fronts; and the outer or western one was greatly extended by two flanking wings projecting forward at right angles, so as to enclose the platform to which an ascent of steps led up from below, and above which the portico and the two lesser colonnades forming the sides of the wings were raised upon three other steps. Thus the platform (78 feet from north to south, by 40 east and west) became an elevated open fore-court, presenting a principal portico in front crowned by a pediment, and two colonnades, which being considerably lower (their columns 19 feet, the others 28½ feet high) gave greater importance to the former; and a degree of scenic effect—combination, contrast, and variety was produced, very unusual in Grecian architecture, and which must originally have been very striking when the lower flight of steps existed, of which however there now exists no trace, they having been destroyed to make way for a Turkish battery to defend the approach to the Acropolis. In the second century of the Christian æra that first ascent was flanked on each side by an equestrian statue (one of them conjectured by Chandler, from an inscription, to have been that of Agrippa, wherefore it is probable that the other was that of Augustus), which, though later additions to the structure, must have greatly enhanced the general appearance of the architectural ensemble.

But one of the most remarkable circumstances which served to distinguish the Propylæum from a portico is that in the western or outer division there were two rows of inner columns placed not parallel with, but at right angles to the columns in front, and in a line with the two middle ones, thereby dividing the plan internally into three compartments, the centre one narrower than the other two, and forming an avenue to the principal doorway, which was the largest and loftiest of the five openings in the transverse wall, and the two end ones the smallest. These inner columns, too, instead of being of the same order as the exterior, were Ionic,—a very remarkable peculiarity, inasmuch as it evidences an intermingling of styles almost unknown to Grecian architecture. The licence—so to call it—was, however, fully justified by the circumstances of the case, because columns of lesser diameter than the external ones were required, and also of such height as to reach the architrave soffits of the internal ceiling, which are in a line with the top of the architrave of the external order.

The Eleusis propylæum resembled that of the Acropolis in nearly all particulars, except that it had no wings attached to it. Like the Athenian one, it was of the Doric order, hexastyle on both fronts, and had six Ionic columns within, similarly in two rows.

As modern structures partaking of the antient Greek propylæum character, may be mentioned Cagnola's Porta Ticinense at Milan [CAGNOLA, P. C. S.], and the London Terminus of the London and Birmingham Railway, in Euston-square, which, though only a distyle in antis in both fronts, is a fine example of Grecian Doric upon a scale of extraordinary magnitude. Both the modern examples, however, differ from the antient ones in being entirely open, without any internal transverse wall; and the Italian one has, moreover, a large open arch on each side, forming a passage through it in that direction.

PRO'TEA, PROTEA'CEÆ. [XYLOMELON, P. C.]

PROTEIN. [CHEMISTRY, P. C. S.]

PROTEST. [PARLIAMENT, P. C.]

PROTOCOCCUS. [SNOW, RED, P. C.]

PROTO'PTERIS, a genus of fossil plants, from the coal formation, includes Sigillaria punctata of Brongniart. (Presl.)

PROVIDENCE, OLD, is an island in the Caribbean Sea, about 125 miles from the Mosquito Coast, and between 13° 19′ and 13° 32′ N. lat. and 81° 20′ and 81° 23′ W. long. This island is nearly four miles and a quarter long, and two and a half in its greatest breadth: it is of an irregular oval shape. The highest ground near the centre of the island rises to 1190 feet above the level of the sea, so that it can be seen at a distance of from 33 to 36 miles. From this point other hills, mostly wooded to their summits, diverge towards the shore and terminate in a bold coast. Separated from its northern end by a cut or channel of from forty to sixty yards wide, is the island of Santa Catalina, 1800 yards long by 1300 in its greatest breadth, forming the northern boundary of a harbour in Old Providence which affords secure anchorage in two to three and a half fathoms.

These islands are surrounded by an extensive bank of coral and coarse sand, which stretches to the northward a distance of ten miles and a half. The larger part of the island is unfit for cultivation, owing to its being extremely hilly. But the soil is very productive, and affords rich crops with very little cultivation. Cotton is the chief object of cultivation, and is annually exported to the amount of 30,000 pounds; the sugar-cane and coffee are also grown, but only in sufficient quantities for the consumption of the inhabitants. Fruits of various kind, such as sapodillas, mangoes, oranges, tamarinds, plums, and limes are plentiful, and also cocoa-nuts. Yams and plantains are extensively grown, and afford the principal food. Cattle, horses, fowls and turkeys are numerous. Wild pigeons, iguanas, and land turtles abound: the last are found in the mountains, and form a delicious article of food. Sea-turtle and fish are very numerous. The exports consist of cotton, turtle-shells, and a few hides, which are paid for by the traders from Jamaica with calicoes, cloth, and a few articles of cutlery.

It is not well known when this island was discovered and taken possession of by the Spaniards. In 1664 it was taken from them by the famous buccaneer Mansvelt, who considered it well adapted to be the head-quarters of the lawless band of which he was the leader. After his death Morgan kept it, and fortified the island of Santa Catalina, but he left it when he was appointed deputy governor of Jamaica (1677). After that time it appears only to have been visited occasionally, and remained uninhabited until 1795, when a few families from Blewfields on the Mosquito Coast settled there by the permission of the Spaniards. From this time to 1817 it remained quite tranquil, when General Avery, a bold and energetic man, who had become a privateer, took possession of it and repaired the principal fort. The spoil, collected during his predatory excursions, was brought to this island, when a considerable trade was established. At his death (1822) the privateers dispersed, and the island returned to the dominion of the republic of New Granada. By the last census (1835) the population amounted to only 342 persons, about one-half of whom were slaves. They employ themselves principally in taking turtle, and they visit with their three vessels, from ten to fifteen tons burthen, the banks in the neighbourhood. They speak the English language.

(Collett, *On the Island of Old Providence*, in 'London Geographical Journal,' vol. vii.)

PRUNELLA, a genus of plants belonging to the natural order Labiatæ. It has two inferior stamens. The filaments bifid, one branch barren. The anthers all 2-celled. The corolla ringent, the upper lip concave, entire, the calyx ultimately closed and compressed, the upper lip flat, truncate, 3-toothed, the lower lip bifid.

P. vulgaris, Self-heal, is a native of Europe and Asia, very plentiful in America and Australia, and also in England. The leaves are stalked, ovate or oblong, toothed or deeply pinnatifid, the upper lip of the calyx with short truncate mucronate teeth, the lower lip with ovate-lanceolate mucronate teeth, the two longest stamens with a straight spinous root at their apex. The flowers are purple, white, or nearly red. In the British specimens the leaves are nearly entire. This plant is considered astringent, and was formerly used in fluxes and gargarisms for apthæ and inflammation of the fauces. Its repute is now merely in name.

P. grandiflora has petiolate ovate leaves, quite entire or toothed, the lateral teeth of the upper lip of the corolla lanceolate, the corollas large, more than twice as long as the calyx. It is native throughout Europe in woods and shady places; the flowers are of a purple or violet colour, seldom white. All the species of Prunella are showy when in blossom, and are therefore worth cultivation in flower-gardens and rock-work. They grow in any common garden soil, but thrive best in a damp moist situation. They are readily propagated by seed or division.

(Don, *Gardener's Dictionary;* Babington, *New British Botany;* Lindley, *Vegetable Kingdom.*)

PRUSSIC ACID—*Medical Properties of.* This acid, termed also hydrocyanic acid, has been described according to its chemical relations in P. C. Its medical employment, and its connection with medical jurisprudence, from the frequent use of it in cases of death, accidental or intentional, merit the most attentive consideration. But these are unsuited for popular discussion. A few important rules and cautions can alone be furnished here.

Much variation in strength exists in the acid (that is, the dilute acid, for the anhydrous is always of definite strength), owing to different methods of preparation Thus not only does a difference of strength exist in the acid as it is enjoined to be prepared by the Edinburgh and London colleges, but even in England two preparations are commonly met with, that enjoined by the London Pharmaeopœia, which contains 2 per cent. of real acid, and that which has been long known as Scheele's, containing 4 per cent. The substitution of the one for the other in preparing a prescription might lead to serious if not fatal consequences. A still greater difference exists in the strength of the preparations met with in different countries of the Continent. No one in travelling should ever prescribe prussic acid, unless he has previously ascertained what preparation will be employed in compounding the prescription.

As it undergoes decomposition by time, especially if exposed to the light, and is readily volatilized at a high temperature, it should be kept in the dark, and in a cool place. As it is specifically lighter than water, it rises to the surface in watery fluids. The fluid in which it is kept should be well shaken before pouring it out. When employed externally as a lotion, in which case it is used in larger doses than when meant for internal employment, great care should be observed to distinguish it, lest it should be accidentally taken internally. Even its external employment demands great care, for when the cuticle is abraded or cracked, it is readily absorbed, and may prove fatal. The cuticle, even when in a state of integrity, is not proof against the vapour of prussic acid. All bottles containing the acid should be kept well corked, as the vapour is the most potent form which can influence the human frame.

When first introduced into medical practice, high expectations were formed of the utility of Prussic Acid. Subsequent experience has moderated these expectations; but there is no doubt that it might be found useful in many instances where it is not employed, the dread of accidents deterring many medical men from using it. Such hesitation displayed by those who know its properties should furnish a salutary caution to all persons against employing it on their own responsibility. The diseases in which it has been most recommended are—affections of the lungs, whether acute inflammation, after the active stage is passed, or those of irritation. Among the former, hooping-cough is unquestionably benefited by it. But here great caution is necessary. Its premature employment, by checking the cough, induces inflammation, often of a very alarming kind. The dose should at first be very small, and most slowly increased. In some works, even emanating from medical men, large doses are most culpably ordered. More relief is obtained in consumption from Conium than from this acid. Some affections of the stomach receive signal relief; others derive not the least benefit from it. The explanation of this appears to be that in the former the causes of the disorder, as well as its seat, are in the stomach itself; while in the latter the pain is felt chiefly in the stomach, but the cause is in the spinal chord. Treatment directed to the spine will in general quickly and often permanently relieve the sufferer. (Teale's *Treatise on Neuralgic Diseases.*) Cutaneous diseases are alleviated by lotions and ointments containing hydrocyanic acid. But the cautions above given must be carefully observed during their employment.

The most useful hints which can be here given relate to the treatment of poisoning by prussic acid. So soon as it is ascertained or suspected that any one has taken an over or poisonous dose, cold water should be dashed over the head and back. The vapour of ammonia (common smelling salts) or of chlorine should be applied to the nostrils; or very dilute liquor ammoniæ may be thrown into the stomach. While these things are doing, other persons may prepare a weak solution of carbonate of potash (common pearlashes will answer); and some sulphate of iron (copperas) is to be dissolved in a large quantity of water. Some of the solution of the carbonate of potash is to be given to the patient, followed immediately by some of the solution of copperas. This, if done promptly, will save the patient. Artificial respiration, if speedily resorted to, is useful, as is likewise bleeding from the jugular vein.

PSALI'ODUS, a genus of fossil fishes, from Sheppey. (Egerton.)

PSA'MMODUS, a genus of fossil placoid fishes, from the mountain-limestone of Bristol and Armagh. (Agassiz.)

PSEUDOLI'VA, a genus of Gasteropoda, which includes one fossil species from the London clay. (Sowerby.)

PSI'DIUM (from ψίδιον, the Greek name for a pomegranate), a genus of plants belonging to the natural order Myrtaceæ. The tube of the calyx is ellipsoid or obovate, usually contracted at the apex; the limb ovate, undivided, but afterwards from 1- to 5-cleft. There are five petals and numerous free stamens inserted in a broad circle, almost through the whole undivided part of the limb; the style is filiform, the stigma capitate: the ovules are numerous, horizontal, and fixed to the margin of the placenta; the berry is many-seeded, corticate by the tube of the calyx, and crowned by its lobes. The seeds imbedded in the pulp in the mature fruit with a bony testa. The species are trees or shrubs, natives of America within the tropics. The fruit is edible, and is known by the name of Guava. It has a fragrant but peculiar odour and very sapid taste, and is eaten both raw and when made into jelly.

P. pomiferum, Apple-bearing or common Red Guava, has tetragonal branches, oval or oblong lanceolate leaves, pubescent beneath, from 3 to 8 peduncles or many-flowered. The fruit is globose, yellow, and somewhat astringent, with an agreeable odour; the root and young leaves are astringent, and are esteemed strengthening to the stomach. It is native of the West Indies, Mexico, and South America.

P. montanum has tetragonal branches, oval oblong leaves, acuminated and quite glabrous; the peduncles many-flowered, and the fruit roundish. It is native of Jamaica on the mountains. The fruit is small, acid, and smells strongly like bitter almonds, hence it is called *Almandron*. The wood is very hard and of a fine colour and grain. It works well, takes a fine polish, and is much esteemed for ornamental purposes. The species of Guava grow freely in a mixture of loam and peat. Cuttings will strike root in sand with a hand-glass over them. Some of the species bear fruit in the stoves of this country, but they are hardly worth the trouble of growing for this purpose.

(Don, *Gardener's Dictionary;* Burnett, *Outlines of Botany.*)

PSYCHO'TRIA (from ψυχή, breath, life, in allusion to the powerful medicinal qualities of some of the species), a genus of plants belonging to the natural order Chinchonaceæ and the tribe Coffeæ. The limb of the calyx is 5-lobed, 5-toothed, or nearly entire. The corolla funnel-shaped, short, 5-cleft; the limb spreading or recurved, the throat bearded or glabrous. There are 5 stamens, the anthers exserted or enclosed. The berry is drupaceous, crowned by the limb of the calyx, furnished with 10 blunt ribs in the dried state. The species are small trees or shrubs, natives within the tropics; they are very numerous and intricate.

P. emetica has a perpendicular knotted branched root with a slender axis, and a thick friable back. It is an erect simple hairy under-shrub, with oblong acuminate leaves narrowed at the base, membranous ciliated, rather pilose beneath; stipules ovate acuminate and very short. The peduncles are axillary and few, flowered somewhat racemose and white. It is the ipecacuanha supplied by South America, and is the striated ipecacuanha of some authors. The root possesses similar qualities to those of ipecacuanha, and contains, according to M. Pelletier, 9 per cent. of emetine.

P. noxia is a native of Brazil, with compressed branchlets furnished with two rows of hairs; the leaves are lanceolate, acuminated, on short petioles, approximate, glabrous; the stipules short, bipartite, the flowers 2-4 in a fascicle, sessile, bracteate, terminal, and axillary. This species is accounted poisonous in Brazil; it is known by tho name ol *Erva de rata*, and is used for the destruction of rats and mice.

P. speciosa is employed in Brazil in the same diseases as sarsaparilla; and *P. tinctoria* forms a fine red dye much valued in Peru. All the species of *Psychotria* are of most easy culture and propagation. They grow best in a mixture of loam, peat, and sand, and cuttings will strike root readily if planted in sand underneath a hand-glass. Some of them bear handsome foliage, but the flowers of all are insignificant.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*; Lindley, *Vegetable Kingdom*.)

PSY'THIRUS, a genus of Hymenopterous insects of the family *Apidæ* and the division *Sociales*. It includes certain humble-bees structurally incapable of forming their own nests, and considered parasitic by St. Fargeau, the entomologist who established this genus.

PTA'RMICA, a genus of plants belonging to the natural order Asteraceæ. It has a campanulate involucre with the scales brown and scarious at the edge. The receptacle is flat or scarcely convex, broad, and paleaceous. The ligulæ from 5 to 20, flat, expanded, much longer than the involucre. The achænia are bald, obcompressed, the outer often somewhat winged at the edge.

P. vulgaris has a widely creeping root, very difficult to extirpate when the soil is moist. Upright stems about two feet high, angular, smooth, hollow, leafy, with small axillary rudiments of branches corymbose at the top. The leaves are sessile, linear, or slightly lanceolate acute, very minutely serrated with bristly teeth. Smooth on both sides and of a dark green. The flowers are milk-white, larger than most others of the same genus. The whole plant is pungent, and provokes a flow of saliva. Its dried leaves produce sneezing, but this is thought to be owing to their little sharp marginal teeth: the root is aromatic. The heads of *P. nana, atrata*, and *moschata* are used in the Swiss Alps as a substitute for tea. *P. moschata* is the basis of the aromatic liqueur called Esprit d'Iva.

(Lindley, *Veget. Kingdom*; Lindley, *Flora Medica*.)

PTERI'CHTHYS, a singular genus of fossil ganoid fishes, from the old red-sandstone of Scotland and Orkney. (Agassiz.)

PTERI'NEA, a fossil genus of Conchifera, allied to Avicula, and hitherto confined to the Palæozoic, and chiefly found in the Devonian strata. (Goldfuss.)

PTERIS (from πτέρον, a wing), a genus of plants belonging to the natural order Filices. The thecæ arise from the points of veins placed on a nerve-like receptacle running along the edge of the leaf, forming an uninterrupted marginal sorus; the involucres are continuous with the edge of the leaf, scarious, and opening inwards.

P. aquilina, common Fern, or Bracken, is the most abundant of our British species. It has a long tapering creeping rhizoma, externally black. The leaves are erect, from one to six feet high, repeatedly compound with horizontally spreading divisions, whose ribs are smooth; the primary leaves are nearly opposite, the lower ones more alternate, pinnatifid segments oblong, obtuse. They are all of a light bright green colour, slightly brown at the edge, which is revolute and crisped, or wavy, sheltering the dense linear masses of tawny thecæ. The main stalks are angular and sharp-edged, wounding the hands severely if plucked incautiously. When cut across, the rhizoma has a branched appearance resembling a spread eagle, whence the Latin name. There is scarcely any wood, heath, or forest in the United Kingdom where this plant does not make its appearance. It is said to be indicative of poor soil, but it is more probable that its absence from cultivated ground is to be attributed to the effects of the hoe and the plough, rather than to the quality of the soil. The geographical range of this species is very extensive; it is included in every European list, and is found also in Asia and Africa. It is used in many parts of England and Scotland for manure, and in the Western Isles the poor people gain considerable profit by collecting the leaves, and selling the ashes to soap and glass makers, on account of the large quantities of alkali contained in them. As a litter for horses, brakes or fern is in great request in Wales, Scotland, and Ireland, and when chopped up with hay they are sometimes fed upon it. In Invernesshire the poorer classes thatch the tops of their houses with the leaves, and they form a very durable covering. Pigs are fed upon the roots boiled down into a mucilaginous mass. This species is tho *Filix fœmina* of our older authors. It is likewise the θηλυπτέρις of Theophrastus, 'Hist. Pl.' 9. 18, and of Dioscorides, 4. 184. The antients are said to have used both tho rhizomas and fronds of this fern in decoctions and diet-drinks, in chronic disorders of all kinds arising from obstruction of the viscera and spleen. Some modern authors give it a high character for the same purposes, but it is now seldom used by medical practitioners. In Haller's time its reputation was very extensive as a destroyer of worms, and a bed of the green fronds was esteemed a sovereign remedy for rickets in children. The rhizoma is so astringent that in some places it is used for tanning and dressing red and chamois leather. It has been employed as a substitute for hops, and in the Canaries a miserable sort of bread is made by grinding the root with barley.

(Newman, *British Ferns*; Babington, *Manual of British Botany*; Lindley, *Flora Medica*.)

PTEROCARPUS (from πτέρον, a wing, and κάρπος, a fruit, in reference to the pods being girded with a broad wing). It has a 5-cleft calyx, a corolla with 5 petals, disposed into a papilionaceous form; 10 monadelphous or diadelphous stamens, an irregular indehiscent legume, somewhat orbicular, surrounded by a wing, woody, and often rugose, in the middle 1-3-celled. The leaves are unequally pinnated The racemes axillary, or forming terminal panicles. Tho species are unarmed trees or shrubs.

P. Draco, Dragon's-blood Pterocarpus, is a tree nearly 30 feet high, with alternate shining leaflets, about 5 on each side, and an odd one, rather obtuse, entire, veined, smooth, pale green below; the legumes nearly smooth. The wood of this tree is white and heavy, the bark thick and of a rusty grey colour. When first cut it presents no marks of redness, but in a little time red drops of juice begin to collect and exude from the wood. If left in the sun for about ten minutes they become hard and clear, and are collected under the name of *sanguis draconis*, or dragon's-blood. This resin formerly constituted an extensive article of commerce from Carthagena, but from its diminished consumption its collection has ceased, and all the dragon's-blood obtained now in the market is the produce of *Calamus Draco*.

P. marsupium is a tree with a very high trunk, scarcely ever found straight. The bark has a brown outer coat which is thin and spongy, and falls off in flakes, disclosing the inner bark, which is fibrous, red, and astringent. Tho branches are numerous, horizontal, and spreading. The leaves subbifarious, alternate, pinnate, with an odd one, 8 or 9 inches long. The panicles are terminal and very large, ramifications bifarious. The flowers are very numerous, white, and with a small spot of yellow in the centre. The bracts small, caducous, solitary below each division and subdivision of the panicle. The seed is solitary and kidney-shaped. This tree is thought by Roxburgh to be the one yielding *gum kino*, a well known astringent,—the juice hardening into a dark red and very brittle gum resin, which, on being powdered, changes to a light brown, not unlike Peruvian bark. Its taste is strong, but simply astringent. The real kino-tree however appears to be the next species.

P. erinaceus is a tree 40 or 50 feet in height. It has unequally pinnate leaves, smooth above, downy beneath; from 11 to 15 leaflets, alternate, distant, on short stalks, ovate, oblong, obtuse, or emarginate, wiry at the edge; lanceolate stipules, solitary or clustered racemes, downy from the old wood below, the young branches much shorter than the leaves. The flowers are yellow, the legumes stipulate, compressed, membranous, velvety, serrated, and undulated, prickly on the centre. When the branches are wounded, a clear bright gum exudes from them, which is the real *gum kino* of commerce, and is mentioned as such by Mr. Mungo Park. It is a very powerful remedy in obstinate chronic diarrhœas and dysenteries, and in all diseases arising from laxity of tissue. Externally it is applied as a styptic to check hæmorrhages from wounds and ulcers, and to diminish discharges.

P. santalinus is a lofty tree having alternate stalked ternate leaves, petiolate alternate leaflets smooth above, hoary beneath. The racemes are axillary, simple, or branched, and erect. The legume roundish, stalked, falcate upwards, compressed, smooth, keeled on the lower edge, the keel being membranous and undulated. From this tree is obtained the Red Sandal-wood, a timber chiefly used by dyers and colour manufacturers of the present day, but which is also used to colour several officinal preparations, such as compound tincture of lavender. Its colouring matter forms beautiful coloured precipitates with many metallic solutions.

P. flavus is the *yellow sandal-tree*, and is used for dyeing yellow. Its bark is very bitter.

The species of this genus thrive best in a loamy soil, and young cuttings not deprived of their leaves root readily in sand under a hand-glass in heat.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany*.)

PTEROPHY'LLUM, a genus of fossil Cycadeous plants from the oolite of Yorkshire and beds of the same age in Scania. (Brongniart.)

PTILODI'CTYA, a genus of fossil corals from the Silurian strata of Salop, Westmoreland, and Tyrone. (Lonsdale.)

PTYCACA'NTHUS, a genus of fossil placoid fishes from the old red and mountain limestone strata. (Agassiz.)

PTYCHO'CERAS, a fossil genus of Cephalopoda from the gault of Folkstone. (D'Orbigny.)

PTY'CHODUS, a genus of fossil fishes from the Cretaceous system of England. (Agassiz.)

PTYCHO'LEPIS, a genus of fossil ganoid fishes from the lias of England, &c. (Agassiz.)

PUBLIC HEALTH. On the 14th May, 1838, the Poor Law Commissioners presented to Lord John Russell, then Secretary of State for Home Affairs, a Report by Dr. Arnott and Dr. Kay, and two Reports by Dr. Southwood Smith, relative to the prevalence of disease among the labouring classes in certain districts of the metropolis. The House of Lords having, on the 19th of August, 1839, presented an address to her Majesty requesting her to direct an inquiry to be made as to the extent of the causes of disease mentioned in those Reports, the Poor Law Commissioners received a letter from Lord John Russell, in which he stated that her Majesty required them to make such inquiry, not only as to the metropolis, but as to other parts of England and Wales, and to prepare a Report stating the result of such inquiry.

In 1840 the subject was investigated by a Committee of the House of Commons, the result of which was a Report 'On the Health of Large Towns and Populous Districts.'

In July, 1842, the Report of the Poor Law Commissioners was presented to both Houses of Parliament, entitled a 'Report on the Sanitary Condition of the Labouring Population of Great Britain,' by Edwin Chadwick, Esq. 'Local Reports on the Sanitary Condition of the Labouring Population of England,' were presented at the same time. Of these local Reports there were twenty-six, some of which relate to certain counties and others to particular towns. At the same time were presented 'Reports on the Sanitary Condition of the Labouring Population of Scotland.' In 1843 a 'Supplementary Report on the Results of a Special Inquiry into the Practice of Interment in Towns,' by Edwin Chadwick, Esq., was presented. On this subject see some remarks under INTERMENT, P. C. S.

On the 9th of May, 1843, Commissioners were appointed by the Queen for the purpose of 'inquiring into the present state of large towns and populous districts in England and Wales, with reference to the causes of disease among the inhabitants, and into the best means of promoting and securing the public health, under the operation of the laws and regulations now in force, and the usages at present prevailing with regard to the drainage of lands, the erection, drainage, and ventilation of buildings, and the supply of water, in such towns and districts, whether for purposes of health, or for the better protection of property from fire; and how far the public health and the condition of the poorer classes of the people of this realm, and the salubrity and safety of their dwellings, may be promoted by the amendment of such laws, regulations, and usages.'

The first Report of the Commissioners was presented to both Houses of Parliament at the end of June, 1844. The Report is accompanied by 437 folio pages of evidence on which the Report is founded, an Appendix of Special Reports on the sanatory condition of several towns, among the most important of which are—Liverpool, by W. H. Duncan, M.D.; Ashton-under-Lyne, by John Ross Coulthart, Esq.; the City of York, by Thomas Laycock, M.D.; and Nottingham, by Thomas Hawksley, Esq.; besides other information on the Supply and Filtration of Water, on the Obstacles to Improvement in the Structure of Buildings, on the Cleansing of Streets and Houses, and on the application of Refuse.

The Second Report of the Commissioners was presented to Parliament in February, 1845. It treats briefly of the Causes of Disease, and at considerable length of Remedial Measures. It is followed by a Report on the State of Birmingham and other Towns, by R. A. Slaney, Esq.; a Report on the State of Bristol and other Towns, by Sir Henry T. de la Beche; a Report on the State of Large Towns in Lancashire, by Dr. Lyon Playfair; and a Supplement containing information on sewers, lodging-houses, and other matters connected with the inquiries of the Commissioners.

We have thus briefly stated the origin and progress of this important investigation into the sanatory condition of the population of Great Britain, chiefly indeed of the labouring and poorer inhabitants, but extending indirectly to all classes.

Other agencies for improving the physical condition of the labouring classes and of the poor are also at work. Among these is the 'Health of Towns' Association,' of which the Committee includes noblemen, dignitaries of the church, members of parliament, and other gentlemen. They have published a 'Lecture on the Unhealthiness of Towns, its Causes and Remedies, delivered at Crosby Hall, London, by William Augustus Guy, M.B., Physician to King's College Hospital;' a 'Lecture on the Unhealthiness of Towns, its Causes and Remedies, delivered Dec. 10, 1845, at the Mechanics' Institute at Plymouth, by Viscount Ebrington, M.P.;' and a 'Report of the Committee to the Members of the Association, on Lord Lincoln's Bill.' (Lord Lincoln's Bill was introduced into Parliament at the close of the session of 1845.)

These important inquiries have proved by undeniable evidence, that the districts inhabited by the labouring classes, and often by tradesmen, in large towns, in many small towns, and in several parts of the country, are in a very noxious state, from want of drainage, want of cleanliness, imperfect ventilation, deficiency of water, and density of population; the consequences of which are great frequency of sickness, and excessive destruction of human life. Typhus fever, cholera, consumption, scrofulous and other chronic complaints, mostly arising from causes which might have been prevented, are found to exist to an extent which it is painful to contemplate. The causes of sickness are generally most numerous and most intense in the crowded districts, and the mortality is found to be, with few exceptions, in proportion to the density of population. In the metropolis, for instance, the annual mortality is 3 per cent. in Whitechapel, but only 2 per cent in St. George's, Hanover Square. In the district of Bethnal-Green, 57 houses, on an average, were found to contain 580 persons; and in some cases there were 30 persons in a single house.

Of fifty towns which were visited by direction of the Commissioners, only eight were found to be in a tolerable state as to drainage and cleansing; and as to the supply of water the reports were still more unfavourable.

The annual average mortality in England is 2·207 per cent., or 1 in 45. In healthy districts it is 2 per cent., or 1 in 50. In the metropolis the deaths are 1 in 39; in Birmingham and Leeds 1 in 37; in Sheffield, 1 in 33; in Bristol 1 in 32; in Manchester, 1 in 30; in Liverpool 1 in 29. In Brussels they have been found to be 1 in 24. The mortality was found to be greater in Liverpool than in any other town in England. By the return made to the Town Council of Liverpool in 1841, by their surveyors, it appears that there were then 2398 courts, which contained a population of 68,345 persons. In these courts 1272 cellars were occupied by 6290 persons; of the number of cellars occupied in streets, 2848 were described as damp, and 240 as wet. The gentry in Liverpool live 35 years; the tradesmen 22; the working class 15. The average of the whole town is only 17 years. By extracting from the mortuary registers of the metropolis for 1834, the ages at death of the gentry, the tradesmen, and the working classes, who died at the age of 15 and upwards, Mr. Guy ascertained that the gentry lived 59 years, the tradesmen 49, and the working classes 48. In 1844 the deaths in the metropolis were 50,423. If the rate of mortality had been 1 in 50 instead of 1 in 39, the deaths would have been only 40,145, thus giving a saving of 10,278 lives in one year. From a Report of the Registrar-General it appears that out of every million of inhabitants 27,000 die every year in the large towns, and only 19,300 in the rural districts.

The large towns have already begun to make improvements. The improved drainage in twenty streets of Manchester has been found to diminish the annual number of deaths by more than 20 in every 110; and similar results of structural improvement have followed in other instances.

The loss of life, and the pecuniary charges consequent upon it to individuals and the community, are not the only considerations to be attended to. Not only the sickness which precedes death, but the sickness which is cured, renders the sufferers incapable of following their usual occupations, and obliges them and their families to seek relief from the parish, and from public and private charity. It has been shown that pecuniary saving would result from sanatory improvements to such an amount as to justify the action of the legislature, if it were only from motives of public economy.

The power vested in courts-leet by antient usage is resorted to in a few towns for the abatement of minor nuisances. Mr. Coulthart gives a detailed description of the various matters which have been taken cognizance of by the leet juries at Ashton-under-Lyne with beneficial effect. In most places, however, the exercise of these powers has fallen into desuetude, even where the courts still continue to be held.

The measures necessary to be adopted in order to improve the sanatory condition of large towns and populous districts are comprised under tho following heads:—

1. Drainage, including house and street drainage, and the drainage of any place not covered with houses, yet influencing the health of the inhabitants.
2. The paving of streets, courts, and alleys.
3. Cleansing, comprising the removal of all refuse matter not carried off by drainage, and the removal of nuisances.
4. A sufficient supply of water for public purposes and domestic use.
5. The construction and ventilation of buildings in such a manner as to promote rather than injure the health of the inhabitants.

The Second Report of the Commissioners gives Thirty Recommendations to the legislature, each of which is preceded by the reasons on which the recommendation is founded. We can only afford space for a summary of these recommendations.

No. 1 recommends that in all cases the local administrative body shall have the special charge and direction of all works required for sanatory purposes, but that the crown shall possess a general power of supervision.

Nos. 2 to 11 relate to *Drainage;* surveys and plans; definition of area for drainage by the crown; appointment of surveyors; investigations by authority of the crown, on representations duly made; management of the drainage of the entire area by one body; purchase of rights of mill-owners and others; construction of sewers, branch sewers, and house-drains; rating of landlords when house is let in separate apartments, or when the rent is collected more frequently than once a quarter, or when the yearly rent is less than 10*l.*; providing of funds by the local administrative body, distribution of cost among the owners of the properties benefited, and charge of house-drains on owners of houses to which they belong; power to raise money, and provision for gradual liquidation of debt incurred.

No. 12 recommends that the *Paving* be under the same management as the draining; but that it be performed by the local public officers.

Nos. 13, 14, and 15, relate to the *Cleansing* of all privies and cess-pools at proper times and on due notice; removal of large collections of dung; and abatement of nuisances arising from noxious exhalations from factories.

Nos. 17 to 21 relate to the supply of *Water*, in sufficient quantities not only for the domestic wants of the inhabitants, but also for cleansing the streets, scouring the sewers and drains, and the extinction of fires; purchase of the interests of water-companies, and placing the management of the supply of water under the local administrative body; the establishment of *public baths* and *wash-houses* for the poorer classes; and especially recommending that the supply of water in the mains be not only constant, but at as high a pressure as circumstances will permit.

Nos. 22 to 26 are regulations for *Buildings*, including power to raise money for the purchase of property, for the purpose of opening thoroughfares, and widening streets, courts, and alleys; prohibition of use of cellars as dwellings, except when they are of certain dimensions and properly ventilated; provision for building all new houses with proper privies, and for a good system of ventilation in all edifices for public assemblage and resort, especially school-houses.

Nos. 27 and 28 recommend that power be given to the local administrative body to compel landlords to cleanse houses duly reported to be in a noxious state from filthiness —and that power be given to the magistrates to license and issue rules for regulation of lodging-houses for the reception of vagrants, trampers, and persons of similar wayfaring habits.

No 29 recommends the appointment of a medical officer in each town or district, who shall report periodically on the sanatory condition of such town or district.

No. 30 recommends the establishment of *Public Walks*, and that the local administrative body be empowered to raise the necessary funds for the management and care of the walks when established.

A large portion of the 'Report of the Committee on Lord Lincoln's Bill,' before mentioned, is occupied with showing that the supply of water, wherever practicable, should be constant, not only in the main pipes, but in the branch-pipes, thus doing away entirely with the use of water-butts; and contending that in most cases such a constant supply is not only practicable but economical, and that it would contribute in the highest degree to the cleanliness of houses in crowded districts, and consequently to the health of the inhabitants.

PUBLIC POLICY. This expression sometimes occurs in the reports of law cases, and sometimes the expression 'policy of the law' occurs; neither of these expressions has a sufficiently definite meaning. An example will best explain how they are applied. One man may agree with another for a certain valuable consideration to give up to him premises in which he carried on some trade, art, or business, and agree that he will not carry on the same within the realm of England. The object of the bargain is to secure to him who pays his money, all the benefit which can be derived from it. But he who has received the money may happen to break his contract by commencing the same trade, art, or business in a distant part of the realm, as at the Land's End or Newcastle-on-Tyne, the original place of his trade, art, or business being supposed to be in London. Now if an action were brought on such a contract, it could not be maintained, and the reason would be that the contract was against public policy, which would be explained to mean that the public ought not to be deprived of a man's services by such an unreasonable contract. Yet it would be said that if the contract were that the man who received the money should not exercise his trade, art, or business within a certain limited distance of London, the contract would be valid. This would imply that the public of a given district may be deprived of a man's services in order that another individual may have an advantage, or that he may receive the full benefit of his contract. It would be a more consistent conclusion to declare the contract altogether invalid, if reasons of public policy, as they are called, are to be taken into the account in forming a judgment of the validity of the contract. But the admission that the contract is valid if it applies to a limited district, contains by implication a better reason for declaring the contract in its full extent to be invalid than reasons of public policy. The implied assumption is, that the person who pays the money is entitled to the full benefit of his contract and no more. If then it shall appear that he can sustain no real damage by the receiver of the money carrying on his trade, or art, or business at a remote place, that is a sufficient answer to his complaint. (Horner *v.* Graves, 7 Bing. 743.)

Still it may be said that there are contracts which ought to be declared void for reasons of public policy, or, to use a more correct expression of Lord Hardwicke, reasons of public utility (Earl of Chesterfield, &c., *versus* Sir Abraham Jannsen, 2 Vez. 156). Lord Hardwicke observes, 'Particular persons in contracts shall not only transact *bonâ fide* between themselves, but shall not transact *malâ fide* in respect of other persons, who stand in such a relation to either as to be affected by the contract or the consequences of it; and as the rest of mankind besides the parties contracting are concerned, it is properly said to be governed by public utility.' He gives as an instance 'premiums contracted to be given for preferring or recommending to public office or employment; none of the parties are defrauded, but the persons having the legal appointment of these offices are or may be deceived thereby.' We may suppose a case in which the person recommended is a fit person, and no damage is caused by the bargain to give a premium.

But then it may be urged, as Lord Hardwicke would argue, that damage to the public service may be caused by such bargain, and we may admit that generally it would be so. But the possible, the probable damage to the public service is perhaps not the best ground on which to assume the invalidity of such bargains. If the person who has the appointment to a place in the public service receives the power of appointment on the condition, expressed or implied, that he shall get no profit from the appointment, any premium that he might bargain for would clearly make the bargain illegal; because the thing is not a subject of bargain or sale. The same reason is equally applicable to any other person whose recommendation may help another to an office, for by the supposition the office is not a thing that can be the subject of bargain and sale. (Compare *Inst.* iii. tit. 19, s. 2.)

Possibly the so-called cases of contract which are against public policy might be determined on some legal principle, which should not require the introduction of the principle of determining that a contract shall be void because 'it is prejudicial to the public.' (Mallan *v.* May, M. & W. ii. 665.) If the validity of a contract is to be determined on this principle, it is very difficult to say what limits must be set to its application.

PULICA'RIA, a genus of plants belonging to the natural order Asteraceæ. It has an involucre laxly imbricated in few rows. The pappus in two rows, the outer one short, cup-like, membranous, and toothed, the inner one pilose.

P. vulgaris has lanceolate wavy leaves, narrow at the base and somewhat clasping; the stem much branched and downy; the heads lateral and terminal, hemispherical, with very short rays. It is the *Inula* of Linnæus. The heads are small, the florets yellow. It is found on moist sandy heaths in Great Britain. This species is the common Flea-bane; so called from its being disliked by vermin and used to drive away fleas.

P. dysenterica has a creeping root, and is a herb more or less woolly or cottony, glutinous, and with a peculiar and aromatic smell. The stem rises 12 or 15 inches high: it is round, leafy, cottony, corymbose at the summit, with many bright yellow flower-heads, whose disk is of a darker hue than their numerous spreading rays. The leaves are acute, veiny, and wrinkled, or slightly toothed or serrated, from one to two inches long, sessile, clasping the stem, the under side cottony. The fruit is bristly and obovate, the pappus rough, the receptacle slightly cellular, unequally toothed or scaly. Linnæus states, on the authority of General Keith, that this plant cured the Russian army of the dysentery. But Haller speaks contemptuously of the medical virtues of this plant, because he says it abounds in earthy matter. It is found in damp places in Great Britain.

(Burnett, *Outlines of Botany*; Lindley, *Flora Medica*; Lindley, *Vegetable Kingdom*.)

PULMONA'RIA (so named from its being supposed efficacious in disorders of the lungs, or from the spots on the leaves resembling those on some diseased lungs), a genus of plants belonging to the natural order Boragineæ. It has a tubular 5-cleft calyx, a funnel-shaped corolla with a naked throat. The stamens included in the tube filaments very short. The style is simple, the nuts smooth, attached by their truncate base with a central tubercle. The species are herbaceous plants with spotted leaves and terminal corymbose racemes of flowers.

P. officinalis, Lungwort, has ovate leaves, roundish or cordate, the upper leaves oblong. The root is thick and black. The corollas are red before expansion and then purple. The whole plant is more or less hispid. It is found in the woods and thickets of England, and is native of Europe and the Caucasus. The leaves, which are the parts of the plant recommended in medicine, have no peculiar smell, but in their recent state manifest a slightly astringent and mucilaginous taste,—hence they are supposed to be demulcent and pectoral, and have been prescribed in consumption. All these plants contain nitre in considerable quantities, and when burnt this species yields one-seventh of its weight in ashes. In the north of Europe it is eaten as a potherb, and according to Ray in his time it was brought to table in Scotland.

P. angustifolia has all lanceolate leaves. It is difficult to distinguish from the former species, but is more pubescent, and has narrower spotless leaves. The corolla is purple, and there is a variety with white flowers. It is native of Europe. All the species of *Pulmonaria* are pretty plants when in blossom, and are desirable for gardens on account of their early flowering. They are very easily cultivated, and will grow in any common garden soil: they are readily propagated by division. Most of the species grow well under the drip of trees and in moist situations.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*; Burnett, *Outlines of Botany*.)

PUNCTUM CAECUM, in the eye, is the part of the surface of the retina which is immediately about the spot at which the optic nerve appears to be united to that membrane. At this spot the retina has not sufficient delicacy of fibre to receive impressions from the rays of light which, coming from external objects and converging there, should form images of those objects: consequently the part contributes nothing to the perception of vision.

Its existence in each eye is proved by a well-known experiment, which was first made by Marriotte:—on a dark ground, as a black board, in a vertical position, place on a level with the eye two disks of white paper about half an inch in diameter (or on a white ground, as a wall, place two disks of black paper), the disks being from three inches to two feet asunder from centre to centre: then, standing with the right eye directly before the left hand disk, at a distance from it equal to four or five times the interval between the disks, and closing the left eye, look with the other at that object; it will be found that the right hand disk is invisible, in consequence of the light from it falling on the spot in the eye at which no image is formed. The left hand disk would disappear if the spectator, closing his right eye, should stand with his left directly before the right hand disk.

The experiment may be varied by standing with the right eye directly before the right hand object, then closing the left eye, and looking, without turning the head, obliquely at the left hand object: the right hand disk will then disappear. The left hand object will disappear if the left eye be brought directly before it, the right eye be closed, and the other be directed obliquely to the right hand object. The experiment may also be performed with three disks; the spectator should then place himself directly before the middle object, at a distance from it equal to four or five times the distances of the disks from one other; when closing the left eye, for example, and looking, without turning the head, at the left hand object, the middle disk will disappear while the others remain visible.

From an experiment made by Daniel Bernoulli it is found that the part of the retina on which the rays of light produce no impression, is a circular spot whose diameter is one-seventh of the diameter of the eye, and having its centre a little way distant from the axis, or point directly opposite the centre of the pupil. This is precisely the spot from which the optic nerve appears to expand in the interior of the eye.

PURBECK. [DORSETSHIRE, P. C.]

PURCHASE, which is corrupted from the Latin word Perquisitio, is defined by Littleton (i. 12) to be 'the possession of lands or tenements that a man hath by his deed or agreement, unto which possession he cometh not by title of descent from any of his ancestors, or of his cousins (consanguinei), but by his own deed.' Purchase as thus defined comprehends all the modes of acquiring property in land by deed or agreement, and not by descent; but it is not a complete description of purchase, as now understood, for it omits the mode of acquisition by will or testament, which however, when Littleton wrote, was of comparatively small importance, as the power of devising lands did not then exist, except by the custom of particular places. Blackstone makes the following enumeration of the modes of purchase — Escheat Occupancy, Prescription, Forfeiture, and Alienation. As to escheat, there is some difficulty in the classification, as the title appears to be partly by descent and partly by purchase; and alienation is here used in a larger sense than that which this term has in the Roman law, in which it does not comprehend acquisition by testament. Generally then, purchase is any mode of acquiring lands or tenements, except by Descent. [DESCENT, P. C.]

PURL. [ARTEMISIA ABSINTHIUM, P. C. S.]

PUTREFACTION. [ANTISEPTICS, P. C.]

PY'CNODUS, an extensive genus of fossil placoid fishes from the oolitic and cretaceous strata of England. (Agassiz.)

PYE, HENRY JAMES, was the son of a Berkshire gentleman who represented that county in parliament. He took the degree of M.A. at Oxford in 1766. Several small volumes of poems, and a translation of Aristotle's Poetry, with a commentary, were held to give him, on Thomas Warton's death in 1790, a claim to the office of poet-laureate, to the fame of which, however, he added nothing either before or after his appointment. He was for a good many years member of parliament for his native county; and on the changes which took place in the magistracy of Westminster, he was appointed one of the commissioners of police. He died in 1813, and was succeeded in the laureateship by Southey.

PY'RAMIS, a genus of Gasteropoda, which includes two species from the shales near Hebden Bridge. (Brown, *Manch. Geol. Trans.*)

PYRETHRUM (from πῦρ, fire, because of the hot taste of the root), a genus of Composite plants belonging to the tribe Asteraceæ. It has a hemispherical involucre, the receptacle flat or convex. The fruit angular and not winged. The pappus an elevated membranous border.

P. Parthenium, Feverfew, has stalked pinnate leaves, with ovate or oblong segments, and pinnatifid; they are of a hoary green, the leaflets incline to ovate decurrent and cut. The flower-heads are erect, about half an inch broad, with a convex yellow disk, and numerous short broad abrupt 2-ribbed white rays, often wanting, sometimes multiplied, and the disk being obliterated constituting a double flower. The whole plant is bitter and strong scented, reckoned tonic, stimulating, and anti-hysteric. It was once a popular remedy in ague. It is said that the odour is peculiarly disagreeable to bees, and that these insects may be easily kept at a distance by carrying a handful of the flower-heads. It is common in many parts of Europe and in England.

P. inodorum has sessile pinnatifid leaves, in numerous capillary pointed segments. A branched stem, solitary heads, the involucral scales lanceolate obtuse; the fruit rugose with two round glandular dots on the external face just below the elevated entire border. It is found in fields and waste places in Great Britain.

P. maritimum has sessile doubly pinnate leaves, with fleshy segments, convex above, keeled beneath. The stem diffuse and branched, the heads solitary; the fruit rugose, and with 2 elongated glandular spots on the external face, just below the elevated lobed border. It is found on sea-shores in Great Britain.

P. officinale is the Pellitory of Spain, once much esteemed as a sialagogue, and resorted to for relief in toothache. Grew says that 'when the root of *pyrethrum* is chewed, it makes a sensible impression on the lips, which continues like the flame of a coal betwixt in and out for nine or ten minutes.' When extracted, the acrid oil contained in the root is said to be serviceable in cases of palsy, and when cutaneous action is required, as a liniment. Ainslie says it is administered in typhus fever by the Indian practitioners.

(Burnett, *Outlines of Botany;* Lindley, *Flora Medica;* Babington, *Manual of British Botany.*)

PYRINA, a fossil genus of Echinodermata proposed by Des Moulins for the Nucleolites depressa of the green-sand.

PY'ROGEN is a term very recently applied to the electric fluid, derived from the Greek word πῦρ, fire. The views of Mr. Lake, who first proposed it a short time since, are novel, and certainly deserve consideration. He submits the change of name 'because there appears to be a degree of indefiniteness in the terms *electricity*, *electric fluid*,' &c., and hoping that he has produced sufficient evidence 'in support of its materiality and existence as a chemical body,' he conceives 'it might be an advantage if this or some similar name were adopted. *Electrine* might have been used, but as the fluid has no more connection with amber (ἤλεκτρον) than many other substances possessing like properties, he has chosen to propose an entire change of name; and as it bears the greatest resemblance to fire, and seems to have a most intimate connection with that element, the word *Pyrogen* is submitted.'

He maintains, in the first place, that as electricity produces mechanical effects upon matter (for instance, reduces the strongest oak to splinters, and some substances into powder, removes large blocks of stone out of their places, drills holes in metal vessels, and occasions earthquakes), it must be matter, as nothing of an immaterial nature can produce mechanical effects upon material bodies.

He was led, he says, to deduce the material nature of electricity from the above considerations, and a simple experiment with a small galvanic arrangement, consisting of a pair of plates 2 inches by 4 inches, in a half-pint drinking-glass, in which the wires connecting the poles were joined together and insulated by non-conducting supports. From this arrangement and the wires being insulated, the fluid could not have proceeded from without, and he considers that it was developed on pouring the acid solution into the glass, from a new chemical arrangement of the liquid matter, and, as water is the only ingredient actually decomposed, the fluid must enter into the composition of it together with oxygen and hydrogen; which view receives much support from the fact that water is formed on the combustion of these gases by the electric spark.

A difficulty however arises on this point, for these gases may be exploded by the application of any flame. But Mr. Lake removes this by proposing a new theory of combustion, or rather, ignition, by showing that flame is the electric fluid rendered visible whilst effecting the decomposition of air, and the union of the oxygen obtained from it with the hydrogen of the burning body; and in proof of this theory advances the facts, that in all the various methods adopted to obtain fire, it is generated by electric excitation (except when obtained by a burning-glass from the sun), and that in damp weather, when the atmosphere is deprived of the electric fluid, held in suspension by it at other times to a very considerable extent, fires and lights burn very dull.

In further support of this theory he offers the following explanation of the ingenious experiments of Messrs. Pollock, Gann, and Mackrell on the ignition of metals in acid solutions. It may be well to premise that the acid solution through which the electric currents were passed was composed of one part sulphuric acid and ten parts distilled water, in a common drinking-glass that held about a pint.

'Experiment 1. Fine iron wires (No. 26) were attached to the terminal wires of the battery. That connected with the positive was first immersed in the solution, and the circuit was completed by the immersion of the negative wire. The latter burned with a beautiful reddish flame. This would seem to result from the following cause:—Hydrogen and pyrogen being released at the negative pole on the decomposition of the water, and the oxygen of the acid having a greater affinity for these than for sulphur, the acid is decomposed, the sulphur is deposited on the negative electrode, and the released gas combining with the hydrogen and pyrogen, combustion (ignition) takes place. When the experiment is reversed, and the negative wire first brought into the solution, the circuit being completed by the positive, the latter became red-hot to the extent of an inch and a half under the solution. This resulted from the accumulation, as it is called, at the poles of the unconnected piles, rendering the pyrogenic current more powerful when contact is first made than at any time during its continuation. No flame appeared at the positive pole, there being no hydrogen present, all that obtained having escaped at the negative electrode.

'Experiment 2. A platinum plate, an inch long by half an inch wide, being attached to the negative wire, and a small iron wire at the positive, the platinum being first immersed in the solution, and the circuit completed by the positive wire, it became red-hot an inch and a half under the solution, as in the last experiment, and from the same cause; but when it was only brought into contact with the surface of the solution it fused, which was prevented when it was immersed.

'Experiment 3. When the iron wire was placed at the negative end of the battery and the platinum at the positive, the platinum being first put into the solution and the circuit completed by the iron wire, the latter burned with a red flame. This resulted from both oxygen and hydrogen being present at the negative pole, as in the first experiment.

'Experiment 4. A fine copper wire was attached to the positive terminal, and a platinum wire to the negative. The platinum being as usual first immersed, and the circuit completed by the insertion of the copper wire, the latter was heated an inch under the water. The cause of there being no flame is the same as in the former experiments, for the copper wire being at the positive electrode, no hydrogen was present to produce it. But when the experiment was reversed, and the copper wire placed at the negative termination and the platinum at the positive, the latter being first immersed and the circuit completed by the former, the copper or negative wire burned with a bluish flame, oxygen and hydrogen being, as before, present at that pole.

'Experiment 5. A slip of zinc was used instead of copper wire, and with the same result; for when placed at the positive termination, and the platinum at the negative, and the latter being first immersed in the solution, the zinc was heated an inch below the surface of the liquid, but when the zinc was placed at the negative, the platinum at the positive, and the latter first immersed, the zinc at the negative burned with a purple flame, hydrogen being present, as before, at that pole.

'Experiment 6. With platinum at the positive and sulphuret of antimony at the negative, the platinum being first immersed, the antimony or negative electrode fused and inflamed, depositing on the glass and surface of the solution an orange-coloured powder resembling Kermes' mineral. When the sulphuret was at the positive, the platinum at the negative, and the latter first immersed in the solution, white fumes were given off by the sulphuret, but it was not ignited, for, as in the preceding experiments, there was not any hydrogen at the positive pole.

'Experiment 7. When an iron wire was fixed to the positive, and a charcoal point at the negative termination, the iron wire being first immersed, immediately the charcoal touched the solution it became very brilliant. But when the experiment was reversed this did not occur; for when charcoal was at the negative hydrogen was present, but not when at the positive.'

Mr. Lake considers that in these experiments the ignition could only have resulted from the presence of electricity and the power it possesses of causing matter to vary its form; and that they particularly evince its property of ready combination with oxygen and hydrogen and formation of flame.

This discovery will produce an important revolution in chemical science; for if electricity enters into the composition of water it must also be a constituent part of every body into the formation of which water enters.

Mr. Lake also shows that the fluid is a component part of oxides; that, in fact, it is the medium by which the union of oxygen with its bases is brought about, and that it was by its abstraction Sir H. Davy reduced potash, magnesia, and other substances. It would also appear that it is a most important ingredient in acids, and that it forms ozone by combining with oxygen. [OZONE, P. C. S.] 'Water,' he says, 'is the medium by which many chemical substances amalgamate, or are decomposed, and new forms of matter produced. Many bodies may be placed together, ground together, and every device adopted to produce chemical action among them in vain; but let only a little water be introduced, and immediately the desired effect is produced; the substances are in part, or entirely, decomposed, and the matter of which they consisted assumes altogether different forms, and acquires different properties.

'Pyrogen acts in a similar manner, and by its abstraction or introduction chemical action takes place. Thus it is found that by discharges of it in common air nitric acid is produced; and when mercury is placed in contact with a solution of ammonia, and negatively electrified,—that is, the pyrogen drawn from it,—it expands in volume and becomes a soft solid. But the presence of pyrogen, which returns to it on breaking communication with the galvanic battery, destroys the affinity between the mercury and ammonia. Therefore, when the product of this experiment is exposed to water, the latter is decomposed by it, giving out hydrogen, whilst the former absorbs oxygen and pyrogen, leaving mercury and a solution of ammonia. If exposed to air this is also decomposed, and oxygen and pyrogen absorbed.

'Potassium, sodium, calcium, barium, strontium, and many other bodies, are obtained by the abstraction of pyrogen from their oxides, by which means the affinity between them and oxygen is destroyed, and they separate. But, as in the case of the amalgam of mercury and ammonia, and from the same cause, as soon as they are exposed to air or water, they absorb oxygen and pyrogen, and return to oxides.

'The chemical affinity of pyrogen and oxygen appears to be less with ammonia than potassium, sodium, calcium, barium, strontium, and some others; for when any of these are united as an amalgam with mercury, and exhibited in this state to ammonia, an amalgam of mercury and the bases of ammonia is formed, and the fixed alkalies or earths are reproduced, the first amalgam having absorbed the pyrogen and oxygen of the second.'

In explaining the experiments of Messrs. Schönbein and Gann with ozone, Mr. Lake deduces that zinc, nitrogen, and hydrogen, and perhaps iron and copper, are not simple bodies. He draws this conclusion as regards the metals from the different colours of the flames in the experiments of Messrs. Pollock and others on the ignition of metals in acid solutions, and, in respect to zinc, the additional singularity of the smell produced by it when used as an electrode in obtaining ozone. As to the opinion concerning the gases, he arrives at it from ozone (which he considers to be a compound of oxygen and the electric fluid) being obtained from them. [OZONE, P. C. S.]

One other point remains to be noticed, namely, the connection of the electric fluid with the acids. Concerning this our author says,—'Pyrogen enters into the composition of carbonic acid, which may be generated by the passage of a current of the former from charcoal (that is, carbon) points. By this means the oxygen of the atmosphere unites with the carbon, which has the greatest possible affinity for it when pyrogen is present in motion.' Again, 'Carbonic acid can be dissolved by the abstraction of pyrogen from it, by exhibiting to it other substances which have a greater affinity for the latter. When carbonate of ammonia is employed in producing an amalgam of the bases of ammonia and mercury, there is a most decided decomposition of this acid and formation of carbonaceous matter.'

'Pyrogen also enters into the composition of nitric acid, which is produced on passing sparks or discharges of it through atmospheric air. . . . . . By analysis, pyrogen may be obtained from nitric acid by using a solution of the latter in the experiments' on the ignition of metals in acid solutions. [OZONE, P. C. S.] In a similar manner it may be procured 'from muriatic, phosphoric, and many other acids.'

These views of this subject certainly explain many phenomena going on around us, the causes of which have hitherto been inexplicable. Thus, in one of his papers Mr. Lake says that the development of carbonic acid by plants results from the electric fluid, which is in a constant state of circulation, uniting with the carbon of the plants and oxygen of the air. He might have gone farther, and shown, upon his own theory, that plants not only make use of the fluid in this manner, but that they actually produce it from the water with which they are supplied, as is proved by Pouillet's experiments with insulated corn-plants.

The subject being new, we will not enter into further details; but the above is the substance of what has appeared concerning it.

(*Polytechnic Review*, April, 1844, p. 227; New Series, vol. i. p. 349; vol. ii. pp. 4, 93, 259; *Proceedings of London Electrical Society*, 1841-42, p. 6; Sir H. Davy, 'On the Earths,' *Philosophical Transactions*, 1808; Noad's *Lectures on Electricity*, Lecture 2.)

QUADRATURE. Not thinking of this Supplement, we inserted in the article TRISECTION, P. C., the extension given to the approximate arithmetical quadrature by Mr. Rutherford (Phil. Trans., 1841). With this reference, we take the opportunity of saying that we have re-examined the numbers, and find them correctly printed.

Strange as it may seem, this problem of the quadrature of the circle still engages attention: and persons are found to believe that they have attained even the arithmetical quadrature. It has been stated in foreign newspapers within these few years that the British government does offer, and always has offered, a large reward for the solution of this problem. This, we need hardly say, is a complete mistake: the government never at any time offered one farthing for the quadrature of the circle. The only problem for the solution of which any reward was at any time offered, was the practical mode of finding longitude: and even this offer is now retracted; rewards having been, in fact, received by several persons. Should this article fall into the hands of any, at home or abroad, who are working at any mathematical or astronomical difficulty under the impression that our government is pledged to remunerate them in case of success, they may rest assured that their information is incorrect, and that they will find it to be so on inquiry.

QUICKSANDS are those masses of loose or moving sand which are formed on many sea-coasts and generally at the mouths of rivers: those of the Nile and Senegal are among the most remarkable for these accumulations. The sands are generally conveyed by the rivers from the interior of the country, and being at first arrested by the waters of the ocean, they become, by the action of the winds and tides, moveable *bars*, which are very dangerous to shipping. The loose sands on the coasts are, when dry, driven by winds over the land, which they then cover often to a considerable depth, overlaying the fertile ground and occasionally entombing whole villages: the coasts of Cornwall in England and of Jutland in Denmark are particularly subject to these encroachments; and it is stated that, in the latter country, there are vast beds of sand so loose as to be incapable of supporting the weight of a man. In Greenland there is a chain of ice-hills between two promontories of moving sand, which is driven by the winds far out to sea.

The sand of Bagshot Heath, which rests on London clay, is in many places, at a few feet below the surface, saturated with water so as to constitute a perfect quicksand: and, on the borders of Oman, in Arabia, there was discovered by Baron von Wrede a remarkable quicksand, which is said to be more than 60 feet deep.

R.

RADIATA. [Rayed or Radiated Animals, P. C.]

RADIOLA (from *radiolus*, little ray, in allusion to the rayed capsules), a genus of plants belonging to the natural order Lineæ. It has a calyx of 4 sepals connected below, deeply trifid. There are 4 petals, 4 stamens, 4 capsules, with 8 cells and 8 valves.

R. milligrana is the only species of this genus. It is the *R. linoides* of some botanists, and is a British plant. The stem is from one to two feet high, repeatedly forked, with solitary flowers in the axils as well as at the extremities of the branches. The flowers are small and white; the capsules light brown and slightly depressed; the sepals deeply and acutely 3-cleft, connected below into a tube. The seeds of this very small plant should be sown in a moist situation where they may afterwards be allowed to scatter themselves.

(Babington, *Manual of British Botany;* Don, *Gardener's Dictionary.*)

RAIA, a genus of cartilaginous fishes, established by Linnæus, and since much subdivided by ichthyologists. The rays differ from the sharks in being horizontally flattened so that their bodies with their broad and fleshy pectoral fins resemble large expanded disks. The eyes and spiracles are placed above the mouth, nostrils and bronchial orifices below. The dorsal fins spring from the tail. The common skate and the ray are familiar examples.

The following are the principal sub-genera into which *Raia* has been divided:—

Torpedo. Rays with short and rather thick tails, and having the disk of their bodies nearly circular. Their teeth are small and sharp. The torpedos are remarkable for the electrical apparatus with which they are provided; it is seated in the part between the pectorals, head, and branchiæ. Fishes of this genus are rare in the British seas, but common on the coasts of southern Europe.

Raia. The tail of the typical Rays is slender, and bears two small dorsal fins towards the extremity, with sometimes an imperfect caudal fin. The disk of the body is rhomboidal; the mouth is armed with slender thickly-set teeth arranged in quincuncial order.

Trygon. The Sting-rays, which have a slender finless tail armed with a sharp serrated spine by which the fish can inflict severe wounds; hence its popular name. The head is enveloped in the pectorals, and the teeth are slender and arranged as in *Raia* proper.

Myliobatis. Tail very long, armed and bearing a small dorsal fin; head projecting from between the pectorals, which are very broad. Teeth flat and arranged like stones in a pavement. The Whip-ray belongs to this sub-genus.

Cephaloptera. Tail also armed, and bearing a small dorsal, but the head is curiously truncated, and is placed between two horn-like processes of the broad pectoral fins, giving the creature a very extraordinary and incomplete or mutilated aspect. The teeth are small and very slender.

RAILWAYS. [Transit, Railway, P. C. S.]

RAIMBACH, ABRAHAM, one of the most distinguished English line engravers, was born in London in 1776; his father was a Swiss by birth, but he settled in England at the early age of twelve, and never afterwards quitted it; his mother was the daughter of an English farmer in Warwickshire. When an infant, Raimbach escaped from one of those rare but awful accidents which occasionally happen through the negligence of nurses; he fell from the arms of his nurse from a second-floor window; but his life was saved, partly by the inflation of his long clothes, and partly by his fall being broken by some leads below. The girl from whose arms he fell was seized with such a panic that she rushed out of the house, and was never heard of by any of the Raimbachs afterwards.

Raimbach was educated in Archbishop Tennison's library-school, where he was the fellow-pupil of the late Charles Matthews; he, however, showed an early disposition to excel in the arts, and his father apprenticed him in 1789 to J. Hall, the engraver; Sharp and J. Heath had both declined to take him. The first work engraved by the young apprentice was the explanatory key to Copley's Death of Chatham in the National Gallery, where the print also is now hanging, framed and glazed, beneath the picture. After his term of apprenticeship was over he entered as a student in the Royal Academy, anxious to qualify himself in every way for his art; he at the same time did what work he could for the booksellers; but at this period he seems to have had a difficulty in earning as much as thirty shillings a week. His first patron was a bookseller of the name of Stockdale. But, by his general attention and assiduity, he was enabled to unite the profession of a miniature painter with that of engraver, and he prospered in a short period so well in both, that he was under the necessity of giving one of them up, and confining himself to the other. According to his own account, he was influenced not a little in his choice by the uniform difficulties he met with in satisfying his sitters with his miniatures. All had opinions of their own about their looks, which it was necessary to attend to; he therefore gave up portrait painting, as he found engraving a much more independent art.

In 1802, through some prints he executed for Smirke and Forster's illustrated edition of the Arabian Nights, he was in such circumstances as enabled him to take advantage of the temporary peace, and he paid a visit to Paris to view the great galaxy of works of art which the victories of Napoleon had collected together in the Louvre. He has himself given a long account of this tour in his autobiography, published by his son. In 1805 he married and established himself in a house of his own in Warren-Street, Fitzroy-Square, in which he lived twenty-six years, and executed all his great works; the house was given to him by his father on his marriage, and his father died in the same year; in 1807 he lost his mother also. In this year he made the acquaintance of Wilkie, and soon became that painter's most intimate friend. In 1812 he became Wilkie's engraver, supplanting Burnet, who had already engraved some of Wilkie's pictures in an admirable manner. The chief reason of Wilkie's breaking with Burnet appears to have been what he considered the smallness of his interest in the prints—one-third of the profits. Burnet would not allow more than this, and Wilkie left him for Raimbach, with whom, however, he was contented with the same arrangement; and, indeed, he himself afterwards voluntarily reduced his share to one-fourth of the profits. The first fruit of this partnership was the celebrated print of the 'Village Politicians.' This print however, owing, it appears, to the indifference of printsellers to anything out of the ordinary way of business, at first went off slowly; but eventually the sale was large and steady, and a proof, of which there were 274, has sometimes been sold at auctions for fourteen or fifteen pounds. The next print was 'The Rent Day,' published in 1816; after which Wilkie and Raimbach made a tour together in the Netherlands. The rest appeared in the following order: 'The Cut Finger,' 'The Errand-Boy,' 'Blindman's Buff,' 'Distraining for Rent,' 'The Parish Beadle,' and, in 1836, 'The Spanish Mother and Child.' The last prints, compared with the 'The Village Politicians' and 'The Rent-Day,' were very unsuccessful speculations, and Raimbach thus accounts for the fact in his autobiography: For the long term of more than twenty years the prints from Wilkie's pictures had enjoyed an almost unprecedented popularity; and it can scarcely be held as a matter of reproach to the public if, after so long a period of favour in one direction, the desire of some sort of change of object should be entertained. The great talents of Edwin Landseer had been already well appreciated, when his picture of the Monks of Bolton Abbey appeared, and placed his reputation on a still higher elevation. Seconded by Cousin's admirable mezzotinto from it, there followed a rush in the track thus so auspiciously commenced, and the new lights (as in Aladdin's lamp) were preferred to the old. Raimbach never employed an assistant, but executed the whole of the plate himself. 'The Rent-Day' cost him two years and a half of incessant labour. His prints are very masterly works, and possess every quality but colour. He died January 17th, 1843, in very easy circumstances. His autobiography was published by his son in the same year, under the following title:—'Memoirs and Recollections of the late Abraham Raimbach; including a Memoir of Sir David Wilkie.' (*Athenæum*, 1843.)

RAMEAU, JEAN-PHILIPPE, a very celebrated musician, equally distinguished by his compositions and by his numerous writings on the science, was born at Dijon, in 1683. It may be presumed that he inherited a taste for music, for his father was so passionately fond of the art that after he had passed his thirtieth year he commenced studying it as a profession, and obtained the organist's chair in the *Sainte-Chapelle* of the above-named city. He taught his children to play from notes before they could read from letters, and the success of this plan, so far as relates to musical education, was manifested in the instance of his eldest son, the subject of the present notice, who when only seven years of age was thought an able performer on the harpsichord. He pursued the usual studies at the college, where his knowledge of Latin, &c. was acquired without reluctance and readily; but an invincible desire, or instinct, as his biographer calls it, led him to music, to which he at length wholly devoted himself. At eighteen he set out for Italy, in order to complete his knowledge of the art to which his future life was to be dedicated, but proceeded no farther than Milan, where he became acquainted with a professor with whom he returned to France, and together they visited several of the principal cities, exercising their talents at each with pecuniary views. Soon, however, tired of a wandering life, that allowed him no opportunity for indulging in those speculative inquiries to which he was prone, he went to Paris, and there added largely to his stock of information. Afterwards he became organist of the cathedral of Clermont, in Auvergne, and continued long in that city, in which he wrote his 'Traité de l'Harmonie;' but not finding the means for printing a large quarto volume in a provincial town, he proceeded to the capital of France, where in 1722 he published his great work, and finally fixed himself. He was soon appointed organist of Sainte Croix de la Bretonnerie, and employed his spare time in writing his various theoretical treatises, in composing his harpsichord lessons, and in teaching. He did not distinguish himself in that line in which he was destined to excel till the year 1733, when, at fifty years of age, he produced the opera of 'Hippolyte et Aricie,' the drama by the Abbé Pellegrin. The success of this provoked much professional envy, if not national discord, and a feud was raised among the admirers of Lulli [LULLI, P.C.] and Rameau, similar to that which in after times was carried to greater excess by the Gluckists and Piccinists. [GLUCK, P. C.; PICCINI, P. C.] The Prince de Conti asked Campra, the celebrated Maître de Musique of Notre-Dame, what he thought of the new work? He replied, 'There is enough of music in it to make six operas.' Till the production of Hippolyte,' Voltaire alone had discovered Rameau's genius for composition. He previously gave him his tragedy of 'Samson' to set, and discerned the beauty of the music; but its performance was prohibited under the pretext that it prostituted a sacred subject.

Of the many operas by Rameau, his 'Castor and Pollux,' produced at the Académie Royale de Musique in 1737, is the best: it was represented one hundred times. There are parts of it that must always excite the admiration of true connoisseurs. A chorus in this, of Spartans, 'Que tout gemisse,' has but few rivals, in either antient or modern theatrical music. Even M. Ginguené, who estimates his countryman at a low rate, admits the merit of this composition. His 'Dardanus,' his 'Zoroaster,' and other pieces, were equally successful. From 1733 to 1760 he produced twenty-one operas and ballets, besides harpsichord and other compositions; together with many theoretical and controversial works. His merit, long contested by envious rivals, was at length generally acknowledged. The king created for him the office of cabinet composer. Afterwards he granted him letters of nobility, and named him 'Chevalier de Saint-Michel.' The Academy of Dijon had previously received him among their members, and the magistrates of that city exempted him, and his family, in perpetuity, from the tax called 'La Taille.' He died in 1764, leaving a son and a daughter, and was interred with every mark of respect and distinction.

As a theorist Rameau is best known by his large and laboured work on the *basse fondamentale*, which he and his advocates treat as a discovery. [FUNDAMENTAL BASE, P. C.] But under other names the inversions of the perfect chord, or triad, and the chord of the seventh, were known long before Rameau entered on the subject. Brossard, in 1702, in defining *Trias Harmonica*, calls the under-note *basse*, or *son fondamentale*; and afterwards remarks that among the three sounds which compose the *triade Harmonique*, the lowest is called *basis*, or *sonus fundamentalis*. But our limits do not allow us to go further into a subject which, to explain clearly, would fill many pages with arguments and examples. It is well considered by Dr. Burney, in his 'History of Music;' and by the same in Rees's 'Cyclopædia.' Rameau's style of writing is not remarkable for perspicuity. This was felt and acknowledged by his most zealous partizan, D'Alembert, who, in his 'Elémens de Musique, théorique et pratique, suivant les Principes de M. Rameau,' has endeavoured to clear the work from the obscurity in which it undeniably is involved; but the great French geometrician has only partially succeeded in his attempt. Nevertheless, the editor of the early edition of the 'Encyclopædia Britannica' adopted D'Alembert's work. In later editions the article has been omitted, and a much better one substituted.

(*Biographie Universelle;* De Laborde, tome iii.; Burney, vol. iv.)

RAMENGHI, BARTOLOMEO, called IL BAGNACAVALLO, from the place of his birth, Bagnacavallo, on the road from Ravenna to Lugo, where he was born in 1484. He was a pupil of Raphael, and one of his principal assistants in the Vatican; and after the death of his great master he carried the principles of his style to Bologna, and assisted to enlarge the character of that school. Raphael was his model and test of excellence, and he did not attempt to look beyond him, presuming that little was to be acquired by ordinary abilities from nature compared with what the works of Raphael afforded for imitation. Though possessing less vigour than Giulio Romano or Perino del Vaga, Bagnacavallo acquired more of the peculiar grace of Raphael's style, especially in his infants, and his works were much studied by the great scholars of the Carracci. There are, or rather were, works by Bagnacavallo in San Michele in Bosco, San Martino, Santa Maria Maggiore, and Sant' Agostino agli Scopettini, in Bologna. He died at Bologna in 1542, according to documents discovered by Baruffaldi. Giovanni Battista Bagnacavallo, who assisted Vasari in Rome, and Primaticcio at Fontainebleau, was the son of Bartolomeo Ramenghi.

(Baruffaldi, *Le Vite de' più insigni Pittori e Scultori Ferraresi;* this excellent work was used by Lanzi in MS., but it has been recently (1846) published for the first time at Ferrara by Domenico Taddei, after lying in MS. for nearly a century. Lanzi, *Storia Pittorica*, &c.)

RAMMOHUN ROY, Rajah, was born about 1774, in the district of Burdwan, in Bengal, Hindustan. His paternal ancestors were Brahmins of a high order, and were devoted to the religious duties of their race, till about the beginning of the seventeenth century, when they gave up spiritual exercises for worldly pursuits. His maternal ancestors, also of high Brahminical rank, and priests by profession as well as by birth, uniformly adhered to a life of religious observances. Rammohun Roy was taught Persian under his father's roof, was sent to Patna to be instructed in Arabic, and afterwards, at the request of his maternal relations, went to Benares, in order to acquire the Sanscrit.

Rammohun Roy was a Brahmin by birth, and was trained by his father in the doctrines and observances of his sect; but his opinions seem to have become heretical at an early age. 'When about the age of sixteen,' he says, 'I wrote a manuscript calling in question the validity of the idolatrous system of the Hindus. This, together with my known sentiments on that subject, having produced a coolness between me and my immediate kindred, I proceeded on my travels, and passed through different countries, chiefly within, but some beyond, the bounds of Hindustan. When I had reached the age of twenty my father recalled me, and restored me to his favour.' Afterwards he says, 'My continued controversies with the Brahmins on the subject of their idolatry and superstition, and my interference with their custom of burning widows, and other pernicious practices, revived and increased their animosity against me; and through their influence with my family, my father was again obliged to withdraw his countenance openly, though his limited pecuniary support was still continued to me.' His father died in 1803, and he then published various books and pamphlets against the errors of the Brahmins, in the native and foreign languages. 'The ground which I took in all my controversies was, not that of opposition to Brahminism, but to a perversion of it; and I endeavoured to show that the idolatry of the Brahmins was contrary to the practice of their ancestors, and to the principles of the antient books and authorities which they profess to revere and obey.' In order to deprive him of caste, the Brahmins commenced a suit against him, which, after many years of litigation, was decided in his favour.

Of the body of Hindu theology comprised in the Vedas [VEDA, P. C.], there is an antient abstract called the 'Vedant, or the Resolution of all the Veds,' written in Sanscrit.

Rammohun Roy translated it into Bengalee and Hindustanee; and afterwards published an abridgment of it for gratuitous circulation. Of this abridgment he published an English translation in 1816, the title of which states that the 'Vedant is the most celebrated and revered work of Brahminical theology, establishing the unity of the Supreme Being, and that he alone is the object of propitiation and worship.' He afterwards published some of the principal chapters of the Vedas, in Bengalee and English. He was at different times the proprietor or publisher of newspapers in the native languages, in which he expressed his opinion freely against abuses political as well as religious, especially the burning of widows. In conjunction with the late Dwarkanath Tagore and Neel Rutton Holdar, he was proprietor of the 'Bengal Herald,' an English newspaper. Dwarkanath Tagore, an enlightened Hindoo, of liberal opinions, very rich, and a munificent benefactor to schools and charities, was born in 1795, in or near Calcutta, and died in London, Aug. 1, 1846. In 1820 Rammohun Roy published, in English, Sanscrit, and Bengalee, a series of selections from the New Testament, entitled 'The Precepts of Jesus the Guide to Peace and Happiness.' In this selection he omits the miracles and doctrinal parts, and confines himself to the simple religious and moral precepts. In 1830 he was engaged by the King of Delhi to make a representation of grievances to the British government, for which purpose the King conferred on him by firman the title of Rajah, and appointed him ambassador to the British court. He arrived at London in April, 1831. The British ministers recognised his embassy and title, though the Court of East India Directors objected to both. His negotiation was successful, and added 30,000*l.* a-year to the income of the King. He intended to return to India in 1834, but he was taken ill when on a visit at Stapleton Grove, near Bristol, where he died September 27, 1833. He was buried in a shrubbery of Stapleton Grove, without a pall over the coffin and in silence. The Christian observances were carefully avoided at his own request, lest it should be made an accusation against him by the Brahmins, and, by causing him to lose caste, deprive his children of their inheritance. His funeral was attended by his youngest son, and two native servants, who had come to England with him. Two other sons survived him in India.

Rammohun Roy was acquainted more or less with ten languages—Sanscrit, Arabic, Persian, Hindustanee, Bengalee, English, French, Hebrew, Latin, and Greek. Sanscrit and Arabic he knew critically, and as a scholar; Persian, Hindustanee, Bengalee, and English, he spoke and wrote fluently. Of the other languages his knowledge was less perfect. In person he was tall and somewhat unwieldy; his features were handsome, his complexion dark, and the general expression of his face was very pleasing. He associated a good deal with the Unitarians in this country, and frequently attended their chapels. He was a believer in the divine mission of Christ, and seems to have considered the acceptance of the doctrines of Christ to be quite consistent with a belief in the Brahminical religion as it is in the antient Sanscrit authorities.

(*Annual Biography and Obituary*, 1834; *Review of the Labours, Opinions, and Character of Rajah Rammohun Roy*, by Lant Carpenter, LL.D.)

RAMPART, probably from Ripa, an embankment, from which is derived the Italian word 'Riparo,' and the French word 'Rempart,' is, in modern fortification, a mass of earth often nearly 80 feet thick, surrounding a town or a military position, or constituting the faces of an outwork; and its use is to protect the interior of the place or work against any sudden enterprise of the enemy, as well as to give the defenders a superiority of elevation with respect to the works of the besiegers.

The ramparts of ancient fortresses were walls of stone or brick, frequently from 60 to 100 feet high and 20 feet broad, including the galleries made in them: round or angular towers were formed at intervals along the walls: and, by means of the galleries, the defenders could pass within the thickness of the wall from each tower to the next. The rampart was surmounted by a parapet seven feet high and two feet thick, which was provided with battlements; the rampart was loop-holed, and, in order that the exterior foot of the high wall might be defended, machicolations were formed at the top, particularly over the entrances. [BASTION, P. C.] A great mass of earth was raised against the interior side of the walls, nearly as high as the top, in places where elevated ground or the enemy's works on the exterior allowed access to the top of the wall to be gained in force; and on this mass the cohorts were drawn up in order of battle. (Vitruvius, lib. I., cap. v.)

The modern rampart is surmounted by a parapet of earth, on the interior side of which, towards the town, is a nearly level space, varying in breadth from 35 to 40 feet, called the terreplein of the rampart; on this terreplein the artillery is placed: and in the rear of the guns there is room for the movements of the defenders and the conveyance of the ammunition. The exterior and interior sides of the rampart are formed with slopes making angles of about 45 degrees with the horizon: or they are retained by revetments, or walls of brick or stone, nearly upright, the exterior face of the rampart constituting the *escarp* of the ditch in front. The rampart immediately surrounding a place is divided, in the direction of its length, into parts making salient or re-entering angles with one another; and these parts constitute the faces and flanks of the bastions, and the curtains which connect the latter together. Not more than 30 feet are allowed for the breadth of the terrepleins of the ramparts of outworks, measured from the foot of the parapets, in order that the enemy may not be able to form batteries for artillery upon these terrepleins. The terrepleins of all ramparts should have a small slope down, towards the interior, in order that the rain-water may not lodge on them, and that the defenders near the interior edge of the rampart may be effectually covered by the parapet. The terreplein and the interior slope of a rampart, as well as the surface of the parapet, are generally covered with turf. A rampart whose exterior side is of earth, or without a revetment of brick or stone, might be easily ascended by an enemy at the time of an assault; and the palisades or fraizes which, in that case, would be planted in it for the purpose of impeding the progress of the enemy, might be easily destroyed by artillery, so that the place would be liable to be carried by a sudden assault.

The relief, or height, of a rampart is regulated by the occasional necessity of employing a fire of artillery from the rampart, and, at the same time, a fire of musketry made over the glacis by men stationed in the covered way beyond the ditch in front of the rampart: for this purpose a line of fire from the rampart should pass three or four feet above the crest of the glacis in its front, in order that the wind of the shot may not injure the defenders. The relief of a rampart with its parapet may, therefore, be thus determined:—On a drawing representing a vertical section of the works let a line be drawn from the foot of the glacis, through a point taken at 3 or 4 feet above the crest of that work, and let it be produced till it cuts the interior slope of the parapet on the rampart: this intersection will give a point in the axis of a gun placed on the rampart, or a point a few inches above the sole of the embrazure, that is, about 3½ feet above the terreplein of the rampart; and, because the artillery and the gunners are to be protected by the parapet, if 7½ feet be added to the height of the terreplein of the rampart, above the ground, the sum will be the required height of the crest of the parapet.

RAMPOOR, a town of Hindustan, in the district of Bareilly, province of Delhi, and presidency of Bengal, on the east bank of the Cosila river, in 28° 48′ N. lat., and 79° E. long., 105 miles E. by N. from Delhi, direct distance. The town, at the time of the death of Fyzoola Khan, a Rohilla chief to whom it had been secured by the peace of Lalldong in 1774, was four miles in circumference and the centre of a flourishing district, but has since been greatly reduced. The district was granted to the nawâb of Oude on the termination of the Rohilla war, and the town was ceded to the British in 1801, by whom it was transferred to the nawâb of Rampoor, together with a small territory.

Rampoor is chiefly remarkable for the curious kind of fortification by which it is surrounded, a high and thick hedge of bamboos faced on the outside by a prickly underwood of cactus and bâbool. The entrances are by narrow passages, defended by strong wooden barriers. It is said to be an extremely effective defence against irregular troops, since neither cavalry nor infantry can be brought to act against an enemy whom they cannot see, and who is firing at them from among the close stems of the bamboos, and under cover of the almost impenetrable cover on the outside.

(Hamilton's *East India Gazetteer*; Heber's *Narrative of a Journey through the Upper Provinces of India in* 1824 *and* 1825.)

RAMSAY, ANDREW MICHAEL, generally known as the Chevalier Ramsay, was born at Ayr, in Scotland, the year 1686. He was educated at Edinburgh, where chiefly devoted himself to the study of mathematics and theology; the distinction he obtained as a scholar procured for him the appointment of tutor to the son of the Earl of Wemys, at the University of St. Andrew's. Having entertained some doubts respecting the tenets of the Protestant faith, he went to Holland for the purpose of visiting a Protestant divine of the name of Poiret, who had obtained a certain celebrity as one of the leaders of the Quietist party. With him Ramsay entered into a religious controversy, the fruits of which were an increase of his doubts and even an inclination to general scepticism on the great doctrines of the Christian religion. In this state of mind he determined on having recourse to Fénélon, who was at that time residing in his diocese of Cambray. Ramsay was but twenty years of age when he formed the acquaintance of the Archbishop of Cambray, but his mind had already been sufficiently trained by study and meditation to enable him to appreciate the talents and to recognize the virtues of that eminent divine. Towards him Fénélon exercised his instructive talent as a moral teacher, and in short time made him a convert to the Roman faith. He soon became the disciple of Fénélon, not only in religious matters, but also in his literary taste and opinions. His writings were formed on the style and after the manner of his great master, whose examples and precepts he ever gratefully acknowledged. Ramsay rapidly acquired so perfect a knowledge of the French language as to become an excellent writer. Some of his earlier productions were the means of obtaining for him the situation of tutor to the Duke of Château Thierry and afterwards to the Prince of Turenne; he was also created a knight of the order of St. Lazarus. His reputation induced the Pretender, in 1724, to invite him to Rome, and to entrust him with the education of his children. He remained however only a year in that city, and left it in disgust with the petty intrigues which he found to form the principal occupation of the miniature court of the son of the exiled king. The next year he revisited Scotland, where he remained a considerable time, which he employed in literary labour. On visiting England, he obtained, through the influence of Dr. King, the degree of doctor of civil law in the University of Oxford; he was also admitted a member of the Royal Society of London. After his return to France he was appointed intendant to the Prince of Turenne, who afterwards became Duke of Bouillon; he held this situation till his death, which took place at St. Germain-en-Laye in the year 1743.

The writings of the Chevalier Ramsay are more remarkable for the purity of their style and the perfect knowledge which they manifest of the French language, than for their depth or originality of thought. As a theologian he was visionary in the extreme, and his orthodoxy, even according to the principles of the church he had adopted, is open to considerable suspicion. It is fortunate for his religious reputation that he did not live to publish some philosophical works which he was preparing, such as his answer to Spinosa, and a treatise on the Progress of Human Understanding, 'in which,' says Spence, 'there were several notions that would have made him be looked upon as a heretic in our church, as well as in his own.' (Spence's Anecdotes, p. 34.) The work by which he is best known, is his 'Voyages de Cyrus,' an imitation of the Telemachus of Fénélon, but, according to Voltaire, a very feeble one. The character of Zarina gave considerable offence to the Princess de Conti, one of the most learned ladies of the age, who imagined that she was pourtrayed in it. There is an excellent translation of that work, by Hooke, though said to have been accomplished in the short space of twenty days [HOOKE, NATHANIEL, P. C.]; it was for a long time mistaken for an original, the general belief respecting it being that Ramsay had written the Voyages of Cyrus in English as well as in French. The best edition of the French is that of 'Paris et Londres,' 1727, 2 vols. 8vo. The work, however, for which posterity is most indebted to him is that entitled 'L'Histoiro de la Vie de François de Salignac de la Motte Fénélon.' Hague, 1723; published also in London the same year. His great intimacy with Fénélon has made us acquainted with many interesting facts of his private life, and it contains a valuable record of his opinions. His other published writings are 1°. 'Discours sur le Poëme E'pique,' originally forming the preface of his edition of Telemachus, in 1717. 2°. 'Essai Philosophique sur le Gouvernement Civil.' London, 1721; it was afterwards reprinted under the title 'Essai de Politique.' 3°. 'Histoire de Turenne.' Paris, 1735, 2 vols. in 8vo. and 4 vols. 12mo. With some affectation in the style and a redundancy of reflections this history possesses much merit from the precision of its facts and the lively portraiture of its characters. 4°. 'Le Psychomètre, ou Reflexions sur les différens Caractères de l'Esprit, par un Mylord Anglais.' 5°. A posthumous work published at Glasgow in 1749, 2 vols. 12mo., in English, entitled 'Philosophical Principles of Natural and Revealed Religion explained and unfolded in a Geometrical Order.'

(*Dictionnaire Historique*, 4 vols., Amsterdam, 1766; *Dictionnaire Historique Classique*, Paris, 1826; Spence's *Anecdotes of Books and Men*, London, 1820. The details of his conversion to the Roman Church will be found in the life of Fénélon by le Père Querbeuf, appended to his edition of his works. Paris, 1787—1792.)

RAMSAY, ALLAN, an eminent portrait painter in his time, and the son of Allan Ramsay the poet, was born in 1713, in Edinburgh, the birth-place of his father also; the circumstance is alluded to by Churchill, in his satire of the 'Prophecy of Famine:'—

> 'Thence came the Ramsays, men of worthy note,
> Of which one painted, as the other wrote.'

'Ramsay,' says Edwards, 'may be called self-taught; but he studied a short time in Italy with Solimena, and F. Fernandi, called Imperiali. After practising a short time in Edinburgh, he settled in London, where he was introduced by Lord Bute to George III. when Prince of Wales. He painted two portraits of the Prince, which were engraved, one by Ryland, and the other by Woollett. At the death of Mr. Shakelton, in 1767, Ramsay succeeded him as principal painter to the king: he retained the place until his death, when he was succeeded by Sir Joshua Reynolds. He died at Dover in 1784, on his return from a fourth visit to Rome; he had a daughter, who was born in Rome. Ramsay, though not an excellent portrait painter, was superior to the generality of the painters of his time; he was Walpole's contemporary, and is noticed in somewhat flattering terms by that universal critic, considering with whom he is coupled: he says, 'Reynolds and Ramsay have wanted subjects, not genius.' Edwards says that Ramsay was not devoted to his art: he allowed literature to divide much of his time with it. He was acquainted with Latin, French, and Italian; and, in his latter days, like the elder Cato, acquired some knowledge of Greek. He was the author of some political papers. He was twice married; his second wife was a daughter of Sir David Lindsey. His son and daughter survived him: the son became a general in the British army, the daughter was married to Sir Archibald Campbell.

(Edwards, *Anecdotes of Painters;* Cunningham, *Lives of the British Painters*, &c.)

RANDIA (named after Isaac Rand, M.D., once a demonstrator of botany at the Chelsea botanic gardens), a genus of plants belonging to the natural order Rubiaceæ.

R. dumetorum, Bush-Randia, is a thorny branching small shrub or tree, with oval leaves, rather blunt, cuneate at the base and smooth. The flowers are very sweet-scented, sessile, solitary, mostly terminal. The calyx has oblong lobes, rather shorter than the villous corolla. The fruit is smooth, yellow, resembling a small crab-apple, firm and fleshy. The seeds are oval, numerous, and lying in mucus. The fruit when bruised and thrown into water intoxicates or even kills fish, having the same effect as the *Cocculus Indicus*, which is not, however, known in the East Indies, where this plant grows. In the form of powder it is a powerful emetic. An infusion of the bark of the root is employed to nauseate in bowel complaints.

R. uliginosa, Bog-Randia, has almost terminal opposite thorns, tetragonal branches, oblong leaves somewhat cuneated, glabrous; the flowers solitary, sessile, almost terminal. It is a native of the East Indies, in moist places. The flowers are large, white, and fragrant, and in twos or threes at the top of the branchlets. The berry is about the size of a pullet's egg, ash-coloured or olive-grey, and 2-celled. The seeds are flattish, nestling in the pulp. The flowers of this species render it deserving of a conspicuous place in the hothouse. The uncommon appearance of this plant is also in its favour. There are 39 species of *Randia*, none of which, however, are applied to any useful purpose. They are generally free flowerers. The soil best suited for them is a mixture of loam, peat, and sand. The stove species thrive best in a moist heat; and cuttings root readily if taken up when not too ripe, planted in a pot of sand, which should be plunged in a moist heat under a glass. They are very showy, usually bearing large white fragrant flowers, and are worth cultivating in every collection of stove-plants.

(Don, *Gardener's Dictionary;* Lindley, *Flora Medica.*)

RANG'ONE, a noble family of Modena, which became illustrious in the middle ages, not only for the part which it took in the political and military vicissitudes of Italy, but more particularly for the patronage which it gave to learning and to the learned. Count Nicolò Rangone, who lived in the latter part of the fifteenth century, was the father of eight sons and two daughters, whom he caused to be instructed with great care, and all of whom became distinguished for their love of science and literature. The learned Visdomini, who was preceptor to several of them, has left an interesting memorial of the care bestwed on their education in his Dialogues entitled 'Antonii Mariæ Visdomini de Ocio et Sybillis.' One of his pupils, Count Guido Rangone, figured as a distinguished general in the Venetian service, and afterwards in the service of King Francis I. Filelfo, in his book 'de Optima Hominum Felicitate,' which he addressed to Count Guido, enumerates the feats he had performed in his military career, and praises him likewise for the liberal encouragement which he afforded to the learned. Bernardo Tasso, father of the great poet, was for a long time secretary to Count Guido. Guido died at Venice in 1537. His brother, Cardinal Ercole Rangone, who died young during the pillage of Rome in 1527, is likewise extolled for his love of learning by Giglio Giraldi, and also by Vida in his second book 'de Arte Poetica.'

Costanza Rangone, sister of the preceding, took for her second husband Cesare Fregoso, a well-known Genoese emigrant in the service of Francis I., who was murdered in 1541 by the emissaries of the Marquis del Vasto, Governor of Milan for Charles V. She then retired to France together with Bandello, the celebrated novelist, who wrote many of his tales for her entertainment. Ginevra Rangone, sister of Costanza, married first a nobleman of the Correggio family, and afterwards Luigi Gonzaga, Marquis of Castiglione. She has been praised by Scaligero for her intellectual accomplishments. Her nephew, Count Fulvio Rangone, a pupil of Carlo Sigonio, was employed by Alfonso II. of Este in a diplomatic capacity, and his sister Claudia fixed her residence at Rome, where she enjoyed considerable interest at the Papal court, and was even consulted on matters of state. The love of learning and the patronage of the learned appear to have been hereditary in the family of Rangone. The Marquis Gherardo Rangone founded in 1783 a Scientific Academy in his palace at Modona, which awarded prizes for physiological and other studies and discoveries.

(Litta, *Famiglie celebri Italiane*; Tiraboschi, *Storia della Letteratura Italiana*; *Memorie intorno alla Vita del Marchese Gherardo Rangone*, Modena, 1818.)

RANUNCULUS (from *rana*, a frog, because many of the species inhabit humid places frequented by that reptile), a genus of plants, the type of the natural order Ranunculaceæ. It has 5 sepals, occasionally 10, with a nectariferous excavated scale at the base. The stamens and ovaries are numerous, the achenia ovate, somewhat compressed, mucronate, arranged on globose or cylindrical receptacles. The species are mostly acrid, and if applied when fresh to the skin will produce blisters: this quality is destroyed by drying or by heat.

R. aquatilis, Water-Crowfoot, has a floating stem and submersed leaves divided into numerous capillary segments spreading on all sides. The floating leaves are reniform, from 3- to 5-parted, the lobes wedge-shaped, toothed at the top, the petals obovate, larger than the calyx, the flowers white. It is native throughout Europe, Western Asia, North Africa, and also in America and England, in pools and stagnant waters. It is the Βατράχιον ἕτερον of Dioscorides, 2, 206. Sometimes it produces very large flowers, and makes a handsome show in ponds and ditches; the curious variety in the floating and immersed leaves adds greatly to its beauty. Dr. Pulteney contradicts the assertion of its deleterious qualities, and says that it is not merely harmless but nutritive to cattle, and tells us that on the borders of the Avon the cottagers support their cows and horses almost wholly on this plant. Hogs are also fed upon this plant, and appear to thrive on it, so that it seems we cannot class this species with others of the same genus as having poisonous qualities.

R. flammula, Flame-Crowfoot, is a smooth plant with a rooting decumbent stem, branched, leafy, and hollow, sometimes hairy near the top. The leaves are on flat channelled half-sheathing stalks, alternate, usually ovate, lanceolate, but varying much in breadth, often serrated. The flowers are terminal, opposite the leaves, and of a bright yellow colour. The leaves are vesicant. Dr. Withering recommends the distilled water as an instantaneous emetic in cases of poison. Lightfoot says the bruised leaves are used to raise blisters in the Isle of Skye and the Highlands of Scotland. It is native of Europe, Asia, North America, and Great Britain.

R. glacialis has stalked radical leaves, palmated and trifid, the lobes rather blunt and thick; the stem is generally one-flowered; the calyx very hairy, the carpels compressed and sharp-edged; the petals white. It is native of the higher Alps of Europe, among rocks, near the limits of perpetual snow, and of Lapland and Iceland. The mountaineers of Dauphiny call this 'Carlive' or 'Caralline,' and employ an infusion of it in hot water as a powerful sudorific in colds and rheumatism.

R. acris, Buttercup, has a fibrous root, the stem about two feet high, erect, round, hollow, leafy, clothed with close-pressed hairs, branched above and many flowered. The radical leaves are on long upright footstalks, in 3 or 5 deep lobes, the stem-leaves are nearly sessile, with fewer and narrower segments, the uppermost much smaller in 3 linear entire lobes, or sometimes simple and linear. The flowers are of a bright yellow, on round even stalks covered with close hairs and not furrowed. The calyx is hairy, spreading, and deciduous; the carpels smooth, lenticular, with a slightly curved point. This species is extremely acrid and dangerous. Mr. Curtis says that even pulling up the plant and carrying it to some little distance has produced inflammation in the hand. Cattle in general will not eat it, but sometimes when they have been turned hungry into a field they have fed upon it, and in consequence their mouths have become sore and blistered. According to Linnæus sheep and goats eat it, but cows, horses, and swine refuse it. When made into hay however, its noxious qualities are lost. It is commonly called *buttercup*, under a notion that the yellow colour of butter is owing to these plants. A double variety of this species is cultivated in gardens under the name of 'Bachelor's Button.'

R. sceleratus, Celery-leaved Crowfoot, has a fibrous root, the radical leaves with 3 stalked trifid and cut leaflets, furrowed peduncles and reflexed calyx, the heads of the fruit oblong, the carpels minute and wrinkled. The flowers very small and pale yellow, numerous, on solitary stalks, either terminal, axillary, or opposite the leaves. The bruised leaves raise blisters on the skin, which are not soon healed, and are said to be used by impostors to cause ulcers on their bodies, and thus excite compassion. It is one of the most virulent poisons of our native plants. The distilled water of this species is highly acrimonious, and when cold deposits crystals which are scarcely soluble, and are of an inflammable nature. The deleterious qualities are, however, dispelled in decoction, and accordingly the shepherds of Wallachia boil and eat it.

R. Thira has an extremely acrid and poisonous root, and is native of the Alps of Europe. It is said to yield the juice formerly used by the Swiss hunters to poison their darts; wounds so produced speedily become fatal.

R. ficaria, Pilewort, has a root with fasciculated tubers, cordate stalked leaves, angular, or crenate, or leafy; single flowered stem, usually three sepals, and smooth blunt carpels. The flowers are golden yellow, and it is native throughout the whole of Europe in meadows, bushy places, and about hedge-banks; it is plentiful in Britain. The young leaves of this plant, according to Linnæus, are used as greens in Sweden. A notion that the root is efficacious in the cure of piles gives it its common English name. We usually find the flower closed from five to nine in the evening, and in wet weather. It is the χελιδόνιον of Theophrastus, *Hist. Plant.* 7, 14, and the χελιδόνιον μικρόν of Dioscorides, 2. 212, and of Pliny, *Hist. Nat.* 258.

R. arvensis, Corn Crowfoot, has a fibrous root, the radical leaves 3-cleft, dentate, the stem-leaves once or twice ternate, with linear lanceolate segments, the calyx erecto-patent, the carpels margined, beaked, and spinous; the flowers are pale yellow. It is native throughout Europe, in North America and Great Britain. It is very acrid and dangerous to cattle, though they are said to eat it greedily.

M. Brugnon, who has given a particular account of its qualities, relates that three ounces of the juice killed a dog in four minutes. Several sheep were killed by eating this herb at Turin, which first led to an investigation of the matter.

R. bulbosus, like others of the genus, is extremely acrid, and raises blisters and produces extensive inflammation of the skin. Gilibert states that it vesicates with less pain than cantharides and without affecting the urinary passages.

R. asiaticus, common Garden Ranunculus, has ternate or riternate leaves, the segments toothed or deeply trifid, the stem erect, simple, or branched at the base, the calyx spreading, efterwards reflexed, the spikes of the carpels cylindrical. It is a native of the Levant, and is referred to by Dioscorides, 2. 206. Three varieties of this favourite plant in our gardens have been described, which some have regarded as species:—1. *R. a. vulgaris*, with the stem branched at the bottom, the leaves ternate, the segments trifid, cut, acute. The flowers of this variety are generally formed double, and heve all colours except blue. It is called the Persian Ranunculus. 2. *R. a. sanguineus*, with e simple stem, ternate leaves, aud obtuse toothed segments. The flowers are orange or yellow. This is called the Turkey Ranunculus. 3. *R. a. tenuilobus*, with e somewhat branched stem, end multifid leaves with linear ecute lobes. It is e native of the island of Cyprus, and has white or yellow or purple flowers.

The Garden Ranunculus is a florist's plant, and has been cultiveted with great care. The garden varieties of this species are very numerous, as no two plants produce flowers precisely alike. Maddock, who wrote on these plants, had e collection of 800 varieties, all with proper names. In judging of e Ranunculus the following qualities are desirable:—'The flowers should be of a hemispherical form, et least two inches in diameter, consisting of numerous petals, gradually diminishing in size to the centre, lying over cach other, so as neither to be too close nor too much separated, but having more of a perpendicular than a horizontal direction, in order to display the colours with better effect. The petals with entire well-rounded edges, their colours dark, cleer, rich, or brilliant, either of one colour or variously diversified on en ash, white, sulphur or fire-coloured ground, or else regularly striped, spotted or mottled in an elegant menner.' (Geo. Don.) In cultivation this plant prefers a rich losmy soil, which should be well manured, and it is customary when forming beds for it to place e layer of well-rotted cow-dung seven or eight inches below the surface. They are usually propagated by dividing the roots, which mey cither be planted in November or March. The former is the best time, but the roots should then be mulched. In order to obtain varieties, seeds should be obtained from the single or semidouble plants, and planted in August. The following year, when their leeves drop off, the roots should be taken up and dried in the same manner as the old roots, and planted with them in November.

The *R. lanuginosus* of Linnæus is the *βατράχιον ἕτερον χνοωδέστερον* of Dioscorides, loc. cit. The *R muricatus*, Linn. is the *βατράχιον τρίτον* of Discorides, loc. cit.

RAPHIOSAU'RUS, e genus of fossil Reptiles from the lower parts of the Cretaceous system. (Owen.)

RAPE. [Rape, P. C.; Law, Criminal, P. C. S.]

RASK, RASMUS CHRISTIAN, one of the most distinguished linguists of modern times, was born on the 2nd of November, 1787, at Brendekilde, near Odense, in the island of Fyen, or Funen, in the kingdom of Denmark. His parents were poor people, but the boy's talents and inclinations procured him friends who afforded him the means of prosecuting his favourite studies in the university of Copenhagen. He efterwards spent some time in Iceland, and also made journeys to Sweden, Finland, and Russia for the purpose of increasing his knowledge of languages, for which he had a very extraordinary talent. In 1808 he obtained e situation connected with the university library at Copenhagen, and he availed himself of the opportunity by making himself acquainted with the most ancient documents of northern history and literature. His knowledge of languages led him to devote himself to comparative philology, to search after the connecting links and trace them to their common origin; and in order to complete this branch of study, he undertook in 1817, with the support of the Danish government, a journey to Russia, whence he proceeded in 1819 to Persie. He made some stay at Teheran, Persepolis, and Shiras, and in 1820 went to Indie, from whence he returned in 1822 to his native country. In this expedition he had purchased for the Copenhagen library 113 encient and rare oriental manuscripts, among which those in the Pali language were the most valuable. Soon after his return he was invited to e professorship in the university of Edinburgh, but as he declined the offer, he was appointed professor of the history of literature in the university of Copenhagen. The king had promised him his support, if Rask would prosecute his oriental studies, but for some time he neglected them, and devoted his time to an analysis of the Danish language. In 1827, however, he returned to his oriental pursuits, and wrote on Egyptian and Hebrew chronology, and on the age and authenticity of the Zend a Vesta. In the meantime he had become president of the Icelandic society of literature, and of the society for the investigation of northern antiquities, and he took en active part in the management and editorship of the journals of these societies. At the same time he was engaged in the preparation of an Armenian Dictionary, an Italian, Low German, and English Grammar. In 1829 he was eppointed professor of oriental lenguages and chief librarian of the university library. Henceforth his ettention was engaged almost exclusively by the eastern languages, but his edition of Lokman's Fables, Copenhagen, 1832, shows thet his knowledge of Arabic was very deficient; and it may be said in general that, as far as the oriental languages are concerned, he had more skill in general comparisons and investigations of their grammatical structure than an exect knowledge of any particular language. His works show that there was scarcely a language worth studying of which he had not some knowledge: and all the civilized languages of Europe were almost as familiar to him as his own mother-tongue, and his knowledge of the northern languages is unrivelled. He died at Copenhagen on the 14th of November, 1832, and his numerous MSS. relating to philology were given up by his relatives to the king's library at Copenhagen.

The principal works of Rask are, 1. An Introdnction to the study of the Icelendic and antient Northern Languages, Copenhagen, 1811; 2. An Anglo-Saxon Grammer, Stockholm, 1817, one of his best works, has been translated into German end English; 3. Investigations concerning the Origin of the antient Northern or Icelandic Language, Copenhagen, 1814; 4. An edition of Björn Haldorsen's Icelandic Dictionary, Copenhagen, 1814; 5. A Spanish Grammar, Copenhagen, 1824; 6. A Frisian Grammar, Copenhagen, 1825; 7. An attempt to reduce the Orthogrsphy of the Danish Language to Principles, Copenhagen, 1826, is a strange work in which Rask attempted to introduce a complete reform in Daniah orthography. He did not succeed in his ettempt, but the work is full of the most extraordinary linguistic learning; 8. On the age end authenticity of the Zend a Vesta, Copenhagen, 1826, was transleted into German by F. H. von der Hagen, Berlin, 1826; 9. A small Grammar and Vocabulary of the Acra Language. In the last year of his life he finished e very complete Grammar of the Language of Lapland. A number of essays on linguistic subjects appeared in various journals, and in Vater's 'Vergleichungststfeln,' there is one on 'Die Thrakische Sprachclasse,' which is of great importance and interest. Comparative philology is greatly indebted to Rask, for he was the first who pointed out the connexion between the ancient northern and Gothic on the one hand, and of the Lithuanian, Sclavonic, Greek, and Latin on the other hand. (*Zeitgenossen*, third Series, No. xxxvii.)

RATIO, COMPOSITION OF. To the few worda which are said on this subject in Ratio, P. C., p. 309, it will be worth while to edd considerable development. The idea implied in composition of ratio is very imperfectly treated in Euclid: and yet upon the correct understanding of it depends whether the boasted victory over the difficultics of incommensurables which the fifth book gives is real or imaginary.

In every metter connected with elementary geometry, confusion mey and often does arise from mixing together criticisms of two different kinds; on Euclid as a writer, and on the subject as a matter of thought. To avoid such confusion in the present instance, we shall begin with the consideration of what we find in Euclid—not in Simson's Euclid, nor Pleyfair's Euclid—but in Euclid of Alexandria.

There is nothing on ratio compounded (*συγκειμένος*) of ratios in the fifth book; the word transleted composition (*σύνθεσις*) refers to such a process as the formation of the ratio of A+B to B from that of A to B. But the definitions of duplicate, triplicate, &c. ratio are laid down; which, as we shall see, are particular cases of compounded ratios. These definitions are as follows:—if A, B, C, D, &c., be in continued proportion, so thet as A to B, so B to C, C to D, and so on, then the ratio of A to C is called the duplicate ratio of that of A to B, the ratio of A to D is called the triplicete ratio of A to B, and so on.

In one proposition, and in one only, is the phrase composition of ratios used: in the 23rd of the sixth book, where it is said 'Equiangular parallelograms heve to one anoth r the *ratio compounded of the sides*.' There is no definition at least, it is now so supposed; here however we must refer to our next paragraph) given of the words in italics, and on looking into the demonstration of the proposition, we find we must assume, as a matter of phraseology merely, that of any three quantities of the same kind, K, L, M, we are to say the ratio of K to M is compounded of the ratios of K to L and of L to M. And further that if A be to B as K to L, and V to W as L to M, then the ratio of K to M is to be said to be the ratio compounded of the ratios of A to B and of V to W. If there be anything more than mere phraseology in this, it must be because Euclid makes a tacit reference to some arithmetical system current in his time.

It is true that there is found in a great preponderance of manuscripts (in all, we believe) a definition of compound ratio. It is among the definitions of the sixth book, and literally translated* is as follows:—'A ratio is said to be compounded of ratios, when the πηλικότητες of the ratios multiplied together make a certain [ratio].' On the word left untranslated (which, we believe, must be translated by *quantuplicities*), we refer to Ratio, P. C. This definition is admitted into the editions of Basle and Oxford, and into Briggs's edition of the six books. Peyrard has omitted it in the Paris edition, because, in his celebrated Vatican manuscript, it is not in the text, but has been added at the side. The Berlin editor admits it in parentheses as a disputable passage. Set a scholar to make the text of Euclid from the ordinary mode of weighing the evidence of manuscripts, and there is little doubt this definition must appear as a part of the elements. Set a geometrical reasoner to settle the question by the internal evidence of the passage, and its keeping with the rest of the book, and there is as little doubt that it would be rejected. The meaning of the passage is, apparently, that if two ratios be expressed numerically, as those of 7 to 4 and 6 to 11, the ratio compounded of those ratios is to be the ratio of 7×6 to 4×11; or possibly, that, expressing the above ratios as those of $\frac{7}{4}$ to 1, and $\frac{6}{11}$ to 1, the compounded ratio is that of $\frac{7}{4} \times \frac{6}{11}$ to 1.

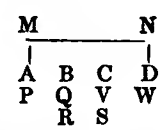
In the early translations from the Arabic, the definition is omitted, and reference is made in demonstrating vi. 23 to a note inserted among the definitions of the fifth book, which is very insufficient. But the phrase there is that the ratio of f to h is *produced* from those of f to g and g to h: and to the definitions of the seventh book several are added, one of which is, that in a series of numbers the ratio of the first to the last is produced from the successive ratios of each to the one following.

In many manuscripts there is a scholium preceding the sixth book, which August, the Berlin editor, though not admitting it into Euclid, thinks must be of high antiquity; in which we fully agree with him. It is to be found in the Basle edition, and in the notes to the Berlin. This scholium, while it gives confirmation to the preceding view (which hardly wants it), takes the same side on the meaning of the word πηλικότης as we have done. [Ratio, P. C.] And we find that Wallis was the person who suggested to Gregory *quantuplicitas* instead of *quantitas* as the translation. See his discussion of this point at length in his English Algebra (1684), ch. 19 and 20; revised in his Latin Algebra (Works, vol. ii. ch. 19, 20), and again at p. 665 of the same volume, where there is a defence of this definition against Henry Savile, who (*Prælect. in Eucl.*) had considered it as a great defect. To the text of Euclid we have only further to say, that this consent of Savile, Wallis, and Gregory, as to the genuineness of the definition in question, is of great weight. But with regard to the matter of the definition we agree entirely with Savile. The word πηλικότης needs definition quite as much as the term *composition of ratios* itself. This definition, it will be observed, either restricts the composition to ratios which are of commensurable magnitudes, or implies and assumes the multiplication of two interminable decimal fractions. An old scholiast on Euclid (cited from Dasypodius by Meibomius and Wallis) is of opinion that πηλικότης is used rather than the more natural word ποσότης, precisely that it may be understood in a wider sense, so as to include fractional and incommensurable ratios. That is, as Wallis expresses it, *how-much-fold* is used instead of *how-many-fold*, that *much* may suggest the idea of a part of a time (commensurable or not) where *many* would only suggest that of an integer. We cannot much admire this refinement; nor does it give any help: for the introduction of the idea of *incommensurability* numerically expressed, so as to be fit for arithmetical multiplication, would vitiate Euclid's whole system of proportion.

But the oldest testimony, both to the existence of the definition, and the meaning of the disputed word, is Eutocius, in his commentary on book ii. prop. 5 (of Torelli, 4 of preceding editors). He here cites, expressly from the elements, the definition as given; and adds, as the explanation of πηλικότης, that it is the number which, by multiplication, turns the consequent into the antecedent. This number, he says, gives name to the ratio, and he cites Nicomachus and Heron as understanding it in the same way. But, he goes on to say, the word is more properly taken when this number is an integer.

Leaving now out of view what Euclid really did write, we shall proceed to consider the subject of composition of ratios, so as to supply what, on any supposition, must be acknowledged to be wanted in the elements. The notion of a ratio is easily and almost necessarily connected with the idea of alteration *in that ratio*. We cannot express a ratio without two magnitudes, the first of which, altered in the ratio given, becomes the second. If we want to alter in the ratio of P to Q, this is easily done when the quantity to be altered is P; for then the process is only writing Q instead of P. But if the quantity be A, then B must be found, so that A and B shall have the same ratio as P and Q.

If it be a numerical ratio which we consider, say that of 3 to 5, alteration of any number in that ratio implies that we change all its *threes* into *fives*, and any remaining fraction of three into the same fraction of five. Alteration of any magnitude, say a length, in that ratio implies that, choosing any length as a measure, we alter every three such lengths which the given magnitude contains into five, and every fraction of three into the same fraction of five. This amounts to changing the number or magnitude into five-thirds of what it was; and generally, alteration in the ratio of a to b (numbers) is nothing but multiplication by $\frac{b}{a}$



Take a magnitude A, alter it in the ratio of P to Q; say that it then becomes B; that is, A is to B as P to Q. Take the magnitude we left off with, B, alter it in the ratio of R to S, making it C. Take C, alter it the ratio of V to W, making it D. Then at three processes, by three successive alterations dictated by given ratios, we have changed A into D, or have altered A in the ratio of A to D. Say that the ratio of A to D is simply expressed by that of M to N. Then, if we begin with A, and alter it at once in the ratio of M to N, we change it into D, producing the same effect as if we had successively altered in the ratios of P to Q, R to S, and V to W. Hence the ratio of M to N is properly said to be compounded of the ratios of P to Q, R to S, and V to W: it dictates the alteration which will produce at once the effect of the three alterations prescribed by the three other ratios. In like manner, we say in addition, that 10 is compounded of 6 and 4; for addition of 10 is equivalent to the addition of 6 and of 4. In multiplication we say that 24 is compounded of 6 and 4. And generally, the compound should be defined as that which produces the united effect of all the components, when both components and compound are used in the same way. Euclid, vi. 23, is now more than a mere addition to the phraseology of geometry. The parallelograms ABCD and EFGH [the reader may draw the figure for himself] being equiangular, it tells us that if we take any magnitude and alter it in the ratio of AC to EG, and then alter the result in the ratio of AB to EF, the change thus made at two steps might be made in one by altering the original magnitude in the ratio of the area ABCD to the area EFGH.

This process applies equally to commensurable and incommensurable ratios; but in the former case of course the arithmetical substitute for composition of ratios is easy. We want to compound the ratios of m to n and of a to b, all four

*Λόγος ἐκ λόγων συγκεῖσθαι λέγεται ὅταν αἱ τῶν λόγων πηλικότητες ἐφ' ἑαυτὰς πολλαπλασιασθεῖσαι ποιῶσί τινα. The Scholium presently cited gives it with λόγον for τινα in one place, and πηλικότητα λόγου in another.

being integer numbers: it being known that every commensurable ratio is expressible by the ratio of two integer numbers. Take any magnitude P, and alter it in the ratio of m to n: it becomes n-$m$ths of P. Alter this in the ratio of a to b: we have then b-$a$ths of n-$m$ths of P, or bn-amths of P, which would also be obtained by altering P in the ratio of $a \times m$ to $b \times n$. Hence composition of numerical ratios is performed by multiplication of the antecedents for an antecedent, and of the consequents for a consequent. The process then is merely equivalent to that of the multiplication of fractions. If $\frac{n}{m}$ and $\frac{b}{a}$ were called the quantuplicities (πηλικότητες) of the ratios, then the quantuplicity of the compound ratio is the product of the quantuplicities of the components, as in the definition (be it Euclid's or no) which is found in the manuscripts of the elements.

Duplicate ratio (διπλασίων λόγος) has been defined by Euclid in the manner hereinbefore given. But it is in fact the ratio arising from the composition of two equal ratios. Suppose we want to compound the ratio of P to Q with the ratio of P to Q. Take a magnitude to begin with, which may as well be P itself: alter it in the ratio of P to Q; it then becomes Q. Alter Q into R in the ratio of P to Q; that is, let R be a third proportional to P and Q. Then P is changed into R at these two steps, each involving an alteration in the ratio of P to Q: hence Euclid's duplicate ratio is the ratio compounded of two equal ratios; and, similarly, triplicate ratio (τριπλασίων) is that compounded of three equal ratios, and so on.

The subduplicate, subtriplicate, sesquiplicate, &c. ratios, which later geometers used, completed that language of multiplication and division applied to operations of powers and roots which finally suggested the idea of logarithms. [See also ADDITION OF RATIOS, P. C.]

The propositions requisite for the establishment of the direct use of compound ratio are contained in the fifth book. But in the inverse use there is a manifest hiatus in the converse part of vi. 22. It is supplied by a lemma added at the end of the proposition; which is found in almost all the manuscripts (even in the Vatican manuscript, and Peyrard admits it accordingly). This is a pretty sure sign that Euclid did not give the lemma; for he never refers to anything which is to come after what he has in hand. Robert Simson omits this lemma, and so leaves the proposition undemonstrated. What is wanted is the following:—It is impossible that the same ratio should be the duplicate ratio of two different ratios; or, if A be to B in the duplicate ratio of A to X, and also in the duplicate ratio of A to Y, then X and Y must be equal. If possible, let them be unequal; say that X is the greater:

A X B
A Y B

Then because X is greater than Y, the ratio of A to X is less than that of A to Y. But the ratio of A to X is that of X to B; and the ratio of A to Y is that of Y to B; therefore the ratio of X to B is less than that of Y to B. Therefore X is less than Y; but it is also greater, which is absurd. Consequently X and Y cannot be unequal, &c. By a continuation of this process it may easily be established that a given ratio can only be the triplicate of one ratio, only the quadruplicate of one, and so on.

It is unnecessary to say anything on the *decomposition* of ratios. Clear as it becomes in arithmetic, after a while, that every multiplication is a division and every division a multiplication, it is much clearer from the beginning, in this subject, that every composition is a decomposition, and every decomposition a composition. Suppose that P to Q is the ratio compounded of A to B and C to D, and we wish to return back again to the ratio of A to B. We must compound the ratio of P to Q with that of D to C; for it is easily made obvious that the ratios of C to D and D to C compounded give the ratio of a magnitude to itself, the ratio of equality, the use of which effects no alteration.

It is now easy to see that all the operations of algebra which spring from multiplication inclusive, must be represented in geometry by operations of composition, &c. Robert Simson, who, as we have seen, has left a demonstration of the sixth book absolutely unfinished, though "Theon or some unskilful commentator" had provided a lemma which supplied what was wanting, has thought it necessary to add some very complicated propositions on compound ratio at the end of the fifth book. If they were intended as illustrations of the great difficulty of rendering the commonest propositions of algebra into geometrical language (and what else could have been meant it is hard to imagine) the algebraical equivalents should have been introduced. Take the proposition K, for instance, which it may safely be asserted no beginner ever fathomed. The following is an arithmetical case of it. If

$$\frac{a}{b}\cdot\frac{c}{d}\cdot\frac{e}{f}\cdot\frac{g}{h} = \frac{i}{k}\cdot\frac{l}{m}\cdot\frac{n}{o}$$

$$\text{And } \frac{a}{b}\cdot\frac{c}{d} = \frac{i}{k}\cdot\frac{l}{m}$$

$$\text{Then } \frac{e}{f}\cdot\frac{g}{h} = \frac{n}{o}$$

REAUMURIACEÆ, a natural order of plants belonging to the Exogenous class. It has a 5-parted calyx, surrounded externally by imbricated bracts; 5 petals, hypogynous, unequal-sided, sometimes having a pair of membranous plates planted upon their middle; definite or indefinite hypogynous, monadelphous, or polyadelphous stamens, with or without a hypogynous disk; the anthers ovate, turned inwards, and bursting longitudinally; 2-4-5 carpels, partially separate from each other, surrounding a central placenta which passes into the base of each; 2 or 4 ascending anatropal ovules, with filiform or subulate styles; a capsular fruit with 2 to 5 valves and as many cells, unless the number is diminished by abortion; shaggy definite erect seeds, with a straight embryo surrounded by a small quantity of mealy albumen, and the radicle next the hilum. The species of this order are small shrubs, with fleshy scale-like leaves, which are alternate and have no stipules, and are overspread by resinous sunk glands.

This little order consists of three genera, Reaumuria, Hololachna, and Eichwaldia, which were formerly referred to Tamaricaceæ; they have, however, but little affinity with that order. Their true affinities seem to be with Hypericaceæ, near to which Lindley has placed them. The species are generally natives of the coast of the Mediterranean, and of salt plains in the milder parts of northern Asia.

The genus *Reaumuria* was named by Haselquist in honour of René Antoine Ferchault de Reaumur. [REAUMUR, P. C.] It has a 5-parted involucred calyx; 5 petals, permanent, furnished at the base on each side with a ciliated appendage; numerous pentadelphous stamens; 5-6 stigmas; a 5-valved 5-celled capsule, with valves easily separating from the septa, and shaggy seeds.

R. vermiculata has subulate semiterete imbricated leaves, crowded on the branches. It is a native of Sicily, Bombay, and Egypt. This plant resembles Salsola fruticosa. It is used at Alexandria as a remedy for the itch, being bruised and applied externally, and a decoction taken internally.

R. hypericoides has lanceolate flat rather remote leaves. It is a native of Syria and Persia. These plants are elegant little shrubs of easy culture, which thrive well in a mixture of sandy loam and peat; and young cuttings will grow freely in sand under a hand-glass.

Hololachna (from ὅλος, 'entire,' and λάχνη, 'wool,' or 'thick hair') has a 4-5 parted calyx; 4-5 petals; 8-10 hypogynous monadelphous stamens inserted into an hypogynous gland; 2-4 short subulate styles; the capsule 2-4 angled, 2-4 valved, 2-4 celled; the seeds few, large, surface shaggy. The only species is *H. Songarica*, found by Ehrenberg in the Soongarian desert of Siberia. In cultivation this plant requires to be watered with salt-water. All the plants of this order abound in saline matter in their tissues.

(Lindley, *Vegetable Kingdom*; Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

REBATE is the old English word for DISCOUNT [P. C.]. The discounting of a sum of money, or the paying something less for it before it becomes due, is now always done by striking off a certain per centage from the sum. Thus, if a sum be due a year hence, say 100*l*., discounting at five per cent. means paying 95*l*. now in lieu of 100*l*. a year hence.

There are one or two old difficulties connected with discount, which we intended, and omitted, to notice under other heads. The first is that of the *equation of payments*. Were it not for the difficulty, and its principle, this would not be worth notice. It was at one time the custom of the works on arithmetic to point out, when sums of money are due at different times, at what time the total amount is to be paid at once, in such manner that the receiver may gain, by the sums which are prepaid, what he loses by those which are overdue.

To take a simple case, say it is nnderstood that money makes five per cent. simple interest, that 100*l.* is due in three years, and 300*l.* more in seven years. The first rule that was given leads, as the reader knows, to the payment of the whole 400*l.* in six years; by which the interest on 300*l.* paid a year before its time balances that on 100*l.* paid threo years after its time. But this, it is said, was not fair; for not interest, but discount, should be allowed for the sum paid before it is due. That is, the 400*l.* paid at the intermediate time should yield 100*l.* due + interest on it since it was due + a sum which pnt out to interest will mako the 300*l.* at the end of the seven years. The rule for this case gives a result 5·9615574 years, instead of six years; which will be found to satisfy the conditions.

In truth, however, it depends entirely upon what the notion of fairness is, whether one rule is better than the other, or whether either will do. And it must be remembered that *simple interest* is a fiction in real business. A creditor cannot demand more than simple interest by law; but it does not therefore follow that because certain money is paid under the name of interest, the receiver will let it lie barren in a bag. But what we say is this: keep to the fiction on which both rules are constructed, let all interest-money remain barren, and the two rules will come to the same thing in the end. And it is not fair to construct rules on the supposition of simple interest, and then to complain of the inaptitude of these rules to represent the results of real business. Remaining by simple interest, let us see how tho receiver will stand at the end of the seven years, upon the different suppositions:—

1. If no equation of payments be made, he will have 100*l.* + four years' interest + 300*l.* just received, 420*l.* in all, with which he is to go on making interest on 400*l.* only.

2. If he receive by the first rule 400*l.* at the end of six years, he will at the end of the seventh year have 420*l.*, of which 400*l.* is to go on at interest as before.

3. If he receive by the second rule he will have at the end of the seventh year (100*l.* + 2·961... years' interest) which he received + 1·038... years' interest which he makes on the 100*l.* (the other part not making interest) + the sum which will in 1·038... years yield 300*l.* (285·19*l.*...) + the interest on this. That is, 420*l.* altogether, of which 20*l.* is interest only: for the last-mentioned item, though gained in the manner of interest, is discount intended to make up a *principal.* Or, if any one will not admit this last distinction, then the most approved rule puts the receiver in a worse position than the old rule.

The fact is, that if equation of payments were ever made, it ought to be supposed that all money, principal and interest, becomes productive money to the receiver from the moment it is received: or compound interest should be supposed. This puts the parties into a state of eqnity at all times, both during the longest term of debt and after. To show this, suppose that A is due at the end of a years and B at the end of b years, interest being r per pound. To satisfy this debt by a sum A+B paid at x years from this time, the equation to determine x is

$$A+B=A(1+r)^{x-a}+\frac{B}{(1+r)^{b-x}}$$

and the receiver of the equated sum, m years after its receipt, or $x+m$ years from the present time, will have $(A+B)(1+r)^{m}$ which is

$$A(1+r)^{x+m-a}+B\frac{(1+r)^{m}}{(1+r)^{b-x}}$$

Or

$$A(1+r)^{x+m-a}+B(1+r)^{x+m-b}$$

And this is precisely what he would have had from the payments themselves. And the accumulations or present value of the equated sum are at all times equal to the accumulations or present values of the payments.

There is another remarkable case of the same kind, in which discount at simple interest is compared with notions derived from compound interest, and a rule is consequently said to be false which is, upon its own hypothesis, perfectly true. The value of an interminable annuity, calculated at simple interest, comes out infinitely great: or no sum is large enough to pay t. Now it is clear that 20*l.* will pay an annuity of 1*l.* a year at five per cent. for ever. And this may even be called simple interest, for at the end of a year the interest of the 20*l.* is paid away, and the original principal only remains: so that there is no interest upon interest. But the truth is, that in the construction of all rules at simple interest, the money is arbitrarily divided into two parts, productive and unproductive, and a rule which expressly requires payment to be made from time to time out of the productive part, may produce very different results from another in which the unproductive part is paid away first. Now take the case of an annuity for three years, of 1*l.*, money making r per pound. The ordinary rule gives

$$(1+r)^{-1}+(1+2r)^{-1}+(1+3r)^{-1}$$

At the end of a year, this becomes

$$1+\frac{1+r}{1+2r}+\frac{1+r}{1+3r}$$

The first term 1 is partly principal, partly interest: and 1*l.* of annuity has become due. But the manner in which the rule was framed does not allow us to pay away the $r(1+2r)^{-1}$ and $r(1+3r)^{-1}$, which are never to make interest again, in part of the first year's annuity, but requires that the 1, part of which will make interest, should all be so paid. And, when the productive money is broken in upon before the unproductive is all gone, it is perfectly true that no sum is large enough to pay a perpetual annuity: and, if this be done, not only may the rule for a perpetual annuity be objected to, but with as much justice that for a finite term of years. For instance, at 10 per cent., an annuity of 1*l.* for five years, is worth, according to the usual simple-interest suppositions, 3·89261*l.* A year's interest is ·389261*l.*; let this all be paid away, and the balance of 1*l.* made up out of the principal, and so on, and it will be found that there is a sum in hand at the end of the ten years: in fact 3·79079*l.* will in this way be enough to meet all demands. But the manner in which the rule is constructed supposes the annual demands to be made up out of principal and interest in the following way, the sums before the lines showing how the pound yearly accruing due is raised, partly out of principal, partly out of interest:—

	Principal.		Interest.	
	3·89261		·38926	
Pay	·90909	+	·09091	= £1.
	2·98352		·29835	
			·29835	
Pay	·83333	+	·16667	= £1.
	2·15019		·43003	
			·21502	
Pay	·76923	+	·23077	= £1.
	1·38096		·41428	
			·13810	
Pay	·71429	+	·28571	= £1.
	·66667		·26667	
			·06667	
Pay	·66667	+	·33333	= £1.
	·00000		·00001	

While if interest were made to go as far as it could, we should have

3·89261		
·38926		
3·28187	after paying £1.	
·32819		
2·61006	do.	do.
·26101		
1·87107	do.	do.
·18711		
1·05818	do.	do.
·10582		
·16400	do.	do.

So that there would remain ·164*l.*

The truth is, that the rule for annuities by discounting at simple interest *is* wrong except upon the condition that principal and interest are to be rated in a specified way (which those who understand the formula will easily collect) to meet the accruing demands. And moreover, when interest is to be all disposed of first, before any principal is touched, *the rules for simple and compound interest are identical.*

RECEPTACULITES, a genus of fossils proposed by Defrance, synonymous with Ischadites of Murchison.

RECORD. [Pleading, P. C.]

REFINING is a term applied to various processes in the useful arts, and especially in metallurgy, whereby the substances acted upon are purified by the chemical separation of dross and impurities, and of such foreign matters as may be in combination with them. The refining of metals generally is treated of under Assaying, P. C., p. 495; and further particulars respecting the refining of the more important metals are given under Copper, P. C., p. 502; Iron, P. C., p. 34; Lead, P. C., p. 371; Silver, P. C., p. 23; and Tin, P. C., p. 472. Some writers apply the name of refining to the preparation of cast-steel, noticed under Steel, P. C., p. 3; a process which is certainly analogous, in many respects, to the processes to which that name is more usually limited. The term is applied to the purification of sugar, of which process an account is given under Sugar, P. C., p. 231.

REFLECTION. [Light, P. C.; Optics, P. C.]

REFRACTION, DOUBLE. [Polarization of Light, P. C.]

REFUGE, HARBOURS OF. In the year 1840 a Commission was appointed 'to visit the coast between the mouth of the Thames and Selsea Bill; to examine the ports with reference to their being available as places of shelter for vessels passing through the Channel in cases of distress from weather, and also as places of refuge for merchant vessels from enemies' cruisers in time of war, and more especially as to their being made stations for armed steamers employed for the protection of our trade in the narrow parts of the Channel.' The Commission made a Report, but no measures appear to have been taken in consequence.

A Select Committee of the House of Commons on Shipwrecks, in a Report presented in 1843, recommended the formation of Harbours of Refuge in the British Channel, at the same time stating that they refrained from pointing out any particular situations for such harbours, from a conviction that such situations would be best decided on by a body of scientific and experienced persons whose attention should be specially and exclusively directed to the subject.

On the 2nd of April, 1844, the Lords of the Treasury, on the suggestion of Sir Robert Peel, then First Lord of the Treasury, apppointed a commission consisting of twelve experienced naval and military officers and civil engineers to inquire into the most eligible situations for a Harbour or Harbours of Refuge in the Channel.

The Report of the Commissioners is dated August 7, 1844, and was presented to the House of Commons pursuant to an address dated March 6, 1845. The Treasury Minute under which the Commissioners acted assigned three principal objects of investigation:—1, the selection or formation of Harbours of Refuge for the safety and convenience of vessels navigating the Channel; 2, that in times of war, such harbours might become stations for ships of war; 3, the expense of constructing new works, as compared with the public advantages likely to result from such works. The Commissioners express their unanimous conviction that additional means of protection for the south-eastern coast of England are absolutely necessary. The harbours between Portsmouth and the Thames are only tidal harbours, and none of them is at present accessible to large steamers. The Report recommends certain ports and positions as Harbours of Refuge and Roadsteads, and certain breakwaters and military defences in connexion with them, so as not only to afford shelter to merchant ships, but by means of which, with the advantages of steam by sea, and railroads and telegraphic communication by land, the naval and military force of the country may be thrown on any point of the south-eastern coast in a few hours.

The following harbours and positions were especially examined:—Foreness, near the North Foreland; Ramsgate; the Brake, or Small Downs; Dover; Dungeness; Beachy Head, East Bourne, and Seaford; Newhaven; Portland and Weymouth; Harwich Harbour. Of these places four are selected, Dover, Seaford, Portland, and Harwich, of which the Commissioners estimate the expense required for the construction of the works which they recommend as follows:—Dover, 2,500,000*l.*; Seaford, 1,250,000*l.*; Portland, 500,000*l.*; Harwich, 50,000*l.* It is recommended that Dover Bay should be converted into a large harbour by means of breakwaters, with an area of 520 acres up to low-water mark, and an entrance 700 feet wide on the south front and another 150 feet wide at the east end. Its situation, four miles and a half from the Goodwin Sands and standing out favourably to protect the navigation of the narrow seas, is peculiarly suitable as a station for a squadron of ships of war. It is recommended to construct a breakwater in Seaford Road, for the protection of trade and as a station for armed vessels. Portland, as the boundary of the narrow part of the Channel, and with reference to the Channel Islands, is recommended as another station for a squadron. The construction of a breakwater there, it is stated, would be easy, cheap, and expeditious, as a large part of the island facing the bay is crown property, and contains abundance of stone: the holding-ground is exceedingly good, and the island has abundance of water for the supply of ships. The island has great natural advantages for defence, and for the formation of a naval and military depôt during war to any extent that may be required. Harwich Harbour, formed by the junction of the rivers Stour and Orwell, is stated to have sufficient depth of water and good holding-ground over an extent capable of containing many hundred ships. By the construction of a breakwater and dredging to get rid of certain shoals, the Commissioners consider that it might be converted into one of the finest and most useful harbours in the kingdom.

The military members of the Commission recommend that casemated batteries be constructed on the breakwaters themselves, supported by defences on the shore flanking the approaches to the breakwaters and harbours.

At the end of the Report, W. Symonds, Surveyor of the Navy, says, 'I dissent from this Report, because I consider the mass of evidence to be in favour of Dungeness, and because I cannot recommend a large close harbour at Dover, where the pilots consider the holding-ground generally indifferent, and the engineers say it will silt up.' With respect to Dungeness, the Commissioners say that it is remarkable for its good holding-ground, and that 300 sail have been well sheltered in the East Bay at one time, and that more than 100 vessels were at anchor in the West Bay a few days before the Commission arrived there. As however it has not the advantage of an inner harbour like Dover, Seaford, and Portland, the commissioners do not recommend any breakwater to be constructed, but prefer leaving it as it is, to be used as a roadstead for merchant-ships and ships of war. The holding-ground in Dover Bay was tested by Captain Washington in the steam-vessel Blazer of 500 tons burthen and 150 horse-power, and the results were satisfactory. As to the probability of silting, samples of the water, taken up at different times of tide and different depths, were examined by Mr. Phillips, of the Museum of Economic Geology, as to the quantity of matter held in suspension. The impurity of the sea-water, as compared with the water of the Thames taken up at Brentford, Hammersmith, and Chelsea, was, taking the mean of the experiments on each side, as 16 to 5. The Commissioners recommend further experiments as to the probability of silting in Dover Bay before anything is determined on.

The Commission of 1840 recommended three places as suitable for Harbours of Refuge—Dover, as first in importance; Beachy-Head, as second; and Foreness, as third.

(*Report of the Commissioners upon the Subject of Harbours of Refuge*, 1845.)

REGISTRATION OF BIRTHS, DEATHS, AND MARRIAGES. Parish registers were not kept in England till after the dissolution of the monasteries. The 12th article of the injunctions issued by Cromwell, Henry the Eighth's secretary, in 1538, directs that every clergyman shall, for every church, keep a book wherein he shall register weekly every marriage, christening, and death, any neglect being made penal. In the first year of the reign of Edward VI. (1547) ecclesiastical visitors were sent through the different dioceses in order to enforce various injunctions, and, among others, that of Cromwell with respect to parish registers. In the beginning of Elizabeth's reign this injunction was repeated, when the clergy were required to make a protestation in which, among other things, they promised to keep the register-book in a proper and regular manner. In 1694 an Act (6 & 7 Wm. III. c. 6) for a general registration of marriages, births, and deaths, was passed merely for purposes of revenue: it is entitled 'An Act for granting to his Majesty certain rates and duties upon Marriages, Births, and Burials, and upon bachelors and widowers, for the term of five years, for carrying on the war against France with vigour.' It is a very long Act, in which the duties are minutely set down. A supplementary Act was passed (9 Wm. III. c. 32), entitled 'An Act for preventing frauds and abuses in the charging, collecting, and paying the duties upon marriages, births, burials, bachelors, and widowers.' The 52 Geo. III. c. 146 (28 July, 1812) entitled 'An Act for the better regulating and preserving parish and other registers of births, baptisms, marriages, and burials, in England,' made some alteration in the law, chiefly with reference to having the books made of parchment or strong paper, and to their being kept in dry and well-painted iron chests.

The Registration Act (6 & 7 Wm. IV. c. 86: 17 Aug., 1836), entitled 'An Act for registering Births, Deaths, and Marriages, in England,' came into operation July 1, 1837. By the 44th section of the 6 & 7 Wm. IV. c. 85, entitled 'An Act for Marriages in England,' the provisions of this Registration Act are extended to the Marriage Act.

The most important provisions of this Registration Act are the following:—A general registry-office is to be provided in London and Westminster (§ 2). Lord Treasurer and Lords Commissioners of his Majesty's Treasury to appoint officers, and fix salaries, to be paid out of the consolidated fund (§§ 3 and 4). Regulations for conduct of officers to be framed under direction of the Secretary of State (§ 5). Annual abstract of registers to be laid before parliament (§ 6). The guardians of the poor of a union or parish shall, on the 1st of October, 1836, if the board is established at the passing of the Act, or, if not, within three months after its establishment, divide the union or parish into districts as directed by the registrar-general, and appoint registrars and superintendent registrar, if the clerk of the guardians will not or cannot execute that office (§ 7). Register-offices to be provided in each union by the guardians, and to be under the care of the superintendent-registrar (§ 9). Temporary registrars and superintendent-registrars to be appointed, for parishes not having guardians under the Poor-law Act, by the Poor-law Commissioners; but in case of subsequent unions, previous appointments to be vacated (§§ 10 and 11). Deputy-registrars may be appointed by the registrars (§ 12). All books, &c. to be transferred on removal of registrar or superintendent, under a penalty of committal to gaol (§ 15). Registrar and deputy to dwell in the district, and their names and additions to be put on their dwelling-houses (§ 16). Register-books to be provided by the registrar-general, for making entries of all births, deaths, and marriages of his majesty's subjects in England, according to the forms of schedules (A, B, C) annexed to the Act (§ 17). Registrars authorised and required to inform themselves carefully of every birth and death which shall happen within their district after the first day of March, 1837, and to learn and register as soon after the event as conveniently may be done, without fee or reward, save as hereinafter mentioned, in one of the said books, the particulars required to be registered according to the forms of the said schedules (A and B) respectively, touching every such birth or every such death not already registered (§ 18). After March 1, 1837, parents and occupiers may within forty-two days after birth and five after death, give notice thereof to registrar; and owners and coroners must do so forthwith in cases of foundlings and exposed dead bodies (§ 19). Parents and occupiers, on being required by the registrar, within forty-two days, must give all the particulars required to be registered respecting birth (§ 20). Children born at sea must be registered by the captain (§ 21). After the expiration of forty-two days from the birth of the child, it can only be registered within six months, on the solemn declaration of the particulars before the superintendent-registrar, who is to sign the entry, and to receive 2s. 6d. and registrar 5s., extra fee; and no registration, after forty-two days, shall be made otherwise than as above, under a penalty of 50l. (§ 22). Births not to be registered after six months, under a penalty not exceeding 50l., and no registration after that date shall be evidence (§ 23). Name given in baptism may be registered within six months after registration of birth, on production of a certificate by the minister (§ 24). Some person present at death, or occupier of house, required to give particulars of death, on application by registrar, within eight days; registrar to make entry of finding of jury upon coroner's inquests (§ 25). Registry of persons dying at sea, containing particulars, to be kept by the captain (§ 26). Registrar to give certificate of death to undertaker, who shall deliver the same to the minister or officiating person, and unless such certificate is delivered the minister must give notice to the registrar; but the coroner may order body to be buried, and give certificate thereof; and if any dead body shall be buried without certificate of registry or of inquest, and no notice given to the registrar within seven days, the party shall forfeit 10l. (§ 27). Every register must be signed by the informant (§ 28). Registrars to make out accounts quarterly, to be verified by the superintendent, and are to be paid by the guardians, as directed (§ 29). Marriage register books to be provided by the registrar general for ministers (§ 30). Marriage registers to be kept in duplicate, containing the several particulars of schedule C; and every entry shall be signed by the clergyman, or the registering officer, or secretary of Quakers and Jews, and by persons married, and by two witnesses (§ 31). Certified copies of registers of births and deaths to be sent quarterly, and the register-books when filled, to the superintendent-registrar (§ 32). Duplicates and certified copies of registers of marriages to be sent to superintendent-registrar (§ 33). Superintendent-registrars to send certified copies of registers to the general register-office (§ 34). Searches may be made and certificates given by the persons keeping the registers, on payment of the fees prescribed (§ 35). Indexes to be made at the superintendent-registrar's office, searches allowed, and certified copies given (§ 36). Indexes to be kept at general register-office, searches allowed, and certified copies given (§ 37). Certified copies given at general register-office to be sealed, and shall then be evidence without farther proof (§ 38). Ministers, &c. may ask parties married the particulars required to be registered; and wilfully giving false information is perjury (§§ 40 and 41). Penalty for not duly registering births, deaths, and marriages, or for losing or injuring the registers, not exceeding 50l. Penalty for destroying or falsifying register-books, or entries therein, or giving false certificates, is felony (§ 43). Accidental errors may be corrected, within one month, in the presence of the parties (§ 44). Modes of recovering penalties and of making appeals are provided for by §§ 45 and 46. Registers of baptism and burials may be kept as heretofore (§ 49). Registrar-general to furnish notices to guardians of unions, &c. specifying acts required to be done by parties registering, and which are to be published in conspicuous places of the unions or parishes (§ 50).

Another act was passed (1 Vict. c. 22—June 30, 1837), entitled 'An Act to explain and amend two Acts passed in the last session of Parliament, for Marriages, and for registering Births, Deaths, and Marriages, in England.' This act consists chiefly of arrangements necessary to extend and improve the provisions of the Registration Act.

Previous to the Registration Act coming into operation it was necessary to divide the country into districts of convenient size for equalizing the labours of the registrars by contracting the area where the population was dense and extending it where the population was thin. The Registrar-general issued a circular letter in September 1836, to the boards of guardians throughout the country, on whom devolved the duty of forming each poor-law union into registration districts, and as the unions differed much from each other in population, ranging from 2000 to 80,000, the Registrar-general left the arrangement to the guardians, simply referring them to certain principles for their guidance. Parishes and townships not under the Poor-law Commissioners were formed into temporary districts, or, where more convenient, were annexed to a district already comprised in a poor-law union. To each district a registrar of births and deaths is appointed, and also a registrar of marriages; and in each union there is a superintendent-registrar. The registrar of births and deaths is appointed by the guardians, and is always a resident in the district in which he acts. The registrar of marriages is appointed by the superintendent-registrar, subject to the approval of the guardians.

The total number of registrars of births and deaths at the end of September, 1838, was 2193, of whom 1021 were officers in poor-law unions. At the end of December 1838, the number of superintendent-registrars was 618, of whom 56 were superintendent-registrars of temporary districts; at the same period the number of registrars of marriages was 817, of whom 419 were also registrars of births and deaths. In the first year, under the new Act, there were registered in England and Wales—

Births	399,712
Deaths	335,956
Marriages	111,814

Mr. Finlaison, in an estimate of the number of births, deaths, and marriages, which might require to be registered in the first year, calculated the number of births at 550,085; of deaths at 335,968; and of marriages at 114,947. The approximation as to deaths is remarkable, and not less so the deficiency in the births and in some degree in the marriages. The imperfection in the registration of births, which seems to have arisen partly from the opposition of interested persons, partly from the erroneous notions of the ignorant, and partly from mere negligence, has since been in some degree remedled, but is still imperfect.

The registrar-general, in his 6th Report, dated August 10, 1844, states, that four inspectors had been appointed to visit every district into which England has been divided, in order to examine into the mode in which the registrars perform their duties. These inspectors, among other important directions given to them, are required to see 'that the places of birth or death are accurately recorded; that the ages and professions of those who die are duly registered; that exertions are used to impress upon persons giving information of deaths the importance of producing a certificate of cause of death, in the hand-writing of the medical men who attended the deceased in their last illness,' &c.

By the end of 1839 about 350 new register-offices had been built, and the use of temporary offices had been sanctioned in many places. The ordnance-office supplied iron boxes for holding the register-books of each district. By the end of September, 1838, register-books of births and deaths, and forms for certified copies thereof, had been provided by the registrar-general for 2193 registrars of births and deaths; and marriage register-books, and forms for certified copies, had been supplied to 11,694 clergymen of the established church, to 817 registrars of marriages, to 90 registering offices of the Society of Friends, and to 36 secretaries of Jewish synagogues. They are each required to transmit certified copies on paper having a peculiar water-mark as a safeguard against the substitution of false entries, every three months, to the superintendent-registrar of each district, who transmits, once a quarter, to the registrar-general the certified copies of all the births, deaths, and marriages, which have occurred within the district during the preceding three months. These certified copies, having been deposited in the register-office in London, are there examined and arranged; and alphabetical indexes are then formed, and abstracts of them are compiled. In a few years millions of entries will have been made, and yet, for legal or other purposes, it will be as easy to find out the name of any individual from among so great a number as it is to find out a word in a dictionary or a cyclopædia.

The registration for 1839 was

Births	480,540
Deaths	331,007
Marriages	121,083

The improvement in the registration of births, as compared with that for 1838, is sufficiently obvious.

The registrations for 1839-40 and 1840-41 are as follows:—

	1839-40.	1840-4.
Births	501,589	504,543
Deaths	350,101	355,622
Marriages	124,329	122,482

The number of births not registered still amounts to some thousands annually, and the registrar-general is of opinion that 'the registration of births will not be complete until it is enacted by law that the father or mother, or some other qualified informant, shall give notice within a fixed period, of a birth having taken place.'

In 1841 and 1842 the number of marriages celebrated according to the rites of the Established Church were:—

	1841.	1842.
By special licence	13	9
Licence	15,792	14,935
Banns	78,015	75,744
By registrar's certificates	972	944
Form not stated	19,579	18,415
Total	114,371	110,047

Other marriages not celebrated according to the forms of the Established Church:—

	1841.	1842.
In registered places of worship	5882	6200
In registrar's offices	2064	2357
Between Jews	66	58
Between Quakers	113	168
	8125	8778

In each of the four years from 30th June, 1837, to July 1st, 1841, the marriages celebrated in registered places of worship and in registrars' offices were as under:—

	In Registered Places of Worship.	In Registrar's Offices.
1837-38	2976	1093
1838-39	4654	1564
1839-40	5140	1938
1840-41	5816	2036

The proportion of marriages at registered places of worship and at the registrars' offices has slowly increased, and in 1842 the number of marriages so performed represented a population of about 1,160,000. The number of buildings registered in England and Wales for the solemnization of marriages was 2232 on the 30th of June, 1844. They belonged to the following denominations:—

Presbyterians	186
Independents or Congregationalists	903
Baptists	539
Methodists (Arminian)	204
Methodists (Calvinistic)	69
Roman Catholics	284
Foreign Churches	5
Miscellaneous	42

A parliamentary paper gives the number of marriages, births, and deaths, registered in 1839, 1840, 1841, and 1842, as follows:—

	1839:	1840:	1841:	1842:
Marriages	123,166	122,665	122,496	118,825
Births	492,574	502,303	512,518	517,739
Deaths	338,979	359,634	343,847	349,519

REGISTRATION. (*Scotland.*) The registration of documents in Scotland is a great and important system intimately connected with the titles of real or heritable property, and with the execution of the law. It is thus divided into two distinct departments, which may be considered separately—Registration for Preservation, and Registration for Execution.

Registration for Preservation, in its simplest form, is merely the preserving of an attested transcript of any deed in a public register, that thus an authentic copy may be had recourse to in case the original should be lost. Besides the regular statutory records of particular deeds, there are books attached to the several courts of civil jurisdiction, in which parties may for their own convenience register such documents as do not require by any special obligatory law to be recorded. It is a general rule that extracts from any such records may stand in the place of the originals when these are not forthcoming, but that a party is not to found on an extract if he have the original deed in his possession and can produce it. In the case of sasines, however, and other deeds, of which, as will be seen below, it is not the deed itself, but its registration, that makes the completed title, an extract from the register is the proper document to be produced. There is a certain class of actions, however, to meet which the original must be produced if it be accessible. These are called Actions of Reduction-Improbation. Such an action is raised against the party favoured by the deed, by some other party, and its object is the annulling the deed on some legal ground. As a matter of form, in commencing such an action, the pursuer states, along with whatever other grounds of objection he may have, that the deed is forged, and he desires the original to be produced, that it may be judicially examined. The rule for production of the original is subject to modifications, where the ground of the action is extrinsic of anything peculiar to the original document; and if the original be lost without being intentionally destroyed, the inquiry must proceed on the extract and the other circumstances that can be adduced. It is usual to speak of registration for preservation, as being also for publication; and in this sense, when a deed is of such a character that to make it effectual in the grantee's favour it must have been delivered to him by the grantor, such registration is in the general case equivalent to the delivery. It will operate in this respect in adjusting questions of competing right, as where a father makes over to one child the property that, in case of his dying intestate, would go to another, and registers the deed. It is questioned however if the mere registration would be in all cases that complete transference of property which is necessary to bar the claims of creditors under the statutes against alienations to their prejudice by insolvents. The registration of ordinary documents for preservation was sanctioned by the Act 1698, c. 4, which generally extends to registration 'in any authentic public register that is competent.' Besides the central register attached to the supreme court, there are others connected with the Sheriff and Corporation Courts; but it does not appear to be distinctly settled what may be, with reference to various descriptions of documents in each case, a 'competent' register.

By far the most remarkable of the registers for preservation is that of the 'Sasines *and* Reversions,' the former word expressing the Act by which an estate is created or transferred in heritable (*i.e.* real) property, the latter the attestation of the extinction of a burden, *i.e.* of the devolution of a temporary estate on the person entitled to the remainder. This system has been gradually formed. In its present state its main operative principle is, that when a title to land appears on the register, no latent title derived from the same authority can compete with it, and that registered titles rank according to their priority; so that if A first sell his property to B and execute the proper conveyance, and subsequently sell the same property to C, if C get this title first recorded it cannot be questioned by B, who has only his pecuniary recourse against A. In pursuance of this system, in transactions regarding land, the public records are relied on as affording the means of ascertaining the character and title, and after they have searched for the period of prescription, or examined over a period of forty years [PRESCRIPTION, P. C. S.], parties can trust that there are no latent rights, and may safely deal with the person who professes to dispose of any right connected with it. The origin of this system may be traced to the commencement of the sixteenth century, when the notaries were required to record their proceedings in their protocols, and the other officers connected with the feudal transference of land were bound to make returns of their official acts. In 1599 an Act was passed in which an effort was made to produce regularity in these registers, by penalties. It was by the Act 1617, c. 16, that the system was founded on its right principle. The preamble of that statute bears 'considering the great hurt sustained by his Majesty's lieges by the fraudulent dealing of parties who having annallied [alienated] their lands, and received great summes of money therefore, yet by their unjust concealing of some private right formerly made by them, render the subsequent alienation done for great summes of money altogether unprofitable; which cannot be avoided unless the said private rights be made public and patent to her Majesty's lieges.' The Act then appoints the sasines, reversions, &c., to be registered within threescore days after execution, otherwise they are 'to make no faith in judgment, by way of action or exception, in prejudice of a third party, who hath acquired a perfect and lawful right to the said lands and heritages: But prejudice alwayes to them to use the said writs against the party maker thereof, his heirs, and successors.' By the other clauses of the Act the superintendence of the system is given to the Clerk-Register, and the country is divided into Registration Districts. There is one defective provision in this Act, which is still in force. Parties are allowed to register their titles either in the particular register of their district or in the general register at Edinburgh. It is unusual to adopt the latter alternative, and when it is followed, it is generally for the purpose of concealing instead of publishing the transaction. There was another material defect in the old Act. A person might have his title immediately registered, but was liable to have it superseded by any other person able to register a title on a warrant previously obtained. This was remedied by the Act 1693, c. 13, which gave the registerable titles priority not according to the date of their execution, but to that of their registration. To prevent injustice by the accumulation of unregistered deeds at the office, a minute-book was, by a contemporary Act, appointed to be kept, in which the keeper enters an outline of each document as it is presented to him. By the present practice, when a sasine or other writing belonging to this register is presented to the keeper, he marks in the minute-book the day and hour of presentation. This is indorsed on the deed itself, and marks the date of registration. When the deed is engrossed at length in the register, a certificate to that effect is endorsed on the deed, mentioning the pages of the register in which it is to be found, and the deed is then returned. Registration volumes, with minute-books accompanying them, are from time to time issued from the General Register-house to the district registrars, so systematically marked and certified, as to prevent them from being tampered with without either interpolation or mutilation being easily perceptible. When a volume is finished, it is returned with the corresponding minute-book to the General Register-house, the keeper of the District Register retaining a copy of the minute-book for general reference. The real titles of all the heritable property in Scotland are thus preserved in a seriatim and indexed collection, in the General Register-house at Edinburgh. When property is offered for sale or mortgage, a 'search' generally forms part of the titles offered for inspection to the parties treating for it. This is a certificate by the proper officer, describing all registered documents regarding that particular piece of land which have been recorded during forty years. The documents that require to be registered have lately been much simplified and abbreviated by the act 8 & 9 Vict. c. 35. It has to be kept in view that the execution of the real title which may be registered within the sixty days only gives a *preferable* title. It is not necessary to create a title; and if the receiver of a conveyance have an absolute reliance on the integrity of the granter and all from whom that person may have derived his title, he may defer completing and recording it, and may encounter the risk of some other person obtaining a title and getting on the register before him. The simplification of the documents to be registered tends to lessen the temptation to delay their completion and registration. It is remarkable that the enlightened mind of Cromwell appears to have comprehended the utility of this system, and that he made an effort to introduce it into England. We are told by Ludlow (Memoirs, I. p. 436), 'In the meantime the reformation of the law went on but slowly, it being the interest of the lawyers to preserve the lives, liberties, and estates of the whole nation in their own hands, so that upon the debate of registering deeds in each county, for want of which within a certain time fixed after the sales, such sales should be void, and being so registered that land should not be subject to any incumbrance, this word incumbrance was so managed by the lawyers, that it took up three months' time before it could be ascertained by the committee.'

Registration for Execution is another peculiarity of the law of Scotland, although the system of warrants to confess judgment in England in some measure resembles it. The party to a solemn deed incorporates with it a clause of registration, by which, on the deed being registered in the books of a court competent to put the deed in force, the decision of the court shall be held as pronounced in terms of the deed, and execution may proceed against the party on an extract, as if it were the decree of a court. The engagement on which such execution may issue must be very distinctly set forth. Thus, if it be for payment of money, it must be for a sum named in the deed, and not for the balance that may be due on an account arising out of the transactions to which the deed refers. This method of execution was by statute (1681, c. 20) made applicable to bills and promissory notes without their containing any clause of registration. To entitle it to this privilege, the bill or note must be apparently without flaw, must bear the appearance of due negotiation, and must have been protested. The operation of this system was much widened by the Act 1 & 2 Vict. c. 114, which extended registration for execution to the Sheriff Courts.

REGISTRY OF SHIPS. [SHIPS, P. C.]

REGNARD, JEAN FRANCOIS, was born at Paris, according to most accounts, in 1647, though in a short biography prefixed to an edition of his works (Paris, 1818, 4 vols. 18mo.), he is said to have been born in 1656. An only son and heir to considerable wealth, he received an education qualified to fit him for the position in life he was likely to occupy. The death of his father soon after he had completed his studies enabled him to gratify his desire for travelling. The first country that he visited was Italy, where he spent the year 1676, a date which, connected with other circumstances, renders it probable that 1656 was the real year of his birth. He revisited Italy a second time in 1678, on which occasion he formed an intimacy with the Eloise, whose memory he has consecrated in his pleasing little novel entitled 'La Provençale,' a work published after his death. This lady and her husband were induced by him to visit France, and for that purpose they all sailed from Civita Vecchia in an English vessel bound for Toulon. On the voyage, however, the vessel was captured by Algerine pirates, and Regnard and his companions were taken captives to Algiers. The adventures of their captivity form the basis of the novel above mentioned, and they are sufficiently interesting and romantic in themselves without the colouring of fiction. The only talent of Regnard which became serviceable to him on that occasion, was one which his love for good fare had excited, and his wealth had enabled him to gratify, the skilful preparation of comestibles according to the most improved principles of Parisian cookery. His culinary abilities secured for him the good will of his master and the favour of the ladies of his household. During his captivity he was taken to Constantinople, where he remained two years. On his return to Algiers he was ransomed for a considerable sum by the French consul; a ransom which came most opportunely, as he was about to suffer the last penalty for an intrigue in which he had been detected. He took with him to France the chain he had worn as a captive, which he carefully preserved. His love of travelling, however, had not been abated by his unlucky adventures, and, on the 26th of April, 1681, he set out from Paris on a journey over the north of Europe. On arriving at Stockholm, he was induced by the King of Sweden to visit Lapland. He journeyed thither by way of Tornea, ascended the river of that name, and reached the borders of the Frozen Ocean. On one of the rocks of the mountain of Metewara, the limit of his excursion, he engraved the following Latin verses.

> 'Gallia nos genuit; vidit nos Africa; Gangem
> Hausimus, Europamque oculis lustravimus omnem,
> Casibus et variis acti terrâque marique,
> Hic tandem stetimus nobis ubi defuit orbis.'—
> (Anno 1681, die 22 Augusti).

On his return from Lapland he made a short sojourn at the Court of Sweden, and, after having travelled over Poland, Hungary, and Germany, came to Paris on the 4th of December, 1683, where, satiated with the wandering life he had led, he determined upon settling. Having purchased some lucrative situations under government, he there devoted a part of his time to literary pursuits, but spent the greater part of it in the society of his friends, and in the enjoyment of the capital; the summer he was in the habit of passing on an estate which he had purchased near Paris. He has given us ample details of his manner of life, in his 5th epistle and his 'Mariage de la folie.' His devotion to gaiety and pleasure, as it was the means of lessening his utility and reputation as a writer, was the cause of his untimely death, which occurred on the 5th of September, 1710.

As a dramatic writer, the reputation of Regnard stands deservedly high; in comedy he is generally considered second only to Molière; and Voltaire has remarked that 'no one can appreciate that great dramatist who feels no pleasure in reading Regnard.' His finest and most perfect production is the comedy of 'le Joueur,' written in 1696; some scenes in it, more especially the thirteenth scene of the fourth act, are equal to anything written by Molière. Himself a gambler, he has given a dark but faithful colouring to the portraiture of a vice which had embittered his life, and he has translated his own sad sentiments on the subject into the language of the most beautiful and energetic poetry. His next best piece is 'le Légataire Universel,' in five acts, in which the humour and the versification are alike deserving of admiration. (P. C. vol. ix. 421.) Had Regnard produced many comedies of similar merit to the two which we have mentioned, he would have relieved French literature of the reproach which has often been made to it of having had no worthy successor to Molière. The fault into which he has fallen is that, like Piron, Gresset, and Marivaux, he has rather delineated an exaggerated representation of some particular vice or folly, than, like his great original, human nature in its every-day proportions. This fault however is still more conspicuous in the French dramatists who succeeded him, whose portraits are, in most instances, only coarsely drawn caricatures of nature.

The other dramatic writings of Regnard, in five acts, are,—1, 'Le Distrait,' which appeared in 1697, and is taken from one of the characters of La Bruyère. This piece failed on its first representation, but was afterwards, in 1731, reproduced on the French stage with considerable success. 2, 'Démocrite' (1700). 3, 'Les Ménechmes' (1705); a comedy dedicated by the author to Boileau on a reconciliation with him which his friends had effected; between these two poets there had been a long literary warfare [Boileau, P. C.]; it is rather an imitation of the Ménechmes of Rotrou than of the antient comedy of Plautus. His shorter pieces are mostly in prose; the principal of them are—1, 'Le Divorce,' in three acts (1688). 2, 'La Descente de Mezetin aux Enfers' (1689); 3, 'L'Homme à bonnes Fortunes' (1690); Regnard has also written a criticism on this comedy in a small piece of one act which was represented in the same year. 4, 'Les Filles Errantes' (1690). 5, 'La Coquette' (1691); all in three acts. 6, 'Les Chinois' (1692), four acts, and several one-act pieces, such as 'La Sérénade,' 'La Foire de St. Germain,' &c. He also wrote an opera entitled 'Le Carnaval de Venice' (1699), the music of which is by Campra, and a tragedy called 'Sapor,' which has not been represented. His other writings are some Epistles and two Satires, one of them directed against Boileau, another against husbands, which have been much admired, besides several shorter poems. In prose he has composed a relation of his various travels, and the Provençale already alluded to.

The best editions of his works are those by Lequien, published in 1820, 6 vols. 8vo., and by Crapelet in 1822 and 1823, 6 vols. 8vo.

REGULATORS OF MOTION. Fly wheels are the means usually employed to render the movements of machines as nearly as possible uniform; and the nature as well as the applications of these have been described under Wheels, (P. C. p. 316, col. 2), and under Steam-Engine (P. C., p. 447, col. 1). Pendulums, as regulators of motion for clock-work, are described under Pendulum (P. C.); and the *Governor*, by which the supply of steam is regulated, has been described under Steam-Engine (P. C., p. 415, col. 1). Some account of air-vessels for regulating motion in the tread-wheels, which are employed in prisons, has been given under Air-Vessel (P. C. S.), and it may be added that a particular kind of fly has been occasionally used for the like purpose. This consists of a vertical rod or shaft about 20 feet high, carrying at its upper extremity, on opposite sides, a long rectangular frame, which is provided with shutters turning on hinges; by the revolution of the shaft these frames turn round horizontally; and the shutters being connected with two governor-balls by means of wheel-work, when the motion of the tread-wheel becomes too rapid, the diverging balls cause the shutters to close, and thus the resistance of the air diminishes the velocity. Should the movement of the tread-wheel become too slow, the balls collapsing allow the shutters to open, when the resistance of the air is diminished and the velocity of revolution increases.

REICHA, ANTOINE-JOSEPH, a musical composer and theorist, was born at Prague in 1770, and having in his infancy lost his father, was educated first by his uncle, and finally at the university of Bonn, where he very successfully completed his studies. His relation having been appointed *maître de chapelle* to the Elector of Cologne, placed his nephew in the same service. On the French invasion in 1794 Reicha sought refuge in Hamburg, and there composed an opera, 'Ohalda, ou les Français en Egypte,' but it was not represented. He then repaired to Paris, in 1798, but failed in his endeavour to obtain a hearing for his work, on account of the feebleness of the drama. However he there produced a grand symphony which met with applause. In 1802 he proceeded to Vienna, and resided six years in that capital, enjoying the friendship of Haydn and Beethoven. During that period he published an Oratorio, and a collection of fugues. On the invitation of Prince Louis Ferdinand of Prussia, who was a superior performer on the piano-forte, and who desired instructions in composition from Reicha, he prepared to visit Berlin; but the death of that accomplished and amiable prince obliged him to change his intention. In 1808 he returned to Paris, and gave a course of lectures on composition, which were well attended; and some quintets for wind-instruments which he there produced, were much admired. But an opera, 'Cagliostro,' which he gave in 1810 at the Opéra Comique, was allowed only a single representation, and that a stormy one. In 1816 he produced, at the Académie Royale de Musique, 'Nathalie, ou la Famille Suisse;' and in 1822 'Sappho.' But this able theorist and learned harmonist had not the talent for creating melody, which genius alone can produce; and he might with propriety have said to his élèves, 'follow my precepts, but not my examples.' He then prudently renounced the composition of operas; and having been named professor at the Conservatoire de Musique, on the death of Mehul, in 1818, he there attracted a numerous class of pupils, many of whom, crowned by the Institut, have since become highly esteemed masters. He originated a method of instruction more clear and precise than any that had been in use; and the publication of his didactic works, which soon made them known in most parts of Europe, has in no inconsiderable degree improved the study and advanced the knowledge of music. These opened to him the doors of the Institut de France, in May, 1835. Unfortunately for the science, he enjoyed this high honour but a very short time, his death taking place in May, 1836. His chief works on the theory of music are—1, 'Traité de Melodie,' &c. 4to. 1814; 2, 'Cours de Composition Musicale,' 4to., 1818; 3, 'Traité do Haute Composition,' 4to., 1824; 4, 'Petit Traité d'Harmonic Pratique à deux Parties,' 4to.; 5, 'Art du Compositeur

Dramatique,' 4to., 1833; and many articles on music in 'l'Encyclopédie des Gens du Monde.' (*Biographie Universelle.*)

RELEASE REMAINDER. [RELEASE and REMAINDER, P. C., and TRANSFER OF REAL PROPERTY, P. C. S.]

REMOPLEU'RIDES, a singular fossil genus of Trilobites found in the Silurian strata of Tyrone by Portlock, who describes it in his Geological Report on Tyrone.

RENAISSANCE. Perpetually as they are occurring, neither this nor the term *Cinque-cento* have found their way into any of our architectural dictionaries and glossaries. The term Renaissance indicates the period of the *Revival*, when the classic began to be re-introduced after the mediæval styles. But this is not the case with the term *Cinque-cento*, which literally means five hundred, whereas it is used as equivalent to mille cinque-cento, the *mille* being understood though not expressed, therefore it stands for fifteen hundred, and in its technical sense among artists signifies the style of architecture and general decoration in vogue during the 16th century, or rather the earlier part of it; nor is it so restricted, for without exact reference to date, it also applied to what belongs to the style so denoted though it may happen to be *before* the year 1500, which period may be taken as the equator-line laid down by the historians of art. Both terms, however, are now generally used as synonymous, that of cinque-cento therefore very loosely and arbitrarily.

Although all were derived from that of Italy, each country had its peculiar Renaissance, described accordingly as French, German, English Renaissance [ELIZABETHAN ARCHITECTURE, P. C. S.], preserving a general family likeness, but exhibiting traits exclusively its own. It is therefore rather singular that no one should have taken up so fertile a subject, and have treated of it expressly and at due length, instead of merely touching upon it hurriedly. The Renaissance in general is usually spoken of as if it were nothing more than a direct but unskilful imitation of the antique, previously to the orders being so well understood as they were afterwards when studied through the text of Vitruvius, and reduced to a methodical system of 'bookish rules,' by Palladio and Vignola. But in the first place it was founded only upon the *Roman* antique, and in the next, not upon the temple style of the Romans, but their triumphal arches, baths, and other edifices. It was not either the portico, or the continuous colonnade, where columniation displays itself in all its purity, that was taken as a model, but rather such structures as the Colosseum [AMPHITHEATRE, P. C.], where several small orders—that is, small in proportion to the general mass—are introduced for little more than decoration to it. And in the Renaissance and Cinque-cento styles, entire orders are used only as embellishment, and avowedly so. Where columns are employed for actual support, as in open loggie, it is only in combination with arches springing from them, the columns performing the office of piers to the latter; which is regarded by some as a most indefensible heresy and utter violation of good taste, though for no better argument than that columns were never so employed in the classical style, but were originally intended to support a horizontal entablature: in other words, *trabeation* is essential to them. Essential it certainly is to the completion of an entire 'order,' but it cannot be a whit more contrary to either good taste or good sense to employ columns as actual pillars or supports to arches resting upon them than it is to employ the *trabeation* or entablature without columns, as decoration in astylar buildings. [ASTYLAR, P. C. S.] In fact, a great deal of Italian Renaissance is astylar, with either a full entablature, or a cornicione crowning and proportioned to the entire mass. This large and simple mode of treatment was greatly affected by the Florentine and Roman architects of the period of the revival, and contrasts very strikingly with the Transalpine Renaissance in France and other countries, which is characterized by multiplicity of parts, and numerous divisions and breaks. It contrasts also with the contemporary practice of the Italian architects themselves when they employed the orders, in doing which they made their compositions *microstylar*, applying a separate small order to each floor or horizontal division of a façade, above the ground floor; and they further reduced the height of the columns by giving a considerable proportion of each order to high pedestals beneath the columns. In Transalpine Renaissance such application of the orders was greatly exaggerated, they being employed for the ground floor as well as the others, and the spaces between the columns being filled in, either entirely or nearly so, with large windows, so that the columns or pilasters between them show only as accessories to the windows themselves, and as narrow piers between them. Fenestration completely predominates, both as to the quantity of surface the openings occupy, and the architectural character occasioned by it. One of the earliest importations of the Renaissance into this country, Longleat House, Wilts, erected by John of Padua, 1567, and extolled for 'the singular purity of taste' displayed in it, is an instance of such mode of composition, and shows how greatly the borrowed style was transformed in its general physiognomy, even when treated faithfully with regard to details, among which may be reckoned the orders themselves, which amount in fact, when so applied, to no more than such.

One deviation from Italian practice was the frequent employment of coupled columns or pilasters, which was in some cases (as at Wollaton Hall) caused by the necessity for wider piers between the windows, at the same time that the intercolumns were completely occupied by the windows, which last, it should be observed, retained their Tudor or English character, being very spacious and divided by mullions and transoms.

In much of the Italian cinque-cento, especially in that for which purity and correctness were affected, the character of the detail is somewhat dry and meagre, and there is very little of ornamentation, even the entablatures to Corinthian columns consisting of only plain mouldings. Florid Renaissance, as it may for distinction's sake be called—seems, on the contrary, to have been most in favour both in France and in our country, probably in consequence of the taste for luxuriant enrichment which had been indulged during that period of Gothic architecture which the new style was beginning to replace. Besides which, it was there adopted as a 'peregrine' and exotic fashion, owing to which and to its being at first employed for palatial and sumptuous structures, it was displayed in all its luxuriance. This florid species of the style and period is marked by a profusion of enrichment and carvings in mouldings and pannels, by arabesque foliage and medallions, with which surfaces of considerable extent are oftentimes covered. Even the shafts of columns are frequently damasked or broidered, if not for their entire height, for a considerable portion of it, and generally the lower one, with foliage and other chasing; besides which they are further enriched by one or more bands embossed in similar manner. The faces both of pilasters and pedestals are also highly decorated by being pannelled, and filled up with arabesque work or other sculptures. Niches, too, are frequent features in composition, and within, their heads are generally carved to resemble a shell. Escutcheons and armorial bearings are not spared; neither are devices, mottos, and other inscriptions. This profusion of minute ornament is eminently characteristic of the Renaissance taste in building, furniture, and decoration generally; and though it was then carried to excess, and the combinations themselves were often very uncouth, grotesque, and what is understood by the term quaint (oddly picturesque but not beautiful), much of the ornament is, taken separately, marked by elegance as well as fancy; therefore it would not be difficult to refine upon the style by employing it more discreetly—by selecting all its better qualities and elements, and combining them with better taste,—more sparingly, instead of cramming a bit of everything into the same composition. But architects have not distinguished between the mere copying of a former style and the free artistic imitation of it by selecting what is valuable in it, and leaving its dross, or by borrowing ideas from it and working them out afresh.

French Renaissance is truly cinque-cento, since it may be dated almost with chronological precision from the year 1500, in the reign of Louis XII., who employed Italian artists, and among others the architect Giocondo [GIOCONDO, P. C. S.,] who erected for Cardinal d'Amboise, the minister of that monarch, the celebrated Château Gaillon. Though that edifice—at least what remained of it, was taken down some years ago, it is known from the representations of it, and also from such fragments of it as have been preserved by being reconstructed at the Ecole des Beaux Arts, Paris, to have been an exceedingly sumptuous pile. The buildings towards the court were almost entirely incrusted over—some would call it 'tatooed'—with pannelled pilasters, arabesques, medallions, and other sculpture. The Château de Blois, the birthplace of Louis XII., and restored and decorated by him, was another distinguished work of that period, and probably one of those on which Giocondo was employed. In the reign of Francis I., the culminating point of French Renaissance, the palaces erected by that sumptuous prince and his nobles attested tho magnificence if not the refinement of that age. As a retreat for himself in tho immediate vicinity of his capital, Francis built (about 1530) the Château de Madrid in the Bois de Boulogne, whose façades were decorated with coloured glazed bricks or enamelled tiles, constituting a species of polychromic decoration. Of that building nothing now remains, it having been taken down at the end of the last century; but another architectural specimen of the same period, the house or casino of Francis I., erected at Moret, near Fontainebleau, has been preserved by being removed to Paris, where it was re-erected in its primitive state, in the Bois de Boulogne, by the architect Biet, in 1823. Of this interesting monument of the Renaissance, which has also some polychromic *fayence* decoration, plans, elevations, and sections, are given in Normand's Paris Moderne, but being only in outline, a great deal of the effect is lost in them. The palace of Fontainebleau itself, in its interior at least (now restored by Louis Philippe), records the magnificence of Francis, his taste for splendour, and his liberal encouragement of arts.

In Germany, the castle or rather palace of Heidelberg would, if completed, have been a most gorgeous pile in the Renaissance style, as it showed itself in that country; and though now a ruin, tho principal portion of tho exterior is in sufficiently good preservation to admit of faithful restoration in a series of architectural engravings—and it is infinitely worthier of being so recorded than are the mere shapeless fragments of buildings—a few blocks of stono and columns which are regarded as interesting and curious only because discovered where they were not before known to exist.

The architecture of Spain at various periods is as yet so imperfectly illustrated that very little is here known of its Renaissance edifices; but from the views of some of them in the 'España Artistica,' that country would appear to contain several interesting and striking specimens of the kind; and among them may be mentioned, as deserving of particular notice for the elegant taste it displays, the upper gallery of the cloister of the Convent of Huerta.

We may conclude this imperfect sketch by observing that the Renaissance is well worth studying, if only because such study will enable us to avoid what was faulty in it, and to catch some of its freedom and spirit without falling into the licentiousness for which it may justly be censured.

REPEAL OF STATUTES. [Statutes, P. C.]

REPRESENTATION. [Descent, P. C.]

REPTON, HUMPHRY, tho celebrated practitioner and writer upon his art, who first assumed professionally the title of Landscape Gardener, was born at Bury St. Edmund's, where his father held the lucrative situation of collector of Excise, May 2nd, 1752. After being placed first at the grammar-school at Bury, and then at that of Norwich, he was sent by his father, who intended to make a man of business of him, to Gorkum in Holland, in the summer of 1764; a suitable place enough for tho future merchant or manufacturer who was to be intent upon thrift—which seems, according to a remark of Repton's own, to have been his father's chief ambition for him—but almost the very worst for the future landscape gardener, Dutch gardening being the very reverse of nature and picturesque landscape. At the age of sixteen he returned to England, and was placed in a merchant's counting-house at Norwich, but all his leisure was devoted to poetry, music, and drawing. At the age of twenty-one he married, and was set up in business as a general merchant by his father, and for a while affairs prospered with him; but after a few years took an unfavourable turn, owing to losses of vessels at sea, and other circumstances in trade; wherefore having lost both his parents, he determined upon following his own inclination. He accordingly settled at Sustead, near Aylsham, in Norfolk, where his sister resided in a house left them by their father. The change was to him a delightful one, and there he passed five years of almost uninterrupted happiness, occupying himself with farming experiments, gardening, and the study of rural scenery. An event however occurred in 1783, which promised to open a widely different career from that in which he afterwards distinguished himself; for in that year his friend and neighbour Mr. Wyndham of Felbrigg was appointed secretary to the Lord-Lieutenant of Ireland, and Repton, feeling that as the opportunity offered he ought exert himself for the sake of an increasing family, agreed to accompany him as his confidential secretary. The flattering expectations thus suddenly raised, were as suddenly blighted; for his patron gave up his post almost immediately; and Repton returned to Sustead and domestic privacy. There however he did not long remain, for, compelled to retrench, he took a small house at Harestreet, Essex, to which ho became so much attached as ever after to reside there. Just at this time (1784) he became acquainted with Mr. Palmer, who introduced the mail-coach system, and whose project he aided not only by his advice and personal exertions, but by advancing a considerable portion of his small remaining capital. Yet though the scheme prospered, Repton received no recompense: on the contrary, he had to put up with pecuniary loss. Thus every successive speculation and enterprise of his seem doomed to prove a failure; yet had it not been so, he might never have been heard of unless it had been as an author, and by such productions as his 'Odd Whims.' Fortunately though easy ho was not indolent, neither was he of a desponding temper, and he resolved to try whether he could not extricate himself from his embarrassments by gratifying his own tastes at the samo time, and accordingly announced to his friends his intention of practising as a 'Landscape Gardener:' the field was open, for Brown had been dead some years [Brown, P. C. S.], and there was no one besides of any note. With what success this last scheme was crowned, needs hardly be said, for business soon began to pour in upon him, and he was consulted by the owners of 'places' in almost every part of the kingdom. The list of his *Red Books* alone—as he called his Reports on the seats whose grounds he was employed to lay out or improve, testifies to the great extent of his professional labours —or rather his professional enjoyments—enhanced by intercourse with polished society, in which his accomplishments and good because unaffectedly amiable manners and address enabled him to sustain a proper part. Nothing proves the real worth of his character more strongly than his not being corrupted by sudden good fortune, or by being lifted into a higher sphere: home and domestic tranquillity were still dearer to him; and few had greater cause to be attached to a domestic circle, whose happiness was marred only by the loss of so many of its members, for out of sixteen children, only seven attained the age of manhood, and only five, together with their mother, survived him, a daughter and four sons. The eldest of them is John Adey Repton, who follows his father's profession, but is better known as a very able architectural antiquary; the fourth, George Stanley, who just before his father's death, married a daughter of Lord Chancellor Eldon, was brought up as an architect.

Among the blessings which fell to Repton's lot, was that of an excellent constitution and uninterrupted good health up to January 29th, 1811, when being upset in his carriage, he received a severe injury in the spine, which rendered him a long while an invalid, and he was some time afterwards attacked with *angina pectoris*, which caused him at intervals great suffering during the remainder of his life, and carried him off quite suddenly as he was entering his breakfast-room on the morning of the 24th March, 1818, apparently in his usual health.

His professional publications consist of 'Sketches and Hints on Landscape Gardening,' 4to., 1795: 'Observation on tho Theory and Practice of Landscape Gardening,' 4to., 1803; 'Inquiry into the changes of Taste in Landscape Gardening,' 8vo., 1806; 'Designs for the Pavilion at Brighton,' folio, 1808; (though these designs are said to have met the approbation of the Prince of Wales, and were, like the building afterwards erected by Nash, in a fancy Oriental style, they were not adopted); and 'Fragments on the Theory, &c. of Landscape Gardening,' 4to., 1816, in which he was assisted by his eldest son. These different publications on his art, which at their original price cost collectively 20*l*. 2*s*. 6*d*., were reprinted in 1840, by the late Mr. Loudon [Loudon, P. C. S.], in a single octavo volume, accompanied with a portrait and memoir of the author from autograph memoranda (which has here been made use of). Though this compressed and economic edition has not the attractions of the larger coloured plates, the same subjects being shown in small woodcuts, it is far more convenient as a volume for perusal and study, and moreover contains several notes and remarks by the editor.

REPUBLICATION. [Will and Testament, P. C.]

RESEDA'CEÆ, a natural order of plants belonging to the class of Exogens. It has a many-parted calyx; the petals unequal, of broad fleshy plates having lacerated appendages at the back; an hypogynous one-sided glandular disk; definite stamens inserted into the disk, the filaments erect, the anthers 2-celled, opening longitudinally; a 3-lobed 1-celled many-seeded sessile ovary, scarcely closed, usually with 3-6 parietal placentæ, sometimes surrounding a free central ovule-bearing body; 3 glandular sessile stigmas; campulitropal or amphitropal ovules; the fruit dry and membranous or succulent, opening at the apex, or apocarpous, with empty carpels surrounding a central placenta, or even hooded and 1-seeded; the seeds several, reniform, with a taper arcuate embryo without albumen, and a radicle next the hilum. The species of this order are soft herbaceous plants, or in a few instances small shrubs with alternate entire or pinnately divided leaves, and minute gland-like stipules. The flowers in racemes or spikes. They are natives of Europe, the adjoining parts of Asia, the basin of the Mediterranean, and the adjacent islands. A few species occur in the north of India, the Cape of Good Hope, and California.

This order embraces the genera Reseda, Ochradenus, Oligomeris, Holopetalum, Astrocarpus, and Caylusea.

None of the species possess very active properties. *Reseda luteola* is the Woold, Woad, or Weld, that is used in dyeing. [Woold, P. C.] *R. odorata* is the common Mignonette. It has lanceolate bluntish entire or trifid leaves, a 6-parted calyx equal in length to the petals, which are finely cleft into many club-shaped divisions, the two lowest simple, the capsules 3-toothed. It is a native of the North of Africa and Egypt, but its delicious fragrance has caused it to be cultivated all over the world. It is naturally a herb, but when trained in the greenhouse it becomes shrubby. This plant is in great demand in the London markets, and is very extensively cultivated. The seeds should be sown in pots or transplanted into pots 4 or 6 plants to a pot 4 inches in diameter. 'To obtain plants for flowering from December to February, a sowing should be made in July, in the open ground, and the plants potted in September. The crop for March, April, and May should be sown in pots not later than the 25th of August; the plants from this sowing will not suffer from exposure to rain whilst they are young; they must however be protected from early frosts like the winter-crop; they are to be thinned in November, leaving not more than 8 or 10 plants in a pot; and at the same time the pots should be sunk 3 or 4 inches in some old tan or coal-ashes and should be covered with a frame, which it is best to place fronting the west, for then the lights may be left open in the evening, to catch the sun whenever it sets clear. The third or spring crop should be sown in pots not later than the 25th of February. These must be placed in a frame on a gentle heat; and as the heat declines, the pots must be let down three or four inches into the dung-bed, which will keep the roots moist, and prevent their leaves turning brown from the heat of the sun in April and May. The plants thus obtained will be in perfection by the end of May and be ready to succeed those raised by the autumnal sowing.' ('Hort. Trans.,' vol. 2.)

The arborescent plant is often called Tree-Mignonette. It may be propagated by seeds or by cuttings, which readily strike root. The young plants should be potted singly, and brought forward by heat. As they grow they should be tied to a stick, and all side shoots should be pinched off. As the plants attain a greater size they should be shifted progressively into larger pots.

R. phyteuma has lanceolate spatulate leaves, the upper ones sometimes a little divided; the calyx 5-parted, spatulate, ciliated, much longer than the petals. It is a native of France, Austria, Italy, Switzerland, and the Levant. This plant is the φύτευμα of Dioscorides, 4. 128.

R. undata, a native of the south of Europe, with pinnatifid leaves and linear-lanceolate segments, trifid petals and 3-4-horned capsules, is the σησαμοειδὲς μέγα of Dioscorides, 4. 150. It grows at the present day on the way-sides in Attica and Corinth.

R. lutea and *R. fruticulosa* are British species as well as *R. luteola*. The first has 6 very unequal petals and 3-cleft or pinnatifid leaves. It grows in waste places in chalky and limestone districts. The second has 5 nearly equal petals, with pinnatifid leaves, and grows in waste sandy places near the sea.

(Babington, *Manual of British Botany*; Don, *Gardener's Dictionary*; Burnett, *Outlines of Botany*; Lindley, *Vegetable Kingdom*.)

RESULTING TRUSTS. [Trust and Trustee, P. C.]

RHAM, WILLIAM LEWIS, was born at Utrecht, in the Netherlands, in 1778; and of this country his father was, we believe, a native, but his mother was of Swiss birth. Mr. Rham came to England in early life. He studied for some time at Edinburgh, with a view to the medical profession, but eventually the church became his destination, and he entered at Trinity College, Cambridge. In 1806, being then in his twenty-eighth year, he took his degree, and his name appears on the Tripos as tenth wrangler. In 1808 Mr. Rham was presented by the dean and chapter of Salisbury to the living of Winkfield, Berkshire; and a few years afterwards the Nassau family presented him to that of Fersfield, in Norfolk. He died unmarried at Winkfield, after a short illness, on the 31st of October, 1843.

The life of Mr. Rham was characterized by active and unremitting usefulness as a parochial clergyman. He was the friend of the poor in the best sense of the term. He looked beyond the wants of the moment, and sought the means to improve and elevate as well as temporarily to benefit the objects of his benevolence. At the Winkfield School of Industry, which, under his fostering care, became a model for all similar institutions in country parishes, the young were taught not only the elements of knowledge, but were instructed in useful arts, and trained to habits of industry. Such were the means by which he endeavoured to promote the best interests of his parishioners.

The school which Mr. Rham founded at Winkfield is thus described by Mr. Tremenheere, in his Report to the Council of Education in March, 1843:—'This school was established in 1835 for 50 boys and 50 girls. The building consists of a house for the master and mistress, two schoolrooms, a workshop, shed, &c. It is surrounded by two acres of garden, to which two more acres have been lately added, to be also cultivated, by the master and the boys, with the various agricultural crops, according to the most approved method and rotations. The industrial work originally projected for the boys was—gardening, the use of carpenters' and joiners' tools, basket and mat making; for the girls, the usual needle-work, washing, ironing, cooking, and the common household employments, under the direction of the mistress. The manual instruction of the boys in the workshop has been hitherto of a limited kind; but the garden presented very satisfactory evidences of their skill and industry. It is cultivated in common, with the exception of small plots about twelve feet square, which belong to the boys, and of the produce of which they keep a debtor and creditor account. The produce of the rest is sold to persons who take it off to market, and the proceeds are carried to the general account of the establishment. The crops were abundant, and more varied than it is usual to see in common gardens. Something was found to fill up every space, and to suit every spot—either one of the ordinary garden crops, or some of the useful herbs, or some kind of plant or flower; and thus a lesson of considerable use to a cottager is early communicated, in the habit of making the most of even the smallest portion of ground, however apparently unpromising. The practical instruction, and the valuable example, of which the pupils here have the benefit in their garden-work, will be greatly extended when the agricultural operations commence in the field just added to the establishment. They will then enjoy the further advantage of pursuing all the details of the most skilful husbandry, under the same good guidance, namely that of the benevolent originator of this institution, the Rev. W. L. Rham, so well known as an accomplished agriculturist. The school will, indeed, from that period be able to offer to the children of the agricultural labourer a course of practical training in garden and farm management of no ordinary excellence.'

But it is as a scientific agriculturist that Mr. Rham's name is most widely known; and, until recently, it was perhaps better known in other countries than in England. His early connection with the Continent, which was kept up in after-life, afforded scope for observation of the husbandry of different countries; and his thorough knowledge of several living languages gave him access to the works of scientific writers on foreign agriculture. In the next place, his chemical studies at Edinburgh, while preparing for the medical profession, were of eminent service to him; and scarcely less so was the proficiency in mathematics which he attained at Cambridge. It may safely be asserted that no other writer on agriculture ever enjoyed in so great a degree such a combination of advantages; and to his knowledge of the chemical and mechanical departments of agriculture there was united a thorough acquaintance with its routine details. We would simply refer to the article Plough, P. C., as an example of this combination of science with practical knowledge. On his farm at Winkfield he engaged in his favourite pursuit, with a practical perception of its details, and a scientific knowledge of its processes, which has probably never before been possessed by one person. Thus, above all other writers of the present day on the subject of agriculture, Mr. Rham was eminently fitted, by his excellent judgment and sound sense, to be useful to the country in the existing state of its husbandry and rural economy, when, probably, we are on the eve of great improvements in every department of these important branches of industry. He was an active member of the council and upon the committees of the Royal Society of Agriculture, from its formation in 1838. A volume entitled 'The Dictionary of the Farm,' which contains his views on all the principal subjects of interest to the agriculturist, has been published by C. Knight and Co. It is compiled, without alteration, from the articles which he wrote in the 'Penny Cyclopædia,' the first article [AFTER-MATH, P. C.] being contributed by him in 1833, and the last [YORKSHIRE AGRICULTURE, P. C.] in 1843, only a few weeks before his death. He was also the author of 'Flemish Husbandry,' a small work written for the 'Farmers' Series of the Library of Useful Knowledge.' This work was founded on a pedestrian tour in Flanders, in which, for many weeks, he walked from farm to farm, enjoying the rough hospitality of an industrious population, speaking their language readily, and entering into their pursuits with the zeal of a skilful and sympathizing friend. The Essay on the Analysis of Soils, for which he obtained the prize offered by the Royal Society of Agriculture, is published in the Society's 'Journal,' which also contains some other valuable contributions from his pen. Not long before his death he had also commenced a series of papers on agriculture and rural economy in the 'Gardeners' Chronicle,' edited by Dr. Lindley.

Mr. Rham's correspondence on agricultural subjects, both in this country and on the Continent, was extensive; and he gave his opinion with the utmost readiness. Nor did he stop here, or remain content with having acquitted himself with extreme urbanity and courtesy, but not unfrequently pressed his hospitality upon those who had consulted him. Great as was the respect paid to his opinions, he gave them without the least dogmatism. In one of his last communications to a valued friend (Joshua Rodwell, Esq., of Alderton Hall, Suffolk), there is a passage at once characteristic of his unassuming disposition and of his deference to humble practical experience, which men who have acquired a scientific knowledge of any art are usually too apt to despise. 'Whatever,' he remarks, 'great chemists may say about the component parts of soils, I am persuaded they can never decide as to the aptitude of any soil to produce a crop till experience has shown it. I believe we have all overlooked some electromagnetic qualities which we have not yet instruments to measure.' It was this reliance upon experience, in connection with a bold but searching investigation of theory, which renders Mr. Rham's writings so well adapted for the present time. In the eagerness for improvement, a writer is best calculated ultimately to benefit his country who unites scientific attainments of a high character with a rational degree of respect for the practice of ages.

RHAMNUS. [ATTICA, P. C.]

RHAPSODY (ῥαψῳδία) is a poem sung by a rhapsodist, and is generally applied to detached parts of the Homeric poems, the Iliad and the Odyssey, which were sung or recited by rhapsodists. But the word rhapsodist properly signifies one who sews or fastens things together; and it was specially applied to those who arranged or are supposed to have arranged the parts of the Homeric poems and of other old poems, so as to make one entire work of them, and who went about from place to place to sing and recite these poems.

RHEOMETER. From the Greek words ῥέω, *flow*, and μέτρον, a *measure*, is an instrument by which the force of an electric, galvanic, or magnetic current may be measured. The word was first proposed by M. Peclet as a synonym for galvanometer; and it has since been employed by Professor Wheatstone in a general sense, together with *Rheoscope*, denoting an instrument by which the existence of an electric, &c. current may be ascertained; and *Rheomotor*, expressing any apparatus, as an electrical or galvanic battery, by which a current of that kind is originated.

The rheometer or galvanometer employed by Mr. Wheatstone is a glass cylinder resting on a stand, and containing within it a magnetized needle, which is suspended from the cover. A graduated circle serves to show the deviations of the needle from the zero of the graduations, and the amount of deviation is read by means of a microscope. For forces or resistances which are considerable, there are placed below the circle numerous coils of fine wire; but for small forces a thick plate or wire making but one coil is used.

From the poles of the battery, or rheomotor, proceed the two conducting wires to the rheometer, one directly, and the other through the intervention of a slender brass-wire wound in numerous coils round two cylinders, one of wood and the other of brass, each about 1½ inch diameter. On the former the wire is coiled in spiral grooves, like those of a screw, so that the several coils are isolated from one another; and the brass cylinder is provided with a handle for the purpose of turning it on its axis, in order to permit more or less of the wire on the wooden cylinder to be uncoiled from it and wound about the other; by which means a variable quantity of the wire, forming part of the *circuit*, may remain on that cylinder; this apparatus is called a *rheostat*.

In employing the instrument, an object whose resistance to the passage of the electric, galvanic, or magnetic fluid is to be ascertained, is placed so as to form part of the circuit, and the point at which the needle in the rheometer stands is to be observed; then, removing the object, and turning the cylinders till such a quantity of wire is coiled on the wooden cylinder as will bring the needle to the same point, that quantity of wire, which can be measured by a scale on the instrument, will serve to indicate the resistance caused by the presence of the object which had been interposed. A copper wire one foot long and 0·71 inch in diameter being taken to denote the unit of resistance.

The Bakerian Lecture for 1843, by Professor Wheatstone, which is published in the 'Philosophical Transactions' for that year, contains a description of the apparatus above mentioned, with an account of the processes for determining the constants of a voltaic circuit.

The advantage of the rheostat, in enabling the operator to keep the needle of a galvanometer at the same point during the continuance of an experiment, will be found to be great when, as in volatyping, electro-gilding, &c., it is necessary to maintain a constant degree of energy in the current.

RHINACANTHUS (from ῥίν, a snout, and ἄκανθα, a thorn), a genus of plants belonging to the natural order Acanthaceæ. It has a regularly 5-parted calyx with small subulate bracts and bractlets: a hypocrateriform 2-lipped corolla, with a long slender tube, the upper lip narrow, the lower trifid, with equal segments; 2 stamens inserted in the throat of the corolla, the anthers 2-celled, awnless, with 1 cell placed above the other almost in a line; a clavate capsule much compressed at the base, with the commissure of the valves in contact and seedless; the upper part 4-seeded, or by abortion 2-seeded; the dissepiment complete, adnate; the seeds ovate, biconvex, augmented with hooks which are concave and obtuse.

R. communis is a native of the continent of India, with opposite stalked broad-lanceolate obtuse leaves, above smooth, below a little downy, entire, from 2 to 4 inches long and from 1 to 2 broad, and a fleshy ring surrounding the base of the ovary. The roots of this plant are boiled in milk, and are reckoned by the natives of India an aphrodisiac. In conjunction with lime-juice and pepper they are used as an external application for ringworm.

(Lindley, *Flora Medica.*)

RHINANTHUS (from ῥίν, a snout, and ἄνθος, a flower), a genus of plants belonging to the natural order Scrophulariaceæ of Jussieu, and the type of the order Rhinanthaceæ of De Candolle. It has a compressed membranous inflated 4-toothed calyx; the superior lip of the corolla galeate, compressed, bidentate at the apex, the lower one spreading, 3-lobed; the anthers bipartite, mutic, villous; the capsule 2-celled, obtuse, compressed; the seeds compressed, marginate, or girded by a membranous wing. The species are annual plants, inhabiting marshes and confined in their geographical distribution to Europe.

R. crista galli, Cockscomb, or common Yellow Rattle, has oblong-lanceolate serrate leaves; the flowers in lax spikes, the calyx glabrous, the lobes of the upper lip of the corolla short, roundish, the bracts ovate inciso-serrate, the seeds with a broad membranous border. This plant has the name of Yellow Rattle from the colour of its flowers, and the rattling noise made by the seeds in the capsule when ripe. On this account the fruits are called rattle-boxes in Ireland. In some parts of England this plant is known by the name of Pennygrass, and in Yorkshire it is called Henpenny, from the seed-vessels resembling in shape and size a silver penny. The term Cockscomb has been applied to this plant from the fringed appearance of the bracts which surround the flowers. The seeds of a species of Rhinanthus were at one time used in infusion for destroying vermin in bedsteads and furniture.

R. major has linear-lanceolate serrate leaves; the flowers in crowded spikes, the calyx glabrous, the lobes of the upper lip of the corolla oblong, the bracts inciso serrate, with an attenuated point, the seeds with a very narrow membranous border. This is the plant of British botanists, but the *R. major* of Koch and Reichenbach has a broad membranous margin to the seed, and the central part of the upper lip of the corolla as prominent as the lateral lobes. This plant is found in meadows and corn-fields in the North of England, and also in Scotland.

Several other species of this genus have been described. Koch, in his 'Flora Germanica,' has five,—*R. minor*, the *R. crista galli* above described, *R. major*, *R. alectorolophus*, *R. angustifolius*, and *R. alpinus*.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

RHI'ZODUS, a genus of fossil fishes from the carboniferous strata of Scotland. (Owen.)

RHO'DEA, a genus of fossil Ferns proposed by Presl. The species belong chiefly to the Coal formation.

RHYNCHOSAU'RUS, a fossil genus of Reptiles. It was found in the new red-sandstone of Grinsill in Warwickshire. (Owen.)

RHYNCO'SPORA, a genus of plants belonging to the natural order Cyperaceæ. It has few-flowered spikelets, 6 or 7 glumes, the lower ones empty or smaller; about 6 bristles; the nut compressed, convex on both sides, crowned with the dilated base of the style. There are two British species; *R. alba*, not uncommon on turfy bogs, and *R. fusca*, a rare species found in the south-west of England and in Ireland.

(Babington, *Manual of British Botany*.)

RIBALTA, FRANCISCO, a distinguished Spanish painter of the school of Valencia, was born at Castellon do la Plana in 1551. When very young he fell in love with his master's daughter, but the father (his name is not mentioned) would not consent to a marriage, on the plea that Ribalta was not sufficiently advanced in his profession. Upon this he determined to go to Rome, and his mistress plighted her faith to him. At Rome he studied the works of Raphael, and particularly Sebastian del Piombo, and, according to Cean Bermudez, those of the Carracci also, but this is an error; none of the Carracci were in Rome before 1600, some years therefore after Ribalta must have left it.

Upon his return to Valencia after an absence of three or four years he immediately repaired to the house of his master, who was absent; but upon an easel in his study was standing an unfinished sketch, which the young painter as rapidly as possible completed in the presence of his still faithful mistress, and immediately retired. The father was much surprised at what he saw, and asked his daughter who had been there, at the same time observing, 'If this were your lover, willingly should you marry him, but not the poor Ribalta.' 'Ribalta himself has done it,' said his daughter, and of course the marriage of the lovers soon followed.

Ribalta soon obtained great reputation. His first public work was the Last Supper, ordered by archbishop Don Juan de Ribera for the grand altar of the college of Corpus Christi, at Valencia. He painted the portrait of a venerable friar of the place Pedro Muñoz as St. Andrew; and as Judas, a shoemaker of the name of Pradas, whose vicinity was a nuisance to him. He died in 1628, and was buried in the church of San Juan del Mercado, in Valencia.

Ribalta's design was correct and vigorous; he was a good anatomist; and his compositions are often grand. In colouring also he was generally good, much resembling Sebastiano and Titian, though occasionally dry; but the works of some of his principal scholars, as Castañed and Bausa, are sometimes attributed to him. His works are or were very numerous in Valencia, and there are several at Castellon de la Plana, and Madrid; and some at San Ildefonso, Toledo, Zaragoza, Andilla, Algemesi, Torrente, Portaceli, Morella, and Carcaxente.

The 'Entombment' by Ribalta, in the cathedral of Valencia, is an excellent work, and there are also many admirable pictures by him in private collections in Valencia, as those of the Conde de Parcent, and the Marques del Rafol. The Corpus Christi College is, according to Mr. Ford, a complete museum of Ribaltas. It was founded by Ribalta's patron, the Archbishop Juan de Ribera, commonly called 'El Santo Ribera.' He was canonized in 1797. Ribalta is to be seen to greatest advantage in the church of this college, which contains some of his greatest works, as 'San Vicente de Ferrer visited on his sick Bed by our Saviour and Saints;' the 'Last Supper,' already mentioned; and a 'Holy Family.' In other parts of the same building are 'Christ in the Garden of Olives;' 'Christ at the Column,' and a saint or *Beata* in a brown habit. There are also some works by Ribalta in the Museo (the former *Carmen*) of Valencia. The pictures of the church of the small hamlet of Andilla are also among the best works of Ribalta. At Segorbe, in the church of San Martin de las Monjas, is also a noble picture by Ribalta of Christ descending into Hades. In the church of his native place Castellon de la Plana there is still a 'Purgatory' by him; other fine works that were in this place have been allowed to perish. The picture of 'Christ bearing his Cross' in Magdalen College, Oxford, of which there is a print by Sherwin, and which is ascribed to Guido, Lodovico Carracci, and to Moralez el Divino, is, according to Mr. Ford, certainly a picture by Ribalta. It is the chapel altar-piece, and was presented to the college by William Freeman, of Hamels, in Hertfordshire; it was originally brought from Spain by the last duke of Ormond from Vigo in 1702.

Juan de Ribalta, an able painter, and of great promise, was the son and pupil of Francisco, but he died in the same year as his father, aged only 31; he was born in 1597. Ribera also, or Spagnoletto, is said to have been the pupil of Ribalta.

(Cean Bermudez, *Diccionario Historico de los mas illustres Profesores, &c.*; Ford, *Handbook for Travellers in Spain, &c.*; *English Connoisseur*; *Oxford Guide*.)

RIBGRASS. [PLANTAGINACEÆ, P.C.]

RICCIO, DOME'NICO, called il Brusasorci, a celebrated Venetian painter, was born at Verona in 1494. He was the pupil of Giolfino, and is supposed also to have studied under Titian, in Venice, where he at least studied his works and those of Giorgione. He is called the Titian of the Veronese painters. His name of Brusa Sorci (rat-burner) was acquired from his father Giacomo Riccio, who invented a rat-trap, and had what he caught in his own house burnt, whence he was commonly called by his neighbours Brusasorci, a name which descended to his children and grandchildren. Among Domenico's first and principal works in Verona were the frescoes of the Palazzo de' Murari, near the Ponte Nuovo, which he decorated exteriorly in chiaroscuro with scenes from the fable of Cupid and Psyche, and the marriage festival of Benacus (the Lago di Garda) with the nymph Charis represented by Garda; he painted numerous nymphs, with Hymen, as he is described by Catullus (Carmen 61-2), and all the characteristics of rural and sylvan life, poetical and real; and also in distinct compartments extensive groups of marine deities, and other corresponding mythic creations, for all of which he received only forty ducats. In the Palazzo Ridolfi he painted the celebrated cavalcade of Clement VII. and Charles V., at Bologna, on the consecration of the emperor, in which he introduced many portraits; these frescoes are still in preservation. Riccio painted also many excellent works in oil, including several large altar-pieces for some of the principal churches in and near Verona, and other works in the ducal palace in Mantua. Venuses and nymphs were also favourite subjects with him; and such pictures frequently occur in picture galleries. He died in 1567.

Felice Riccio, or Brusasorci, his son, was also a distinguished painter; but having studied under Ligozzi at Florence, he painted in a different style from his father: more delicate, but with less power; he was a good portrait painter. He died in 1605, aged 65. His sister Cecilia Brusasorci was also an excellent painter of portraits. Giovanni Battista Brusasorci, another son of Domenico, was painter to one of the German emperors, and died in Germany.

(Ridolfi, *Vite de' Pittori Veneti*, &c.; Dal Pozzo, *Vite de' Pittori Veronesi*; Lanzi, *Storia Pittorica*, &c.)

RICHARDSON, WILLIAM, the son of a parish clergyman in Perthshire, was born in 1743. He was educated for the church in the university of Glasgow, became tutor to the sons of Earl Cathcart, and spent two years with these youths at Eton. Afterwards, when their father became ambassador extraordinary to Russia, he accompanied the family to St. Petersburg, where he acted for four years as the earl's private secretary. In 1773 he was appointed professor of Humanity in the university of Glasgow, and discharged the duties of this office till his death, which took place in 1814. Professor Richardson was a highly popular and successful teacher, and also published several literary works of some merit. He was a contributor to the Mirror and Lounger, and the author of two dramas, of 'Anecdotes of the Russian Empire,' and of a series of periodical essays called 'The

Philanthrope.' He was best known however for a series of Essays on the principal Characters of Shakspere, which appeared in three successive volumes beginning in 1775, and were in 1797 collected into one volume, which became very popular and has been reprinted several times. These essays show considerable critical talent, and some eloquence in writing: their chief fault is the depreciatory spirit in which they treat the great poet, and which has exposed them to severe censure from Mr. Knight and some other recent critics.

RICKMAN, THOMAS, a distinguished writer on Gothic architecture, whose work has become a standard authority in this country, and in whose personal history there is something remarkable; for though neither his education nor his first pursuits in life were calculated to direct his attention to the study of architecture, while the religious tenets in which he was brought up by his parents (those of the Society of Friends) were ill fitted to inspire a taste for that particular branch of the art which he especially cultivated, he not only made it his study, but when he had reached the meridian of life, took up architecture as his profession, and obtained extensive practice.

He was born at Maidenhead June 8th, 1776, and brought up by his father, who was a surgeon and apothecary in that town, to the same profession. He went in 1797 to London, where he became for a while assistant, first to Mr. Stringer, chemist to the royal family, and next to Mr. Atkinson, in Jermyn-street; but disliking the confinement, he changed not his situation only but his vocation also, and entered into the employment of Messrs. Day and Green, extensive grocers, at Saffron Walden. His residence at Saffron-Walden was not, however, of very long continuance, for in compliance with the wishes of his father, who was anxious that he should complete his medical education, he went again to London, and 'walked the hospitals:' after which he returned, in 1801, to his father, who was then settled at Lewes, but did not remain with him above two years, when he repaired again to the metropolis, and engaged himself as clerk to a corn-factor,—a stop likely to lead him further from than bring him at all nearer to his ultimate destination. Nevertheless it proved a stepping-stone to him, so far that he became a partner in the business. In 1808, about the time of the death of his first wife (his cousin Lucy Rickman, to whom he had not been married above a year), he removed to Liverpool, where he made another change, for he took a situation in the counting-house of one of the principal insurance-brokers there. Uncongenial and unpromising as it apparently was in itself, this new situation proved the making of his fortune and fame; for as the attention to business it required occupied him only a few hours in the day, he devoted his leisure to the study of architecture. But here there is evidently a gap in this most important and interesting phase of his history, for we are left altogether in uncertainty as to the influence or impulse which directed him to a pursuit so remote from his habits and employments.

However, having once taken up the study he pursued it zealously; examined ancient buildings with diligence—in a word, educated himself; and perhaps saw all the clearer because he was not tramelled in his inquiries by the prejudices and conventionalities of a professional education. He was also industrious with his pencil, and carefully noted all those distinctions in the different modes of the pointed style on which he founded his valuable system of classification for it. About this period he married his second wife, Christiana Horner, sister to Thomas Horner, the artist who painted the large panorama of London, in the 'Coloseum,' in the Regent's-Park.

On the grant of a million for additional churches being made by Parliament, Rickman, who had previously made attempts at original design, became a competitor, and a design sent in by him being accepted, he determined to establish himself as an architect: he quitted Liverpool and removed to Birmingham, as being in his opinion a likelier situation for obtaining practice from various quarters. Having no practical experience at that time himself, and being unacquainted with the business routine of the profession, he engaged Mr. Henry Hutchinson as his managing assistant in all matters of business, and after his death (1830) entered into partnership with Mr. Hussey.

In 1835 he married his third wife, Elizabeth Miller, of Edinburgh, by whom he had a son, and who survived him. Some years previous to his decease he had had an apoplectic tack, but his naturally strong constitution prevailed against its effects, and he continued to exercise his profession up to the time of his death, which happened March 4th, 1841.

Had Rickman been known only as a writer, his 'Attempt to discriminate the Styles of Architecture in England' (originally written for a publication called 'Smith's Panorama of Science and Art,' but greatly extended as a separate work, and improved in each fresh edition), it would have obtained for him celebrity, for it has become a standard book, and one almost indispensable to the student. Nevertheless it is omitted among those on the subject of Gothic architecture, of which a list is given in Gwilt's Encyclopædia. The work itself, however, recommended him to all lovers of Gothic architecture, opened the road to extensive practice, and procured him patronage in very influential quarters, where as a sectarian he could hardly look for direct countenance and employment. It is to be observed however that 'latterly'—by which it no doubt is to be understood when his profession brought him into contact with the clergy—he withdrew from the Society of Friends. In all probability he had already done so when he was employed at Cambridge and at Rose Castle, the palace of the Bishop of Carlisle, which was restored by him. At Cambridge he executed the new court and buildings (begun in 1827) of St. John's College. Perhaps hardly any individual in the profession was ever employed upon so many churches as Rickman, and a list of them and of other buildings by him is given in the 4th edition of his book; but, long as it is, that list is incomplete, because it does not come down later than 1835. It is also to be regretted that it is a mere list, without so much as any dates. This it is to be hoped will still be done, and the list itself completed in the next edition of the work, which we understand has been long in preparation by his surviving partner, Mr. Hussey. Perhaps a full memoir of Rickman will then be given; and one very desirable improvement it would be were a descriptive catalogue of his buildings to be illustrated by wood-cuts of them—if not of all, of the best among them.

RIDOLFI. [VENETIAN SCHOOL, P. C.]

RIGIDITY OF ROPES. In estimating the powers of machines, it is frequently necessary to take into consideration the effects arising from the rigidity or stiffness of the ropes which pass over the pulleys or the axles of the wheels; and, in order to understand how this condition affects the relation between the moving power and the resistance, let it be observed that when a stiff rope is bent over the upper part of a wheel or pulley in a vertical plane, for example, the weights or powers applied at its extremities may not be sufficient to draw the descending portions into the positions of two vertical lines. Now, if one of the parts of the rope should take such a direction that a vertical line drawn through the weight attached to that part, cuts the horizontal diameter of the wheel or pulley at a point between the centre and one extremity of the diameter; and if, at the same time, the other part should take such a direction that a vertical line drawn through the attached weight cuts the horizontal diameter at a point beyond the extremity of the latter, the distances of these vertical lines from the extremities of the diameter being represented by x and x' respectively, the corresponding weights by W and W′ and the radius of the wheel by R; the conditions of equilibrium instead of being $W = W'$ will be

$$W\,(R-x) = W'\,(R+x')$$

But, if W be the weight which by descending raises up the other, the value of x is generally so small that it may be disregarded, so that we have, in the case of equilibrium,

$$WR = W'(R+x') \text{ or } (W-W')R = W'x',$$

$$\text{or again, } W - W' = W'\frac{x'}{R};$$

that is, in order to put the system in a state of equilibrium, the excess of W above W′ should be equal to $W'\frac{x'}{R}$.

The formula given by Coulomb to express the force necessary for overcoming the rigidity of a rope, or the equivalent of $W'\frac{x'}{R}$, is

$$\frac{r^m}{R}\,(a+bW');$$

r being the semi-diameter of the rope, a the force arising from the warping or twisting of the rope, and b that which depends on the tension arising from the weight W; the values of m, a and b may be determined by experiments made with cords of different diameters; and thus x' may be found. M. Coulomb ascertained that for slender string, $m=1$, and that for stiff cordage the value of m varied from 1·5 to 2; also, from some experiments made with ropes consisting of 30 threads and $2\frac{1}{2}$ inches in circumference, he found that the weights requisite to overcome the rigidity, when the ropes passed over a pulley four inches diameter, and were strained by weights equal to 25 lbs., 125 lbs., and 425 lbs., were 5 lbs., $8\frac{1}{2}$ lbs., and 23 lbs. respectively.

Unfortunately ropes of equal dimensions differ much in rigidity, so that little dependence can be placed on the results of general formulæ in estimating its value. White ropes when wet are more stiff than those which are dry, and the rigidity of ropes is greatly increased by tarring them. In general the weights necessary to overcome the resistance of tarred ropes is proportional to the number of the threads of which they are composed.

RINCON, ANTONIO DEL, court painter to Ferdinand and Isabella, and the first good Spanish painter, was born in Guadalaxara in the middle of the fifteenth century, or probably as early as 1446. From the largeness of his style compared with the generally then prevailing Gothic design, not only in Spain but in the greater part of Italy, he is supposed to have studied in Florence, and probably with Andrea del Castagno, or Domenico Ghirlandajo. Most of Rincon's works have already perished, but there is still an altar-piece, consisting of seventeen pictures from the life of the Virgin by him in the church of Robledo de Chavela, on the road from Madrid to Avila, near the Escorial, which display many excellent qualities of art. In 1483 he executed some works in the old sacristy of the cathedral of Toledo; he was employed by Ferdinand and Isabella in several of the royal palaces of Spain, but both pictures and palaces have long since perished by fire, and otherwise. Rincon was decorated with the order of Santiago; he died at Seville in 1500. Antonio's son, Fernando del Rincon, was a good fresco painter.

(Cean Bermudez, *Diccionario Historico*, &c.)

RIZI, DON FRANCISCO, a distinguished Spanish painter, was born at Madrid in 1608. He was the pupil of Vincenzo Carduccio, and had an extraordinary readiness of invention and execution, but was at the same time, as is usual in such cases, superficial and incorrect: still his readiness to design and facility to execute ensured him a brilliant career. It was not till 1656, however, that he was appointed principal painter to Philip IV.; and he held the same place under Charles II., who gave him the additional place of deputy keeper of the royal keys. He was appointed in 1653 painter to the cathedral of Toledo, a post often in Spain more important than that of painter to the king, for he has the charge of all existing works in the cathedral, and generally the execution of all new works undertaken in his time, which in Spanish cathedrals were at one time numerous and important. Francisco Rizi is, however, one of those painters to whom the decline of painting in Spain is attributed, through the mere superficial attractions of his works; and he is said also, by his capricious decorations of the theatre of Buenretiro, to have done equal injury to the architectural taste of the period. Rizi's last work was a sketch for the great altar-piece of the *Retablo de la Santa Forma* in the Sacristy of the Escorial, which Charles II. ordered for the veil of the magnificent tabernacle and altar, which Rizi had also assisted in making, to contain the Host (La Santa Forma). The subject was the ceremony of the Collocation of the Host by Charles II. in 1684; but Rizi died the following year at the Escorial, having only executed the sketch; the picture was painted by Coello from a sketch of his own, and it is one of the finest pictures in Spain. [Coello, Claudio, P. C. S.]

This Host, or Santa Forma Incorrupta, is the miraculous wafer which bled at Gorkum in 1525 when trampled on by the followers of Zwingli. Rudolf II., Emperor of Germany, gave it to Philip II. of Spain, whither it was transported in 1592, and in 1684 Charles II. constructed the present gorgeous altar and tabernacle for its reception, and the present altarpiece is the ceremony of its collocation. The altar is inscribed—'En magni operis miraculum, intra miraculum mundi, coeli miraculum consecratum.' When the *Forma* is exhibited for adoration, the picture, which forms a veil, is let down, and is accordingly much injured. The French, under La Houssaye, who pillaged the Escorial in 1808, carried off all the gold and silver of this altar: the monks hid the *wafer* in a cellar, and it was restored with great pomp by Ferdinand VII. in 1814.

The pictures, both frescoes and in oil by Rizi, are very numerous; there are several in the Museo of the Prado at Madrid, and many in the churches of Madrid and Toledo, especially in the cathedral of Toledo. Fray Juan Rizi, Francisco's elder brother, born at Madrid in 1595, was also an eminent painter. His principal works are in the Benedictine Monastery of San Martin at Madrid. His design was more correct than his brother's, and his pictures are distinguished for force of light and shade. He retired to Rome and joined the Benedictines of Monte Casino. He was, while in Italy, made an archbishop, in 1675, by the pope Clement X., but he died in the same year at Monte Casino before entering upon the duties of his office.

(Cean Bermudez, *Diccionario Historico*, &c.; Ford, *Guide for Travellers in Spain*, &c.)

ROADS. In Scotland the public highways used for purposes of general transit throughout the country, and suited for the use of vehicles, are under three separate kinds of management. The country in general, with the exception of some Highland districts, is penetrated by turnpike-roads managed by district trusts in terms of local statutes. These are interpreted along with the Act 1 & 2 Wm. IV. c. 43, for the general regulation of turnpike-roads. According to returns of the rents of the various bars, 'the smallness of the sum at which tolls are occasionally farmed is conspicuous. There are some instances where the rent does not exceed 10*l.* Thirty-six bars bear to have been let for sums not exceeding 20*l.* each, and the number let at sums between 20*l.* and 100*l.* is 338.' ('Local Taxes of the United Kingdom,' published by direction of the Poor Law Commissioners, p. 203.) It is obvious that in such a system the rent of the bars, which is the sum available for expenditure on the roads, must be small in proportion to the sum paid by the public, as the lessee who pays 10*l.* or 20*l.* a year must collect an additional sum sufficient for his own support. The highways throughout the country, which are neither turnpikes nor part of the system to be presently noticed, are called 'commutation' or 'statute-labour' roads. They were to a comparatively late period kept up by an allotment of labour on the individual householders and other persons within their respective districts. The liabilities of the individuals came, especially with reference to the richer classes, to be commuted into a proportional annual tax; and from this circumstance the highways so supported are called 'commutation roads.' The management of these roads is settled by local Acts referring to the several counties. From various reports made to parliament, it appears that the counties are divided into small districts, generally corresponding with the parochial division, and that the sums collected throughout the counties are distributed among these districts, and subjected to management and disbursement by petty local boards, more apt to consider the convenience of the roads in reference to their own property and habitations than to consult the general advantage of the public. A third system of roads is under commissioners appointed in terms of statute (59 Geo. III. c. 135), called the Commissioners of Highland Roads and Bridges. A fourth of the expense of this system of transit is paid from the exchequer, and the other three-fourths are assessed on the proprietors of land in the several Highland counties. The commissioners make an annual report to parliament. By the 4 Geo. IV. c. 56, provision was made for the landed proprietors and the commissioners of supply of any of the counties, agreeing to relieve the parliamentary commissioners of the burden of any of these Highland roads, and supporting them by the produce of tolls.

The law as to footpaths and other roads which do not belong to any of the above three systems, is not in a very clear state in Scotland. The right of transit in such cases is founded on the Roman system of servitudes (servitutes); and even where the public enjoy it, it generally rests on the title of the occupants of some districts of land having a right of pathway through some adjoining place. Sometimes the right is of a purely private character, and is confined to the proprietor or tenant of some tenement. At other times it is in the possession of a community, as a village or parish; and in such a case it is not lawful to stop any person who may use the path, on the ground that he is not a member of the privileged community. Such paths are virtually public; but there is no such principle applicable to them as that which stamps the publicity of a highway in England by rendering the parish liable to repair it.

ROASTING is that culinary process by which meat is brought from a raw to a cooked state more directly by the action of fire than by any other means except that of *broiling*.

By the latter, the heat is applied immediately and suddenly to the surface, by which it is hardened, so that the juices of the meat are greatly retained, evaporation being thereby prevented; while by the former the heat is applied gradually, the watery portion is evaporated, as well as the fat melted out to a considerable extent, till the progressive browning and hardening of the surface prevent the further escape of the juices. The loss of weight in roasting meat is much greater than by boiling: 'By this latter process, mutton loses one-fifth, and beef one-fourth; but by roasting, these meats lose about one-third of their weight. In roasting, the loss arises from the melting out of the fat, and the evaporation of the water; but the nutritious matter remains condensed in the cooked solid; whereas, in boiling the gelatine is partly abstracted. Roasted are therefore more nutritive than boiled meats.' (Paris *On Diet.*) The digestibility is also increased, especially in young meats, which are deficient in osmazome, to which the sapidity is mainly owing, and which during boiling passes into the water employed, while in roasting it is powerfully developed and almost entirely retained. 'Young and viscid food, therefore, such as veal, chickens, &c., are more wholesome when roasted than when boiled, and are more easily digested.' The best and most tender meat may, however, be rendered hard and indigestible by a careless or ignorant cook. 'Everybody knows the advantage of *slow boiling*—*slow roasting* is equally important,' See Dr. Kitchener's Cook's Oracle, in which the most sensible and racy instructions on this head are given.

The digestibility is increased by the meat being well done, rather than under-done; 'for though in this latter state it may contain most nutriment, yet it will be less digestible on account of the density of its texture.' This is of importance to remember when it is intended for the diet of convalescents, for whom broiled and roast meats are preferable to boiled.

ROATAN, or Rattan, is an island in the Caribbean Sea, opposite the coast of Honduras, one of the states of Central America. It lies between 10° 5′ and 10° 10′ N. lat., and between 86° 5′ and 86° 25′ W. long., and extends from east-north-east to west-south-west about twenty miles, or somewhat more; the width in no part exceeds five miles, which is about its breadth for the greater part of its extent. The area hardly exceeds 100 square miles. This island is one mass of rocks, but covered with a deep soil, which, united to a moist and warm climate, produces an unusual activity of vegetation. It is overgrown with high trees, except at the western end, where there are some savannahs, on which formerly mules and other cattle were raised. The highest part of the rock is 800 feet above the sea-level. The woods abound in deer, wild hogs, gibeonites, pigeons, parrots, and other birds, many of which afford excellent food. The whole coast swarms with fish and turtle. On the southern shores are three small harbours, Port Royal, Dixon's Cove, and Cozen's Cove. This island was discovered by Columbus on his fourth voyage, in 1502. The English formed a settlement on it in 1742, when they had numerous settlements on the Mosquito Shore, but it was abandoned in 1783, when the English withdrew their garrisons from the Mosquito Shore. In 1794, when the Caribbees on the Island of St. Vincent had rebelled against the English and were compelled to submit, nearly all the prisoners with their families were transported to Roatan. But they soon abandoned the island, and passed over to the continent of America, where they settled near Truxillo, in which town their descendants still form the bulk of the population. When Orlando Roberts visited Roatan (1822), it was uninhabited. But it appears that more recently some families have again settled there, under the protection of the government of Belize, especially for the purpose of fishing and taking turtles.

(Henderson, *Account of the British Settlement of Honduras*, &c.; Orlando Roberts, *Narrative of Voyages and Excursions on the East Coast and in the Interior of Central America.*)

ROEBUCK, JOHN, M.D., the son of a Sheffield manufacturer, was born in 1718, received a liberal education at Northampton under Dr. Doddridge, and subsequently in the university of Leyden, and settled in Birmingham as a physician. Pursuing an early taste for chemistry, he introduced some improvements in the processes of refining gold and silver, and established, in connection with Mr. Samuel Garbet, an extensive refinery and chemical manufactory at Birmingham. He there effected such improvements in the manufacture of sulphuric acid (formerly called vitriolic acid, or oil of vitriol), by the use of leaden instead of glass vessels, and by other modifications of the process, as enabled him to reduce its price from sixteen-pence to four-pence per lb., and thus to render it available for many new and important purposes in connection with manufactures; and, in conjunction with Garbet, he established, in 1749, vitriol-works at Prestonpans for the purpose of bringing these improvements into practice, thereby rendering a great service to our rising manufactures, and securing to himself and his partner a handsome return. He is said to have tried bleaching with sulphuric acid, but the subsequent introduction of this valuable process does not appear to be traceable to his experiments. Abandoning his medical practice, Roebuck henceforward resided chiefly in Scotland, where he perfected improved methods of smelting and manufacturing iron with pit-coal instead of charcoal, and founded the great iron-works at Carron [CARRON, P. C., p. 319], for which he chiefly designed the furnaces and machinery, calling in the aid of Smeaton, and subsequently of Watt. The first furnace at this great establishment, the formation of which constitutes an era in the history of British manufactures, was blown on the 1st of January, 1760. Unfortunately for himself, Roebuck subsequently became the lessee of extensive coal and salt-works at Borrowstounness, belonging to the Duke of Hamilton. For the carrying on of these works, on which he employed nearly a thousand persons, he was obliged to withdraw his capital successively from his other undertakings, and he nevertheless became so involved as to derive only a bare subsistence from the collieries, although his improved modes of working were highly beneficial to the country. While engaged in this speculation he became connected, as stated under WATT, P. C., p. 138, with some of the early experiments of the author of the modern steam-engine, in the first patent for which he had a share. He died on the 17th of July, 1794. In a copious memoir in the fourth volume of the 'Transactions of the Royal Society of Edinburgh,' of which he was a fellow, he is stated to have been the author of a few papers read before that and the Royal Society of London, and to have published two political pamphlets.

ROE'LAS, JUAN DE LAS, one of the most distinguished of the Spanish painters, commonly known among Andalucian artists as el Clerigo Roelas, was born at Seville, of a distinguished family, about the years 1558 and 1560: his father, Pedro de las Ruélas, was a Spanish admiral, and died in 1566. Roelas is styled in documents and in books 'el licenciado Juan,' which signifies, probably, merely that he was a graduate of the University of Seville. Little is known about his education: he is supposed to have studied in Italy, and, from his style, with some of the scholars of Titian in Venice. In 1603 he painted four pictures for the college of Olivares. From 1607 until 1624, he lived chiefly at Seville and Madrid; and in 1616, after the death of F. Castello, he was a competitor for the place of cabinet painter to the king, Philip III.; notwithstanding the 'many years' service of Roelas's father,' however, Bartolomé Gonzalez succeeded Castello. Roélas settled in Olivares in 1624, when he was appointed one of the canons of the college, but he died there in the following year, April 23rd, 1625. Francisco Zurbaran was the scholar of Roélas.

The works of Roélas are very numerous in Seville; and there are still many in the College of Olivares, and there are some at Madrid. His master-piece is the death or 'el Transito' of San Isidoro, in the church of that saint at Seville; this is a large majestic composition, in two compartments, similar to the communion of St. Jerome by Domenichino, and other Italian pictures, but on a larger scale. In the lower part is the archbishop in a church in the attitude of prayer and about to die, supported and surrounded by his numerous clergy, among which are some magnificent heads; in the upper part of the picture is our Saviour on his throne, with the Madonna by his side, and surrounded by angels; the attention of all is directed to the dying saint. This picture, it appears, has never been engraved; indeed, very few good Spanish pictures have been engraved, and it is owing to this circumstance that the great painters of Spain are so little known out of their own provinces. One of his best works also is the Sant Iago, in the Capilla de Santiago, in the Cathedral of Seville: the saint is riding over Moors; it was painted in 1609: Bermudez speaks of it as full of fire, majesty, and decorum. According to Mr. Ford (*Handbook of Spain*), it is surpassed by the picture of the Conception, by Roélas, in the academy; and by three in the chapel of the University of Seville—a Holy Family, with Jesuits; a Nativity; and an Adoration. 'No one,' says this writer, 'ever painted the sleek grimalkin Jesuit like Roélas.' Pacheco, who was censor of pictures in Seville [PACHECO, P. C. S.], reproached Roélas with want of decorum in a picture, in the Merced Calzada, of St. Anne teaching the Virgin to read, for representing some sweetmeats and some articles of common domestic life upon a table in the picture; and also for painting a sheet, intended to wrap the infant Saviour in, who is naked, in the picture of the Nativity, in the chapel of the university.

Roélas is compared with Tintoretto and the Carracci; he is the best of the Andalucian painters in design and composition, and displays frequently a grandeur of form and majesty of character which belong only to the greatest masters: in colouring also he may be compared with the Venetians. His last picture is apparently the Nativity, at Olivares. Palomino's account of this painter is almost wholly incorrect; he calls him Doctor Pablo de las Roélas.

(Cean Bermudez, *Diccionario Historico*, &c.)

ROEMERIA (named after Dr. John James Römer, professor of botany at Landshut; he was author of several botanical works, and died in 1820), a genus of plants belonging to the natural order Papaveraceæ. It has 4 petals, numerous stamens, 2-4 sessile stigmas, an elongated 2-4-valved 1-celled capsule with distinct placentas. The species are annual herbs yielding a yellow juice, with violet flowers.

R. hybrida, Hybrid Roemeria, has a 3-valved erect pod with a few rigid leaves at its extremity. This plant is a native of Europe and the north of Africa, in cultivated fields and vineyards, especially on the coasts of the Mediterranean. It is also found in England in chalky corn-fields in Cambridgeshire and Norfolk. Although now having the appearance of a native, this plant has been probably introduced into this country. Two other species, *R. refracta* and *R. bivalvis*, have been described, the first a native of Tauria, the second of Syria.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

ROMAN ARCHITECTURE. [CIVIL ARCHITECTURE, P. C.]

ROMAN CATHOLICS AND JEWS.* An act was passed on the 18th August, 1846, 9 & 10 Vict. c. 59, intituled 'An Act to relieve Her Majesty's Subjects from certain Penalties and Disabilities in regard to Religious Opinions.'

This act repeals the statutes or ordinances and the several acts herein-after mentioned, or so much and such parts of any of the said acts as are herein-after specified, that is to say:—

The statute or ordinance of the fifty-fourth and fifty-fifth years of the reign of King Henry III., and the statute or ordinance commonly called Statutum (de) Judæismo. [The effect of the repeal of these statutes may be understood by referring to the article JEWS, P. C. The Statutum de Judæismo was made in the third year of Edward I.]

Also so much of an act passed in the fifth and sixth years of the reign of King Edward VI., c. 1, intituled 'An Act for the Uniformity of Service and Administration of Sacraments throughout the Realm,' as enacts 'that from and after the feast of All Saints next coming all and every person and persons inhabiting within this realm, or any other the king's majesty's dominions, shall diligently and faithfully, having no lawful or reasonable excuse to be absent, endeavour themselves to resort to their parish church or chapel accustomed, or, upon reasonable let thereof, to some usual place where common prayer and such service of God shall be used in such time of let, upon every Sunday, and other days ordained and used to be kept as holy days, and then and there to abide orderly and soberly during the time of common prayer, preachings, or other service of God there to be used and ministered, upon pain of punishment by the censures of the church,' so far as the same affects persons dissenting from the worship or doctrines of the United Church of England and Ireland, and usually attending some place of worship other than the Established Church: provided always, that no pecuniary penalty shall be imposed upon any person by reason of his so absenting himself as aforesaid. [Members of the United Church of England and Ireland are still liable to the censures of the church, if they do not attend the services; those who dissent from the church are exempt from these censures if they usually attend some other place of worship. Members of the United Church of England and Ireland are however protected by this act against pecuniary penalties for non-attendance at church.]

Also so much of the said act as enacts, 'that if any manner of person or persons inhabiting and being within this realm, or any other the king's majesty's dominions, shall, after the said feast of All Saints, willingly and wittingly hear and be present at any other manner or form of common prayer, of administration of the sacraments, of making of ministers in the churches, or of any other rites contained in the book annexed to this act, than is mentioned and set forth in the said book, or that is contrary to the form of sundry provisions and exceptions contained in the aforesaid former statute, and shall be thereof convicted according to the laws of this realm, before the justices of assize, justices of oyer and determiner, justices of peace in their sessions, or any of them, by the verdict of twelve men, or by his or their own confession, or otherwise, shall, for the first offence suffer imprisonment for six months, without bail or mainprize; and for the second offence, being likewise convicted as is abovesaid, imprisonment for one whole year; and for the third offence, in like manner, imprisonment during his or their lives.'

Also so much of the said act as enacts, 'that for the more knowledge to be given hereof, and better observation of this law, all and singular curates shall, upon one Sunday every quarter of the year, during one whole year next following the foresaid feast of All Saints next coming, read this present act in the church at the time of the most assembly, and likewise once in every year following, at the same time declaring unto the people, by the authority of the Scripture, how the mercy and goodness of God hath in all ages been shown to his people in their necessities and extremities, by means of hearty and faithful prayers made to Almighty God, especially where people be gathered together with one faith and mind to offer up their hearts by prayer as the best sacrifices that Christian men can yield.'

Also so much of any act or acts of the parliament of Ireland as may have extended to Ireland the provisions of the said act of the fifth and sixth years of the reign of King Edward the Sixth, so far as the same is hereby repealed.

Also so much of an act passed in the first year of the reign of Queen Elizabeth (1 Eliz. c. 1), intituled 'An Act to restore to the Crown the ancient Jurisdiction over the Estate Ecclesiastical and Spiritual, and abolishing all Foreign Powers repugnant to the same,' and of an act of the Parliament of Ireland passed in the second year of the same queen's reign, (2 Eliz. c. 1, [I.]) intituled 'An Act restoring to the Crown the ancient Jurisdiction of the State Ecclesiasticall and Spirituall, and abolishing all Forreinne Power repugnant to the same,' as makes it punishable to affirm, hold, stand with, set forth, maintain, or defend, as therein is mentioned, the authority, pre-eminence, power, or jurisdiction, spiritual or ecclesiastical, of any foreign prince, prelate, person, state, or potentate theretofore claimed, used, or usurped within this realm, or any dominion or country being within or under the power, dominion, or obeisance of her highness, or to put in ure or execute anything for the extolling, advancement, setting forth, maintenance, or defence of any such pretended or usurped jurisdiction, power, pre-eminence, and authority, or any part thereof, or to abet, aid, procure, or counsel any person so offending: provided always, and be it declared, that nothing in this enactment contained shall authorize or render it lawful for any person or persons to affirm, hold, stand with, set forth, maintain, or defend any such foreign power, pre-eminence, jurisdiction, or authority; nor shall the same extend further than to the repeal of the particular penalties and punishments therein referred to, but in all other respects the law shall continue the same as if this enactment had not been made: provided further, that if any person in holy orders according to the rites and ceremonies of the United Church of England and Ireland shall affirm, hold, stand with, set forth, maintain, or defend any such foreign power, pre-eminence, jurisdiction, or authority, such person shall be incapable of holding any ecclesiastical promotion, and, if in possession of any such promotion, may be deprived thereof by due course of law, in the same manner as for any other cause of deprivation.

Also so much of another act passed in the first year of the same queen's reign (1 Eliz. c. 2) intituled 'An Act for the Uniformity of Common Prayer and Service in the Church, and Administration of the Sacraments,' and of another act of the parliament of Ireland passed in the second year of the same queen's reign (2 Eliz. c. 2 [I.]), intituled 'An Act for the Uniformity of Common Prayer and Service in the Church, and the Administration of the Sacraments' as relates to a person's resorting to his parish church or chapel accustomed, or, upon reasonable let thereof, to some usual place where

* This act was passed too late to be noticed under the title of RELIGIOUS OPINIONS, and therefore it has been placed under this head in order that a notice of it might be given.

common prayer and such service of God as in such acts are mentioned are used in such time of let, upon Sundays and other days ordained and used to be kept as holy days, and to his then and there abiding orderly and soberly during the time of the common prayer, preaching, or other service of God there used and ministered: [The penalties from which persons are hereby relieved will appear by referring to LAW, CRIMINAL, P. C. S., p. 179; RECUSANTS, P. C.]

Also an act passed in the fifth year of the same queen's reign (5 Eliz. c. 1), intituled 'An Act for the Assurance of the Queen's Royal Power over all Estates and Subjects within Her Dominions.'

Also an act passed in the thirteenth year of the same queen's reign (13 Eliz. c. 2), intituled 'An Act against the bringing in and putting in execution of Bulls, Writings, or Instruments, and other superstitious Things from the See of Rome,' so far only as the same imposes the penalties or punishments therein mentioned; but it is hereby declared that nothing in this enactment contained shall authorize or render it lawful for any person or persons to import, bring in, or put in execution within this realm any such bulls, writings, or instruments, and that in all respects, save as to the said penalties or punishments, the law shall continue the same as if this enactment had not been made.

Also an act passed in the twenty-ninth year of the same queen's reign (29 Eliz. c. 6), intituled 'An Act for the more speedy and due Execution of certain Branches of the Statute made in the Twenty-third Year of the Queen's Majesty's Reign, intituled "An Act to retain the Queen's Majesty's Subjects in their due Obedience."' [LAW, CRIMINAL, P. C. S., p. 179.]

Also an act passed in the first year of the reign of King James the First (1 Jac. I. c. 4), intituled 'An Act for the due Execution of the Statutes against Jesuits, Seminary Priests, Recusants,' &c. [PARENT AND CHILD, P. C.]

Also so much of an act passed in the third year of the reign of the said King James the First (3 Jac. I. c. 1, § 2 in part), intituled 'An Act for a public Thanksgiving to Almighty God every Year on the Fifth Day of November,' as enacts 'that all and every person and persons inhabiting this realm of England and the dominions of the same shall always upon that day diligently and faithfully resort to the parish church or chapel accustomed, or to some usual church or chapel where the said morning prayer, preaching, or other service of God shall be used, and then and there to abide orderly and soberly during the time of the said prayers, preaching, or other service of God there to be used and ministered.'

Also an act passed in the said third year of the said King James's reign (3 Jac. I. c. 4), intituled 'An act for the better discovering and repressing of Popish Recusants.' [LAW, CRIMINAL, P. C. S., p. 179.]

Also an act passed in the seventh year of the same king's reign (7 Jac. I. c. 6), intituled 'An Act for administering the Oath of Allegiance, and Reformation of married Women Recusants.'

Also so much of an act passed in the thirteenth and fourteenth years of the reign of King Charles the Second (13 & 14 Car. II. c. 4, § 11), intituled 'An Act for the Uniformity of Public Prayers, and Administration of Sacraments, and other Rites and Ceremonies, and for establishing the Form of making, ordaining, and consecrating Bishops, Priests, and Deacons in the Church of England,' as makes any schoolmaster or other person instructing or teaching youth in any private house or family as a tutor or schoolmaster punishable for instructing or teaching any youth as a tutor or schoolmaster before licence obtained from his respective archbishop, bishop, or ordinary of the diocese, according to the laws and statutes of this realm, and before such subscription and acknowledgment made as in the said act is mentioned.

Also so much of the last-mentioned act whereby any act or part of any act herein-before repealed has been confirmed or kept in force. [LAW, CRIMINAL, P. C. S., p. 179.] [This statute against teaching in a private house or family has long since fallen into disuse, but the formal repeal of it is an admission of the freedom of teaching. There still remains the 77th canon of the Church [CONSTITUTIONS AND CANONS, ECCLESIASTICAL, P. C. S.], which goes further than the statute of Charles II., but this canon may be safely neglected by any man who shall choose to teach in 'public school or private house.' The canon forbids only men from teaching without licence or subscription. At that time of day women probably did not teach.]

And also so much of any act or acts of parliament whereby the said parts of the said act of the thirteenth and fourteenth years of the reign of King Charles the Second herein-before repealed have been confirmed or incorporated in any other act or acts of parliament.

Also so much of an act of the parliament of Ireland passed in the seventeenth and eighteenth years of the reign of the said King Charles (17 & 18 Car. II. c. 6, § 6, [I.]), as requires that schoolmasters or other persons instructing or teaching youth in private houses or families as tutors or schoolmasters should take the oath of allegiance and supremacy, and as makes such schoolmasters or other persons punishable for so instructing or teaching youth before licence obtained from their respective archbishop, bishop, or ordinary of the diocese, and before such subscription and acknowledgment made as in the said act is mentioned.

Also so much of an act passed in the thirtieth year of the reign of the said King Charles (30 Car. II. st. 2, § 5 in part), intituled 'An Act for the more effectual preserving the King's Person and Government by disabling Papists from sitting in either House of Parliament,' as enacts that 'every person now or hereafter convicted of Popish recusancy who hereafter shall, at any time after the said first day of December, come advisedly into or remain in the presence of the king's majesty or queen's majesty, or shall come into the court or house where they or any of them reside, as well during the reign of his present majesty (whose life God long preserve) as during the reigns of any of his royal successors, kings or queens of England, shall incur and suffer all the pains, penalties, forfeitures, and disabilities in this act mentioned or contained.'

Also an act of the parliament of Scotland passed in the eighth and ninth session of the first parliament of King William the Third (8 & 9 W. III. c. 3, S.), intituled 'An Act for preventing the growth of Popery,' and all laws, statutes, and acts of parliament revived, ratified, and perpetually confirmed by the said act of King William's first parliament, except as to the form of the formula in such last-mentioned act contained.

Also an act passed in the eleventh and twelfth years of the reign of the said King William the Third (11 & 12 W. III. c. 4), intituled 'An Act for further preventing the growth of Popery:' [LAW, CRIMINAL, P. C. S., p. 179; PARENT AND CHILD, P. C.]

Also an act passed in the first year of the reign of Queen Anne (1 Anne, st. 1, c. 30), intituled 'An Act to oblige Jews to maintain and provide for their Protestant children:

[This statute empowered the Lord Chancellor, on complaint being made to him, to order a Jewish parent to allow his Protestant children a maintenance suitable to the fortune of the parent. [PARENT AND CHILD, P. C.]

Also so much of an act of the parliament of Ireland passed in the second year of the reign of the said Queen Anne (2 Anne, c. 6, s. 1, I.), intituled 'An Act to prevent the further growth of Popery,' as enacts 'that if any person or persons shall seduce, persuade, or pervert any person or persons professing or that shall profess the Protestant religion, to renounce, forsake, or abjure the same, and to profess the Popish religion, or reconcile him or them to the Church of Rome, then and in such case every such person and persons so seducing, as also every such Protestant and Protestants who shall be so seduced, perverted, and reconciled to Popery, shall for the said offences, being thereof lawfully convicted, incur the danger and penalty of præmunire mentioned in the statute of præmunire made in England in the sixteenth year of the reign of King Richard the Second.'

Also so much of the said last-mentioned act of Queen Anne (s. 3) as empowers the Court of Chancery to make such order for the maintenance of Protestant children not maintained by their Popish parents, suitable to the degree and ability of such parents and to the age of such child, and also for the portions of Protestant children to be paid at the decease of their Popish parents as that court shall adjudge fit, suitable to the degree and ability of such parents, and as empowers the said court to make such order for the educating in the Protestant religion the children of Papists, where either the father or mother of such children shall be Protestants, till the age of eighteen years of such children, as to that court shall seem meet, and in order thereto to limit and appoint where and in what manner, and by whom, such children shall be educated (s. 4); and as enacts that the father of such children shall pay the charges of such education as shall be directed by the said court.

And an act passed in the eleventh year of the reign of King George the Second (2 Geo. II. c. 17), intituled 'An

Act for securing the Estates of Papists conforming to the Protestant Religion against Disabilities created by several Acts of Parliament relating to Papists; and for rendering more effectual the several Acts of Parliament made for investing in the two Universities in that Part of Great Britain called England the Presentation of Benefices belonging to Papists,' except so much of the said act as relates to any advowson, or right of presentation, collation, nomination, or donation of or to any benefice, prebend, or ecclesiastical living, school, hospital, or donative, or any grant or avoidance thereof, or any admission, institution, or induction to be made thereupon, but so as that the repeal of the said act shall not in anywise affect or prejudice the right, title, or interest of any person in or to any lands, tenements, or hereditaments under and by virtue of the provisions of the said act at the time of such repeal.

Also so much of an act of the parliament of Ireland passed in the seventeenth and eighteenth years of the reign of King George the Third (17 & 18 Geo. III. c. 49, s. 5 [I.]), intituled 'An Act for the Relief of His Majesty's Subjects of this Kingdom professing the Popish Religion,' as enacts 'that no maintenance or portion shall be granted to any child of a Popish parent, upon a bill filed against such parent pursuant to the aforesaid act of the second of Queen Anne, out of the personal property of such Papists, except out of such leases which they may hereafter take under the powers granted in this act.'

Also so much of an act passed in the eighteenth year of the reign of the said King George the Third (18 Geo. III. c. 60, s. 5), intituled 'An Act for relieving His Majesty's Subjects professing the Popish Religion from certain Penalties and Disabilities imposed on them by an Act made in the eleventh and twelfth Years of the Reign of King William the Third, intituled "An Act for the further preventing the Growth of Popery,"' as enacts 'that nothing in this act contained shall extend or be construed to extend to any Popish bishop, priest, Jesuit, or schoolmaster who shall not have taken and subscribed the above oath in the above words before he shall have been apprehended, or any prosecution commenced against him.'

Also so much of an act of the parliament of Ireland passed in the twenty-third and twenty-fourth years of the reign of the said King George the Third (23 & 24 Geo. III. c. 38 [I.]), intituled 'An Act for extending the Provisions of an Act passed in this Kingdom in the nineteenth and twentieth Years of His Majesty's Reign, intituled "An Act for naturalizing such foreign Merchants, Traders, Artificers, Artizans, Manufacturers, Workmen, Seamen, Farmers, and others, as shall settle in this Kingdom,"' as excepts out of the benefit of that act persons professing the Jewish religion.

Also so much of an act passed in the thirty-first year of the reign of the said King George the Third (31 Geo. III. c. 32), intituled 'An Act to relieve, upon Conditions and under Restrictions, the Persons therein described from certain Penalties and Disabilities to which Papists or Persons professing the Popish Religion are by Law subject,' as enacts (s. 12) 'that nothing herein contained shall be construed to give any ease, benefit, or advantage to any person who shall, by preaching, teaching, or writing, deny or gainsay the oath of allegiance, abjuration, and declaration herein-before mentioned and appointed to be taken as aforesaid, or the declarations or doctrines therein contained, or any of them.'

Also so much of the said last-mentioned act (s. 15) as provides and enacts, 'that no schoolmaster professing the Roman Catholic religion shall receive into his school for education the child of any Protestant father.' [LAW, CRIMINAL, P. C. S., p. 180.]

Also so much of the said last-mentioned act (s. 16) as provides and enacts, 'that no person professing the Roman Catholic religion shall be permitted to keep a school for the education of youth until his or her name and description as a Roman Catholic schoolmaster or schoolmistress shall have been recorded at the quarter or general session of the peace for the county or other division or place where such school shall be situated, by the clerk of the peace of the said court, who is hereby required to record such name and description accordingly upon demand by such person, and to give a certificate thereof to such person as shall at any time demand the same, and no person offending in the premises shall receive any benefit of this act.

Also so much of an act of the parliament of Ireland passed in the thirty-third year of the reign of the said King George the Third (33 Geo. III. c. 21, s. 14 [I.]), intituled 'An Act for the Relief of His Majesty's Popish or Roman Catholic Subjects of Ireland,' as provides 'that no Papist or Roman Catholic, or person professing the Roman Catholic or Popish religion, shall take any benefit by or under this act, unless he shall have first taken and subscribed the oath and declaration in this act contained and set forth, and also the said oath appointed by the said act passed in the thirteenth and fourteenth years of his majesty's reign, intituled 'An Act to enable His Majesty's Subjects, of whatever Persuasion, to testify their Allegiance to him in some one of His Majesty's four Courts in Dublin, or at the General Sessions of the Peace, or at any Adjournment thereof, to be holden for the County, City, or Borough wherein such Papist or Roman Catholic, or Person professing the Roman Catholic or Popish Religion, doth inhabit or dwell, or before the going Judge or Judges of Assize in the County wherein such Papist or Roman Catholic, or person professing the Roman Catholic or Popish Religion, doth inhabit and dwell, in open Court.'

Also an act passed in the said thirty-third year of the reign of the said King George the Third (33 Geo. III. c. 44), intituled 'An Act for requiring a certain Form of Oath of Abjuration and Declaration from His Majesty's Subjects professing the Roman Catholic Religion in that Part of Great Britain called Scotland.'

II. And be it enacted, that from and after the commencement of this act her majesty's subjects professing the Jewish religion, in respect to their schools, places for religious worship, education, and charitable purposes, and the property held therewith, shall be subject to the same laws as her Majesty's Protestant subjects dissenting from the Church of England are subject to, and not further or otherwise. [This section makes a considerable change by placing Jews on the same footing as to the things enumerated as Protestant Dissenters; and it will enable any person to leave a legacy for the instruction of Jews in their religion, which up to the passing of this act could not be done.] [JEWS, P. C., p. 123.]

III. Provided, that nothing in this act contained shall affect any action or suit actually pending or commenced, or any property now in litigation, discussion, or dispute, in any of her majesty's courts of law or equity.

IV. That from and after the commencement of this act all laws now in force against the wilfully and maliciously or contemptuously disquieting or disturbing any meeting, assembly, or congregation of persons assembled for religious worship, permitted or authorized by any former act or acts of parliament, or the disturbing, molesting, or misusing any preacher, teacher, or person officiating at such meeting, assembly, or congregation, or any person or persons there assembled, shall apply respectively to all meetings, assemblies, or congregations whatsoever of persons lawfully assembled for religious worship, and the preachers, teachers, or persons officiating at such last-mentioned meeting, assemblies, or congregations, and the persons there assembled.

ROMAN EMPIRE, EASTERN DIVISION OF—frequently designated the EASTERN EMPIRE, GREEK EMPIRE, BYZANTINE EMPIRE, or LOWER EMPIRE. The actual separation of the Roman Empire into two parts occurred at an earlier period than the epoch usually fixed, viz. the death of Theodosius the Great; and was the result of causes which had been long at work. The warlike pre-eminence of Italy had enabled the Romans to achieve the conquest of the various and distant provinces which constituted the Roman empire, and the vigour of their central government, and the practical wisdom which usually guided it, enabled them to consolidate these provinces under an effective control. The reality and unity of the Roman government for the first three centuries of the empire, form a remarkable contrast to the disorderly independence of the satrapies of the Persian empire; and its permanence contrasts in an equally striking degree with the immediate dissolution of the Macedonian empire, consequent upon the death of Alexander the Great. Dissensions and civil wars did indeed repeatedly agitate the Roman empire during the period mentioned, but they did not arise from attempts at separation or local independence, but from competition for the possession of the whole. Dismemberment was not thought of.

These contests however shook the whole framework of the empire: and as Italy lost its pre-eminence in warlike energy and political skill; and the emperors, on whose personal qualities, from the despotic character of the government, the condition and spirit of the empire depended, arose from provincial rather than Italian families; the sentiment of unity was weakened, and Rome was no longer felt to be the real capital of the empire. Had the empire, however, been assailed by any one hostile power capable of affecting the safety of the whole, a sense of the common danger might have supplied a principle of cohesion; but each part had its peculiar enemies to contend with, and apprehended little injury from those who assailed the other portions of the empire. The Germanic confederations of the Alemanni and Franks [ALEMANNI, P.C.; FRANCE, P. C.] might threaten the Rhenish and upper Danubian frontiers, but neither Greece, Syria, Egypt, nor even the lower Danubian provinces were endangered by them: the Goths [GOTHS, P. C.] might overrun Maesia and Thrace, but were little thought of on the Asiatic side of the Hellespont; while the revived Persian kingdom, under the dynasty of the Sassanidae [PERSIA, P. C.], which threatened the subjugation of the East, was little regarded in Gaul or Africa. This mutual independence of the assailing nations tended to promote the dissolution of the empire by fixing the attention of its several parts on the enemies immediately opposed to them, and allowed neither leisure to attend to nor sympathy to feel for others.

The direction in which the fracture was likely to take place was indicated by the geographical and other circumstances of the empire. The principal extension of the empire was from east to west: and the Romans were not enough of a naval people to avail themselves fully of the facilities which the Mediterranean Sea afforded for keeping up the connection between their more distant provinces. The military communications were maintained by land, except where this was impracticable, rather than by water. Had the Hellespont and the Bosporus been wider, the separation would perhaps have been made there; but the narrowness of those straits, and the maritime tendencies of the adjacent Greek population, so closely united the opposite shores, that the separation of the European and Asiatic continents was of little practical moment: and tho place of the fracture was determined to that part of the empire where the communication by land, narrowed between the shores of the Adriatic and the nearest part of the Danubian frontier, was impeded by the difficulties of traversing the Illyrian offshoots of the great Alpine mountain system. South of the Mediterranean, the place of fracture was determined by the great Libyan desert west of Egypt and of Cyrenaica.

Another circumstance which tended to determine the point of separation was difference of language. Before the Roman arms had crossed the Adriatic the Greek language had become the language of literature and education in the countries to the east of that sea, and formed an important bond of union. The native languages of the East remained in use as spoken languages, and after the diffusion of Christianity some of them (*e. g.* the Syriac and Coptic and Armenian) came into use again as written languages; but the profane, and, to a large extent, the sacred literature of Asia Minor, Syria, and Egypt was Greek. West of the Adriatic the Latin tongue acquired a similar or even a greater supremacy; for it superseded, though probably in a corrupt form, the antient languages of Gaul and Spain and Italy in popular use, as well as for literary purposes, and forms the basis of the modern languages of those countries.

Had the African provinces west of the Libyan desert possessed the warlike resources of the other parts of the empire it is not unlikely that they would have formed a separate portion, and thus havo led to a threefold division. But neither did their internal resources allow this, nor was the frontier of the Atlas pressed by any foe so formidable as to require the presence of an emperor in that part. The Moorish tribes of the desert, however formidable as marauders, were impotent for conquest. The feeble attempts of provincial governors, *e. g.* Julius in the time of Diocletian, and Firmus and Heraclian in the reign of Honorius, to acquire independence in Africa were soon put down: and the African provinces, until their subjugation by the Vandals, remained in subjection, except during a few brief intervals, to the sovereigns of the West.

(A.D. 286.) The first emperor of the Eastern part of the empire, as separate from the West, was DIOCLETIANUS, who, on appointing Maximian as his colleague, retained to himself the government of the Eastern portion, which he held till his abdication, A.D. 305. [DIOCLETIANUS, CAIUS VALERIUS, P. C.; MAXIMIANUS, MARCUS VALERIUS, P. C.]

(305.) VALERIUS MAXIMIANUS GALERIUS, usually known as GALERIUS, who had, under Diocletian, governed the Danubian Provinces, with the subordinate rank of Caesar, succeeded that prince as Augustus or Emperor in the East, and reigned till A.D. 311. [MAXIMIANUS GALERIUS, VALERIUS, P. C.]

(311.) FLAVIUS VALERIUS LICINIUS and MAXIMINUS DAIA or DAZA succeeded Galerius. Maximin, who was nephew of that emperor, or was otherwise related to him, was appointed Caesar shortly after the abdication of Diocletian. Licinius was appointed Augustus by Galerius, apparently without passing through the subordinate rank of Caesar, A.D. 307; and Maximin, offended at the elevation of another to a rank superior to himself, assumed the title of Augustus also. Both however appear to have conceded a sort of precedence to Galerius during his life. After his death they divided the East between them, Maximin having the Asiatic provinces, and Licinius the European. The West was meanwhile (A.D. 312) reduced under the sole dominion of Constantine. In A.D. 313 Licinius and Maximin quarrelled; and the latter, after being defeated by his rival, poisoned himself at Tarsus. In A.D. 315 war broke out between Licinius, now sole Emperor of the East, and Constantine, which ended in the defeat of the former, who ceded nearly the whole of his European provinces to the conqueror. After an interval of eight years, war was renewed between them; and the defeat and capture of Licinius (A.D. 323) reunited the whole empire under Constantine. [MAXIMINUS DAIA, P. C.; CONSTANTINUS, FLAVIUS VALERIUS, P. C.]

Family of Constantine.

(323.) CONSTANTINUS I. MAGNUS, who reigned till his death, A.D. 337. [CONSTANTINUS, FLAVIUS VALERIUS, P. C.] From him succeeding emperors seem to have taken in almost every case the name of Flavius.

(337.) CONSTANTIUS II. In the division of the dominions of Constantine the Great among his three sons, Constantius, the second son, had the East. He is known as Constantius II., his grandfather, who was emperor of the West [CONSTANTIUS I. CHLORUS, P. C.] being known as Constantius I. On the defeat of Magnentius, A.D. 353 [MAGNENTIUS, P. C.], the whole empire was reunited under Constantius II., who died A.D. 361. [CONSTANTIUS II., FLAVIUS JULIUS, P. C.]

(361.) JULIANUS, FLAVIUS CLAUDIUS, commonly known as JULIAN THE APOSTATE, nephew of Constantine the Great by his half-brother Constantius, ruled the whole empire for two years after Constantius. [JULIANUS, FLAVIUS CLAUDIUS, P. C.] With Julian the family of Constantine ends.

(363.) JOVIANUS held the whole empire only three months. [JOVIANUS, FLAVIUS CLAUDIUS, P. C.]

Family of Valentinian.

(364.) VALENTINIANUS I., almost immediately on his appointment to the empire, resigned the east to his brother Valens. [VALENTINIAN I., FLAVIUS, P. C.]

(364.) VALENS governed the East till his death in the Gothic War, A.D. 378. [VALENS, FLAVIUS, P. C.]

(378.) GRATIANUS, son of Valentinian I., succeeded Valens in the East, but almost immediately resigned it to Theodosius the Great, retaining the West, which he had held from his father's death in A.D. 375. [GRATIANUS AUGUSTUS, P. C.]

Theodosian Family.

(379.) THEODOSIUS I., the GREAT, ruled the East during the remainder of his life, during the last year of which he acquired the West also, thus for the last time uniting the whole empire under one supreme ruler. [THEODOSIUS I., FLAVIUS, P. C.]

(395.) ARCADIUS, the elder son of Theodosius, succeeded his father in the East, and Honorius, the younger son, in the West. [ARCADIUS, P. C.]

(408.) THEODOSIUS II., or the YOUNGER, son of Arcadius, succeeded his father while yet in his childhood. He died A.D. 450. His government was principally directed by his sister Pulcheria and his wife Eudocia. [THEODOSIUS II., P. C.; EUDOCIA, daughter of Leontius, P. C.]

(450.) PULCHERIA, daughter of Arcadius, succeeded her brother Theodosius: she had devoted herself to a life of religious celibacy, but upon her brother's death she chose as her associate in the empire Marcian, a Thracian, whose merit had raised him from an humble station to high rank. She married him under an agreement that she was to remain a virgin. She died before her husband.

(450.) MARCIANUS may be classed with tho Theodosian family, his connection with which raised him to the empire. [MARCIANUS, P. C.] He died A.D. 457.

The history of the East during the eventful period (about 170 years) from the first division of the empire under Diocletian to the death of Marcian has to be gathered from many authorities. For the first part of it, comprehending the reign of Constantine and the preceding Augusti, we have as contemporaries Lactantius [LACTANTIUS, P. C.], or the author, whoever he was, of the book *De Mortibus Persecutorum*, and Eusebius in his *Life of Constantine*. [EUSEBIUS PAMPHILI, P. C.] The *Ecclesiastical History* of the latter writer furnishes some notices of such events as are connected with the Christian Church before the reign of Constantine. Ammianus Marcellinus [AMMIANUS MARCELLINUS, P. C.] is a valuable contemporary authority for the period (A.D. 353-378) included in the extant portion of his history. Aurelius Victor in his *De Caesaribus*, and the author of the *Epitome* which passes under his name [AURELIUS VICTOR, P. C.], give an abridgment of the history both of East and West; the *De Caesaribus* comes down to the reign of Constantius II., and the *Epitome* to the time of Theodosius the Great. Eutropius [EUTROPIUS, P. C.] in his *Breviarium* comes down to the accession of Valens, at whose command he wrote, and Orosius in his History to the reign of Honorius [OROSIUS PAULUS, P. C.]. But these writers are brief, and relate chiefly to the affairs of the West. This is also the case with the more copious and valuable work of Olympiodorus [OLYMPIODORUS, P. C.], which is known to us only by the abridgment and extracts given by Photius (*Bibliotheca*, Cod. 80). It relates chiefly or wholly to the reign of Honorius. The history of Zosimus, who lived apparently under Theodosius II., probably came down to his own time; but the extant portion extends only to A.D. 409. [ZOSIMUS, P. C.] Notices of the affairs of the East are to be gleaned from the Western Chroniclers, Marcellinus, Prosper of Aquitaine, Prosper Tyro, and Victor of Tunes; from the poems of Claudian [CLAUDIANUS, P. C.]; and from the writings of the Emperor Julian, and of the Christian fathers Athanasius, Gregory Nazianzen, and Chrysostom. [ATHANASIUS, ST., P. C.; CHRYSOSTOM, ST. JOHN, P. C.; GREGORY OF NAZIANZUS, P. C.] Of the later Byzantine writers [BYZANTINE HISTORIANS, P. C.], there are several whose Chronicles or Histories include this period; the most valuable are Theophanes Isaacius in his *Chronographia* and Zonaras in his *Annales*. Cedrenus, Glycas, Malalas, Joel, and the versifying chroniclers, Constantine Manasses and Ephraemius, are of less value; the *Chronicon Paschale* or Alexandrian Chronicle, though meagre, is of more value. Ecclesiastical History, after the time at which Eusebius closes his history, was written by Socrates [SOCRATES, P. C. S.], Sozomen, and Theodoret [SOZOMENUS, P. C.; THEODORETUS, P. C.], whose works extend from the time of Constantine to that of Theodosius II.; and by Evagrius [EVAGRIUS, P. C.], whose work, designed as a sequel to those of the three writers just mentioned, comes down to near the close of the sixth century. These histories are valuable, not only from the importance of ecclesiastical affairs after the conversion of Constantine, but from their frequent notice of secular events. The history of the whole period is contained in the *Fall of the Roman Empire* by Sismondi, in Lardner's Cyclopædia; and in the great work of Gibbon [GIBBON, EDWARD, P. C.], and with greater minuteness in the *Histoire des Empereurs* of Tillemont [TILLEMONT, SEB. LE NAIN DE, P. C.], who has carefully collected almost every thing that has been recorded, and has examined and digested it with critical accuracy and generally sound judgment. The copious but wearisome *Histoire du Bas Empire* of Le Beau embraces the period subsequent to the death of Constantius Chlorus and the accession of Constantine the Great to the rank and authority of Cæsar. To these works we may add the *Historia Byzantina* of Ducange.

The Family of Leo I.

(457.) LEO I., called THRAX (the THRACIAN), MAGNUS (the GREAT), and MACELLES (Μακέλλης), the BUTCHER, was, like his predecessor Marcian, a Thracian of an obscure family. He reigned seventeen years. [LEO I., P. C.]

(474.) LEO II., grandson of Leo I. by his daughter Ariadne, came to the throne at the age of four years, and reigned less than a year. [LEO II., P. C.]

(474.) ZENO, called ISAURUS, an Isaurian, who had married Ariadne, daughter of Leo I., and was father by her of Leo II., succeeded on the death of the latter. His reign, which was troubled by successive rebellions, is described elsewhere. [ZENO, P. C.] He was for a short time expelled from his throne by

(475.) BASILISCUS, who occupied Constantinople nearly two years. He fell at last into the hands of Zeno, A.D. 477, and was starved to death, A.D. 477 or 478.

(491.) ANASTASIUS I., surnamed SILENTIANUS, from his being one of the emperor's Silentiarii, or life-guards, a native of Dyracchium in Epirus, ascended the throne on Zeno's death, by the help of the dowager Empress Ariadne, whom he afterwards married. [ANASTASIUS I., P. C.] His long reign of twenty-seven years was as much affected by foreign invasion and the dissensions of the church as that of Zeno had been by rebellion.

With Anastasius ends the dynasty of Leo I., with which indeed both Zeno and Anastasius can only be classed by virtue of their marriage with Ariadne.

Family of Justin.

(518.) JUSTINUS I., a Dacian peasant who had risen to be general of the emperor's guards, succeeded Anastasius, and reigned nine years, when he abdicated the throne, and died soon after. [JUSTINUS I., P. C.]

(527.) JUSTINIANUS I. was nephew by his mother's side of Justin I. Justinian's reign of thirty-eight years was distinguished by the victories of Belisarius, Narses the Eunuch, and Germanus the emperor's own nephew; and more honourably by his compilation of the Roman law. [JUSTINIANUS, P. C.; JUSTINIAN'S LEGISLATION, P. C.; BELISARIUS, P. C.; NARSES, P. C.; LONGOBARDS, P. C.; OSTROGOTHS, P. C.; THEODORIC, P. C.]

(565.) JUSTINUS II., nephew by his mother Vigilantia to JUSTINIAN I., succeeded to the throne, but, worn down and disabled by illness, he resigned the exercise of sovereignty A.D. 574 to Tiberius, who was created Cæsar; but Justin retained the title of Augustus until his death A.D. 578. [JUSTINUS II., P. C.]

The dynasty of Justin I. ends with Justin II.

(578.) TIBERIUS II., or more fully FLAVIUS CONSTANTINUS TIBERIUS AMICUS THRAX, wielded the sovereign power with the title of Cæsar from A.D. 574, and received the title and authority of Augustus just before the death of Justin II., from which latter period he reigned four years. [TIBERIUS II., P. C.]

(582.) MAURITIUS or MAURICIUS, had been created Cæsar by Tiberius II., whose daughter Constantina he had married. The reign of Mauricius was chiefly marked by wars and negotiations with Persia. Having become unpopular, he was murdered, with most of his family, by the centurion Phocas.

(602.) PHOCAS, who headed a revolt of the army in Thrace [PHOCAS, P. C.], murdered Mauricius, and succeeded to the throne. This bloodthirsty tyrant occupied the throne till he was deposed and put to death by Heraclius, A.D. 610.

From the time of Diocletian to that of Justin I. the limits of the Eastern empire underwent little alteration except by the acquisition of Northern Mesopotamia and of five provinces east of the Tigris, in the reign of Diocletian, and by the cession of these acquisitions by Jovian after the death of Julian the Apostate. Part of the Greater Armenia was annexed to the empire by Theodosius the Great. The Eastern empire was indeed repeatedly invaded; and the Goths in the time of Valens, and the Bulgarians in the reign of Anastasius, had nearly overthrown it. The eastern frontier was almost continually the seat of war with the Persians, and civil dissension in the time of Zeno shook the empire to its centre; but it recovered from these shocks, and the reign of Justinian I. was successful in aggression. The Western empire had been extinguished during the reign of Leo I., and the invasions of Justinian were directed against the provinces of the West, which different nations of barbarians had occupied. Africa and apparently Mauritania, and even a small part of Spain, were recovered from the Vandals by Belisarius, and preserved by Germanus; and Italy, with Sicily, Sardinia, and Corsica, were conquered by Belisarius and Narses. The northern part of Italy and the inland parts as far south as Beneventum were indeed soon lost again, being conquered in the reigns of Justin II. and Tiberius II. by the Lombards [LONGOBARDS, P. C.], who gradually extended their encroachments; and the African conquests of Belisarius were in the next century overrun by the victorious Saracens under the successors of Mohammed [ARABIA, P. C.], but Rome and the coast of the central and southern parts of Italy (under the designation of Longobardia), as well as Sicily, remained in the possession of the Byzantine emperors; who retained a footing in Italy and Sicily (though their possessions were continually disputed by the Latins and the Saracens) almost to the time of the Crusades.

The period from Justinian to Heraclius, the successor of Phocas, was that of the greatest extension of the Eastern empire. The cession of the provinces east of the Tigris in the reign of Jovian was far more than counterbalanced by the acquisition of part of Armenia under Theodosius the Great, by the western conquests of Belisarius and Narses, and by the extension of the Byzantine territory by conquest or settlement along the eastern and northern coasts of the Euxine, the progress of which is not easy to trace. Even after the loss of the northern part of Italy, the Eastern empire was larger than it had been under the emperors who preceded Justinian.

The principal historical authorities for the period from Leo the Thracian to Phocas are Theophanes Isaacius, Zonaras, the Paschal or Alexandrian Chronicle, Cedrenus, Joannes Malalas or Malelas, Michael Glycas, Joel, and the versifiers: these several writers comprehend the whole period, with the exception of Malalas, whose '*Chronographia*' ends during the reign of Justinian I., A.D. 563. The wars of Belisarius are related by Procopius [PROCOPIUS, P. C.], whose introductory chapters to his *Bellum Vandalicum*, *Bellum Geticum* or *Gotthicum*, and *Bellum Persicum*, contain some important notices of events previous to that time. The Secret History (*Historia Arcana*) of Procopius relates to the same period. Agathias relates the events of A.D. 553-559. The history of the Emperor Mauricius (*Historia Mauriciana*) is related by Theophylactus Simocatta; and the reign of Phocas is included in the work of Nicephorus of Constantinople, *De Rebus post Mauricium gestis*. The Ecclesiastical History of Evagrius, a contemporary, comes down to the reign of Maurice, A.D. 594; and that of Nicephorus Callisti, a writer of much later date, to the accession of Heraclius. After the reign of Anastasius, we lose the valuable assistance of Tillemont; but the whole period is included in the works of Ducange, Gibbon, Sismondi, and Le Beau.

Heraclian Dynasty.

(610.) HERACLIUS, son of the patrician Heraclius, governor of Africa, dethroned Phocas and put him to death. His reign was one of the most interesting and eventful in the whole course of Byzantine history; and his character one of the most striking and inexplicable. The middle part of it was characterized by brilliant and successful warlike exertions, by which the empire was saved from impending ruin. The earlier part was characterized by inertness, and the latter part by sensuality and carelessness. [HERACLIUS, P. C. and P. C. S.] He reigned above thirty years.

(641.) CONSTANTINUS III., or more fully FLAVIUS HERACLIUS CONSTANTINUS, or NOVUS CONSTANTINUS, was the son of Heraclius by his first wife Eudocia Fabia. The name of Constantinus was given in the hope that he would renew the glory of the great Constantine. He reigned only about three months, being, as was suspected, poisoned by his step-mother Martina, niece and second wife of Heraclius; she being anxious to make her son Heracleonas (who had been, by his father's will, made colleague with Constantine) sole occupant of the throne.

(641.) HERACLEONAS. The death of Constantine III. excited a revolt against the government of Martina, who ruled in the name of her son; and both she and Heracleonas were compelled by Valentinus or Valentine (who had forced her to raise him to the dignity of Caesar) to admit Constans, son of Constantine III., to a share in the empire; and were soon afterwards deposed, imprisoned, mutilated, and sent into exile, where they died.

(641.) CONSTANS II. (Constans I., son of Constantine the Great, had ruled the Western empire) was originally named Heraclius. He acceded to the throne in his eleventh year, and reigned for twenty-seven years. During the first few years of this reign the government was virtually in the hands of Valentine; but Constans, when he attained to manhood, manifested considerable energy both in military and ecclesiastical affairs. He was however violent and unfortunate: his eastern territories, already much diminished by the progress of the Caliphate, were still further diminished by the extension of that rising empire [ARABIA, P. C., vol. ii. p. 217]; and his Italian dominions were shaken by religious troubles. The murder of his brother Theodosius by the emperor's order (A.D. 661) made Constans a prey to the horrors of remorse. His palace at Constantinople became odious to him; and this, combined perhaps with political reasons, led him to contemplate the reconquest of Italy, and the restoration of the seat of empire to Rome. The ill success of his Italian warfare however made him give up this plan, and he fixed himself at Syracuse, where he was murdered, A.D. 668.

(668.) CONSTANTINUS IV., POGONATUS, or BARBATUS, the BEARDED, eldest son of Constans II., succeeded his father. He had been left by his father governor of Constantinople A.D. 662, and on the news of the assassination of Constans, and of the revolt of his murderers and their partizans in Sicily, fitted out an expedition, which he headed in person, and quelled the revolt (A.D. 669); and having put Mizizus, the emperor whom they had elected, to death, returned to Constantinople. The revolt of the army in Asia followed his return; the troops, by a fanciful analogy drawn from the prevalent theology, requiring to be governed by a trinity of sovereigns, and demanding that Heraclius and Tiberius, brothers of Constantine, should be declared joint emperors with him. The revolt was quelled; but the brothers were pardoned. The Arabs of the Caliphate conquered Asia Minor and the Greek islands, and besieged Constantinople, but were defeated chiefly by the agency of the Greek fire, then just invented [FIRE, GREEK, P. C.]; and the tide of success turning, the emperor recovered Asia Minor and the islands. The Bulgarians however conquered the province now known as Bulgaria, south of the Danube. The empire was divided either in or before the reign of Constantine IV., according to a new system, into military districts, called themata. Constantine IV. died A.D. 685.

(685.) JUSTINIANUS II., sometimes called RHINOTMETUS, or CUT-NOSE, son of Constantine IV., succeeded his father. After an oppressive reign of ten years he was dethroned, had his nose cut off, and was banished to the Crimea by Leontius.

(695.) LEONTIUS reigned three years; and being unfortunate in the war with the Arabs, was in turn dethroned, had his nose cut off, and was confined in a monastery, by Absimarus, one of his generals, who took the name of Tiberius.

(698.) TIBERIUS III. was a vigorous and, for a time, successful prince. He recovered Syria from the Arabs, and had considerable influence in Italy. He was dethroned, and, with his brother Heraclius and his predecessor Leontius, put to death (A.D. 705) by Justinian II., who was restored. [TIBERIUS ABSIMARUS, P. C.]

(705.) JUSTINIANUS II. Justinian regained his throne by the help of the Bulgarians; and continued to abuse his power till he was dethroned and put to death by Philippicus Bardanes, A.D. 711. [JUSTINIANUS II., P. C.]

The Heraclian dynasty ends with Justinian II. It occupied the Byzantine throne (including the period of Justinian's exile) rather more than a century; a period marked by the decided diminution of the empire, though not without temporary vicissitudes and gleams of brilliant but transient success. The enemies from whom the empire suffered most were the Arabs, then invigorated by the fresh infusion of Mohammedan fanaticism. Under Mohammed himself [MOHAMMED ABUL KASEM IBN ABDOLLAH, P.C.] their conquests scarcely encroached upon the boundary of the empire; but under his successors Abu Bekr [ABU BEKR, P. C.] and Omar [OMAR I., P. C.], Palestine, Syria [SYRIA, P. C.], Roman Arabia, Egypt [EGYPT, P. C.], and Cyrenaica [CYRENAICA, P.C.] were subdued. These conquests were made during the latter years of Heraclius. Tripolitana and Africa Proper, the modern states of Tripoli and Tunis [BARBARY, P.C.; TRIPOLI, P.C.; TUNIS, P. C.], were conquered by the same foe during the reign of Constans II., in which also Sicily [SICILY, P. C.] was attacked, though the assailants made but little progress; Cyprus and Rhodes were also taken by them [CYPRUS, P. C.; RHODES, P. C.]; but Cyprus was soon recovered, and, after a longer time, Rhodes also. The contraction of the European territory by the settlement of the Bulgarians, took place under Constantine IV. Africa was wholly and finally lost before the Heraclian family ceased to reign; and although Syria was temporarily recovered by Heraclius, brother and general of Tiberius Absimar, A.D. 699 and 700, it was soon lost again.

To the other evils of the period religious dissension was added. The Monothelite controversy raged during the latter part of the reign of Heraclius and in the reigns of his successors, until it was settled in the sixth general or second Constantinopolitan counci, A.D. 680. Heraclius and his grandson Constans were patrons of the so-called heresy of the Monothelites.

The principal antient authorities for the period of the Heraclian dynasty are Theophanes, Cedrenus, Glycas, Zonaras, Nicephorus of Constantinople, Joel, Ephraemius, and Constantine Manasses. The *Chronicon Paschale*, or *Alexandrinum*, reaches down to the earlier years of the reign of Heraclius; and the wars of that prince with the Persians and Avars are commemorated in the poems of George the Pisidian, an ecclesiastic of that time, and probably an eye-witness of the events which he relates. The Monothelite controversy is discussed largely by St. Maximus, one of the Greek fathers.

(711.) PHILIPPICUS BARDANES succeeded to the now vacant throne. He patronized the Monothelites. His reign was short: he was deposed, blinded and imprisoned, A.D. 713, by Rufus, an officer sent by the one of his generals, George Buraphus, who had rebelled in Asia Minor.

(713.) ANASTASIUS II. (previously to his accession he was called ARTEMIUS) succeeded Philippicus. He patronized the orthodox faith in opposition to the Monothelites. He was dethroned A.D. 715 by the troops which he had sent to attack the Saracens in the port of Alexandria. [ANASTASIUS II., P. C.]

(715.) THEODOSIUS III. made some cessions of territory in Thrace to the Bulgarians. He was deposed (A.D. 718) by Leo, one of his officers, who commanded in Asia Minor. [THEODOSIUS III., P. C.]

Isaurian dynasty.

(718.) LEO III. ISAURUS, the ISAURIAN, had borne in early life the name of Conon: he was a native of Isauria in Asia Minor, from which circumstance he is known in history as Leo Isaurus, or the Isaurian. [Leo III., P. C.] He died A.D. 741, after a reign of twenty-three years.

(741.) CONSTANTINUS V. surnamed COPRONYMUS, because when baptized in his infancy he defiled the font, was an able and energetic prince; but his reign was characterized by varied success in the field, and by the religious troubles aroused by the Iconoclastic controversy. He is charged with every crime by orthodox writers; and was probably a cruel oppressor of the so-called orthodox party; but the Iconoclasts, whom he favoured, revered him as a saint. The revolt of his brother-in-law Artabazes, or Artavasdes, or Artavasdus, who at the commencement of his reign disputed the crown with him, and was apparently supported by the image-worshipping party, was near proving fatal to him; but in the end (A.D. 743) he recovered Constantinople, which Artavasdus had occupied, and deposed that usurper. Constantine died A.D. 775, and was succeeded by his son Leo.

(775.) LEO IV., surnamed CHAZARUS, which name he derived from his mother Irene, who was a daughter of the Chagan or Khan of the Chazars, a Turkish nation settled near the Volga. [TARTARS—*Chazars*, P. C., vol. xxiv. p. 73.] The reign of Leo was short, but was disturbed by the revolt of his brothers, who were exiled, and by hostilities with the Saracens, who were defeated. Leo died A.D. 780. [LEO IV., P. C.]

[780.] CONSTANTINUS VI., sometimes called PORPHYROGENITUS, or more accurately PORPHYROGENNETUS, which title is however usually appropriated to Constantine VII., son of Leo VI., succeeded his father, while yet a minor, under the guardianship of his mother Irene, an Athenian whose beauty and genius had captivated Leo. Her endeavours to prolong her influence led to dissensions which ended in the deposition and blinding, if not the death, of Constantine, A.D. 797.

(797.) IRENE, widow of Leo. IV., succeeded her son. A project is said to have been formed of reuniting the Eastern and Western empires by a marriage between Irene and the Emperor Charlemagne. According to Theophanes and Zonaras and Cedrenus, Charlemagne sent ambassadors for the purpose of arranging the marriage, which was defeated by the influence of Aëtius, then powerful at the Byzantine court. The Western writers, while speaking of the embassy, are silent as to the marriage being one of its objects. Irene was deposed A.D. 802, by Nicephorus, one of her officers, who usurped the throne. The Isaurian dynasty ends with her. It occupied the Byzantine throne eighty-four years.

During the reign of the Isaurian princes the empire continued to decline. Though Leo III. and Constantine V. were able and active, their power was weakened by religious dissension. A few years after the commencement of his reign Leo had attempted to put an end to the use of images in Christian worship. The attempt, which was followed up with even greater earnestness by Constantine, convulsed the whole empire. The successive popes and the bulk of the clergy declared in favour of images; the secular power was wielded by the Iconoclasts or Iconomachi, the opponents of images. The quarrels thus produced between the emperors and the popes combined with the rise of the Frankish power under Pepin and Charlemagne [PEPIN, P. C.; CHARLEMAGNE, P. C., and STEPHEN III. Pope, P. C.] to separate Rome and the adjacent parts of Italy from the Byzantine Empire, which retained only the southern extremity of that country. This formed an adjunct of the province of Sicily, under the title of Sicilia Secunda, 'the Second Sicily;' from which circumstance has arisen the designation of 'the two Sicilies,' as applied in modern times to the kingdom of Naples. The use of images was restored by the influence of Irene and by the authority of the seventh general or second Nicene Council, A.D. 787.

The authorities for the Isaurian dynasty are the same as for the Heraclian; but Nicephorus of Constantinople does not come lower than the reign of Constantine V. The history of the Iconoclastic controversy is given in Gibbon (chap. xlix.) and in the various modern ecclesiastical histories. In that published by the Useful Knowledge Society the account will be found in chap. xi. § 6.

(802.) NICEPHORUS I. [NICEPHORUS I., P. C.] fell in battle against the Bulgarians after a short and calamitous reign of nearly nine years.

(811.) STAURACIUS, son of Nicephorus, was mortally wounded in the same battle in which his father fell: but lingered for some months, during which he was deposed, and was succeeded by Michael Rhangabe.

(811.) MICHAEL I., surnamed RHANGABE, had married Procopia, daughter of Nicephorus. His short reign was unfortunate: and being defeated by the Bulgarians and threatened by the revolt of Leo the Armenian, he abdicated the throne A.D. 813.

The *Chronographia* of Theophanes, one of the most important authorities in Byzantine history, ends with the reign of Michael Rhangabe.

(813.) LEO V. [LEO V., P. C.], surnamed from the country of his birth ARMENUS, THE ARMENIAN, seized the sceptre from the feeble grasp of Michael Rhangabe. He defeated the Bulgarians, who had penetrated to the walls of Constantinople, and reformed the whole administration of the empire. He patronized the Iconoclasts, who now gained the ascendant and persecuted the orthodox. After a vigorous and successful reign, he was murdered by the friends of Michael, one of his officers whom he had condemned to death and was on the point of executing.

Dynasty of Amorium.

(820.) MICHAEL II., surnamed BALBUS or the STAMMERER, or, from his birth-place, MICHAEL OF AMORIUM, was rescued from prison by his friends, and placed on the throne. He also favoured the Iconoclasts. His reign was unfortunate. The Saracens conquered Crete and Sicily, and almost conquered what remained to the Eastern Empire in Italy; and Michael was twice besieged in his capital by one of his own subjects, Thomas, who had rebelled, but whom, by the aid of the Bulgarians, he at length conquered. He died A.D. 829, and was succeeded by his son Theophilus.

(829.) THEOPHILUS, a vigorous and active prince, was continually engaged in war, but with little success. He protected the Iconoclasts and persecuted the orthodox, yet he has escaped the reproaches which were so liberally heaped on the Isaurian princes who followed the same course. He died A.D. 842, and was succeeded by his son Michael.

(842.) MICHAEL III., surnamed EBRIOSUS, THE DRUNKEN, came to the crown a minor, under the care of his mother Theodora, who restored the use of images and finally crushed the Iconoclastic party. During the reign of the dissolute Michael war was carried on unfortunately against the Saracens in the neighbourhood of the Caucasus, in Crete, and in Asia Minor; but the Sclavonians, who had possessed themselves of Greece, were subdued, and the Bulgarians and the Chazars were converted to Christianity; a change which either abated their warlike restlessness, or diminished their hostility to the empire. Michael was assassinated (A.D. 867) by Basilius or Basil I., whom he had raised to be his colleague in the empire. The Amorian dynasty ended with him.

During the reigns of the Amorian princes the decline of the empire continued, and would have been more rapid but for the diminished power and energy of its great rival the Caliphate. Cyprus (if indeed it had not been conquered at an earlier period), Crete, and Sicily were lost; and the remaining Byzantine territories in Italy were nearly lost in the reign of Michael II.; and the activity and valour of Theophilus were fully tasked in contesting with the caliph Motassem the possession of the central parts of Asia Minor: for the regions south of the Taurus appear to have been already subdued.

The history of Leo the Armenian and of the Amorian dynasty is contained in the works of Zonaras, Cedrenus, Glycas, Joel, Ephraemius and Constantine Manasses; in the *Chronographia* of the anonymous continuator of Theophanes, in the works of Leo Grammaticus and Symeon Magister, in the *Vitæ Imperatorum Recentiorum* of Georgius Monachus, and in the *Reges* of Genesius: the continuator of Theophanes and the writers subsequently enumerated, all commence their histories with the reign of Leo V., at the point where Theophanes ceases.

Macedonian Dynasty.

(867.) Basilius I. Macedo, or the Macedonian, an extraordinary man, the son of a small landowner in Macedonia or Thrace, rose from the low condition of a slave among the Bulgarians, by whom in his youth he had been carried captive, to the possession of the Byzantine throne, by becoming the colleague of Michael III., whom he soon after murdered. He subdued the Paulicians, a warlike sect, whom long persecution had driven into revolt, and recovered a considerable part of Asia Minor and the south of Italy and Sicily from the Saracens, who had conquered them. He died A.D. 886, and was succeeded by his son Leo. [Basilius the Macedonian, P. C.]

(886.) Leo VI., surnamed Philosophus, the Philosopher, or Sapiens, the Wise, was engaged in wars with the Bulgarians in the north, and in the south with the Arabs, who attempted to recover Sicily; but his wars were on the whole unfortunate. He died A.D. 911, and was succeeded by his son Constantine. He was the author of various works, the chief of which are noticed elsewhere. [Leo VI., P. C.]

(911.) Constantinus VII. Porphyrogenitus, or Porphyrogennetus, succeeded his father while yet a child of six years. He had for his first colleague

(911.) Alexander, the son of Basilius I., next in order of birth to Leo VI. He died after a reign of a year A.D. 912. The next colleague of Constantine was

(919.) Romanus I., surnamed Lecapenus or Lacapenus [Romanus I., P. C.], who assumed the Imperial power A.D. 919, and successively raised his three sons, Christophorus in A.D. 919, and Stephanus, and Constantinus VIII. in A.D. 928, to the title at least of emperors. Romanus engrossed the administration of affairs and left to Constantine VII. only the title of emperor, compelling him to pass his time in retirement, in which he became distinguished by his literary and other accomplishments. But in A.D. 944 Constantine was restored to the possession of the imperial power: Christopher had been for some time dead (A.D. 931 or perhaps 926), and Stephen and Constantine, the surviving sons of Romanus, had just before expelled their father from the throne, and were themselves deposed by the people, who restored Constantine to the actual possession of the sovereignty, which he retained till his death A.D. 959, carrying on war with considerable success against the Arabs, and receiving the submission of the Iberian mountaineers. His literary works are of considerable importance [Byzantine Historians, P. C.] and include: 1, The life of his grandfather Basil the Macedonian, incorporated in the Continuation of the *Chronographia* of Theophanes. 2, *De Thematibus*, a description of the themata or military provinces of the empire. 3, *De Administrando Imperio*, 'On the administration of the Empire,' written for the instruction of Romanus, son and successor of Constantine. 'It contains' (says Dr. Plate, in Dr. Smith's *Dictionary of Greek and Roman Biography*) abundance of geographical, historical, ethnographical, and political facts of great importance; and without it our knowledge of the times of the author, and the nations which were either his subjects or his neighbours, would be little more than vagueness, error, or complete darkness.' 4, 5, Two works on military affairs, respectively styled *Tactica*, 'Tactics,' and *Strategica*, 'Strategics.' 6, *De Ceremoniis Aulae Byzantinae*, 'On the Ceremonies of the Byzantine Court,' a detailed account of the observances of royalty and administration at that time. We owe also to Constantine various valuable *Collectanea* or compilations, especially that *De Legationibus*, on the Embassies of the Romans to other nations and of other nations to them; which contains numerous valuable Excerpta from Polybius and other writers. Others of these *Collectanea* are on veterinary medicine and on agriculture. [Geoponika, P. C.]

(959.) Romanus II. [Romanus II., P. C.] distinguished as Junior, the Younger, sometimes as Puer, the Boy, reigned only four years, dying in A.D. 963 of poison administered to him by his wife Theophano.

(963.) Basilius II. and Constantinus IX., or as some call him (not recognising the son of Romanus Lecapenus) Constantinus VIII., aged respectively five and two years, were nominally the successors of their father Romanus II.; but their profligate mother and guardian Theophano married Nicephorus, a valiant and successful general, and raised him, nominally to a share, but actually to the sole possession of the empire.

(963.) Nicephorus II. Phocas exhibited as a sovereign the same military skill and valour which he had previously shown. [Nicephorus II., P. C.] His reign was a constant scene of warfare: in the east he was successful: Cilicia and the north of Syria, with the strong cities of Tarsus, Antioch, and Aleppo, were recovered; and even Mesopotamia was invaded, though with less success. In the west his success was less signal and complete: he could only dispute with the Saracens and with the Western Emperor Otho the possession of the southern extremity of Italy and of the island of Sicily. But wars are costly: and the necessities, perhaps the avarice, of Nicephorus made him unpopular, and the infamous Theophano, who was weary of him, conspired with her paramour Joannes or John Zimisces to assassinate him. He was murdered A.D. 969.

(969.) Joannes I. Zimisces or Tzimisces (Τζιμισκής) succeeded to the sovereignty of Nicephorus; and, like him, was distinguished by warlike pre-eminence, both as a subject and as emperor. One of his first acts was to banish the guilty Theophano. A rebellion, raised by Bardas Phocas, was soon suppressed; and Joannes was equally successful against foreign foes. He defeated the Russians, who had nearly conquered Bulgaria, and restored the Bulgarian king to his throne, but in subordination to the empire: he recovered to the empire, though only for a short time, its long lost possessions in Mesopotamia, and extended the conquests which Nicephorus had already made in Syria. His victorious career was cut short by poison administered by some of his own courtiers, after a reign of only six years.

From A.D. 975 begins the actual reign of Basil II. [Basilius II., P. C.], now arrived at an age to exercise the sovereign power, and of his brother Constantine; but the youth of Constantine in the first instance, and afterwards his luxurious indolence and carelessness, left the government to the able and energetic Basil. A dangerous rebellion, raised by Bardas Sclerus, was with much difficulty suppressed, and the conquest of Byzantine Italy and Sicily by Otho or the Saracens was prevented chiefly by their wars with each other, which enabled Basil to renew with greater prospect of success the struggle for the possession of those countries. His martial prowess retained the conquests of his predecessors in Syria, despite of the efforts of the adjacent Saracen powers. By the complete overthrow of the Bulgarian kingdom he restored the long lost frontier of the lower Danube, as far up as Sirmium: he defeated the Caucasian mountaineers and protected the Byzantine part of Armenia from invasion: and he was preparing for the complete conquest of Sicily and Byzantine Italy when he died A.D. 1025. Constantine survived his brother only three years; and his death A.D. 1028 closed the commonly reputed period of the Macedonian dynasty (though it continued in the female line still longer), the supremacy of which was of longer duration than that of any other Imperial dynasty, except the closing one of the Palaeologi.

The Macedonian period of a hundred and sixty years was one of apparent, if not of real revival. The frontiers of the empire had been extended in the north from the defiles of Mount Haemus to the bank of the Danube, and in the south from the range of the Taurus to the heights of Lebanon and the banks of the Euphrates and even of the Tigris. The throne had been occupied by several warlike princes, and the decay of the rival powers, the Caliphate [Caliph, P. C.] and the Bulgarian kingdom, rendered their prowess effectual for the revival of Byzantine greatness. The literary taste and acquirements of Leo VI. and Constantine VII. conduced also to the revival of literature; and several valuable writers belong to this period. The history of this æra is contained in Zonaras [Zonaras, Joannes, P. C.], Cedrenus, Glycas, Ephraemius, and Constantinus Manasses; the anonymous continuator (or continuators) of Theophanes (sometimes called, but on insufficient ground, Leontius), Symeon Magister, Georgius Monachus, Leo Grammaticus, and Genesius. Of these authorities Genesius ends with the death of Basil I., A.D. 886; Leo Grammaticus and Georgius Monachus, with the death of Romanus I. Lecapenus (A.D. 948 or 949), a few years after his deposition; and the continuator of Theophanes and Symeon Magister, with the early part of Romanus II. To these we may add Leo Diaconus, who lived in the reign of Basil II., and whose history comprehends the reigns of Romanus II., Nicephorus Phocas, and Joannes Zimisces (A.D. 959-975). [Byzantine His-

TORIANS.] Sismondi's *Fall of the Roman Empire* ends with the tenth century.

(1028.) ROMANUS III. surnamed Argyrus or Argyropulus, ascended the throne as the husband of Zoë, one of the daughters of Constantine IX., who also left another daughter, Theodora. Romanus, after a short reign, in which his troops were defeated by the Saracens, both in Sicily and in Syria, was assassinated by his wife and her paramour Michael, whom she elevated to the throne. [ROMANUS III., P. C.]

(1034.) MICHAEL IV. PAPHLAGO, the PAPHLAGONIAN, reigned meanly and miserably for more than seven years and a half.

(1041.) MICHAEL V. CALAPHATES or CALAPHATA (*i. e.* a repairer of vessels, a name derived from the occupation of his father) succeeded his uncle Michael IV. He banished Zoë, but the people of Constantinople, inspired with indignation at this punishment inflicted on one of her high birth, insisted on her recal, and on the release of her sister Theodora from the monastery in which she had been placed, and deposed Michael, depriving him of his eyes, after he had reigned little more than a year.

(1042.) ZOE and THEODORA reigned jointly for a few months, when Zoë married and raised to partnership in the empire

(1042.) CONSTANTINUS X., or as some reckon CONSTANTINUS IX., surnamed, from his valour, MONOMACHUS, the SINGLE COMBATANT. This emperor had to repress a revolt in Cyprus, to repel the Servians on the Illyrian frontier, and to defend his throne from his rival, Georgius Maniaces, the greatest of the Byzantine warriors of his day, who being driven by injustice to revolt, advanced against Constantinople and defeated the imperial army, but fell, probably by assassination, in the moment of victory. Another rebel, Leo Tornicius, a relative of the emperor, was defeated by Constantine, who also vanquished a Russian fleet which threatened Constantinople [RUSSIA, P. C.], and extended the limits of the empire in the East by incorporating the territory of a subordinate chieftain of Armenia and Iberia who had revolted and was subdued. Zoë died A.D. 1050 and Constantine A.D. 1054.

Theodora was thus left sole inheritor of the sovereignty. She had previously refused to marry; but toward the close of her short reign, she consented, on her death-bed, to a nominal union with an aged warrior named Michael.

(1056.) MICHAEL VI., STRATIOTICUS, thus succeeded to the empire, which he held for about a year, when he was deposed. Theodora had died a few days after their marriage. The short reign of Michael VI. was troubled by the unsuccessful revolt of Theodosius, a cousin of the late emperor Constantine X.

(1057.) ISAACUS I. COMNENUS, whose successful revolt had deposed Michael VI., obtained the empire, but was soon after induced by his failing health to resign it. The succession was offered first to Joannes Comnenus, the Emperor's brother, who declined it; and then to Constantine Ducas.

Family of Ducas.

(1059.) CONSTANTINUS XI. (or X.), surnamed DUCAS reigned seven years, in which the empire was assailed by the Hungarians and other enemies on the side of the Danube. On his death the throne was occupied by his sons.

(1067.) MICHAEL VII. surnamed PARAPINACES, ANDRONICUS I., and CONSTANTINUS XII. (or XI.) PORPHYROGENITUS, or PORPHYROGENNETUS, all minors, succeeded to the nominal possession of the throne, under the guardianship of their mother EUDOCIA [EUDOCIA, P. C.], who after a regency of some months conveyed by marriage the actual sovereignty to Romanus, one of the officers of her army.

(1068.) ROMANUS IV. surnamed DIOGENES, valiantly opposed the progress of the Turks, who were in force in Asia Minor, but his efforts resulted in his defeat and captivity (A.D. 1071). [SELJUKIDES, P. C.] On his release, he attempted to recover his throne, his title to which was considered as lost by his captivity, but he was defeated, taken prisoner, and deprived of his eyes with such cruelty, that he died a few days after. [ROMANUS IV., P. C.] Eudocia had, during his captivity, been confined in a convent.

MICHAEL VII. then assumed the exercise of the sovereign power: but by his cowardice he incurred the contempt of his subjects, and he was, with his brothers, deposed by the rebel Nicephorus Botaniotes, who succeeded to the throne. The reign of the family of Ducas ended with Michael VII. It occupied the Byzantine throne less than twenty years.

(1078.) NICEPHORUS III. BOTANIOTES [NICEPHORUS III., P. C.] had to struggle for the throne with a rival, NICEPHORUS BRYENNIUS, who had revolted against Michael at the same time as his namesake. Alexius Comnenus, the general of Botaniotes, defeated Bryennius, and compelled him to surrender, but shortly afterwards raised a revolt on his own account, and succeeded (A.D. 1081) in deposing Botaniotes and acquiring possession of the throne. He was the nephew of the Emperor Isaac I., and son of that Joannes or John Comnenus who, on Isaac's resignation, had refused the crown. The accession of Alexis was the commencement of the permanent sway of the Comnenian family or dynasty.

The century and a half which elapsed from the close, at least in the male line, of the Macedonian dynasty, and the accession of the Comnenian, was a period of disaster and decline. The various domestic revolutions, several of them accompanied by bloody civil wars, have been noticed. In the west, the Normans, who had first visited southern Italy as pilgrims, then, on the invitation of a fugitive revolter of the Byzantine city of Bari, as mercenary soldiers, had gradually conquered, between A.D. 1040 and 1080, the Byzantine portions of Italy and Sicily, the last relics of the conquests of Belisarius and the other generals of Justinian. In the East, the Turks, under their sovereigns of the Seljukian dynasty [SELJUKIDES, P. C.; TURKEY, TURKS, P. C.], conquered the Caucasian and Armenian provinces of the empire, and either before or very soon after the accession of Alexius, succeeded in establishing in Asia Minor a kingdom of which the capital was fixed at Nicaea, or Nice, in Bithynia, about a hundred miles from Constantinople.

The disasters of the period were augmented by the increasing bitterness and the complete separation of the Greek and Latin churches [GREEK CHURCH, P. C.], which weakened the small degree of sympathy yet remaining between the East and the West of Europe; and led the latter to regard with comparative indifference the threatening progress of revived Mohammedanism under the protection of the Turkish power.

For the history of this period we have still the chroniclers already enumerated; but Cedrenus ends with the year 1058, and Constantine Manasses with A.D. 1081. To these we may add Joannes Scylitzes Curopalates, the fragments of whose history refer to the period from A.D. 1058 to 1078; Nicephorus Bryennius (not the Emperor so called, but the son-in-law of Alexius Comnenus), whose *Commentarii* give the history of Alexius before his accession to the empire; and Anna Comnena, daughter of Alexius, and wife of this Nicephorus, who has in her *Alexias* given the history of her father's life.

Comnenian Dynasty.

(1081.) ALEXIUS or ALEXIS I. COMNENUS. The commencement of the long reign of this prince was unfortunate: the Turks pursued their conquests on the east, and the Normans, crossing the Adriatic, inflicted some severe defeats on the Emperor. The hostility of the Turks was however repelled, and that of the Normans diverted by the first Crusade; and Alexius, following in the wake of the Crusaders, recovered possession of Asia Minor, with the exception of the inland and mountainous districts. He died A.D. 1118. [ALEXIS COMNENUS I., P. C.; CRUSADES, P. C.]

(1118.) JOANNES II. COMNENUS, or as he is commonly termed CALO-JOANNES, HANDSOME JOHN, given ironically on account of his diminutive stature and homely features, succeeded his father Alexius. His eminent virtues rendered his reign one of the most truly glorious in the Byzantine annals. He repelled the hostile attempts of the Hungarians and others on the Danube, and of the Turks in Asia. A vain attempt to dispossess him of the throne at the commencement of his reign was made by his accomplished but ambitious sister Anna Comnena and her husband Nicephorus Bryennius. [ANNA COMNENA, P. C.] Joannes II. died of a wound received while hunting, A.D. 1143, just as he was on the point of attempting to subjugate the Latin States founded by the Crusaders in Syria. He was succeeded by his son Manuel.

(1143.) MANUEL I. COMNENUS bore, in character, a singular resemblance to our own Richard I. He continued the warlike exertions which his father had made, and against the same enemies; but his intervals of remission from warlike toil were spent in indolence, his wars and luxuries alike exhausted his subjects, and his long struggles merely maintained, without extending, the limits of the empire.

(1180.) ALEXIUS or ALEXIS II. COMNENUS ascended the throne on the death of his father Manuel I. He was only ten years of age at his accession, and was under the guardianship of his mother Maria: but both mother and son were, in about three years, put to death by Andronicus Comnenus, son of Isaac Comnenus, who was a younger son of Alexius I.

(1183.) ANDRONICUS I. COMNENUS then usurped the throne, but after a reign of two years was murdered by the people of Constantinople. [ANDRONICUS COMNENUS, P. C.] In him the male line of the Comneni ends. He was succeeded by Isaac Angelus, whom he had attempted to put to death, and compassion for whom had roused the populace against Andronicus.

(1185.) ISAACUS II. ANGELUS was descended from the youngest daughter of Alexius I. His contemptible reign was marked with the final loss of the isle of Cyprus, usurped by a rebel, another Isaac Comnenus, from whom it was taken by Richard I. of England and given to Guy of Lusignan, the expelled King of Jerusalem; and of the territory between the Haemus and the Danube, which was lost by the revolt of the Bulgarians and the re-establishment of their kingdom, the princes of which united themselves and their people to the Latin church. Isaac recovered, however, some parts of the European Albania and Epirus from the Normans of Italy and Sicily. Isaac was dethroned and blinded after a reign of ten years by his own brother, Alexius, who succeeded him.

(1195.) ALEXIUS or ALEXIS III. ANGELUS or COMNENUS (which latter name he assumed), after an unfortunate reign in which he was defeated by the Turks in Asia Minor and by the Bulgarians and Comani in Europe, was dethroned by Alexis, son of Isaac II., who was assisted by the Crusaders of the fourth Crusade.

(1203.) ISAACUS II., the deposed and blinded emperor, and his son ALEXIUS or ALEXIS IV. ANGELUS, were, in consequence of this revolution, placed on the throne; but a revolt of the people, excited by Alexius, a prince of the house of Ducas, led to their deposition and to the murder of Alexius IV., whom Isaac II. soon followed to the grave. The branch family of the Angeli, and indeed the dynasty of the Comneni, ends with these princes.

(1204.) ALEXIUS or ALEXIS V. DUCAS, surnamed MURZUPHLUS, *i.e.*, of the SHAGGY EYEBROWS, the successful revolter, succeeded to the throne (which a shadow of an emperor, NICOLAUS CANABUS, had for an instant occupied), but was at once besieged, and after a few months taken prisoner and put to death by the Crusaders, who captured Constantinople, divided a considerable part of the conquered territory into several Latin principalities, and established a line of Latin princes on the throne of the Eastern Empire. [BALDWIN I., Emperor of Constantinople, P. C.; DANDOLO, ENRICO, P. C.]

The period from the accession of Alexius I. to the capture of Constantinople by the Latins is one of great vicissitude. Alexius I. found the empire reduced in limits and exhausted in resources; but his dexterity in availing himself of the results of the first crusade, and the ability and valour of his successors Joannes II. and Manuel I. extended the limits without perhaps materially increasing the strength of the empire. From the death of Manuel we have a period of rapid contraction and of decline, the Seljukian Turks gradually recovering a considerable part of what they had lost in Asia Minor: until the empire was limited to Thrace, Macedonia, Epirus, Greece and its islands (of which, however, Candia and others were lost by the events of 1204), and a portion of Asia Minor, especially on the coast. Of this diminished territory a considerable part fell with the capital into the hands of the Latins. Of that part which escaped their power, the eastern coast of the Euxine was appropriated to form the new Greek empire of Trebizond or 'Anatolia' [TREBIZOND, EMPIRE OF, P. C.]; and two other fragments were detached in the west to form the despotates of Epirus and Thessaly, the former of which, though sometimes tributary to the Eastern Empire, was never again incorporated with it. [ALBANIA, P. C.] The remainder of the independent portion of the Greek empire, the rulers of which assumed the imperial title, fixed the seat of their government at Nicaea, or Nice, in Asia Minor, and afterward recovered Constantinople, will be regarded as the connecting link between the overthrown and the restored Greek empire. All these states were formed by the Greeks almost immediately after the fall of Constantinople.

The history of Alexius I. is contained in Zonaras and Glycas; both of whom conclude their Annals with his death, in the shorter work of Joel, in the Metrical Chronicle of Ephraemius, which becomes from his reign now more full and important; and especially in the *Alexias* of his daughter Anna Comnena. [ANNA COMNENA, P. C.] The history of the subsequent period is narrated by Ephraemius and Joel, of whom the latter ends with A.D. 1204; and in the histories of Cinnamus, which comprehends the reign of Joannes II. and nearly the whole of that of Manuel I.; and of Nicetas Acominatus, or Nicetas Choniates, which extends from the death of Alexius I. to the death of Baldwin I., first Latin emperor, A.D. 1206. The Latin authorities, Gulielmus Tyrensis (William of Tyre), and the others contained in the *Gesta Dei per Francos* of Bongarsius, or Bongars, and others not in that collection, are enumerated in Michaud's *Bibliographie des Croisades*. [CRUSADES, P. C.]

Latin Emperors of Constantinople.

(1204.) BALDUINUS I. [BALDWIN I., P. C.], Count of Flanders and Hainault, was appointed Emperor by the victorious crusaders; but was, after a year's reign, captured in battle by the revolted population of Thrace and the Bulgarians their allies, and died in captivity.

(1206.) HENRICUS or HENRY, surnamed ANDEGAVENSIS, of ANJOU, brother of Baldwin I., succeeded him. He died after a reign of incessant warfare A.D. 1216.

(1216.) PETRUS DE CURTENAIO, PETER OF COURTENAY, Count of Auxerre, ascended the throne in conjunction with and in the right of his wife IOLANDIS or YOLANDE, sister of Baldwin and Henry. He never reached Constantinople, but was taken prisoner on his way thither by the despot of Epirus, and died in captivity A.D. 1219. Yolande died soon after.

(1219, or, according to others, 1221.) ROBERTUS, or ROBERT, second son of Peter of Courtenay and Yolande, succeeded to the throne. He was, some time after, expelled by his own subjects, and died A.D. 1228.

(1228.) BALDUINUS II. [BALDWIN II., Emperor of Constantinople, P. C.], youngest son of Peter of Courtenay and Yolande, succeeded his brother Robert; but, as he was a minor, JOANNES BRIENNENSIS (JOHN OF BRIENNE), titular king of Jerusalem, a veteran of nearly fourscore years, was appointed (A.D. 1229) his colleague. John repelled the Nicene Greeks and the Bulgarians, who had besieged Constantinople, and died soon after A.D. 1237. The reign of Baldwin in Constantinople lasted till A.D. 1261, when the city was surprised and recovered by the Greeks under the Cæsar Alexius Strategopulus. Baldwin escaped and survived the event about fourteen years. The principal western historian of this transient Latin empire is Villehardouin, one of the leaders in the capture of Constantinople.

The Greek writers will be noticed when speaking of the authorities for the contemporary Greek emperors of Nice.

Greek Emperors of Nicaea or Nice.

(1204.) THEODORUS I. LASCARIS [THEODORUS LASCARIS, P. C.], in an active reign of eighteen years, re-established the Eastern Empire in a portion of its antient Asiatic territory, of which Nice was made the capital. He had married Anna, daughter of Alexius III. Angelus or Comnenus.

(1222.) JOANNES III. DUCAS VATATZES succeeded Theodore Lascaris by virtue of his marriage with Irene, daughter of Theodore Lascaris, or rather by his merit, which induced that prince to prefer him to his own four brothers. His prudence and valour gradually extended his dominions, until he had recovered nearly all that the Latins had conquered in Asia and Thrace, except Constantinople itself. He crushed the Greek principality, or despotate, of which Thessalonica was the capital, and recovered a portion of territory from the Greek empire of Trebizond. He died A.D. 1255.

(1255.) THEODORUS II. LASCARIS, son of John III., succeeded his father, and died after a reign of four years.

(1259.) JOANNES IV. LASCARIS, a minor, son of Theodore II., succeeded, but he was soon virtually and afterwards openly deposed, and then blinded by Michael Palaeologus, first emperor of the family of the Palaeologi, and first of the restored Greek emperors of Constantinople.

The historians of this period are Georgius Acropolita, whose history just comprehends the period when the seat of the empire was at Nice (A.D. 1204-1261); Nicephorus Gregoras, whose history begins at the same point but comes down later than that of Acropolita; and the Metrical Chronicle of Ephraemius, which ends with the recapture of Constantinople in 1261. The history of Nicetas Choniates comprehends only a year or two after the capture of Constantinople by the Latins.

Restoration of the Seat of the Eastern or Greek Empire to Constantinople.

Family of the Palaeologi.

(1260.) MICHAEL VIII., PALAEOLOGUS, or more fully PALAEOLOGUS COMNENUS, great-grandson, through his mother, of Alexius III., ascended the throne as the colleague of the boy Emperor Joannes IV. In 1261 Constantinople was recovered by Alexis Strategopulus, and Michael restored the seat of government to that city. But if the Latins were expelled, the empire never recovered the extent which it had before the Latin conquest. It had been dismembered on the east and west by the empire of Trebizond and the despotate of Epirus; though the despot of Epirus had, in the reign of Joannes Vatatzes, recognised that prince as his lord paramount. Some petty Latin principalities remained in Greece, especially the Duchy of Athens, which continued till the time of Mahomet II. [Athens, P. C., vol. iii. p. 19.] The important islands of Corfu, Cephalonia, and Candia, were finally separated from the empire by the Venetians or other western powers: Cyprus had been previously lost in the reign of the weak Isaac II. Lesbos, Chios, and Rhodes were however recovered. Michael acted with great prudence: he allowed and encouraged the Venetians, Pisans, and other Latins engaged in commerce or manufactures to remain at Constantinople, or in the suburbs, and established a Genoese colony in the suburb of Galata. His guilt in blinding and exiling his unhappy colleague Joannes was punished by Arsenius, patriarch of Constantinople, with excommunication; and the retaliatory measure of the deposition of Arsenius led to serious schism in the church of nearly fifty years' duration. A hypocritical union with the Latin church, ratified at the Council of Lyon, A.D. 1274, augmented the religious troubles of the Greeks, though it averted the threatened attempts to re-establish the Latin throne of Constantinople. Michael died A.D. 1283.

(1283.) Andronicus II. Palaeologus, or more fully Ducas Comnenus Angelus Palaeologus, distinguished as the Elder [Andronicus Palaeologus, P. C.], succeeded his father Michael VIII.; and reversing the policy which Michael had pursued, dissolved the hollow union of the churches and was excommunicated by the Pope (A.D. 1307.) His reign is marked by the establishment in Asia Minor (about A.D. 1300) of the rising monarchy of the Osmanli, or Ottoman Turks, so called from Othman their founder, in place of the declining kingdom of the Seljukians, which was finally overthrown (A.D. 1307) by the Mogul ...ans of Persia, the descendants of Zinghis or Gengis Khan. [Turkey; Turks, P. C., vol. xxv. p. 395, &c.] The devastating invasion of the remaining Asiatic provinces of the Eastern Empire by the Ottomans was repelled by some Catalan and other mercenaries under Roger de Flor, whose assassination, by order of Andronicus, in consequence of the disasters occasioned by him and his men, led to intestine war, which was at length ended by the retreat and establishment of the Catalans in the Duchy of Athens. The closing years of the reign of Andronicus were clouded by another intestine war or succession of wars between himself and his grandson and colleague Andronicus III. (A.D. 1321-1328), who obliged the old emperor to abdicate. Andronicus died four years after his abdication (A.D. 1332.)

(1328.) Andronicus III. Palaeologus, or more fully Ducas Comnenus Angelus Palaeologus, distinguished as the Younger, succeeded on the abdication of his grandfather. He was defeated by the Catalans of Athens, and by the Turks, who conquered all or nearly all of the empire that remained in Asia Minor. Rhodes, after a short period of virtual independence, had been occupied by the Knights of St. John of Jerusalem [Hospitallers, P. C.], in the reign of Andronicus the Elder. Andronicus III. died A.D. 1341.

(1341.) Joannes V. Palaeologus, called by some Joannes Palaeologus I., and (1342) Joannes VI. Cantacuzenus, or more fully Angelus Comnenus Palaeologus Cantacuzenus. Some writers number these princes differently, making Palaeologus Joannes VI., and Cantacuzenus Joannes V. Palaeologus, while yet a minor, succeeded his father, Andronicus I., under the guardianship of Cantacuzenus, who had been chief minister and captain of Andronicus III. The overthrow of Cantacuzenus's power and his condemnation to death drove him to rebellion, and he was crowned at Adrianople A.D. 1342. A civil war, in which Turks, Bulgarians, Servians, and Latins were engaged as auxiliaries or mercenaries, ended favourably for Cantacuzenus: and he became the recognised colleague of Palaeologus, who accepted his daughter in marriage. Cantacuzenus was again crowned, A.D. 1347, at Constantinople. The fierce theological controversy about the light of Mount Tabor [Barlaam, P. C.] added to the agitation of the period: and a new civil war between the emperors broke out A.D. 1353, in which the Turks aided Cantacuzenus, but which ended in his abdication (A.D. 1355), and his retirement to a monastery, where he employed himself in writing a history of his own time (from A.D. 1321 to 1357) and where he died. From the abdication of Cantacuzenus begins the actual reign of Joannes Palaeologus, which was marked by the extension of the power of the Turks in Europe, and their capture of Adrianople (A.D. 1361), which they made their capital. They first gained a permanent footing on the European side of the Dardanelles in A.D. 1354, during the second civil war between Cantacuzenus and Palaeologus, by capturing the castle of Tzympe, now Chini or Jemenlik, near Gallipoli. [Turkey, Turks, P. C., vol. xxv. p. 396.] Palaeologus, to save the relics of his empire, now reduced to Constantinople and the immediately adjacent parts of Thrace, and some portions of Macedonia, Northern Greece, and the Morea, hastened into the west to solicit aid from the Pope and the western princes, to obtain which he professed himself a Roman Catholic: but he not only failed in his purpose, but was arrested for debt at Venice. Released by the intervention of his son Manuel, despot of Thessalonica, he returned home, where he had to suppress a revolt of his son, Andronicus (A.D. 1385), who was taken prisoner and condemned to lose his sight. The operation of blinding was not effectually performed, and Andronicus escaped and imprisoned his father, but was obliged to release him. He obtained, however, the cession of a portion of Thrace, which was formed into the vassal principality of Selybria. Joannes Palaeologus died, after an unhappy reign, in A.D. 1390 or 1391.

(1391.) Manuel II. Palaeologus succeeded his father, Joannes V., during whose life he had shared both the name and exercise of sovereignty. He was attacked by the Turks, and by his brother Andronicus, prince of Selybria; but made a treaty with the latter, left him in Constantinople as regent if not co-emperor; and visited Italy, France, England, and Germany (A.D. 1400-1402), to solicit aid against the Turks. Bajazet, the Turkish sultan [Bayazid I., P. C.], meanwhile threatened the overthrow of Constantinople and the extinction of the empire, which was saved rather by the opportune victory of Timour or Tamerlane [Timur, P. C.] over the Turks at Angora, and the captivity of Bajazet (A.D. 1402), than by Latin aid. Manuel recovered to the empire the whole of the Morea. He died A.D. 1425.

(1425.) Joannes VII., Palaeologus, surnamed Porphyrogenitus or Porphyrogennetus sometimes called Joannes Palaeologus II., succeeded his father Manuel, and followed the same policy of seeking aid from the west, to conciliate which he brought about the hollow union of the Greek and Latin churches at the council of Florence, A.D. 1439, to be present at which, he visited Italy. He ruled personally in Constantinople: the fragments of the empire in the Morea and in the Tauric Chersonnesus, the Crimea, were ruled by his brothers as his vassals. His reign precipitated the downfall of the empire, for his project of union with the Latin church disgusted his subjects; the allies secured by it were defeated by the Turks at Varna A.D. 1444 [Murad II., P.C.], and the Turks attacked the Morea and allowed its ruler, Constantine, the Emperor's brother, to retain it only on condition of paying tribute. Joannes VII. died A.D. 1448.

(1448.) Constantinus XIII. (some call him XII.) Palaeologus, surnamed Dragases, last emperor of the East, succeeded his brother Joannes VII. He resigned his possessions in the Morea to his brothers Demetrius and Thomas. His brief reign was ended by the capture of Constantinople by the Turkish Sultan Mahomet II. A.D. 1453. Constantine fell bravely in the defence of his capital; and the empire of the East fell with him: its dismembered portions were subdued by the ambitious and powerful Mahomet a few years after, except such as were occupied by the stronger hand of the Latins. Demetrius and Thomas Palaeologus were expelled from the Morea in or soon after A.D. 1460; the empire of Trebizond was extinguished in A.D. 1464, and all the valour of Scanderbeg [Scander-Beg, P. C.], who died a fugitive in A.D. 1467, did not prevent the final subjugation of Epirus. [Mahomet II., P. C.]

Thus were extinguished the name and the last remains of the Roman state. From its reputed foundation by Romulus it had subsisted for twenty-two centuries; from the settlement of the empire by Augustus nearly fifteen centuries; a duration as yet unexampled in the history of the world, unless it be in China. From the establishment of Constantinople by the first Constantine to the capture of the city in the time of the last Constantine, that magnificent city was never in the possession of an enemy except during the half century of Latin occupation, and even then the continuity of the Imperial power was hardly interrupted though the seat of empire was temporarily fixed at Nice. The despotic character of the government, if it prevented the growth of that national spirit and character which really constitute the strength and prosperity of a nation, yet prevented the dissolution of the empire, which presents amid frequent disasters a remarkable cohesiveness and unity, until the Latin conquest in A.D. 1204. But as from the same despotism the prosperity of the empire depended on the personal character of its ruler, its history exhibits alternations of decline and recovery according as the emperors were men of feeble character or of vigour and ability; but each instance of the recovery generally fell short of its predecessors. During the temporary fluctuations of the condition of the empire, the tide of its greatness and prosperity was gradually ebbing. Theodosius the Great died in possession of the whole extent of the empire both in the east and west. Justinian recovered only a portion of the latter. Heraclius saved the empire from extinction at the hands of the Persians, and effectively crushed their power; but he did not recover what had been taken by the Lombards in the west, and Africa and Palestine, which were wrested from his successors by the Saracens, were never recovered. The revival effected in the Macedonian period by Basil I., Nicephorus, John Tzimiscea, and Basil II., fell short of that of Heraclius; and that of the earlier Comneni fell short of the success of the Macedonian princes. The restored empire of Lascaris and Vatatzes, never more than a fragment of the empire of the Comneni, grew less and less until its extinction by the Turks. Yet this fragment preserved the name of the 'Roman Empire,' which it has transmitted to the provinces of modern Turkey, Roumelia or Rum-ili in Europe, the last seat of the Byzantine Empire [RUM-ILI, P. C.], and Roum or Rúm, in Asia Minor, the seat of the empire of Trebizond.

The history of the last period of the empire is contained in the 'Roman History,' or rather 'Romaic History,' of Nicephorus Gregoras (from A.D. 1204 to 1351); in the history of the emperors (from Michael Palaeologus to Andronicus the Elder, A.D. 1308) by Georgius Pachymeres; in the history of the Emperor Joannes Cantacuzenus, containing the account of his own time; in the 'Historia Byzantina' of Ducas, especially including the reigns of the two Johns, V. and VI., and their successors to 1462; in the Chronicle or Annals of Georgius Phrantzes or Phrantza, from the recovery of Constantinople in 1261 to A.D. 1477; and in the History of the Turks by Laonicus Chalcocondyles. We do not mention the contemporary Latin historians whose works include notices of Byzantine history; and of modern historians we shall only mention Ducange, Le Beau, with his continuator Ameilhon, and Gibbon. Much valuable information is contained in the articles on the Byzantine Emperors and other eminent personages connected with the Eastern Empire, chiefly written by Dr. Plate in Dr. Smith's *Dictionary of Greek and Roman Biography*. Gibbon's *Decline and Fall of the Roman Empire*, with all its admirable qualities, is unsatisfactory as a history of the Eastern Empire. The unity which he has given to his episodes has destroyed that of his main subject; and we have to gather from different parts of his work the various portions which constitute the history of a reign or period. The empire itself is forgotten while we follow his absorbing narratives of the migrations of the Huns, the conquests of the Saracens or Moguls, and the vicissitudes of the Crusades; and the Byzantine history, interesting and important as it is, is yet to be written in a form suitable for the English reader.

ROMANELLI, GIOVANNI FRANCESCO, was born at Viterbo in 1617. He studied a short time with Domenichino, but he is chiefly known as the scholar of Pietro da Cortona; and he was one of the principal hangers on of Bernini, who appears to have selected Romanelli as a rival to Carlo Maratta and the school of Sacchi; and even to Pietro Cortona himself. Romanelli's picture of the Deposition, in the church of Sant' Ambrogio della Massima, gave him a temporary reputation above all his rivals, which induced Pietro da Cortona to paint a picture for the same church, his San Stefano, which, when it was hung up in its place, so far eclipsed the picture of Romanelli, that Bernini himself observed that it was easy to see who was the master and who the scholar. Romanelli showed more delicacy of execution but considerably less power than Cortona. There is a Presentation in the Temple in one of the chapels of St. Peter's, worked in mosaic, from a picture by Romanelli which is in the church of the Certosa. He was twice in Paris with his patron Cardinal Barberini, and he died at Viterbo in 1662, when about to set out with his family upon a third visit to that capital. There is a large copy of Guido's Triumph of Bacchus at Hampton-Court, by Romanelli.

(Pascoli, *Vite de' Pittori &c. Moderni*; Lanzi, *Storia Pittorica*, &c.)

ROMBERG, ANDREAS and BERNHARD, eminent German composers, were the eldest sons of brothers who enjoyed a considerable share of reputation as instrumental performers during the middle and latter part of the last century.

ANDREAS was born at Osnabruck in 1767; BERNHARD in 1770. Both held appointments in the royal chapel of the Elector of Cologne, at Bonn, about the year 1790. The former was distinguished by his superior performance on the violin; the latter as an almost unrivalled player on the violoncello; and both by their compositions, even at that early period of their career. The progress of the French armies at the commencement of the revolutionary war drove the two cousins to Hamburg, where their talents immediately procured them engagements. In 1795 they quitted that city, and visited many parts of Germany and Italy, establishing their reputation, wherever they presented themselves, as professors of the first class. They returned to Hamburg in 1797, where the elder remained; but the younger left that city two years after, and proceeded alone through England and Spain to Lisbon, and subsequently obtained a good situation in the royal chapel at Berlin. Andreas in the meantime turned his attention more exclusively to composition, and produced four operettas; he also set Schiller's 'Ode to Music.' For the church he wrote a 'Dixit Dominus' and a 'Te Deum,' each for four voices, and a 'Pater Noster' for three, besides many psalms. For the chamber or concert-room he composed much music, Schiller's 'Song of the Bell' ('Das Lied von der Glocke'), among other things, which is well known to connoisseurs in every part of Europe. He also produced two full operas, 'Die Grossmuth des Scipio' ('The Magnanimity of Scipio'), and 'Die Ruinen von Paluzzi' ('The Ruins of Paluzzi'), the drama of the latter from Mrs. Radcliffe's 'Italian;' and, if an opinion of the work may be formed from a pianoforte arrangement, it seems to be an opera that might be successfully adapted to one of our musical theatres.

Bernhard, while in Berlin, wrote two operettas and much instrumental music, particularly for the violoncello. Both cousins indeed were for a time chiefly known as authors by their compositions for their respective instruments. Their posthumous fame is mainly attributable to their symphonies and overtures, the best of which have become familiar to the amateurs of this country by the admirable performance of them at the concerts of the Philharmonic Society.

Andreas Romberg died in 1821, and leaving a family in embarrassed circumstances, a concert for their benefit was generously got up in London by the Philharmonic Society, which afforded them temporary relief. Bernhard was appointed one of the professors at the Conservatoire de Musique at Paris, in 1801, and created Chevalier of the Legion of Honour, but retired from the office two years after. He came to London a second time in 1814, when the allied sovereigns visited this country, and gave a concert, by which he was no gainer, either in purse or reputation; for imprudently, not to say presumptuously, fixing his tickets of admission at a guinea, his auditors were few, and his own performance too plainly announced either the decay of his powers, or that he had not kept pace with others in the improvements of his art. He died in 1841.

(*Biographisches Lexicon*; *Harmonicon*, vol. ix.)

ROMISH CHURCH. An account has been elsewhere given [PATRIARCH, P. C., vol. xvii. p. 317] of the rise and nature of the patriarchal dignity. It may be added to what is there stated, that the increase in the number of these dignitaries in the fifth century was occasioned by the erection of the bishopric of Jerusalem (which had previously been subordinate to the archbishopric of Caesaraea) into a patriarchate. It is a curious illustration of the little reverence actually paid to superior antiquity and apostolic origin, that the Christian Church first established, and which enjoyed, at its origin, the care and instruction, not of one only of the apostles, but of all, was the last which received the highest ecclesiastical rank; and hardly ever were its patriarchs enabled to compete in power and influence with their fellows of Rome or Constantinople, Alexandria or Antioch.

We here give a table of the patriarchs down to the capture of Constantinople and the overthrow of the Eastern Empire, A.D. 1453. We give the occupants of the patriarchal sees from the time of their asserted foundation, with the date of the accession of the respective bishops or patriarchs, according to the generally received computation: but we may observe that the succession of the earlier bishops is very obscure, and that the asserted apostolic foundation of the several churches (with the exception of Jerusalem) is quite destitute of Scriptural support, and has been vehemently disputed: not to speak of the question as to whether the government of the primitive Church was, in the modern sense of the word, episcopal or not. The bishops of Constantinople before Metrophanes, who was bishop in the early part of the fourth century, are especially doubtful.

In the fourth century the succession is perplexed by the schism occasioned by the Arian controversy; and from the sixth century, owing to the Jacobite schism, there has been a double succession in the patriarchates of Alexandria (the Jacobite patriarchs of which are sometimes, from their nation, called the Coptic patriarchs) and Antioch: and the perplexity in the patriarchate of Antioch has been occasionally increased by the rivalry of contending Jacobites, as in the schisms of the thirteenth, fourteenth, and fifteenth centuries. After the conquest of Palestine and the greater part of Syria, by the first crusaders, and the capture of Constantinople in the fourth crusade, the confusion was made still greater by the appointment of Latin patriarchs at Antioch, Jerusalem, and Constantinople. In order to prevent mistake, we give in Roman letter the prelates who were regarded by the Greek government and church as the legitimate holders of the see, without regard to the orthodoxy or heterodoxy of their opinions individually: the Jacobite prelates are given in italics, and the Latin patriarchs of the East in small capitals. We give the names in the usual Latin form, which has, in most cases, continued in use in English books; the few cases in which the names have been Anglicized will cause no difficulty, as the reader will easily recognise John in Joannes, Peter in Petrus, Mark in Marcus, Theodore in Theodorus, &c.

The list of the popes given elsewhere [Pope, P. C., vol. xviii. p. 405] is repeated here for the convenience of comparing dates, &c. The chief authorities employed by us are Le Quien, *Oriens Christianus*; Fabricius, *Bibliotheca Graeca*, vols. vi., viii., x., xi., xiv., ed vet., viii., ix., xi., ed Harles; the *Tractatus Praeliminares*, given in the *Acta Sanctorum* of the Bollandists, *Maii*, vol. iii., *Julii*, vol. iv., *Augusti*, vol. i.; Bandurius, *Imperium Orientale*, vol. i., p. 187, &c.; and *L'Art de Vérifier les Dates*. The lists in Fabricius are generally taken from the *Acta Sanctorum*, so that these two authorities are, in most cases, identical.

When two years not consecutive are assigned as the date of accession, it must be understood that the time of accession is not agreed upon, but that it occurred either in the years marked, or in the interval between them. Dates at the end of a name show that the person named was patriarch in that year or in those years, but that the year of accession is unknown. A, subjoined to a name, denotes Arian; M, Monothelite; Ic., Iconoclast; J, Jacobite, or Monophysite; H, Heretic (reputed), without refference to the nature of his heresy.

336, Marcus				
336-337, Julius I.	341, *Gregorius*, A.	345, Stephanus I., A.		

* It is very doubtful if there were more Popes than one of the name of Cletus or Anacletus at this early period; and whether, if there was only one, he is to be placed before or after Clemens I.

† Eustathius was deposed by the Arians, to whose doctrines he was earnestly opposed, and died in exile. A party of his adherents broke off from the church and formed a sect which existed for some time under the name of Eustathians.

‡ Most of the authorities give the bishops between Onesimus and Olympianus in the following order; and omit the length of each episcopate, which, as given above, is evidently too great, as may be seen by adding them together.

Polycarpus I.	Sedecion	Eleutherius	Polycarpus II.	Euzoius	Alypius
Plutarchus	Diogenes	Felix	Athenodorus	Laurentius	Pertinax

* Previous to or during the Patriarchate of Apollinaris the Gaianists had elected Elpidius for their patriarch, while the Theodosians elected Dorotheus: then the two sects united to choose Joannes, a monk, for their Patriarch; or rather, as the passage in Theophanes, which is evidently corrupt, may be understood, accepted the Theodosian Dorotheus as bishop of the united body, which appears to have held Monophysite or Jacobite principles. See Theophanes, *Chronographia*, A.M. 6057 Alex. æra = A.D. 565. Petrus, who succeeded either Joannes or Dorotheus, appears in our table, with the succeeding Jacobite patriarchs. The orthodox (or Melchite) patriarchs who admitted the authority and held the doctrines of the Council of Chalcedon, were however recognised by the Byzantine Emperors and by the Greek Church.

† From the time of Meletius to that of Flavianus, the succession is very much perplexed. Meletius, who was orthodox, was deposed and exiled, and his successors Euzoius and Dorotheus, though Arians, were recognised by the Byzantine government. The orthodox withdrew with Meletius, whom they still recognised for their Patriarch, on whose death Flavianus was elected by them. The Eustathian seceders, already noticed, continued separate from the Meletians, and in A.D. 388 or 389 elected Evagrius for their patriarch; but his death, and that of Dorotheus, and the overthrow of the Arian party, left Flavianus in or soon after A.D. 392 in sole possession of the patriarchate.

CONSTANTINOPLE.

A.D.
705, Cyrus
711-712, Joannes VI.
715, Germanus I. abdicated
730, Anastasius, Ic.
754, Constantinus II., Ic.
766, Nicetas I., Ic.
780, Paulus IV.
784, Tarasius
806, Nicephorus I. banished
815-816, Theodotus I. Cassiteras, Ic.
821, Antonius I., Ic.
832 Joannes VII., or Jannes Lecanomantes, Ic., deposed
842, Methodius I.
846, Ignatius, deposed
857, Photius, deposed
867, Ignatius restored
877, Photius, restored but again deposed
886, Stephanus
893, Antonius II.
895-896, Nicolaus I. Mysticus, deposed
906, Euthymius I. deposed
911, Nicolaus I. restored
925, Stephanus II.
928, Tryphon
931-933, Patriarchate vacant
933, Theophylactus
936, Polyeuctus
970, Basilius I. Scamandrinus, banished
974, Antonius III. Studita, abdicated
979-982, Patriarchate vacant
982-983, Nicolaus II. Chrysoberges
995-996, Sisinnius II.
999, Sergius II.
1019-20, Eustathius
1025, Alexius or Alexis
1043, Michael I. Cerularius, deposed

JERUSALEM.

A.D.
705, Patriarchate re-established in the person of Joannes V. who died, according to some, in A.D. 735
735, Eusebius or Basilius, but his existence is doubtful
742-754, Theodorus, who, according to some authorities, was still patriarch in 767
Basilius or Eusebius, said to have been patriarch in 772 or 773, but his existence is doubtful
Elias II. Some authorities place his exaltation in 760; others some time before 785, when he was expelled by Theodorus, a monk
785, *Theodorus*, usurper
Elias II. restored, and died A.D. 807 at latest
796-799? Georgius I. or Gregorius I., or Sergius I.
801-803, Fortunatus? but he was probably not patriarch of Jerusalem
801-807, Thomas I.
821-829, Basilius
835-843, Sergius
856-859, Salomon
862-863, Theodosius
879, or perhaps earlier, Elias III.
907, Sergius II. or Georgius II.
911, Leo or Leontius
927-928, Anastasius or Athanasius I. His existence is doubtful
928, Nicolaus I., also doubtful
Christophorus, or Christodorus, or Christodulus, in A.D. 937
Agathon, or Agathonus. His existence is doubtful
Joannes VI., burnt by the Saracens A.D. 969
Christophorus, or Christodorus, or Christodulus II.
Thomas II.
Josephus
Alexander, some time in the reign of the Byzantine Emperor, Basilius II., *i. e.*, from A.D. 976 to 1025; but his existence, at least his occupation of the patriarchate, is doubtful
Agapius. His patriarchate is doubtful
984, or later. Jeremias, or Joannes, or Orestes, martyred, or died from injuries received, A.D. 1012
1009? Theophilus I.
1010? Arsenius I. perhaps till A.D. 1023
Jordanus in A.D. 1033
Nicephorus I. in A.D. 1048, but some place him before Arsenius and Jordanus
Mennas. His existence is very doubtful

ROPES, RIGIDITY OF. [RIGIDITY OF ROPES, P.C.S.]

ROSALI'NA. [FORAMINIFERA, P. C. S.]

ROSELLI, COSIMO, a celebrated old Florentine painter, was born at Florence, according to Gayo, in 1439. There are few of his works remaining; the principal is the fresco in the convent of Sant' Ambrogio, at Florence, painted in 1456, according to an inscription seen upon it by Rumohr, when Cosimo cannot have been more than eighteen years of age according to the above date: Vasari however says it was painted in his youth. And Rumohr observes that Cosimo, in the commencement of his career, followed the path which was opened by Angelico da Fiesole and Masaccio; but that after a few brilliant examples of his ability, he left the approximation of the representation of things as they really appear, to follow an uninteresting, inanimate, and ugly manner. The fresco represents the transportation of a miracle-working chalice from the church of Sant' Ambrogio to the episcopal palace; the abbess and nuns follow in the procession, and at the palace-gate is a group of priests and choristers ready to receive it: around is a crowd of curious spectators. The story is told, and the picture described, in Richa's 'Chiese di Firenze.' The picture has been engraved by Lasinio for his series of old Florentine paintings, and there is a group from it in Lastri's 'Etruria Pittrice.'

Cosimo was one of the painters invited by Pope Sixtus IV. to Rome to paint the Cappella Sistina, built in 1473, by Baccio Pintelli [PINTELLI, P. C. S.], for that pope. Cosimo's paintings in this chapel are still in good preservation; they are—the Destruction of Pharaoh's Host in the Red Sea, in which the Israelites are also represented returning thanks for their deliverance; Moses receiving the Tables of the Law while the Israelites are worshipping the golden Calf; the Sermon on the Mount and the healing of the Leper; and the Last Supper. The landscape of the third picture was painted by Cosimo's pupil, the eccentric Piero di Cosimo, afterwards the master of Andrea del Sarto. These works were painted for a prize in competition with others in the same chapel by Sandro Botticelli, Domenico Ghirlandajo, Don Bartolomeo, Luca da Cortona, and Pietro Perugino. Cosimo was very anxious to get the prize, but he doubted his ability, at the same time that he had little faith in the pope's judgment; he therefore, knowing his weakness in composition and design, painted his picture very high in colour, and used plenty of ultramarine and gold, counting upon attracting the pope's fancy by his gaudy display. When the pictures were all uncovered, his fellow painters laughed at Cosimo for his puerilities. Cosimo however proved himself a good man of the world, if not a good painter; his gay works fixed the pope's attention and he obtained the prize; the other painters were censured by his holiness for not using finer colours, and they were obliged to retouch them and heighten their effect in the same manner, to the great triumph of Cosimo, whose works however were in reality inferior to all the others.

Cosimo Roselli was still living in 1506: Vasari says he was sixty-eight years old when he died; if therefore he were born in 1439, 1507 may have been the year of his death. He was the master of Fra Bartolomeo.

(Vasari, *Vite de' Pittori*, &c., ed. Schorn; Rumohr, *Italienische Forschungen*; Platner und Bunsen, *Beschreibung der Stadt Rom.*, vol. ii., pt. 1; Gaye, *Carteggio inedito d'Artisti*, vol. ii., ap. 1.)

ROSELLI'NI, IPPO'LITO, Cavaliere, was born August 13, 1800, at Pisa. His father was a merchant, and Rosellini himself was designed for his father's business; but he acquired such a love of the study of antiquities from his first tutor, Padre Battini, a Servitant monk of St. Antonio, who was a tolerable numismatist, that he commenced at an early age to give himself up to those studies for which he afterwards distinguished himself, and the mercantile career was wholly abandoned. In 1821 he finished his university studies in Pisa, and took the degree of Doctor of Theology. He afterwards studied the Oriental languages for three years with the celebrated (now Cardinal) Mezzofante at Bologna; and in 1824 he was appointed professor of Oriental languages in the university of Pisa. In 1825 he appears to have devoted himself with much zeal to the study of Egyptian hieroglyphics, following the steps of Champollion, of whose discoveries he was an ardent advocate. When Champollion, in 1826, for the further development of his system, examined the Egyptian monuments in Rome, Naples, and Turin, Rosellini, by the permission of the Tuscan government, attended him in his researches; and he accompanied him to Paris, and there spent the autumn of that year in similar researches: he published also in the same year an explanation of an Egyptian monument in the gallery degl' Uffizj at Florence.

In the autumn of 1827 the Grand Duke Leopoldo II. granted Rosellini a year and a half leave of absence, with funds for himself and six companions, to carry out his design of personally exploring the monuments of Egypt. After a considerable delay in Paris the French government of Charles X. determined upon sending Champollion with five companions upon a similar expedition at the same time, and they all embarked together at Toulon, July 31, 1828, and landed on the 18th of August following in Egypt, where they remained fifteen months, exploring all the principal monuments of Egypt and Nubia.

Rosellini arrived at Pisa January 6, 1830, and commenced immediately a course of lectures on the Egyptian hieroglyphics, the substance of which is in the 'Elementa Linguæ Ægyptiacæ' of Padre Ungarelli, published at Romo, in 1837. Rosellini had himself made his principles known in a letter to M. Peyron, in 1831. Tho great results of the expedition however were to appear in a joint production by Champollion and Rosellini; the former undertaking to explain all the historical monuments, and Rosellini the civil and religious. This design was however rendered impossible by the death of Champollion, which took place March 5, 1832, and Rossellini expressed his sincere regret and disappointment in a eulogium on his departed friend, which he published under the following title:—'Tributo di riconoscenza ed amore alla memoria di Champollion.' Rosellini was thus compelled to undertake the whole work himself, which was his original design, and the prospectus explaining the plan of the work had already appeared in January, 1831. Accordingly in November, 1832, appeared the first volume of 'I Monumenti dell' Egitto e della Nubia,' by Rosellini alone, explaining the historical monuments; the second appeared in 1833; and by 1836 three more, explaining civil monuments, were published; but between the publication of the fifth and sixth volumes a long interval occurred, partly through Rosellini's appointment as librarian of the university of Pisa, but chiefly through a serious illness with which he was afflicted in the chest, and which incapacitated him for nearly two years. At the same time, with the above volumes of letter-press, appeared two large folios of illustrations, the historical monuments in 1832, and the civil in 1834. The description of the historical monuments was completed in 1838-41, in two volumes, the third being divided into two parts, making in all four volumes in five on the historical, and three on the civil monuments, and these were all that were published during Rosellini's lifetime. The remaining part were the religious monuments of the Egyptians, which he was occupied upon until the period of his death, and though he did not live to see the publication, he completed the MS. of this part.

In 1839 he gave up the professorship of Oriental languages and commenced a series of archæological lectures; but in 1841 these labours were remitted him on account of his extremely bad health, and in order that he might bestow what time he could devote to study to the completion of his great work on Egypt. On the 16th of May, 1843, however, his case was found hopeless, and he died on the 4th of June following, in his forty-third year. The third part of the work was published in 1844, under the direction of the professors Bonaini and Severi, in one volume of illustrations and one volume of text.

This great work on Egypt, yet unrivalled as a review of Egyptian art and customs, though in a scientific-literary view it treads only upon the threshold of Egyptian history and antiquities, may be thus briefly described:—its title is—'I Monumenti dell' Egitto e della Nubia disegnati della Spedizione Scientifico-Letteraria Toscana in Egitto, distribuiti in Ordine di Materie, interpretati ed illustrati del Dottore Ippolito Rosellini'—The Monuments of Egypt and of Nubia drawn by the Tuscan Literary and Scientific Expedition in Egypt, arranged according to their Subjects, and explained and illustrated by Dr. Ippolito Rosellini. It is in three parts, each of which is in one large folio volume with illustrative letter-press in octavo. The first volume, Tavole, M. R., contains the historical monuments, *Monumenti Storici*, in 169 plates, with four volumes of text, 1832-41; the second, Tavole M. C., contains the civil monuments, *Monumenti Civili*, in 135 plates, with three volumes of text, 1834-36; and the third, Tavole, M. D. C., the monuments of religious worship, *Monumenti del Culto*, in 86 plates, with one volume of text, 1844. An index of the whole work is said to be in preparation by Rosellini's pupil Giuseppe Bardelli, who published a short life of Rosellini at Florence in 1843—'Biografia del Professore Ippolito Rosellini,' of which an abstract appeared in the 'Allgemeine Zeitung' and in the 'Kunstblatt' in the following year; the latter notice has been used in the biographical portion of this article. Rosellini bequeathed his Egyptian MSS. to the university of Pisa; the drawings and plates are all the property of the Grand Duke. Among the MSS. is a voluminous but unfinished 'Diccionario Geroglyphico,' Hieroglyphic Dictionary, with several thousand names.

ROSHAN is a small tract, and a part of that immense region of Central Asia which is called Turan or Independent Turkistan. It lies between 37° and 38° N. lat., and between 70° and 72° E. long., but its extent is not well known, as the country has never been visited by Europeans. It is a very mountainous tract, being traversed in every direction by those ranges which constitute the western declivity of the Bolor Tagh, and surround the elevated table-land of Pamir. Along its southern boundary runs the river Oxus, which in these countries is called Panj. Its course is here so rapid that it cannot be crossed for the greater part of the year. This circumstance, and the great quantity of snow which covers the higher portions of the mountains for nine or ten months, render the country almost inaccessible except after midsummer, and in tho month of January, when the river, notwithstanding its rapidity, is frozen over in many places. Tho cultivation of grain is limited to wheat and barley; several kinds of fruit are plentiful, especially stone-fruits. The mulberry-tree is much cultivated, and the fruit is used for making flour. Horses are not numerous: the camel with two hunches is the principal beast of burden. Cattle and sheep, both of the usual description, constitute the principal stock. The inhabitants, whose number is stated not to exceed a thousand families, speak a peculiar language. The sovereign of this country is dependent on the khan of Kunduz, but this dependance is only nominal.

(Wood, *Journey to the Source of the River Oxus.*)

ROSMI'NI, CARLO DE', born in 1758 at Roveredo, in the Italian Tyrol, studied first at Innsbruck, and then in his native town, where he began early to show his aptitude for literary composition by writing several disquisitions on poetry. He afterwards removed to Ferrara, where he published in 1789 a Life of Ovid:—'Vita di Ovidio Nasone,' to which were added a letter by Vannetti on the style and the language of Ovid, and a parallel between the Orpheus of Ovid and the same character in Virgil. This work obtained for Rosmini the honour of being inscribed among the members of the Florentine academy. He next wrote: 'Della Vita di L. Anneo Seneca libri quattro,' Roveredo, 1793. In 1801 he wrote an account of Vittorino da Feltre, a celebrated preceptor of the fifteenth century, and of his system of education: 'Idea dell' ottimo Precettore nella Vita e Disciplina di Vittorino da Feltre e de' suoi Discepoli.' This book may be called a treatise on pedagogy, as well as the next work published by Rosmini on Guarino Veronese, a contemporary of Vittorino da Feltre, and upon his school: 'Vita e Disciplina di Guarino Veronese e de' suoi Discepoli,' 3 vols. 8vo., Brescia, 1805-6. In 1808 Rosmini published an elaborate biography of the learned Filelfo: 'Vita di Francesco Filelfo da Tolentino,' 3 vols. 8vo. His next work was a Life of Trivulzio, a great captain of the sixteenth century: 'Dell' Istoria intorne alle Militari Imprese ed alla Vita di Gian Jacopo Trivulzio detto il Magno Libri XV.,' 2 vols. 4to., 1815, a biography enriched with handsome engravings and valuable documents. The last work of Rosmini was his history of Milan: 'Dell' Istoria di Milano Libri XVIII.' This history embraces the period from the reign of Frederic Barbarossa down to 1535, when Milan was annexed to the dominions of Charles V. Tho author wrote a continuation of it down to the beginning of the reign of the Empress Maria Theresa in 1740, which continuation is still inedited. Rosmini ranks among the principal Italian biographers of our times. He died at Milan in 1827.

(Tipaldo, *Biografia degli Italiani illustri.*)

ROSSI, ROSSO DE', or IL ROSSO, called in France, Maître Roux, a celebrated Florentine painter, was born in Florence in 1496. He studied the works of Michael Angelo, and was distinguished for the boldness and freedom of his style. He executed several works in various cities of Italy, but his paintings are not numerous in Italy, as he passed the best portion of his career from about 1530 in the service of Francis I. at Fontainebleau, where he superintended all the works of the palace, with a princely allowance, and a house in Paris, given to him by Francis. In the year 1541, however, while still at Fontainebleau, a few hundred ducats were stolen from him, and he accused his friend and assistant Francesco Pellegrini of the theft, who was put to the torture and was declared to be innocent. Rosso's sorrow for what had happened, and the taunts of Pellegrini and his friends together, annoyed him to that extent that ho poisoned himself, to the great astonishment and grief of Francis and his own pupils and assistants. He is said to have been called Il Rosso on account of his red hair: he was remarkable for his large and handsome person and general accomplishments and acquirements. Rosso was the boldest painter that had appeared in Italy up to the time of Vasari. Very few of his works were left at Fontainebleau; many of them were destroyed by his successor Primaticcio. Many of his works have been engraved.

(Vasari, *Vite de' Pittori, &c; Lettere Pittoriche;* D'Argenville, *Vies des Peintres.*)

ROSSI, JOHN CHARLES FELIX, R.A., was born at Nottingham in 1762; his father, a native of Siena, though not a licensed practitioner, practised as a medical man at Nottingham. Young Rossi was apprenticed very early to a sculptor of the name of Luccatella, with whom he remained, after he had served his time, as a journeyman, at eighteen shillings per week; but being employed by his master to correct some work on which Luccatella's principal assistants had been engaged, he suspected that his own abilities were of a superior class, and he demanded and obtained higher wages. It was now, however, having once felt the longing for praise, impossible for him to remain in his then subordinate situation, and he determined upon trying to better himself in London. There, still a boy, he entered himself as a student of the Royal Academy; and in 1781 he obtained the silver medal, and in 1784 the gold one, which entitled him to three years' maintenance at Rome. He went to Rome in 1785; in 1788 he returned to London; in 1800 he was elected an associate of the academy; and only two years afterwards, a very short interval, he was elected an academician. He was subsequently appointed sculptor to the Prince Regent, and he was employed in decorating Buckingham Palace. He was afterwards sculptor to William IV. But he had little to do after the completion of his great public monuments in St. Paul's Cathedral, and he depended in the latter years of his life chiefly upon a pension from the Royal Academy. He died February 21, 1839. He was twice married, and had eight children by each wife.

Rossi was both a classical and a monumental sculptor, and his style was manly and vigorous, especially in his monumental works, but they are not remarkable for any refinement either of sentiment or execution. Of the first class the following may be mentioned:—A Mercury in marble, executed in Rome; a recumbent figure of Eve, in marble; Edwin and Eleanora; Celadon and Amelia; Musidora; Zephyrus and Aurora; and Venus and Cupid. A statue of Thomson the poet by him is in the possession of Sir Robert Peel; and there is a large colossal statue of Britannia on the Exchange at Liverpool. His best works, however, and those by which he is and will be known, are the following monuments in St. Paul's Cathedral:—The Marquis Cornwallis, in the nave; Captain Faulkner and Lord Heathfield, in the south transept; and Captains Mosse and Riou, and Lord Rodney, in the north transept. The principal of these are those to Lords Cornwallis, Heathfield, and Rodney, and Captain Faulkner; all of which, except the second, are groups of three or more figures of the heroic size. That to Lord Cornwallis is placed opposite to Flaxman's monument to Nelson, and is in a similar style of composition and on a similar scale: it is a pyramidal group, the Marquis, as a Knight of the Garter, on a pedestal forming the apex; below are three allegorical figures—Britannia, and impersonations of the Begareth and Ganges, representing the British empire in the East. The sitting male figure or Ganges has much grandeur of form. Lord Heathfield is a single statue, represented in his regimentals: on the pedestal is an alto-rilievo of Victory descending from a castellated rock to crown a warrior on the sea-shore with laurel. Against the same pier is tho monument to Captain Faulkner, R.N., who was killed on board the Blanche frigate in 1795: Neptune, seated on a rock, is in the act of catching the naked figure of a dying sailor; Victory is about to crown him with a laurel. Lord Rodney's monument is a pyramidal group, the statue of the admiral forming the apex; below is Fame communicating with History.

(*Art-Union Journal; Companion to St. Paul's Cathedral.*)

ROTA'LIA. [FORAMINIFERA, P. C. S.] The most abundant genus of the Foraminiferous order, in the Cretaceous system of strata.

ROTTECK, KARL WENCESLAUS RODECKER VON, was born on the 18th of June, 1775, at Freiburg-im-Breisgau, which now belongs to the Grand Duchy of Baden, but at that time was subject to the House of Austria. His father, Auton Rodecker, was ennobled by the Emperor Joseph II. nnder the name Rodecker von Rotteck, on account of the eminent services which he had dono to his country and the emperor as perpetual dean of the Medical Faculty in the University of Freiburg, and as one of the councillors in the board of administration of Austrian Suabia. His mother, Charlotto Poirot d'Ogeron, a native of Remiremont in Lorraine, is described as a lady of rare virtue and attainments. Karl von Rotteck received a very careful education, and as early as 1790 was admitted a student in the faculty of law in the university of his native town. He took the degree of doctor of civil law in 1797, yet he always preferred history to law, and in 1798 was appointed professor of history at Freiburg. In this capacity he met with just approbation. Although he did not appear as a writer before 1811, except as the author of a few minor productions, he nevertheless devoted all his spare time towards the accomplishment of a great historical work, which secured him a high rank among the historians of Europe. Of his 'Allgemeine Weltgeschichte,' (Universal History,) the first volumo was published in 1811, but it was only finished in 1827. Germany having recovered its independence through the treaties of 1814 and 1815, and political liberty having been promised to its inhabitants, Rotteck made the constitutional law of Germany an object of his particular attention; and desiring to propagate his ideas, gave up his chair of history, and petitioned for that of politics and the law of nations in the same university, which he obtained in 1818. On those subjects he published a great number of works and memoirs as well as articles in the leading liberal periodicals of Germany, and the princes of Germany being then active in checking the rising liberal spirit of the nation, he obtained great popularity. In 1819 he was chosen by his university as their representative in the first chamber of the States of Baden. In the same year appeared his 'Ideen über Landstände,' (Ideas on Representative Bodies,) a work distinguished by great historical learning, liberal views, and that lucid and attractive style for which he is remarkable among the German historians and publicists. Some time afterwards he wrote a work on standing armies, the danger of which he endeavoured to show, and a history of the transactions of the States of Baden, which were well received by the people, but made him many enemies among the friends of the old state of things. Thus, lecturing in the university, propagating his liberal views through countless minor productions, and representing Freiburg in the states, he continued till 1830. The ontbreak of the French revolution in 1830 gave fresh vigour to his activity; he became the leading spirit of the best among the liberal periodicals of Germany, several of which were founded by bim; and giving up his seat in the first chamber of the states as member for the university, he accepted the membership for the city of Freiburg, which placed him in the second chamber, among the representatives of the people. At the head of those members who by their unremitting zeal in developing political freedom in Baden set an example to all Germany, Rotteck was exposed to slander, and at last violent attacks. As soon as the fear of France had subsided, the German governments took courage to punish those who had given offence. In consequence of a decree of the Diet, in 1832, the Baden government forbade Rotteck to lecture in the University of Freiburg, and he was declared to have forfeited, for fivo years, the right of editing any newspaper. Germany now looked upon him as a political martyr, and from its most distant provinces he received addresses and presents. His native city elected him mayor, but the government refused to give their sanction: they likewise tried to exclude him from the second chamber of the states, and to prevent his re-election; bnt there they failed, and from 1830 to 1840 he continned to represent Freiburg without any interruption. In 1840 the Baden government re-admitted him as a lecturer at Freiburg, but it was too late: after a severe illness, rendered worse through the moral sufferings he had been exposed to, Rotteck died on the 20th of November, 1840. His death was mourned as a public calamity in all Germany.

The principal work of Rotteck is his 'Allgemeine Weltgeschichte' mentioned above, which extends from the commencement of authentic history to 1815. It went through fifteen editions: the last with a continuation gives the history of the years from 1815 to 1840, by K. H. Hermes, Brunswick, 1841-45, 11 vols. 8vo., of which nine are the work of Rotteck, and the two last the continuation of Hermes. No general history ever enjoyed such popularity as this splendid production of Rotteck; in Germany it is in the hands of almost every educated family; its fame soon spread over Europe and America; and it was consequently translated into most of the European languages. The English translation by T. Jones, Philadelphia, 1840-1842, four vols. 8vo., 2nd edition, London, 1842, is however only a translation of an extract of the 'General History,' which Rotteck published under the title 'Auszug aus der Weltgeschichte,' Freiburg, 1831, &c. four vols. 8vo. Contrary to the practice of most German historians, Rotteck simply relates history, indulging neither in critical investigation of trifles, nor in metaphysical contemplation of the broad facts of human deeds. But the whole is represented from a liberal point of view, and enlivened by sound reflections on the origin of freedom and slavery, and the causes of the rise and fall of nations. The style of Rotteck is clear and attractive, but sometimes a little rhetorical; the logical order is never interrupted; and every page shows that the author possessed that rare taste and that discretion which enable a man to distinguish between trifles and important facts, and to give neither too much nor too little. The reader who wishes to obtain a strong impression of the peculiar merits of this work, as the production of a German historian, need only compare it with Hammer's far-famed History of the Turkish Empire. Among the other works of Rotteck we mention 'Kleinere Schriften' (Minor Works), five vols. 8vo., 1829-1835, which contain a great number of valuable memoirs, essays, letters, &c., on various, mostly historical subjects; 'Lehrbuch des Vernunftrechts und der Staatswissenschaften' (Doctrine of Law as a Metaphysical Science, and of Public and Constitutional Law), four vols. 8vo., 1829, &c.; 'Staatsrecht der Constitutionellen Monarchie' (The Public Law of Constitutional Monarchies), three vols. 8vo., 1824, &c. Rotteck was the co-editor, with Welcker, of that excellent work 'Staats-Lexicon,' &c. (Political Dictionary), which is still unfinished. Dr. Hermann Rotteck, the son of the late historian, published 'Rotteck's Nachgelassene Schriften' (Posthumous Works), Freiburg, five vols. 8vo., 1841-43, which contain also most of the 'Minor Works' mentioned above.

(The Life of Rotteck by his Son, in the fourth vol. of *Nachgelassene Schriften*; Rotteck's *Ehrentempel*, Freiburg, 1842; *Conversations-Lexicon Supplement*.)

ROTTI. [SUNDA ISLANDS, P. C.]

ROTULI'NA. [FORAMINIFERA, P. C. S.]

RO'VERE, DELLA, the name of a noble family originally from Savona, in the territory of Genoa, which gave to the church two celebrated Popes [SIXTUS IV. and JULIUS II., P. C.] besides many cardinals and other distinguished persons. Pope Julius II. caused his nephew Francesco Maria Della Rovere to be adopted by Guidobaldo of Montefeltro, Duke of Urbino, who was childless, as his successor in the duchy. Accordingly, after the death of Guidobaldo in 1507, Francesco Maria took possession of Urbino. Under Leo X. he was driven away from his duchy to make room for Lorenzo de' Medici, a relative of the new Pope. But after the death of Leo X., Francesco Maria was reinstated in the dominion of Urbino and Pesaro. He was much engaged in the Italian wars of that age, in which he acquired the reputation of an able commander. He died in 1538, and was succeeded by his son Guidobaldo, who was a patron of learning and of the arts. Guidobaldo died in 1574, and was succeeded by Francesco Maria II. This prince surpassed his predecessors as a patron of learning, and was himself learned in various branches of knowledge. Urbino continued to be under him, what it had been from the times of the Montefeltro family, a favourite resort of men of science and of literature. Francesco Maria II. by his liberality assisted the celebrated naturalist Aldovrandi of Bologna, in forming his rich museum of natural history. Duke Francesco Maria II. lost his only son Federico in 1623, and the court of Rome claimed the reversion of the duchy as a fief of the Papal see. Ferdinand II., Grand Duke of Tuscany, who had married the Princess Vittoria della Rovere, daughter of the Duke of Urbino, was induced, chiefly through religious scruples, to give up his claims to the succession; and thus Tuscany lost the chance of extending its sway from sea to sea as far as the Adriatic. In 1632 Duke Francesco Maria died, when his dominions were seized by Pope Urban VIII. and annexed to the Papal territories.

(Sansovino, *Famiglie Illustri d'Italia*; Tiraboschi, *Storia della Letteratura Italiana*.)

ROY, GENERAL. [TRIGONOMETRICAL SURVEY, P. C.]

RUAULT, JEAN, more generally known by his Latin name Rualdus, was born at Coutances, in Normandy, about the year 1580. He distinguished himself in early life by his knowledge of the classical languages and of ancient history. He afterwards obtained considerable success as a teacher, and was for several years professor of classical literature at the university of Rouen; from whence he went to Paris, where his lectures were attended with similar success. His fame as a scholar caused him to be twice appointed to the important office of rector of the university of Paris, and in 1629 he succeeded the celebrated Frederic Morel as Professor of 'Belles Lettres' in the Collège Royal. He died in the year 1636. The erudition of Rualdus is described as having been exact and profound, but fault is found with him as a writer on account of the prolixity of his style and its want of elegance. His oral teaching procured for him a greater reputation than his writings. The work by which he is best known is a valuable edition of Plutarch. The best copy of it is that printed at Paris, of which, as it is now rarely to be met with, we give the title in full:—'Eorundem Plutarchi Operum editio altera Gr. et Lat., ex interpretatione Hermani Cruserii et Wilhelmi Xylandri, cum notis doctorum variorum et Johannis Rualdi variantibus lectionibus è MSS. codicibus excerptis et indicibus, ex recensione Philippi Joannis Mausaci.' Parisiis. Typis Regiis, 1624, 2 vols. folio (*Bibliographie*, &c. de Do Bure, art. 6080, Paris, 1768). On account of the rarity of this edition that of Frankfort, 1620, likewise in 2 vols. folio, is generally used, but it is far inferior to it. Clarke however, in his Bibliographical Dictionary, gives the preference to the Frankfort edition (vol. v. p. 249, London, 1804). There also remain of Ruault—1, A Collection of Latin Poems, Paris, 1610, 12mo.; the volume contains two books of epigrams and one of religious poems, besides two harangues on scriptural subjects and panegyrics of St. John the Baptist and St. Ursula. 2, 'Controversia de Duellis,' Paris, 1625, 8vo. 3, A Latin funeral oration on Achille de Harlay. 4, 'Preuves de l'Histoire du Royaume d'Yvetot,' Paris, 1631, 8vo. (*Dict. Bibliographique*, Cailleau, Paris, 1790, vol. ii. p. 513). This being the only edition of this curious work it is an object of research among the collectors of rare books. Ruault attempts to show that the territory of Yvetot, so celebrated in one of the most popular of French songs, was really constituted a kingdom by Clotaire. [YVETOT, P. C.]

The name of Ruault is not found in most Biographical Dictionaries; we are indebted for the short details of his life to the 'Biographie Universelle,' vol. xxxix. It is there stated that the notice of Ruault in l'Abbé Gougot's 'Hist. du Collège Royal de France' is incomplete.

RUBRUQUIS, WILLIAM DE. This distinguished traveller of the middle ages, was a friar of the Minorite or Franciscan order. Pits, or Pitseus, an English Catholic of the sixteenth century, in his curious biographical work—'Lives of the Kings, Bishops, Apostolical Men, and Writers of England,' claims him as an Englishman, and as one that did honour to his country. It appears, however, pretty plainly that he was a native of Brabant. His real name was Ruysbrock, or Rysbruck, which, according to the fashion of the times, he Latinized into Rubruquis. The date of his birth is not preserved, but he was probably born about the year 1228. He entered the cloisters early in life, and soon after completing his noviciate and taking the major vows, he went to the Holy Land, with other monks and missionaries. The recent successes of the fourth grand crusade under Louis IX. of France, afterwards canonized as Saint Louis, had revived the hopes of the Christians of the West. Fresh streams of pilgrims were flowing thither; and some of these counted upon setting up their tabernacle of rest in Jerusalem, and upon finding provision and settlement for life in the Holy Land.

But before Rubruquis could reach the Syrian shore these hopes were overcast; the devout French king had been defeated near Tunis, rather by endemic diseases than by the sword of the Saracen, and had been made prisoner, with the remnant of his host, by the Mohammedans. Louis, however, was soon released upon paying a ransom, and entering into a treaty with the Soldan; and he was in Palestine in 1253. Although some monkish envoys, who had previously been sent in quest of that great, undiscoverable, Christian potentate of the East, Prester, or Priest John, had returned disappointed, and with very discouraging accounts of the difficulties and perils of their journey, King Louis could not discharge his imagination of that visionary personage; and being more anxious than ever to contract an alliance with that fancied Christian prince, he resolved to send another mission in search of him. A report had reached Louis that the great Tartar, Sartach, son of Baatu-Khan, who commanded in the western parts of Tartary, was a good Christian. If this Sartach were not Prester John, still his faith and devoutness, if truly reported, must make him a valuable ally to the Christians who were warring in the Holy Land against the Paynim. The mission of Louis was, therefore, to find that Tartar prince, wherever he might be, and at whatsoever toil and danger. It was composed of Rubruquis, friar Bartholomew of Cremona, and a certain friar Andrew, whose country or birth-place is not named. Rubruquis, though the youngest of the three, appears to have been considered as the head of the mission. He, no doubt, owed this pre-eminence to his superior scholarship, wit, and courage. Before his departure King Louis strictly enjoined him to write down everything he saw and heard among the Tartars; and, by conscientiously obeying the royal order, and by making a good use of his eyes (his ignorance of the Tartar languages made his ears of less account), he brought back a great deal of curious information on the subject of that nomadic people.

After spending a short time at Constantinople among the Greek Christians, whose schism gave them great offence, Rubruquis and his companions took shipping, and entered the Euxine, or Black Sea. On the 21st of May, 1253, they were safely landed at Soldaia, now Soudac or Soujac, in the Crimea, not far from Cherson, where Howard the philanthropist died in 1790. But here their troubles began. They had brought no presents of any value, and presents are necessary passports all through the East. They were told that they would never get at Sartach unless they had rich gifts to lay at his feet. They, however, pleaded their vow of poverty, as Franciscans, and boldly went on, travelling sometimes in carts, and sometimes on rough horses. They crossed the Steppes which separate the Dnieper or Borysthenes, from the river Don, or Tanaïs, and then directed their course due east, over immense desert plains where nothing was to be seen but earth and sky, and here and there the barrows or tumuli of the Comans. On the 22nd of July, being in a famishing condition, they reached the banks of the Don, where they found some fish, flesh, and dry bread. Crossing the river they plunged again into the hungry desert. On the 2nd of August they reached the temporary residence or encampment of the great Sartach. As they had nothing to give, beyond a little sweet wine, a few preserved fruits, and a bag full of sweet biscuits, their reception was of the sourest. They soon discovered that Sartach's Christianity was all a dream. That Tartar chief, however, determined to send them on to his father Baatu. From his encampment they had to travel solely on horseback, in the break-neck Tartar fashion. After dreadful fatigue, and many privations and dangers, they reached Baatu, who was encamped on the banks of the Volga, not far from its confluence with the Caspian. Baatu told them that he could enter into no negociations, and that they must continue their journey until they came to Manchu-Khan, the great Tartar Emperor, who was to be found somewhere in the direction of China. Of this long journey 'of hunger and thirst, cold and fatigue, there was no end.' At last, on the 27th of December, the poor monks arrived at the camp and court of the Tartar Emperor; and were lodged in a small dirty hovel. It is not possible to fix the spot where the erratic Manchu-Khan was then residing. Rubruquis only tells us that it was in a vast plain, as flat as the surface of a lake; that, before reaching the plain, he had crossed a lofty range of mountains, and had travelled due north. The emperor was attended by many Chinese mandarins, and by ambassadors from India, from Persia, and from Turkey. He gave a grand feast, at which all the great men got drunk on cosmos, or the fermented milk of mares. On the 5th of January (1254) the friars were presented at court, where they had to perform several humiliating ceremonies. Manchu-Khan gave them to understand that he was master of the whole world, and that the King of France and all the monarchs of christendom must submit to him. About the court were a good many Nestorian Christians; but their faith was sadly corrupted, and their priests were little better than conjurors and quacks.

A week or two before Easter Manchu-Khan removed to Kara-Corum or Kara-Kûm, a royal city on the east side of the river Orchan. The monks followed him, and were kindly entertained by a French goldsmith, his wife, a Hungarian woman, and one Basilicus, the son of an Englishman, who had been born in Hungary.

On Whitsunday Rubruquis was called into the presence of the emperor, who had been told that the friars had called him a foul infidel. Rubruquis solemnly denied the fact. 'Then,' said the Khan, 'be not afraid.' The brave monk smiled and said, 'If I had feared, I should not have come hither!' He was then told that he must return the way he had come, and make himself strong for the journey by eating good meat. He took his departure a fortnight after Midsummer day. 'From Kara-Corum,' says the good friar, 'unto the court of Baatu, our journey lasted four months and ten days, during all which time we never saw a town, or so much as a single fixed house, except one village in which we did not break bread; nor in all this time did we ever rest from our rough riding, except one day when we could find no horses.' The court of Baatu was then about to migrate to Sarai, on the eastern bank of the Volga. Rubruquis accompanied it during a whole month; but then, tired of the slow and indirect movements of the Tartars, who, as usual, were conducting their flocks and herds with them, he procured a guide and pushed rapidly forward for Sarai, keeping due south and always near to the Volga. After a very remarkable journey, the dangers and fatigues of which were supported with admirable temper, and in the course of which he threaded the great defiles of Mount Caucasus, crossed the Araxes, and traversed Armenia, Persia, and Asia Minor, Rubruquis reached Tripoli, in Syria, in the month of August, 1255. He had been, altogether, about two years and six months on his laborious travels, and he now earnestly besought his superior to allow him to go to King Louis at Paris; for that devout prince had quitted the East after witnessing the failure of all his high hopes. But the Franciscan provincial, being a strict disciplinarian, ordered the poor friar to write to Louis, and then retire to the convent of his order at Acre. The manuscript account of the travels was soon transmitted to Paris, together with an earnest prayer that his Christian Majesty would obtain the provincial's permission for his going, for a short season, to France. It has not been ascertained whether he obtained the favour, or whether he remained shut up in his cell at Acre. Indeed, after his return to Syria, nothing more seems to be known about Rubruquis except that he was living, somewhere, as late as the year 1293, when Marco Polo was on his way back to Europe from the remotest regions of the East. He was a man of rare good sense. The sobriety of his descriptions is marvellous for the time in which he lived. He was the first European traveller that gave a correct account of the Caspian Sea.

(Hakluyt, *Collection of Voyages and Travels*, A.D. 1600; Purchas, *his Pilgrimes*, 1625; *Recent Edition of Rubruquis's Travels from a MS. in the British Museum collated with other MSS. at Cambridge and Leyden, published by the Geographical Society of Paris*; Charles Mac Farlane, *Romance of Travel.*)

RUFFO, FABRI'ZIO, born about the middle of the eighteenth century, was a younger son of a noble and wealthy Neapolitan family. He was brought up for the church, for which however he had little disposition. Being introduced at Rome to Pope Pius VI., he was appointed treasurer, in which capacity he exhibited considerable economic abilities, and he incurred the jealousy of many of the older members of the Roman court. At last he resigned his office on being made a cardinal, and returned to Naples, where King Ferdinand appointed him intendant or chief administrator of his palace and domain of Caserta. Ruffo was fond of agriculture, and he applied himself to make improvements on the estate. When King Ferdinand was driven away from Naples by the French republican army in 1798, Ruffo followed him to Sicily. He had disapproved of the provocation given to the French by the court of Naples, and he was consequently at variance with the favourite minister Acton. The latter, in order to get rid of his presence, recommended him to Queen Caroline as a fit man to recover the kingdom of Naples by placing himself at the head of the Royalist population of Calabria, in which province the family of Ruffo had large estates, and exercised considerable local influence. The queen approved of the plan, however hazardous it might appear, and made the king sanction it by bestowing on Ruffo the rank of his vicar-general, with full powers to act. Ruffo, glad to escape from the intrigues and vexations of the court of Palermo, accepted the office. In February, 1799, he crossed over in a boat with an escort of only five men and 3000 ducats, and landed at Bagnara, a fief of his family. He collected a number of adherents, and unfurling the royal flag with a white cross, proclaimed a crusade against the French and their partisans. The republicans of Naples had committed many errors and acts of oppression in the provinces, and had exasperated the rustic population, which were not ripe for the change from old absolutism to a republican form of government. The Calabrians flocked by thousands to Ruffo's standard. The army of 'the Holy Faith,' which was the name it assumed, marched against the town of Monteleone, which surrendered by capitulation, as well as Catanzaro; it afterwards stormed Cotrone, which was given up to plunder; took Cosenza though the treason of its commander; and thus in less than a month Ruffo was master of all Calabria, where he re-established the king's government. He was joined by many regular officers and soldiers, and was supplied with artillery. He then took the road to Apulia, and laid siege to Altamura, which opposed his passage. The inhabitants defended themselves desperately, but the town was taken and plundered for three days with circumstances of great atrocity. The people in other parts of Apulia hoisted the royal flag; the Abruzzo was already in open revolt against the republicans of Naples, who were soon after abandoned by the French troops, which withdrew at the beginning of May towards North Italy, in order to oppose the Austrians and Russians, who were predominant in that quarter. Naples was left to its fate with only a small French garrison in one of the castles. On the other side Ruffo was joined by some regular Russian and Albanian forces from Corfu. He then advanced towards Naples by Avellino, and surrounded the capital at the head of from fifty to sixty thousand men, mostly irregulars. After some fighting outside of the town, an insurrection of the lower orders from within facilitated the entrance of Ruffo's bands, and the town became a scene of carnage; but the republicans still defended themselves in the castles and the adjacent districts, where they had fortified the massive palaces and houses. Ruffo, willing to spare further destruction, entered into a convention with the republicans, who were to be shipped off for France. The capitulation was signed by him, and a part of the republicans were actually sent off to France, when King Ferdinand arrived from Sicily in the bay, at the end of June, on board the English admiral Nelson's ship, and refused to sanction the capitulation, saying that Ruffo had exceeded his powers in treating with rebels, and he appointed a special court to try the republicans, many of whom, chiefly of the higher orders of society, were put to death. The minister Acton charged Ruffo with partiality for the Jacobins, as they were called, and the cardinal, disappointed and humiliated, seized the opportunity of leaving Naples for the conclave, which had been summoned to assemble at Venice for the election of a pope. Ruffo followed the new pope, Pius VII., to Rome, where he was made Prefect of the Annona. Some years after he returned to Naples, where he resumed his place at the court. When the court of Naples was obliged to emigrate a second time to Sicily in 1805, in consequence of its own imprudence and tergiversations, Queen Caroline proposed to Ruffo to put himself again at the head of the country people to oppose the French, but Ruffo replied that 'once was quite enough in a man's life for such vagaries.' He retired to Rome, where he remained till 1809, when he went to France and made his peace with Napoleon, and he was one of the cardinals who sanctioned by his presence his second marriage. In 1814 he rejoined Pope Pius VII. at Rome. After a time he returned to Naples, and took again his seat in the council, where he displayed a marked moderation of sentiments. He went to Rome in 1823 to the conclave in which Leo XII. was elected, and died at Naples in 1827 at an advanced age.

Ruffo was a man of ability and accomplishments. He was worldly and lax in principles, by no means fanatical or cruel; and the atrocities which disgraced his otherwise romantic expedition of 1799 cannot be justly attributed to him, although he may be blamed for not reckoning on them before he put himself at the head of the insurrectionary movement. There was blame attached to all parties in those times; the republicans of Naples had assumed a task beyond their strength; they mistook their own coterie for the nation, and they suffered cruelly for it, for the people were not on their side. The same error has been repeated again and again in other countries in our times. There is a graphic sketch of Ruffo's expedition in a miscellany entitled 'Sketches of popular Tumults,' published by Knight & Co. in 1837.

Contemporary with this Ruffo, there was another Cardinal Ruffo, of another branch of the same family, who was long archbishop of Naples.

(Petromasi, *Storia della Spedizione del Cardinal Ruffo*; Colletta, *Storia del Reame di Napoli*; Coppi, *Annali d'Italia*.)

RUFI'NUS, LICINIUS, a Roman jurist, who lived under Antoninus Caracalla (A.D. 211-217), whom he mentions once (*Dig.* 24, tit. i. s. 41). He was also consulted by Paulus (*Dig.* 40, tit. 13, s. 4). There are seventeen excerpts in the Digest from a work of Rufinus entitled Regularia. The Florentine Index mentions only twelve books of this work, and the superscription 'Lib. xiii.' in a passage of the Digest (42, tit. 1, s. 34) may be a mistake.

(Zimmern, *Geschichte des Röm. Privatrechts*, i. 382.)

RUGENDAS, GEORG PHILIPP, a celebrated German battle painter, was born at Augsburg in 1666. He was the pupil of Isaias Fisches, an eminent historical painter in his time; but Rugendas devoted himself at an early age almost exclusively to battle painting, in which he was partly confirmed by the admirable battle-pieces of Bourguignon, Lembke, and Tempesta, which he studied on his journey to Vienna, Venice, and Rome. At Rome he entered the famous Flemish Schilder-Bent, or Society of Painters, in which he was received, from his predilection for battle painting, under the nickname of Schild: all the members of this society were known only by nicknames.

In 1795, after an absence of five years, he returned to Augsburg, and had the opportunity of witnessing its siege in 1703, and of thus studying from nature what he had hitherto only acquired from his imagination and from the pictures of others. He lost a great portion of his property through this siege, but what he lost in substance he more than gained by excellent opportunities he found of perfecting himself in the line of art which he had adopted, and he acquired extraordinary excellence as a battle painter; and became distinguished also for his etchings of battles and skirmishes: he excelled in the manner in which he represented smoke, and made use of it in separating and arranging his groups. There is or was a large picture of the siege of Augsburg in the Stetten collection at Augsburg. Rugendas was made director of the Academy of Augsburg in 1710: he died at Augsburg in 1742. His pictures are very numerous, and there are not many collections without one or more examples of his style. He painted besides battles and skirmishes, horse-markets, and horse-exercises, and he generally introduced many objects into his pictures. His design is vigorous and bold, but his colouring is unequal, sometimes being high and warm, and at others heavy and monotonous; and though his light and shade is often well studied and very effective, many of his pictures are now black and obscure. Owing to an illness he painted many years with his left hand. There is a picture of the battle of Blenheim by Rugendas. He was the ancestor of a numerous family of painters and engravers, sons and grandsons. A Life of him by J. C. Füssli was published, together with a Life of Kupetzky, by the same writer: Leben Georg Philipp Rugendas and G. Johann Kupetzky; Zürich, 1758.

Christian Rugendas, his second son, engraved about sixty of his father's designs in a very spirited manner, chiefly in mezzotinto. His own etchings, of which there are about thirty, are also much prized.

RUISCH, RACHEL, a distinguished Dutch flower-painter, was born at Amsterdam in 1664: she was the daughter of Professor Ruisch, who had her taught flower-painting by Wilhelm Van Delst. In 1695 she was married to the portrait-painter Juriaen Pool, who was two years her junior, to whom she bore ten children and with whom she lived fifty years. In 1701 she and her husband were elected members of the Society of Painters of the Hague, and in 1708 John William elector of the Pfalz, appointed her his court painter. She died at Amsterdam in 1750, aged eighty-six, and she continued to paint till she was upwards of eighty years old. Her works have been compared with those of Van Huysum and De Heem, and have sometimes been sold for very high prices, even 8,500 francs for a single picture.

(Van Gool, *Nieuwe Schouburg der Nederlantsche Kunstschilders*, &c.; Van Eynden and Vander Willigen, *Geschiedenis der Vaderlandsche Schilderkunst*, &c.)

RULER, PARALLEL. A good form of this instrument is explained in MARQUOI'S RULERS, P. C. S., which is particularly applicable to the case in which numerous and related parallels or perpendiculars are to be drawn. The ordinary instruments are of two kinds, which might well be called parallel *rulers* and parallel *rollers*.

The principle of the common parallel ruler is a parallelogram of constant sides and changeable angles: one side being fixed and the angles altered, the other side changes position, it and its parallels always remaining parallel to the first side and its parallels. Two rectangular rulers are connected by two cross-bars of equal lengths, which move on pivots in the rulers in such manner that the four pivots, two in each ruler, shall be the four points of a parallelogram. The line joining two pivots on the same ruler is always made parallel to the length of the ruler. One ruler being held fixed, and a line drawn with the edge of the other ruler in any position, then any motion given to the other ruler by the rotation of the cross-bars gives, on the edge of the moving ruler, a line parallel to the first line. The defects of this construction are, that the four pivots may not make an accurate parallelogram, in which case the instrument is worthless: and the sides of the two rulers, when the instrument is closed, may not be parallel to one another, in which case all the lines must always be taken off the same ruler. Moreover, one ruler remaining fixed, there is but a small command of distance from it; so that, to gain the parallel required, it may happen that the first ruler has to be advanced, the second brought up to it, the first ruler advanced again, and so on. Now, owing to the rotation of the pivots, this gives an oblique motion to the instrument; so that it often happens, by the time that the required parallel is gained, the point through which it is to be drawn is off the ruler. To meet this disadvantage, and to give the instrument more extent, three rulers are sometimes put together, each connected with the next by cross-bars in such manner that the cross-bars connecting the first and second have an opposite revolution to those connecting the second and third. At its best however this instrument is rather clumsy; but, such as it is, it is safe and easily learnt, when well made.

The simplest kind of roller is the common round ruler, which, with a little practice, will draw parallels for ordinary use very well. It is good practice in the use of instruments to draw parallels in this way; the ruler being held in the middle and gently allowed to take its own rolling motion. If a ring be well drawn round the ruler, it is good practice in drawing perpendiculars to adjust the ruler so that the ring may roll over the line to which perpendiculars are to be drawn. But a roller which is more easily used is sold in all the shops. It consists of an ordinary ruler of rectangular form, both edges of which are bevelled and divided into equal parts: one side into inches and tenths, the other into inches and twelfths; the inch divisions being made to come exactly opposite each other. A roller is let into room cut out of the middle of the ruler, in such manner as to project a very little way from the under and upper faces of the ruler. When the instrument is put down on the paper, either of the bevelled edges may be brought down on the paper, or both may be clear of it. In this last case the roller (the efficient ends of which are *toothed* cylinders, the middle part being in a frame) rolls easily, and additional stability is given if, while it rolls, one of the bevelled edges be kept slightly on the paper. The ends of the roller are graduated and a fixed index is in the frame, so that by allowing equal numbers of divisions to pass the index at each roll, a good approximation (though not quite with a draughtman's accuracy) may be made to equidistant parallels. Perpendiculars to a given line are drawn by adjusting the ruler so that opposite divisions of the bevelled edges may travel on the given line. With a very little practice this is an instrument of great power and accuracy. Before using it, draw a line with it, roll it away, and then roll it up again to that line, and see if the coincidence is as perfect as before. Various other modes of trial will suggest themselves: indeed no one should use a parallel ruler at all until he has drawn pairs of parallels across each other, and satisfied himself that he can get the opposite sides quite equal.

A rough construction of this kind is now (very recently, September, 1846) sold under the title of 'Schlesinger's Patent,' in which a round ruler of wood is simply connected with a flat bevelled ruler, so as to carry it when it rolls. This is meant to rule lines for writing, but it may be made to do good service as a parallel ruler for other purposes.

RUMOHR, CARL FRIEDRICH LUDWIG FELIX, VON a distinguished writer on art, was born of an old family at Reinhardsgrimma, his father's estate near Dresden, in 1785. He was educated at the Gymnasium, or high school of Holzmünden, in Brunswick, whence he went to the university of Göttingen, but already at the age of fifteen he neglected every other study for that of art, abruptly discontinuing his studies at the university and placing himself with the painter J. D. Fiorillo, well known as the author of a general history of modern painting, and then established in Göttingen. From Fiorillo Rumohr heard much about Italy which excited his imagination and determined him to visit that country as soon as he had acquired some knowledge of the various schools and styles of art. He accordingly visited many collections, but above all the celebrated gallery of Dresden attracted his attention, and especially the works of Raphael and Paul Veronese. In 1804, in his twentieth year, he made his first tour in Italy, and visited Bologna, Florence, Siena, and Rome. In Rome he made the acquaintance of Thorwaldsen, Schick, Friedrich Tieck, and Koch the landscape painter: Carstens had already left. He further enjoyed the friendship of Wilhelm and Alexander von Humboldt, and Monsignore della Genga, nineteen years afterwards Pope Leo XII.

From Rome Rumohr went to Naples, and there commenced the formation of a collection of antiquities; he had already been collecting prints for some years. He returned to Germany in 1805, in the company of Ludwig Tieck. In Bavaria he was honoured with the confidence of the crown prince, the present King of Bavaria. From 1805 to 1815 his time was passed chiefly in Bavaria and on his own estates in Holstein. Though he took great interest in the political changes of that time he meddled very little with them. His literary activity commenced soon after his return from Italy, but his first publication appeared in 1811—'Erläuterungen einiger artistischen Bemerkungen in der Abhandlung des Herrn Hofraths Jacobs über den Reichthum der Griechen an Plastischen Kunstwerken.' This was followed by other essays on various departments of art, and among them a work entitled 'Sammlung für Kunst und Historie,' at Hamburg, in 1816, 2 vols. 8vo.

In 1815 he revisited Italy, and commenced in Florence the researches for his principal work, the 'Italienische Forschungen,' of which the three volumes were published in two portions in a later period of his life. In Rome he found Overbeck leading the German artists into a new or rather old sphere of art, of which a conventional sentimentality is the principal feature, and which forcibly impressed Rumohr. In 1827 appeared at Berlin the first and second volumes of the 'Italian Researches' ('Italienische Forschungen') a critical work on the history of art, and compiled exclusively from the original archives and documents in various buildings at Florence; in this work Rumohr clears up many obscurities and corrects several errors in Vasari. In 1828 he paid a third visit to Italy, when he was consulted in the purchases for the new picture-gallery which was then being established at Berlin, and he acted as Cicerone to the present King of Prussia in Florence, when crown-prince. He was employed by the prince in several purchases, and upon his return to Germany was engaged with others in the selection and arrangement of the objects of art in the Museum. In 1831 Rumohr published the third and last volume of his 'Italienische Forschungen,' and various literary works now followed in rapid succession and on various subjects. In 1832 appeared 'König's Geist der Kochkunst,' at Stuttgart; 'Deutsche Denkwürdigkeiten,' at Berlin; 'Drei Reisen nach Italien,' at Leipzig; and the first volume of his 'Novellen,' at Munich. In 1834, 'S ule der Höflichkeit für Alt und Jung,' at Stuttgart; and in the Leipzig pocket-book Urania, 'Der Letzte Surillo,' a poem, said to be his best production of that class. In 1835, in Munich, the second volume of 'Novellen;' and in Lübeck, 'Kynalopekomachia, der Hundefuchsstreit, mit Bildern von Speckter,' Dog and Fox Fight, a satirical poem on the times. Erwin Speckter was a young artist of Hamburg, much admired by Rumohr: he died in that year. [SPECKTER, ERWIN, P. C. S.] In the same year also appeared the History of the Royal Collection of Prints at Copenhagen, drawn up by Rumohr and the keeper of the collection, Professor Thiele; and at Leipzig, Contributions towards the History of Art and the greater completeness of the Works of Bartsch and Brulliot. [BARTSCH, BRULLIOT.] In 1836 he publishd at Leipzig two works on wood-engraving, 'Hans Holbein der Jüngere in seinem Verhältniss zum Deutschen Formschnittwesen,' and an answer to a censure of this work, 'Auf Veranlassung und Erwiedrung von Einwürfen eines Sachkundigen gegen die Schrift Hans Holbein,' &c. These were followed, in 1837, by a treatise, 'Zur Geschichte und Theorie der Formschneidekunst.'

In 1837 he made a fourth journey into Italy, but he did not go beyond Milan, and this tour was made rather with political views than as an artist. He published an account of his journey at Lübeck in 1838, under the following title:—'Reise durch die östlichen Bundesstaaten in die Lombardei und zurück über die Schweiz und den obern Rhein, in besonderer Beziehung auf Völkerkunde, Landbau, und Staatswirthschaft;' to which he published some additions in the following year—'Historische Beilege,' &c. He had previously published a work of the same kind on Tuscany, namely,—'Ueber die Besitzlosigkeit der Colonen im Neuern Toscana, aus den Urkunden;' Hamburg, 1830. In 1841, however, after a fifth visit to Italy, to Venice, in the previous year, he returned to his more genial subject the history of art, and published in Leipzig an inquiry into the invention attributed to Finiguerra of printing with engraved plates on damped paper—'Untersuchung, dass Maso di Finiguerra Erfinder des Handgriffs sey gestochene Metallplatten auf genetztes Papier abzudrucken.' This was his last labour in the history of art, and his last poetical production of this class was 'Raphaels Lehr-und-Wander-Jahre.'

In 1841 he purchased a house in Lübeck intending to end his days there, and he fitted it up according to his own fancy. The winter of 1842 he spent in Berlin, and he was then attacked with water on the chest: he returned in the spring to Lübeck, where his physician recommended him to visit the baths in Bohemia; he accordingly set out, but being too ill to proceed he remained at Dresden, where he died of apoplexy July 25, 1843.

Rumohr's last literary production was a preface to 'Kampf Demokratischer und Aristokratischer Principien zu Anfang des sechszehnten Jahrhunderts,' Lübeck, 1843. It is a translation from three papers presented to him by Professor Altmeyer of Brussels. His 'Italienische Forschungen' will remain as a monument of his judgment and industry when probably nearly all his other works are forgotten. It is one of the best documentary works in the literature of art, and at the same time abounds in critical and theoretical reflections; it is likewise a work of great interest, though there may be different opinions about the correctness of Rumohr's theories. The two first volumes are upon modern art in Italy generally, from its origin to its decline in the 16th century, which is distributed under fourteen distinct heads; many errors in Vasari are corrected; much obscurity of the 12th, 13th, 14th, and 15th centuries is cleared up by authentic documents; and various false notions concerning the development of art are dissipated by critical reflections: the third volume is under two heads only, which treat chiefly of Raphael, and the architecture of the middle ages.

(*Kunstblatt*, 1844.)

RUNCIMAN, ALEXANDER, an eminent Scotch painter, was born at Edinburgh in 1736. His father was an architect, and Runciman was brought up to the arts from his childhood, and he made coloured sketches in the fields as early as his twelfth year. At the age of fourteen he was placed in the studio of John and Robert Norris, John being considered in his day a famous landscape painter. When only nineteen years of age he set up as an independent landscape painter in Edinburgh, but it seems the people of Edinburgh, like those of many other places, though lavish of their praises were very cautious in their purchases, and Runciman had the gratification of dwelling on his own pictures, for they were left on his hands. This state of affairs continued for about five years, when in 1760 he took to historical painting, and though he had more ability for this line of art his fortune seems to have been very little if at all improved. In 1766 he visited Italy, and at Rome made the acquaintance of Fuseli. Their tastes in art were very similar: both were absorbed by what is termed the sublime, and both were alike wild and extravagant in their execution. 'They were,' says Allan Cunningham, 'rivals in that unbridled licence of imagination, which introduced an air of inspired madness and considerate extravagance into the sublimest and sternest subjects on which they employed their pencils.' Runciman remained five years in Rome, and when he returned home he carried from Fuseli a letter of introduction to a friend, in which was the following passage: 'I send this by the hands of Runciman, whom I am sure you will like: he is one of the best of us here.'

He arrived at Edinburgh in 1771, a fortunate time for him, for Pavillion, the director of the new academy of the arts which had been established at Edinburgh in 1760, had very recently died, and Runciman was appointed to fill his place, with a salary of 120*l.* per annum, then a sufficient income in Scotland. He was further fortunate in finding two generous patrons in Sir J. Clerk, of Pennycuick, and Robert Alexander, an Edinburgh merchant. The former employed him on a great work at Pennycuick, suggested by himself, neither more nor less than the decoration of the hall of that place with twelve great compositions from Macpherson's Ossian, which at that time was believed in Scotland to be authentic. The subjects are—Ossian singing to Malvina; the Valour of Oscar; the Death of Oscar; the Death of Agandecca; the Hunting of Catholda; the Finding of Corban Cargloss; Golchossa mourning over Lamderg; Oina Morval; Cormac attacking the Spirit of the Waters; the Death of Cormac; Scandinavian Wizards making Incantations; and Fingal engaging the Spirit of Loda. The picture of Agandecca is reckoned the best. One cannot but respect the enthusiasm of the painter of such a series as this, but as works of art they are extravagant in treatment and in composition, and incorrect in design. While engaged in this work Runciman painted also 'The Ascension' on the ceiling over the altar of the episcopal chapel in the Cowgate of Edinburgh. He painted also King Lear; Andromeda; Nausicaa and her Nymphs surprised at the Water Side by Ulysses; and Agrippina landing with the Ashes of Germanicus.

Runciman visited London in 1772 and exhibited some pictures there, but all that is remembered of him, says Allan Cunningham, is that he took up his quarters with the widow of Hogarth, who was in those days reduced to let lodgings for subsistance. Runciman died suddenly before his own door in West Nicholson-street, October 21, 1785, in his forty-ninth year. He had contracted an illness while painting the Pennicuick cupola, being forced to lie much on his back, and to this is attributed the shortness of his life.

Runciman's best works are his sketches; his faults are only multiplied in his pictures. The most offensive of his peculiarities of design is his huge length and uniformity of limb, the glaring defect also of the works of Fuseli; he was also invariably extravagant in his attitudes, and was conventional, mannered, and unnatural in his draperies. Indeed, to the precise and academic taste, the works of Runciman will, says Allan Cunningham, be ranked among the crude attempts of arrogant imbecility. In execution he was least defective in his colouring, but in composition he was ever ready, and his invention was grand and fertile. There are a few etchings by him from his own designs: the best is considered 'Sigismunda weeping over the Heart of Tancred.' He is said to have been lively and agreeable in conversation; Hume, Robertson, Lord Kames, and Monboddo were among his associates.

(Cunningham, *Lives of Eminent British Painters*, &c.)

RUSSELL, WILLIAM, LL.D., the son of poor parents, was born in the county of Selkirk in 1741, and educated, very imperfectly, in the country and in Edinburgh. He served a regular apprenticeship as a printer, and, while working as a journeyman in Edinburgh, edited a collection of modern poetry and executed a translation of a tragedy of Crebillon, which was submitted to Garrick, but rejected. In 1767 he went to London to seek his fortune, but for some time found nothing better than a place as corrector of the press for Strachan the printer. While so employed, he contributed to periodicals, and published unsuccessfully several poetical and other volumes, among which was a History of America. In 1779 appeared the first two volumes of the meritorious and popular compilation by which he is now known, 'The History of Modern Europe.' The third, fourth, and fifth volumes, bringing down the narrative to 1763, were published in 1784. In 1787 he married, and took up his residence on a farm in Dumfries-shire, where he spent the remainder of his life. In 1793 he published the first two volumes of a 'History of Ancient Europe;' and he had also begun, in terms of an engagement with Mr. Cadell, to compose a History of England from the Accession of George III. These unfinished works, however, as well as several tragedies and comedies, were stopped by his death, which took place on the 25th of December, 1793.

RYLAND, WILLIAM WYNNE, one of the best English engravers of the eighteenth century, was born in London in 1732. He was apprenticed to S. F. Ravenet, a French engraver, who was settled in England. After the completion of his term of apprenticeship he went to Paris, and studied there chiefly under Le Bas for five years. He did not confine himself however to engraving, but applied himself also much to drawing, under Boucher, a painter of eminence, and after whom he engraved, besides some others, an excellent plate of Jupiter and Leda; he also etched some plates after Oudry while at Paris, illustrating the fables of Fontaine.

Soon after his return to England Ryland was appointed engraver to George III., with a pension of 200*l.* per annum. He engraved two portraits of George III. after Ramsay, and one of Queen Charlotte holding the Princess Royal on her lap after Cotes; it was one of Cotes's principal works. 'It is greatly to be lamented,' says Strutt, in his Dictionary of Engravers, 'that Ryland's engagements in the mercantile line as a printseller, deprived him of so considerable and so precious a part of his time, and prevented his pursuing the arts with that alacrity the strength of his genius required, which seemed formed for great and extensive exertions. The works which he has left behind him abundantly prove that he had sufficient knowledge and judgment to have carried them to great perfection.' These last words refer to the sad event which abruptly put an end to Ryland's labours and life at once, but which Strutt, who must have known Ryland well, does not more particularly allude to. He was executed for forgery in the prime of life, July 28th, 1783.

Strutt, whose work was published only two years after Ryland's execution, seems to have abstained, from delicacy probably towards his widow, from a more particular notice of the disgraceful termination to his brother engraver's otherwise successful career. As this case is not known and as Ryland persisted in his innocence to the last, it may be here briefly related as the facts appeared on the trial:—Ryland appears to have been a discounter of bills, and that he was otherwise commercially engaged as a printseller, has been already noticed. He had once failed in this business, but he afterwards honourably repaid all his creditors in full, though not bound to do so by law. In the spring of 1783 the agents and servants of the East India Company in London appear to have detected several forgeries of their bills, and suspicion attached to Ryland, apparently in more than one case. He received however intimation of his approaching arrest, and by the advice of his wife concealed himself, whereupon the East India Company immediately offered a reward for his detection. He had concealed himself in the house of a shoemaker at Stepney, under the name of Jackson: having however given the man some shoes to mend, the shoemaker discovered the real name of his lodger, and gave notice to the police. When Ryland found that he was discovered, in a fit of despair he attempted to cut his throat: the attempt failed, but he seriously injured himself. A true bill was found against him by the grand jury, June 5, and he was tried at the Old Bailey July 26, before Judge Buller. The specific charge against him was for forging and uttering knowing to be forged a bill of 210*l.* on the East India Company. The case for the prosecution was this: Ryland had uttered or negotiated two bills on the East India Company for 210*l.* and of the same date, the original bill in May, 1782, and the forged bill in November of the same year. The two bills were so much alike that none could swear which was the true bill, except by two small holes through which a needle and thread had passed; and, what was of chief importance, the paper-maker gave evidence to the paper of the other bill being made after the date of the bill. The first bill had been fairly negotiated, but the party from whom Ryland asserted that he had received the second, a Mr. Hagglestone, was nowhere to be found. These facts and the circumstances of his flight and attempted suicide were urged against him by the council for the prosecution. Ryland made his own defence, but owing to the soreness of his throat from his recent attempt, it was written, and read by the clerk of the court: the following were its concluding words, as reported in the Morning Herald of July 28:—'The prosecution has endeavoured to substantiate my guilt by my flight; but let them figure to themselves the fears, the dread, the horrors, of an honest mind, pursued by officers of justice, to take my life, if I could not prove my innocence; let them reflect on the tears, the entreaties and prayers of a fond, loving, and beloved wife, and then conclude my guilt from my flight. They have also presumed to drag into evidence my attempt on my own life. I confess the attempt with shame, horror, and remorse; driven into a state of insanity, how then will they, how can they, torture insanity into a proof of my guilt!

'Two bills, one a good one, one a bad one, have been attempted to be proved in my possession: supposing that to be true, can any man say either is the forged one? Mr. Holt, from his infirmity, may easily make a mistake; and where then is any forgery? I cannot think that the court and jury will sacrifice my life to presumption, and, where there is a possibility of innocence, take it away on groundless suspicions.'

He was found guilty of uttering the bill knowing it to be forged.

After the verdict was pronounced, which he bore with the greatest calmness, he merely observed—'I dare not challenge the justness of my verdict: I am, however, conscious of my innocence; and I hope that my life will be preserved by the royal clemency of my sovereign, on whose bounty it has long subsisted.' He heard his sentence pronounced without being moved, and retired from the court as if unconcerned in the proceedings. He was executed at Tyburn on the 29th of August, about twelve o'clock, in company with five other convicts, four of whom were executed for highway robbery and burglary, the fifth for forgery. The execution was delayed some time by a violent thunder-storm. A white handkerchief was bandaged round the cap of Ryland. The curiosity of the public was so great to witness the execution of this unfortunate man, that as much as ten guineas were paid for a single room which commanded a view of the barbarous and disgusting exhibition: so great a concourse of people had not met for a similar purpose since the execution of Dr. Dodd six years previously.

Character and probability were much in favour of Ryland's innocence, though circumstantial evidence was against him. He was wealthy, according to his own account. Besides the salary of 200*l.* per annum as engraver to the king, he exercised a very lucrative profession, possessed a great stock in trade, and had a large property in the Liverpool water-works. And many witnesses bore testimony to his high character. Strutt says of him—'He was a man respected and beloved by all that were well acquainted with him; for few men in private life ever possessed more amiable qualities than he did. He was a tender husband, a kind father, and a sincere friend. He frequently straitened his own circumstances to alleviate the sorrows of others; for his heart was always open to receive the solicitations of distress.'

Ryland introduced chalk-engraving (lines composed of dots) into England, and in the latter years of his life devoted himself exclusively to engraving in this style, in which he had no equal, but chiefly, except a few drawings by the old masters, after the works of Angelica Kauffmann, a circumstance which is to be regretted, as the works of that lady have little to recommend them to the lovers of art. Ryland engraved twenty-four prints after Angelica, and one of these, Edgar and Elfrida, a large plate, which was finished by Sharp for the benefit of Mrs. Ryland, is one of his principal works. King John ratifying the Magna Charta, a large plate after Mortimer and in a similar style, was generally bought as a companion to it. Ryland left this plate also unfinished, and it was completed by Bartolozzi, likewise for the benefit of his widow. It is his best plate in this style; but the best of these chalk engravings have a very inferior effect to etchings, or line and mezzotinto engravings: the style was, however, like the insipid drawings of Cipriani, much in vogue in the time of Ryland and Bartolozzi.

As an etcher, or where the needle and graver are combined, Ryland was also excellent. The prints which he engraved in France were executed in this style, and Watelet terms his execution in this style most picturesque, and adds that one would suppose his etchings to be the work of a painter. The chalk manner is exactly in its place in imitations of chalk drawings, of which there are no better examples than Ryland's own in the fine Collection of Drawings published by Charles Rogers, as the two of St. Francis, after Carlo Maratti and Guercino, and many others. This work is entitled, 'A Collection of Prints in imitation of Drawings; to which are annexed Lives of their Authors, with explanatory and critical Notes, by Charles Rogers,' &c. 2 vols. fol. London, 1778; containing in all 116 prints, some of considerable size, of which 57 are by Ryland, besides the admirable mezzotinto portrait of Mr. Rogers at the commencement of the work. Among these imitations of drawings, in various styles, the following are particularly worthy of note, either for their excellence or on account of their authors:—The Last Supper, by Leonardo Da Vinci; two drawings, by Michael Angelo, one of which is a sketch of an attempt to restore the Torso of Apollonius; God the Father blessing the Creation, three young men naked, and another drawing, by Raphael; St. Francis, by Carlo Maratti; part of the Cupola of Parma, by Correggio; Jupiter delivering Bacchus to Mercury, by Lodovico Carracci; Joseph and Jesus, and Caricatures of Painters, by Albani; Lot and his Daughters, St. Dominic presenting St. Catherine of Siena to the Madonna del Rosario, St. Francis, St. Cecilia, and Chastity burning the Arms of Cupid, by Guercino; Bathsheba, by Boucher; Jacob persuaded to send Benjamin with his Brethren into Egypt, by Vandyck; and a Monk in his Cell, by Rembrandt. Besides these there are drawings by the following masters:—Baccio Bandinelli, Battista Franco, Perino del Vaga, Bernini, Andrea Sacchi, Steffano della Bella, Borgognone, Filippo Lauri, Cav. Ghezzi, J. Palma the younger, Parmigiano, Cam. Procaccini, An. Carracci, Schidone, F. Mola, Eliz. Sirani, L. Cambiaso, S. Rosa, Jan Breughel, and P. Wouverman. He engraved a few other prints also after P. da Cortona, Vandyck, Cipriani, Boucher, Ramsay, J. B. Oudry, and others.

RYSBRACK, MICHAEL. The date of the birth and the birth-place of this distinguished Flemish sculptor are differently given by different writers, but Charles Rogers, the publisher of the 'Century of Drawings,' &c., who was well acquainted with him, states that he was born at Antwerp June 24, 1693. He was the son of the landscape-painter Pieter Rysbrack, who, after he had given his son some instruction in design, placed him in 1706 with the sculptor Michael Vander Vorst, with whom he remained six years.

In 1720 Rysbrack came to London and distinguished himself for his small models in clay. He was the first sculptor who was extensively employed in England, and he spread a general taste for the art over the country by his fine monumental works. His progress in London was at first slow, and his first work which attracted notice was a bust of the Earl of Nottingham. He was for some time engaged by Gibbs, who contracted with the original parties for monuments, for which he, on his part, contracted with Rysbrack, greatly to his own advantage. For instance, Gibbs received from Lord Oxford 100*l*. each for the statues on Prior's monument in the south transept (or Poet's Corner) in Westminster Abbey, while he gave Rysbrack only 35*l*. each. Rysbrack, however, soon became aware of his own merit, and shook off all dependence on Gibbs. Engagements crowded upon him, and there was not a work of sculpture of any consequence undertaken in England that was not entrusted to Rysbrack. When men found, says Walpole, that there was a man capable of furnishing statues, the taste for monuments was much improved and greatly spread. 'Our monuments until Rysbrack's time,' says the same writer, 'had depended more on masonry and marbles than statuary. Gothic tombs owed their chief grandeur to rich canopies, fretwork, and abundance of small niches and trifling figures. Bishops in cumbent attitudes and cross-legged Templars admitted no grace nor required any. In the reigns of Queen Elizabeth and King James I. a single figure reclining at length on the elbow in robes or serjeant's gown, was commonly overwhelmed and surrounded by diminutive pillars and obelisks of various marbles; and if particularly sumptuous, of alabaster gilt. Gibbs, in the Duke of Newcastle's monument in the Abbey, seems to have had an eye to that kind of tasteless expense. From the reign of Charles I. altar tombs or mural tablets, with cherubims and flaming urns, generally satisfied the piety of families. Bird indeed bestowed busts and bas-reliefs on those he decorated, but Sir Cloudesley Shovel's, and other monuments by him, made men of taste dread such honours.' 'The abilities of Rysbrack,' continues Walpole, 'taught the age to depend on statuary for its best ornaments, and though he was too fond of pyramids for back-grounds, his figures are well disposed, simple, and great.'

Rysbrack, unlike most of the artists of his age, studied exclusively nature and the antique; he had no respect for the works of his great countryman Rubens, and those of Rembrandt he would not look at, in which he was of course actuated wholly by the feelings of a sculptor, form and character being his exclusive study. He was a most industrious sculptor: fine works are to be seen by him in many parts of England, but especially in Westminster Abbey, at Blenheim, at Stourhead, and at Bristol. In few sculptors' workshops has there been more activity than there was in those of Rysbrack in Vere-street, Oxford-street, during about forty years of the half century that he dwelt in England, though latterly, through his successful rivals Scheemaker and Roubiliac, his occupation sensibly diminished.

Rysbrack's busts were very numerous, and include those of many distinguished characters. His first great public work was the bronze equestrian statue of William III., which was made for the city of Bristol, and erected in Queen's Square in 1733. Scheemaker also competed for this statue, and his model was thought so excellent that he was presented with 50*l*., though it was rejected for the design of Rysbrack, who received 3000*l*. for it; Walpole says 1800*l*. The monument to Sir Isaac Newton in Westminster Abbey, which was exposed in 1731, was executed by Rysbrack from a design by Kent. One to Mrs. Oldfield, in the cloisters, put up the year before, was apparently his first independent monument in the Abbey.

In 1735 he finished a colossal statue of George II. for the parade of Greenwich Hospital, at the expense of Sir John Jennings, the then governor: it was cut out of a single block of marble weighing eleven tons, which had been captured from the French by Sir George Rooke. He made also the statue of George II., which was in the old Royal Exchange, London. He obtained however most reputation by his monument to John Duke of Marlborough and his duchess in the chapel at Blenheim. They are represented with their two sons, who died young, supported by Fame and History; in the lower part is a basso-rilievo of the surrender of Marshal Tallard. At Blenheim also, in the library, is a beautiful marble statue of Queen Anne; it was erected in 1726.

In Christ Church College, Oxford, there is a statue of Locke by Rysbrack, which is in the 'Oxford Guide' erroneously attributed to Roubiliac; it was made in 1757. This college contains also some busts of distinguished members by Rysbrack. Besides what have been already mentioned there are the following monuments by him in Wesminster Abbey:—to Admiral Vernon, and Richard Kane, governor of Minorca, in the north transept; to James Earl Stanhope, in the north aisle; to John Friend, M.D.; and John Methuen, in the south aisle; to Sir Godfrey Kneller, in the nave; to John Gay, Nicholas Rowe, John Milton, and Ben Jonson, in the south transept or Poet's Corner; and one to Daniel Pulteney in the cloisters.

The erection of Shakspere's monument by Scheemaker, in Westminster Abbey, is said to have greatly obscured the reputation of Rysbrack; but it only stimulated the industrious sculptor to make still greater exertions. This dread rivalry was the cause of his making his Palladio, Inigo Jones, and Fiammingo, at Chiswick; and subsequently his masterpiece, the Hercules, at Stourhead, the seat of Sir Richard Colt Hoare. This Hercules is a species of historical figure, a record of the English gymnasium or amphitheatre for boxing, an institution which was put an end to, as the principal gymnasiasts generally ended their career by being hanged. The figure was made for Henry Hoare, Esq., who built a temple expressly for it. It is of the heroic size, seven feet high, and cost Rysbrack three years' labour. The head is copied from the Farnese Hercules; the limbs are taken from several different English frequenters of this gymnastic amphitheatre. 'The arms,' says Walpolo, 'were Broughton's; the breast a celebrated coachman's, a bruiser; and the legs were those of Ellis the painter, a great frequenter of that gymnasium.'

There are many other statues by Rysbrack—as a Flora, from the antique, at Stourhead; the Duke of Somerset, at Cambridge, presented by his daughters the Marchioness of Granby and Lady Guernsey; Charles Duke of Somerset and his Duchess, in Salisbury Cathedral; Sir Hans Sloane, in the botanical garden at Chelsea, and his bust in the British Museum; Lady Folkestone, Coleshill, Berks; Lady Besborough, Derby; the second, third, and fourth Dukes of Beaufort, at Badminton, Gloucestershire; Dr. Radcliffe, at Oxford; John Willet, Esq., Merly House, Dorsetshire; a statue of Charles I., for George Selwyn; and the following busts:—Pope, Gibbs, Sir Robert Walpole, Duke and Duchess of Argyle, Lord Bolingbroke, Wooton the landscape-painter, Martin Folkes, Ben Jonson, Butler, Milton, Cromwell, the heads in the Hermitage at Richmond, and those of the English Worthies in the Elysian Fields at Stowe: he made also a good bust of himself. Notwithstanding his industry, Rysbrack was not rich, and when at the age of seventy he gave up his profession, he made a sale of his principal effects—his remaining works and his collections of prints, pictures, drawings, marbles, casts, models, &c., including a large collection of his own drawings, which, says Walpole, were conceived and executed in the true taste of the great Italian masters. The chief amusement of the last three years of his life was in making such drawings in bistre, and many were sold at the two auctions of his effects which took place after his death. He died January 8, 1770.

RYSO'STEUS, a fossil genus of Reptiles from the bone-bed of the lias on the banks of the Severn. (Owen.)

INDEX TO THE LETTER R.

VOLUME II.

SABI'NEA (named by De Candolle, in honour of Joseph Sabine, F.R.S., long time Secretary to the Horticultural Society of London), a genus of plants belonging to the natural order Leguminosae. It has a cup-shaped campanulate calyx with a truncate nearly entire border, a papilionaceous corolla, with an obtuse keel, rather shorter than the vexillum. The stamens are diadelphous, the free one and four others half as short as the rest. The style is filiform, glabrous, and rolled up with the stamens. The legume stipitate, compressed, linear, elongated, many-seeded, mucronate by the style. The species are unarmed West Indian shrubs, with abruptly pinnated leaves, smooth mucronated leaflets, and one-flowered fascicled pedicels.

S. Florida has its leaflets in 8 or 9 pairs, elliptic oblong, the flowers rising before the leaves. It is native of the American Islands of St. John, Krabben Island, and St. Thomas. The violet flowers are considered poisonous.

S. dubia has its leaflets in 10-12 pairs, elliptic oblong, the flowers appearing after the leaves. It is native of Martinique and Porto Rico.

(Lindley, *Flora Medica*; Don, *Gardener's Dictionary*.)

SABI'NUS, MASSU'RIUS, a Roman jurist, a pupil of Aleius Capito, and the contemporary of Cocceius Nerva. He lived under Tiberius, but he did not die in that reign, as is generally asserted, if the passage of Gaius (ii. 218) refers to Massurius Sabinus, of which indeed there can be no doubt. Massurius Sabinus gave the name of Sabiniani to the school which was opposed to that of the Proculiani. [ROMAN LAW, P. C., p. 118.] He was near fifty years of age when he was raised to the equestrian rank, and was in such poor circumstances that he was mainly supported by the fees of his pupils (Pompon. *Dig.* i., tit. 2, s. 2, § 47). It is said of him by Pomponius 'publicè primus respondit' (he was the first who gave opinions publicly). Though the word is respondit in the common editions of the Digest, the passage is quoted thus by Zimmern: 'publicè primus scripsit.' It follows however from what Pomponius says, that with Massurius began the practice of giving written opinions, which were sealed with the seal of the jurist (responsa signata).

The reputation of Sabinus is shown by the publicity of his name, which was equivalent to the title of a great lawyer (Persius, *Sat.* v. 90; Arrian, *Epictetus*, iv. 3); and by giving his name to the school, of which his master Capito was considered to be the real founder. This is evidence of the greater originality and more enlarged views of Sabinus. His great work was 'Libri III. Juris Civilis,' from which there is no direct excerpt in the Digest, though there are various fragments in Gellius, iv. 1; v. 13, &c.). The system followed in this work had a great influence on subsequent writers. Pomponius wrote at least 36 Libri ad Sabinum, Paulus 47, and Ulpian 51. The arrangement of the matter of the work of Sabinus is made out conjecturally by J. Gothofredus from the labours of his three commentators (Zimmern, p. 313, n. 7).

The other works of Sabinus were—'Commentarii de Indigenis,' 'Libri Memorialium,' 'Fasti,' books of Responsa, a Commentary Ad Edictum, and 'Libri ad Vitellium.'

(Zimmern, *Geschichte des Röm. Privatrechts;* Index to A. Gellius, ed. Gronov. 1706; Grotius, *Vitae Jurisconsultorum.*)

SABINUS, CAELIUS, M., a Roman jurist, and the successor of Cassius Longinus. He was made Consul Designatus by Otho (Tacit. *Hist.* i. 77); and his consulship belongs to the year A.D. 69, in which Otho died and Vitellius became Emperor. He belongs chiefly to the time of Vespasian. He wrote a work, Ad Edictum Aedilium Curulium, which is cited by other jurists (Gaius, Dig. 20, tit. 1, s. 20): but there is no excerpt from Caelius Sabinus in the Digest. He also wrote on other subjects (Dig. 35, tit. 1, s. 72, § 7). The extract in Gellius (vii. 4, Pileatos servos, &c.) is probably from the treatise Ad Edictum, for Gellius in another passage (iv. 2) speaks of Sabinus as the author of such a treatise, though he calls him in this passage, according to some MSS., Caecilius. He is often cited in the Digest simply by the name of Sabinus or Caelius (Dig. 20, tit. 1, s. 14, 17, 65). Caelius Sabinus is cited by Gaius in his Institutiones (iii. 70, 141).

SACCHOLACTIC ACID. [CHEMISTRY—*Mucid Acid*, P. C. S.]

SADI. [SAADI, P. C.]

SAFETY-VALVE. [STEAM-ENGINE, P. C.]

SAGENA'RIA, a fossil genus of plants belonging to the coal-formation. (Brongniart.) It includes species ranked by Sternberg as Lepidodendron.

SAGENO'CRINUS, a genus of fossil crinoidea. (Austin.) From the Silurian strata of Dudley.

SAGENO'PTERIS, a genus of fossil ferns. (Presl.) It occurs in the shales of the Yorkshire coast, and includes part of Glossopteris. (Brong.)

SAGRA. [EUPODA, P. C. S.]

SAHARUNPOOR, a district in the province of Delhi and presidency of Bengal, in Hindustan, formerly extended northward from the city of Delhi as far as the Sewalic Mountains, which form the northern limit of the immense valley through which the Ganges flows. The Ganges and Jumna, north of the city of Delhi, run nearly parallel to each other at a distance of about 53 miles, and the district of Saharunpoor occupied the doab, or flat space, between them. The soil of the whole of this space is exceedingly fertile, producing grain of all kinds, sugar, cotton, indigo, and tobacco. Madajee Sindia obtained possession of it in 1788, and it was held by the Mahrattas till 1803, when it was given up to the British. In 1804 it was formed into two divisions, Northern Saharunpoor and Southern Saharunpoor, with a civil establishment for each; but this arrangement has been since modified, and the greater part of Southern Saharunpoor has been included in the district of Merut. Of the district of Merut, or Southern Saharunpoor as it is still sometimes called, the chief town is Merut, in 28° 53′ N. lat., 77° 45′ E. long. Of the district of Northern Saharunpoor the chief town is Saharunpoor, in 29° 53′ N. lat., 77° 33′ E. long., and about 90 miles, direct distance, N. by E. from the city of Delhi.

(Hamilton, *East India Gazetteer*.)

SAILORS. [SHIPS, P. C.; SEAMEN, P. C. S.]

SAILS. Accidents involving serious loss of life and property are continually occurring from the inability of ordinary sails to resist violent gusts of wind. The sails of a ship [SAIL, P. C., p. 318] usually consist of several widths of canvass sewn together side by side, with the seams arranged vertically; and the principal strength which they have to resist tearing arises from cords sewn along the edges of the sail. If these give way, or if from any accident a tear is commenced, the rupture frequently extends at once along the whole length of the canvass, and the sail is thereby, in nautical phrase, 'torn into ribands.' To provide a remedy for this formidable evil, Mr. Archibald Trail patented in 1844 an improved kind of sail, which, from their fitness to resist violent winds, he terms *Storm-sails.* These are made in the usual manner, and subsequently strengthened by sewing to their surface a number of canvass bands about an inch broad, with cords woven in them, such bands being secured at their ends into the bolt-ropes, or cords forming the boundaries of the sail, and carried diagonally across the surface of the sail at an angle of 45° with the seams, and at a distance of about three feet from each other. Two sets of bands are used, crossing the sail in opposite directions, one set being attached on each side of the canvass; and the distance of the bands from each other is so adjusted with reference to the width of the canvass, that the points where the two sets cross each other may fall upon the vertical seams. By this simple contrivance the strain is so equalized as to render tearing less probable than with an ordinary sail; while, if any injury be inflicted, the rent is confined within the narrow limits of one of the diamond-shaped compartments into which the sail is divided by the protecting bands. In ordinary cases it is proposed to apply these bands not to new sails, but to such as are half-worn; and the patentee states that such sails may be thus protected at one-fifth of their original cost. Many nautical men, after putting the invention to the test of experience, have testified their hearty approval; and it is suggested by some that its adoption may lead to the use of lighter canvass than would be safe with sails of the ordinary make, by which means the sails may be more easily handled, a circumstance of great importance in a gale of wind, while a saving may be effected in the cost of the canvass sufficient to make the extra cost of the protection only one-ninth instead of one-fifth.

SAINT GEORGE, SAINT MARY, SAINT MICHAEL, Islands. [George, St.; Mary, St.; Michael, St.; P. C. S.]

SAINT HILAIRE, GEOFFROY ETIENNE, was born at Etampes, in France, the 15th of April, 1772. He was destined by his father for the church, and received the appointment to a canonry in his twelfth year. He was, however, sent to the college of Navarre, where Brisson lectured on experimental philosophy, and under him he acquired a taste for the natural sciences. He first devoted himself to mineralogy, in which Haüy was his preceptor. On coming to Paris he studied very diligently, and in 1793 was appointed subcurator and demonstrator of the Natural History cabinet, in the Jardin des Plantes. He was subsequently appointed professor of zoology, and lectured conjointly with Cuvier. In 1798 he accompanied the French expedition to Egypt. He was made a member of the Institute in 1807, and appointed professor of anatomy and physiology in the faculty of sciences in 1809. He was sent by the government on a scientific expedition to Portugal in 1808. In 1815 he was returned as a member of the Chamber of Deputies for his native city of Etampes. He died at Paris in July, 1844.

Geoffroy St. Hilaire was one of the most assiduous cultivators and ablest expounders of what is called philosophical anatomy. The idea on which this department of science was founded had been developed in Germany, and successfully applied to zoology and comparative anatomy during the latter part of the last century. It was however, amongst the rich collections of the Jardin des Plantes, and the activity and zeal of such men as Cuvier, Lamarck, Temminck, Desmarest, Valenciennes, Serres, and St. Hilaire, that it received its most important applications and its greatest development. The fundamental idea of this system is the unity of the composition of the various parts of an organic body, and that this unity is capable of expression in a few simple laws. What, in fact, might be predicated in botany of the various parts of a plant by a knowledge of the structure of the leaf, might, in the same way, be predicated of the structure of animals by a knowledge of certain fundamental parts of their organisation. Thus Geoffroy St. Hilaire, amongst his other labours, established the fact that the numerous bones of the head of the fish, and by consequence those of the higher animals, were transformations of the simple vertebræ; and that the laws of development which applied to the one applied to the other.

These views, equally applicable to every organ of the body, were generally developed by St. Hilaire in a work published in 1818, entitled 'Philosophie Anatomique,' which was illustrated with an Atlas of folio plates. He also published several papers and essays on the principles of philosophical anatomy. In 1828 a small work appeared as an introduction to the lectures delivered on natural history in the Jardin des Plantes on the principle of the unity of organic composition, with the title, 'Sur le Principe de l'Unité de Composition Organique,' 8vo. Although previous to the time of Geoffroy the morphological idea lying at the basis of philosophical anatomy had been applied to the explanation of the phenomena of abnormal forms of animals, just as it had been of plants, yet the subject had not been fully developed. In 1822 he published his great work on the anatomical philosophy of human monsters. These beings, which had formerly been regarded as mere unaccountable freaks of nature, were now found to be the result of the action of fixed laws, and their various forms susceptible of the strictest classification. This work contained a new classification of monsters, with a description of and comparison of their different forms, and a history of the various causes supposed to produce them. It also comprehended some new views on the nutrition of the fœtus, and an accurate estimate of the phenomena attending the development of the sexual organs in the male and female fœtus, in which the author pointed out the fact of a unity of composition in the reproductive apparatus of the two sexes in birds and mammalia.

A list of the papers which St. Hilaire contributed to the various departments of natural history would be very long. There is scarcely a branch of zoology to which he did not successfully apply the great principles of his anatomical philosophy; and few indeed are the works on natural history published during the present century that do not bear testimony to the great influence he has exerted. At the same time the views held by the school, at the head of which Geoffroy St. Hilaire may be justly placed, have led to great controversy. Fully as Cuvier was impressed with the importance of Geoffroy's works, he opposed him in some of his conclusions, and this led to a controversy which developed, in these inquiries, a theological element: Geoffroy opposed the doctrine of final causes, as being in opposition to the theory of a unity of composition. In his philosophy he states that he knows nothing of 'intentions' or 'objects' in creation; and when Cuvier spoke of the part an animal 'had to play' in nature, he rejoined that there were 'no animals which had a part to play in nature.' This controversy has recently, in this country, assumed a popular form; but it is obvious, from the use made by the advocates of the doctrine of final causes, of the principles of the 'Anatomical Philosophy,' that this theory is not incompatible with their views.

A complete edition of the works of Geoffroy has been published in France under the title of 'Professional Studies of a Naturalist,' in 42 volumes. Etienne Geoffroy St. Hilaire has left behind him a son, Isidore, now Professor of Zoology at Bordeaux, and formerly at Paris, who has successfully cultivated the favourite science of his father. A complete list of Etienne Geoffroy St. Hilaire's works will be found in Callisen's 'Medicinisches-Schriftsteller Lexicon.'

SALE'NIA, a genus of Echinodermata, remarkably prolific of species in the lower part of the cretaceous system. (Agassiz.)

SALES, DE, FRANCIS, SAINT, was born at the Castle of Sales, near Annecy, in Savoy, on 21st August, 1567. His parents, the Count and Countess de Sales, are described as having adorned a noble birth and elevated station by a life of the strictest piety. The early years of Francis, their eldest son, were spent in acquiring the rudiments of learning at the colleges of La Roche and Annecy. The more effectually to pursue his studies he was, in 1578, sent to Paris, and placed under the care of the Jesuits. He soon became a proficient in rhetoric and philosophy, and, at the same time, he did not neglect those arts which are calculated to adorn an intercourse with society, though in doing so he appears rather to have obeyed the wishes of his father than to have followed his natural inclination. He remained in Paris till 1584, when he was sent to Padua to study civil law under Guy Pancirolli. At Padua he formed an acquaintance, which afterwards increased into friendship, with the Jesuit Antonio Possevino, under whose spiritual direction he placed himself. His success at Padua exceeded the expectation of his friends, and, at the age of twenty-four, he left that university with a high reputation for learning and piety. He afterwards spent some time in Italy, and made a pilgrimage to Notre Dame of Loretto. On his return to his native country, he found that his father had obtained for him from the Duke of Savoy the appointment of Counsellor in the Senate of Chambery, and was desirous of uniting him with a rich heiress, whose fortune would enable him to support the title which he was to inherit. The mind of Francis, for a long time directed towards theological pursuits, had however gradually acquired a disposition which could only be satisfied by an entire devotion to them, and he was anxious to enter the church. But accustomed from his childhood to yield obedience to his father's wishes, he feared to make him acquainted with his desire. In this difficulty he consulted a relation, Louis de Sales, who was canon of the church of Geneva, and through his mediation the Count de Sales was induced to abandon his favourite project, and allowed his son to devote himself to the ministry of the church. After receiving the first orders he was permitted by the bishop to preach. The greatest success attended his first efforts in pulpit oratory. He possessed, indeed, all the qualities calculated to gain the attention of his hearers; a voice powerful and pleasing, an animated and persuasive action, an earnestness which gave evidence that he was himself deeply convinced of the truths he was advocating, were heightened in their effect by a strikingly handsome person and a mild and modest demeanour. In the fulfilment of his pastoral duties he was not less remarkable: he united the most untiring activity in visiting his flock and in relieving the wants of the sick and poor with an unaffected solicitude and evangelical patience. 'His fair, mild countenance,' says a French writer, the bias of whose writings is most unfavourable to the priesthood, 'with rather a childish expression, pleased at first sight; little children in their nurses' arms could not take their eyes off him. He was equally delighted with them, and would exclaim, as he fondly caressed them—here is my little family. The children ran after him, and the mothers followed them.' (Michelet, *Priests, Women, and Families*, translated by Cocks.)

We must now present him exercising these qualities in a larger sphere, and applying them to the conversion of those who differed from him in religious faith. The better to understand the peculiarly difficult nature of the mission with which he was intrusted it will be necessary to give some account of the scene of his labours. The city of Geneva had long renounced the authority of its bishop and that of the Duke of Savoy; it was an independent republic and the stronghold of the Calvinistic party. It had become possessed of the antient duchy of Chablais [GENEVA, P. C.], together with the territories of Gex, Terni, and Gaillard; coincident with these changes was a substitution among the inhabitants of the creed of Calvin for the faith of Rome. In 1590, Charles Emmanuel Duke of Savoy, had wrested from the Genevese this antient portion of his duchy, and his first care was to attempt to bring back the inhabitants to their former religion. (De Thou, *Hist. Univ.*, l. xcix.) For this purpose he applied to the titular bishop of Geneva, Claude de Granier, to send missionaries over the conquered country. Francis de Sales, and his relation Louis, the canon of Geneva, were among the first to undertake an enterprise in the prosecution of which much opposition and some personal danger were to be apprehended.

On the 9th September, 1594, the two missionaries arrived at the frontiers of Chablais, where they dismissed their servants and equipages and determined to travel on foot, in order more nearly to conform to the example of the Apostles. The town of Tonon, the capital of the Chablais [CHABLAIS, P. C.], which contained only seven Roman Catholics, was the first place in which they exercised their mission; the fruit of it may be judged of from the fact that on the Christmas-eve of 1597 eight hundred persons were admitted to the communion of the Eucharist in the church of St. Hippolytus in that town. But the most important object Francis had in view was the conversion of the leaders of the Calvinistic party. To effect it he first solicited an interview with Theodore de Beza [BEZA, P. C.], who was then fast sinking under the weight of age and infirmities; several conferences took place between them at Geneva, and the result of them is very differently related according to the religious persuasion of the narrators. Whatever change however took place in the mind of Beza through his intercourse with Francis, it is certain that it was accompanied by no public profession.* Michelet, without however citing his authority, remarks, that the Roman Catholic missionary added to his spiritual inducements the weight of temporal advantages, and made him an offer of a pension of 4000 crowns if be would conform to his church.

On the return of Francis to Annecy, in 1596, he was appointed coadjutor to Claude de Granier, the bishop of Geneva, with the title of Bishop of Nicopolis 'in partibus infidelium;' this dignity he for a long time refused to accept, and only yielded on the earnest solicitation of the pope, Innocent IX.

In 1602 he visited the court of France for the purpose of obtaining permission from the king, Henry IV., to pursue his missionary labours in the territory of Gex, which had been given up to France by a treaty of peace concluded between Henry and the Duke of Savoy. A course of Lent sermons, which he preached in the chapel of the Louvre, is said to have created considerable sensation, and to have become the means of recalling several of the most influential of the Calvinistic nobility to a belief in their antient faith. The king, desirous of retaining him in France, made him the offer of the first bishopric which might become vacant and the immediate enjoyment of a considerable pension. These offers however he declined, declaring that his chief wish was to be permitted to live and die among those whom Providence had intrusted to his care.

On his return to his native country, after a residence of nine months in Paris, he was, by the death of De Granier, a prelate who appears to have been worthy of so illustrious a colleague, appointed to the bishopric of Geneva. He prepared himself by a close retirement of twenty days at the castle of Sales, for his consecration to this important office. In this retirement he framed for himself a rule of life by which he was in future to be guided; the details of it are given with elaborate minuteness by his biographers, and are so far interesting as they show that he considered the faithful fulfilment of duty of greater importance in the sight of God than the exercise of bodily mortifications or the display of an ascetic austerity. On the 8th December, 1602, he was consecrated bishop of Geneva. His first care was to introduce a uniformity of usage among the clergy of his diocese, and to reform various abuses which time had gradually introduced; these measures he chiefly effected by the issue of mandates in which the most judicious advice was conveyed in the language of Christian charity. In short, he showed himself a worthy disciple of St. Charles Borromeo, whom he professed to take as his model in the discharge of his episcopal duties. [BORROMEO, ST. CHARLES, P. C.] In 1605 he devoted himself effectually to the task of reforming the monasteries in his diocese. The following year be preached during Lent at Dijon, in France, where he was again successful in making several converts from Calvinism. On this occasion, likewise, he refused the repeated offers of advancement from the French king, while at the time he gave proof of his consistency in declining the proffered honour of a cardinal's hat from the pope, Leo XI. In 1607 he was applied to by the reigning pontiff, Paul V., to express his opinions on the extent of the efficacy of Divine Grace on the free will of man. It was principally on this question that the Dominicans and Jesuits were divided [BLACK FRIARS, P. C.; JESUITS, P. C.]. His answer is expressed with so much caution that it is difficult to discover from it his real sentiments; they are, however, more clearly shown in his other writings, especially in his treatise on the Love of God. About this period was published his 'Introduction to a Religious Life,' a book which still maintains a merited popularity. The style, though perhaps too full of metaphor for modern taste, is devoid of affectation, and breathes throughout the genuine spirit of Christian simplicity. 'Everywhere we find, as it were, living fountains springing up, flowers after flowers, rivulets meandering as in a lovely spring morning after a shower. It might be said that he amuses himself too much with flowerets; that his nosegay is no longer such as shepherdesses gather, but such as would suit a flower-girl: as his Philothea would say, he takes them all and takes too many; there are some colours among them badly matched, and have a strange effect.' (Michelet, *transl.* by Cocks.)

In 1609, Jean Pierre Camus was named Bishop of Bellay, and he wrote to the Bishop of Geneva to request him to perform the ceremony of his consecration. Between these two remarkable men, whose habits and dispositions were very dissimilar, the closest friendship ever after subsisted. It is to Camus that we are indebted for a most interesting work, 'The Spirit of St. Francis de Sales,' which, more than any other, developes the private excellences of the saint. The following year Francis founded a religious order for females, called the Order of the Visitation, and placed it under the superintendence of a pious lady, Madame de Chantal, sister of the Archbishop of Bourges, with whom he had become acquainted on his visit to Dijon. The fervent admiration of this lady for the qualities of the Bishop of Geneva, to whom she had intrusted the guidance of her spiritual life, the letters of perhaps too impassioned piety which she so frequently addressed him, and which may be seen in the collection published at Paris in 1660, have been malignly dwelt upon by some writers who have hazarded to attack the church in the persons of such men as Bossuet, Fenelon, and De Sales. The increasing infirmities of the Bishop of Geneva, arising from the constant application to the duties of his office, obliged him, in 1618, to seek for the assistance of a coadjutor bishop; and, at the suggestion of Cardinal Frederick Borromeo, his brother, John Francis de Sales, was consecrated to that charge with the title of Bishop of Chalcedon. In 1619 he accompanied to Paris the Cardinal of Savoy, to whom the mission had been intrusted of soliciting for the Prince of Piedmont the hand of Christina, sister of Louis XIII. On the marriage of this princess he was appointed her almoner, an office which he at first declined, and only accepted on condition that it should not be allowed to interfere with the discharge of his other duties. But the undiminished energy of such a spirit was too overpowering for so feeble a frame. In 1622 he foresaw his approaching end, and prepared himself for it by severer mortifications and a closer communion with God. He preached for the last time on the Christmas-eve of that year; the next day he was seized with a paralytic attack, under which he succumbed on the 28th December, 1622. He was buried in the Church of the Visitation at Lyon, but his remains were afterwards transferred to Annecy. In 1665, his memory was canonized by the pope, Alexander VII., who appointed the 29th of January, the day on which his body was conveyed to Annecy, as his festival in the Roman calendar.

* 'La veine poëtique de Bèze,' says Bayle, 'n'étoit point tellement tarie l'an 1597, qu'il ne fit de vers pleins de feu contre les Jésuites, à l'occasion du bruit que l'on fit courir qu'il étoit mort, et qu'avant d'expirer il avoit fait profession de la foi Romaine.' (Bayle, *Dict. Hist.*, art. 'Bèze.' See also Jacob Spon, *Hist. de Genève*, liv. 3, p. 313. Utrecht, 1685.)

The claims of St. Francis de Sales as a devoted servant of the church have never been disputed, though they have been differently esteemed and represented. Humility and zeal were the two prominent virtues by which he was distinguished; the former taught him to forget himself, the latter to be ever mindful of the wants of others. Between him and Fenelon a closer comparison might perhaps be made than with any other name celebrated in the annals of sanctity. They possessed in common noble birth and a high station, with the tone and manner which these advantages are calculated to produce; the same talent in captivating the attention and winning the sympathies of those among whom they laboured; in the discharge of their pastoral duties they were alike successful, and by the use of the same means, a careful adaptation of advice to the temper and disposition of the advised. While, however, it must be admitted that Fenelon was superior to De Sales as a writer and a theologian, he was probably inferior to him in genuine disinterestedness and the practice of self-denial: he loved rather to labour among the rich and great than, like De Sales, to abandon the court in order to mingle with the crowd of the poor and suffering. Fenelon, it is true, performed with zeal those essential duties of a pastor when he was banished to his diocese; De Sales was continually separating himself from the court in order to perform them. [FENELON, P.C.]

The most known of his writings, which are not very numerous, have been noticed in this article; the best edition of them is that of Paris, 1641, 2 vols. folio.

His principal biographers are his nephew, Charles Augustus De Sales, Henri De Maupas, Bishop of Evreux, Le Père Goulu, Mad. De Bussy Rabutin, and the Jansenist Binet. See also Alban Butler's *Lives of the Saints*; Moreri, *Dict. Historique*; and the *Biographie Universelle*.

SA'MARA. [SIMBIRSK, P. C.]

SAMEN or SEMIEN MOUNTAINS. [ABYSSINIA, P. C. S.]

SAMENESS or IDENTITY. This term is generally applied to what is called personal identity, or the sameness of a living and intellectual being, as man. There are some remarks on this subject by Bishop Butler in his 'Dissertation of Personal Identity.'

The sameness of objects which are external to a man consists in the perception of a variety of circumstances as to these external objects and at different times, from which arises an opinion of sameness in a certain sense. A man sees a tree growing in a certain place, and he may have remembered it for many years. But in the mean time the tree may have increased a hundred-fold in bulk, and therefore its substance is not the same as that of the tree which he first saw there; and besides this, there may not be a single particle of matter the same in the tree at two remote times of his observation. The tree then is by the supposition not the same in a strict sense; but for all practical purpose it is called and is the same. A man can no more believe that all the change that the tree has undergone belongs to some other tree, than he can believe that the growth of his own body belongs to another being than himself.

When sameness is applied to a living and intellectual being, it includes both the matter of the body and something else. A man can have no doubt that his body is not entirely the same in youth, in middle age, and in old age. He can view his body as he does any thing external, and he has a belief that it undergoes changes, and is therefore not the same in the strict sense. But yet he considers himself the same person; person here including something besides the body, whether that something be a property of an organized body or something else. 'The ground of the doubt,' says Locke, as quoted by Butler, 'whether the same person be the same substance, is said to be this—that the consciousness of our own existence, in youth and in old age, or in any two successive moments, is not the same individual action, *i. e.* not the same consciousness, but different successive consciousnesses.' Butler's answer to this vague talk is sufficient. But more may be said. How is consciousness of our personal identity, or if this form of words be objected to as a way of begging the question, how is the thing called 'consciousness of our existence' at any two successive moments shown to be 'not the same consciousness, but different successive consciousnesses?' What are successive moments in a man's consciousness of his own existence? It is more consistent with that consciousness which we have, to say that the consciousness of our personal identity is one and the same always; and if it is allowed that there is in man a belief that he is at different times the same being, in some sense which he cannot otherwise explain than that he feels that he is, it follows that this consciousness of personal identity is one indivisible thing, that it is as continuous as the personal identity itself which it presupposes. Nor is it any objection that a man's faculties may be temporarily impaired by illness, and he may lose the exercise of his reason and recover it; or an accident may befall him, which for a time renders his bodily and mental powers inactive, though he may finally recover both. On his recovery he does not doubt that he is the same person that he was before his illness or accident, and therefore his consciousness is one. The division of consciousness by successive times, corresponding to certain external signs, and the making that supposed succession a ground of objection to personal identity, is to confound things that are unlike, and to apply a measure to both that does not fit one of the things.

'Every person,' says Butler, 'is conscious that he is now the same person or self he was, as far back as his remembrance reaches.' This cannot be disputed. It is a bare fact that this consciousness does exist in us. We have not this consciousness from the time of our birth up to manhood and old age: it does not go further back in its particular manifestations than our remembrance does; yet we doubt not that we, the man, were once that particular child of our parents rather than any other child of these parents or of any other parents. But this belief is derived from evidence: our consciousness in its particular manifestations does not extend farther back than our remembrance. Yet remembrance does not make personal identity, as Butler remarks: 'Consciousness of personal identity presupposes, and therefore cannot constitute personal identity, any more than knowledge, in any other case, can constitute truth, which it presupposes.'

The remembrance of particular things is a very different thing from the consciousness of personal identity. When this consciousness begins, when it ends, how its activity is suspended, we know not: but we know that it is a law of our nature that, in the ordinary state of a man's bodily and intellectual faculties, he has a perception, whatever it may be and however it may arise, whenever he reviews certain acts of his own or events in his life, that he the perceiver, and no other person, is the agent or is the person affected by these events. The remembrance then merely makes the consciousness of personal identity active; and this consciousness of personal identity is not constituted of the remembrance of different acts or events, but is as permanent and uninterrupted as the animal life itself, which nobody supposes to consist of successive lives, but to be one life. And it should be observed that the question of personal identity only arises upon the suggestion of the memory. Every man all through his life feels that he is in some sense or in some way, which he expresses by that term 'is.' And he is never without this present consciousness of existence. There is therefore an uninterrupted consciousness, which, as already observed, is one, and not divisible by a measure of time. The remembrance of any particular act of a man's own or of any event in his own life, is a present act, and the consciousness of such present act of memory accompanies the act of memory as it does any other present act; and as the act of memory is retrospective, so is the consciousness of that act of memory retrospective, but only incidentally, according to the nature of the act. The memory merely directs the conscious agent to an act of the kind called passed, and to a passed act of such a kind that the consciousness of sameness in the agent is inseparable from the notion of the act that is remembered.

SA'MOLUS, a genus of plants belonging to the natural order Primulaceae. It has a 5-parted calyx, its tube adhering to the lower half of the germen. The corolla is salver-shaped with a short tube and a 5-parted limb with interposed converging scales. The stamens, 5 in number, are inserted near to the base of the tube of the corolla. The capsules half covered by the persistent calyx, many-seeded, and opening with reflexed teeth.

S. valerandi, brook-weed, has obovate or roundish blunt leaves, the upper leaves blunt with a point, the racemes many-flowered ultimately elongated, the capsules subglobose. It is found in damp, watery places in Great Britain.

(Lindley, *Vegetable Kingdom*; Burnett, *Outlines of Botany*; Babington, *Man. Brit. Bot.*)

SAND-EEL. [AMMODYTES, P. C. S.]

SANDARAC. [THUJA, P. C.]

SA'PIUM, a genus of plants belonging to the natural order Euphorbiaceae. The flowers are monœcious, the calyx bifid and 3-toothed, the style trifid, and the capsule 3-coccous.

S. aucuparium is a tree 30 feet high, with oblong lanceolate, acute, serrate leaves, with an intermixture of larger and rounder teeth, coriaceous, shining, and about 6 inches long. The spikes are terminal, lax, thick, green, and about 6 inches long; the male above, the female below. The calyx of both of a dark purple. It is native of the woods of Carthagena.

S. indicum has alternate stalked leaves somewhat pendulous, broad, lanceolate, serrate, smooth, and of a deep shining green, from 2 to 4 inches long, and broad in proportion; the stipules small and deciduous. The calyx is 3-parted, the divisions somewhat cordate and expanding. The filaments longer than the calyx, the anthers ovate. The female flowers at the base of the catkins often solitary. The capsule or nut is globular, of the size of a nutmeg, 3-celled, 6-valved, thick, and exceedingly hard. The seed is solitary, affixed by the apex, oval, and smooth. The juice of this species, like the former, is highly poisonous.

(Lindley, *Flora Medica;* Burnett, *Outlines of Bot.*)

SAPONA'RIA (from the Latin '*sapo*,' 'soap,' so called because the bruised leaves are said to produce a lather like soap when agitated in water), a genus of plants belonging to the natural order Caryophylleae. It has a 5-toothed calyx naked at the base, 5 clawed petals, 10 stamens, and 2 styles. The capsules are 1-celled, opening at the top with 4 valves. The seeds are globular or reniform.

S. officinalis, soap-wort, has fasciculate corymbose flowers, a cylindrical slightly downy calyx, retuse crowned petals, elliptic lanceolate-ribbed leaves, and an erect stem. It is native of many parts of Europe by the road-side, and in Britain in meadows by river-sides and under hedges. The flowers are either single or double, of a rose or pink colour, seldom white. The double variety of this plant is esteemed as an ornament to the flower-border, but is found inconvenient, unless planted in pots, from the spreading nature of the roots, which extend under-ground like those of couch.

S. vaccaria has panicled flowers, pyramidsl, smooth, fine-angled calyxes; membranaceous acute bracteas; ovate, lanceolate, sessile leaves. It is native among corn in many parts of Europe, particularly Germany, Switzerland, and the Levant. It derives its specific name from the idea that it increases the lacteal secretion in cows.

All the species of this genus are very ornamental. *S. ocymoides* is one of the most elegant plants we have in our gardens, and is well adapted for rock-work. It has red or pink flowers and is a trailing plant. A mixture of sand, loam, and peat is best adapted for all the species, and they are easily propagated by dividing at the root, or by seeds; the young cuttings taking root freely under a hand-glass.

(Don, *Gardener's Dict.;* Babington, *Man. Brit. Bot.;* Burnett, *Outlines of Botany.*)

SARCOSTE'MMA (from σάρξ, flesh, and στέμμα, a crown, in reference to the leaflets of the inner corolla being fleshy), a genus of plants belonging to the natural order Asclepiadaceae. It has a rotate corolla, a coronet of double stamens; the outer one cup-shaped or annular crenated, the inner one 5-leaved, higher than the outer one, with fleshy segments. The stigma is nearly blunt. The follicles slender and smooth, and the seeds comose. The species of the genus are natives of New Holland and the East Indies as well as of South America.

S. glaucum, glaucous-leaved Sarcostemma, is a lactescent smooth twining herbaceous plant. The leaves are lanceolate, short-stalked, slightly revolute, membranous, being with the midrib prominent on the under side, which is glaucous. The umbels are many-flowered between the petioles, on very long peduncles. The segments of the calyx lanceolate, ciliated, and acuminate. The corolla white with a large fleshy annular wavy coronet; the segments of the corolla fringed and spreading.

S. Brownii is a twining glabrous plant, with lanceolate acuminated glabrous leaves, and interpetiolar umbels; the pedicels, calyxes, and corolla downy; the segments of the corolla ovate, bluntish, concave, and glabrous inside; the outer corona an entire narrow ring; the leaflets of the inner corona ovate, bluntish, and glabrous a little higher than the gynostegium. The lower leaves are large and ovate oblong, the upper ones becoming gradually narrower with revolute edges; painted with white on the nerves, and greenish blue on the veins. The calyx is small; the pollen masses oblong, a little curved, hairy, hanging by short pedicels rising from blackish glands These plants thrive best in a mixture of peat, sand, and vegetable mould; cuttings of them root readily in sand, if placed in heat without any hand-glass over them. They should have little or no water when in a dormant state, particularly the tuberous-rooted kind.

(Don, *Gardener's Dictionary;* Lindley, *Flora Medica.*)

SAROTHAMNUS, a genus of plants belonging to the natural order Leguminosae. It has a 2-lipped calyx, the upper lip with 2, the lower with 3 teeth. The style is long, curved, thickened upwards, and channelled within. The stigma terminal, capitate, and small. The pod is flat.

S. scoparius, broom. The only British species is a well-known plant, with a stem 2 or 3 feet high, angular, and glabrous. The leaves are ternate or simple, the leaflets obovate. The flowers are axillary, solitary, or in pairs, shortly stalked, large, and of a bright yellow. The pods are dark brown, hairy at the edges, and have numerous seeds. It is found on dry hills and heaths.

(Babington, *Man. Brit. Bot.*)

SATURNI'NUS, a name of several Roman jurists.

Claudius Saturninus is the name of a Roman to whom two Rescripts of Antoninus Pius are addressed (Dig. 20, tit. 3, s. 1, § 2; 50, tit. 7, s. 4); and a person of the same name was praetor under the Divi Fratres, the successors of Pius. He is generally considered to be the author of a work in a single book, 'De Poenis Paganorum,' which in the Florentine Index is attributed to Venuleius Saturninus. There is a single excerpt from this work in the Digest (48, tit. 19, s. 16).

Quintus Saturninus is cited in the Digest (34, tit. 2, s. 19, § 7) as the author of a work 'Ad Edictum,' in ten books at least. Whether he is the same as Claudius or Venuleius, or is a third person, is uncertain.

Venuleius Saturninus, a Roman jurist, who is simply called Venuleius in the Florentine Index, though in the titles of the Excerpts in the Digest he is often called Venuleius Saturninus. Lampridius (*Alexander Severus*, 68) says that he lived under Alexander Severus; but there is some doubt about his period. His writings mentioned in the Florentine Index are, Ten Books of Actiones, Six of Interdicta, Four on the Office of Proconsul, Three on Publica Judicia, and Nineteen of Stipulationes. The book De Poenis Paganorum has been already mentioned.

(Grotius, *Vitae Jurisconsultorum;* Zimmern, *Geschichte des Röm. Privatrechts*, pp. 354, 379.)

SAURI'CHTHYS, a fossil genus of fishes from Axmouth. (Agassiz.)

SAUROCE'PHALUS, a fossil genus of fishes from the chalk series of England and America. (Harlan.)

SAU'RODON, a genus of fossil fishes from the chalk series of England and America. (Hays.)

SAURO'PSIS, a genus of fossil fishes from the oolite and lias strata. (Agassiz.)

SAURUREA, a genus of composite plants belonging to the sub-order Cynarocephaleae. The florets are all hermaphrodite and tubular. The anthers with ciliated setae at the base. The involucre is imbricated and unarmed, the receptacle scaly. The pappus in 2 rows, the outer oue consisting of short, rough bristles, the inner one feathery.

S. alpina has a stem from 3 to 12 inches high, erect, downy, and simple, terminating in a small corymb of heads with pinkish florets and purple anthers. The leaves are nearly glabrous above, cottony beneath, the lower ones ovate lanceolate, the upper ones sessile lanceolate, all distantly-toothed, the heads in a dense corymb, the involucre sub-cylindrical, with depressed hairy scales. This is the only British species: it is found in alpine situations.

(Babington, *Man. Brit. Bot.*)

SAUSMAREZ, DE, JAMES, ADMIRAL LORD, was born at St. Peter Port, in the island of Guernsey, on the 11th of March, 1757. His family name, De Sausmarez, bears evidence of Norman extraction, and mention of it is to be found in the earliest records of the Channel Islands. From early youth he manifested a strong inclination for the naval service, in which several members of his family had distinguished themselves. When thirteen years of age he entered as a midshipman on board the Montreal, and afterwards served in the Winchelsea and Levant frigates, under the respective commands of Admirals Goodall and Thompson. On his return to England in 1775, he joined the Bristol, of 50 guns, under the command of Sir Peter Parker, and was present at the attack on Charlestown, in America: the courage he displayed on that occasion was rewarded by promotion to the rank of lieutenant. From that period to 1779 he was actively employed in America, and was enabled to render considerable service to the expedition under Lord Cornwallis. He was afterwards appointed second-lieutenant to the Fortitude, Admiral Sir Hydo Parker, and he was in the engagement which took place with the Dutch fleet under Admiral Zoutman, off the Dogger Bank, on the 5th of August, 1781. His behaviour in this action, in which he was wounded, caused him to be promoted to the rank of commander, and appointed to the Tisiphone fire-ship.

In the month of December following, Captain Saumarez was ordered to place himself under the command of Admiral Kempenfelt who, with twelve sail of the line, was commissioned to intercept the French fleet, commanded by the Comte de Guichen, and which was destined to assist tho Comte de Grasse in the capture of Jamaica. To inform Sir Samuel Hood, the English Admiral in the West Indies, of the sailing of this fleet, became a matter of the highest importance, and Captain Sausmarez was selected for this service. While at Jamaica he was enabled, through an exchange, to obtain post rank and the command of the Russell, a ship of the line. In this ship he greatly distinguished himself at the memorable battle of the 12th April, 1782. [HOOD, P. C.; RODNEY, P. C.] On the 29th July following, he returned in the Russell to England, and from thence to his native island, where he enjoyed in the society of his friends the peace which was soon after proclaimed. On the breaking out of the war of the French revolution (January 1793), Captain Sausmarez was appointed to the command of the Crescent, of 36 guns. In this frigate he captured off Cherbourg, after a warm action of nearly two hours and a half, the French frigate 'la Réunion,' of 36 guns, but of larger size and with a much more numerous crew. Though the French had 120 men killed and wounded, the Crescent had only one man wounded, and that by the recoil of a gun. The success of this action procured for him the honour of knighthood, and he was presented by the merchants of London with a valuable piece of plate. In the month of November following, Sir James Sausmarez was placed under the orders of Admiral Macbride, who gave him the command of a squadron consisting of the Crescent and Druid frigates, a brig, and a cutter, destined to assist the attempts made by the French Royalists to join the rising of the Vendéans. On the 5th of June, 1794, an opportunity was presented him of displaying his skill and intrepidity: whilo proceeding from Plymouth to Guernsey with the Crescent, Druid, and Eurydice frigates, he was attacked by a French squadron of more than double his force. A running-fight ensued, the brunt of which was borne by the Crescent and the Druid, to cover tho escape of the Eurydice, which, on account of its inferior sailing, ran considerable risk of being captured. This object being effected, he closed in with the enemy in the Crescent, and thus enabled the Druid also to take refuge into the roads of Guernsey. He effected the escape of the Crescent by his cool intrepidity and a perfect knowledge of the difficult coast in which he was engaged. As soon as the other ships were secure, he bore up as if to run the Crescent on the rocks to avoid being taken, ordering the pilot, a native of Guernsey, to steer through a narrow passage between the rocks, which had never before been attempted by a ship of her size; he thus reached in safety an anchorage where he was enabled to defy every effort of the enemy to take his vessel.

In March, 1795, Sir James was appointed to the Orion, 74, and placed under the orders of Lord Bridport, in which ship he opened the memorable battle which took place on the 23rd of Juno. In 1797 the Orion was attached to the squadron sent to reinforce the fleet of Sir John Jervis off Cape St. Vincent, and took a prominent part in the glorious engagement with the Spanish fleet. [JERVIS, JOHN, P. C.] He was after this battle employed till the end of April, 1798, in the blockade of Cadiz, and then selected by Lord St. Vincent to join the squadron under Sir Horatio Nelson destined to watch the operations of the French armament at Toulon. At the important victory of the Nile, Sir James, as senior captain, was the second in command, and his ship was the third which entered into action; the courage which ho displayed on this occasion was enhanced by his humano endeavours to save the remnants of the unfortunate crew of the Orient. [NELSON, P. C.]. A wound which he received during the action was so severe as to prevent his leaving the Orion, after the victory, to present his congratulations to Lord Nelson. Shortly after his return to England, on the 14th of February, 1799, Sir James Sausmarez was promoted to one of the vacant colonelcies of marines, and to the command of the Cæsar, of 84 guns, in which he sailed with a detachment of the Channel fleet, under Sir Alan Gardner, to bring home from Lisbon the ships captured at the battle of the Nile. During the winters of 1799 and 1800 he was entrusted with the command of the squadron which was commissioned to watch the French fleet in Brest. The difficulties to be encountered in this arduous service, particularly during the winter season, were very great; and it is no small praise to the careful vigilance of this commander to remark, that, during the whole time he remained on that station, not a single vessel sailed from or entered tho port of Brest.

At the commencement of the year 1801, he was promoted to the rank of rear-admiral of the blue, and in the month of June following was appointed to the command of a squadron to watch the movements of the Spanish fleet at Cadiz. On this occasion he was created a baronet. On his arrival at Cadiz, information was given him that three French line-of-battle ships and a frigate were in the bay of Algeziras, and he immediately determined upon attacking them. The position of the French was one of great strength, defended by the batteries in the bay and fourteen large gun-boats. The action commenced on the morning of the 6th of July, in which he had the misfortune to lose the Hannibal, 74, which accidentally grounded, and, after a long and sanguinary engagement, Sir James found himself compelled to repair to Gibraltar. The failure of his first attempt on the French fleet did not discourage him. Expecting that the enemy's squadron at Cadiz would make use of the first opportunity which the weather might afford of rescuing the French ships at Algeziras, he hastened to put his vessels in a state of repair. This object was effected in a remarkably short space of time. On the 10th of July, a French and Spanish fleet, consisting, with the captured Hannibal, of ten sail of the line and four frigates, was seen steering for Algeziras, with a squadron of not more than half the strength of the enemy; the admiral determined to attack them, for the purpose of preventing their return to Cadiz, and, on the 12th, sailed out to meet them. The enemy formed their line-of-battle off Cabrita. Shortly after the commencement of the engagement two of the enemy's ships were discovered to be on fire, and about midnight blew up with a tremendous explosion. An accident which occurred at daylight to the Venerable, Captain Brenton, the disabled state of the English ships, and the sudden failing of the wind, prevented the admiral from attaining his object, which was to prevent the French and Spaniards re-entering Cadiz; they did so, however, with the loss of three sail of the line, and upwards of 3000 men, blown up, killed in action, and taken prisoners. An important result of this victory was the preservation of a large fleet of British merchantmen, which it was the object of the French to seize. A most unfounded imputation has been attempted to be cast on the military character of Sir James Sausmarez by a well-known modern French historian, who has asserted that, contrary to the rules of war, red-hot shot was used by him in that engagement, and that it was owing to these means that the burning of the Spanish ships occurred. This assertion has been indignantly refuted by the concurrent testimony of several who were present at the action. The admiral was rewarded by receiving the Order of the Bath. On the meeting of parliament, a motion made by the Earl St. Vincent, and seconded by Lord Nelson, was carried, in which Sir James received the thanks of the House for his gallant conduct in his late actions with the combined fleets of France and Spain. Lord Nelson remarked that 'a greater action was never fought.' The thanks and freedom of the City of London were also voted to him, with a valuable sword.

At the peace of Amiens, Sir James Sausmarez returned to England, and, in 1803, a pension of 1200*l.* a year was conferred upon him. On the renewal of hostilities, he was appointed to the naval command of Guernsey, which he held till 1806, when he was promoted to the rank of second in command of the Channel fleet under Earl St. Vincent. On the breaking out of the war with Russia, he was intrusted with the important command of the Baltic fleet. He there displayed considerable diplomatic talent, and, by his firm but conciliatory conduct, he was powerfully instrumental in detaching Russia from her alliance with France. The judicious policy he pursued towards the Northern States has been clearly detailed by his impartial biographer Sir John Ross in the work referred to at the end of this article. As an expression of gratitude for the services rendered by Sir James to the court of Sweden, the Grand Cross of the Military Order of the Sword was conferred upon him by the king, Charles XIII. His influence with the king of Sweden was also the chief means by which the neutrality of Sweden was preserved on the accession of Marshal Bernadotte as crown prince. [CHARLES XIV. of Sweden, P. C. S.]

The changes which took place in the aspect of affairs on the Continent having rendered the presence of a British fleet in the Baltic no longer necessary, Sir James was recalled, and his recal accompanied by a letter from the Lords Commissioners of the Admiralty, in which they expressed 'their marked approbation for the zeal, judgment, and ability evinced by him during his late command.'

At the peace of 1814 he was raised to the rank of full admiral; on the visit of the allied sovereigns to England he received their personal thanks for the services which he had rendered to their cause, and, having accompanied them to Oxford, he obtained the honorary degree of Doctor of Civil Law. In 1819 he was appointed rear-admiral, and in 1821 vice-admiral of Great Britain. In 1824 he was preferred to the command of port-admiral of Plymouth, which he held till 1827, and with it may be said to have closed his professional career. At the coronation of William IV. in 1831, he was raised to the peerage of the United Kingdom, with the title of Baron de Sausmarez, of Sausmarez, in the island of Guernsey—a reward which his long and important services had merited, and which it was expected he would have received at an earlier period. He was shortly afterwards made general of marines, and in 1834 an elder brother of the Trinity House. In the same year he was presented by the King of Sweden with a full-length portrait of himself, accompanied by a most gratifying letter, which showed that time had not effaced from the mind of tho king the services rendered by Lord de Sausmarez to Sweden. The remainder of his life was for the most part spent in the enjoyment of quiet and repose on his country estate in Guernsey. His religious zeal, charity, and affable demeanour had endeared him to his countrymen; and his death, which occurred on the 9th of October, 1836, was lamented as a public loss. He was succeeded in his title by his eldest son, James, the present peer, who is in holy orders.

(*Memoirs and Correspondence of Admiral Lord de Sausmarez*, by Sir John Ross, 2 vols. 8vo., London, 1838; *Biographical Sketch of Lord de Sausmarez*, appended to Dnncan's *Hist. of Guernsey*, London, 1841; James's *Naval History*, London, 1822.)

SAVINGS' BANKS. The 5 and 6 Wm. IV. c. 57, passed in September, 1835, extended the provisions of the 9 Geo. IV. c. 92, and of 3 Wm. IV. c. 14, to savings' banks in Scotland, and enabled existing banks to conform to the said acts by preparing and depositing their rules pursuant to these acts.

Military or Regimental Savings Banks were established by warrant dated October 11, 1843. Tho following is the amount of all sums deposited in them within the year onded March 31, 1844; of all sums withdrawn during the same period; and of the interest allowed upon such deposits; and also of the nnmber of depositors on the 31st of March, 1844:—

	£	*s.*	*d.*
Amount of sums deposited . .	15,069	8	2
Amount of deposits withdrawn	316	11	$5\frac{1}{4}$
Amount of interest allowed .	96	10	$1\frac{3}{4}$
Balance due by the public . .	14,849	1	$11\frac{1}{2}$

Number of depositors, 1890.

SUMMARY of the 577 SAVINGS BANKS in ENGLAND, SCOTLAND, WALES, and IRELAND, on the 20th Nov. 1844.

On the 9th of August, 1844, the royal assent was given to an act (7 & 8 Vict. c. 83) entitled 'An Act to amend the Laws relating to Savings' Banks, and to the Purchase of Government Annuities through the Medium of Savings' Banks.'

The first clause of this act reduces, from and after the 20th of November, 1844, the interest of all moneys invested by the trustees of savings' banks in the national funds, to the rate of 3*l.* 5*s.* per cent.; and s. 2 declares that the maximum of interest to be allowed to depositors shall not exceed the rate of 3*l.* 0*s.* 10*d.* per cent.

From the same date every depositor, on making his first deposit (s. 3), shall sign a declaration as provided by previous acts, a copy of which is to be annexed to the deposit-book; and once in every year at least this book (s. 5) is to be produced at the institution for the purpose of examination.

Any actuary, cashier, or other person holding a situation at a savings' bank (s. 4), receiving deposits and not paying over the samo to the managers, is declared guilty of a misdemeanor; but no trustee or manager to be liable (s. 6) for any deficiency unless they have declared in writing their willingness to be so responsible, and this responsibility may be limited, except in cases of money actually and personally received by them.

When deposits are made in trust for another (s. 7), the sum is to be invested in the names of the trustees and the person on whose account the same is so invested; and repayment is not to be mado without the receipt of both, or of their trustees, executors, or agents appointed by power of attorney.

Annuities under the 3 and 4 Wm. IV. c. 14, are not to exceed (s. 8) the sum of 30*l.* in the whole, but separate annuities to that amount may be granted to a husband and wife; but instead of the charges nnder the former act, the charges are to be now (s. 9), for an annuity under 5*l.*, the sum of 5*s.*; 5*l.* and under 10*l.*, 10*s.*; 10*l.* and under 15*l.*, 15*s.*; 15*l.* and under 20*l.*, 20*s.*; 20*l.* and nnder 25*l.*, 25*s.*; 25*l.* and not exceeding 30*l.*, 30*s.*

Where deposits exclusive of interest do not exceed 50*l.* (s. 10), if a will or letters of administration are not produced within a month, the money may be paid to the widow, or the person entitled to the effects of the deceased; if a depositor be illegitimate and die intestate, the managers (s. 11), with the sanction of the barrister appointed to certify the rules, may pay the same to such persons as wonld be entitled to the same under the statute of distribution, if all the parties were legitimate; and where married women have made deposits it is lawful for the managers (s. 12) to repay such woman, unless the husband give notice to the contrary.

The time for issuing the half-yearly receipts for interest is extended (s. 13) to sixty days from and after the 20th of May and 20th of November; and the time for transmitting the annual statement is extended to nine weeks after the 20th of November in each year.

Any disputo between the depositors and the managers is to be settled (s. 14) by arbitration of the barrister appointed under the previous acts, whose award is to be exempt from stamp-duty; the barrister is empowered for this purpose

(s. 15) to inspect the books of the institution, and to examine witnesses on oath or affirmation: false evidence to be punished as perjury.

Bonds given as security under previous acts (9 Geo. IV. c. 92, and 3 & 4 Wm. IV. c. 14) are to be deposited with the Commissioners for the Reduction of the National Debt (s. 16), to be delivered up on the application of not less than two trustees and three managers when required to be cancelled. Every officer trusted with the receipt or custody of money (s. 17) is to give sufficient security, such security, when given by the treasurer, actuary, or any other officer receiving a salary, shall be by bond, which is exempted from stamp-duty.

The direction for depositing the rules of a savings' bank with the clerk of the peace (s. 18) is repealed; but two written or printed copies of them are to be transmitted (s. 19) to the barrister for his certificate, who, on approval, is to return one copy to the institution, and transmit the other to the commissioners.

Payments to the relations of intestate depositors (s. 20) are to be made to the next of kin by the law of Scotland, in the case of deposits in that country.

The act is declared (s. 21) to extend to societies for purchasing annuities as well as to savings' banks, and (s. 22) to Great Britain and Ireland, Berwick-upon-Tweed, Guernsey, Jersey, and Isle of Man.

SCABIO'SA (from *scabies*, the Latin word for scab or itch, which disorder the common sort is said to cure), a genus of plants belonging to the natural order Dipsaceæ. The inner calyx consists of 5 bristles, the outer one is membranous and plaited. The receptacles scaly. The fruit nearly cylindrical, with 8 excavations. The corollas 4 or 5-cleft with 4 stamens. The species are perennial or suffruticose herbs with variable leaves.

S. succisa, Devil's-bit, has an abrupt root appearing as if it were bitten off at the end, the heads of the flower and fruit nearly globose, the outer calyx hairy, 4-cleft, the lobes ovate acute, the inner calyx consisting of 5 bristles. The corolla is 4-cleft, the lower leaves toothed, the upper ones entire. The stem and both sides of the leaves hairy or glabrous. The flowers are dark violet or purple, varying to flesh-colour and white. It is native of Europe to the Caucasus, and is very plentiful in Britain. In cultivation the plant becomes much more branched than in a wild state. In days of superstition it was fabled that the devil, envying the good this plant might do mankind, bit away part of the root, and hence its common specific name. According to Bergen, the root is astringent, and an infusion of it is bitter but not unpleasant. A strong decoction of it was formerly an empirical secret for gonorrhœa. Linnæus says the dried leaves are used to dye wool yellow or green. It is usually regarded as the πυκνόκομον of Dioscorides, 4, 173, but Fraas thinks the plant of Dioscorides is the *S. Ambrosioides*.

S. Columbaria has the outer calyx membranous, plaited, and notched, the inner one of 5 nerveless bristles; the corolla 5-cleft, the radical leaves oblong, stalked, crenate, entire, or lyrate, the upper leaves pinnatifid, with linear segments. The flowers are purplish, the involucres narrow. It is native of Europe, Caucasus, and Siberia, and is very common on chalky soil in Britain. It is a very polymorphous plant.

S. grandiflora has a branched downy stem, with rather villous leaves, the radical ones oblong crenated, the cauline ones pinnatifid, with lanceolate, linear spreading segments. The corollas amply radiant, of a cream colour or white, with reddish tubes. The calyx consists of 5 reddish brown bristles. It is native of Barbary, Italy, and Sicily in fields, and is worth cultivation.

Many of the species of this genus are well adapted for garden borders. The perennial and herbaceous kinds are easily increased by seed or by dividing at the root. The seeds of the annual kinds only require to be sown in the open ground. The shrubby species are increased by cuttings under a hand-glass or by seed.

(Don, *Gardener's Dictionary*; Lindley, *Vegetable Kingdom*; Babington, *Manual of British Botany*.)

SCAE'VOLA, QU. CERVI'DIUS, a Roman jurist, probably gave responsa in the time of Antoninus Pius (Dig. 34, tit. 1, s. 13); but he was certainly employed by Marcus Antoninus as a legal adviser (J. Capitolinus, *Marcus*, 11; Dig. 36, tit. 1, s. 22); and in his writings he speaks of the constitutions of Marcus and Verus, in terms which imply that they were then alive. Septimius Severus, afterwards emperor, and Papinian, were pupils of Cervidius, who probably died in the reign of Severus (Spartianus, *Caracalla*, 8). His responsa were often very brief, expressed in a single word (Dig. 17, tit. 1, s. 62); but the facts on which the opinion is given are clearly stated. His style has been blamed as obscure; but there is evidence of his great capacity, and he left a name behind him.

There are excerpts in the Digest of Justinian from his forty books of Digesta, six books of Responsa, twenty Libri Quaestionum, four Libri Regularum, and one book Quaestionum publice tractatarum, probably a book of decided cases. The Florentine Index also mentions a single book 'De Quaestione Familiae,' but there is no excerpt from it in the Digest. There are 307 excerpts from the writings of Scaevola in the Digest.

Many of the Responsa of Scaevola appear twice, both in the Responsa and the Digesta. Conradi, followed by Blume, supposes that the Digesta contained a fuller statement of the matters which are briefly indicated in the Responsa, and were a kind of commentary to the Digesta. Puchta says that the passages in the Digesta do not show this; and that this relation is rather that of the Quaestiones to the Responsa: 'the Quaestiones were devoted to the complete examination and justification of the opinions.'

Claudius Tryphoninus and Paulus commented on Scaevola; and he is often cited by Marcianus, Tryphoninus, Ulpian, Paulus, and Modestinus. Scaevola commented on Julian and Ulpius Marcellus.

(Grotius, *Vitae Jurisconsultorum*; Puchta, *Cursus*, *&c.*, i. 453; Zimmern, *Geschichte des Röm. Privatrechts*, p. 361.)

SCALE, MUSICAL, of the GREEKS. [MUSIC, P.C., p. 24.]

SCAPHI'TES, a remarkable cephalopodous fossil genus, irregularly convoluted at both ends, and occurring in the lower parts of the cretaceous system. (Parkinson.)

SCA'PHODUS, a genus of fossil fishes from the oolite of Stonesfield. (Agassiz.)

SCARLET FEVER. [SCARLATINA, P. C.]

SCARLETT, RIGHT HON. SIR JAMES, LORD ABINGER, was a native of Jamaica, where his family was wealthy and of long standing. He was the second son of Robert Scarlett, Esq., and was born in or about the year 1769. His mother's name was Elizabeth Anglin. The family estates went, it may be presumed, to the eldest son; a third son, who also remained at home and followed the profession of the law there, became Sir William Anglin Scarlett and Chief Justice of Jamaica, and died not long ago after having held that office for many years; James was at an early age sent to England. Having finished his elementary education, he was, about the year 1786, entered a Fellow Commoner at Trinity College, Cambridge; and he was also, a year or two after, admitted a student of the Inner Temple. He took his degree of B.A. in 1790; was called to the bar 8th July, 1791; and graduated M.A. in 1794. His success at the bar was very decided from the first, and every year added to his reputation and his emoluments. It was soon discovered that, from whatever cause, no young barrister gained so large a proportion of verdicts. Even while he was still a junior counsel, he was very frequently entrusted with the sole conduct of important cases. At last, in 1816, he received a silk gown; and from that date he was recognised as the leader of his circuit (the Northern), and as occupying also a foremost place in Westminster Hall.

He had made an attempt to be returned to parliament for the borough of Lewes at the general election in October, 1812, but was defeated by Mr. George Shiffner, who was brought in, as second member, by a majority of 164 to 154; and he failed also in a second attempt on the same borough when a vacancy was occasioned in 1816 by the death of the other member, Mr. T. R. Kemp, being then defeated by Sir John Shelley. He was first introduced to the House of Commons in 1818, as one of the members for the city of Peterborough, under the patronage of Earl Fitzwilliam. He did not, however, make a figure in parliament corresponding to his eminence at the bar; nor was he a frequent speaker, although he both supported Sir Samuel Romilly and Sir James Macintosh in their efforts to mitigate the severity of the criminal law, and also occasionally took part in debates on financial subjects.

He was returned again for Peterborough at the general election in 1820; but he resigned his seat in 1822 to stand for the University of Cambridge, when, however, he was left at the bottom of the poll. Upon this he was re-elected for Peterborough, but not till after a contest with Mr. Samuel Wells. Up to this time he had been considered as distinctly belonging to the Whig party, although to the most moderate section of it; but his opinions gradually assumed more of a

Conservative complexion, and when the new Tory or mixed administration of Canning came into power in April, 1827, Mr. Scarlett, having been again returned for Peterborough at the general election in the preceding year, accepted the office of attorney-general. He was at the same time knighted. Having been once more returned for Peterborough he retained his place throughout the administration of Lord Goderich; was succeeded by Sir Charles Wetherell when the Duke of Wellington became premier in January, 1828; but was reinstated in May, 1829, upon the dismissal of Sir Charles for his opposition to the Roman Catholic Emancipation Bill; and, having been returned for Maldon at the general election in 1830, he remained attorney-general till the accession to office of the Whigs in November of that year, when he was succeeded by Mr. (now Lord) Denman.

At the general election in May, 1831, Sir James Scarlett was returned to parliament for Cockermouth. At the next, which took place after the passing of the Reform Bill, in December, 1832, he was returned, after a contest, for Norwich, along with Lord Stormont (now Earl of Mansfield). When this parliament was dissolved in December, 1834, on Sir Robert Peel being appointed premier, Sir James Scarlett was made Chief Baron, and a peer by the title of Baron Abinger, of Abinger, in the county of Surrey, and of the city of Norwich.

Lord Abinger died of a sudden attack of illness at Bury St. Edmunds, while on the circuit, on the 7th of April, 1844. He had been twice married; first in August, 1792, to the third daughter of Peter Campbell, Esq., of Kilmorey, in Argyleshire, who died in March, 1829; secondly, in September, 1843, to Elizabeth, daughter of Lee Steere Steere, Esq., of Jays, Surrey, and widow of the Rev. H. J. Ridley, of Ockley. By his first wife he had three sons and two daughters, by the eldest of the former of whom he is succeeded in his title and estates. His eldest daughter married Mr. (now Lord) Campbell in 1821, and was created a peeress in 1836 by the title of Baroness Stratheden.

Lord Abinger was a skilful and dexterous rather than an eloquent advocate, and while on the bench he was more distinguished for the clearness with which he summed up a case to a jury than for the profoundness or subtlety of his legal views. Yet he was considered also a sound and good lawyer. In the great art of gaining verdicts he was unrivalled; and no practitioner at the bar had ever before received so large sum in fees in any year as he drew in the height of his practice. His conduct as attorney-general under the Tories in 1829, when he filed a number of criminal informations against the opposition newspapers, naturally exposed him to some severe animadversions from those who still continued attached to the more democratic political creed which he had originally been accustomed to profess.

(*Gent. Mag.* for June, 1844.)

SCHEELE'S GREEN. [COPPER, P. C., p. 504.]

SCHEEMAKERS, PETER, a Flemish sculptor who obtained great celebrity in England. He was born at Antwerp in 1691, and he was the pupil of his father and a sculptor of the name of Delvaux. While still young he visited Denmark, where he worked as a journeyman. About the year 1728 he walked to Rome, and he was then so poor that he was forced to sell a considerable portion of his clothes to obtain subsistence. From Rome, after only a short stay, Scheemakers journeyed again on foot to England, and here he obtained considerable employment; but he paid a second visit to Rome, and after a two years' residence there he settled about 1735 for many years in England. He lived in Old Palace-yard, Westminster, until 1741, when he removed to Vine Street, Piccadilly, when he became the rival of Rysbrack and Roubiliac, and executed many important works, including some of the principal monuments in Westminster Abbey. The time of his death is not known, but according to his pupil Nollekens, as related by Smith, he returned to Antwerp in 1770, and there soon after died. Two sales, however, of his effects took place in Covent Garden in 1756 and 1757. Among the articles sold was a beautiful small copy in marble of the Laocoon, which was bought by the Earl of Lincoln: a good mould was taken from it by a figure-maker of the name of Vevini, from which excellent casts were made. Scheemakers' works are very numerous; they are elaborate in design and costume, but rather effective than grand; the marble is always remarkably well worked. There are monuments by him in Westminster Abbey to Shakspere; Dryden; George, Duke of Albemarle; John Sheffield, Duke of Buckingham; Admirals Watson, Sir C. Wager, and Sir J. Balchen; Commander Lord Aubrey Beauclerk; and Doctors Chamberlin, Mead, and Woodward. He made also the statue of Sir John Barnard in the old Royal Exchange; the statues in the India House of Admiral Pocock, Major Lawrence, and Lord Clive; the bronze statue of Guy in Guy's Hospital; and the bronze statue of Edward VI. in St. Thomas's Hospital. He executed also some busts, and many other sculptures for the gardens of Stowe.

(Smith, *Nollekens and his Times*, &c.; Immerzeel, *De Levens en Werken der Hollandsche en Vlaamsche Kunstchilders*, &c.)

SCHEUCHZE'RIA, a genus of plants belonging to the natural order Alismaceæ and the sub-order Juncagineæ. The perianth is composed of 6 leaves; it has 6 stamens with slender filaments. The ovaries with 2 ovules. The stigma adnate to the ovary and downy. The capsules compressed and inflated, one or two seeded.

S. palustris is the only known species of this genus. It has a stem from 6 to 8 inches high, the leaves are distichous, few, alternate, semicylindrical, obtuse, and with a minute pore on the upper side at the apex. The raceme is terminal, and consists of about 5 greenish flowers. The capsules about 3, and much inflated. It is found in England and Scotland in bogs.

(Babington, *Manual British of Botany*.)

SCHEUFFELIN or SCHAEUFFELEIN, HANS LEONARD, commonly called Hans Scheuffelin, a very celebrated old German painter and wood engraver, was born at Nürnberg about 1490. His father Franz Scheuffelin was a merchant of Nördlingen who settled in Nürnberg. Young Hans was placed with Albert Dürer, with whom he was a great favourite. He remained in Nürnberg until 1515, when he removed to Nördlingen, where he died in 1539 or 1540; probably the former year, as his widow was married again in 1540 to the painter Hans Schwarz.

There are several of Scheuffelin's paintings in Nördlingen, of which the principal is the Taking down from the Cross in the church of St. George; it is a picture with two revolving wings, and was painted in 1521. There are several good paintings by Scheuffelin also in Nürnberg, Tübingen, Stuttgart, Oberdorf, and other neighbouring places; and there are some in the galleries of Munich and Berlin.

There are also many woodcuts by Scheuffelin, and both woodcuts and pictures are sometimes attributed to Albert Dürer, to whom however Scheuffelin was inferior in all respects.

(Bartsch, *Peintre Graveur*; Nagler, *Neues Allgemeines Künstler Lexicon*.)

SCHINKEL, KARL FRIEDRICH, in the opinion of his own countrymen the great architectural artist of his age, and whose name has obtained European and permanent celebrity, was born March 13, 1781, at Neu-Ruppin, in Brandenburg, where his father was 'super-intendent.' When only six years old he lost his father, and was placed by his mother in the 'Gymnasium' of his native town, where he remained till the age of fourteen, when he removed to Berlin. Soon afterwards an opportunity presented itself of becoming a pupil of the elder Gilly (David Gilly, born 1745, died 1808), a clever practical man in his profession, and author of several works on subjects relating to it. Hardly could he have been more fortunately placed; for about a twelvemonth afterwards, the younger Gilly (Friedrich) returned from his travels with an imagination warmed by his recent studies, and from him it was that Schinkel derived his best instruction, and together with an ardent relish for his art, more liberal and enlightened idea of its powers as a fine art than were generally entertained in those days, when a system of mere routine both in theory and practice prevailed almost universally. Friedrich Gilly was a truly genial mind, who was ambitious of elevating architecture to the level of the other arts of design, and to bring it into immediate contact with them, whereas it was then, and perhaps now is, too much regarded as one entirely apart from and independent of them. What Gilly himself would have achieved in his profession can only be conjectured, for he died within two years after his return, August, 1800, before he had completed his thirtieth year, leaving Schinkel to inherit the fame that might else perhaps have been divided between them.

Although so young, Schinkel had been intrusted by Gilly to superintend the execution of some of his buildings, and after his death, he continued the engagements. Having acquired such proficiency in practice it would not have been difficult for him to have adhered to that course under others in the profession, and in the course of time establish himself in business: but he preferred pursuing his theoretical and artistic studies; during which time he turned his exercises in them to account by making designs of various ornamental articles for modellers, metal-workers, and other artizans of that class. Out of such earnings he laid by sufficient to enable him to accomplish his cherished scheme of a pilgrimage to the 'holy land of art.' In 1803 he set out for Italy, first visiting Dresden, Prague, and Vienna; and after extending his route to Naples and Sicily, returned to Berlin in the spring of 1805. But there the state of things was at that juncture anything but propitious to art, more especially architecture, to which the state of public affairs in 1806 and following years threatened a complete stoppage. He turned to landscape-painting, therefore, as an occupation and a resource, making use of the studies of scenery which he brought home from Italy, and embellishing his compositions with architectural accessories, or else making the architecture the principal and the landscape the accessorial portion of the subject. One work of note and which gained him distinction with the public was a large panorama of Palermo; and he also designed for the theatre many sets of scenes, a collection of which, including those for the Zauberflöte, Die Braut von Messina, &c., were afterwards published in a series of coloured engravings, whereby they are rescued from the usual fate of similar productions of the pencil. His various artistical labours during this period were beneficial to him in his after-career, serving as they did to call forth and exercise those two faculties in which those who are otherwise able architects are generally deficient—taste and imagination. Even had they been serviceable to him in no other respect, they were eminently so in recommending him to the king, who, as soon as restored tranquillity in public affairs permitted him to turn his attention to the improvement and embellishment of his capital, began to employ Schinkel on those structures which have stamped a new aspect on Berlin, and conferred on it a high architectural character. One of the earliest commissions of importance which he received from the king (who was then at London with the allied sovereigns) was to make designs for a national cathedral intended to commemorate the pacification of Europe; but though the architect's ideas excited great admiration, the scheme itself was dropt. Whatever the disappointment may have been at first, he had no time to dwell upon it, for from the period of 1815 he was incessantly and most actively engaged. Among his earliest buildings were the Hauptwache, Theatre, and Museum at Berlin, all of them treated in a pure Hellenic style—a style which had only been hinted at in such previous attempts at correct Grecian architecture as Langhans's once celebrated 'Brandenburg Gate.' The façade of the Museum more especially displays, together with severe simplicity of outline, a fulness of refined ornateness unknown to and unthought of for any previous modern example which is called Greek. The external elevation consists of merely a single line of eighteen columns in antis (Erechtheum Ionic) raised on a lofty stylobate, in the centre of which is a flight of steps, enclosed by pedestal walls (in continuation of the stylobate) and forming the ascent to the colonnade. Taken by itself, however, there would be nothing very remarkable in the general idea, whereas an extraordinary degree and kind also of variety and effect are given to the whole by the inner elevation or background behind the outer row of columns; which presents in the centre portion of it a second colonnade (four columns in antis), with a screen-wall rising about half its height, and above and beyond that the upper part of the open staircase, whereby the whole composition acquires singular movement and play both of perspective and light and shade; besides which the wall forming the rest of this inner elevation, instead of being left a blank surface, or nearly so, is completely decorated from top to bottom, or rather was intended to be so, the upper division of it on each side of that inner colonnade being to be filled up by a single large fresco, the cartoons or designs for which were prepared by Schinkel himself, and have been extolled as masterly compositions. There is reason, however, to suppose that either they or similar decorations will yet be executed, Cornelius being spoken of as the artist to whom the task is to be confided; and only when the frescos shall have been added, will Schinkel's idea and the effect contemplated by him for the building have been realized. Neither is the Museum the only one of his works which have not been completed—not yet, at least, according to his designs; for the two other buildings above mentioned have not received their full complement of sculpture, which, though it may be dispensed with for them as structures, is essential to them as works of architecture. It is fortunate, therefore, that in any case we have Schinkel's own ideas exhibited to us in his 'Entwürfe,' an unusually full and extensive series of designs of all his principal buildings, some of which are illustrated and explained far less sparingly than is the custom in similar collections; for besides ornamental details, many of them strikingly original as well as tasteful, perspective views interior as well as exterior, and different ones of the same building are given; besides which, the engravings themselves are illustrated by the information contained in the letter-press. The publication of his designs contributed no doubt to spread Schinkel's fame much more rapidly than would otherwise have been the case; and it is one that forms a very complete gallery of his unusually numerous and no less varied architectural productions. With such ready materials, a descriptive catalogue of his buildings might be easily drawn up, but we can merely mention a few of them: the Werder Kirche (Gothic), Bauschule, and Observatory, at Berlin; the Theatre at Hamburg; Schloss Krzescowice, Charlottenhof, and the Nicolai Kirche at Potsdam, which last would have been a most imposing structure had the design been carried out, instead of being cut down altogether by the omission of the cupola. His 'Entwürfe' also contains his design for the Sing-Academie at Berlin—one of his happiest ideas, which was unfortunately set aside for that by Ottmer [OTTMER, P. C. S.]; and six several designs for a monument to Frederick the Great, in which he gave free scope to his imagination, and indulged in luxuriant architectural pomp. Another publication, entitled 'Werke der Höheren Baukunst,' gives us a series of designs by him for the Palace at Athens, which he proposed to erect upon the Acropolis, forming an irregular assemblage of courts, colonnades, and buildings, some of which, especially one magnificent saloon, would have been marked by originality of character as well as by striking effect. His design was much superior to that by Klenze, which is also published among those of the latter architect's; but, as has been said already elsewhere [ATHENS, P. C. S.], neither of them was adopted. Another remarkable project of Schinkel's, his latest though not his least poetical conception, was a design for a summer palace at Orianda, in the Crimea, for the Empress of Russia, surrounded by terraces and hanging gardens on a lofty eminence, commanding a prospect of the Black Sea. That was in 1839, the same year in which was conferred upon him the highest rank in his profession—that of Ober-Landes-Bau-director; but it was to him a mere honour, for his career was closed: his health immediately afterwards began to decline, and in the autumn of the following year, on his return from the baths, by whose waters he had hoped to benefit, he was attacked by an organic affection of the brain, which reduced him to a state of almost complete insensibility to all external objects; and in that deplorable condition he remained upwards of a twelvemonth, till released from it by death on October 9th, 1841.

Schinkel has been called by some of his countrymen the Luther of Architecture; and he certainly gave a fresh impulse to the art: and if he himself did much, his example and influence have perhaps accomplished more; for by venturing to think for himself, he has led others to do the same. Yet with all his freedom and originality, he was, perhaps, rather too timid than too bold in his reforms, adhering in many respects too strictly to the original letter of Grecian examples, particularly in regard to the orders. As to Gothic, it would have been better had he abstained from it entirely, and given his undivided attention to the other style, first eliciting and then maturing new ideas from it. With all his invention, too, he exercised none upon such important features as doors and windows, for which he repeats the very same design again and again in different buildings.

Schinkel has been made the subject of biographical notice and of criticism more than any other modern architect. Of two separate publications relative to him, one entitled 'K. F. Schinkel, Eine Characteristik,' &c., 1842, is by Dr. Kugler; the other by O. F. Gruppe; and both of them have portraits of him, the former from Rauch's bust of him, the other represents him in his usual dress, and with his hat on, and therefore conveys a better idea of his personal appearance.

SCHIʹZODUS, a fossil genus of conchifera, proposed to include species of Axinus of Sowerby.

SCHIZOʹPTERIS, a genus of fossil ferns (Brongniart) in the shales of the Yorkshire coast.

SCHIZO'STOMA, a fossil genus of fossil gasteropoda (Bronn). Included in Euomphalus, or Pleurotomaria by other writers. Found in the palæozoic strata.

SCHLEGEL, AUGUST WILHELM VON, was descended from a family in which learning and literary fame had been hereditary during several generations, in Germany as well as in Denmark, where a branch of the family settled early in the past century. His father was John Adolphus Schlegel, D.D., who died in 1793, as Superintendent General of the Lutheran Church of Hanover. John Adolphus had four sons, Charles Augustus Maurice, superintendent-general at Harburg, in Hanover, who died in 1826; John Charles Fürchtegott, one of the councillors at the Ecclesiastical Court at Hanover, and well-known as the author of 'Hanoversches Kirchenrecht' (The Ecclesiastical Law of Hanover), 3 vols. 8vo., 1801-1805, and 'Das Kirchenrecht von Nord-Deutschland,' (The Ecclesiastical Law of Northern Germany), 3 vols. 8vo., 1828-32, &c., who died in 1831; Augustus William, the subject of this sketch; and lastly Frederic Charles William, who obtained a fame still more solid though less brilliant than his eldest brother.

Augustus William was born at Hanover on the 8th of September, 1767, and after having received a careful education was sent to Göttingen to study divinity, which he soon abandoned to devote his time to philology. Though young, he was no common classical scholar, for his Latin dissertation on the geography of Homer was highly thought of by Voss, the most competent judge of his age on that subject, and Heine intrusted him with making an index to his edition of Virgil. For some years Schlegel lectured at the university of Göttingen: his contributions to Bürger's 'Akademie der Schönen Künste' (especially his poem 'Ariadne,' and his essay on Dante), and to Schiller's 'Musen-Almanach' and 'Horen,' especially his translations from Dante with commentaries, secured him an honourable rank among the best writers of Germany. In 1797 he published the first volume of his translation of Shakespere. In the same year he was appointed professor of Humaniora in the university of Jena, and continuing his literary activity he soon placed himself among the leaders of German literature. He remained at Jena till 1802, a friend of Schiller, and an admirer of Göthe then at Weimar, who, however, did not return the sentiment. Pushed by ambition, Schlegel left the little town of Jena, and repaired to Berlin, where he gave public lectures to a mixed but highly intelligent public on literature and the fine arts. He remained there till 1805, having meanwhile imbibed that puerile passion for little court distinctions, titles, and crosses, which in later years proved such a severe drawback on his real merits. Among the specimens of his literary activity in the period from 1797 to 1805, may be mentioned, besides the continuation of his translation of Shakespere's plays, the 'Athenæum,' a critical review, which he edited with his brother Frederic, and which did a great deal of good towards purifying the taste of the public; 'Gedichte' (Poems), Tübingen, 1800; 'Musen-Almanach,' which he edited together with Tieck, and in which he first betrayed his growing tendency towards Romanism and mysticism; 'Vorlesungen über Literatur und Kunst des Zeitalters,' (Lectures on the Literature and the Fine Arts of the Age), which appeared in the 'Europa,' a review edited by Frederic Schlegel. In 1805 he made the acquaintance of Madame de Stael-Holstein. Surprised at finding so rare a combination of deep learning, uncommon poetical talents, and the manners of a courtier as Schlegel presented, she became his sincere friend, and he henceforth accompanied her during several years on her travels through various parts of Europe. The reciprocal influence of these two distinguished persons upon each other was very great, and may be traced in their works: the result was, that he made her popular in Germany, and she brought him out in France, where his vanity afterwards met with so much gratification. At her suggestion he published in French a comparison between the Phèdre of Racine and the Hippolytus of Euripides, and this work was the foundation of his subsequent fame among the French. In 1808 Schlegel delivered at Vienna a course of lectures on dramatic art which are an everlasting monument of his genius. They were published under the title 'Vorlesungen über Dramatische Kunst und Literatur,' Heidelberg, 1809-1811, 3 vols. in 8vo.; 2nd edition, 1817. A new collection of his poems appeared in 1811, 2nd edition, 1820, among which are his masterpieces, Arion, Pygmalion, Saint Lucas, and others. At that time Schlegel and his brother Frederic had already succeeded in founding, in opposition to the models commonly called classical, the modern romantic school of poetry and fine arts which had its origin, in a great measure, in the depressed state of Germany and the deep wishes of the people for a moral, religious, and political regeneration. The brothers Schlegel were considered as enthusiastical patriots, and Augustus William having ventured to depreciate the French drama and to call Molière a mountebank, at a time when such liberties met with punishment or cruel persecution from the French invaders, his name became popular to a degree which he would perhaps not have enjoyed at another time. 'Das Deutsche Museum,' a review which the brothers Schlegel founded in 1812, was the chief organ of tho new school, and the middle ages became the inexhaustible source where the reformers quenched their thirst for piety, sentimentality, and chivalry, and whence they drew forth everything except that rude power softened down by uncorrupted feelings which forms the true character of that age. Göthe, who never called himself a romantic poet, but was nevertheless the first of all, knew that character much better than the devout Frederic, or the effeminate Augustus William Schlegel. The excitement of 1813 produced a strange effect upon Augustus William: he accepted a secretaryship from Bernadotte, the crown-prince of Sweden, and wrote political essays. No sooner however was Paris taken than he repaired to the country-seat whither Madame de Stael had retired, and kept her company till her death in 1818. She remembered him in her will. About that time he was placed among the titular nobility of Germany, the privilege of which consists in putting the preposition 'Von' between the Christian and the family name of the person thus distinguished.

In 1819, Augustus William von Schlegel was appointed professor of history in the university of Bonn, which had just been founded by the king of Prussia: it is not known why he was made professor of history, for he had never written on history. He had now ceased to be a poet, but still ambitious of tho honour of being a European author, he published several critical essays—of undoubted merit, however—in foreign languages. Such are, 'Le Couronnement de la Ste. Vierge, et les Miracles de St. Dominique: Tableau de Jean de Fiesole; avec une notice sur la Vie du Peintre,' Paris, 1817, fol.; an essay on the famous Venetian horses, which he declared to be of Greek workmanship, in Italian, in the 'Biblioteca Italiana;' 'Réflexions sur l'Etude des Langues Asiatiques, adressées à Sir J. Macintosh, suivies d'une Lettre à Mr. H. H. Wilson,' Bonn, 1832, &c. To such minor works, however, he devoted only part of his time, for even provious to his appointment at Bonn, and at the suggestion of his brother Frederic, he had made up his mind to study Sanscrit. He soon attracted a small number of students round him, and thus became one of the principal promoters of the study of that language in Germany: the Sanscrit printing-office at Bonn owes its foundation to Schlegel, who, it is said, purchased the types at his own expense. Although he did not attain the exact knowledge of that difficult language by which Bopp and Lassen have distinguished themselves, he was yet no contemptible Sanscrit scholar, and surpassed Bopp and others in his general views: and it may be said that his principal merit consisted in encouraging students and aiding them in pursuing tho study of the Sanscrit, Zend, Pehlvi, and other Indo-Persian languages. Schlegel in his turn was assisted by tho superior learning of Professor Lassen. As early as 1820 he founded the 'Indische Bibliothek,' a review exclusively devoted to Indian languages and antiquities. Specimens of Schlegel's Sanscrit scholarship are, 'Ramâyana,' with a Latin translation and critical notes, Bonn, 1829; 'Bhagavad-Gîta,' an episode of the celebrated Indian epic 'Mahabharata.' It is especially to his endeavours to promote the study of the Indian languages, as well as to some of his critical essays on subjects connected with the fine arts and poetry that Schlegel owes the great esteem which he enjoyed in this country. Some time before his death, which took place in May, 1845, he published 'Essais littéraires et historiques,' Bonn, 1842, 8vo.

Schlegel ranks high among the lyric poets of Germany. 'Arion' is a wonderful romance or ballad, if the expression can at all be applied to such a production; and his sonnets are little pieces of perfection. The smoothness of his style, and his elegant clearness, have not been surpassed in Germany. But as a genius he stands far below the great leader of German literature; he could appreciate the grand and sublimo, but he was unable to create it, as his tragedy of Ion shows. He must have felt his own comparative weakness when he called Göthe a god. Next to Count Platen, Schlegel was the most perfect metrist; but feeling his superiority in this respect he made too much of it, and sometimes produced most musical sonnets, embodying feelings of such an exquisite delicacy as to leave no impression whatsoever upon the mind of less gifted mortals than the author. His translation of Shakespere, which was continued hy Tieck, is the best among the numerous German translations of the great bard, but Tieck's translations are still better than those of Schlegel, whose version is too elegant, too elaborate, too smooth; his Falstaff, and the like characters, leave an impression as if previous to appearing in public they had received some private lessons from the accomplished translator to behave with decency in his and his equals' company. The work which does him most credit is the Lectures on Dramatic Art and Literature, which have been translated into all the modern languages: into English by John Black, London, 1840, 3 vols., 8vo In his criticism on the French drama he is however one-sided. His appointment as professor of history at Bonn was a mistake: he ought to have remained at Berlin or Vienna, lecturing before an elegant puhlic of fashionable ladies and gentlemen. Vexed at seeing in Niebuhr, then likewise at Bonn, a star still brighter than his own, he endeavoured to darken him since he could not outshine him, and wrote his critique of Niebuhr's Roman History, which appeared in the 'Heidelberger Jahrhücher,' of 1828; and he likewise began to lecture on Roman history in the university. But his critique msde him ridiculous among the learned, and his lectures added nothing to his reputation.

(*Conversations-Lexicon*; Menzel, *History of German Literature*, translated hy Gordon, Oxford, 1840, 4 vols., 8vo.)

SCHLEICHE'RA, a genus of plants belonging to the natural order Sapindaceæ. It has a 5-toothed calyx. Petals absent; the disk occupying the bottom of the calyx. The stamens from 6 to 10, inserted between the margin of the disk and the ovary. The ovary is 3-celled, with one erect ovule in each cell. The stigma 3-cleft. The fruit is an indehiscent drupe, with 1, 2, or rarely 3 cells. The seeds are solitary in each cell, and covered with a pulpy arillus; the embryo much curved. The species are trees; the leaves abruptly pinnate, the leaflets nearly opposite. The flowers are small, disposed in spike-like racemes.

L. trijuga has abruptly pinnate leaves from 8 to 16 inches long, the leaflets from 2 to 4, opposite, sessile, broad, lanceolate or oblong entire, rather smooth on both sides the lower pairs, the smallest from 3 to 8 inches long. The petioles are a little downy, the stipules wanting. The racemes are axillary, or below the leaves round the base of the young shoots, solitary, in the male simple, in the hermaphrodite often compound, from 2 to 4 inches long. In the male flowers the calyx is cup-like, and 5-toothed. The corolla wanting, the filaments from 6 to 10 erect, and many times longer than the calyx. The anthers oval and erect; the pistil a mere rudiment. The hermaphrodite flowers on a separate tree. The calyx, corolla, and stamens as in the male flower. The disk a fleshy yellow ring, surrounding the insertions of the filaments. The ovary superior, ovate, 3 celled, with one ascending ovule in each cell. The style short, stigma 3-cleft, recurved, slender, and downy. The drupe about the size of a nutmeg, a little pointed, covered with a tender grey dry pericarp. The seeds are oblong, and surrounded with a whitish pulpy aril, which is of a pleasant acid taste, and most grateful during dry weather. It is a native of insular and continental India, where the astringent bark, mixed with oil, is used as a remedy for the itch.

(Lindley, *Flora Medica*; Lindley, *Vegetable Kingdom*.)

SCHMIEDELIA (in honour of Casimer Christopher Schmiedel, once a professor at Erlangen), a genus of plants belonging to the natural order Sapindaceae. It hss a 4-parted unequal calyx, 4 petals, the 5th or superior one wanting. The disk incomplete, with 4 glands opposite the petals, 8 stamens inserted in the receptacle, and connate around the ovary at the base. The fruit is indehiscent, 1- 2- or rarely 3-lobed. The lobes roundish, fleshy, or dry, and 1-seeded. The seeds with or without an arillus. The species are trees or shrubs, usually with trifoliate, rarely with simple exstipulate leaves, and racemose white flowers. The racemes are axillary.

S. serrata has ternate leaves, the leaflets ovate, pointed, serrate, generally blistered, smooth on the back, and from 2 to 3 inches long. The racemes axillary, single, and erect. The flowers small, white, and polygamous. In the hermaphrodite flower the calyx is 4-leaved, and the petals 4, unilateral. The filaments very woolly near the base. The fruit is small, red, and succulent, and is eaten by the natives of Coromandel. The root is astringent, and is employed by the native practitioners in diarrhœa.

S. cochinchinensis has its leaves on long petioles, with serrated leaflets, terminal racemes, pilose small petals. The flower is small and white. It is native of Cochin-China, on the banks of rivers. The leaves are used as cataplasms in contusions. The species of this genus are not worth cultivation unless in general collections. A mixture of loam and sand suits them best.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

SCHOBE'RIA, a genus of plants belonging to the natural order Chenopodiaceae. It has a 5-parted perianth, without appendages, 5 stamens springing from the receptacle, and from 2 to 3 stigmas. The pericarp is membranous, the seed horizontal, the testa crustaceous.

S. fruticosa has an erect shrubby stem, with obtuse semicylindrical leaves, 3 styles, and smooth shining seeds. It is found on the south and east coasts of Great Britain.

S. maritima is found on the sea-shore in England. It has a procumbent stem, with numerous spreading branches, acute semicylindrical leaves, 2 styles, with reticulate, striate, shining seeds. (Babington, *Manual of British Botany*.)

SCHOEN or SCHONGAUER, MARTIN, one of the most celebrated of the early German painters and engravers, was, according to recent discoveries, born at Ulm of a family which produced many artists in the early part of the fifteenth century; his name occurs in Ulm documents from 1441 to 1461. The inscription therefore upon the back of his portrait in the gallery at Munich, though probably authentic, is apparently erroneous. He settled about 1461 in Colmar, and died there in 1485 or 86, Sandrart says 86, and various incidents which are recapitulated by Nagler tend to establish this date. The time of this painter's death has until very lately been a matter of much dispute.

Martin appears to have been chiefly an engraver in his youth, and to have devoted his attention principally to painting after a visit to the Netherlands, where he became acquainted with the excellent works of the Van Eycks and their scholars. He probably resided some time at Antwerp, as he was sometimes called by the Italians Martino d'Anversa; and from a letter of Lambertus Lombardus to Vasari dated April 27, 1565, and published by Gaye in his Carteggio Inedito d' Artisti, iii. 177, it is supposed that he studied under Roger Van Bruges, now from good evidence considered to be the painter of the portable altar of Charles V., which has been hitherto attributed to Memling. [MEMLING, P. C. S.]

The best works of Martin Schön are still at Colmar in the college library, but there are many which are attributed to him in the collections of Munich, Vienna, Nürnberg, and Schleissheim, and in other places, as Ulm, Stuttgart, Basel, Berlin, &c. His pictures are in all respects similar to those of other pupils of the Van Eyck school, but are inferior in colour to those of his master Roger Van Bruges; they are notwithstanding among the best works of their style. Many of the pictures of an inferior painter, Martin Schaffner, have been and still are ascribed to Martin Schön. None of his pictures are signed with either a name or monogram, but his prints are generally marked with a monogram.

Schön's prints, though crude in light and shade, aro among the very best of the early productions of the Germans in this class. Bartsch enumerates and describes 116. Seventeen others bear his monogram, but are supposed not to be by him; and twelve very douhtful prints are enumerated by Heineken: the list is reprinted in Nagler's 'Künstler Lexicon.' Schön, which in German signifies excellent and beautiful, is supposed to be a nickname of this artist, whose real name was Schongauer; he was formerly called Hübsch Martin by tho Germans, and Bel Martino and Buon Martino by the Italians. There was an earlier painter and wood engraver of the name of Msrtin Schoen at Ulm, who was active from 1394 until 1416. Some of his works still exist, bnt they are in a ruinous condition.

(Sandrart, *Deutsche Academie, &c.*; Bartsch, *Peintre Graveur*; Grüneisen und Mauch, *Ulms Kuntsleben im Mittelalter*; Von Quandt, *Kuntsblatt*, 1840; Waagen, *Kuntswerke und Künstler in Deutschland*, vol. iii.; Nagler, *Neues Allgemeines Künstler Lexicon*.)

SCHOENUS, a genus of plants belonging to the natural order Cyperaceae. The spikelets are 2-ranked, from 2- to 4-flowered. The glumes from 6 to 9, the lower ones small and empty. Bristles few or wanting.

S. myricans is found on turfy bogs in Great Britain. It has a round naked stem, from 5 to 10 spikelets, collected into a terminal roundish head, overtopped by the lower bract; the glumes scabrous at the keel. The stem is clothed at the base with dark-brown smooth shining scales, some of which terminate in setaceous erect leaves, which are shorter than the stem. The glumes are dark-brown or black. This is the μελάγκρανις of Theophrastus, *Hist. Plant.* 4. 18.

(Babington, *Manual of British Botany*; Fraas, *Synopsis Plantarum Florae Classicae*.)

SCHOOLS, INFANT. In the article SCHOOLS, P. C. p. 38, in speaking of the foundation of the Infant Schools at New Lanark, it is said that Robert Owen 'was aided in forming the idea by the wife of the Rev. William Turner, of Newcastle-on-Tyne, who, in the year 1818, when in conversation with Mr. Owen, remarked that in her attention to the education of girls, she had frequently wished some means could be adopted for getting poor children taken out of the hands of their parents at an earlier age, before they had formed bad habits at home and among the idle children around them. Much was said on both sides on the desirableness of infant-schools, which Mr. Owen immediately established on his return to Lanark.'

The author of the article SCHOOLS has informed the editor of the P. C. that his authority for this statement was a written communication from the Rev. William Turner before-mentioned. The statement however is proved to be erroneous by the evidence which Mr. Owen gave before a committee of the House of Commons in 1816. Henry Brougham, now Lord Brougham, was chairman of the committee, and the evidence is printed in the 'Report from the Select Committee of the House of Commons on the Education of the Lower Orders in the Metropolis, June 1816.'

Mr. Owen stated before the committee that he had paid particular attention to the education of children for twenty-five years, but that he had no opportunity of putting any of his plans into execution till after he went to New Lanark. He stated that he had been upwards of sixteen years in the superintendence of the cotton-mills there, and that there were 444 children in his schools at the time when he was examined (1816) of from three to ten years of age, inclusive. As to the origin of these schools he says, 'I have been led in the establishment at Lanark, to receive children at the age of three years, principally for the purpose of preventing them from acquiring bad habits, which they would have done if they had been permitted to ramble in the streets among children who were ill instructed, and whose habits were bad; and also for the purpose of giving them good habits, and for settling the knowledge they acquire more firmly in their minds. They are continued in the school upwards of seven years.'

Mr. Owen gave the following account of the management of the schools:—

'The children are received into a preparatory or training school at the age of three, in which they are perpetually superintended, to prevent them acquiring bad habits, to give them good ones, and to form their dispositions to mutual kindness and a sincere desire to contribute all in their power to benefit each other. These effects are chiefly accomplished by example and practice, precept being found of little use, and not comprehended by them at this early age. The children are taught also whatever may be supposed useful that they can understand, and this instruction is combined with as much amusement as is found to be requisite for their health, and to render them active, cheerful, and happy, fond of the school and of their instructors. The school in bad weather is held in apartments properly arranged for the purpose; but in fine weather the children are much out of doors, that they may have the benefit of sufficient exercise in the open air. In this training school the children remain two or three years, according to their bodily strength and mental capacity. When they have attained so much strength and instruction as to enable them to unite without creating confusion with the youngest classes in the superior school, they are admitted into it; and in this school they are taught to read, write, account, and the girls, in addition, to sew; but the leading object in this more advanced stage of their instruction is to form their habits and dispositions. The children generally attend this superior day school till they are ten years old; and they are instructed in healthy and useful amusements for an hour or two every day during the whole of this latter period.'

In the year 1819 Henry Brougham, the Marquis of Lansdowne, Joseph Wilson, John Smith (who had seen the schools at New Lanark five years previously), Joseph Wilson, and other gentlemen, established, by subscription among themselves, a school in Brewer's Green (now Vincent Square), Tothill Fields, Westminster, on the plan of Mr. Owen's schools at New Lanark; and James Buchanan, an experienced teacher in those schools, came to London, with Mr. Owen's approbation, to superintend the new school.

On the 24th of July, 1820, an Infant school was opened in Quaker Street, Spitalfields, London. This school was established at the sole expense of Joseph Wilson, above mentioned. Samuel Wilderspin and his wife were engaged to manage the school, and their salaries were fixed and paid by Mr. Wilson. Mr. Wilderspin had been previously a clerk in a mercantile house in the city. He remained in this situation some years, and published a small work 'On the Importance of educating the Infant Poor from the age of eighteen months to seven years, containing an account of the Spitalfields Infant School, and the new System of Instruction there adopted. By S. Wilderspin, master of the above school. 12mo., 2nd edition, with considerable additions, Lond., 1824.' The first edition was probably published in 1823, but we have no evidence. Mr. Wilderspin was afterwards employed in delivering lectures on infant education, in assisting in the establishment of new schools, and in otherwise promoting the cause of infant education in all parts of Great Britain as well as in London. Mr. Buchanan was master of the Westminster infant school about twenty years, and then went to America.

A pension of 100*l.* a year was granted (August, 1846) to Mr. Wilderspin by the Queen; and Lord Brougham having, on the 3rd of August, 1846, in the House of Lords, made some remarks on Robert Owen's right to be considered the founder of infant schools, in which the Marquis of Lansdowne coincided, Mr. Wilderspin published in the 'Times' newspaper, August 6, 1846, two letters, one to Lord Brougham and another to the Marquis of Lansdowne, in the former of which Mr. Wilderspin says—'With regard to Robert Owen and the system which Buchanan brought from Lanark, your Lordship must be aware that the room at Brewer's Green was called *an asylum*, as was also the one afterwards established in Vincent Square, and that both contained a mere assemblage of children of all ages from two to fourteen, and were in fact what they purposed to be, mere asylums as a refuge for destitute children, but not infant schools conducted on the system now called the Infant school system. Buchanan did not become an infant teacher, nor did his school become an infant school until it had been re-organized by me, and he himself had been instructed by me at the express desire of the committee. The system therefore which Buchanan taught was not Mr. Owen's, nor his own, but mine. If therefore your Lordship means to state that Oberlin, Fellenberg, or Robert Owen, was the founder or inventor of the present infant school system, with its various arrangements, details, and implements, I must demur to your Lordship's decision,' &c. Dated Barton-upon-Humber, August 6, 1846.

In the year 1824, Mr. Wilderspin, in the preface to the book before mentioned, says, 'I do not know with whom the idea [of establishing infant schools] originated, nor do I think it of much importance to know this.' 'The first infant school that we heard of in this country was established at Westminster, in the year 1819. The master of that institution is J. Buchanan, who came from Mr. Owen's establishment at New Lanark.' That Mr. Wilderspin made alterations, and also improvements in some respects, in the system, will be readily admitted; but from the evidence which has been quoted, it is obvious that the leading principles of infant education had been developed and the establishment of infant schools accomplished before Mr. Wilderspin was engaged in the pursuits for which the British public are so much indebted to him. His labours in the cause of infant education are described and highly praised in the 'Journal of Education,' vol. v., p. 131, &c. Of the infant schools established by Oberlin in the Ban de la Roche an account is also given in the 'Journal of Education,' vol. i., p. 362, &c. [OBERLIN, P. C.]

SCIÆNU'RUS, a genus of fishes fossil in the London clay. (Agassiz.)

SCIENOIDES, a family of Acanthopterygious osseous fishes, of which the genus *Sciaena* is the type. They are closely allied to the perches, and resemble them in their general characters, but differ in having no teeth on the vomer and palatines. The preoperele is denticulated; the opercle is armed with spines; the bones of the face and head are often cavernous, forming a protruding snout.

The *Scienoides* are divided into those having two dorsal fins and such as have only one. In the first section we find the genus *Sciaena*, of which a single species, the maigre, *Sciaena aquila*, occasionally wanders from the seas of Southern Europe into our own. *Haemulon*, *Pristoma*, *Diagramma*, and *Amphiprion* are among the many genera belonging to the second section.

SCINA', DOME'NICO, born at Palermo in 1765, studied in his native town under Rosario Gregorio and other good masters, and became a proficient in classical erudition. He afterwards applied himself to the study of the mathematical and physical sciences, and to these the remainder of his life was chiefly devoted. In 1796 he was appointed Professor of Physics in the University of Palermo. He was repeatedly sent by the government to various parts of Sicily to explore the natural phenomena of the island, and he published the results of his observations. He gave an account of the eruption of Ætna of 1811, in two letters: 'Lettere scritte da Catania à Monsignor Grano in Messina.' He wrote on the currents of the straits of Messina: 'Memoria sù i Fili Refluì, e i Vortici apparenti dello Stretto di Messina,' in which he gave a better explanation of them than either Spallanzani or Brocchi has done. In 1818 he published an interesting 'Topografia di Palermo e de' suoi Contorni,' in which he describes the physical geography of the tract, its geological and mineral formation, its vegetable and animal productions, and its meteorology, the whole accompanied by a map. In the following year he was sent to explore the mountainous group called Monti Madonie, the ancient Nebrodes, which rises in the centre of the island, especially with regard to the frequent earthquakes to which that region is subject, 'Rapporto del Viaggio alle Madonie, intrapreso per Ordine del Governo,' Palermo, 1819. In 1823 he went on a like mission to the district of Ogliastro, near Termini, where an earthquake had made ravages, and among other things had affected the springs of the mineral waters from which the town of Termini takes its name. He wrote two reports on the subject, which were inserted in the Sicilian 'Giornale di Scienze, Lettere, ed Arti.' In 1830, on the occasion of some fossil remains found in the neighbourhood of Palermo, Scinà wrote a 'Rapporto sull' Ossa Fossili di Mardolce e degli altri Contorni di Palermo,' which attracted much attention. When a volcanic island arose suddenly off the southern coast of Sicily, Scinà was sent to examine the new phenomenon, and he wrote a 'Brevo Ragguaglio del novello Vulcano.' Scinà was not neglected by the Sicilian government. Both King Ferdinand and his successor King Francis bestowed their favour upon him. In 1815 he was appointed historiographer of Sicily. In 1822 he was made chancellor of the university of Palermo, and a member of the commission of public instruction and education for the whole island. In 1823 he was made curator of the public library of Palermo, and also rector of the 'Educandario dello Nobili Donzelle,' or 'House of Education for young Ladies of Rank.' In 1828 King Francis presented him to the abbacy of S. Angelo di Brolo, and in the following year gave him the decoration of his own order. Scinà was also the author of the following works: 1. 'Introduzione alla Fisica Sperimentale,' 1803, a work which established his reputation as a man of science. 2. 'Elementi di Fisica.' 3. 'Elogio di Francesco Maurolico,' a distinguished mathematician of Messina in the sixteenth century. 4. 'Memorie sulla Vita c Filosofia di Empedocle, Girgentino,' in 2 vols. 8vo., Palermo, 1813, a work more concise but not less accurate and interesting than that of F. W. Sturz, Leipzig, 1805, on the same subject. Scinà's book is divided into four parts: the first treats of the time in which Empedocles lived; the second is a biography of the Agrigentine philosopher; the third treats of his philosophy; and the fourth is a collection of the fragments of his works translated into Italian. 5. 'Discorso intorno ad Archimede.' 6. 'I Frammenti della Gastronomia d' Archestrato,' Palermo, 1823, with a biography of that antient and little-known Sicilian poet. 7. 'Prospetto della Storia Letteraria di Sicilia.' This is one of Scinà's most esteemed works, although it bears a very modest title. 8. 'Lettera al Padre Piazzi intorno a Girolamo Settimo, Matematico Palermitano.' 9. 'Esperienze e Scoverte sull' Elettro-magnetismo.' Scinà died of the Asiatic cholera, which afflicted Palermo in July, 1837. He was one of the most learned men that modern Sicily has produced.

(Tipaldo, *Biografia degli Italiani Illustri*; Mortillaro, *Sulla Vita e sù le Opere dell' Abate Domenico Scinà*, Palermo, 1837.)

SCINK (*Reptilia*). [SCINCOIDEANS, P. C.]

SCIOPTIC BALL is a globe of wood about five inches diameter, with a cylindrical perforation 2½ inches diameter passing centrally through it, and having at one extremity of the perforation a glass lens. The globe or ball is, by means of screws, fixed in a socket, which is made in a board about 8 or 10 inches square, in such a manner that while it cannot fall out, it is capable of being turned on its centre, to a small extent, in any direction.

The board being screwed to a window-shutter, or to the vertical face of a building in which an aperture has been made for the reception of the globe; the rays of light from external objects, after being refracted in the lens, form pleasing images of those objects on the opposite wall of the apartment, or on a white screen placed in a vertical position to receive the light; the apartment being darkened in order that the images may be distinct. The images on a vertical screen being inverted, two arms generally project from the board, within the room, and carry a plane mirror which turns on an axis so as to allow the rays of light, after passing through the lens, to fall on a screen placed in a horizontal position: by this means the spectators are enabled to see the images in erect positions. [CAMERA LUCIDA AND CAMERA OBSCURA, P. C.]

When the construction of the building is such as to allow the ball and lens to be fixed at an aperture in the roof, a plane mirror being placed above it at an angle of 45 degrees with the horizon, so as to reflect the rays from external objects down on the lens, the images formed on a screen within the darkened apartment are more distinctly formed and more conveniently seen. An apparatus of this nature was formerly applied to the roof of a building connected with the astronomical observatory at Greenwich, Edinburgh, and Glasgow, for the amusement of visitors.

SCIRPUS, a genus of plants belonging to the natural order Cyperaceae and the tribe Scirpeæ. It has fertile nearly equal glumes; the lower ones are perhaps the largest, and one or two of them empty. The bristles are either absent, or about six in number. The nut is plano convex or trigonous, tipped with the filiform not dilated base of the style.

S. maritimus has stalked or sessile spikes in a dense terminal cluster, several foliaceous bracts, bifid glumes, with an intermediate point; acute segments and a trigonous smooth nut. The stem is from one to three feet high and leafy. It is found in salt marshes in Great Britain, and is much relished by cattle. Withering says that the roots of this species are esculent, and have been ground down and used instead of flour in times of scarcity.

S. lacustris, Bullrush, has a round stem from four to six feet high, naked, with one or two long sheaths at the base, the spikes in a terminal twice compound panicle; the glumes are emarginate, mucronate, glabrous, and fringed. The nut obtusely trigonous and obovate; stigmas three. The panicle is not lateral, although the bract closely resembles a continuation of the stem. It is found in rivers and ponds in England. The root is astringent and diuretic, and was once used in medicine. The leaves are employed for making matting, chair bottoms, and many other domestic purposes.

S. triqueter has a stem acutely triquetrous throughout, flat or concave between the angles, with one or two long sheaths at the base, the upper one terminating in a very broad triquetrous leaf. The spikes are in a small cymose panicle, the glumes emarginate, mucronate, glabrous, and fringed, the lobes rounded obtuse, and the nut roundish obovate, plano-convex, and smooth. This species is found on the muddy banks of the Thames, near London, and the Arun, near Amberly, Sussex.

S. Holoschœnus is the ὁλόσχοινος of Theophrastus.

S. tuberosus is the Pi-tsi, or water-chesnut, of the Chinese, and is cultivated by them for food in large tanks, which are regularly manured and the water at intervals drawn off. The tubers are eaten both raw and cooked, and are esteemed both as food and medicine. There are fourteen British species of *Scirpus*, none of which however are worth description on account of any qualities they possess.

(Babington, *Man. Brit. Bot.*; Lindley, *Veg. King.*; Burnett, *Outlines of Bot.*)

SCLERANTHUS (from σκληρὸς, hard, and ἄνθος, a flower, in reference to the dry juiceless calyx), a genus of plants belonging to the natural order Paronycheae. It has a permanent 5-cleft calyx, with an urceolate tube contracted at the mouth with a glandular ring. The petals are absent; the stamens inserted in the throat of the calyx; the fruit membranous, one-seeded, indehiscent, included in the hardened calyx. The species are small herbs with opposite linear leaves which are rather connate at the base. The flowers are small, greenish white, and sessile in the axils of the forks of the branches.

S. annuus, Annual Knawel, has subdecandrous flowers, segments of the calyx of the fruit, patent acute, with a very membranous margin as long as their tube. The styles are longer than the stamens, the stem green and repeatedly dichostomous. The flower green, often solitary. It is found in sandy fields in Great Britain. The Swedes and Germans inhale the vapour arising from a decoction of this plant as a cure for the toothache.

S. perennis has decandrous flowers, the lobes of the calyx of the fruit closed, obtuse, with white and membranous edges. The styles are usually shorter than the stamens. The stem nearly simple, or irregularly branched, procumbent, and glaucous. The flowers green and white variegated. It is found in sandy places in Europe, the Levant, and in England. The Polish cochineal (*Coccus Polonicus*) is frequently found on the roots and leaves of this plant in the summer months. The seeds of these plants only require to be sown in the open border. None of the species are worth cultivating except in botanical collections.

(Don, *Gardener's Dict.*; Babington, *Man. Brit. Bot.*)

SCLERO'CHLOA (from σκληρὸς 'hard,' and χλόη 'grass'), a genus of grasses belonging to the tribe Festucineae. It has unequal acute membranous glumes. The outer palea with 5 faint but distinct and parallel nerves, membranous, cylindrical below, unarmed, often keeled at the tip or with a very minute mucro. The styles are terminal.

S. maritima has a branched panicle, the lowermost branches in pairs or simple, the branches alternately erect, the spikelets linear, adpressed, from 4 to 8 flowered, the rachis terete, the outer palea obtuse, apiculate, the midrib not reaching the apex, the root stoloniferous, fibrous, with rooting or ascending scions. It is found on sea-coasts and damp places in Great Britain.

S. distans is the *Glyceria* of Smith. It has a branched panicle, the branches elongated, ultimately spreading or deflexed, the lowermost in fours or fives, the spikelets linear, from 3 to 6 flowered, the outer palea obtuse, the midrib not reaching to the apex, the root fibrous without rooting scions. It is found on sandy sea-shores in England.

S. procumbens is known by its ovate lanceolate compact panicle, linear lanceolate spikelets of about 4 flowers, the rachis terete, angular, the outer palea obtuse, with an apiculus formed by the extremity of the dorsal nerve; the root is fibrous; the flower large. It is found in salt marshes in Britain.

There are six British species of this genus.

SCLERODERMI, the second family of Plectognathous fishes (such as have incomplete and soldered jaws). The *Sclerodermi* are distinguished by their conical or pyramidal snouts, ending in a small mouth, with distinct teeth in each jaw. The skin is rough, or covered with large hard scales.

The first division of *Plectognathi* is named *Gymnodontes*. The fishes included in it have no true teeth, but a substitute in a lamellated substance resembling ivory, which covers the jaws. It includes the *Tetrodon*, the *Diodon*, the *Orthagoriscus*, or sun-fish, and other genera.

The *Sclerodermi* are mostly tropical fishes, and are remarkable for their brilliant colours. One genus only occurs in the British seas, and that but very rarely; the *Balistes*, or file-fish, is the one alluded to. The *Ostracion* is remarkable for having its body clothed in an inflexible armour of hard plates, the tail-fins, mouth, and gill-openings passing through holes in its coat of mail.

SCLE'RODUS, a genus of fossil fishes from the upper Silurian strata of Ludlow, &c. (Agassiz.)

SCLOPE'NDRUM, a genus of ferns belonging to the tribe Aspleneae. The sori elongate, straight, and two together. The indusia of each pair opening towards each other.

S. vulgare, Hart's tongue, is a particularly handsome and ornamental fern, and very different from every other British species. It is universally and abundantly distributed throughout the British isles. It is very commonly found on old walls and ruins. It is also found in Europe, sparingly towards the North and in the United States. It is not however described as growing in Africa, Asia, or South America. The roots are black, stout, and very long and strong, the rhizoma is tufted, blackish, scaly, almost spherical, the young fronds make their appearance in April, growing in an erect position; by degrees they become horizontal, and at last pendulous. They arrive at maturity at the end of September, and continue in full vigour throughout the whole winter. The form of the frond is linear, elongated, and quite undivided, acute at the apex, and cordate at the base. This fern is the *Phyllitis* of Ray and all older botanists. It was once much in vogue as a medicine; Ray mentions it as an astringent, and speaks of its healing powers, applied as an ointment to wounds and ulcers. Lightfoot says it is used by the country people in Scotland as a vulnerary for burns and scalds, and we learn from the Flore Français that it is used in France as an astringent in cases of diarrhœa and hæmorrhage.

(Newman, *British Ferns*; Babington, *Manual of British Botany*.)

SCORPÆNA, a genus of Acanthopterygious osseous fishes of the family *Loricati*. Their heads are large, compressed, and more or less armed with spines or tubercles; the body is oblong and scaly. On the back is a single dorsal fin; the branchiostegous membrane has seven rays; and the jaws and palatines are armed with velvety teeth. They reside mostly on rocky grounds, feeding on crustacea and small fish. One only inhabits our seas, and is very rare, the Bergylt, or Norway haddock, a fish resembling the perch and attaining a length of two feet and more. In the Mediterranean are some beautifully-coloured species of this genus.

SCOTLAND, CHURCH OF. The constitution of this church has been considered under the heads of GENERAL ASSEMBLY, P. C., and SESSION, KIRK, P. C. An important portion of its history, throwing light on its present position, is narrated under the head FREE CHURCH, P. C. S. It remains only chronologically to mention the chief events in the history of the church. The main struggles of the reformation in Scotland date at the middle of the sixteenth century. On 1st August, 1560, a convention parliament abolished the Romish hierarchy, and on 20th December of the same year, the first general assembly was held in Edinburgh. In the ensuing year, the 'First Book of Discipline,' still an important part of the ecclesiastical code of the established church and the various sects into which the Presbyterians of Scotland are now divided, was compiled. The fundamental principles of the reformed church were passed into an act of parliament in 1567 (Act 1567, c. 3), with the title: 'The Confession of the Faith and Doctrine believed and possessed by the Protestants of Scotland, exhibited to the Estates of the same Parliament, and be their publick Votis authorized, as a Doctrine grounded on the infallible Word of God.' This constitution however had more reference to doctrine than to church polity. It condemned some of the more prominent features of the system of the abjured hierarchy, but did not contain any announcement of the new system of church government. The early constitution of the church as approved of by Knox and his friends, admitted of a difference of grades, certain clergymen being called 'Superintendents' of Provinces, which actually or nearly corresponded with the bounds of the old bishoprics. The Presbyterian polity was at length established by the act of 1592 (c. 114), called 'Ratification of the Libertie of the trew Kirk: of Generall and Synodall Assemblies: of Presbyteries: of Discipline.' In the mean time, those who had been the zealous clerical supporters of the reformation expected that the temporalities of the Roman Catholic church, or at least a considerable portion of them, would be applied to ecclesiastical purposes under the new system. They found however that the powerful laymen who assisted in the demolition of the old system had very different views. They spoke of this notion as 'a devout imagination,' and kept by far the larger portion of the spoil to themselves. After some hard struggles, in which the national feeling in favour of Presbyterianism was driven very nearly to an outbreak, Episcopacy was re-established by the parliament of 1612. In 1637, the celebrated Liturgy, concocted by Laud and West, on principles nearer approaching to the Roman Catholic forms than those of the English Liturgy, created the convulsions which ended in the civil war and the re-establishment of Presbytery. On this occasion, great part of the assistance which the Covenanters received from the landed gentry was owing to their dread of a plan for restoring church lands to the hierarchy. On the restoration of Charles II., all the acts of the previous reign subsequent to the year 1623 were 'rescinded' or repealed, and consequently the Episcopal form of church government was restored. The persecutions that arose out of the attempt to enforce this system on a people who abhorred it the more, the more stringently it was enforced on them by penal laws, is well known in history. These laws were relaxed, but not in a manner to satisfy the Presbyterians, by the indulgences of James to all who differed with the established Episcopal church. At the revolution the presbyterian form was re-established. The followers of this system, who through the times of the hottest persecution did not ask to be *tolerated* but to be made an exclusive establishment, now thought that the hour was come for the 'extermination' of their opponents; but they were told by King William that that was a word not in his vocabulary. In 1699 lay patronage was abolished by an act of the Scottish parliament. It was re-established by an act of the British parliament in 1710. This act created many disputes in the church; it occasioned the secession of 1736, elsewhere mentioned [Erskine, P. C. S.], and it was the cause of the great severance in 1843 [Free Church, P. C. S.]. In the same year with that severance an act was passed for modifying the right of patronage, called 'Lord Aberdeen's Act,' (6 & 7 Vict. c. 61, passed 17th August, 1843): a measure said to have been passed for the purpose of satisfying the scruples of some clergymen who would not remain in the church as it was, but would be content with a less comprehensive measure than the Veto Act. The difference between these two systems was, in the first place, that the Veto Act bore to be passed by authority of the church, its supporters denying that they required the interposition of any lay legislature. By that measure, the simple objection, of a certain number of the male communicants without any reason given, was a cause of disqualification to a presentee. By Lord Aberdeen's Act, any members of the congregation may object to the presentee, stating their objections: and the church courts, if they think them good, whether in their general tenor, or with respect to the particular circumstances of the charge, may give effect to them by rejecting the presentee.

SCOTT. [Eldon, Earl of, P. C. S.]

SCOTT. [Stowell, Lord, P. C. S.]

SCREW-PILES. [Sea-Lights, P. C. S.]

SCREW-PROPELLER. [Steam-Vessel Screw, P.C.S.]

SCROPHULA'RIA (so named from its supposed use in cases of scrofula), a genus of plants belonging to the natural order Scrophularineæ. It has a 5-parted nearly equal calyx, a globose corolla, with a short 5-lobed limb, the segments of which are rounded, and the uppermost united into an upper lip. The style is simple thickened at the apex, the stigma emarginate. There are four fertile didynamous declinate stamens, with the rudiment of a fifth appearing. The species are herbs or under shrubs with an unpleasant smell.

S. peregrina, Figwort, has cordate shining glabrous leaves, alternate peduncles from 2 to 5 flowered, the lobes of the calyx not membranous, glabrous and acute. The stem is acute-angled at the base, but obtuse angled at the apex, and of a dark purple. The leaves are full of pellucid dots. The corollas small, purple, and veiny, the lobes all denticulated. This species is the γαλιόψις of Dioscorides, 4. 95.

S. nodosa has a nearly smooth herbage, which when bruised smells like elder. The root is whitish, tubular, and beset with fleshy knots. The leaves are stalked ovate oblong, acute, sharply and unequally serrated, heart-shaped at the base, where they are cut away as it were to the two small lateral ribs. The flowers are a little drooping, the corollas of a dull green, with a livid purple lip, the calyx is smooth, the capsule ovate oblong. The leaves and roots are said to be purgative and emetic. They have a bitter taste and a disagreeable smell. A decoction is used by farmers to cure the scab in swine. Wasps greatly resort to the flowers. Goats eat the plant, but all other animals refuse it. It is native mostly throughout Europe.

S. aquatica has an entirely fibrous root. It is a smooth plant of a deep shining green colour, the stem is quadrangular downy, the leaves copiously and finely serrated, heart-shaped at the base. The flowers are in clusters, their tube is green, the corolla of a deep red. The capsule globular. This plant is called ***Water Betony***, ***Bishop's leaves***, and ***Broadwort***. Its medicinal properties are the same as those of *S. nodosa*. It is called by the French herbe du siége, because during the siege of Rochelle by Cardinal Richelieu the garrison supported themselves in extremity by eating the roots.

M. Marchant has reported, in his memoirs of the French Academy, that the plant is identical with the *Equetaia* of the Brazilians, celebrated as a corrective of the unpleasant flavour of senna. The Edinburgh college, in their common infusion of that drug, formerly sanctioned its use, but as they have discontinued it, we infer that it was not found to exercise the desired effect. The disagreeable smell of the plant causes cattle to reject it as food. Bees collect much honey from the flowers.

There are 73 species of Figwort, of these six are recognised British plants. They are of very easy culture and propagation, but prefer a moist situation. They are all readily propagated by seeds. The shrubby species require protection during the winter in a frame.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*; Burnett, *Outlines of Botany*.)

SCUTELLA'RIA (from the Latin 'Scutella,' 'a little saucer,' in reference to the form of the calyx), a genus of plants belonging to the natural order Labiatae. It has a campanulate bilabiate calyx, the lips entire, the upper one with a concave scale on its back. The tube of the corolla, much exserted, 2-lipped, the upper lip concave. The filaments simple; the anthers of the two longer and inferior stamens 1-celled, of the shorter and superior one 2-celled. The species are annual or perennial herbs, rarely shrubs.

S. galericulata, Skullcap, has branched divaricate stems, leaves on short petioles, oblong, lanceolate, cordate below, crenate, serrate; flowers axillary, opposite, and on short pedicels. The corolla is large and blue. The whole genus is remarkable for being provided with a curved, elongated support to its nut. This species was once considered efficacious in certain fevers. It is plentiful in Europe, Asia, and North America, in humid places, and in Britain.

S. minor, smaller Skullcap, is a humble glabrous plant, with its leaves on short petioles, the lower ones broadly ovate, the middle ones ovate-lanceolate with the base cordate, the upper ones lanceolate, rounded at the base; the flowers axillary, opposite, secured; the corolla almost glabrous, with the throat hardly dilated. It is native of Europe and Siberia, in damp places, and of Great Britain.

S. lateriflora has erect fleshy stems, petiolate ovate lanceolate acuminated leaves rounded at the base; the upper floral leaves hardly exceeding the calyxes, the racemes axillary and terminal, the flowers opposite and secund. It is native of North America, on the margins of ponds, and was once extolled as a remedy for hydrophobia, but on no good grounds. Most of the species of *Scutellaria* are very pretty ornamental plants, and will grow in any common soil.

SCYLLI'ODUS, a genus of fossil fishes. (Agassiz.) From the chalk.

SCYPHIA, a fossil genus of Spongiadæ. Chiefly in the chalk. (Goldfuss.)

SEA-LIGHTS. Since the publication of the article Light-Houses, P. C., p. 478, some changes have been effected in the management of the coast-lights and beacons of the United Kingdom, and many important inventions for increasing the efficiency of sea-lights have been introduced. Our brief notice of these will be chiefly founded upon the Report of the Select Committee of the House of Commons on Light-Houses, in the session of 1845, and upon two papers on 'Recent Improvements in Light-Houses,' published in the 'Penny Magazine' for 1842, pp. 286 and 294.

The Select Committee of 1845, having directed their attention chiefly to the alterations made in the lights and light-house establishments of the British Islands subsequently to the date of the Report of the Committee of 1834 (extracts from which are given under Light-Houses), report that by an act of 1836 (6 & 7 Will. 4, c. 79), all light-houses and sea-marks on the coasts of England were vested in the corporation of the Trinity House [Trinity House of Deptford Strond, P. C., p. 245], which was empowered by the act to purchase the private light-houses of Harwich, Dungeness, Winterton, Hunstanton, and Orford, which were held by individuals under leases from the crown; the Smalls and Long-ships, which were held on leases under the Trinity House itself; and the Skerries, Spurn, and Tynemouth lights, which were held by private parties in perpetuity under acts of parliament. The purchase of these ten lights was effected (the last in September, 1842), at an expense, by way of payment for the interests of individuals, of 1,182,546*l.*; and the rights of the crown on the five first were surrendered 'on condition that the Possessions and Land Revenues of the Crown should be released from a debt of 300,000*l.* advanced by the consolidated fund' on their security. Thus, at a very large cost, the recommendation of the Select Committee of 1834 'to have all public lights placed under one board, and free from private claims' has, so far as England is concerned, been carried into effect, and, as the Committee of 1845 observe in their Report, 'parliament will thereby be enabled to legislate freely respecting them, in such manner as shall be considered best for the public interest.'

Sea-lights are commonly divided into two principal classes, of which the first, called in the Committee's Report *Public General* Lights, embraces such as are of use to all vessels passing the coasts; while the second, called *Harbour or Local* Lights, includes such as are intended specially for the use of vessels resorting to particular ports. The first class, or Public General Lights, are now, if in England, all under the management of the Trinity House; if in Scotland, under the Commissioners of Northern Lights; and if in Ireland, under the Ballast Board of Dublin. [BALLAST OFFICE CORPORATION, P. C., p. 330.] The second class, or Harbour or Local Lights, are 'managed, under powers given by the legislature, or emanating from other authorities, by corporations and local trustees,' who collect the dues necessary for their support; but, under the act of 1836, the Trinity House has a general superintendence over those of England, their sanction being necessary to the establishment of new lights, and they giving directions as to the kind of light to be used, to avoid interference with the general coast lights. In Ireland, all the harbour lights, with the exception of one at Belfast, are managed by the Ballast Board, who receive the dues and pay the expenses of maintenance in the same way as for the public general lights.

From returns laid before the committee of 1845, it appears that the number of lights of all kinds has been greatly increased within a few years, as will be evident from the following details. The comparative number of lights of various kinds in England in 1834 and 1844 was as follows:—

	1834.			1844.		
	Fixed.	Floating.	Total.	Fixed.	Floating.	Total.
Public General . .	57*	14†	71	65	26‡	91
Local or Harbour .	51	4	55	75	9	84
Totals . .	108	18	126	140	35	175

In Scotland (where, from the returns, all appear to be fixed lights), the numbers were—

	1834.	1844.
Public General	25	29
Local or Harbour	28	38
Totals	53	67§

In Ireland, at the same periods, the numbers were

	1834.			1844.		
	Fixed.	Floating.	Total.	Fixed.	Floating.	Total.
Public General .	23	3	26	27	3	30
Local or Harbour	14	0	14	30	0	30
Totals . .	37	3	40	57	3	60

in which returns are included 5 local lights which, in 1834, were not under the management of the Ballast Board, and, in the second division, 1 such (that at Belfast) which was still, in 1844, out of their jurisdiction.

The aggregate statement, without distinguishing floating from fixed lights, stands thus for the two periods:—

	1834.			1844.		
	Public General.	Local or Harbour.	Total.	Public General.	Local or Harbour.	Total.
England . . .	71	55	126	91	84	175
Scotland . . .	25	28	53	29	38	67
Ireland . . .	26	14	40	30	30	60
Totals . .	122	97	219	150	152	302

showing an increase in little more than ten years (for the returns dated 1834 refer, at least in some cases, to 1833, while those given under 1844 appear to be actually for that year), of 83 lights, classified as follows:—

	Public General.	Local or Harbour.	Total.
England . .	20	29	49
Scotland . .	4	10	14
Ireland . . .	4	16	20
Totals	28	55	83

* 42 belonging to the Trinity House, 1 under their management, and 14 in private hands: viz. 3 on lease from the Trinity House, 7 on lease from the crown, and 4 held by patent and act of Parliament.

† 13 belonging to the Trinity House, and 1 onder their management.

‡ Including 1 at the Plymouth Breakwater, which is given separately in the Committee's Report.

§ There were, at the date of this return, only 25 poblic general lighthouse stations, but as four of these, viz. the Isle of May, Pentland Skerries, Pladda, and Girdleness, were *double*, that is, had two light-houses each, the number of lights was as given in the text. Three new light houses, not included in the return, were stated to be in preparation. In addition to the 38 permanent local or harbour lights reported, there were some used in the fishing season only.

In addition to the above there were, in 1844, 7 local lights belonging to the Isle of Man, which, not having been included in the returns for 1833, we have omitted in those for 1844. These raise the number of local lights for the United Kingdom to 159, and the gross number of lights to 309.

Of the 94 fixed general lights in England and Scotland 76 were, in 1844, *catoptric* lights, with an aggregate number of 1098 burners, which gives an average of nearly 14½ burners to each light, and 18 were *dioptric*, of power equal to an aggregate of 258 burners, which gives an average power of 14⅓ burners to each light. The aggregate illuminating power of the fixed general lights in England and Scotland was, therefore, equal to 1356 burners, while that of the 25 English floating general lights (exclusivo of that at Plymouth breakwater) was 288 burners, giving an average power of 11½ burners to each light. In Ireland the 27 fixed general lights had an aggregate power of 583 burners, which gives an average of rather more than 21½ per light, and the 29 harbour lights under the Ballast Board an aggregate of 216 burners, which gives an average of rather less than 7½ per light.

From the evidence laid before the committee of 1845 it would appear that the public general lights of the United Kingdom are in an efficient state, and, according to a witness who had ample opportunities of comparison, on the whole superior to those of the United States of America; but while no complaints were made of their want of brilliancy or general efficiency, many were laid before the committee, both by petitions and from witnesses, of the high charge for light dues, the mode of levying them, or the irregularity of their rates. How greatly the gross amount levied upon commerce in the shape of light dues has increased since the date of the Report of 1834, will be seen from the following comparative statement of dues levied in each division of the United Kingdom in 1832 and 1843. The return for England and Scotland appears to apply solely to general coast lights, no complete account being given of the dues from harbour lights; but that for Ireland embraces such, they being, as before stated, in the hands of the Ballast Board. Of the dues levied in England in 1832, only 83,041*l.* belonged to the Trinity House, and 79,676*l.* to private individuals; but in 1843 the whole fell into the hands of the Trinity House.

	1832. £.	1843. £.	Increase. £.
England	162,717	257,776	95,059
Scotland	35,526	43,840	8,314
Ireland	42,061	55,289	13,228
Totals . . .	240,304	356,905	116,601

From the statements laid before the committee of 1845, it appears that these charges, which, in consequence of the general reduction of freight and the competition to which ship-owners are increasingly subject, are becoming more and more oppressive to trade, are not only far higher than is necessary for the mere maintenance of the lights, but are also levied in such a manner as to press with peculiar severity upon particular branches of the shipping interest. Steam-packet companies especially complain of the amount of the dues as compared with the advantages derived. The Peninsular and Oriental Steam-packet Company state that four of their vessels employed on the Peninsular line, of an average tonnage of 368 tons, and making fifty-two voyages in the year 1844, paid 12*l.* 7*s.* 4*d.* per voyage for light dues, or 643*l.* 1*s.* 4*d.* in the course of the year; and that two others, plying between Southampton and Alexandria, averaging 888 tons each, and making twelve voyages in the year, paid 29*l.* 14*s.* per voyage, or 356*l.* 8*s.* per annum. One case that appears of peculiar hardship is that of a small steamer plying between Granton, in the Firth of Forth, and Dundee, completing its voyages entirely by daylight, and therefore deriving no benefit whatever from the lights, but which, nevertheless, paid dues to the following amount in one year, during which it was at work for forty-nine weeks, and three weeks refitting:—

Thirteen weeks of double voyages, at 16*l.* 13*s.* 9*d.* per week	212*l.* 18*s.*
Thirty-six weeks of single voyages, at 10*l.* 10*s.* per week	489*l.* 6*s.*
Total for forty-nine weeks . .	702*l.* 4*s.*

On the coasting trade also the light dues are found very burdensome, especially where the competition of railways is felt. One vessel employed in the coal-trade, of which particulars were laid before the committee, made in the years

1843 and 1844 thirteen voyages, with an average load of 400 tons, earning a gross freight of 2007*l.* 18*s.* 1*d.*; out of which 69*l.* 10*s.* 7*d.*, or more than 3½ per cent., had to be paid for light dues; and Mr. Ogilby, a London shipbroker of forty years' standing, stated in evidence 'that the traders to the principal ports of Ireland have paid on the average 5*s.* 1½*d.* per ton on the average of the year; that vessels from the Mediterranean and the South of Europe, making a less number of voyages, pay 3*s.* 6½*d.* per ton; and ships to India and China, making one voyage in the year, 1*s.* 1¾*d.* per ton; and that the coasting trade, now in the greatest depression, would consequently benefit the most by the abolition of the light dues.' The following table, compiled from the returns given in the Committee's Report, show what proportion of the light dues of each division of the United Kingdom is derived from each class of ships.—

	England. £.	Scotland. £.	Ireland. £.	Total. £.
Coasting trade . . .	126,673	27,743	19,991	174,407
British over-sea vessels	97,454	11,601	24,718	133,773
Foreign vessels . .	33,648	4,496	18,580	48,724
Totals . . .	257,775*	43,840	55,289	356,904*

The light-dues are, it should be observed, charged upon the whole tonnage of a vessel, however small may be the cargo actually on board; 'indeed,' observes the Report, 'if one ton, or one box, or one passenger paying freight be on board from port to port, light-dues for the whole ship's tonnage is invariably charged; and consequently the ships often are sent in ballast from port to port rather than take a small quantity of cargo; a course of proceeding which, in the corn-trade of Ireland, operates very injuriously on the merchants, and on the consumers in the smaller ports to which the vessels go for corn.'

Of the recommendations of the Committee of 1845 for removing the evils complained of we need say very little, especially as nothing has, down to the close of the session of 1846, been done to give them legislative effect. Their principal features are the proposed transfer of the management of all public lights, buoys, and beacons, on the coasts of England, Ireland, and Scotland, to one central board, which it is suggested should be the Corporation of the Trinity House, with some modifications in its constitution; the defraying by government of the heavy debt incurred by the Trinity House in buying up private lights; and the future maintenance of public lights, buoys, and beacons either out of the public revenues of the country, or by a small tonnage-rate on all the registered tonnage of the United Kingdom, and all colonial and foreign vessels entering its ports: such rate being made only sufficient for the purpose, instead of producing, like the present light-dues, a large surplus revenue for pensions and charitable purposes. They suggest that it may deserve to be considered whether the ships of the Navy, and those in the Customs, Excise, and Preventive Service should continue to be, as they now are, exempted from the payment of light-dues; and they conceive that a more economical mode of collection, by the agency of the officers of Customs, might be substituted for the present.

One interesting department of the investigations of the late parliamentary Committee is that relating to the cost of various modes of illumination. Their Report states that for many years past the French have used colza or rape-seed oil, which costs about 3*s.* 8*d.* per gallon, while the best sperm oil, which is usually burnt in English light-houses, costs from 6*s.* to 8*s.* per gallon. It is admitted that a greater quantity of colza than of sperm oil is necessary to produce the same effect, yet some of the witnesses examined expressed an opinion that one-half of the expense of the oil consumed might be saved by its use, and how seriously any such saving would affect the general cost of maintaining light-houses may be perceived from the statement that, out of 701*l.*, the total expense of the Flamborough light in 1843, 303*l.* was expended upon oil, and that in the Dungeness light-house the same item amounts to 229*l.* in a total expenditure of 532*l.* Mr. Alexander Gordon, however, in his evidence, objects to rape-seed oil because, in common with all other vegetable oils, it wastes by burning to overflow, and occasions increased labour in trimming the lamps. He greatly prefers sperm oil, notwithstanding its cost, and places next to it some of the South Sea whale oils, and then cocoa-nut and palm oils. In the United States, where the cost of maintaining light-houses is far less than in this country, experiments have been made on the comparative economy of various substances, from which it appears that, burning for the whole night, and giving the same degree of light,

3·05 burners using	lard-oil	cost	32·49	cents.
5·00 ,, ,,	resin-gas	,,	88·47	,,
and 10·00 ,, ,,	sperm-oil	,,	105·95	,,

The following statement shows the average total cost per burner and per light-house of the public general lights of each division of the United Kingdom, and of the harbour-lights of Ireland, in 1843 or 1844. It indicates an important reduction on the returns of 1832, the average cost for the United Kingdom being 459*l.* per annum in 1843-44, and 508*l.* in 1832:—

	Per burner. £.	s.	d.	Per light-house. £.	s.	d.
England (1843) . .	31	14	6	409	0	0
Scotland (1843) . .	29	13	0	516	0	0
Ireland (1844) . .	22	13	9	454	0	0
Ditto, harbour-lights	26	4	0	195	0	0

We may conclude our statistical returns for England by noticing the number of buoys and beacons maintained by the Trinity House, and add, for the sake of comparison, some figures relating to the sea-lights of France and America.

The beacons in charge of the Trinity House in 1834 were 33, and in 1844, 48, showing an increase of 15. In 1833 the number of buoys under the same management was 227, and in 1844, 299, being an increase of 72. The beaconage and other dues levied by the Trinity House in 1843 for beacons and buoys amounted to 14,207*l.* 0*s.* 10½*d.* No corresponding dues are charged in Scotland and Ireland by the Northern Lights Commissioners and the Ballast Board, and the Light-houses Committee of 1845 recommended the abolition of such in England.

In France the light-houses and harbour-lights are all under a public board, and their expenses are paid out of the treasury, and met by levying a port-charge of 10*d.* per ton upon shipping instead of light-dues. There were, in 1834, 23 light-houses and 51 harbour-lights, making a total of 74; of which 29 were provided with lenticular apparatus, the nature of which is explained under LIGHT-HOUSES, P. C. The establishment of new lights has there proceeded more rapidly than with ourselves, the number having more than doubled in about ten years. In April, 1845, it was reported as 52 general coast light-houses and 101 harbour-lights, making a total of 153; of which 98 have lenticular apparatus. Some of these lights being grouped in twos and threes, the total number of light-house stations or separate establishments is only 108.

In the United States of America, where the lights are supported by the general government, there were, on the 1st of July, 1842, 242 fixed and 30 floating lights, having an aggregate power of 2671 burners.

In adverting to some of the more important mechanical improvements recently introduced in the construction of light-houses, we may first notice the construction of such buildings wholly of iron or other metal. Though first carried into effect by Mr. Alexander Gordon, this improvement would appear, from the first of the papers already referred to in the 'Penny Magazine,' to have been previously suggested by the ingenious Captain (afterwards Sir) Samuel Brown, who is best known for his share in the introduction of suspension-bridges and piers, and who proposed to erect a light-house of either iron or bronze upon the Wolf Rock, near the Land's End. His plan was to construct a tower 90 feet high, 14 feet in diameter at the bottom, and 4 at the thinnest part, composed of several truncated conical pieces of cast metal, fitting one another like the joints of a telescope. Within the body of this metallic column were to be sleeping-berths for the attendants, and store-rooms for provisions, fuel, water, and oil; and at the top was to be the keeper's house, surrounded by an open over-hanging gallery, and surmounted by the lantern. Captain Brown conceived that such a structure would possess the advantages of being much less costly than a stone light-house; of requiring much less time for its erection; of presenting a much narrower surface for the sea to act against; and of greater security and stability, seeing that it was intended to have but eight joints from the ground to the lantern, while a stone structure would have many thousands, and that, the whole circumference of each stage or story being cast in one piece, it would be capable of resisting enormous pressure.

Captain Brown's simple and ingenious design was not carried

* The discrepancy of 1*l.* between these sums and those in a preceding table arises, we presume, from the omission of fractions. The *items* given above are as in the Report.

into effect, but a cast-iron lighthouse on a somewhat different plan was erected in 1842, by Mr. Alexander Gordon, upon an unhealthy lagoon in Jamaica, where, owing to local difficulties, it was computed that a tower of masonry could not have been constructed for less than 20,000*l.*, or in a less period than six years, with the almost inevitable loss of many lives. For this locality Mr. Gordon designed an iron tower formed on the model of the antient Celtic round towers of Ireland. The erection was determined on by the commissioners in Jamaica on the 8th of March, 1841; eight months after that date it was ready for shipment; and it was ready for lighting early in August, 1842, though not actually lighted until November. The cost of the tower and lantern, including the fitting up in London, taking to pieces, packing, and shipping for its destination, was 3,500*l.*, and the putting up (exclusive of the excavation of the coral rock upon which it stands) cost about 600*l.* additional. The diameter of the tower is 18 feet 6 inches at the base, and diminishes regularly to 11 feet at the top; and instead of being formed, as in Captain Brown's plan, of a few large castings, each embracing the whole circumference, it is formed of nine tiers of cast-iron plates, each 10 feet high, from 4 feet to 5 feet wide, and nearly an inch thick, the circumference being composed of eleven such plates at the base of the tower, and nine at the top. These are cast with flanges all round their inner edges, and, when put together, these flanges form the joints, which are fastened together with nut-and-screw bolts, and caulked with iron cement. The cap or top of the column consists of ten radiating plates, which form the floor of the light-room, these being secured to the tower upon twenty pierced brackets, and finished above by an iron railing. The lantern is also of iron, glazed with plate glass, and it is supplied with a revolving light, consisting of fifteen Argand lamps and reflectors, five in each side of an equilateral triangle; so arranged as to produce a continuous light, but with periodical flashes. The tower rests upon a coral rock, upon which is laid a grooved course of granite to receive the flange of the lower plates, from which lightning conductors extend into the sea. The base is also encased with granite, to protect the iron from the action of such sea-water as might filter through the stratum of sand which covers the coral rock; and the protection is increased by coating the exterior of the iron with tar. The interior of the tower, to about one-fourth of its height, is filled up with masonry and concrete so as to form a solid core, which imparts great stability to the structure; and above this are the necessary rooms. Of the precise nature of the arrangements actually adopted for securing comfort in this singular habitation we are not informed, but it is stated in the 'Penny Magazine,' on the authority of a paper in the 'Civil Engineer's Journal,' published while the structure was yet in progress, that in order 'to preserve as low a temperature as the circumstances and climate will permit, the iron shaft or tower is to be lined with a non-conducting material, such as slate or wood, leaving an interstice through which a constant ventilation will be effected, so as to carry off the excessive heat.' In his evidence before the parliamentary committee of 1845 Mr. Gordon stated that a taller and better lighthouse of similar construction was in progress for Bermuda, which would weigh about 120 tons, and would contain in its base about 450 tons of masonry and concrete. Among the numerous advantages of this kind of lighthouse may be mentioned their superior safety in thunder-storms, the whole structure constituting a great unbroken conductor for the lightning; and the safety arising from the whole being virtually in a single piece, and therefore far better able than a tower of masonry to resist the shocks of earthquakes, to which, as well as to violent thunder-storms, the Jamaica lighthouse has been repeatedly exposed. The iron-work is so constructed as to be readily put together from inside, without any external scaffolding; and these, in common with other iron lighthouses and beacons, have the convenient property of being easily removable, in case the shifting of sands or any other circumstance should render a change of position desirable; a contingency which, as will be seen by reference to SUNDERLAND, P. C., p. 295, has already occurred, and which is very likely to recur as the substitution of fixed for floating lights in the vicinity of shifting sands, and the general extension of harbour lights, proceeds.

A somewhat similar construction of lighthouse was proposed in 1836 to a Select Committee of the House of Commons on Shipwrecks, by Mr. Bush, as suitable for erection on the Goodwin Sands, where the extreme difficulties of the locality have hitherto deterred the Trinity House from establishing any other than a floating light or light-ship. Mr. Bush's plan, as then proposed, was to construct, on land, a wooden truncated cone 100 feet high, 60 feet in diameter at the base, and 20 feet at the top, surrounded by another similar cone which should be in contact with it at the base, but, diminishing less rapidly as it rose, should gradually recede from it towards the upper part. The interveuing space between the two was to be filled with sand or other heavy materials after the structure was floated to the required position, so as to sink it in the sea until it found a firm bottom. The sand included in the inner cone was then to be drawn out, leaving the double cone as a kind of cofferdam, and its place supplied with a solid mass of masonry or concrete, which might form a secure foundation for an iron lighthouse. The outer cone might, it was suggested, be eventually removed without endangering the structure. Since 1836 Mr. Bush has, at his own expense, partially carried out his scheme in a modified form, using a cylindrical caisson of iron 64 feet high and 30 feet in diameter in lieu of the proposed timber cone; but it appears by the evidence laid before the Lighthouse Committee of 1845, that the Trinity House refused to sanction the lighting of his unfinished structure, and that some of its officers deemed Bush's plan to be impracticable. Mr. Bush proposed not merely a lighthouse, but an extensive asylum for shipwrecked sailors, and even the construction of a harbour of refuge at the Goodwin Sands. In connection with this scheme we may notice, though not strictly falling within the limits of our subject, the experimental safety-beacon erected in 1840 upon another part of the same dangerous sands by Captain Bullock. This beacon, which is intended simply as a refuge for shipwrecked sailors, and not for a light, nor even as a beacon of direction, consists of a strong mast or spar about 40 feet high, surmounted by a flag-staff 10 feet high, and supporting, near its upper extremity, a gallery 9 feet in diameter, constructed principally of sail-cloth, and capable of holding forty persons, to which access may be obtained from below by means of ropes and cleats or notches in the mast. The mast or shaft is secured to a massive platform of oak, sunk several feet below the surface of the sand, and loaded with upwards of three tons of iron ballast; and it is further supported by oblique bars of iron and chains. The mainmast or shaft of the beacon stands 30 feet above the dry sand at low water, and 17 feet 6 inches above high water at spring tides. In the gallery is placed a barrel of fresh water and a bag containing a blue flag, which is to be hoisted when assistance is required from the land, which is seven miles distant; and to render the beacon available to all who are likely to make use of it, directions to 'hoist the flag' are painted in eight different languages on the sides of the gallery.

Perhaps the most curious recent invention connected with our subject is that of Mr. Alexander Mitchell, of Belfast, for constructing lighthouses and beacons entirely supported by piles, which, instead of being driven into the ground like ordinary piles, are screwed in by the aid of a peculiar kind of screw attached to their lower extremities. These screws, which were first employed instead of mooring-anchors, are of cast-iron, and consist of a broad thin plate or share winding round, and attached by its edge to an axis or shaft, the diameter of the screw being from two to five feet, and the thread or share taking only one turn and a half round its axis, and having its outer edge sharp, so as to cut its way readily, when the axis is turned round by suitable means, into sand or earth, while its broad surface offers great resistance to any attempt to pull it out of its place. The great success of this invention, as applied to moorings, led to the attempt to apply it to the erection of lighthouses upon sands, for which purpose it bids fair to become highly important, as such lighthouses may be erected where there is not sufficient depth of water to moor a light-ship, and fixed lights are always more secure and less expensive to maintain than floating lights. The first screw-pile lighthouse was commenced on the Maplin sands, at the mouth of the Thames, in 1838, by screwing into the sands eight wrought-iron shafts, arranged so as to form an octagon of about 40 feet diameter, with a slight inclination inwards at the upper extremities, and a ninth perfectly upright, in the centre. These shafts were about 25 feet long, and were screwed 20 feet into the sand; and to their upper ends were secured a series of cast-iron pillars, strongly braced and bound together, supporting a massive timber framework upon which is built the lighthouse, comprising store-rooms and apartments for the keepers. This lighthouse was not completed until February, 1841; but in

November, 1839, a similar stru ture, supported upon seven instead of nine piles, was commenced at the mouth of the river Wyre, to facilitate the entrance of shipping into the new port of Fleetwood, which was completed in June, 1840, at a cost of about 3500*l.* In both these structures the supporting framework is left open to a considerable height above the highest water-line, so that they present no extended surface for the waves to beat against, and are thus protected from the violent shocks to which other lighthouses are subject. A third lighthouse of similar character was erected in Carrickfergus Bay in 1844, at a cost, for materials and labour only (Mr. Mitchell giving his services as engineer gratuitously), of only 1300*l.*, although the building, being used also as a pilot station, is large enough for the residence of twelve or more men, and has accommodation for suspending to the framework two heavy pilot-boats. Economy of maintenance appears to be as striking a feature of this kind of lighthouse as economy of construction, that at Fleetwood having, in the five years between its erection and the date of Mitchell's evidence before the committee of 1845, cost nothing for repair beyond occasional painting. It has been suggested that life-boats might be kept suspended to such lighthouses, like the pilot-boats at Carrickfergus Bay. The parliamentary report of 1845 refers to another mode of inserting piles in sand for the purpose of supporting lighthouses, the invention of Dr. Potts, as being under experiment by the Trinity House. It is stated to consist in the sinking of hollow cylinders by pumping out the air from their interior, and thus forcing them into the sand by atmospheric pressure.

Some ingenious suggestions of Mr. Alexander Gordon, which are fully explained and illustrated in the Committee's report, relate to the use of a kind of hollow iron tower or funnel in light-ships, through which the lanterns might be hoisted and lowered for trimming more safely and conveniently than when attached to a mast, and through which men might ascend when necessary to attend to the lights, secure from the effect of rough weather; and also to a plan for distributing in foggy weather, by means of revolving paraboloids or parabolic reflectors, the sound of a powerful whistle, constructed like the steam-whistle of a railway locomotive.

The second of the two papers above referred to in the 'Penny Magazine' contains a notice of an important suggestion made by Captain Basil Hall in a letter to the 'United Service Journal,' in reference to revolving lights. A fixed light, if required to be seen in one direction only, may be readily mounted with a parabolic reflector, so as to show at a very great distance; but where the light is required to be seen in all directions a difficulty arises, because, even supposing twenty-four distinct lamps, each having its own reflector, to be arranged in a circle, they will, owing to the light being reflected forward in parallel rays, only light so many points of the horizon, leaving the intervening portions in darkness, while at the same time the light will, from being so divided and scattered, be less efficient than if it were concentrated upon a smaller number of points. Hence arises one of the greatest advantages of revolving lights, for if, as the case is put by Captain Hall, instead of twenty-four lamps arranged at equidistant intervals round the circle, six be directed, by their reflectors, due north, six due south, six due east, and six due west, and then that part of the lighthouse upon which the four sets of lamps is mounted be caused to revolve upon a vertical axis, the four concentrated blazes of light, instead of illuminating only the four points to which they were originally directed, will light up, in succession, every part of the horizon, and that with a blaze of light six times more powerful than in the case first described. As, however, variety is essential to prevent one light being mistaken for another, it frequently happens that a fixed light must be adopted for the sake of distinction, notwithstanding its inferiority. Captain Hall suggests, therefore, that a revolving light might be made to rotate on its axis with such rapidity as to exhibit an unbroken line of light along its path, on the principle of a burning stick whirled round so as to produce the appearance of a circle of fire. If this could be accomplished, the resulting light would, with the superior brilliancy of the revolving light, be continuous in every direction.

An important improvement has recently been introduced by Professor Faraday in the ventilation of lighthouse lanterns, upon which a paper was read before the Institute of Civil Engineers on the 27th of June, 1843. The want of proper ventilation in ordinary lanterns occasions the production, by the combustion of the oil, of water and carbonic acid. The water condenses upon the glass windows and dims them, while the carbonic acid often renders the air in the lantern so irrespirable as to render it very difficult for the keepers to attend to their duties. Owing to the exposed position of lighthouses generally, ordinary means of ventilation, by allowing the free admission and egress of air, are inapplicable; but Mr. Faraday, having his attention directed to the subject by the Trinity House, has devised a kind of chimney which has answered well, and which does not endanger the lights by permitting gusts of wind to get into the cowl. The contrivance is pretty fully described in an abstract of the paper referred to, in the 'Athenæum' for 1843, p. 637.

SEA-NETTLE. [ACTINIA, P. C.]

SEAMEN. *Employment, Wages, &c., of Merchant Seamen.*—The 5 & 6 Wm. IV. c. 19 repealed all former acts which regulated the hiring of seamen; and the 5 & 6 Wm. IV. c. 19 has been repealed, (except so far as such act repeals the acts thereby repealed, and except so far as relates to the establishment, maintenance, and regulations of the office called 'The General Register Office of Merchant Seamen'), by the 7 & 8 Vict. c. 112, which contains the present law relating to merchant-seamen and for keeping a Register of them. This act contains sixty-four sections: s. 2, &c. regulate the agreement of hiring seamen; s. 6, &c. assign the punishment of seamen for refusing to join the ship, or absenting themselves from it; s. 9 fixes the forfeiture for desertion; s. 11 the periods within which wages must be paid; s. 15 provides a summary mode of recovering wages not exceeding twenty pounds; s. 17 provides for seamen being sent home when the ship is sold in a foreign port; s. 18 regulates the supply of medicines, lime or lemon juice, and other things necessary for the health of the crew, and declares in what cases there shall be a physician, surgeon, or apothecary on board; s. 19, &c. provide for a general register and record office of seamen; s. 31 provides for the disposal of the effects of seamen who die abroad elsewhere than on board a British ship, and leaving money or effects not on board such ship; s. 32, &c. provide for apprenticing parish boys to the sea-service; s. 46 provides against masters of ships discharging seamen at any of her Majesty's colonies or plantations, or at any other place abroad, except as herein provided; s. 50 provides for seamen being at liberty to leave any ship and enter the naval service of her Majesty; s. 58 provides for offences against the property or person of any subject of her Majesty, or of any foreigner, committed at any port or place, either ashore or afloat, out of the dominions of her Majesty, by the master and crew; s. 61 declares in what cases this act shall not apply.

Seamen in the Royal Navy and *Impressment.*—It is stated by Blackstone, on the authority of Foster, 'that the practice of impressing and granting power to the admiralty for that purpose is of very ancient date, and hath been uniformly continued by a series of precedents to the present time, whence he concludes it to be a part of the common law.' As impressment is effected by the king's commission, the power of impressment belongs to the crown. Barrington, in his 'Observations on Ancient Statutes,' p. 334, 5th ed., shows that the king used once to exercise the power of impressing men for the land service also, and even for his own private service, as in the case of goldsmiths. The legality of impressment is fully established, though the practice cannot be defended even on the ground of the safety of the state, until it has been shown that seamen for the royal navy cannot be procured by other means. The general rule is that all seamen are liable to impressment. There are several legal decisions as to the question who are seamen, and who may be privileged.

Volunteer seamen are induced to enter the royal navy by higher wages; and every foreign seamen who shall have served in a ship of war, a merchant-ship, or privateer for two years during a war, is thereby naturalized. The 7 & 8 Vict. c. 112, s. 32, enacts that overseers of the poor, or other persons having the authority of overseers of the poor, in and for any district, union, parish, township, or place in the United Kingdom, may put out as an apprentice in the British merchant sea-service, any boy who is twelve years of age and of sufficient health and strength, with his consent, who, or his parent or parents is or are chargeable to or maintained by such district, &c., or who shall beg for alms therein: the apprenticeship is to last till such a boy attain the age of twenty-one years, or shall have served seven years as an apprentice, whichever shall first happen. Section 33 of the same act provides for turning over, with their consent, of parish apprentices, who shall have been bound to a service on shore, to the sea-service, to be employed as is provided in the case of apprentices to the sea-service under s. 32, for the period then remaining unexpired of their apprenticeship. Section 37 provides that all British ships of the burden of eighty tons and upwards, except pleasure-yachts, shall have apprentices in proportion to their tonnage, as in this section provided; all which apprentices must at the time of being bound to British subjects be above twelve and under seventeen years of age, and be duly bound for four years at least. Section 50 provides, 'That nothing in this Act, or in any agreement contained, shall prevent any seaman or person belonging to any ship or vessel whatever from entering or being received into the naval service of her majesty, nor shall any such entry be deemed a desertion from the ship or vessel, nor shall such seaman or other person thereby incur any penalty or forfeiture whatsoever either of wages, clothes, or effects, or other matter or thing.'

The commerce of Great Britain gives regular employment to a vast body of seamen, and the habits and occupation of a large number of people on the sea-coast give them a relish and a capacity for sea-service. With the great increase of the commercial navy of Great Britain which has taken place of late years, and the prospect of still greater increase of commerce by the restrictions on trade being removed, we may always reckon on a sufficient number of seamen in the commercial navy to make up the deficiency in the royal navy in case of a sudden war. The apprenticeship system also is well devised to keep up a regular supply of young seamen. It is probable that ten or twenty thousand men might be at once drawn from the commercial navy for the royal navy on any emergency by offering them better wages, and thus the necessity of impressment might be removed. The amount of inconvenience that may be sustained by the merchant-service by the withdrawal of a great number of seamen at once, is the same, whether the seamen are impressed or go as volunteers; but to the inconvenience arising from the actual withdrawal of seamen by impressment must be added the loss and inconvenience to the merchant-service which may arise from seamen keeping out of the way in order to avoid being impressed.

SEDITION (from the Latin *seditio*). It is stated that in many of the old English common law writers treason is sometimes expressed by the term Sedition; and that when law proceedings were in Latin, *seditio* was the technical word used in indictments for treason, till it was superseded by the word *proditio*.

Sedition does not appear to be very exactly defined. It is stated to comprehend contemptuous, indecent, or malicious observations upon the king or his government, whether made in words only, or in writing, or by tokens (which last term must comprehend pictures or drawings), calculated to lower him in the opinion of the subjects or to weaken his government. All these offences fall short of treason; but they are considered crimes at common law, and punishable by fine and imprisonment.

There are also statutes against particular acts of sedition, such as seditious libels. [Law, Criminal, P. C. S., p. 176, No. 40.] There are also various acts against societies established for seditious and treasonable purposes, and against seditious meetings and assemblies.

The Roman sense of Seditio (*sed* or *se*, and *itio*, a going apart, a separation) is properly a disunion among the citizens, a riot, or turbulent assemblage of people for the purpose of accomplishing some object by violence or causing fear. It was included among other forbidden acts in the Lex Julia de Majestate. (Dig. 48, tit. 4.) It is often used in connection with 'tumultus' and 'turba;' and the three terms seem to have the same signification. (Rein, *Römisches Criminalrecht*, p. 522.)

SELIM III., son of Sultan Mustapha III., was born Dec. 24, 1761. Mustapha III. was succeeded by his only brother Abdu-l-Hamid, and Selim was shut up in the seraglio among the women and eunuchs. Abdu-l-Hamid died April 7, 1789, and Selim then became sultan. The principal events of his reign are related in the article Turkey, Turks, P. C., p. 404. He was deposed May 29, 1807, and Mustapha IV., son of Abdu-l-Hamid, was elected in his place. Selim was put in confinement, and was strangled by order of Mustapha, July 28, 1808. Mustapha was deposed immediately afterwards, and was succeeded by Mahmud II. [Mahmud II., P. C. S.; Mustapha IV., P. C.]

SELVA, GIANNANTONIO, was born of respectable parents, at Venice, June 13, 1753, and had for his earliest instructor his uncle the Abbate Gianmaria Selva, a man of considerable literary and scientific attainments. His inclination leading him to make choice of art as his future profession, he was placed under Pietro Antonio Novelli (a painter who died in 1804, aged 75); but after he had grounded himself in drawing and the elements of painting, he passed to the study of architecture, and became a pupil of Temanza [Temanza, P. C.]. In 1778 he set out for Rome, where besides studying the various architectural monuments of that capital, he became intimately acquainted with Pindemonte, Piranesi, Battoni, Quarenghi, and others, who either then were, or afterwards became distinguished names, for among them was Canova, with whom he visited Naples, Pompeii, Caserta and Pæstum. While at Rome, he also obtained the notice and favour of his countryman the noble Girolamo Zulian, who was there in quality of ambassador from the republic, and who was a liberal encourager of art. By him Selva was commissioned to embellish and fit up a saloon in his palace expressly for an entertainment given to the Archduke Ferdinand of Austria and his bride; before which he had been similarly employed by the Senator Rezzonico to decorate an apartment for him, which was to have been done by Quarenghi, but that architect was then obliged to depart for Russia. [Quarenghi, P. C.] On quitting Rome Selva visited France and England, in both which countries he diligently collected information of every kind bearing upon architecture and building; and returned to Venice at the close of 1780. There, as opportunity offered, he introduced various practical improvements, and among them greater attention to internal convenience and disposition of plan, setting also the example of a more sober taste in design. Among the private mansions on which he was employed, are the Casa Mangilli, that of Count Guido Erizzo, and the Palazzo Manin, which last, however (a work of Sansovino's), he only restored and altered in the interior, though it was at first intended to greatly enlarge the whole edifice according to fresh designs by him, and a model which is still in existence. He also rebuilt the Palazzo Pisani at Padua. The public work to which he owes his chief reputation is the celebrated Teatro della Fenice, erected 1790-91, his design for which was selected from among those sent in by twenty-nine other architects [Theatre, *Table*, P. C.]. Another structure of the same class designed by him was the theatre at Trieste, but in the execution of the work very great liberties were taken. A third theatre planned by him was never executed, but when he was some years afterwards at Florence, he found that parts of his design had been adopted for a theatre then lately erected there. To the above may be added the façade of the Casa Vigo d' Arzeri, and a Casino at Padua; the Casa Vela at Verona; the façade of the church Spirito Santo at Udine; the façade of San Maurizio at Venice, begun by Zogari, and left unfinished by Selva, after whose death it was completed with some modifications by Diedo. The same fate attended his last and most favourite work, the small church Del Gesù, which was finished after his death by Diedo (author of many of the architectural descriptions in Cicognara's 'Fabbriche piu cospicue di Venezia,') and Giuseppe Borsato. Selva died rather unexpectedly, at the beginning of 1819, and therefore could not have erected, as Nagler says he did, Canova's church at Possagno, the first stone of which was not laid till July 11th in that year. Two years before, indeed, he made a journey to Rome expressly to visit his friend the illustrious sculptor, and he may probably have then given the latter some hints and ideas, but beyond that he certainly had no share in the structure. Selva was also a writer upon subjects of his art; he as well as Diedo contributed to Cicognara's work abovementioned; and also translated Perrault's treatise on the orders, and Chambers's 'Civil Architecture.' There is a portrait and short notice of Selva in Gamba's 'Galleria de' Litterati.'

SEMIONOTUS, a fossil fish from the lias. (Agassiz.)

SEMITIC LANGUAGES. [Arabia, P. C., p. 218; Aramæan or Aramaic Language, P. C.; Hebrew Language, P. C.]

SENEBIERA (in honour of John de Senebier, of Geneva, a vegetable physiologist), a genus of plants belonging to the natural order Cruciferae. The pouch is somewhat kidney-shaped, entire at the end, or notched above and below, and almost 2-lobed, not bursting. The cells one seeded.

S. *coronopus*, common wart-cress, has an undivided uniform crested pouch with little sharp points, the pouches large in dense clusters. The leaves pinnate lobed. The stem much branched and prostrate. The sepals roundish, with white membranous margins. This plant was formerly gathered and eaten as a salad, but it has since been reasonably neglected, as it is acrid and unpleasant, and must require much boiling to render it eatable. It is native of Europe, North America, and England. It is the γλαύξ of Dioscorides, 4. 139.

S. didyma, has a pouch notched by two wrinkled lobes, an extremely short style, and pinnatifid leaves. The stem is spreading, about a foot in length. The flowers small and white in long lax clusters. It is found on waste ground near the sea in Great Britain.

S. nilotica is eaten as a salad in Egypt. As these plants possess no beauty, they are not worth cultivating except in botanical gardens.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

SENTENCE. [Judgment, P. C. S.]

SEPARATION. [Wife, P. C.]

SEPTA'RIA, a genus of acephalous mollusks, belonging to the family Tubicolées in the arrangement of Lamarck, who defined the shell thus:—Tube testaceous, very long, gently attenuated posteriorly and divided internally by arched, incomplete partitions. Anterior extremity terminated by two slender tubes, which are not chambered in the interior. The *Septaria arenaria* is the type. It is the same shell described and figured by Sir Everard Home in the Philosophical Transactions for 1806, under the name of *Teredo gigantea*. It lives in sand in the Indian seas. A second species, unknown to Lamarck, lives in the Mediterranean, and has been described by M. Matheron, who has shown that the animal is similar to that of Teredo. M. Deshayes considers the two genera identical, and his opinion will probably be hereafter adopted by most naturalists.

SEQUESTRATION. [Benefice, P. C. p. 221.]

SEQUESTRATION (Scotland). [Bankruptcy, P. C. S.]

SERAMPORE MISSION. A brief account of the origin of the Baptist Missionary Society, and of the history of this, one of the most important establishments connected with it, having been given under Missions, P. C., p. 270, an article under this head is chiefly required to supply the omission in its proper place of a memoir of William Carey, D.D., its principal founder.

Dr. Carey was the son of the master of a small free-school at the village of Paulerspury, in Northamptonshire, where he was born on the 17th of August, 1761. Even in childhood he was remarkable for his intense love of knowledge and ardour in its pursuit. He was apprenticed to a shoemaker at Hackleton, but becoming early the subject of deep religious impressions, he began to preach about the age of twenty, and, without entirely giving up his business, settled at Moulton, in his native county, as pastor of a small Baptist church, whence, in 1789, he removed to Leicester. It was during his residence in obscurity at Moulton that Carey wrote the work alluded to in the article Missions as having led, in an important degree, to the formation of the Baptist Missionary Society; but it was not published until some years after it was written, it being found difficult to excite even ministers to any feeling of interest in the subject of foreign missions. The circumstances attending the organization of the society need not be repeated here, but we may state, as an indication of the difficulties to be overcome by its first agents, especially in consequence of the opposition of the English East India Company to any efforts for the evangelization of Hindustan, that Carey and his companion, Mr. Thomas, were, before the ship in which they set sail finally left the coast of England, set ashore in consequence of threats held out in an anonymous letter which followed the captain; and were thus compelled to take passage in a Danish ship, which was not under the Company's control. For some months after their arrival at Calcutta the missionaries endured great trials, and they were at length compelled to accept engagements to superintend indigo-factories in the vicinity of Malda, sparing what time and money they could for the promotion of their primary object. In 1795 Carey began the work of Bible translation; and in 1799, in which year he removed to Kidderpore, he bought a press and printing apparatus. A third missionary had been sent out in 1796 to join Carey and his fellow-labourer; and in 1799 four others, with their wives, including Mr. (afterwards Dr.) Marshman, and Mr. Ward, who had been brought up to the printing business, and to whom Carey had, before leaving England, expressed a hope that he might join the mission, in anticipation of the necessity which might arise for his practical knowledge of the art, were sent out. As the East India Company would not allow them to settle as missionaries in their dominions, the mission establishment was, about the time of their arrival, removed from Kidderpore to the Danish settlement of Serampore [Serampore, P. C., p. 259], where for many years the work of translating and printing the Scriptures and other books in the various languages of Hindustan was carried on with surprising energy. It appears from the appendix to a 'Tenth Memoir respecting the Translation of the Sacred Scriptures into the Oriental Languages, by the Serampore Brethren,' which was published in London in 1834, that the translation and printing of the New Testament into Bengali was completed in 1801; and that between that date and the month of July, 1832, the whole of the Bible was rendered into this language, and either the whole or part into at least thirty-nine other Oriental languages or dialects, 212,565 copies of the New Testament and other portions of the Bible having been issued during that time from the Mission press, in addition to many printed for the British and Foreign and some other Bible Societies. During the same period a great number of religious tracts and miscellaneous works were also produced, in several different languages, including a Bengali map of India, a grammar, two dictionaries, a semi-weekly newspaper, and a Youth's Magazine, in Bengali and English; and, in Bengali alone, several large volumes of Government Regulations, a History of India, a translation of Goldsmith's History of England, a Treatise on Anatomy, intended as the first volume of an Encyclopædia of the Sciences, a Treatise on Geography, and a translation of the Pilgrim's Progress. The list of works in Sanscrit, Chinese, and other languages comprises also many important books.

In these great undertakings Dr. Carey was the chief director, while a very large proportion of the actual literary labour also rested upon him, in addition to which he performed the duties of professor of Oriental languages in the college of Fort William, at Calcutta, from its establishment in 1800 until its virtual abolition by the discontinuance of English professors about the year 1830, when he received a pension from government. He died at Serampore on the 9th of June, 1834, in his seventy-third year, leaving some autobiographical memoranda which have been used by his nephew, the Rev. Eustace Carey, in the 'Memoir' of him published in London in 1836, to which a portrait is prefixed. In a biographical sketch by his son Jonathan, incorporated in the memoir referred to, it is observed that in all objects connected with the general good of his adopted country, Dr. Carey took an active part, and that 'he prepared, under the direction of a noble lady then resident in India, the prospectus of an agricultural society in the East, to which was united an horticultural society, of which he was a member, and in the affairs of which he took a lively interest, till his last illness; and he had the gratification to see that the society became at length the most flourishing and interesting society in the East, in which gentlemen of the first respectability, from all parts of the country, united, and which still continues an eminently useful and flourishing institution.' Botany was, indeed, a very favourite study with Dr. Carey, whose share in the publication of Roxburgh's 'Flora Indica' is noticed under Roxburgh, P. C., p. 197. 'In the Asiatic Society,' continues his son, 'he also took an active part; and for many years, up to his death, was one of the members of the committee of papers, and afforded considerable information, and in various ways promoted the general interests of the institution.' 'At his death,' he adds, 'the Bishop of Calcutta, in a speech, passed the highest encomiums on the character and talents of Dr. Carey; and a minute was recorded expressive of the loss sustained by the society, and their regret at the removal of one of its most excellent members.'

From 'Remarks on the Character and Labours of Dr. Carey, as an Oriental Scholar and Translator,' by H. H. Wilson, Esq., Boden Professor of Sanscrit in the University of Oxford, which is also appended to the 'Memoir' by Eustace Carey, we select the following sketch of his more important and legitimate labours. 'At the time,' observes Mr. Wilson, 'when Dr. Carey commenced his career of Oriental study, the facilities that have since accumulated were wholly wanting, and the student was destitute of all elementary aid. With the exception of those languages which are regarded by the natives of India as sacred and classical, such as the Arabic and Sanscrit, few of the Indian dialects have ever been reduced to their elements by original writers. The principles of their construction are preserved by practice alone, and a grammar or vocabulary forms no part of such scanty literature as they may happen to possess; accustomed from infancy to the familiar use of their vernacular inflexions and idioms, the natives of India never thought it necessary to lay down rules for their application; and even in the present day they cannot, without difficulty, be prevailed upon to study systematically the dialects which they daily and hourly speak. Europeans, however, are differently circumstanced. With them the precept must precede the practice, if they wish to attain a critical knowledge of a foreign tongue. But when the Oriental languages first became the subjects of investigation, those precepts were yet to be developed, and the early students had, therefore, as they gathered words and phrases, to investigate the principles upon which they were constructed, and to frame, as they proceeded, a grammar for themselves.' 'The talents of Dr. Carey were,' he adds, 'eminently adapted to such an undertaking.' Mr. Wilson goes on to state that Dr. Carey's Sanscrit grammar was the first complete one published, his Telinga grammar the first printed in English, his Karnate and Mahratta grammars the first published works developing the structure of those languages, his Mahratta dictionary one of the first attempted, and his Punjabi grammar the only authority for the language of the Sikh nation; 'and although,' he remarks, 'he must concede to Halhed the credit of first reducing to rule the construction of the Bengali tongue, yet by his own grammar and dictionary, and other useful rudimental publications, Dr. Carey may claim the merit of having raised it from the condition of a rude and unsettled dialect to the character of a regular and permanent form of speech, possessing something of a literature, and capable, through its intimate relation to the Sanscrit, of becoming a refined and comprehensive vehicle for the diffusion of sound knowledge and religious truth.' Some of the works here referred to were of great extent; the Sanscrit grammar, for example, comprising upwards of 1000 quarto pages, and the Bengali and English Dictionary, published in 1815 and 1825, in three volumes, upwards of 2000 quarto pages, and about 80,000 words. An abridgment of the latter work, prepared by Dr. Marshman under the supervision of Dr. Carey himself, was published in 1827 in one thick octavo volume. One of the extensive literary productions of the Serampore press was 'The Rámáyana of Valmeeki, in the original Sanscrit, with a Prose Translation, and explanatory Notes,' edited by Drs. Carey and Marshman, of which four quarto volumes were published, in 1806 and subsequent years, under the sanction of the Asiatic Society and the Council of Fort William College, but which, unfortunately, was never completed.

It may, at first sight, excite some surprise that the Serampore missionaries should, in some instances, have issued translations in languages or dialects with which none of them were fully acquainted. 'In this department,' observes Mr. Wilson in explanation, 'Dr. Carey took a leading part, and it was in connection especially with his duty of revising the different translations that he added to his great proficiency in Sanscrit and Bengali, a knowledge of those dialects whose elements he first investigated.' 'Possessed in this way,' he states, 'of at least six different dialects, and of Sanscrit, the parent of the whole family, and endowed with a genius for philological investigation, Dr. Carey was peculiarly qualified to superintend the translation of the Scriptures into a number of cognate languages; and it may be granted that, in combination with his colleagues, he carried the project to as successful an issue as could be expected from the bounded faculties of man.'

In the above sketch of the labours of Dr. Carey frequent allusion has been made to Joshua Marshman, D.D., perhaps the most eminent of his colleagues, but of whose particular share in the great undertakings of the Serampore Brethren, as the band of missionaries among whom he and Carey were the most prominent often styled themselves, it is not necessary to give any account. From a statement in the 'Baptist Magazine' for April, 1838, it would appear that he was born in 1767. As before stated, he embarked for India in 1799. In 1826 he visited England on the subject of the disagreement between the Serampore Brethren and the Baptist Missionary Society, which led to their separation in the following year: his son John having previously visited England in 1822 on the same business. In this disagreement, which arose about 1817, the uncompromising and somewhat impracticable spirit of this otherwise excellent man, appears to have had considerable share. He again reached Serampore in June, 1829, and remained there till his death on the 5th of December, 1837, a few days previous to which event arrangements were concluded in London for the re-union of the Serampore Mission with the parent society, and for retaining him in the superintendence. In a sketch of his character at the end of the first volume of Dr. Cox's 'History of the Baptist Missionary Society' he is said to have been possessed of great mental power and diligence, of firmness bordering upon obstinacy, and of much wariness. Dr. Marshman's name is especially known by his controversy with Rammohun Roy [Rammohun Roy, P. C. S., p. 464], who distinguished himself greatly among his countrymen in India by his spirited attacks upon idolatry, and by the publication of a work entitled 'The Precepts of Jesus, the Guide to Peace,' in which, while exalting the precepts, he asperses the miracles of Christ. Dr. Marshman answered this work by a series of articles in the 'Friend of India,' a periodical issued by the Serampore missionaries, which were subsequently republished in London, in 1822, in a separate volume, entitled 'A Defence of the Deity and Atonement of Jesus Christ, in reply to Rammohun Roy, of Calcutta.' In 1824 appeared a second London edition of Rammohun Roy's work, illustrated with a portrait of the author, and containing replies to Dr. Marshman.

Of the history of the Serampore Mission itself little more need be said. The leading facts are given under Missions, P. C., to which we may add, that although Serampore had been selected as an asylum from the opposition of the East India Company, the missionaries were not disturbed when, shortly after their settlement, the place came into the hands of the British government. Since the death of Dr. Marshman the mission establishment has been removed from Serampore to Calcutta, where a handsome printing-office and other premises have been erected. About 1840 the British and Foreign Bible Society withdrew its support from the translations issued by the Serampore mission, public attention having been drawn to the fact that in those versions the words signifying baptism had been so rendered as to distinctly imply the performance of that rite by immersion; and in consequence of this withdrawal of support a new society was formed, under the name of the 'Bible Translation Society,' to provide for the continued maintenance of the Serampore versions, and, in the language of the constitution adopted at its formation, 'to encourage the production and circulation of complete translations of the Holy Scriptures competently authenticated for fidelity, it being always understood that the words relating to the ordinance of baptism shall be translated by terms signifying immersion.' The question which led to the establishment of this new society occasioned a great deal of controversy, in the course of which there appeared a 'Letter to the Rev. A. Brandram, M.A., on the meaning of the word βαπτίζω, and the manner in which it has been rendered in Versions sanctioned by the Bible Society,' by the Rev. E. Henderson, D.D., of Highbury College, in which the whole question, as affecting the Oriental translations, is very fully and learnedly illustrated. This pamphlet was reprinted verbatim in the 'Evangelical Magazine' for June, 1840. From the sixth annual report of the Bible Translation Society, presented at its anniversary in April, 1846, it appears that 30,000 copies of the whole or parts of the Scriptures had been printed, and 54,000 copies distributed, in the preceding year, in the Oriental versions; and that the total number printed since 1838 was 419,205.

SERAPHINE, a musical instrument of the keyed kind, recently invented, and may be described as a small organ, in which very short, thin, and narrow steel bars, or springs, put into vibratory motion by means of a bellows acted on by the foot, are used instead of pipes.

The principle on which this instrument, as well as every variety of it, is constructed, has been explained under the word Accordion, P. C. S., and referred to under the term Concertina, P. C. S. Nothing therefore remains to be added, except that the Seraphine is in the form of a chiffonier, about thirty-seven inches high, forty wide, and twenty-two deep. Its compass is five octaves, including all the semitones, and it is played on in the same manner as any other keyed instrument. It combines the advantages of both organ and pianoforte, by affording the means of prolonging the sounds, and of increasing or diminishing the strength of these by the more or less pressure of the fingers and the bellows: while further power of augmenting the loudness is obtained by a pedal acting on a swell. The effects to be drawn from so small a machine by a tolerably skilful player are as surprising as various; and its convenient form, moderate price, together with its invaluable property of standing in tune—perhaps we might say of never going out of tune—are such additional recommendations of the Seraphine, that, we are persuaded, it only requires to be generally known to get into general use.

SERGELL, JOHANN TOBIAS, an artist for whom may be claimed the high merit of having commenced that reform in modern sculpture in which he was followed by Canova and Thorwaldsen, was born at Stockholm, September 8th, 1740, and was the son of a gold-lace maker and embroiderer. He himself was at first apprenticed to a stonemason, and worked as such at the royal palace at Stockholm, which was then in progress; and his quickness and cleverness attracting the notice of the sculptor Larchevêque, he was taken by him as a pupil. After assisting him in modelling the two statues of Gustava Wasa, and Gustavus Adolphus, Sergell obtained a travelling pension in 1767, and went to Rome, where he remained nearly twelve years, and produced many works that excited general admiration among the professors and patrons of art. On quitting Italy he visited Paris, where his 'Othryades,' a figure of a wounded Greek soldier, half life size (afterwards placed in the Luxembourg) gained him his reception of the Academy of Fine Arts. From Paris he proceeded to London, whence he was almost immediately summoned by Gustavus III., who conferred upon him the appointment of court sculptor. In 1784 he accompanied that monarch in his visit to Rome; and it was by his advice that Gustavus there purchased among many other valuable works of art, the celebrated 'Endymion,' for the royal museum at Stockholm.

Catherine II. was afterwards desirous of securing his talents in her service, and made him the most flattering offers, but though wealth as well as distinction awaited him at St. Petersburg, Sergell's attachment to his sovereign and his native land, and his indifference to riches, induced him to remain in Sweden with the comparatively trifling pension of six hundred rix-dollars. The untimely end of Gustavus, whom he regarded rather as his friend than his master and patron, so affected him that he fell into a deep melancholy, and was for a length of time wholly incapable of doing anything in his profession. It was not till a few years before his death that he regained something like his wonted composure of mind, but it was then almost too late for him to think of retrieving the time that had been lost to art. He died at Stockholm, February 26th, 1814, in his 74th year.

Sergell's works are distinguished by vigour of conception, by energy and grace of style, and by perfect freedom from that mannerism and sickly affectation into which sculpture had fallen in the hands of his immediate predecessors and contemporaries. Among his principal statues are the group of Cupid and Venus, Diomedes carrying off the Palladium, Othryades, a Faun, Gustavus III., Oxenstierna dictating to the Muse of History the deeds of Gustavus Adolphus, Mars and Venus, a Venus Callipyge, most of which are in the royal museum. One of his finest productions, a composition in alto-rilievo for the Adolph-Frederick Church at Stockholm, exists only in the model, having never been executed in marble; as was the case with a number of other subjects. His busts and portrait medallions were highly esteemed, both for fidelity of likeness, and for artistic merit. Byström, the present eminent Swedish sculptor, was a pupil of Sergell's.

(*Conversations-Lexicon der Gegenwart*; *Biographie Universelle.*)

SERPULITES, a genus of annulose (?) fossils from the Silurian strata of Salop, &c. (Murchison.)

SERRAFALCUS, a genus of grasses belonging to the tribe Festucineae. It has unequal herbaceous many flowered glumes, the lower are from 3 to 5 nerved, the upper 7 to 9. The flower is oblong and trifid. The outer palea with a short seta founded on three nerves from below the tip. The styles lateral below the summit of the fruit. The spikelets narrow at the top.

S. secalinus has a loose panicle slightly compound, the simple peduncles about equalling the oblong glabrous spikelets, the flowers at first loosely imbricated, afterwards distinct, about as long as the straight awn, the outer palea not overlapping the next flower. The flower is large and downy, the leaves hairy with nearly smooth sheaths. It is native of Great Britain.

S. racemosus has a close or elongated erect panicle usually simple, the spikelets glabrous ovate and somewhat compressed. The midrib of the glumes and palea scabrous towards the top, the leaves and sheaths slightly hairy. It is a common species in sandy places in the South of Great Britain.

(Babington, *Manual of British Botany.*)

SERRICORNES (Insects), the third family of Pentamerous Coleoptera. They have four palpi, elytra which cover the abdomen, and antennæ, which are for the most part equal throughout, or smaller at the extremity. The Linnæan genera *Buprestis*, *Elater*, *Lampyris*, and *Ptinus* belong to this family, as also do *Melyris*, *Clerus*, and *Cebrio*. The *Ptinus fur* is the little beetle whose larvæ do so much damage among collections of natural history.

SERVITUDES (servitutes). A servitus in the Roman law signifies that the owner of some particular property is bound in respect to some other person, simply as such person, or as being the owner of a particular property, either not to do certain acts to his property, or to allow that other person to do some particular acts to the property. The rights of this kind which one person may have on the property of another are also called servitutes. The thing which is the object of the servitus is said servire, to owe a servitus. It follows from the definition that a man can only have a servitude in another man's property, and in a corporeal thing; and that the owner of the servient property is not required to do any thing in order that the other may enjoy the servitude (*Dig.* 8, tit. 1, s. 15): his duty consists in not doing, and in permitting to do. The servitude must be a thing which gives some profit or advantage to him to whom it is due; and it gives him a right in rem. In case of doubt there is no presumption in favour of a servitude; the terms in which it is established are to be strictly interpreted, and its exercise to be strictly according to the right, and in the way least prejudicial to the owner of the servient property. A man must be the owner of a property, or have a dominium utile in it, in order to be able to encumber it with a servitude.

Servitutes were either a right belonging to some particular person, which ceased with his life, unless they were granted to him and his heirs, and were called servitutes personarum or personales; or they were attached to a piece of ground as the subject, and could be exercised by any person who was in the possession of the ground, and were called Jura, or servitutes praediorum or rerum, and sometimes Servitutes simply. Personal servitudes were comprehended under the heads of Ususfructus, Usus, Habitatio (a lodging in another person's house), and Operae Servorum et Animalium (the use of another person's slaves or beasts). [USUSFRUCTUS, P.C.]

Praedial Servitudes were either Servitutes Urbanae or Rusticae. They were Urbanae if the property which was entitled to the servitude was a building: they were Rusticae, if it was a piece of ground. There was no limit to the number or kind of servitudes of this class which might be established. Those Servitutes Urbanae which were of ordinary occurrence were such as follow: Servitutes oneris ferendi, the right which a man has to let his building rest on the building, the wall, or the pillar which belongs to another; Tigni immittendi, the right of fixing a man's timbers in his neighbour's wall; Luminum, sive luminis excipiendi, the right of a man's making windows or openings in his neighbour's wall, or in a common wall, in order to get light for his own building, or to make holes or windows in a man's own wall, which holes or windows look into his neighbour's property, in such cases as would be unlawful without the existence of the servitude; Ne luminibus officiatur, the right to prevent a neighbour from obstructing the light that comes to a man's buildings, by raising any obstacle in the way; and others of a like kind. The Servitutes Rusticae were rights of road over another man's property, which were of various kinds according to the kind of road, as Servitus itineris, actus, viae; Pascendi sive pascui, right of pasturing a man's animals on another man's ground; and the various servitudes which have for their object the use of water, as servitus aquae ductus, aquae haustus, and others of a like kind.

Servitudes might be established by contract, at least in the case of a negative servitude, that is one by which the owner of the servient property was bound not to do certain things; by testamentary disposition; by prescription in the Roman sense; and in some other ways.

Servitudes might cease by the party entitled to them renouncing them by express words or tacitly: in the case of praedial servitude, by one person becoming owner of the two properties, but not unless the whole of the servient or the whole of the dominant property was acquired; and in some other ways.

The actions that a man might have in respect to servitudes need not be particularly mentioned here, as the Roman forms were peculiar, and the object of this article is simply to show the general nature of these Roman praedial servitudes, which may be compared with some of the easements and rights of the English system. [WAY, P. C.] The personal servitudes of the Roman law do not correspond, except in some few cases, with any thing in the English law, except limited enjoyments of a thing, as for instance an estate in lands for life. [USUSFRUCTUS, P.C.]

The subject of the Roman servitudes would require a long exposition to be treated fully. A good outline is contained in Thibaut, *System des Pandekten Rechts*, i. § 296, &c., 9th ed.; and in Mackeldey, *Lehrbuch*, &c., ii. § 274, 12th ed.

SESLE'RIA, a genus of grasses belonging to the tribe Sesleriæ. It has a spiked panicle, sessile spikelets tiled all round. The glumes are from 2 to 6-flowered, nearly as long as the spikelet. The outer paleæ keeled and membraneous, with a scarious margin ending in 3 or 5 points, the dorsal rib evanescent.

S. cærulea has an ovate slightly one-sided spike, the outer palea terminating in 4 teeth, the dorsal rib rough, with a short excurrent point, the leaves abrupt, with a minute rough point. The roots are tufted, the stem from 6 to 12 inches high. The spike about ½ an inch long, and of a bluish-purple colour. This is the only British species. It is found chiefly on mountains.

S. quitensis is the *Festuca quadridentata* of Humboldt and others. Humboldt tells us that it is very poisonous.

(Lindley, *Flora Medica*; Babington, *Manual of British Botany*.)

SESSION, COURT OF, is the Principal Tribunal of Civil Jurisdiction in Scotland. As at present constituted it dates back to the year 1532; but it was then reconstructed on the basis of institutions which had existed at a much earlier period. The early records of the Scottish Parliament show that the judicial authority, which in those times was mixed with the legislative functions of that body, was often deputed to committees. These were termed Domini Auditores, or Domini ad Querelas, and received other like titles. We find these committees and their functions placed on a more distinct position in 1503, when a permanent body received the designation of 'The Daily Council.' It is worthy of observation that these incidents in the history of the court explain the absence of jury trial as a fundamental feature in the Court of Session, while in early times it is known to have belonged to the courts of the inferior judges. Parliament being the high jury of the nation, it would be an anomaly that a committee of that body should act through the aid of a jury. The number of the court as finally established in 1532 was fifteen, the usual number of a Scottish jury in former times, and still the number of a jury in a criminal prosecution. There was then a Lord Chancellor of Scotland, whose functions in some degree resembled those of the same official in England. He presided over the Court of Session, and his judicial functions gradually came to be absorbed in those of the court. At the union with England it was deemed unnecessary to retain a separate chancellor of Scotland, and the great seal to be appended to private documents for that part of the country being committed to a keeper, the court was presided over by the lord president, who previously presided in the absence of the chancellor. In 1808 the Court of Session was divided into two divisions: the head of the court, the lord president, who is also now lord justice-general or head of the supreme criminal court, presides in the first division, and the lord justice clerk, or deputy head of the criminal court, presides in the second. In 1815, trial by jury in civil cases on the English system was introduced in Scotland. A separate tribunal was established for jury cases, presided over by a Lord Chief Commissioner, but in 1830 the practice of jury trial was united with that of the Court of Session. It is still only adopted in a limited number of cases, and is far from being popular or satisfactory. The Scottish system of pleading is ill adapted to it, and no means have been found of carrying it through with the promptitude and precision which mark the English practice. Its chief benefit has been in enforcing the separation in all pleadings of the facts stated from the law applied to them. In 1830 two separate courts of limited jurisdiction and small practice—the Admiralty and Commissionary Courts—were absorbed in the Court of Session, and the number of judges was at the same time reduced from fifteen to thirteen. By this measure the court was made to assume less the form of a deliberative assembly acting through a majority, which was the particular characteristic of the court before it was divided, and more judicial work was thrown upon individuals. By the act of 1830 (2 Geo. IV., and 1 Will. IV., c. 69), as carried out by a later act (1 & 2 Vict. c. 118), eight of the judges, formed into two courts of four judges each, sit in the two divisions of the Inner house, where each division form a court of second instance. The other five judges are called the Lords Ordinary, and each of them holds a separate court, which, in reference to the court of further resort is called the 'Outer House.' The judgment of a lord ordinary on a closed record is final in the outer house, but it may, within a limited time, be carried by a 'reclaiming note' to which the record is appended, to the inner house, where it may be pleaded again on the record as made up in the outer house. The system of pleading has of late years been much abbreviated and systematised, and this, added to the reduction of the number of judges who sit and give their views on each case, has materially abbreviated the procedure, although it is still the practice for the whole court to be assembled and consulted in difficult cases. The jurisdiction of the Court of Session embraces all questions of civil right. It gives remedy when other courts whose function it is to regulate the rights and duties of certain sections of the public as members of a particular class—such as courts martial and ecclesiastical—exceed their powers. The proceedings before the Court of Session in relation to the church courts, were the cause of the great secession from the Scottish church in 1843 [FREE CHURCH, P. C.]. As every description of civil question between man and man in Scotland can be competently decided before the Court of Session, it is usual in England to speak of it as a court 'both of law and equity;' but this is a distinction proceeding from incidental circumstances in the character of the English courts, and is no necessary or properly systematic division of the administration of the law. The Court of Session have the authority enjoyed by the equity courts in England, in the appointment of guardians, receivers, &c., or otherwise seeing to the protection of property, or of persons where discretional protection or direction are necessary, and there is no person competent in ordinary course of law to act. In 1839 (2 & 3 Wm. IV. c. 36), the judges of the Court of Session were appointed according to a certain rotation to perform the duty of judges of the court of justiciary in matters criminal, and those of judges of the court of exchequer, where the duty is of a very limited character. This change only introduced the system of rotation in the performance of the duty of courts of which certain of the lords of session had previously been permanently appointed the judges. By an old practice in Scotland each 'Senator of the College of Justice,' as the judges of the Court of Session are officially called, takes the title of lord.

SESSIONS. The criminal jurisdiction of justices in general and quarter-sessions is now defined by the 5 & 6 Vict. c. 38, which enacts 'that after the passing of this Act neither the justices of the peace acting in and for any county, riding, division, or liberty, nor the recorder of any borough, shall at any session of the peace nor the adjournment thereof try any person or persons for any treason, murder, or capital felony, or for any felony which, when committed by a person not previously convicted of felony, is punishable by transportation beyond the seas for life,' or for any of the offences mentioned under the 18 heads contained in the first section of the act. The second section provides that any judge of the supreme courts at Westminster, acting under a commission of oyer and terminer and gaol delivery for any county, may issue a writ or writs of certiorari or other process directed to the justices of the peace acting in and for such county, &c., or to the recorder of any court within the same county, commanding the said justices and recorder severally to certify and return into such court of oyer and terminer, &c. all indictments and presentments found or taken by such justices or recorder of offences which after the passing of this act they will not have jurisdiction to try, and the several recognizances, examinations, and depositions relative to such indictments and presentments; and, if necessary, by writ or writs of Habeas Corpus may cause any person in the custody of any gaol or prison, charged with any such offence, to be removed into the custody of the common gaol of the county, that such offences may be tried under the said commission. The fourth section empowers any court of general or quarter-session or adjourned session of the peace to divide such court into two courts, which may sit apart for the better despatch of business, in the manner and subject to the conditions in this section mentioned.

SETTLE, ELKANAH, is remembered, not for his literary merits, but for the extraordinary fact that he, a person of very small talents, was for a time the successful rival of one of the greatest poets of the nation. The particulars of his history, with specimens of his works, may be gathered from various parts of Scott's edition of the works of Dryden. Settle, born in 1648 at Dunstable, was entered a commoner of Trinity College, Oxford, in 1666, but left the university without a degree, and came to London as a literary adventurer. He first rose into reputation in 1671, by the success of his tragedy of 'Cambyses;' and the profligate Rochester, desirous to humble Dryden, eagerly adopted the new dramatist as his instrument. Settle's next tragedy, 'The Empress of Morocco,' introduced by its unscrupulous patron, enjoyed the honour (never vouchsafed to Dryden, the laureate) of being first acted at Whitehall by the lords and ladies of the court: on being transferred to the theatre it was acted to full houses for a month successively; the printed copies of it were sold for double the usual price; and the author, intoxicated by his undeserved success, prefixed to it a vaunting preface, animadverting severely upon Dryden. Dryden, alarmed and jealous, assisted Shadwell and Crowne in writing scurrilous 'Notes and Observations' on the play, which the author answered in the same strain. Political differences embittered the quarrel thus begun. But poor Settle's fame was short-lived; and Dryden had little cause to fear him when he was so ill-advised as to advocate the cause of his whig patrons, by publishing, in answer to the 'Absalom and Achitophel,' a poem entitled 'Absalom Senior, or Achitophel Transposed.' Nevertheless, the new offence was thought worthy of punishment; and, under the name of Doeg, Elkanah became the victim of some of those contemptuous verses which Dryden contributed to the second part of 'Absalom and Achitophel.' Three of these stanzas, commemorating his smoothness of versification, his bombast, and his real poverty, both of thought and fancy, may be accepted as no unfair criticism on his works in general.

> Doeg, though without knowing how or why,
> Made still a blundering kind of melody;
> Spurred boldly on, and dashed through thick and thin,
> Through sense and nonsense, never out nor in;
> Free from all meaning, whether good or bad,
> And, in one word, heroically mad.

Down to this time Settle had been a trusted servant and pamphleteer of Shaftesbury and the other whig leaders; and in November, 1680, he superintended with much approbation the burning of the pope in effigy. Soon afterwards however he suddenly changed his party, recanting his political heresies in a narrative which he published in 1683. By this change he perhaps preserved for the time his place as poet laureate for the city, and writer of verses for pageants and other civic festivities; but with the revolution his prospects were completely blighted. Although he retained his place as city-poet, he was reduced to great poverty. He had literally to suffer the fate satirically prophesied for him by Dryden, of writing plays for shows at Bartholomew fair in Smithfield; and in one of these he actually performed in person the part of the Dragon slaughtered by St. George, a fact which Pope has chronicled in the Dunciad. At length, in his desolate old age, he was received into the Charter-house, and died there in 1723. He was the author of sixteen original plays that were printed, and of a good many occasional and political pieces both in verse and in prose.

SFAX. [TUNIS, P. C., p. 360.]

SHADOWS, PROJECTION OF. [PERSPECTIVE, P. C., p. 499, &c.]

SHAGNAN is a country in Asia, situated in the Upper Valley of the river Oxus, where that river has not yet left the mountains, which enclose the upper part of its course. It lies between 37° and 38° N. lat. and between 70° and 72° E. lon., but its extent and boundaries are imperfectly known; the river Oxus which runs along its southern and western boundary, divides Shagnan from Badakshan. As the bed of this river in these parts, where it is called Panj, is several thousand feet above the sea-level, its course is extremely rapid, which renders the access to Shagnan from this side very difficult, and for the greater part of the year impossible. The country is traversed by numerous elevated ridges, which are covered with snow for the greater part of the year. These ridges are at their eastern end connected with the immense mountain masses which surround the elevated table-land of Pamir, on which the Oxus originates in the lake of Sir-i-kol. It is probable that the mountains abound in mineral wealth; but nothing is known except that there are rich ruby mines. The valleys between the mountains are said to be fertile, but on account of the cold of the climate they do not produce any grain except wheat and barley. The greater part of the population subsist on the produce of their orchards, and plantations of mulberry-trees, whose dried fruit is ground, and used as flour. Horses and the common animals of burden are not numerous, except camels. These animals are of that description which have two bunches. As the pastures on the declivities of the mountains are extensive, the inhabitants keep a considerable number of cattle and sheep. Very little is known respecting the population. It is stated that a peculiar language is spoken by them. Their number, which formerly amounted to a thousand families and more, has lately been much reduced by the incursions of the Khan of Kunduz, who has subjected Shagnan to a dependency on his authority.

SHAGREEN. [LEATHER, P. C. S.]

SHANGALLAS. [ABYSSINIA, P. C. S.]

SHEATHING. Under SHIP-BUILDING, P. C., p. 396, is given a notice of the introduction of copper sheathing in the British navy, and of Sir Humphrey Davy's experiment for protecting the copper from the destructive action of sea-water, as well as of the unexpected result by which his invention was rendered nugatory.

Owing to the great expense of copper sheathing, which has the effect of limiting its use in mercantile shipping, many attempts have been made to substitute for it either other other metals, or alloys in which it is mixed with cheaper metals, or with such as might increase its durability. In noticing several of these, Hebert, in the 'Engineer's and Mechanic's Encyclopædia,' art. 'Sheathing,' refers to a patent obtained by Mr. Robert Mushet (in what year he does not state), for 'certain means or processes for improving the quality of copper and alloyed copper, so as to render it more durable when employed as sheathing to ships' bottoms,' in which he directs that 100 lbs. of copper should be alloyed either with 2 oz. of the regulus of zinc, 4 oz. of the regulus of antimony, 8 oz. of the regulus of arsenic, or 2 oz. of grain-tin; or instead of using one of these separately, that the whole he used together in the proportion of half an ounce each of the zinc and tin, 1 oz. of the antimony, and 2 oz. of the arsenic, to 100 lbs. of copper. By these mixtures, Mr. Mushet states that the copper is rendered much more cohesive and fibrous in its texture, and the corrosive effect of the sea-water is in a great measure prevented. We may observe, in partial confirmation of the above, that Dr. Ure, in his 'Dictionary of Arts, &c.,' observes, that from a train of researches which he made for an eminent copper company, upon various specimens of sheathing which had been exposed to the action of the sea, 'it appeared that copper containing a minute but definite proportion of tin was by far the most durable.'

The metallic sheathing patented in 1824 by Mr. Christopher Pope, of Bristol, which, however, is said to have been more extensively used in covering roofs than in sheathing ships, consists either of tin and zinc, or of tin, lead, and zinc. If the former mixture be used, the zinc is first melted, an equal quantity of tin is added to it, and the alloy, after being stirred together while fluid, is cast into cakes about three-quarters of an inch thick, which are hammered or rolled out to the required degree of tenuity. In uniting tin, lead, and zinc, the lead is first melted, double its quantity of tin is then added, and the alloy is cast into small lumps. A quantity of zinc equal to the tin and lead united is then separately melted, and the alloy of tin and lead is added to it; the whole, when thoroughly incorporated, being cast into cakes as before, for subsequent rolling out into sheets. The patentee observes that no more heat should be applied than is absolutely required to effect the union of the component metals, any excess tending to harden the metal; and he states that by heating the cakes to the temperature of boiling water they will roll or hammer softer than when cold.

Iron, protected by the galvanic action of zinc, has also been used for sheathing. Hebert refers to a patent for this purpose obtained by Professor Pattison, in which it is proposed to use sheets of iron similar in size to the sheets of copper sheathing, each having at its lower extremity a sheet of zinc from one-eighth to one-fourth of an inch thick, attached in such a way that in sheathing the vessel from the upper part downwards, each succeeding sheet of iron shall be in contact with, and overlap, the zinc plate of the sheet immediately above it. For the protection of the external surface of the iron, there should be as much as 5 inches of zinc to 100 inches of iron, and smaller plates of zinc in the proportion of 3 inches to every 100, should be applied to the inner surface of the iron. Washers or perforated discs of zinc are also applied under the heads of the spikes or bolts used in fastening the sheathing; and the heads of the nails employed are made hollow, and filled with melted zinc. This method is said to have been found effectual in a vessel which had been two years at sea, the corrosion or oxidation of the metal being almost entirely prevented, and the ship returning with a bright and clean surface.

Sheathing of brown paper coated with tar, and of various other non-metallic substances, have also been used, and perhaps the most important of these is a kind of felt, into the composition of which a considerable quantity of cow-hair enters. As this material itself felts very imperfectly, the sheets are passed, in the process of manufacture, through a boiler of pitch or tar, which increases the cohesion of the fabric. This material, which is sometimes used in conjunction with copper sheathing, being laid on immediately beneath it, has, according to Barlow ('Treatise on Machinery and Manufactures' in the 'Encyclopædia Metropolitana') the important qualities of being a perfect protection against the worm, which is probably incapable of working its way against the stiff bristly hair which is incorporated in the felt, and of being at once impermeable to water, and so extensible as not to be easily broken by the working which takes place among the timbers of a crazy ship, and which would otherwise produce many leaks. A sheathing composed of a coarse fabric of fibrous material, saturated with a solution of caoutchouc, together with pitch and tar, has been recommended as a cheap and effectual substitute for felt.

Copper sheathing is usually applied in sheets about four feet long and fourteen inches wide, the thickness being such that a square foot weighs from sixteen to thirty-two ounces,—most commonly from twenty to twenty-eight ounces; and the mode of application does not vary materially whether the copper be laid upon the bare planking or upon an interposed layer of tarred paper, felt, or thin boarding. The sheets are pierced with holes, not only round the edges, but also at intervals of three or four inches over the whole surface; they are laid so as to overlap each other about an inch, and are secured to the ship with flat-headed copper nails. 'Great regularity,' observes the author of 'A Second Day at a Ship-Yard,' 'Penny Magazine,' No. 593, 'is observed in the arrangement of the sheets, so that a certain symmetry of appearance, as well as durability, is attained.' 'After two voyages to the East Indies,' according to this authority, 'the coppering requires to be renewed; and the old copper is found to have lost three or four ounces of its weight in the square foot, by the action of sea-water, friction, and other causes.' It may be mentioned as an illustration of the perfect arrangements of a first-rate ship-yard, that a vessel is frequently stripped of her old copper, the surface of the planking prepared for a new sheathing, and sent out thoroughly new-coppered within two days of the time when she entered the dry-dock in which the operation is performed.

SHEERS, or SHEARS, a contrivance used for hoisting the masts of a ship into or out of their place, and occasionally for loading and unloading heavy goods, or for performing similar operations on shore. The sheers used in masting vessels consist of two large poles, masts, or spars, the lower ends of which rest upon thick planks laid along the sides of the deck, while their upper ends are lashed together so as to cross each other exactly over the hole in the deck through which the mast is to be dropped, they being sustained in this position by ropes radiating from the top to various parts of the vessel. To this apparatus is attached the tackle necessary for lifting the masts out of the water, when they have been floated to the side of the ship, and lowering them gently into their places. This is the apparatus commonly employed in masting merchant-ships; but the like operation is sometimes performed by means of a *sheer-hulk*, and sometimes by a *masting-house*. The *sheer-hulk*, which is commonly used for masting ships of war, is an old man-of-war cut down to the lower deck, and having a mast, a hundred and twenty feet in length, fixed in the hulk, and, supported by the mast, four stout spars or sheers which project obliquely from its side. The tops of these sheers reach to such a height and project to such a distance from the side of the hulk, that the vessel to be masted can come beneath them to be fitted with her lower masts. A *masting-house* is a lofty building erected for the purpose of performing the operation yet more conveniently, by the aid of mechanism overhanging the water to a considerable distance, beneath which ships may be floated. Such a structure, of great elevation, forms a conspicuous feature of the great ship-building establishment on the Thames at Blackwall.

('A Second Day at a Ship-yard,' in the *Penny Magazine* for 1841, p. 253.)

SHEFFIELD, JOHN. [BUCKINGHAM, DUKE OF, P. C., p. 513.]

SHERARDIA (so named by Dillenius after his patron William Sherard, LL.D., consul at Smyrna), a genus of plants belonging to the natural order Rubiaceæ. It has a funnel-shaped corolla, a dry fruit, crowned with the limb of the calyx, which is 6-toothed.

S. arvensis, corn-field madder, is the only species. The stem is mostly decumbent, branched, square, and leafy. The whole plant is rough and hairy. The leaves are 6 in a whorl, acute, and obovate lanceolate; the flower is blue, in a small sessile terminal umbel. It is found on sandy soils, in Great Britain, Europe, and the Crimea.

The seeds only require to be sown in the ground in an open situation.

(Don, *Gardener's Dictionary;* Babington, *Manual of British Botany.*)

SHERIFF (SCOTLAND). In Scotland the duties of the sheriffs are not, as in England, almost entirely executive. He exercises an extensive judicial authority, and a large portion of the general litigation of the country proceeds before this class of local judges. In earlier times his authority appears to have been merely of an executive character, and, appointed by the crown, he was the person to whom the royal writs, issuing from the supreme courts, were usually directed. He was the ordinary conservator of the peace within the local limits of his authority. He was an important fiscal officer, having in the general case the duty of levying the feudal casualties, forfeitures, and other items of revenue; and by statute he was vested with the power of mustering the military force of the country to the weapon-showing. In very early times, his tenure of office appears to have been limited by the grant; at a period comparatively later, the office became, in the general case, hereditary. The precise principle on which that division into shires, by which the boundaries of each sheriff's authority were marked, is not generally known. In all Latin documents he was called the vice-comes, and it might thence be inferred that each sheriff was the deputy of a *comes* or earl. There has, however, no trace been found of the dignity of an earl in Scotland involving the right to exercise judicial or executive functions, nor did that title, like the authority of the sheriff, bear any reference to the boundaries of the shire or to any other territorial allotment. The terms of the act for abolishing heritable jurisdictions in Scotland, which will be noticed below, might encourage the supposition that they were founded on the idea of the sheriff being a depute or subordinate officer, if it were not pretty clear that the structure of that act was in some measure affected by a confusion between the office of high sheriff in England and that of sheriff in Scotland. The act, viewing the appointment of a sheriff-principal or high sheriff from among the unprofessional gentry, and of the acting judicial officer from the legal profession, provides that 'it shall not be lawful for any principal or high sheriff or stewart in Scotland personally to judge in any cause, civil or criminal, within his shire or stewartry in virtue of such his office, any law or usage in any ways to the contrary notwithstanding.' (20 Geo. II. c. 43, s. 30.) By the same statute the principal or high sheriff can only be appointed during pleasure, or for a period not exceeding a year. It is not easy to discover how such a nominal office came into existence, if it actually was in existence before the passing of the act. The commissioners who reported on the courts of justice in Scotland in 1818 stated that they could not discover any functions which it was the duty or privilege of the holder of that office to perform; and in reference to the provisions of the act, they say, 'it is to be noticed that his majesty's right of appointing an officer called a principal or high sheriff was not touched by the statute of George II., although it was no longer competent to confer such an office *heritably*. These appointments continued to be made subsequent to the statute, and it was well known that commissions of this kind have, even in very recent times, been granted by the crown, for purposes of the executive government, and connected with the office of lord-lieutenant. But whatever may have been the views of the legislature as to the proper ministerial or other functions of such an officer in time coming, it is certain that by the enactment referred to the whole judicial powers of the ordinary magistrate for the county are thus expressly reserved and excepted from any grant to be thereafter made of the office of sheriff in this part of the kingdom. And these provisions were in strict conformity with the previous and most antient state of the law. The act above referred to, generally called the Jurisdiction Act, was passed for the purpose of abolishing all those remnants of the feudal courts of Scotland which were hereditary, or in any other shape of the nature of property; of bringing all judicial offices within the appointment of the crown, and their holders under responsibility to the public. It was passed in consequence of the insurrection of 1745, and it is the point from which we have to date the equal administration of justice in Scotland. By the same statute the sheriff is authorised to appoint one or more Substitutes. This was in conformity with old practice, by which the sheriff, who might not himself be trained to the law, generally appointed a legal practitioner to act as his substitute. At the present day there is a substitute in every county, and in the larger counties there are two or more. Both the sheriff and his substitute are lawyers, but the latter is the local resident judge, the former generally frequenting the courts in Edinburgh, where he hears appeals from his substitute, and making occasional visits to his county. By the Jurisdiction Act it was provided that each sheriff should reside in his county during four months in each year. This provision fell into desuetude, and it became the usage for such sheriffs as continued to practise at the bar to remain in Edinburgh, while the greater portion, who had given up or had not obtained practice, resided at their country-seats, or wherever choice or convenience dictated. This circumstance was the object of much animadversion by the friends of law reform, and a wide difference of opinion was expressed on the matter, some maintaining that the sheriff as well as his substitute ought to be a resident judge, while, in the words of the Report above cited, the former (who is styled Sheriff Depute) in Edinburgh 'was in some degree countenanced by high legal authorities, who consider the attendance of the sheriffs-depute in the court of session, during the sittings, to be more useful than a literal adherence to the statutory rule.' It has been supposed that such an attendance tends both towards a higher degree of legal learning in the sheriffs and to uniformity of practice being promoted by their occasionally consulting each other. It was very clear, however, that it was disadvantageous to the public that there should be any of those judges who neither reside within their counties nor at the fountain of Scottish legal learning in Edinburgh, and by the 1 & 2 Vict. c. 119, it was enacted that each sheriff appointed after the 31st December, 1838, shall remain in attendance on the court of session, but shall hold eight courts in his county during the year. The sheriffs of Edinburgh and Lanark are exempted from attendance on the court of session, in the understanding that the business of their respective courts is sufficient fully to occupy their time. It may be mentioned that many law reformers maintain that these two sheriffships are a type of what the others ought to be. The incumbents receive much higher salaries than the other sheriffs, and have their time fully occupied. It has been held that, in regard to the other counties, instead of appointing persons who are endeavouring to have business at the bar, and giving them duties which only occupy part of their time, and salaries for which they would not generally agree to give up their profession, it would be wiser to unite several counties together, and employ lawyers with salaries equal to the full value of their whole time, to these enlarged districts. These various opinions were very actively discussed from ten to fifteen years ago, but it is now pretty clear that it is in the persons of the sheriffs-substitute, or permanent local judges, that the public look for the beneficial working of the system. In civil questions an appeal lies (without new pleadings) from the sheriff-substitute to the sheriff, but wherever the former is a sound lawyer and an industrious man, the privilege is seldom used. The salaries of the sheriffs-substitute have lately been raised, according to a sound policy advocated by many of the most cautious and economical politicians of the country; they average at present about 450*l.* The salaries of the principal sheriffs vary widely, but the whole amount of their aggregate incomes, as returned to parliament in 1843 (*Parliamentary Papers*, 270), when divided by their whole number, gives 551*l.* to each. From the state in which the profession of the bar of Scotland has been for the past ten years, several of its members have been induced to accept the office of sheriff-substitute as vacancies have occurred. Formerly the office fell to country practitioners, who, not quite contented with the emoluments, eked them out by private practice; a state of matters seriously detrimental to the equal administration of justice. In some instances, even retired officers in the army or unprofessional country gentlemen were the best qualified persons who would undertake the office. By the act of 1 & 2 Victoria, it was provided that no sheriff-substitute should act as a law-agent, conveyancer, or banker. By the same act it was provided that though the sheriff-substitute should continue to be appointed by the sheriff, he should not be removable, except with the consent of the lord president and lord justice clerk of the court of session. In terms of the same act, the substitute must not be absent from his county more than six weeks in one year, or more than two weeks at a time, unless he obtain the consent of the sheriff, who must then act personally or appoint another substitute. It may be observed, for the sake of preventing some confusion which the phraseology of the statute law in relation to sheriffs may occasion to the general reader, that in one or two instances, as in that of Kirkcudbright, the persons who exercise the function of Sheriff is called the Stewart. This designation owes its origin to certain peculiarities of territorial tenure which cannot be briefly explained and are subject to doubt and dispute. After the Reformation, the sheriffs were generally appointed commissaries of the local commissariat districts which most nearly conformed with their respective jurisdictions, and in 1823 (4 Geo. IV. c. 97) the commissariat functions were appointed to be merged in those of the sheriff.

The jurisdiction of the sheriff in civil matters does not extend to questions regarding heritable or real property. By the 1 & 2 Vict. c. 119, jurisdiction in all questions as to nuisance or damage arising from the undue exercise of the rights of property, and as to servitudes, was specially conferred on him. He cannot judge in actions which are declaratory of rights, or which are of a recissory nature—for the purpose of nullifying deeds or legal proceedings. In other respects his jurisdiction extends to all actions on debt or obligation, without any limit as to the importance of the interests involved. He does not act by a jury, though it appears that such an institution was formerly connected with the civil jurisdiction of the sheriff. He has authority by special statute summarily to decide small debt cases, *i. e.* cases where the pecuniary value of the matter at issue does not exceed a hundred pounds Scots, or 8*l.* 6*s.* 8*d.* When he acts in the small debts' court, he makes circuits through his county; his ordinary court is stationary. By railway statutes and other acts of local administration special functions are frequently conferred on him, and in the clauses for taking lands he is usually appointed to act as presiding judge when a jury is appointed to be empannelled. By two acts of the 1 & 2 Vict., viz. caps. 114 and 119, much was done to clear up and render efficacious the practical administration of the powers of the sheriffs. They were enabled, by indorsation, to put the writs from other sheriffdoms in force in their respective counties, and were invested with increased powers for putting their judgments and other proceedings in execution. The decisions of the sheriff, when no proceedings have been taken to enforce them, may be carried into the court of session by advocation.

The authority of the sheriff in matters criminal is practically to a great extent measured by the proceedings of the crown lawyers in leaving prosecutions to proceed before his court, or removing them to the Court of Justiciary. It is not very clearly to be traced how far, in old practice, the sheriff's jurisdiction was inferior to that of the Court of Justiciary: he had undoubtedly the power of punishing with death, though it has been long disused. The power of transporting, which is of comparatively late introduction, he never possessed, not having any criminal authority beyond his county. By degrees it came to be considered that the jurisdiction in the four pleas of the crown—murder, rape, robbery, and wilful fire-raising, was exclusively in the higher court. Important cases in the sheriff court are tried by jury. In more trifling matters the sheriff performs the functions of a police magistrate. In these cases the punishment must not exceed a fine of 10*l.* or sixty days' imprisonment (9 Geo. IV. c. 29). There is an intermediate system, by which the sheriff may try more important cases without a jury; but it is so encumbered with formalities—among others, a written authentication of the evidence—as not to hold out much inducement for its practical adoption.

SHIKARPORE is a commercial town, in the province of Sinde, in 27° 58′ N. lat., and 68° 30′ E. long. The town is built on the plain, which extends from the banks of the Indus to the Hala Mountains, and about 26 miles from the western bank of the river. Though more than 250 miles from the sea, it is only 250 feet above the sea-level. The walls enclose a space of 3831 yards in circuit. They are built of unburnt brick, but have entirely fallen to decay, for want of repairs. They have eight gates. The houses are also of unburnt brick, and have more than one floor; those belonging to the soucars or bankers are of a respectable size, and convenient. The streets are narrow, confined, and dirty in the extreme. The great bazaar, which is the centre of all trade and banking transactions, extends 800 yards, running immediately through the centre of the city. It is protected from the excessive heat by mats stretched from the houses on each side, which however produces a stagnation of the air. With the exception of one tolerable moshu on the southern side, Shikarpore possesses no building of importance. The suburbs are very extensive, and a great portion of the population who are considered to belong to the city reside outside, particularly the Mohammedans and labouring classes.

The population of Shikarpore, in 1840, consisted of about 30,000 individuals, of whom about two-thirds are Hindus, and the remainder Mohammedans, inclusive of Afghans and Pattans. The Hindus carry on all the trade, while the cultivation and mechanical arts of almost every denomination are in the hands of the Mohammedans.

The country round the city is low, and admits freely of irrigation from the inundations of the river Indus by means of small nullas, or water-courses, leading from the Sinde Canal. This canal was made by the Mogul emperor for the purposes of irrigation and navigation. It is, in its present state, only navigable from the end of April to the beginning of October, as it has been allowed to choak up at its mouth, and has generally got out of repair. But it is supposed that at no great outlay it may be rendered navigable for nine months of the year. The soil in the vicinity of the city is alluvial, and produces rich crops of rice and jowaree.

A few articles are manufactured at Shikarpore, but not to any extent, except coarse cotton-cloth, silk-cloth, and Sinde caps. There are also several dyeing-houses, in which cloth made in some of the neighbouring places is dyed and prepared for the market; and there are some paper-mills. This town is the centre of a considerable trade. The most convenient commercial road between Hindustan, Afghanistan, and Persia, runs through it, and leads to the Bolan Pass, which, in spite of its formidable aspect, is much safer than the other roads which connect the valley of the Indus with the table-land of Iran, and this safety has been greatly increased since the British have got possession of the province of Sinde, and have suppressed the predatory incursions of the Murries and Boogties, two Beloochee tribes who inhabit the mountains contiguous to the pass. The Bolan Pass is also accessible all the year round, and a good road leads from it to Kandahar, and thence to Persia. Shikarpore is as it were built at the opening of this pass.

European and India goods are brought to Shikarpore by three different routes. From Calcutta they ascend the Ganges, and are taken to Loodiana, whence they go down the Sutlej to Bhawoolpore, and thence they reach Shikarpore by passing through Kyrpore. Some of them go from Loodiana to Lahore and Mooltan. These imports consist of raw Bengal silk, ivory, cochineal, spices of all kinds, coarse cotton cloth, raw China silk, kinkanbs, silk manufactured, sugar-candy, cocoanut, metals, groceries, drugs, indigo, opium, saffron, and dyes. The British textile fabrics which reach Shikarpore by this route are red-dyed cotton cloth, white cotton cloth, partly-coloured cotton cloth, long cloth, glazed chintz, printed, bleached and unbleached cottons, red and white cottons, yellow cottons, Juggernat muslin, black velvet, sheeting cloth, and coloured coarse broad cloth.

The second commercial road connects Central Hindustan with Shikarpore. The goods are brought to Palee in Marwar, situated not far from the Aravulli range, and are taken through Jessulmere and Kyrpore to Shikarpore. Only a few articles reach that place by this road, especially sugar, opium, spices, and groceries.

The same articles with European goods are sent from Bombay to Shikarpore by way of Kurachee, a sea-port of Sinde west of the Indus. From this place they are transported by land to Sehwun and Larkhana, and thus reach Shikarpore. The returns of Shikarpore to British India consist of the produce of the country, especially rice, ghee, hides, and wool; horses brought from Afghanistan are also exported, and dried fruits.

The exports from Shikarpore to Kandahar and Persia (Herat) consist of indigo, henna, metals, coarse and fine cotton cloth, European piece goods; Mooltanee coarse cloth, silks manufactured, groceries, spices, raw cotton, coarse sugar, opium, hemp seed, shields, embroidered horse cloths, and grain. The returns consist of turquoises, raw silk, gum arabic, manufactured silk from Herat of various kinds, dried fruits (prunes, dried black grapes, walnuts, dried apricots, almonds, and dates) in great quantities, tinsel thread for embroidery, *khund seoh* (a preparation from the sugar-cane of Jellalabad), broken copper and brass vessels, madder, saffron, safflower, gum salop from Herat, *masugh*, a dye prepared from the walnut-tree, dried mint, carraway-seed, *airmah*, a very fine description of cotton from Herat, used in embroidery, cochineal, and *Chojgund* and *gooljibeel*, two dyes for silks; the last-mentioned affords a green dye.

From Cutchee, a country west of Shikarpore, are imported alum, colocynth, saltpetre, sulphur, and *kar*, a kind of potash, produced by the incineration of tamarisk and other salt shrubs. From Beloochistan are brought assafœtida, antimony, alum, and copper.

But Shikarpore is best known in the commercial world by its banking transactions. In 1841 there were in that place thirty-five soucars or bankers, who have agents in all large commercial towns in Western Asia, as far as Bokhara and Yarkand in Chinese Turkistan, and even in Astrakhan and Nishnei Novogrod in Russia. Letters of exchange may be got in all these places payable in Shikarpore, Bombay, and Calcutta.

The climate of Shikarpore is sultry, and the heat excessive from the middle of March to the end of August. There are no periodical rains, though storms are generally looked for at the end of June or the middle of July; severe falls of rain occur also at the vernal equinoxes. The air is remarkably dry and clear, and to this circumstance probably it is to be ascribed that the place is not unhealthy, in spite of the low situation of the town, its being surrounded by stagnant pools close to the walls, and a large space of the adjacent country being for a considerable period completely under water. Only for a short period from the middle to the end of September, during which the inundations are drying up, ague in a mild form is prevalent. The cold months commence in September, and last to the middle of March. Frost and ice are not unusual, and vegetation assumes all the appearance of winter in a northern climate. The mornings at Shikarpore are invariably cold.

Shikarpore is a new town. It was built by the Mogul emperor in 1617, and as, during the last century, since the invasion of Nadir Shah (1739) all the neighbouring countries almost without interruption have been in a state of disorder, the town has never had the opportunity of developing all the advantages of its situation; but as it passed three years ago under the dominion of the British, it is hoped that this change will soon improve the condition of the place.

(Burnes's *Travels into Bokhara*; Postans's *Memorandum on the trade between the towns of Shikarpore and Kandahar*; Postans's *Memorandum on the City of Shikarpore*, in the *Journal of the Asiatic Society*, 1841; and Alexander Burnes, *On the Commerce of Shikarpore and Upper Sindh*, in the *Transactions of the Bombay Geographical Society*.)

SHIPS. The different designations which are applied to sailing vessels, according to their sizes, number of masts, and disposition of sails, are mentioned under SHIP-BUILDING, P. C., p. 396.

SHOA. [ABYSSINIA, P. C. S.]

SHOOTING STARS. The phenomena presented by these meteors, with the different hypotheses which have been proposed in order to account for them, have been noticed under AEROLITES, P. C.; it is therefore intended here merely to state the circumstances which have led to an opinion that the appearances are periodical, and the efforts which have been made, by simultaneous observations on them, to determine the differences between the longitudes of places on the Earth.

On the night of the 11th of November, 1799, MM. Humboldt and Bonpland, at Cumana, in South America, observed some thousands of shooting stars in the course of a few hours; and on the same night vast numbers were observed in North America and in Europe. On the night of November 12, 1832, the like meteors were seen in great abundance over all the north of Europe; and on November 12th of the following year, as many as 240,000, according to the computations of Arago, were seen in North America. On the night of November 13, 1834, vast numbers were again observed in America; and on the same day of the same month in the years 1835, 1836, and 1838 the display of meteors in different parts of the world was remarkably numerous. Professor

Quetelet, at Brussels, observed, that during the years 1838, 1839, and 1840 the shooting stars occurred on the nights of the 9th and 10th of August more abundantly than on any other nights of the year except the 12th or 13th of November; and it has been observed that the nights about the 2nd of January, the 23d of April, the 15th of June, and the 6th of December are periods at which the phenomena are, in most years, very frequent. The attention of astonomers has, however, been particularly directed to the 10th of August and the 13th of November as the times at which the recurrence of the phenomena is most probable; but it must be admitted that during the four or five last years the shooting stars have not appeared to be more numerous on those nights than on many others of the year.

With respect to the use of shooting stars as means of finding the differences between the longitudes of terrestrial stations, the idea was first proposed by Dr. Maskelyne, the astronomer royal, in 1783; and it is obvious that, as their appearance or disappearance is instantaneous to persons stationed at two different places, if it can be ascertained that a meteor observed by persons so situated is the same, the method may become one of considerable utility. The first attempt to ascertain a difference of longitudes by such observations was made in the United States of America in 1835; seven simultaneous observations were made at Philadelphia and the College of New Jersey in Princeton, on the 25th of November in that year; and the mean of the differences between the times of observation at the two places gave a result which agreed within $1''\cdot 2$ (in time) with the distance (= 2 minutes, in time) between the meridians of the stations when determined by other methods. (Silliman's *Journal*, October, 1840.) On the 10th of August, 1838, twelve simultaneous observations were made at Altona and Breslau, and from these M. Bogulawski computed the difference ($28' 2''\cdot 07$ in time) between the longitudes of those places, which agrees within one second with the former determinations of that difference. Again, in the same year, the observed times of the first appearances and the extinctions of several meteors were employed in determining the distance between the meridians of Rome and Naples; and though, on comparing the times of appearance, some discrepancies occurred, yet the times of disappearance, which can be observed with greater precision, gave results agreeing with each other within a few tenths of a second. It is easy to perceive that much uncertainty may exist respecting the precise moment of the first appearance of a meteor, it being scarcely probable that the attention of the observers at different stations should be at the same moment directed exactly to the same point in the heavens.

The impossibility, at present, of anticipating the nights in which the phenomena of shooting stars may be observed, and the small number of observations in which the identity of a meteor is free from uncertainty, are the chief obstacles to the general employment of this method of finding the differences of longitude between places. A few observations of such meteors do not afford a result on which much dependence can be placed; and a single observation appears to be liable to a risk of error amounting to several seconds of time in a computed difference of longitude.

(See Abstracts of the papers, by Messrs. Galloway and Drach, read before the Royal Astronomical Society, in the Monthly Notices for January, 1841, and December, 1841.)

SIBBALDIA (in honour of Robert Sibbald, formerly Professor of Physic at Edinburgh), a genus of plants belonging to the natural order Rosaceæ. It has a concave 10-parted calyx, the five outer segments accessory. It has 5 yellow or white petals, 5 sepals, and a lateral style. The fruit consists of from 5 to 10 small nuts seated on a dry receptacle.

S. procumbens has trifoliate leaves, wedge-shaped leaflets, with three teeth at the apex, rather pilose, the flowers corymbose, petals yellow, small, shorter than the calyx. It is found on dry mountains in Scotland, in Europe, Siberia, and North America.

S. parviflora is a native of Cappadocia. It has trifoliate leaves, the leaflets beset with strigose pili on both surfaces, the flowers in glomerate heads, the petals obovate, one half shorter than the calyx.

Sibbaldia is a small genus of Alpine plants. They grow best in small pots containing a mixture of loam, peat, and sand, and are propagated by division.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

SIDDONS, MRS. SARAH, was born at Brecon, in South Wales, July 5, 1755. She was the oldest child of Mr. Roger Kemble and Sarah his wife (whose maiden name was Ward), and, while a mere infant, made her first appearance on the stage on the occasion of her father's benefit. The audience expressed their disapprobation of what they considered too premature an exhibition; but Mrs. Kemble boldly led the child forward, and she disarmed their anger by reciting the well-known fable of 'The Boy and the Frogs.' From that period Miss Kemble continued to perform regularly in her father's company till she attained her fifteenth year; and, at the early age of thirteen, she sustained the principal female parts in several standard English operas. Having formed an attachment to a young actor named Siddons, which was not agreeable to the family, Miss Kemble was removed from the theatre, and placed under the protection of Mrs. Greathead, of Guy's Cliff, Warwickshire, in the capacity of reader and companion. At the age of eighteen the affection of the young couple being undiminished by separation, Mr. and Mrs. Kemble consented to their union. They were married at Trinity Church, Coventry, November 26, 1773, and the young bride returned to the provincial stage at Cheltenham in company with her husband. 'It was a happiness,' remarks Mr. Boaden, in his Life of Mrs. Siddons, 'for the subject of these memoirs to have been born in the exact position of life, and at the precise time she was. Somewhat earlier, her correct feeling might have kept her from the stage, though the true sphere of talent like hers. . . . She started as an actress when the profession did not disgrace a woman of virtue. Becoming early attached to a man of the most honourable and steady character, the incense offered to her beauty did not disturb her peace.' At Cheltenham she attracted the notice of the Hon. Miss Boyle, Lord Bruce, afterwards created Earl of Aylesbury, and some other noble personages. Upon their strong recommendation, Garrick was induced to send King down to Cheltenham, to witness her performance in the 'Fair Penitent.' The Rev. Henry Bate, afterwards Sir Henry Bate Dudley, was also much struck by her Rosalind; and her transfer to the metropolis being at length determined on, she made her first appearance in London at the Theatre Royal, Drury Lane, on Friday, December 29, 1775, being then only twenty years of age, in the character of Portia, in the 'Merchant of Venice:' Garrick performed Shylock. She was announced simply as 'a young lady;' and, though favourably received, failed to make any strong impression, being thought more of as a beautiful young woman than as a great or even promising actress. On the revival of 'Richard the Third,' Garrick not having acted Gloster for five years, he cast Mrs. Siddons the part of Lady Anne. 'She there,' says Mr. Boaden, 'met Roscius in all his terrors;' and on the first night hung a little back from timidity. 'I have mentioned,' he continues, 'in another work the glance of reproach that corrected the failure, and the extreme sensibility with which it was long retained.' The fact was, as Mr. Campbell states it, that instead of advancing to the front of the stage and turning, as Garrick had instructed her, from the audience, she by 'hanging a little back,' compelled *him* to act the scene with *his* back towards the audience, instead of *hers*, an unintentional annoyance which he never forgave her, for at the close of the season when the re-engagements for the next campaign were under consideration, his answer to the person who mentioned in her turn 'the young lady,' was simply 'Let her go.' For this latter circumstance we have the authority of a still living contemporary of Garrick and most intimate friend of Mrs. Siddons, whose memory is as clear and retentive as his means of information were numerous and peculiar. But the triumph of Mrs. Siddons, though retarded, was not to be prevented even by so great a theatrical potentate as Garrick. In the summer of 1776, she appeared at Birmingham, where her genius was acknowledged by the celebrated actor, Henderson, who pronounced her to be 'the first and best of actresses; to have in herself all that her predecessors possessed and all they wanted,' and predicted that 'she would never be surpassed.' From Birmingham she went to Manchester, York, and Bath, increasing her reputation to such a degree that offers were again made to her from the metropolis; and on the 10th of October, 1782, she re-appeared at Drury-lane, as Isabella, in the 'Fatal Marriage.' On the 30th of October, she performed Euphrasia in 'The Grecian Daughter,' and subsequently enacted Jane Shore, Calista in 'The Fair Penitent,' and Belvidera in 'Venice Preserved,' a succession of triumphs which established her fame; and at the end of the season she went to Dublin, where her brother John was engaged for three years. In 1783 the celebrated trial of skill took place between the rival

Lady Randolphs, Mrs. Crawford, at Covent Garden, and Mrs. Siddons, at Drury Lane, and added another leaf to the laurels of the latter. In 1784 a cabal was made against her, upon a most unfounded charge of illiberality towards two brother performers, and she personally addressed the audience at tho opening of Drury Lane, on the 5th of October, having been assailed by hooting and hissing on her appearance as Mrs. Beverley. On the 2nd of February, 1785, Mrs. Siddons first performed Lady Macbeth. In 1794, Mrs. Siddons opened Holland's new Drury Lane Theatre by the performance of Lady Macbeth, on which occasion her brother Charles made his first appearance in the character of Macduff; and, in 1809, she again, as Lady Macbeth, assisted at the opening of the present Covent Garden Theatre, September 18th. The famous or rather *in*famous O. P. Row ensuing, seven months elapsed before she made her second appearance that season, repeating Lady Macbeth on the 24th of April, 1810. 'Such an interval,' says Mr. Boaden, 'spoke loudly for the taste of a London audience.' Two years afterwards, on the 29th of June, 1812, Mrs. Siddons took her leave of the stage she had so long adorned hy her genius and elevated by her private conduct, in the same celebrated character of Lady Macbeth, after which she spoke a farewell address, written by her nephew, Mr. Horace Twiss. Thrice again, however, duriug the next season she was induced to revisit the scenes and revive the recollections of her former glories; she performed on the 25th of May for the Covent Garden Theatrical Fund; on the 11th of June for Mr. Charles Kemble's benefit, and on the 22nd of the same month at Drury Lane for the fund of that theatre. In November, 1815, sho acted for ten nights at Edinburgh for the benefit of the widow and family of her son Henry; again at Covent Garden, four times in 1816, for benefits and charities, and at tho request of the Princess Charlotte of Wales, who was, bowever, unfortunately prevented by illness from witnessing the performance. In 1817 sho performed once (June 5) for Mr. C. Kemble's benefit, and made positively her last appearance upon any stage at Covent Garden, June 9, 1818, for the benefit of Mr. and Mrs. Charles Kemble, in the character of Lady Randolph. For two seasons after her public farewell in 1812, Mrs. Siddons gave occasional readings alternately from Shakspere and Milton at the Argyle Rooms, having been led to do so in tho first instance by the kind desire of serving the widow of Mr. Cherry, author of 'The Soldier's Daughter.' She was also honoured by a command to read to Queen Charlotte and tho Royal family at Frogmore, and an invitation from the Universities of Oxford and Cambridge. 'Whether this great actress regretted the stated calls to exertion,' says Mr. Boaden, 'I know not.' That sho did regret them however there can be little doubt, from the following remarks, which she one day made to an old and attached friend, an eminent physician, still living, from whose lips we heard it. It was about tho period of the evening when she had been accustomed to repair to the theatre to dress for the performance. 'At this time,' she observed, 'every body in London used to be thinking of me—*now*, nobody thinks of me!' The tone in which this was spoken, and the sigh which accompanied it, sufficiently indicated the feeling with which she contrasted her public and private life, although still the queen of every circle she condescended to enter. She died on the 8th of June 1831, about nine in the morning, at her residence in Upper Baker Street, in the 76th year of her age, and the prophecy of Henderson has not yet been falsified. 'The talents of this great woman,' remarks one of her biographers, 'are said to have been slowly developed and the growing claims of her family seemed to be the only unresisted calls upon her genius. At length fully kindled, it burst forth with a brilliancy that in her own sex had never been witnessed, and rivalled in its charm the spell of the great enchanter Garrick in all but his universality.' Mrs. Siddons lost her second daughter, Maria, in 1793; her husband in 1802; her eldest daughter, Sarah, in 1803; and her son, Henry, in 1815; a third daughter, Cecilia, and her son George survived her. Amongst the most celebrated portraits of this unrivalled actress are a full-length in the character of Isabella holding her son Henry by the hand, painted by Hamilton in 1782; another, in the character of the tragic muse, by Sir Joshua Reynolds, painted in 1784, and now in the collection of the Marquis of Westminster; a third, reading 'Paradise Lost,' by Sir Thomas Lawrence; a fourth, as Lady Macbeth, by Harlowe, who also painted her as Queen Katharine in the well-known picture of the trial scene from 'Henry VIII.' executed for Mr. Thomas Welsh; and shortly before her death sho sat to the late H. P. Briggs, Esq., R.A., whose interesting portrait of her (a three-quarter lengtb) was exhibited at Somerset House, hut has not been engraved.

'Memoirs of Mrs. Siddons,' by Mr. Boaden, were published in 1827, 2 vols. 8vo.; and after her decease, Mr. Thomas Campbell became her biographer. His work, published in 1834, is also in two volumes, and partly compiled from the MS. notes of Mrs. Siddons herself. There is also a brief memoir of her in Galt's 'Lives of the Players,' which, the writer informs us, in a postscript, he had but just completed when he received the news of her having that morning expired.

SIDMOUTH, a town on the Devonshire coast, in the east division of Budleigh Hundred, 13½ miles E.S.E. from Exeter. The area of the parish is 1970 acres; the population at the successive enumerations was as follows: 1801, 1252: 1811, 1688; 1821, 2747; 1831, 3126; and 1841, 3309. The number of houses at the last enumeration was 715; namely, 634 inhabited, 77 uninhabited, and 4 building. The town was a borough and market town, governed by a portreeve, in the thirteenth century; and in the middle of tbe fourteenth century, furnished Edward III. with two small ships for the siege of Calais. [EDWARD III., P.C.] From fragments of vessels and other relics, there is reason to believe that the antient harbour has been choked up with sand and pebbles, and that it now constitutes a meadow near the town. Sidmouth was anciently one of the principal fisbing towns of Devonshire, but the fishery bas declined, and the town would have fallen into decay, had it not within the present century risen into some importance as a watering-place.

Sidmouth stands at the mouth of the Sid, in the valley through which that little stream flows. The hills on each side of the valley rise to a considerable elevation, and form, toward the sea, bold and lofty cliffs which constitute a striking feature in the picturesque scenery of the place. The narrowness of the valley does not admit of the town, which is irregularly built, displaying a considerable front to the sea; but the villas and detached houses extend a considerable distance inland, up the valley, on both sides of the stream. There is a public walk along the beach more than half a mile in length, and the baths, public rooms, and library face the sea. There are some good inns, and lodging-houses. These are two well-supplied weekly markets on Tuesday and Saturday, and two yearly fairs, one on Easter Monday, the other on September 3. The parish church, dedicated to St. Nicholas, is an ancient building, recently enlarged; among other monuments, it contains one of Dr. Currie, the biographer of Burns. A new district church, or chapel of ease, dedicated to All Saints, has been lately erected; and there are places of worship for Unitarians, Baptists, and Independents. The living is a vicarage in the rural deanery of Aylisbeare, in the archdeaconry and diocese of Exeter, of the clear yearly value of 481*l.* with a glebe-house. There were in the parish, in the year 1833, an infant-school, with 95 children; namely, 22 boys and 73 girls, supported by voluntary contributions; four day-schools, with 116 children, namely, 80 boys and 36 girls (one of these schools, with 40 scholars, being partly supported by voluntary contributions); a boarding-school, with 12 girls: and a parish-school, with 137 children, namely, 100 boys and 37 girls, giving 360 children (namely 302 boys and 158 girls) or rather more than one in nine of the population, according to the enumeration of 1831, under daily instruction. The parish school was also a Sunday-school, attended by 148 children, namely, 88 boys and 60 girls, and there were two other Sunday-schools, with 145 children, namely 45 boys and 100 girls, giving a total of 293 Sunday-scholars, namely 133 boys and 160 girls, or less than one in ten of the population.

SIDMOUTH, HENRY ADDINGTON, VISCOUNT. The father of Lord Sidmouth was Dr. Anthony Addington, a physician, who, after practising for some time with considerable distinction in London, was induced by the state of his health to retire from the metropolis, and to settle in Reading, where he died in 1790. Dr. Addington married in 1745 Mary, daughter of the Rev. Haviland John Hiley, of Reading; and Henry, who was born at Reading on the 30th of May, 1757, was their eldest son. Mrs. Addington died in 1778. In the beginning of that same year Dr. Addington obtained much notoriety by a strange attempt in which he engaged in conjunction with Sir James Wright, the medical attendant of the Earl of Bute, to bring about a political alliance between that nobleman and the Earl of Chatham, whom Addington had been in the habit of visiting in his professional capacity. The negotiation, which of course came to nothing, appears to have originated solely with the two physicians—who afterwards quarrelled upon the subject and assailed one another, through the press, with mutual contradictions and recriminations—and to have been carried on for the greater part without the knowledge of the two noble persons who were principally concerned. Lord Chatham was at the time on his deathbed.

Meanwhile Addington's son Henry, after having commenced his classical education at Winchester School, had been entered at Brazennose College, Oxford, in January, 1774. He took his degree of B.A. in February, 1778; and in 1779 obtained the Bachelor's Prize for an English essay. On leaving the university he entered himself a student of Lincoln's Inn, and was called to the bar on the 11th of May, 1784.

Events, however, had by this time taken a course which had the effect of withdrawing him from the further pursuit of the profession upon which he had thus entered. His father's connection with the family of Lord Chatham had led to an intimacy while they were yet boys between him and the younger William Pitt, who was his junior by about three years, but had been in parliament since 1780, and was already, when Addington was called to the bar, firmly seated in the post of first minister of the crown. Addington is said to have been previously fond of attending the debates in the House of Commons; his brother-in-law, James Sutton, Esq., of New Park, had much influence at Devizes; and on Mr. Pitt's suggestion he stood for and succeeded in getting himself returned for that borough at the general election which preceded the opening of the new parliament on the 18th of May, 1784.

The long political career upon which he now entered was not marked by many events in which he bore a prominent part, and its general course may be briefly traced. So long as he was only a private member of the House of Commons—in which he retained his seat for Devizes until he became a peer—he was, as might be expected, one of Mr. Pitt's steadiest supporters. Accordingly, when the office of Speaker became vacant in May, 1789, by the promotion of Mr. (afterwards Lord) Grenville to be secretary of state, Addington, although so comparatively young a member, was put forward as the ministerial candidate, and was elected by a large majority. He filled the chair, with considerable credit if not with any remarkable distinction, till on the retirement of Pitt, in March, 1801, he was induced to undertake the formation and chieftainship of a new ministry, with the offices of chancellor of the exchequer and first lord of the treasury, as they had been held by his predecessor. He differed, therefore, it now appeared, from Pitt upon the great question of Catholic Emancipation, upon which that minister had gone out; but there were probably other subjects upon which their opinions and views had by this time considerably diverged. Addington had come to be considered as the leader or head of the class of persons specially styled the King's Friends; and it was understood to have been at the express request of his majesty that he now assumed office.

The most memorable event of Mr. Addington's short administration was the Peace of Amiens, which proved still shorter than its author's tenure of power. Soon after the renewal of the war in the beginning of 1803, Pitt, who had hitherto supported his old friend, began to intimate an apprehension that he was scarcely equal to the crisis, and then openly joined Fox and the regular opposition. The result was that Addington resigned, and Pitt was restored to power in May of the following year.

The displaced minister however made no attempt to form a party against his successor. He would probably indeed have admitted as readily as any one else that Mr. Pitt was the preferable person of the two to be at the head of affairs at such a moment, now that he was willing to accept the post upon the condition—namely, the abandonment of the question of Catholic emancipation—which he had formerly rejected, but which the king, and, it must be added, the great majority of the country and of both houses of parliament, regarded as indispensable. The resumption of office by Pitt in May, 1804, was a concession on his part of a great point and a great principle, and a decided victory obtained by George III. and his friend Addington. The new government was from the first supported by Addington, who, in January, 1805, again took office as president of the council, being at the same time made a peer by the title of Viscount Sidmouth. It is said that he accepted this elevation, which removed him from the House of Commons, with much reluctance.

The writer (probably a near relative) of an extended and elaborate memoir of Lord Sidmouth, in the 'Gentleman's Magazine' for April, 1844, while full to overflowing upon every other event of any importance in his lordship's career, merely informs us, without a word of explanation, that he resigned the presidency of the council in July of the same year in which he accepted that office. The causes are thus stated in the 'Annual Register,' in the relation of the proceedings, so distressing to Pitt, which were this year taken against Lord Melville:—'During the whole of these proceedings the new president of the council and his adherents separated from the minister, and took an eager and an active part in bringing Lord Melville to the bar of public justice: conduct which must have been considered as a defection from the government of which they formed a part, and, as such, must have been deeply resented by the minister. It was also rumoured that other causes of distaste and disagreement existed between Mr. Pitt and Lord Sidmouth at this period: that the former was jealous of the influence which the latter maintained in a certain quarter, which had lately been manifested in the conferring of high ecclesiastical dignities; and that, instead of gaining an useful ally, Mr. Pitt had only exposed himself to the machinations of a dangerous rival. Whether these reports were founded in truth it is not our province to decide; but certain it is that on the 10th day of July the Viscount Sidmouth and the Earl of Buckinghamshire resigned their respective offices.'

When Mr. Fox and Lord Grenville succeeded to power in February, 1806, after the death of Pitt, Lord Sidmouth was made lord privy seal; and when the ministry was re-constructed in October, he was replaced in his former post of president of the council, which he held till the breaking up of Lord Grenville's government in March following. After this he remained out of office for about five years. Then, in April, 1812, in the last moments of Mr. Perceval's administration, he was appointed president of the council for the third time. In June of the same year, when Lord Liverpool assumed the premiership after the assassination of Mr. Perceval, Lord Sidmouth became secretary of state for the home department.

This office, which for the first time gave him much of a real share in the business of government, he continued to hold for the next ten years. His conduct on several occasions, as, for instance, on that of the great meeting for reform, held at Manchester in August, 1819, exposed him to a good deal of popular outcry and obloquy; but he was never charged with being deficient in decision and fearlessness, and he at least succeeded in very difficult times in preventing the public safety from ever being seriously endangered. He resigned his office in 1822; but at the earnest request of Lord Liverpool he retained his seat in the cabinet for two years longer. He finally retired from official life in 1824; but he continued for some years to attend frequently in the House of Lords, though he seldom spoke. He had at no time, indeed, been accustomed to come forward much in debate. He survived till the 15th of February, 1844, when he died at his residence, the White Lodge, in Richmond Park, of which he was deputy ranger. Lord Sidmouth was twice married; first in 1781, to Ursula Mary, daughter of Leonard Hammond, of Cheam, in the county of Surrey, Esq., who died in 1811, after bringing him four sons and four daughters; secondly, in 1823, to the honourable Marianne, widow of Thomas Townshend, of Honington Park, in the county of Warwick, Esq., and only daughter of Lord Stowell, who died also before him in 1842.

(*Gentleman's Magazine*, for April, 1844.)

SIEGEN, LUDWIG VON, the inventor of mezzotinto engraving, was born in Utrecht in 1609, of an ancient and noble family of Westphalia. His mother was a native of Holland, but of Spanish origin; her name was Anna Perez, and Johann von Siegen, the father of Ludwig, was her second husband. Ludwig was the third son of his parents. In 1619 Ludwig's mother died, and his father Johann entered in the following year into the service of Prince Maurice of Hesse and removed to Cassel, where he was placed at the head of the Collegium Mauritianum, founded for the education of nobles by that prince in 1617. Ludwig von Siegen was educated in this college, and was also appointed page to one of the princes. He remained in Cassel until 1626, when the inhabitants of the place were dispersed to various parts in consequence of the plague; and Maurice resigned the government in the year following, and his successor William V. suspended the college altogether. Johann von Siegen retired to Juliers and afterwards to Kampen in Holland, where he died in 1655.

Nothing is known of the life of Ludwig Von Siegen from the time that he left the college of Cassel in 1626 until 1637, except that he was in France and Holland, and it is probable that he was doing military service in this time. In 1637 after the death of the Landgrave of Hesse, he was appointed page to the young prince William VI., by his mother the regent Amelia Elizabeth of Hanau, and in two years afterwards he received the title of Kammerjunker, and served in that capacity until 1641. It was during these years, between 1637 and 1641, that Siegen discovered his new method of engraving, but he removed in 1641, or in the beginning of 1642, to Amsterdam, without imparting his secret in Germany. On the 19th of August, 1642 he sent a letter from Amsterdam to the Landgrave, enclosing some proofs of a portrait of his mother Amelia Elizabeth, and the plate of these prints is the first mezzotinto engraving. Siegen speaks of his portrait in the letter referred to as executed in a new and astonishing manner, invented by him; and he further observes, that no engraver will be able to devise the manner in which it was executed. This letter still exists among the archives in the library of Cassel, and a fac-simile of it is given in Laborde's 'Histoire de la Gravure en Manière Noire,' (History of Mezzotinto Engraving).

This earliest mezzotinto engraving, though as the above letter shows, printed in 1642, was not published until 1643, when it appeared with the date altered to that year, together with a portrait of Elizabeth of Hungary; and the prints drawn off by Siegen himself, not already disposed of, were altered with a pen to the same date; specimens of all three still exist. The inscription of the original print was as follows:—

'Amelia Elizabetha, D. G. Hassiæ Landgravia, &c. Comitissa Hanoviæ Mutzenb.
Illustrissimo ac Cel.simo Pr. ac Dño Dño Wilhelmo VI. D. G. Hassiæ Landgr. etc. hanc Serenissimæ Matris et Incomparabilis Heroinæ Effigiem ad vivum à se primum depictum novoq. jam sculpturæ modo expressam, dedicat consecratq. L. à S. Aº Dni. CIƆ IƆ C XLII.'

It is a bust portrait, 16 French inches high by 12 wide, and is rounded at the top.

After the termination of the Thirty Years War in 1648, Siegen left Holland and entered the military service of the duke of Wolfenbüttel, and he married shortly afterwards the daughter of Michael Call, the bailiff of Hildesheim, by whom he had several children. In 1654 he returned to Holland, and visited also Cologne, where he resumed the style of Siegen von Sechten, from the name of his paternal estate near Cologne, to part of the rents of which he had become entitled. From Cologne he went to Brussels, and there he became acquainted with Prince Rupert, to whom he communicated his new method of engraving. Prince Rupert, to enable him to carry out this new method, communicated it to the portrait painter Wallerant Vaillant, who assisted him in his attempts, and engraved several plates in the style at Brussels and at Frankfort, in 1656 and 1658; a few good prints were also executed by Prince Rupert himself. The secret is, however, said to have been sold by one of Siegen's sons already in the year 1656, and was known at that time at Mainz. This general publication of his discovery, forced Siegen to sign himself, on one or two of his prints of this period, as the inventor of this new method of engraving.

It was, however, in England that Mezzotinto engraving was first cultivated to any very great extent or with very great success. In 1660, Prince Rupert accompanied Charles II. to England, and explained the whole process of the new art to his friend Evelyn, who was then engaged on his history of engraving; and in this book, which was published in 1662, he describes it as Prince Rupert's, and published a specimen of the style by the prince. Through this work, entitled 'Sculptura, or the history and art of Chalcography, and engraving in copper, with an ample enumeration of the most renowned masters and their works, to which is annexed a new manner of engraving or *mezzo tinto*, communicated by his Highness Prince Rupert to the author of this treatise,' Prince Rupert was generally considered the inventor of mezzotinto. Evelyn precisely though briefly states that Prince Rupert was the inventor of the art, yet from a paper which he himself drew up on the subject, to be read before the Royal Society as a communication from the prince himself, the invention is not claimed by the prince, and this paper is noticed by Evelyn in his history, as in preparation: it was written, but was never read before the Royal Society. In his history, Evelyn heads his sixth chapter with the following words: 'Of the new way of engraving, or Mezzotinto, invented and communicated by his Highness Prince Rupert Count Palatine of Rhyne, &c.' In the paper prepared for the Royal Society, the following passage occurs:—'This invention, or new manner of chalcography, was the result of chance, and improved by a German soldier, who, espying some scrape of barrel of his musquet, and being of an ingenious spirit, refined upon it, till it produced the effects you have seen, and which indeed is for the delicacy therefore much superior to any invention extant of this art, for the imitation of those masterly drawings, and as the Italians call it that morbidezza expressed in the best of their designs. I have had the honour to be the first of the English to whom it has been yet communicated, and by a special indulgence of his Highness, who with his own hands was pleased to direct me with permission to publish into the world, but I have esteemed it a thing so curious, that I thought it would be to profane it, before I had first offered it to this illustrious society.'

Sandrart was better informed as to the origin of this art, though he was in error as to the date of the discovery and the title of Siegen: he says, 'the inventor of this art was a lieutenant-colonel in the Hessian service, of the name of Von Slegen, who discovered it after the peace in 1648.'

Siegen was not a lieutenant-colonel of Hesse, but a major in the service of the Duke of Wolfenbüttel, but he did not attain this rank until 1674. He died at Wolfenbüttel, but the date of his death is not known; he was still living in 1676, when he took possession of some property in Antwerp. He then styled himself Ludwig Siegen von Sechten. He appears to have wholly given up engraving in the latter years of his life.

Laborde gives the following list of Siegen's engravings:—the portrait already mentioned of the Landgravin of Hesse, marked L. a S. 1642; Eleanora de Gonzalgue, wife of the Emperor Ferdinand III., sometimes called the Queen of Bohemia, a bust portrait after Hondthorst, 19 inches 3 lines (French) high, by 15-6 wide, marked L. a Siegen Inventor fecit 1643; Prince William of Nassau, Guilhelmus D. G. Princeps auriacus comes Nassaviæ &c., also after Hondthorst, marked L. a Siegen Inventor fecit 1644, 1 foot 7 inches 4 lines high, by 1 foot 3 inches wide; and Augusta Maria Caroli M. B. Rex filia Guilhelmi Princ. avr. sponsa, of the same size and date; the Emperor Ferdinand III., marked Lud. Siegen in Sechten ex. novoq. a se invento modo sculpsit Anno Domini 1654, 1 foot 3 inches 7 lines high, 1 foot 1 line wide; St. Bruno,—L. a S. in S. Ao. 1654, 11 inches high by 6 inches 11 lines wide; and lastly a Holy Family after Annibal Carracci, called La Sainte Famille aux Lunettes; it is dedicated to Prince Leopold of Austria—Ludw. a Siegen humilissime offert, Annib. Caratii pinx., Ludovicq a S. novo suo modo lusit.

(Sandrart, Evelyn, Descamps, Walpole, but especially Laborde, *Histoire de la Gravure en Manière Noire*, Paris, 1839.)

SIEYES, EMMANUEL JOSEPH, Count, more generally known as l'Abbé Sieyes, was born at Fréjus on the 3rd of May, 1748. Destined from early youth to the ecclesiastical profession, he completed his studies with success at the University of Paris, where his mind became imbued with the philosophical speculations prevalent at that period, and he applied himself seriously to political economy, and to the investigation of the various schemes of social reform which were then so frequently suggested. The liberality of his sentiments does not appear to have impeded his advancement in the Church. By the patronage of De Lubersac, Bishop of Chartres, he was appointed to a canonry in that Cathedral, and afterwards became Vicar-General and Chancellor of the diocese. He took an active part in various assemblies of the clergy, and warmly espoused those opinions which were rapidly producing the Revolution of 1789. When the disordered state of the public finances compelled the government to summon the States General, the question arose, in what manner that body was to be convoked? Whether they were to be called upon, as in the last assembly of 1614, to vote by classes, or, as justice and the necessities of the time appeared to require, by individuals? To this important question Sieyes replied by publishing three pamphlets, which were so skilfully adapted to the prevailing opinions on the subject that they at once placed him on the highest pinnacle of political popularity. The first was entitled 'Essai sur les Privilèges:' the second and the most remarkable, 'Qu'est ce que le Tiers Etat?' in which he asserts that the 'Tiers Etat' is the nation itself; he then proceeds to show that it had hitherto exercised no appreciable influence on the government of France, and he demands for it a political recognition. The title of the third pamphlet was 'Moyens d'Exécution dont les Représentans de la France pourront disposer en 1789.' The bold speculations of this political thinker soon became realities through his active influence. On the convocation of the States-General Sieyes was elected deputy for Paris. An opportunity for carrying his scheme into execution was given him by the refusal of the majority of the nobles and clergy to unite with the 'tiers état,' and to verify their powers in common; by his eloquent exertions he induced the representatives of the people to constitute themselves into an independent body styled the National Assembly (June 16, 1789). He it was likewise who proposed the oath which was taken by all the members at the 'Jeu de Paume' [BAILLY, P. C.] 'never to separate themselves, but to assemble wherever circumstances required until the perfect establishment of the constitution.' This sudden and vigorous measure, which must have proved the immediate signal of civil war had not the power of the other orders of the state been already paralyzed, was vehemently opposed by Mirabeau [MIRABEAU, P. C.] at the head of the more moderate of the republican party; it was however carried by a very large majority. So great was the popularity of Sieyes that, on presenting himself before the Assembly, he was greeted by the loud and reiterated applause of the members present, who rose up to receive him. On the meeting of the 23rd of June, when the king declared the resolutions of the Assembly to be null and void, and ordered the members to disperse, Sieyes energetically reminded them that they were 'still the same body to-day that they had been the day before, and bid them proceed in their deliberations.' 'They did deliberate,' says a writer in the 'Foreign Quarterly;' 'and the revolution was the result.' Sieyes was also the framer of the decree which was passed on the 30th of October, by which the antient provinces were abolished, and France was divided into eighty departments all governed by the same law. [FRANCE, P. C.]

He continued to take a prominent part in the deliberations of the National Assembly until the publication of those decrees which he considered of too levelling a nature, and which alarmed him as to the ultimate result of the innovations which he had himself been too eager to introduce. Accustomed to command, he was unable to endure contradiction, and, when he found that the measures which he opposed were carried in spite of his influence, he betook himself to a sullen silence from which even the persuasions of his eloquent colleague, Mirabeau, were unable to rouse him. The most important of these measures was the question of the abolition of tithes. To this he was favourable; but he considered that they should be purchased by the landed proprietors, and an indemnity for their loss made to the tithe-holders. To this indemnity, however, the Assembly was unwilling to acquiesce; and the determined and impassioned manner in which he advocated it well nigh lost him the popularity which his previous conduct had acquired. The discourse he delivered on that occasion is remarkable for the earnest vehemence of the language, and the concise correctness of the arguments; he exposed the impolicy and the injustice of the proposed measure, and showed that the only members of society likely to be benefited by the change were the wealthy proprietors of land, whom they were about to enrich by the gratuitous addition of one-tenth of its value. The energetic exclamation with which he concluded his address will probably be quoted and admired long after the author has been forgotten: 'ils veulent être libres, ils ne savent pas être justes,' 'they would be free, and know not how to be just.' The apt reply of Mirabeau to Sieyes, when the latter was indulging in bitter invectives on the violence and injustice of the decrees of the Assembly which he had created, is characteristic of that remarkable man: 'You have unloosed the bull, and you complain that it gores you.'

Elected, in 1791, member for the department of Paris, in the new legislative assembly, he refused the additional honour, which was offered him by the electoral assembly, of electing him constitutional bishop of that capital. Shortly afterwards he published a letter in which he explained his opinions on monarchical government: he remarks that 'he makes it the object of his preference from no desire to accommodate himself to antient customs or from any superstitious regard for royalty, but because he considers it proved that the citizen enjoys more freedom under a monarchy than under a republic.' He was named deputy for the department of La Sarthe, in the convention of 1792, but, wisely foreseeing the danger of an active participation in the debates, he persevered in the silence he had previously imposed upon himself, and for the most part contented himself with the simple record of his vote. At the trial of the king it has been generally asserted that he accompanied the sentence of death, which he pronounced, with an ill-timed sarcasm on the lengthened arguments with which the deputy who had spoken before him attempted to justify his vote. 'Robespierre's vote,' says Carlyle, 'cannot be doubtful; his speech is long. Men see the figure of shrill Sieyes ascend; hardly pausing, passing merely, the figure says "La mort sans phrase" (Death without phrases).' (*History of the French Revolution*, vol. iii. p. 226, 8vo. ed.) It will be seen, however, by reference to the 'Gazette Nationale' or 'Moniteur Universel,' for January 20, 1793, where the different speeches are given at length, that the vote of Sieyes was simply 'la mort,' and that he gave it a considerable time after those of Robespierre and Philippe l'Egalité, to both of whom the allusion has been supposed to be made. So strongly however was the stigma of this sarcasm attached to his name, that when, at a subsequent period, he was ambassador of the French republic at the court of Berlin, one of the ministers of the king of Prussia having been solicited to show him the attentions due to the office he held, he replied: 'Non, et sans phrase.' (Morellet, *Mémoires*, vol. ii. c. 3.)

While the power of Robespierre [ROBESPIERRE, P. C.] and his colleagues was in the ascendant, Sieyes prudently retired into the country; and when subsequently asked 'What he had done during the reign of terror?' he wittily retorted, 'I have lived;' no small achievement at that time for a man of his political celebrity.

After the fall of Robespierre he returned to the Convention, and by his influence obtained the recall of the proscribed members of the Gironde party. In 1795 he again took an active part in the management of affairs, and was named a member of the new Comité du Salut Public; on the 19th August of the same year he made a proposition to the Convention to establish a constitutional jury, which was however rejected. During this time he chiefly occupied himself with the direction of the foreign affairs, and successfully carried on several important negotiations with the European states, and went to Holland to conclude a treaty of alliance.

In the same year Sieyes was named by the Council of Antients one of the five directors, but he declined the proffered honour, and Carnot was appointed in his stead.

In 1797 he had a narrow escape from the hand of an assassin, l'Abbé Poule, who, entering his room, fired a pistol at him at arm's length, and one of the balls shattered his hand. He behaved on this critical occasion with his usual coolness, and a few days after quietly told his servants, 'If Mons. Poule should return, inform him that I am not at home.'

In 1798 Sieyes was sent on a mission from the French Government to the court of Berlin, in which, though he failed in his attempt to form an alliance with that power, he succeeded in securing its neutrality. On his return to Paris the following year he was named member of the Directory, a nomination which showed the disposition of the councils, as he had openly expressed his dissatisfaction with the directorial government. Placing himself at the head of a conspiracy which had been formed against three of his colleagues, who were known for their republican sentiments, he procured their forced resignation, and a new Directory was formed in which the majority was favourable to his views. Another important measure which he effected through the instrumentality of the Minister of Police, Fouché, was the closing of the Jacobin Club, a body whose name was connected with all the excesses of the Revolution. These measures, as they destroyed the popularity of the author of the Tiers Etat, and exposed him to the vengeance of republican fury, made him anxious to secure the support of some military leader possessed of sufficient talent and energy to take upon himself the sole direction of the affairs of state. 'We must have no more dealings with declaimers,' said he, 'we want a head and a sword.' Military chiefs there were many at that period, some of them of the highest renown, but they appeared to Sieyes to fail in the necessary requisites for a civil ruler. Joubert, in whom he hoped to find them, had recently fallen at Novi. Masséna was merely a brave and skilful soldier, and Augereau and Bernadotte were too well known for their democratical sentiments. The arrival of Bonaparte from Egypt [BONAPARTE, P. C.; KLEBER, P. C. S.] determined the difficulty; the penetration of Sieyes discovered in him a fit associate for his designs. They were favoured by the enthusiastic reception which Bonaparte met with from all ranks and parties on his arrival, by the views of this military chief himself, and by the active co-operation of many of the French generals and the most influential members of the legislature. The talents and influence of Sieyes were appreciated by Bonaparte, while the speculative nature of his views precluded the possibility of his becoming an object of jealousy. Mutual esteem indeed there was none; they were in the frequent habit of expressing their dislike of each other in no measured terms; but to effect his end the soldier felt the necessity of cordially co-operating with the statesman, and the statesman perceived that a salutary change could not take place without the strong support of the soldier.

The Revolution of the 18th Brumaire (9th Nov., 1799) was the result of this co-operation, and Napoleon, Sieyes, and Roger Ducos were the first consuls named, and two commissions of twenty-five members each were appointed from each Council of State to assist the consuls in the formation of a new constitution. In the formation of this constitution, however, Sieyes and Bonaparte soon disagreed; Sieyes was allowed to form a legislature according to his political speculations, and he made it consist of a Senate without the power of debate, and a Tribunate which was to discuss with the Council of State the legislative measures proposed. But to his visionary scheme respecting the executive, which was to be vested in a Grand Elector, whose sole power was to consist in the nomination of two consuls who were to exercise all the powers of government, Bonaparte offered a vigorous and successful resistance. Discontented with the overthrow of his political theory, and discovering with characteristic penetration that he had found his master, he refused to act a subordinate part in the new constitution, which was proclaimed on the 24th December, 1799. At this period he may be said to have terminated his public career. His services however were richly rewarded with 600,000 francs and the estate of Crosne, which was afterwards exchanged for a magnificent hotel in Paris, and the valuable lands of Faisanderie in the park of Versailles. 'Thus the democratic fervour of the author of the pamphlet "What is the Tiers Etat?" sunk into the interested apathy of the proprietor of fifty thousand ponnds' (Alison). This writer quotes also from the 'Memoirs of Gohier' an incident characteristic of the extreme cupidity of Sieyes, to use no severer term (*History of Europe*, vol. iii., p. 785), but it must be remembered that Gohier was the President of the Directory on the 18th Brumaire, that he was strongly opposed to Sieyes in political opinions, and that he evinces throughout his Memoirs much personal hostility towards him.

Under the consulate and the empire, Sieyes studiously avoided all participation in power. He declined the offer of the presidency of the Senate, and contented himself with accepting the title of Count. Napoleon borrowed largely from his theories, which he had the talent to translate into acts, and many of his political ideas formed the basis of the legislative measures which he introduced. At the Restoration he was exiled, and only returned to France after the Revolution of 1830, fifteen years afterwards. He died at Paris, in tranquil obscurity, on the 20th June, 1836.

The character of Sieyes has been graphically depicted by Dumont [DUMONT, P. C.] in his valuable and interesting Memoirs. 'His manner,' he says, 'was neither frank nor engaging; he was a man with whom it was difficult to become intimate, and who was wont to express his opinion without deigning to enter into any discussion upon it. His writings had given him a well established reputation; he was looked upon as the oracle of the Tiers Etat, and the most formidable enemy of privileges. He was easily excited to a display of ill humour, and appeared to hold in extreme contempt the existing state of society (1790). I imagined that this friend of liberty had necessarily a liking for the English nation, and the subject being familiar to me, I introduced it to him, but I discovered to my surprise that the whole English constitution was in his eyes a mere piece of charlatanry to impose upon the people: he seemed to pity my ignorance as I described the various modifications that system had undergone, the cautious regard ('ménagemens réciproques') shown towards each other by the three orders of the state, the hidden checks which they opposed to each other's movements, and the disguised but real dependence which existed between them. The influence of the crown appeared to him venality, the opposition a mere court trick ('manège d'antichambre'). The only thing he approved of among the English was trial by jury, which, however, he but little understood, and, in common with most Frenchmen, he had formed wrong notions respecting it. In a word, it was manifest that he regarded the English but as children in the art of framing a constitution, and that he considered himself capable of giving a much better one to France.' (Dumont, *Souvenirs de Mirabeau*, p. 62, 63, Paris, 1833.) So great indeed was the vanity of this political philosopher that on one occasion he remarked that 'the art of government was a science which he considered he had brought to perfection.' This disposition may have been the cause of the surname of Mahomet, which Mirabeau was in the habit of applying to him. There is also an admirable sketch of his character in Mignet, 'Hist. de la Révolution,' c. ii.

The principal writings of Sieyes, not already mentioned, are, 1, 'Observations sommaires sur les Biens Ecclésiastiques.' 2, 'Préliminaires de la Constitution.' 3, 'Reconnaissance et Exposition des Droits de l'Homme.' 4, Des Opinions Politiques.' 5, Divers Rapports et Projets de Lois.' The following works have been consulted, and may be referred to for a more full detail of the life and character of Sieyes: Alison, 'Hist. of Europe,' vol. i. and iii.; 'Carlyle, 'Revolution in France;' Thiers, 'Hist. de la Révolution,' and 'Hist. du Consulat,' &c., vol. v.; Mignet, 'Notices et Mémoires Historiques,' 2 vols., Paris, 1843; Dumont, 'Souvenirs de Mirabeau,' 'Mémoires de Morellet,' 2 vols., Paris, 1821; Ælsner, 'Des Opinions Politiques de Sieyes et de sa Vie comme Homme Public,' 1800; 'Sayings and Deeds of Napoleon Bonaparte,' 2 vols., London, 1846. His speeches are printed in the 'Moniteur' of the time.

SIGILLA'RIA, a very large group of fossil plants, confined to the Carboniferous strata, in which the great stems of this genns sometimes stand upright *over* beds of coal, while *below* the coal spread the root-like branching forms to which the name of Stigmaria is applied. The genus is supposed to be related both to Ferns and to Carteaceæ. (Brongniart.)

SIGNORELLI, LUCA, a celebrated Italian painter, born at Cortona in 1439, was the son of Egidio di Ventura Signorelli, by the sister of Lazzaro Vasari: he was the pupil of Piero della Francesca, with whom he worked at Arezzo, where he lived with his uncle Lazzaro Vasari.

Vasari mentions many of Luca's works, few of which however still exist; but the altar-piece of St. Onofrio, painted in 1484, is still in the cathedral of Perugia, and there are two other pictures in the cathedral of Volterra; there are also still some pictures by him at Orvieto, Rome, Cortona, at Siena and in its neighbourhood, and in the Florentine gallery. His most celebrated work is the fresco of the Last Judgment in a chapel of the church of the Madonna or cathedral at Orvieto. The painting of this chapel of the Madonna di San Brizio was commenced in 1447 by Fra Giovanni da Fiesole, who however painted only part of the ceiling, and it was completed many years afterwards by Luca Signorelli. The contract concerning the continuation of these frescoes by Signorelli is dated April 5, 1499; he undertook the completion of the ceiling for 200 ducats, and the walls for 600 ducats, besides free lodging, and two measures of wine and two quarters of corn every month. The ceiling was finished in 1500; when the walls were finished is not known, but as the ceiling was done apparently within the first year, and this may from the amount of the remuneration be fairly estimated at about one quarter of the whole, the chapel was probably completed in 1503 at latest. The frescoes comprise the history of Antichrist, the Resurrection of the Dead, Hell, and Paradise; and such is the vigour and boldness displayed in these works, especially in the invention and the naked figure and their foreshortenings, that Vasari and many others have pointed to Signorelli as the immediate precursor of Michael Angelo. Vasari says that Michael Angelo always expressed a high admiration of the works of Signorelli, and observes that all may see that he made use of the inventions of Luca in the Last Judgment in the Sistine Chapel, especially in the forms of the angels and demons, and in the arrangement.

Luca Signorelli was one of those who competed for the prize of Sixtus IV. in the Sistine Chapel, which was won by Cosimo Roselli. [ROSELLI, P. C. S.] He retired in his old age to Cortona, where his Italian fame was rivalled by the personal respect that was shown him. He is represented by Vasari as having been a man of very high character, and he adds that he always lived more like a nobleman than an artist: he died in 1521, aged eighty-two. The frescoes of the cathedral are described and in part engraved in Della Valle's 'Storia del Duomo d' Orvieto,' Rome, 1791. The design, though full of power, is hard, and the colouring wants harmony.

(Vasari, *Vite de' Pittori*, ed. Schorn.)

SI'LAUS (a name used by Pliny (*Hist. Nat.* 26, c. 8, ed. Hard.) for an umbelliferous plant), a genus of plants belonging to the natural order Umbelliferæ, and the tribe Seselineæ. The calyx is obsolete; the petals ovate, oblong, entire, or slightly emarginate, with an inflexed lobe, sessile, truncate, or appendaged at the base.

S. pratensis, Meadow Pepper Saxifrage, has an angular stem, supra-decompound leaves, pinnate leaflets with the segments rather remote. It is a smooth dark-green herb. The umbels consist of several unequal rays. The flowers are yellowish or greenish white. The fruit is roundish and ovate. It is found in damp and moist places in England, Europe, and Siberia. The whole plant has an unpleasant smell when bruised, and is said in some parts of Norfolk to give a bad flavour to the milk of cows feeding on it, and it is generally found that cattle avoid it in pastures. The species of this genus are not numerous. They are principally found in Europe, and will grow in any common garden soil, and may be propagated by seeds or by cuttings.

(Don, *Gardener's Dic.*; Babington, *Man. Brit. Bot.*)

SILVER, GERMAN. [COPPER, P. C., p. 504.]

SILVERING. [GILDING, P. C.]

SI'LYBUM, a genus of composite plants belonging to the tribe Cynareæ and the section Silybeæ. It has an imbricated involucre with leafy scales at the base, narrowed into a long spreading spinous point. The receptacle is scaly. The fruit compressed, its terminal areola surrounded by a papillose ring.

S. marianum, is the only species. It has a stem from 3 to 4 feet high, ribbed and furrowed. The leaves are very large, oblong, lanceolate, wavy, and clasping the radical leaves, pinnatifid, and usually variegated green and white. The involucral scales closely adpressed below. The florets are purple, with a very long tube. This plant is found in waste places in Great Britain.

(Babington, *Manual of British Botany*.)

SINDE or SCINDE is that part of Hindustan which extends on both sides of the river Indus from the sea to near the place where the river is joined by the Chinab, which brings to it the united waters of the five rivers of the Panjab. It lies between 23° 30′ and 29° N. lat., and 67° and 71° E. long. It extends in length from south to north more than 360 miles, and its average width may be 200 miles. This gives an area of 72,000 square miles, or about 14,000 square miles more than England inclusive of Wales, and nearly as much less than the whole area of Great Britain.

On the south and south-west it borders on the Indian Ocean, and its eastern districts are separated from the province of Cutch by the Runn. To the east of it, and chiefly within its boundary, extends the Indian Desert or Thurr, where it borders on the Rajpoot States of Marwar and Jessulmere. On the north-east are the territories of the Khan of Bhawulpore, and north those of the Panjab or Seiks. The north-western corner of Sinde reaches the Boogtee hills, which belong to Afghanistan, but the other parts of the western borders are Beloochistan or the territories of Khelat, from which Sinde is mostly separated by the Hala Mountains.

The sea washes the shores of Sinde for about 150 miles, and is shallow, but the soundings are regular. A vessel will have from 12 to 15 feet of water a mile and a half from shore. A bank however occurs opposite the principal mouth of the Indus, called from it the Gora or Kora Bank, along the edge of which there are breakers for twelve miles. The sailors clear it by stretching out of sight of land and keeping in 12 fathoms water till they have passed the danger; for they state that a vessel would be wrecked on a course where the depth is 10 fathoms. This bank is much resorted to by fishermen. The navigation along this coast is much earlier suspended than in the neighbouring countries. Few vessels approach it after March; for the south-west monsoon, which then partially commences, raises such a sea that the waves break in three or four fathoms water, while the coast is not discernible owing to its lowness till a ship is close upon it, and there is great risk of missing the port, and there is no shelter near.

The tides rise in the mouth of the Indus about 9 feet at full moon; they ebb and flow with great violence, particularly near the sea, where they flood and abandon the banks with incredible velocity. It is dangerous to drop the anchor except at low-water, for the vessel may be left dry a short time afterwards. In the widest mouths of the Indus the tide is not perceptible more than seventy miles from the sea.

The Indus. Sinde is indebted for its fertility to the inundations of the Indus. As far as these inundations extend, the country yields abundant crops; where they cease, and no means of irrigation exist, the country is a desert. These inundations however are not derived from the same cause as those of the Ganges. The inundations in Bengal are almost entirely the effect of the periodical rains during the south-western monsoon, and the addition which the waters receive from the melting of the snow in the Himalaya mountains is comparatively small. The waters of the Indus are very little increased by rains, as the rains which fall in its basin are scanty, and so uncertain, that many parts of it frequently suffer from drought. But the upper course of the Indus traverses countries which for more than six months are covered with snow, and all its great tributaries, including the five rivers of the Panjab, are in their upper courses surrounded by mountains which rise several thousand feet above the snow-line. As in these parts the difference of the snow-line in summer and winter amounts to 3000 feet, an immense volume of snow must annually be dissolved, and the water thus produced must greatly raise the level of the river. Even in the lower course of the Indus the difference of the level between the highest and lowest points amounts to 12 feet. As the banks of the river in very few places attain such a height, the waters spread over the adjacent levels and fertilize the soil.

Artificial means are employed to increase these advantages, especially canals and dams. The canals serve two ends. The water is carried to low tracts, which are not within the reach of the inundations; and where they do not naturally disperse over the adjacent country, they are conveyed there by means of the Persian wheel. These canals are only full during the height of the inundation, and are dry in the winter months. The dams are made across the bed of the river, and are of two different descriptions. Many of them have an opening in the middle, by which all the water escapes when the river is low, but which is not wide enough to receive the whole volume which descends during the freshets. The water thus impeded accumulates above the dam so as to cover a large tract of country. In those arms of the river however which even during the freshets receive only a moderate supply of water, the dams have no opening. The whole volume is thus driven back and spreads over the district above the dam, and the bed of the river below it would remain dry if the water which is carried by canals over the country did not find by these canals a way to the bed of the river below the dam. These dams are called *bunds*.

The river begins to rise in April. Early in May the swell of the waters begins to point out the necessity of deepening and cleaning out the various canals. Towards the middle of June there is sufficient water for sowing the crops, which ripen and are cut down in October. At the end of September the waters are confined to the bed of the river.

A few miles below the point where the Indus is joined by the Chinab, the river enters Sinde. About 60 miles lower down, and only about 24 miles above Bukhur, it begins to divide into arms. At this place (about 28° N. lat.) an arm branches off on the eastern side, which is called the Eastern Narra. It appears that this arm formerly received a great, if not the greatest, part of the waters brought down, but that the river changed its course more to the west. After this event had taken place, a bund was erected across the Narra, near the antient town of Arore, which is still called the Arore Bund. Thus the Narra was deprived of the annual supply of water, except when the water in the Indus rose to an unusual height, as in 1831. Its bed would generally be dry, if it did not receive a small supply of water from a remarkable depression, which extends parallel to the Garra and Chinab rivers from the vicinity of Bhawulpore to that of Arore, and in which running water is found during four or five months of the year. This depression, being considerably lower than the flood-height of the above-named rivers, receives a good deal of water from them through canals or by direct overflows. The drainage of this natural hollow is collected in the Narra, but, except under extraordinary circumstances, is seldom in sufficient quantity to reach the Alla Bund, near 24° N. lat. The Narra extends in a south-south-eastern direction to Omercote, skirting the Thurr or Indian Desert. South of that place the river is called Pooruun, and receives a supply of water from another arm of the Indus, which, under the name of Fulailee, leaves the principal river seven or eight miles above Hyderabad, and which sends two branches to the Pooruun under the name of Goonee. After this accession of water the Pooruun has a well-defined channel from 12 to 20 feet deep and from 600 to 1200 feet wide, but it is obstructed artificially by bunds and naturally by sand-drifts. Farther down the channel of the river is occupied by a chain of pools of salt-water, and is partly separated from Sindree Lake by the Alla Bund. The Alla Bund (Embankment of God) is an immense mound, nearly four miles in width and more than fifty in length, which was thrown up by an earthquake in 1819, the same convulsion of nature having depressed a large tract of land south of it, which, being filled with salt-water through the Lucput Creek, now forms an extensive lake. This mound appeared calculated to cut off the Pooruun from its mouth, called the Koree, but in 1826 an extraordinary flood passed down the Narra and Pooruun, and, forcing a narrow passage through the Alla Bund, found its way into the Sindree Lake, and by it to the Koree month of the Indus.

About 28 miles south of Bukhur the Indus throws off another branch on the right, which is called the Western Narra. It runs about a hundred miles, expands towards the end of its course into the lake of Munchar, and re-joins the river north of the town of Sehwun. About seven or eight miles above Hyderabad, at Meanee, occurs the third bifurcation of the Indus. The eastern branch, called Fulailee, runs southward and receives a considerable supply of water, which however is greatly diminished by the numerous canals which branch off from it. In the lower part of its course it is called Goonee, and sends off two branches to the Pooruun, as observed before. It does not appear that the waters of this branch reach the sea except by the last-mentioned river.

The Indus divides again south of Jurruk, near 25° N. lat. The eastern smaller branch is called Pinjaree, and below Mugrebee it is called Goongra. It has always water enough to be navigable for flat-bottomed boats, north of the bund at Mugrebee, and even below the dam it is a running stream. It enters the sea by a wide mouth, the Seer, which is accessible for boats of 38 tons, to a place called Gunda.

The last great bifurcation of the river takes place below the town of Tatta. The larger volume of water descends nearly due southward in the eastern arm, which is called Sata. It divides towards the sea into several arms; of which four, the Mull, Khaeer, Gora, and Hijamree, enter the sea by wide embouchures. The Mull is navigable for sea-boats up to Shahbunder. The Khaeer and Gora cannot be navigated by sea-boats. The last-mentioned mouth brings the greatest volume of water to the sea, so that fresh-water is found two miles from the shore; but the dangerous bank before the opening prevents it from being navigated. The Hijamree is the most navigable of all the lower branches of the Indus. It may be ascended by sea-boats of fifty tons burden as far as Vikkur, which place is therefore considered as the harbour of the delta, and much frequented. On the bar are fifteen feet of water at high tide, and a depth of four fathoms all the way to Vikkur, even when the tide is out.

The most western arm of the Indus is the Buggaur. It leaves the Sata below Tatta, and runs in a general course duo west, but with several large bends. About twelve miles from the sea it divides into two branches, of which one runs south-south-west; it reaches the sea by the Pieteeanee mouth. The other arm runs west-north-west, and disembogues by the Pittee mouth. Both of these arms divide several times before they reach the sea, and they enter it by several mouths. The two large channels are navigable for sea-boats of fifty tons; but as they are beset at their mouths with sand-banks, which overlap ono another, the navigation is intricate and dangerous: still a few boats ascend them to Darajee.

The Indus, with the exception of the months, which, as above mentioned, are accessible for sea-boats, can only be navigated by flat-bottomed vessels which do not draw more than four feet of water when heavily laden. The largest carry about seventy-five tons. But the navigation is difficult and dangerous, because the numerous sand-banks in the bed of the river are subject to frequent changes, and large portions of the banks frequently fall down into the water, having been undermined by the current.

Surface and Soil.—The Delta, or that part of Sinde which is enclosed by the Sata and Buggaur branches, has an alluvial soil, consisting of successive layers of earth, clay, and sand. As the great branches of the river are here so numerous, and throw off so many arms, the inundation of this tract is general; and in those places which have not this advantage, artificial drains, about four feet wide and three deep, conduct the waters through the fields. Close upon the sea there is abundance of green forage, which furnishes pasture for large herds of buffaloes. At the back of it extends a belt ten miles in width, where the country is so thickly covered with furze and bushes that it is incapable of being brought under tillage. Agriculture is only carried on in those districts which are more distant from tho shores. Rice is grown in large quantities, as also bajree and all other Indian grains, and wheat and barley. There are also large plantations of sugar-cane, which yields a coarse kind of sugar. The soil in many parts is impregnated with saltpetre, which is extracted, but not exported, as formerly. The climate is sultry and disagreeable, the thermometer rising in March as high as 90°. If we except a few small towns and villages, the inhabitants reside in temporary villages, which they remove according as they are compelled by the increase of the inundation or other circumstances.

That extensive tract of country which lies west of the Indus, and extends from the sea-shore to the town of Sehwun (26° 22′ N. lat.) has a different character. It is only along the banks of the river that there is a low alluvial tract, a few miles wide, which can be cultivated, as it has the advantage of being irrigated by short cuts from the river. Beyond its limits the country rises higher, and the soil is gravelly and intermixed with pebbles, and soon passes into low hills composed of sandstone. Their height seldom exceeds two hundred fect; but in approaching the Hala Mountains they rise much higher, and form several short ranges, of which the Garra hills on the south, and the Lakki hills on the north, are laid down in our maps. The small rivers which drain this hilly tract have only water for three or four months; but during the remainder of the year abundance of water is found in pools in the bed of the rivers. The valleys have a light soil, clay and gravel mixed together, but they are not cultivated. In these parts are no fixed villages, the country being inhabited by nomadic tribes, whose wealth consists of camels, goats, sheep, and buffaloes: their number is small. The Hala Mountains, which lie between this tract and Beloochistan, are barren and almost without vegetation.

Proceeding on the same side of the Indus, north of the town of Sehwun, we enter one of the most fertile districts of Sinde, which extends some miles north of Shikarpore. The country is level, and the means of irrigating the land are abundant; for besides the main channel of the Indus, which is used for irrigating the adjacent lands, the interior of this region, for the greatest part of its extent, is traversed by the Western Narra, which partakes of the inundations of the principal river, and at some places is connected with it by transverse canals. The lake of Munchar extends about eighteen miles from north-north-west to south-south-east, and is about eight or nine miles across. But in the dry season its waters are much reduced, and those tracts which are then left dry are cultivated, and yield very rich crops. That part of the plain which lies north of the place where the Narra branches off from tho Indus, derives the same advantages from the Sinde canal, which begins some miles above Bukhur, and extends fifty miles inland, until it joins the Narra, after passing near Shikarpore. The principal articles of cultivation in this plain are cotton, sugar, and rice. Large droves of buffaloes, cows, excellent sheep, and goats, are scattered over the country. Various kinds of trees of great size are found in many places, and yield plenty of timber for the construction of water-wheels and for other agricultural purposes. The river, as well as the lake, is navigated by boats.

The plain properly extends farther northward to the boundary-line of Sinde; but north of Shikarpore it attains a higher level, and as there are no canals, irrigation is not practised. As however the soil is very good, which is shown by the excellent pastures and large trees, this tract would also yield abundant crops if it was well protected against the predatory tribes which inhabit the adjacent Murree and Boogtee Hills. But these tribes have expelled the agricultural population and taken possession of the country, in which they wander about with their herds of buffaloes, sheep, and goats.

The country on the east of the Indus, from the northern boundary-line to the parallel of Hyderabad and Omercote, presents a different aspect. The banks of the river to the distance of two or three miles inland are covered with tamarisk and acacia shrubs, and mostly uninhabited, but frequently cut by canals, which carry the water of the river to the back country. On the edge of this back country the villages are built, and generally raised somewhat above the ordinary level, to avoid the inundations. To the back country the water is carried by numerous canals. They are generally cut in those parts of the river which run east and west, that the water may be thrown south into the interior. Some of these canals are of great extent. One of them, called the Meerwah, conducts by a southerly course the waters of the Indus from the neighbourhood of Bukhur to a distance of ninety miles, where they are lost in sands or dispersed over the fields. The soil of this tract is alluvial, with the exception of a small rocky district which crosses the Indus at Bukhur, and extends on the east of the river for a few miles. The banks of all the canals are fringed with a broad agricultural band, on which numerous large villages are built, many of which contain 500 houses. Besides fertilizing the land, these canals afford the means of transporting by boats the produce of the soil. In the fair season, when dry, they become the beaten footpath of the people and are excellent cart-roads. Beyond the reach of the water of the canals, the country is very little cultivated. Though the components of the soil do not differ from those of the cultivated tracts, it is hard and sandy. Dry and cracked from the heat of the sun, the loosened sand is raised by the prevailing westerly winds into little hillocks from twenty to thirty feet high, which gradually assume the appearance of a desert running imperceptibly into the Thurr. Only at a few places grain is cultivated, as its growth depends on rain, which is very uncertain in these parts of Sinde. The lower parts of the uncultivated ground are generally overrun with tamarisk jungle.

The country south of a line drawn from Hyderabad to Omercote, and included by the Sata and Pooruun branches of the Indus, generally resembles the region just noticed. In its most northern corner, where the Indus and its Fulailee branch run nearly parallel, is a low ridge of rocks which extends for several miles, and opposite the town of Tatta are several isolated hills of limestone, of moderate elevation. Except these hills the country is flat and well cultivated in the vicinity of the numerous canals, which bring to the interior the waters of the Sata and Pinjaree branches. Between the Pinjaree and the Poorunn a considerable extent of country is covered by a salt-marsh. The country near the last-mentioned branch of the Indus is little cultivated, except in the vicinity of the Goonee river. Towards the sea this region is a complete desert, resembling the Runn. There are hardly any plants met with, except a saline plant called *darun*, which forms the principal food of the camels in this uninhabited country. The soil is of such a description as not to absorb water, which therefore remains upon the level surface until it is carried off by evaporation. Indifferent water may be obtained in many parts of this desert by digging wells to the depth of eighteen feet. This sterile tract extends twenty miles from the sea and the Koree mouth of the Indus.

A large portion of the *Thurr*, or Indian Desert, is included within the boundary of Sinde. The course of the Eastern Narra and of the Pooruun lies near the western edge of this region. The Thurr is an extensive sandy tract destitute of trees, but abounding in grass and jungle. It rises from the plains of Sinde and from the Runn in bold relief, with a demarcation as distinct as if it rose from the sea. Its features are peculiar, and throughout its whole extent preserve a uniform character, being composed of innumerable ridges of loose sand of a bright yellow colour, in height varying from 150 to 600 feet. They intersect each other almost every mile so as to form small basins, where there is no evident outlet. All rain is absorbed in the light sand of the soil, and no stream or watercourse is observable. These ranges of hills thus confusedly heaped together preserve a general direction running from south-east to north-west. Northwards they are more defined and open than to the south, where they are more crowded on one another. In a desert of this description water must be scarce, and when found it is uniformly brackish or salt. In the vicinity of the Runn water is found a few feet from the surface, but receding northward it is only procurable at a depth of two or three hundred feet. At first it is fresh, but imperceptibly it becomes brackish; yet almost always it affords a certain supply, which is increased after heavy rains. As a road this desert is impracticable to every animal except the camel. The inhabitants are few and lead nomadic lives, moving with their flocks and herds from spot to spot as water and forage fail. They are chiefly Mohammedans, with here and there a Hindu, who purchases and exports ghee, the sole product of this tract, which however is highly prized all over Hindustan.

The Runn, which extends between the Thurr and Cutch, is a tract of a very peculiar description, which has no counterpart on the globe. In length it extends from the Koree mouth of the Indus to the north-eastern part of the peninsula of Gujerat, a distance of about 200 miles; in breadth it is about 35, but there are various belts and ramifications, by the addition of which its area is increased to 7000 square miles. It is a perfectly level tract, on which no fresh water is found, and not even the most stunted vegetable. The soil is a mixture of mud, sand, and clay, and is covered with a thick incrustation of salt in the dry season, and during the south-western monsoon with water. Though somewhat higher than the common level of the sea, it is lower than the adjacent country. The southern banks are in many places very fertile, often sandy, and in some parts alluvial. On these water of excellent quality is found within a few feet of the surface, and tanks of rain-water, within 200 yards from the Runn itself, retain their sweetness for many months. There are some islands in it where fresh water occurs, but it is scarce. By some the Runn has been called a marsh, but it has none of its characteristics: it is not covered or saturated with water, but at certain periods; it has neither weeds nor grass in its bed, which, instead of being slimy, is hard, dry, and sandy, and of such a consistency as never to become clayey; nor is it otherwise fenny or swampy. That singular phenomenon called mirage nowhere produces such delusions as in this tract; the smallest shrub at a distance assumes the appearance of a forest.

Climate.—The climate of Sinde differs greatly from that of other parts of Hindustan. Though the south-west monsoons blow so hard along the shores as to prevent vessels approaching them from March to October, they do not bring any periodical rains. This probably is to be ascribed to the great distance of the large mountain masses, by which the wind is arrested. These do not occur before the wind reaches the Himalaya Mountains in the Panjab, and so far the monsoon does not extend. Rain is far from being frequent all over Sinde, nor does it occur at certain seasons, though storms may be expected at the end of June or the middle of July. There are also heavy falls at the vernal equinox. The delta frequently suffers from dearth, and sometimes for several years together; but the dews are heavy.

In Upper Sinde (Sirra), that is, north of Hyderabad, the natives of the country divide the year into three seasons, the spring, the hot season, and the cold season. The spring is of very short duration. The cold of the winter continues to the end of February, whilst the heat which commences in the middle of March is so intense, that it is but little exceeded by that of the following months. The temperate weather therefore between the extremes of the cold and hot seasons is very short. The hot season may be said to commence in the middle of March, and it continues generally without intermission till the end of August or the middle of September. The storms of thunder attended by rain which occasionally occur in June or July afford a brief cessation from the intense heat. A curious phenomenon is observed in this country on the setting in of one of these storms, it being always preceded for two or three days by a close atmosphere loaded with a fine description of sand which produces the appearance of a thick fog. But immediately previous to the bursting of a storm the air is literally darkened by immense volumes of sand driven in black masses before the wind, and obscuring the whole surface of the country. These sand-storms, which bear a great resemblance to the pamperos of Buenos Ayres, appear to be the natural effects of the desert countries surrounding Upper Sinde, over which no violent wind can pass without raising clouds of the shifting sands which cover their surface. The heat of Upper Sinde from the middle of April to the end of July is said to exceed that of any part of India, and the thermometer rises sometimes to 120° in the shade. The hot southerly winds which then prevail, continue to blow strong till midnight, but the mornings are generally cool. During the hot season the whole country, except the green forests of babool which skirt the banks of the Indus, presents a most arid appearance, which is only relieved by the annual rise of the river laying much of the country on each bank under water. In September and October, when it leaves the country, the water quickly dries up, and leaves a dry and cracked soil, except in those tracts which have been cultivated.

During the cold season, from October until the end of February, the climate of Upper Sinde is pleasant and salubrious. Frost and ice occasionally occur, and vegetation assumes the appearance of winter in the northern climates. The setting in of the cold and violent northern winds of November stops all vegetation except a few stunted tamarisk and babool bushes. Frost and blighting dews follow, and tend also to destroy a great portion of what otherwise would have been germs of vegetable life, which, if they chance to escape, rise only to be annihilated by the heats of April and May. The sun of Upper Sinde is singularly fatal in its effects, not only to the European, but the native constitution, and during certain periods of the year exposure to it is as much as possibly avoided by the people of the country.

As the country has only lately become accessible to Europeans, we have not yet received any series of meteorological observation extending over a whole year. But we have observations made at Kurachee on the sea-shore, and at Sukkur in Upper Sinde, for five months in 1844, and the result of them is very interesting.

	KURACHEE. Average Heat.			SUKKUR. Average Heat.		
	At sunrise.	At noon.	At 9 p.m.	At sunrise.	At noon.	At 9 p.m.
May . .	82°	86°	84°	88°	90°	94°
June . .	83	87	85	88	90	93
July . .	83	86	84	86	89	92
August .	80	84	81	84	86	90
Sept. . .	77	84	81	81	83	85

From this table we learn that the climate of Sinde is really hotter than in those parts of Hindustan which lie in the vicinity of the equator. The difference between the temperature of Kurachee and Sukkur ought also to be noticed. In the last-mentioned place the thermometer rises at noon from two to four degrees higher, though Kurachee lies nearly four degrees nearer the equator. This difference is to be ascribed to the desert countries by which Sukkur is surrounded. At this place the heat at 9 o'clock in the afternoon during the hottest months is three or four degrees more intense than at noon. This is solely to be ascribed to the hot southerly winds, which invariably continue to blow with considerable force till midnight.

Productions.—Sinde is rich in productions. Though its botanical wealth is not great, the agricultural products are numerous; all the grains and pulse common to India are grown. Rice is the staple in the delta and in the country between the Western Narra and the Indus, but in the other parts wheat and *joowaree* (large maize) are most extensively cultivated; next to these *Holcus spicatus* and *Phaseolus mungo.* Barley is grown in some districts; other articles are, *Phaseolus maximus*, *Ervum lens*, *Panicum italicum*, and *Cicer arietinum.* Indigo is largely grown in the north-eastern districts, but it is inferior to that of Bengal. Opium is cultivated near Shikarpore, and in some other districts. The sugar-cane is pretty generally grown throughout the whole of the province, but its produce is inferior to that of Northern Hindustan and the Panjab. Cotton is cultivated everywhere, but the best is grown in the northern districts. Tobacco of good quality is grown in the vicinity of Khyrpore. Hemp, cucumbers, water melons and musk melons, are extensively cultivated, as are also cummin and anise. There is a great variety of greens and spinach, and among the herbs eaten as vegetables, which grow spontaneously, are purslain and a species of amaranthus. The gardens produce carrots, turnips, radishes, onions, and several kinds of pumpkins, the egg-plant, three kinds of beans, peas, the *Momordica charantia*, dil, and mustard. The root of the lotus, which covers a great portion of the Lake of Munchar, is eaten. Sesamum, garlic, capsicum, and turmeric abound, and the last is used as a dye. Among the fruits are the date, mango, pomegranate, apple, grape, lime, citron, fig, apricot, pistachio, and keora nuts, several kinds of wild plum, and the tamarind, but most of these fruits are indifferent, and much inferior to those of Cabool. About Shikarpore and Bukkur the dates are so plentiful as to constitute the principal food of the lower classes, but they are inferior in size and flavour to the Arabian and Egyptian dates, though superior to those of Northern India.

The tamarisk is the most abundant production of the uncultivated parts, and almost as useful to the inhabitants as the bamboo to the native of India. The flowers form an article of export to Persia and the Panjab under the name of *sakoor.* When dried, pulverized, and infused in water, they yield a red fluid in which cottons are steeped to prepare them for dye. The wood supplies the inhabitants almost exclusively with fuel, and they employ it in the construction of houses, boats, and agricultural implements. The boughs are used for fences and cattle-sheds, to line wells and to thatch houses, and are plaited into baskets and mats for boats. The young shoots form a nutritious food for goats and cattle.

Dromedaries and asses constitute the principal means of conveyance by land. The dromedaries are reared in great numbers, but they are not equal in strength and size to those of the neighbouring countries. The horses of Sinde are small but hardy, and capable of enduring great fatigue. The best horses and asses are imported from Afghanistan and Persia. Mules are only kept at a few places. Immense herds of buffaloes graze on the banks of the Indus and its arms, and at other places common cattle. Ghee and hides constitute important articles of export. Sheep and goats are met with almost everywhere in Upper Sinde, and wool is exported from that tract which lies west of the Indus and north of Shikarpore.

Fowls are plentiful in some places; and tigers, wolves, jackals, wild hogs, porcupines, deer, and hares live in the woods. The tiger is only seen north of Bukkur. Hogs are very numerous, and very destructive to the fields. Among the amphibious animals are the alligator, otter, and badger. Badger and otter skins form an article of export to Afghanistan. Snakes, scorpions, and centipedes abound in rocky situations. Among the birds are a peculiar kind of myrops, or bee-eater, the black partridge, the grey partridge, the quail, two kinds of woodpecker, the razor-beak, several kinds of gulls, the pelican, and a species of plover. Geese, ducks, divers, and other water-fowl are plentiful on the banks of the Indus and those of Lake Munchar, as also on the swampy grounds; they form part of the food of the lower classes.

Fish abounds in the sea, the Indus, and the lakes, and the fisheries in the river and at its mouths are extensive, especially on the Gora Bank. The fins of small sharks, which abound near the Indus, form an article of export to China. Sixteen kinds of river-fish have been noticed. The most important is called *pulla*, and is a kind of carp, which is of delicious flavour, and caught in great quantities, but only in the four months that precede the swell of the river.

In the Murree and Boogtee hills, a spur of the Suliman range, sulphur and alum are found, and form articles of trade. In the delta and other places the soil is impregnated with salt, and some is collected for home consumption. Not a stone of any kind besides the limestone procurable at Sukkur and Roree is found in the level parts of the country.

Population and Inhabitants.—Sinde is a thinly peopled country; the whole population is stated not to exceed one million, but it appears to be underrated. The greatest part is a desert, on which only some nomadic tribes wander about with their herds, and the bulk of the population is settled on the banks of the Indus and on the canals which are fed by its waters. The best populated part is that which extends from Sehwun on the south to Bukkur and Shikarpore on the north.

The population is divided into three distinct classes, the Sindee, the Belooch, and the Hindu. In all the larger towns Hindus are most numerous, but in the smaller villages and agricultural districts the Sindees and Beloochees form the bulk of the people. The Hindus amount to about 200,000, the aborigines to 500,000, and the Beloochees to 300,000. The first are occupied entirely in trade; and in religion, as well as in habits, are perfectly distinct from the two latter, who are Mohammedans, agriculturists, the Beloochee as master and the Sindee as servant, yet there are many villages throughout Sinde wholly composed of natives, and others which are termed Belooch villages, from being the sole property of that nation. The Sindees are the less fixed part of the population, being scattered over the whole country, whilst many thousands lead nomadic lives, moving their villages with the rise and fall of the river Indus; they are also boatmen and fishermen. The Beloochees settled in Sinde preserved their clans, and maintained a degree of wild independence until the country was taken possession of by the British, but they are now entirely subjected. The greatest number of these clans and tribes are dispersed over the plain which lies between the Indus at Bukkur and the Bolan Pass, where till of late years they much impeded the passage of the caravans by their depredations. Some of these clans however have abandoned their wandering life, and become cultivators of the ground. The Beloochees speak a peculiar dialect, which however is considerably mixed up with Pushtoo and Persian. The language of the Sindees is quite different, and is written with peculiar characters, which apparently are a mixture of Guzuratee, Tamul, and Malayalin or a corrupted Marwari. There are no colleges, libraries, or public schools in Sinde, but the higher classes are well versed in Persian literature, and read and write that language.

Divisions and Towns.—Sinde is divided by the natives into two parts: Lar, which comprehends the southern portion as far north as Sehwun; and Sirra, which extends over the northern districts. Lar contains the three seaports of the country, Shah-Bunder, Vikkur, and Kurachee. Shah-Bunder, built on the Mull mouth of the Indus, is a small place, accessible for sea boats of 25 tons burden; it exports rice. Vikkur, situated on the Hujamree mouth, 25 miles from the sea, is larger, the river being navigable to that place for more than 35 miles for sea boats of 40 tons burden; it exports the produce of the delta. Kurachee, on the west, and about 30 miles from the most western mouth of the Indus, the Pittee, is built at the head of a creek, distant from the sea four miles. A harbour, at its entrance protected by a high headland, affords safe anchorage at all seasons to vessels of 300 tons, from whence large boats can pass close up to the town, which is built on a slightly rising ground and surrounded by a mud wall. The bazars are extensive, but the streets are narrow and filthy. The inhabitants amount to 14,000, and carry on an extensive trade by sea with India, Arabia, and Persia, and by land with Shikarpore.

Hyderabad or Haïderabad, the present capital and seat of the government, is built not far from the east bank of the Indus, between this river and the Fulailee branch, on a rocky eminence. It has no remarkable buildings, and the population, amounting to nearly 30,000 individuals, live in mud huts. Nearly halfway between Hyderabad and the Hujamree mouth of the Indus is Tatta, the ancient capital, which formerly was washed by the river, but is now five or six miles distant from it. It presents only a heap of mud ruins, and at present contains hardly 8000 inhabitants. Some good cotton fabrics are still made here. At nearly equal distances between Hyderabad and Tatta, on the western banks of the Indus, is the town of Jurruck, which is built on a hill 150 feet high, has a good bazar, and 4000 inhabitants. Meerpore is built on a canal which runs eastward from the Pinyaree branch into the interior and fertilizes a very large tract of country. This town has mud walls enclosing a circuit of three miles, and contains 10,000 inhabitants. There are more than 300 shops in the bazar. Omercote lies on the banks of the eastern Narra, and is built near the edge of the Thurr. It exports the produce of the desert, and contains 2000 inhabitants, chiefly Rajpoots.

Sirra, or Upper Sinde, contains several large places, especially on the west of the Indus. Sehwun, a large and formerly an important commercial place, is built on a rocky eminence not far from the place where the Arrul, or Western Narra, river joins the Indus. It contains between 10,000 and 12,000 inhabitants, and carries on an active trade with the fertile country to the north. The road between Kurachee and Shikarpore passes through this town. On the banks of a canal connected with the Western Narra is the town of Khyrgaon, which has seven mosques, and between 2000 and 3000 inhabitants, and is a thriving place. Farther north, on another canal of the Western Narra, is Larkhana, situated in the centre of a tract very productive in rice, which is exported in large quantities: it has 12,000 inhabitants. Shikarpore is the principal emporium of Sinde. [Shikarpore, P. C. S.]

On the eastern banks of the Indus stands the town of Roree, which is built on a rocky eminence, and contains about 8000 inhabitants. The streets are narrow and the houses built of sun-burnt bricks; many of them have three or four stories. Opposite this place, on an island of the river, is the fortress Bukkur, and on the other side the small town of Sukkur. Khyrpore, built on the canal of Meerwah, is a miserable-looking place, but it has for some time been the residence of one of the princes of the Talpoor family: it has 18,000 inhabitants; the bazar is spacious, and in the centre of it was the chief's residence. Subzulcote lies on the road leading from Roree to Bhawulpore; it has some trade in the produce of the country, especially ghee, hides, and opium.

Manufactures.—The manufactures of Sinde are not numerous; but they may be considered extensive, when the scantiness of the population is considered. Cotton-cloth of a coarse description is manufactured in the principal towns and villages, chiefly for home consumption, and a little is exported to Afghanistan and Persia. Among the silk manufactures those of Tatta have acquired a repute in India, especially the *lungis*, a rich fabric of silk, cotton, and gold, variegated in pattern and of close texture. Common lungis are fabricated in the villages of Raneepore, Gumbat, Khoora, and Duraz, situated near to one another, south of the town of Khyrpore. They are chiefly of cotton with silk borders, or a few of silk and cotton mixed, and inferior to those of Tatta and Bhawulpore. Some silk-cloths for the lower classes are woven at Roreo, Khyrpore, Shikarpore, and Sehwun. A peculiar kind of caps called Sinde caps are used by all people, and are chiefly made at Shikarpore, Roree, and Sehwun. In Lower Sinde are numerous tanneries, in which good shoe-leather is made. Shoes are exported to the neighbouring countries, but they are inferior to those of Bhawulpore. There are manufactories of paper and gunpowder in all large towns. The best paper-factories are at Shikarpore and Larkhana, but their produce is inferior to that of Cashmere and Delhi. Earthenware of a very superior description is made at Halla, a thriving town on the Indus, north of Hyderabad; in this place also a great number of Sinde caps are made.

Commerce.—Nearly the whole commerce of Sinde is concentrated in that of Shikarpore, under which head an account is given of it. Roree partakes of the commerce carried on between Shikarpore and Bhawulpore. Kurachee has some commerce with Arabia and Persia, but we have no account of its extent and the articles of export. A commercial relation between this place and Bombay has lately sprung up, which probably will become of importance.

History.—Sinde became first known to Europeans by the expedition of Alexander the Great, who followed the course of the Indus to its mouth, and constructed a fleet, which sailed along the coast and up the Persian Gulf to the mouth of the Euphrates. Tatta is considered as the Pattala, and Sehwun the city of Sambus mentioned by Arrian. [Alexander, P. C., p. 301.] It appears that at this time the country was divided among a number of independent sovereigns. Nothing is known of the political changes which took place in this part of the world before Mahmud of Ghizni conquered a part of Hindustan and subjected Sinde to his rule. Since that time up to the last century, Sinde appears always to have been an appendage to that empire, which comprehended the northern parts of Hindustan. But by the peace, which Shah Nadir concluded in 1739 with the Mogul emperor, Sinde was dismembered from it and became a part of the Persian monarchy. After the death of Shah Nadir (1747), Ahmed Khan founded the kingdom of Afghanistan, and Sinde was annexed to it, but the government of the country remained in the hands of a Beloochee family, the Kalhoras, who before that period had settled there and acquired great authority. Among the other Beloochee tribes settled in the country was that of the Talpoorees. Their chief, Byram Khan, was minister of Mirjan Surfuraz Khan, the Kalhora ruler, and was with one of his sons cruelly put to death by him in 1775. His death produced violent disturbances in Sinde, owing to the extensive influence which he had with his tribe and in the country. In 1781 Bejur, another son of Byram Khan, shared his fate by order of Mirjan Abdool Nubbee, uncle of Surfuraz Khan; this exasperated the Talpoorees, who rose in a body, and having dethroned the tyrant, raised Futtih Ulee, the grandson of Byram and chief of their tribe, to the government. Timur Shah, the sovereign of Afghanistan, to whom Sinde was tributary, endeavoured in the commencement of the struggle to restore the Kalhoras, but he had too much to do in the Panjab to assist them effectually, and he thought it prudent to invest the Talpoorees formally with the government. The Talpoorees divided the country into three unequal parts, and each of the three families of which it consisted received a portion of the country. These sovereigns were called Ameers.

When Shah Shoojah had lost the throne of Cabool, these sovereigns considered themselves as quite independent, and in 1834, when he made an attempt to recover the throne of Cabool, they refused him assistance, and opposed the march of his army through their territories. But he beat them in a battle fought seven coss from Roree, and obliged them to pay seven laks of rupees, and to farm from him the district of Shikarpore. Meanwhile Sir Alexander Burnes had visited Sinde (1831) and a treaty of commerce had been concluded between the Ameers and the British government, by which the Indus was to be open to British enterprise. No advantage to British commerce had resulted from this treaty, when the British resolved to replace the dethroned Shah Shoojah on the throne of Cabool. The Ameers, who were still to be considered as dependent on Shah Shoojah, did not oppose the march of the British army through their countries to the Bolan Pass, and surrendered by treaty the fortress of Bukkur and Kurachee to the British commander. When however the British armies in Afghanistan were nearly destroyed (in 1841), a spirit of insurrection manifested itself in Sinde among the Beloochee tribes, which however subsided when the British army had again advanced into Afghanistan. As the navigability of the Indus for flat-bottomed steam-boats was now ascertained, the British wished to retain the places in Sinde which were still in their possession, and they attempted to establish a free navigation by a new treaty. The Ameers, feeling their inability to resist, were willing to grant the proposed conditions, except one, that is, to permit a track-road to be made along the banks of the Indus, because such a road would partly destroy their shooting-ground along the river. They had here immense enclosures for the chace of wild animals; these enclosures were called *shikargurs*. It was however soon evident that this was only a pretext for breaking the treaty; the narrow track along the banks of the river, required for a track-path, would not have sensibly diminished the immense extent of their shikargurs. The negotiations were scarcely broken off, when an army of 22,000 Beloochees was ready to attack the British, and to expel them from Sinde. Sir Charles Napier, who commanded 3000 men, British and native troops, stationed at Bukkur and its vicinity, immediately put them in motion. He found the army of the Ameers near Meeanee, a place near the spot where the Fulailee branch leaves the Indus. On the 17th of February, 1843, an obstinate battle was fought at Meeanee, between the British troops and the Beloochees, and after a spirited resistance the Beloochees were completely defeated. They lost 5000 men, with all their artillery and military stores. The Ameers, six in number, came to the British camp and surrendered unconditionally. On the 20th of February their capital, Hyderabad, was taken possession of by the British. The Ameers were removed to Bombay and received liberal allowances. Thus Sinde became a portion of the British empire in India. Partial insurrections followed, especially among some of the most powerful Beloochee tribes, but the activity of the governor of Sinde, Sir Charles Napier, has put them down, and Sinde begins to enjoy that peace and prosperity which the British arms have conferred on or secured to other parts of Hindustan.

(Burnes' *Travels into Bokhara*, &c.; Wood's *Personal Narrative of a Journey to the Source of the River Oxus;* Hough's *Narrative of the March and Operations of the Army of the Indus;* Orlebar's *Visit of the Towns of Sehewan and Boobuk*, &c.; H. Knight's *Report on the Arrul River, Lake Munchar*, &c.; Macleod's *Report on the Nature and Extent of Gahra Creek;* Del' Hoste's *Route from Diesa to Sukhur;* Nicholson's *Some Account of the Koree, or Eastern Branch of the Indus;* Del' Hoste, *On the Advantages to be derived from establishing a Communication between Kurrachee and Jurruck;* Del' Hoste's *Route from the Town of Mandvee, in Cutch, to Hydrabad, the Capital of Sinde*, &c.; *Some Notes on Sinde*, by Winchester; the eight last-mentioned papers are found in the *Transactions of the Bombay Geographical Society*, 1841-1844. SINGLETON, HENRY, was born in London, 1766. His father died while he was an infant, and he was brought up by an uncle, William Singleton, a miniature-painter, who gave him instruction in drawing: the etchings of Mortimer also were favourite studies with him. At the age of eighteen he obtained the first silver medal for drawing in the Royal Academy; and in 1788 he obtained the gold medal for the best historical painting: the subject was Dryden's 'Ode on Alexander's Feast.' The medal was presented by Sir Joshua Reynolds, the last time but one that he presided at the distribution of the Academy prizes, and he is said on the occasion to have spoken in high terms of Singleton's picture.

Singleton painted portrait and history. The first remarkable picture which he produced was a large portrait piece of all the Academicians assembled in the Council Chamber; this picture was painted in 1793: the late Mr. Smirke was the last of the Academicians who survived; he died in 1845. Singleton was for more than half a century a constant exhibitor in the Royal Academy, and he exhibited many attractive pictures, both portraits and historical pieces, but it was not until 1807 that he put down his name as a candidate for the honours of the academy; he was however passed over, and he had too much pride ever to make a second attempt. He lived in the early part of his career in Norton Street, but removed in 1794 to the Haymarket, where he remained till his death in 1839.

Singleton was versatile and ready in invention, though his style of drawing was uniform; and both his pictures and his designs are very numerous; he was much employed by publishers. West has been heard to say—'Propose to Singleton a subject, and it will be on canvas in five or six hours.' The range of his works is very great, and comprises figure-pieces of almost every class; many of them have been engraved, and some on a large scale. Among his best works are Christ entering Jerusalem; Christ healing the Blind; John Baptizing; Coriolanus and his Mother; and Hannibal swearing enmity to the Romans; which have all been engraved on a large scale in Mezzotinto: further, the Storming of Seringapatam; the Death of Tippoo Saib; and the Surrender of Tippoo's Sons; of which there are large prints by Schiavonetti and Cardon. In his later years he was almost wholly employed upon a large series of illustrations from Shakspere, which are his principal works: the series includes several designs from each play, and many of them appear to be taken from the favourite dramatic representations of Shakspere which in Singleton's time were so abundant. He died on the 15th of September, 1839, and was buried in the vault of St. Martin's near his wife, who died nearly thirty years before. (*Art-Union Journal*, 1839.)

SIPHON BAROMETER. This instrument, which was invented by M. Gay Lussac, is very briefly indicated under BAROMETER (P. C.), and a representation of the tube is given in fig. 14 of that article; but, as this kind of barometer has of late been much employed (several of them, for example, were used by Col. Mudge and Mr. Featherstonehaugh in determining the levels along the ridge of heights in North America from the Penobscot and St. John's rivers to the Bay of Chaleurs), it may be advantageous to introduce here a short notice of the construction of the instrument.

The tube is hermetically sealed at both extremities, the end *a*, in the figure above referred to, being closed after the mercury is introduced, and at *g* a perforation is made, which is so small that, while it allows a communication between the air within and without, it does not, the affinity of mercury for glass being inferior to that of the particles of the fluid for one another, permit the mercury to escape. A scale of inches, each of which is divided into twenty equal parts, is placed by the side of the tube; and by means of a vernier each of these is subdivided into twenty-five equal parts. In the French Siphon Barometer the scale is divided into millimetres (each equal to about $\frac{1}{25}$ inch); and, by means of a vernier and microscope, each of them is divided into one hundred equal parts. Two indices with verniers are applied to the scale, by one of which (at *p*) is read on the scale the graduation corresponding to the top of the mercurial column in the shorter branch of the tube, and by the other (at *s*), is read the graduation corresponding to the top of the column in the longer branch. The zero of the scale is either between these indices or below the lowest of them; in the former case the sum and, in the latter, the difference of the readings is the true height of the mercurial column.

The siphon barometer has an advantage over those of a different kind in requiring no correction for capillary action, since such action equally affects both extremities *p* and *s* of the mercurial column: it is extremely light, and is easily brought to a position proper for the observation, but it requires careful management; and it is particularly necessary to avoid inverting it suddenly, since the glass is liable to be broken by the weight of the mercury when the latter strikes against the end of the tube.

SIPHON GAUGE, in Pneumatics, is a tube of glass bent so as to form two branches equal and parallel to one another, and each from 6 to 8 inches in length; the tube is hermetically closed at one end and left open at the other. One of the branches is filled with mercury; and, both of them being in vertical positions with the closed and open ends upwards, they are, by means of a brass stem terminating in a screw, affixed generally to the under surface of the table carrying the plate of an air-pump. The siphon is contained in a cylindrical glass vessel, a little exceeding it in length, which is closed at the lower and open at the upper extremity; and the open end of the cylinder is screwed to the table of the air-pump immediately about the orifice of a brass tube which passes through the pump-plate and opens into the receiver placed upon the plate, so that there is a free communication between the air in the cylinder, in the open leg of the siphon, and in the receiver. This gauge was invented by Mr. Smeaton.

The degree of rarefaction produced in the receiver of an air-pump is generally ascertained by means of a barometer-tube, open at both ends, the upper extremity being screwed directly under the orifice of a tube which, passing through the pump-plate, opens into the receiver, and the lower end being immersed in a small cistern of mercury; for the air in the receiver and that in the barometer tube having the same density, it is evident that, in proportion as the exhaustion proceeds, the pressure of the external atmosphere on the surface of the mercury in the cistern forces mercury into the tube, so that, if the exhaustion within the receiver could be carried far enough, the column of mercury would stand at the same height in the tube as it stands in the tube of an accurate barometer, and would indicate a perfect vacuum in the receiver. The degree of rarefaction in the receiver is consequently indicated by the number of inches expressing the height of the column of mercury in the tube. The siphon-gauge is also provided with a scale of inches which are decimally subdivided; but, while the pressure of the air in the receiver and in the open branch of the gauge is more than a counterbalance to the weight of the column of mercury in the closed branch, the gauge presents no indications: from the time however that, by continuing the process of exhausting the receiver, the pressure of the air in the open branch becomes less than the weight of the column of mercury in the other, that column descends in the latter branch and rises in the former; and then the degree of rarefaction in the receiver is indicated by the difference between the heights of the columns of mercury in the two branches of the siphon.

The Pear-Gauge alluded to in the article Air-Pump, P. C., and a description of which has been inadvertently omitted, was also invented by Mr. Smeaton for the purpose of determining the degree of rarefaction attained in the receiver of an air-pump. It consists of a small glass vessel nearly similar in form to a pear, or rather to a Florence flask, terminating in a cylindrical stem; the upper or smaller extremity is hermetically sealed, and the lower extremity is open. To the upper extremity of the gauge is affixed a wire which passes through an air-tight orifice at the top of the receiver on the air-pump so as to be capable of sliding up and down, carrying with it the gauge in the interior of the receiver; and under the lower extremity of the gauge is a vessel of mercury.

When the receiver has been exhausted as much as may be thought proper, the gauge is pressed down till its lower or open extremity enters into the mercury in the vessel below it; at which time, evidently, the air in the gauge will have the same degree of rarefaction as that in the receiver. Then, on admitting the air into the receiver, its pressure on the surface of the mercury in the vessel about the bottom of the gauge will force mercury into the latter, when the air which, in its rarefied state, occupied the whole interior of the gauge, will be brought to the same density as that in the receiver, and consequently as that of the atmosphere, and will occupy only a small space at the upper extremity of the gauge. A graduated scale serves to show the volume of the air in its compressed state; and this, being compared with the known volume of the whole gauge, serves to determine the degree of rarefaction which had been produced by the partial exhaustion of the receiver.

At the time when the siphon-gauge and pear-gauge were invented, it was the custom to place the receiver of the air-pump on a ring of leather soaked in oil and laid on the pump-plate, in order to prevent the atmosphere from entering the receiver during the process of exhaustion; when, on the air within being rarefied, a quantity of elastic vapour extricated from the moisture occupied the receiver; now the barometer and siphon gauges show how much the quantity of elastic fluid, air, or vapour, is diminished by the partial exhaustion; but, in employing the pear-gauge, which, during the process of exhaustion, contains a portion of the elastic vapour, on re-admitting the air into the receiver that vapour is immediately reduced to water, and the gauge shows only the quantity of pure air which is left in the receiver after the exhaustion. This discovery was made by the Honourable Mr. Cavendish on witnessing some experiments made by Mr. Nairne, a distinguished optician, in which it was observed that the pear-gauges always indicated much higher degrees of rarefaction than were given by the barometer or siphon gauges. The justness of the explanation proposed in order to account for this discrepancy was soon afterwards proved by Mr. Nairne by means of experiments made with the different kinds of gauges, in which every possible precaution was taken to exclude moisture from the interior of the receiver. The pear-guage was then found to show very nearly the same degrees of rarefaction as were exhibited by the other gauges.

It may be observed here that the pear-gauge is the instrument by which the force of elastic vapour was discovered.

SIROCCO is the name given to a hot and suffocating wind which appears to originate with the rarefied air in the sandy deserts of Arabia, about the season that the overflowing of the Nile commences; it extends eastward over Arabia, Persia, and some parts of Hindustan, and it is felt, but with less inconvenience, in Italy and Spain. This wind is probably only one of the modifications of that which, in different countries, is called *samoom*, *simoom*, *samm* or *samieli*, *khamsin*, and *harmattan*. [Samieli, P. C.]

Under Sirocco, P. C, reference is made to the article Wind; but by inadvertence the notice was, in the place referred to, omitted.

SISMONDI, JEAN CHARLES LEONARD SIMONDE DE, was the son of a Protestant minister of the canton of Geneva; he belonged to an antient family of Tuscan origin, which has become extinct by his death. His ancestors, who were attached to the Ghibelline party, were expelled from Pisa in the fourteenth century, and took refuge in France, where they remained till the revocation of the Edict of Nantes, when they settled at Geneva. Sismondi was born at Geneva on the 9th of May, 1773. He was first placed at the College of Geneva, where he acquired a sound knowledge of classical literature. From the college he was removed to the Auditoire, where he was enabled to pursue a more extended course of study. His education being completed, he was compelled by the change of fortune which befel his family, owing to the events of the French revolution, to enter as clerk in the counting-house of the firm of Eynard and Co. at Lyon. Filial obedience induced him to undertake a duty to which he was unfitted by his previous habits, and which the highly cultivated disposition of his mind rendered scarcely supportable. The moral training, however, which he underwent in mastering the difficulties of his new situation, and in the regular discharge of its duties, produced an effect which, in after life, he acknowledged to have been eminently beneficial; to it he was accustomed to ascribe his taste for the science of political economy, which predominates in his historical writings. The revolutionary troubles, which overtook the city of Lyon in 1792, compelled Sismondi to return to Geneva: this city however, having become annexed to the French republic, proved no asylum from political persecution; his father and himself, though they had carefully abstained from interference in public affairs, were imprisoned; but, as no charge could be brought against them, they were soon after liberated. In February, 1793, he accompanied his family to England, where they intended to settle; but the dilapidated state of his father's fortune rendered their residence in London one of privations to which they had not been accustomed, and, after a year's residence in different parts of England, they returned to their native city. This sojourn in England Sismondi turned to profitable account; besides acquiring a sound knowledge of the language, and, studying the English constitution, he examined our commercial and agricultural system, and was thus enabled, when in after-life he published his peculiar views on political economy, to speak from actual knowledge of the merits and defects of the internal policy of England. His return to Geneva afforded him the painful opportunity of studying the science of politics in a far ruder school; it was his lot to behold the peaceful commonwealth where his fathers had enjoyed liberty of conscience and freedom of speech, suffering under the despotism of what was, by courtesy, termed a popular rule. The frenzy of revolutionary feeling had spread over the city of Geneva, and had converted its quiet money-making citizens into turbulent and suspicious demagogues. In the hope of finding a more quiet abode, and in order to afford a shelter to a friend, M. Caila, who had been proscribed by the revolutionists, the family of Sismondi removed to Châtelaine. The capture of their unfortunate friend, and his immediate execution in their presence, rendered their residence at Châtelaine as distasteful as it was dangerous. Having sold the estate they possessed there, they determined upon emigrating to the country of their ancestors, and arrived at Florence in October, 1795. They invested the produce of the estate which they had sold in purchasing a small farm at Valchiusa, near Pescia, a spot selected by the young Sismondi. Here he divided his time between the active superintendence of his farm and the preparation of a work which he had projected during his travels, 'Recherches sur les Constitutions des Peuples Libres.' These researches, though they have not been published, are generally regarded as the groundwork of his subsequent historical writings; the ideas which he adopted in them have been amplified and illustrated in the work of M. de Tocqueville on the democratical governments of America.

In 1801 appeared at Geneva the first published work of Sismondi, which he had written during the latter part of his stay of Italy; it was entitled 'Tableau de l'Agriculture Toscane.' To his study of this subject may perhaps be attributed the prominence which, in his writings on political economy, he gives to agriculture. Eminently practical in its details, this interesting treatise discards even the appearance of theory, and contents itself with portraying in true but lively colours the actual state of the country and the manner of life of its inhabitants. The year previous to the publication of this work Sismondi and his parents had again returned to Geneva, where they lived on the remnant of a once large property, which his father had sacrificed to his confidence in the financial measures of Necker. [Necker, P. C.] He published, in 1803, his essay on political economy, with the title 'De la Richesse Commerciale, ou Principes d'Economie Politique appliquée à la Législation du Commerce.' This work he afterwards entirely remodelled, and, in 1819, published it under the title 'Nouveaux Principes d'Economie Politique.' The views of Adam Smith [Smith, Adam, P. C.] are almost implicitly followed in this treatise, and, as they happened to coincide with the popular notions on the subject, they brought the writer into repute. The vacant chair of political economy in the university of Wilna was soon after offered to him by Count Plattner, who came purposely to Geneva to urge in person his proposal. Though the offer was advantageous in a pecuniary point of view, and the acceptance of it on that account urged upon him by his parents, it was declined by him from his dislike to teaching. It was at this period that Sismondi began to apply himself in earnest to historical investigations, and, by the advice of his mother, a woman of cultivated mind and sound understanding, to devote himself chiefly to the study of history.

His residence at Geneva, though it was enlivened by his enjoying the intimacy of several literary persons, such as Benjamin Constant and Madame De Stael, could not deliver him from the desponding feelings which are so common to the young author, and, at the suggestion of his excellent mother, he was induced, in 1805, to accompany Madame De Stael in a tour through Italy. Sympathy of literary tastes had produced the sincerest friendship between these two distinguished writers; the influence of the scenes they visited together in that classical country, and the poetic charm cast upon them by the conversation of the authoress of 'Corinne,' [Stael, Anne Germaine de, P. C.], fixed the determination of Sismondi to consecrate the past glories of the land of his ancestors in the page of history. The first-fruits of his historical studies appeared in the first two volumes of his 'Républiques Italiennes,' which were published at Zürich, in 1807. His publisher, Gesner, is stated to have dealt hardly with him, and the publication of the subsequent volumes, the last of which appeared in 1818, was transferred to Treuttel and Würtz. A new and more complete edition, in sixteen volumes, appeared during the years 1825 and 1826, both at Paris and Brussels. In the composition of this his first and most important historical work, Sismondi has been blamed for not having made a sufficient use of public archives and private collections; he is, however, acknowledged to have carefully consulted every printed book from which he could derive information It is to this conscientious examination of authorities, and the absence of political prejudices, that the value of the 'Républiques Italiennes,' as a faithful historical record, is chiefly due. The style is pleasing and attractive, but, though a good French scholar, he never hesitates to use an unauthorised or even ungrammatical phrase in order to convey his meaning with greater precision. The part of the work, which is generally considered to be most defective, is that which treats of the development of the republican constitutions and the modifications which they afterwards experienced; for the full accomplishment of this portion of his task, Sismondi is said not to have possessed sufficient legal knowledge. While engaged in writing this history he was likewise employed as a contributor to the 'Biographie Universelle,' which was publishing in Paris under the editorship of Michaud. The biographies which he contributed to this valuable work were those of the principal historical personages of Italy, for the composition of which the researches he was then making in Italian history eminently fitted him. Sismondi was accustomed regularly to read the manuscript pages of his history to his mother, and, with the humility of filial obedience, to lend an attentive ear to the corrections she suggested. To her pious care he has gratefully acknowledged himself not a little indebted for the eminence he attained as an author; in his desponding moments she was ever a present comforter, and the rough path to literary fame was smoothed by her counsels and cheered by her example. In 1811 he delivered at Geneva a course of lectures upon the Literature of the South of Europe, which were printed at Paris in 1813, and a third edition, in four volumes, was published in 1829. It comprises an introductory history of the decline of the Latin language and the formation of the languages of Southern Europe, and presents us with a history of Italian, Spanish, and Portuguese literature to the end of the eighteenth century. The portion of this work which treats of the literature of Spain and Portugal is the most imperfect, as the information which it contains is derived from secondary sources.

In 1813, Sismondi visited Paris, which at that time presented an interesting study for a political observer; he there formed an acquaintance with an illustrious brother historian, M. Guizot, who, when, in 1819, he became Minister of Public Instruction, made him the offer of a valuable professorship at Paris, which, however, he declined. During the Hundred Days a series of letters, which he published in the Moniteur, on the French Constitution, attracted the attention of Napoleon, who requested an interview with the author. The interesting details of this interview were immediately after reported by Sismondi to his mother, and an abridgment of them may be seen in the article of the 'Quarterly Review' referred to at the end of this article (p. 318-321).

In the year 1819 Sismondi began his longest, and, as it is by some considered, his best work, 'L'Histoire des Français,' which occupied him till the close of his life. It was not at first the intention of the author to bring down this history to a later period than the Edict of Nantes, which terminates the twenty-first volume; he was induced to continue it, on a more abridged scale, to the period of the Revolution, but he carried it no further than the year 1750. His principal motives for undertaking this important work were, the connection of French history with Italian, and the fact that French literature possesses no history of the kind which can be looked upon as a work of authority. To these motives may be added the great interest which Sismondi evinced in the affairs of a country which he had adopted as his own. He has not, however, allowed his bias in favour of France and the French to interfere with the investigation of truth and the declaration of it. So little indeed did he seek to gratify in it the national vanity, that he has not hesitated to expose the weak foundation on which had rested undisturbed for centuries many traditional incidents in the history of France, which, as they responded to the popular feeling, had been fondly cherished in the memory of the people.

The history is divided into eleven periods: the first three treat of the early races of French kings, the Merovingian, Carlovingian, and early Capetian races, to the accession of Louis IX.; the fourth brings it down to the death of Charles IV., 1328; the fifth, from the accession of Philip le Valois to Charles V., 1422; the sixth, from 1422 to 1515; the seventh, and most interesting, presents us with the reign of Francis I., and is a beautiful specimen of historical portraiture, in which the colours, though lively and pleasing, are never exaggerated; the eighth embraces the period of the religious wars of France, which are treated of with an impartiality scarcely to be looked for in a Genevan Protestant; the ninth is the reign of that favourite of French kings, the first of the Bourbons, and here, more perhaps than in any other part of his writings, may be seen the honest spirit by which he was actuated; indeed in his endeavour to be impartial, he has perhaps sometimes been unnecessarily severe on the character of Henry IV. The last three periods embrace the history of France under the Bourbons to the latter period of the reign of Louis XV. [France, P. C.]

In the year 1830 Sismondi published, in 'Lardner's Cabinet Cyclopædia,' an abridgment, in English, of his 'Républiques

Italiennes;' a French edition of this work appeared in Paris in 1832, under the title 'Histoire de la Renaissance de la Liberté en Italie.'

The last and least known of his historical works is entitled 'Histoire de la Chute de l'Empire Romain et du Déclin de la Civilisation.' This work, which was published at Paris in 1835, embraces the history of 750 years, from A.D. 250 to 1000.

The other writings of Sismondi are, 1, 'Julie Sevère,' an historical novel in imitation of Sir Walter Scott, in which he describes the condition of Gaul at the time that Rome was a prey to the barbarians; it was published at Paris in 1822: 2, 'Études sur les Sciences Sociales,' published at Paris in 1836; this work contains a collection of articles which he had previously contributed to various periodicals: 3, 'De la Vie et des Ecrits de Th. Mallet,' 1807, in 8vo.

The above is a brief account of the writings of Sismondi; but it would be doing injustice to his memory to omit some of the details of his private life and character which have been recorded by his biographers. Surrounded by a circle of all that was most distinguished in literature, he was conspicuous among them for the amiability of his disposition and the devotedness of his friendship. Though he never reached a state of affluence, he was liberal in contributing to the necessities of the poor, and he is said to have spent considerable sums in the furtherance of causes which had political freedom for their object. Fond of society, he never allowed his inclination to enjoy it to trespass upon the time he had marked out for study, usually nine or ten hours a day. The time he allotted to this object was never broken in upon, except to assist a friend or to alleviate misfortune. As a public character he displayed considerable firmness in the maintenance of his political opinions, and he was careless of the unpopularity which this conduct often entailed upon him.

About the year 1840 he felt the first symptoms of the cruel malady to which he fell a victim, which was a cancer in the stomach. A short journey which he made to England appears to have aggravated his disease; but his sufferings, though intense, scarcely interrupted his application to study, and he may almost be said to have died with the pen in hand. Indeed three days before his death, which occurred on the 25th of June, 1842, he was occupied in correcting the last proof sheets of his 'Histoire des Français.'

Sismondi married, in 1819, Miss Allen, sister to the late Mr. Allen of Cressilly, member of parliament for Pembrokeshire, and to the second wife of Sir James Mackintosh. [MACKINTOSH, SIR JAMES, P. C.]

The following extract, which we translate from the conclusion of 'L'Histoire des Français,' will be found an interesting supplement to this biographical sketch of Sismondi:—'My life has been divided between the study of political economy and that of history; thus, in this long narration of events, the political economist will ever be discovered conjointly with the historian. I have endeavoured to prevent those lessons being lost which experience has given us on the causes which contribute to create and maintain the prosperity of nations; but, above all, I have always looked upon wealth as a means, not as an end; I have always inquired respecting it, whether it really advanced the well-being of all classes, and I trust my readers will discover, in the constant interest I have taken in the welfare of the cultivator of the land, in the artisan, and in the poor, who has to earn his bread by the sweat of his brow, that all my sympathies belong to the needy and suffering classes of the community.'

An interesting account of the private life of Sismondi may be seen in the 'Magasin Pittoresque,' for 1843, pp. 314-319. For a critical detail of his writings we refer our readers to the 'Quarterly Review,' vol. 72, pp. 300-356, and the 'Foreign Quarterly Review,' vol. 30, pp. 258-261.

SKIN, DISEASES OF. The healthy functions of the skin and its structure have been described under SKIN, P. C. Most of the diseases of the skin have been described in this work under the head of their particular names. In this article we shall supply an arrangement of them, and a description of those which have been omitted. The following arrangement is that adopted by Rayer in his work on diseases of the skin.

Class I. INFLAMMATION OF THE SKIN.

Order 1. *Exanthematous.*—Rubeola, Roseola, Scarlatina, Urticaria, Erythema, Erysipelas.

Order 2. *Bullous.* — Vesication, Ampullæ, Pemphigus, Rupia, Zona.

Order 3. *Vesiculous.*—Herpes, Psora, Eczema, Miliaria.

Order 4. *Pustulous.*—Varicella, Variola, Vaccinia, Vaccinella, Ecthyma, Cuperosa or Acne, Mentagra, Impetigo, Tinea, Artificial pustules.

Order 5. *Furunculous.*—Hordeolum, Furuncle, Anthrax.

Order 6. *Papulous.*—Strophulus, Lichen, Prurigo.

Order 7. *Tuberculous.* — Lupus, Cancer, Elephantiasis of the Greeks.

Order 8 *Squamous.*—Lepra, Psoriasis, Pityriasis.

Order 9. *Linear.*—Fissures.

Order 10. *Gangrenous.*—Malign pustules, Carbuncle of plague.

Order 11. *Multiform.*—Burns, Frost-bite, Syphilitic eruptions.

Class II. CUTANEOUS AND SUBCUTANEOUS CONGESTIONS, AND HÆMORRHAGES.

Cyanosis, Vibices, Petechiæ, Purpura Hæmorrhagica, Ecchymosis, Dermatorrhagia.

Class III. NERVOUS DISEASES OF THE SKIN.

Exaltation, Diminution, Abolition of the sensibility of the skin, without appreciable alteration in the texture of this membrane.

Class IV. ALTERATIONS IN THE COLOUR OF THE SKIN.

Order 1. *Decoloration.* — Leucopathia, partial, general; Chlorosis.

Order 2. *Accidental Colorations.*—Ephelis, Lentigo, Chloasma, Melasdermis, Icterus, Nævus maculosus, Argentism.

Class V. MORBID SECRETIONS.

Ephidrosis, Acne, Folliculous Tumours.

Class VI. DEFECTS OF CONFORMATION AND TEXTURE.

Distention of the Skin, Cicatrices, Vegetations, Nævus hæmatodes, Subcutaneous vascular tumours, warts, pearly granulations; Corns, Ichthyosis, Horny appendages.

The following are the diseases which appear to demand further notice:—

Urticaria (Nettle-rash, Purpura urticata, and Febris urticata). This disease has acquired its name from being attended by prominent elevations of the skin, called wheals, resembling those produced by the sting of the common nettle. The wheals are either paler or redder than the surrounding skin, and seldom permanent, they return in paroxysms, and are attended with a painful sense of itching.

This disease is produced directly by the application of the glandular hairs of species of Urtica and Loasa, the hairs of some caterpillars, and the secretion from the surface of the Acalephæ. Under these circumstances it seldom continues for more than a few hours, and seldom requires anything more than the application of a cooling lotion, although instances are related of very severe inflammation coming on from the stings of some of the tropical species of nettle.

Urticaria is more frequently symptomatic or attendant upon some other derangement of the system. It not unfrequently appears after partaking of indigestible food of any kind, and some persons are liable to it after particular kinds of food. The kinds of food which seem to favour the development of this disease are shell-fish, lobsters and crabs, mushrooms, the spawn of some fishes, &c. Attacks brought on in this way are also generally temporary, and disappear with the cause of the disease. If taken sufficiently early, an emetic of ipecacuanha and tartarised antimony will sometimes afford immediate relief. In other cases a purgative will relieve.

The nettle-rash is frequently an attendant upon prolonged gastro-intestinal irritation, and although disappearing from time to time, cannot be got rid of independently of the primary disease. In these cases the causes of the gastro-intestinal disturbance, such as indulgence in eating and drinking, should be sought out, removed, and medical treatment applied to the organs disordered. Sometimes the gastro-intestinal irritation proceeds to gastro-enteritis, which can only be subdued by active treatment, and in this way alone can the Urticaria be got rid of. This disease has also been observed to accompany ague or intermittent fever, and to yield only by treatment adapted for that disease.

Eczema, Heat-eruption, is an inflammation of the skin, characterised at the outset by small non-contagious vesicles, the fluid of which is finally reabsorbed; by superficial excoriations, attended by a serous discharge, or by a squamous condition of the skin. This disease may be confined to one particular part of the body, or it may attack the whole surface. It may arise from a local cause, as from the direct rays of the sun, or from some general disturbance of the system. The vesicles may be only few and the surrounding skin only slightly inflamed and confined to a very limited surface, or the vesicles may be numerous, the excoriations painful, the surface attacked extensive, and the tendency to inflammatory action in the skin so strong as to produce pustules instead of vesicles. Such are the characters of the three forms of Eczema usually described by writers on diseases of the skin,—*E. solaris*, *E. rubrum*, *E. impetiginoides*. Eczema is more likely to be confounded with itch than any other disease, from which it may be distinguished by its non-contagiousness and the very different parts of the tegumentary system which it occupies.

There is a form of Eczema which comes on from the exhibition of mercury and the external application of other medicines, and which frequently arises from the carelessness of the person attacked, which is called *E. mercuriale*.

The treatment of Eczema must be adapted to the causes which have produced it. According to the general state of health of the person attacked, the disease will be either acute or chronic. Slight cases of acute eczema require only a simple treatment, a light diet, saline purgatives, and cooling or emollient applications to the part being all that is required. In some cases the inflammation is great and the pain intense, and where this occurs bleeding and a more active general treatment should be had recourse to. Chronic eczema is much more difficult to treat. The general health demands attention, and alteratives and tonics, according to circumstances, are demanded. Astringent lotions and ointments, such as the preparations of silver, zinc, alum, &c., may be used; sulphurous baths, and various mineral waters have also been recommended in old chronic cases of this disease. The tincture of cantharides and the preparations of arsenic have also been employed in the chronic forms of eczema.

Miliaria (Febris miliaris, Miliary Eruption) is also a vesiculous disease of the skin, and is described as contagious. It is accompanied with inflammation of the gastro-intestinal mucous membrane, and is accompanied by profuse sweating. Miliaria as an epidemic and independent disease is only seen between the 43rd and 49th degrees of latitude, and its existence has been doubted by some nosologists. It frequently accompanies other diseases, and retires with the cessation of the disease which it attends. When the fever accompanying it is slight it requires little treatment. Gentle purgatives and demulcents will be found sufficient. In the epidemic form however it is often a formidable disease, and requires the same treatment as other epidemic contagious fevers.

Rupia is a bullous disease accompanied with small bullæ, the bases of which are inflamed. The bullæ are not numerous but flat and full of a serous fluid, which becomes thick, puriform, or sanguinolent, and drying up forms blackish thin or prominent crusts. It is commonly developed on the legs, sometimes on the loins or thighs. It attacks children that are of a delicate constitution, and persons weakened by other diseases. The scrofulous are peculiarly liable to it, and it comes on after hard living, insufficient food, exposure to cold, and vicious courses of life. It is generally indicative of an imperfect state of nutrition, and the treatment consists not so much in applications to the diseased skin, as in giving tone to the system by nutritious food, and tonic and alterative medicines.

Ecthyma (Pustulous Scale) is a non-contagious inflammation characterised by large pustules raised upon a hard circular base of a bright red colour. The pustules are of the largest size, the *phlyzaciæ* of Willan, so that ecthyma bears the same relation to pustular diseases that rupia does to vesicular ones. In some stages in fact it is difficult to distinguish one of these diseases from another. Willan describes four varieties of ecthyma, but Rayer recognises but two, acute ecthyma and chronic ecthyma. Acute ecthyma is a comparatively rare disease; it generally appears on the neck and shoulders, and runs its course in a few days. This form requires little treatment; light diet, diluent drinks, mild purgatives, and warm or cold applications to the part will suffice.

In chronic ecthyma the same kind of pustules appear, which discharge their contents in the course of two or three days, leaving behind them thick brown adherent crusts, which sometimes fall off, leaving an ulcer behind, but more frequently leaving a cicatrix. This form of the disease comes on in scrofulous and debilitated subjects, and is frequently modified by a syphilitic taint. Just in proportion to the intensity of the constitutional derangement will be the duration and extent of the disease. In its treatment the general health must be especially attended to; it is more a disease indicating a want of action than of increased action, and alteratives, tonics, nutritious diet, change of air, and sea-bathing are more beneficial than the opposite kind of treatment.

Acne (Gutta rosacea, Rose-Drop) is a chronic inflammation of the skin characterised by an eruption of small pustules surrounded by a hard and inflamed base. They are generally observed on the cheeks, nose, and forehead, and sometimes on the ears and neck. The pustules are sometimes single, constituting the simple form of the disease; at other times they become hardened and the whole skin becomes red, when the disease has different designations. This disease has its origin in the oil-tubes, and arises from an obstruction to the performance of their functions, which produces inflammation. The oil-tubes of the face are very liable to obstruction from exposure to the air and other causes, and may be frequently observed tipped with a little black spot, and when pressed they give out a quantity of their oily secretion in the form of a little maggot. They were at one time supposed really to possess an independent animal life. Although this is not the case with the masses of oil in question, it is now known that a little acarus takes up its abode in these oil-tubes, and is well known to zoologists under the name of Demodex Folliculorum. This little insect may then in some instances be the exciting cause of acne.

In the treatment of acne, regard must be had to the general health. It is frequently connected with a diseased state of the gastro-intestinal mucous system, which requires attention. Where it is connected with general debility from a rapid growth, or with a scrofulous constitution, tonics and alteratives with sea-bathing and regular exercise will be found of service. As external applications, the preparations of copper, zinc, and mercury, have been found most efficient. Where the face is much swelled and inflamed, fomentations will be of service previous to the use of the astringents.

Lichen is a papulous disease, characterised by the simultaneous or successive eruptions of red itching pimples, scattered or disposed in groups over the whole body. It is in the adult what Strophulus is in the child. [STROPHULUS, P. C.]

Diseases of the skin are very numerous and prevalent, but in the case of the majority which occur they arise from the neglect of some of the conditions necessary for the health of the skin. These conditions in general are, good nutritious food, which should be properly digested; a due amount of warm clothing, especially during changeable and cold weather; constant and regular exercise, so as to keep the skin as an excretory organ in perfect order; and daily ablution of every part of the body, without which and the occasional use of soap it is vain to expect to be free from many forms of skin disease.

SKY is the name commonly applied to the infinite space which surrounds the earth, and of which the visible portion, above the horizon of a spectator on any part of the earth's surface, appears to have the form of a concave segment less than a hemisphere. [ENLARGEMENT OF OBJECTS, P. C. S.]

The earth is surrounded by the atmosphere, which is charged with vapours and terrestrial particles; and by the reflections which, in consequence, the rays of light experience in passing to the spectator, the sky assumes the variously-coloured tints under which it is seen.

It is known from many experiments that pure air is devoid of colour; and the observations of M. de Saussure (*Voyages dans les Alpes*) have established the fact that, in an atmosphere free from vapours, such objects as mountains covered with snow, when seen by a spectator at a distance of 20 or 30 leagues from them, by light which is merely transmitted through the air, appear to be white: the same philosopher has observed, however, that at times when the sun is seen to set behind a mountain so covered, the blue rays reflected to the spectator from the parts of the atmosphere on each side of the mountain, cause the latter to assume a blue colour, the direct light from the mountain not being strong enough to interfere sensibly with the reflected rays.

When the sun has considerable elevation, the rays of light which pass through the earth's atmosphere almost perpendicularly to its surface, undergo scarcely any change of direction; but, with respect to the light from the sun which enters obliquely into the atmosphere, the violet and blue rays, or those which are conceived to have less momentum than the red rays, are partially arrested in their course, and are reflected in abundance to the earth; they thus, when the atmosphere is nearly free from clouds, give to the parts of the sky which are remote from the apparent place of the sun an azure tint.

The blue colour of the sky about the zenith increases in proportion as the sun is nearer the horizon; the rays then fall with greater obliquity upon the parts about the zenith, and, at the same time, the blue rays in the beams of light which traverse the atmosphere in directions nearly parallel to the horizon are absorbed, so that those only, as the yellow and red, which have greater momentum, arrive at the eye of the spectator: in consequence of this the sky near the horizon, on the side which is towards the sun, appears to be highly tinted with those colours.

Many of the blue rays, after reflection from the upper parts of the atmosphere, are however absorbed in passing down to the earth; and hence it is that the blue tint of the sky is found to increase in intensity as the spectator ascends above the general surface of the earth. On the top of high mountains, or in balloons at great elevations, the quantity of blue rays which, after reflection in the atmosphere, enter the eye is very great; and the blueness at length becomes a deep black-ground on which the stars appear to shine at all times with as much lustre as at midnight on the earth, during the absence of the moon. It is hence evident that if it were not for the innumerable reflections of the light from the sun or moon, which take place in the atmosphere, total darkness would prevail from the instant of sun-set to that of sun-rise; and even during the day, darkness would ensue, so that the stars would become visible, every time that the sun is obscured by a cloud.

That the blue tint of the sky is caused by light reflected in the atmosphere is abundantly evident from the fact that the light of the sky is found to be polarized: this quality in light, being a result of its reflection. Dr. (Sir David) Brewster, who first made the observation, has moreover ascertained that the light of the sky consists of two parts, one blue and the other nearly without colour; and he discovered that these lights are polarized in different directions. (*Treatise on New Philosophical Instruments, p.* 349.)

The hypothesis that the azure colour of the sky is caused by reflections of blue rays, was at one time objected to on the ground that the shadows of opaque objects, placed on white paper and exposed to the sun's light, should always appear to be blue, since the part of the paper which is in shadow can only be visible by the light of the sky reflected from thence. This phenomenon is, in fact, frequently observed; but M. de Saussure, while admitting that he has often perceived the shadows of objects to be bluish in the mornings and evenings on the general surface of the earth, states that in alpine regions, where the sky is intensely blue, the shadows of objects never appear to be so: he adds that, of fifty-nine observations made for the purpose of ascertaining the colours of shadows on the mountains, thirty-four showed them to be a pale violet, eighteen showed them to be black, six a pale blue, and once they appeared to be yellowish. It may be inferred, therefore, that shadows cast by opaque objects are so much affected by the colours of the neighbouring objects that a right judgment can scarcely be formed of the colour which they receive from the light of the sky. [ACCIDENTAL COLOURS, P. C. S.] To the like interference must be ascribed the variously-coloured shadows which were observed by M. Bouguer. (*Essai d'Optique;* and M. Buffon, *Mémoires de l'Académie des Sciences*, 1748.)

Between the tropics the transparency of the atmosphere is far greater than it is, in general, in regions beyond them towards the north or south; hence the sky there is almost always serene and intensely blue, while the clouds near the setting sun are brightly tinted with the prismatic colours. The skies of the south of Europe and some parts of North America are distinguished for their serenity and beauty; but, in these respects, they are said to be inferior to the skies over the islands in the Pacific Ocean.

For the description of an instrument invented in order to measure the intensity of the blue colour in the sky, see CYANOMETER, P. C. S.

SMEDLEY, EDWARD, Reverend, was born about the year 1789, and was the son of the Rev. Edward Smedley, who died in 1825, after having been one of the ushers of Westminster school for nearly half a century. The elder Smedley was the author of 'Erin, a Geographical and Descriptive Poem,' published by subscription in 1810. His son was admitted a king's scholar at Westminster in 1800; and thence he removed in due course to Trinity College, Cambridge. He took his degree of B.A. in 1809, as tenth Junior Optime, and, having obtained one of the Member's Classical Prizes in 1810, and again in 1811, was then elected a fellow of Sidney College. He obtained no fewer than four of the Seatonian Prizes for English poems; the first on the Death of Saul and Jonathan, 1814; the second, on Jephtha, 1815; the third, on the Marriage at Cana, 1827; the fourth, on Saul at Endor, 1828. In 1829, he was collated by Bishop Tomline to a prebend in the cathedral church of Lincoln, the value of which, however, was only 14*l.* a-year; and this was the only ecclesiastical preferment he ever obtained. Besides his Seatonian Prize poems, he was the author of a poem entitled 'Prescience,' and of some others; and also of a 'History of the Reformed Religion in France,' in five vols. 12mo., and of one volume of a History of France, published under the superintendence of the Society for the Diffusion of Useful Knowledge. At the time of his death he was editor of the 'Encyclopædia Metropolitana;' and he contributed several articles on French biography and English and Roman literature to the earlier volumes of the present work. His death took place at Dulwich on the 29th of June, 1836.

(Memoir in *Gentleman's Magazine* for September, 1836.)

SMIRKE, ROBERT, R.A., of late years the Nestor of the Royal Academy, of which he was a member for fifty-three years, died at his house in Osnaburgh Street, Regent's Park, January 5, 1845, in his ninety-fourth year: he was born in 1751.

Smirke, originally a painter of coach-panels, was one of the most distinguished of the English *genre* painters, and had indeed no great rival before the time of Wilkie. His subjects are various, but his favourite author was Cervantes; a great proportion of his pictures are from Don Quixote. Though so long a member of the Academy, he sent few pictures to its exhibitions, and only three before his election as a member, which were Narcissus, and the Lady and Sabina, from Comus, in 1786; and the Widow in 1791. He was elected an Academican in 1792, the year that Reynolds died, and he gave as his presentation picture Don Quixote and Sancho. He contributed two pictures also in this year to the Academy exhibition: The Lover's Dream, and Musidora, from Thomson's Spring and Summer. In 1793 he exhibited Lavinia, from the Autumn of the same poet. Smirke designed much for booksellers, and for annuals and such works, and he was one of the contributors to Boydell's Shakspere. He painted several pictures from Shakspere, as Catherine and Petruchio, Juliet and her Nurse, Prince Henry and Falstaff—'This chair shall be my state, this dagger my sceptre, and this cushion my crown:'—The Seven Ages; and others. From Don Quixote he painted Sancho's audience of the Duchess; The Countess Dolorado discovering the cause of her grief to Don Quixote; The ceremony of beard-washing performed by Don Quixote at the table of the Duke; Don Quixote addressing the Princess Dulcinea; and The Combat between Don Quixote and the Giants interrupted by the Innkeeper. The last time he exhibited was in 1813: the picture was styled 'Infancy.' In other classes, the following pictures are among his best works. Infant Bacchus; Psyche; the Plague of Serpents; the Angel justifying Providence, from Parnell's Hermit; the Gipsy; the Fortune-tellers, &c. &c. Smirke was the contemporary of Sir Joshua Reynolds—he was the father of the present Sir Robert Smirke.

SMITH, SYDNEY, Reverend, was born in 1768, at the village of Woodford, in Essex. His father was a gentleman, whose residence was at Lydiard, near Taunton, in Somersetshire. Sydney Smith was educated at the collegiate school of Winchester, on William of Wykeham's foundation, and was elected in 1780 a scholar of New College, Oxford, of which college he was elected a fellow in 1790. In 1796 he took the degree of M.A., and soon afterwards obtained the curacy of Nether-Avon, near Amesbury, in Wiltshire, where he remained about two years, and then accepted the office of tutor to the son of Mr. Hicks Beach, a gentleman who resided in the neighbourhood, and who was member of parliament for Cirencester. Sydney Smith was to have gone with his pupil to reside at the University of Weimar, but Germany having just then become the seat of war, he proceeded to Edinburgh, where he remained about five years. Among the first persons with whom he formed an acquaintance in that city were Henry Brougham, now Lord Brougham, Francis Jeffrey, now Lord Jeffrey, and others of similar opinions in politics. This acquaintance led to the establishment of the 'Edinburgh Review,' the origin of which is thus related by Sydney Smith himself:—'One day we happened to meet in the eighth or ninth story or flat in Buccleuch Place, the elevated residence of the then Mr. Jeffrey. I proposed that we should set up a Review; this was acceded to with acclamation. I was appointed editor, and remained long enough in Edinburgh to edit the first number of the Edinburgh Review.' The first number was published in October, 1802. Sydney

Smith while in Edinburgh officiated at the Episcopal chapel there. In 1803 he removed to London, where he married the daughter of Mr. Pybus, the banker, and where he fixed his residence. He became popular as a preacher at the chapel of the Foundling Hospital, and at other places. He also delivered lectures on polite literature with much applause at the Royal Institution in Albemarle Street, and was a regular contributor to the 'Edinburgh Review.'

Lord Erskine, when Lord Chancellor, gave him, in 1806, the rectory of Foston, in Yorkshire. In 1829 he was presented to the rectory of Combe-Florey, in Somersetshire, by Lord Lyndhurst, and in 1831 he was appointed by Earl Grey one of the canons residentiary of St. Paul's Cathedral. Except a few years when he resided at his rectory of Foston, and during which he published anonymously, in 1808, 'Letters on the Subject of the Catholics to my Brother Abraham who lives in the Country, by Peter Plymley,' his place of residence was London, where he associated with literary men and politicians of Whig principles, distinguished for his conversational powers, and consequently a frequent 'diner out.' It is probable however that he kept within reasonable bounds of temperance, for he lived till the age of 77. He died at his house in Green Street, Mayfair, London, Feb. 21, 1845, and was buried in the Kensall Green Cemetery. He left the bulk of his property, which was large, to his widow and his son Wyndham Smith.

The Rev. Sydney Smith published 'Six Sermons,' Edinb., 12mo., 1800; 'Sermons,' 2 vols. 8vo., Lond., 1809; several occasional sermons and political pamphlets; and contributions to the 'Edinburgh Review.' In 1839 he published what he himself probably regarded as the best of his literary compositions, 'The Works of the Rev. Sydney Smith,' 3 vols. 8vo., with a preface by the author and a portrait. The collection consists of his contributions to the 'Edinburgh Review,' Peter Plymley's Letters, and various occasional tracts. With respect to his contributions, he observes, 'I see very little in my reviews to alter or repent of. I always endeavoured to fight against evil, and what I thought evil then I think evil now. I am heartily glad that all our disqualifying laws for religious opinions are abolished, and I see nothing in such measures but unmixed good and real increase of strength to our establishment.' When he wrote this however, '*all* our disqualifying laws' had not been abolished, as may be seen by looking over the act of parliament which is reprinted under the head ROMAN CATHOLICS AND JEWS, P. C. S.

Sydney Smith is a very effective writer; he has considerable argumentative power, united with wit, humour, and poignant satire. His style is clear and forcible, without any apparent aim at elaboration or polish. Two or three letters which he published in the newspapers shortly before his death against the repudiation of their debts by certain States of North America are as strong in argument, as pungent in satire, and as effective in style as anything which he wrote in less advanced age.

(*Athenæum; Gentleman's Magazine; Preface to the Rev. Sydney Smith's Works.*)

SMOKE BALLS. [LIGHT BALLS, P. C. S.]

SNAPDRAGON. [ANTIRRHINUM, P. C. S.]

SOCRATES, the ecclesiastical historian, was born at Constantinople towards the end of the fourth century. He was instructed in grammar and rhetoric by Ammonius and Helladius, of Alexandria, and afterwards followed the profession of scholastic or advocate, on which account he is generally designated as Socrates the Scholastic. He appears, however, to have abandoned this profession in order to devote himself to the study of ecclesiastical history. He is generally considered the most exact and judicious of the three continuators of the history of Eusebius [EUSEBIUS, P.C.]; he is less florid in his style and more careful in his statements than Sozomen [SOZOMEN, P. C.] and less credulous than Theodoret. [THEODORET, P. C.] He is likewise the earliest writer of the three, and Sozomen is supposed to have borrowed some what largely from him. His history extends from the year 306 to 439; it has been abridged by Epiphanius the Scholastic in his 'Historia Tripartita,' and was published for the first time as a continuation of Eusebius, by Robert Stephens, Paris, 1544, in fol. There is a good French translation of it by the President Cousin. The history is divided into seven books; the five last are chiefly composed on the authority of Rufinus [RUFINUS, P. C.], and on the relations he gathered from eye-witnesses of many of the events he records. The two first had also been composed on the same authority; but on reading the writings of St. Athanasius he found that Rufinus had omitted several of the principal circumstances in the life of this celebrated father of the church. [ATHANASIUS, P. C.] He therefore undertook the task of writing them anew, and took occasion of inserting several valuable documents and formularies of faith which throw much light on the Arian heresy.

Though the most exact of the continuators of Eusebius, he has nevertheless allowed himself to fall into error on several important points. For instance, he confounds the Emperor Maximianus with Maximinus (b. 1, c. 1.), a mistake the more surprising as he was a native of Constantinople, and professes to relate the principal events which took place in that city. 'The carelessness of writers of that age,' says Gibbon, 'leaves us in a singular perplexity' ('Hist. of the Dec. and Fall of the Rom. Emp.,' c. vii., note). He is mistaken also respecting the number of bishops who refused to sign the creed drawn up at the Council of Nice (b. 1, c. 8), as it appears clearly from the acts of the council and the authority of St. Jerome, Theodoret, and others, that there were only two, not five, dissentients, as Socrates asserts. His statements respecting a law passed by the Emperor Valentinian authorizing bigamy (b. iv. c. 31), on the occasion of his marriage with Justina, rests on no other known authority, and bears the semblance of a fiction rather than a fact. His account of church discipline has been severely criticized by Baronius, Fleury, and other Roman catholic writers; but he has on this point been very ably defended by Cousin in the preface of the translation to his history. 'His impartiality is so strikingly displayed,' says Waddington, 'as to make his orthodoxy questionable to Baronius, the celebrated Roman catholic historian; but Valesius in his life has clearly shown that there is no reason for such suspicion. We may mention another principle which he has followed, which in the mind of Baronius may have tended to confirm the notion of his heterodoxy—that he is invariably adverse to every form of persecution on account of religious opinions—διωγμὸν δὲ λέγω τὸ ὁπωσοῦν ταράττειν τοὺς ἡσυχάζοντας: and I call it persecution to offer any description of molestation to those who are quiet.' ('Hist. of the Church,' p. 104.) He is, however, very generally suspected of a leaning in favour of the schism of the Novatians, though he shows but little knowledge on the subject, and confounds Novatian, who was a priest of Rome, with Novatian of Africa. [NOVATIANS, P. C.] The date of his death is not ascertained.

(*Hist. de l'Eglise*, traduite par Cousin, vol. ii., Paris, 1775; Fleury, *Hist. Eccles.*, l. xxvi. c. 49; Waddington, *Hist. of the Church*, London, 1833; Moreri, *Dict. Historique*, art. Socrates.)

SOEUR, LE, HUBERT. This excellent sculptor, a Frenchman by birth, according to Walpole, was the pupil of the celebrated John of Bologna. He came to England probably shortly before 1630, in which year he was then living in Bartholomew Close, and a son of his was buried on the 29th of November of that year in Great St. Bartholomew's.

Le Soeur must have been a man of about fifty years of age in 1630, for John of Bologna died in 1608 in Florence at an advanced age, and Le Soeur must have visited Florence therefore about the beginning of the seventeenth century if he were his pupil. The connection with John of Bologna, who was a native of Douay in Flanders, and his subsequent connection with Rubens in England, seem to indicate Flanders as the country of Le Soeur rather than France. Rubens is said to have designed the much-admired bronze or brass statue of William Earl of Pembroke in the picture gallery of Oxford, which was executed and cast by Le Soeur. William Earl of Pembroke was Chancellor of the University of Oxford from 1616 to 1630.

In 1633 Le Soeur cast the well-known equestrian statue of Charles I. at Charing Cross; it was cast in a spot of ground near the church of St. Paul, Covent Garden, but not being put up before the commencement of the great civil war, it was sold by the Parliament to a brazier of the name of John Rivet, living at the 'dial near Holborn Conduit,' who had orders to break it into pieces. Rivet, instead of breaking it up, buried it, and it remained concealed until the restoration. It was placed in its present situation at the expense of the crown, about the year 1678, by an order from the Earl of Danby, afterwards Duke of Leeds. The statue was made for and at the expense of the family of Howard-Arundel, who have still the receipts to show by whom and for whom it was cast. There is a story about Le Soeur's destroying himself when, after the statue was set up, he found that he had omitted the saddle-girth; unfortunately for the truth of this story, however, the saddle-girth is there, and further, Le Soeur can never have seen the statue set up, as he must have died several years before 1678. The figure is dignified and expressive, but the horse is heavy and is generally deficient in modelling; the hinder quarters are especially void of character and motion. The pedestal was made by Grinling Gibbons. Walpole speaks of a bust at Stourhead by Le Soeur of Charles I. in bronze, with a helmet surmounted by a dragon à la Romaine, three feet high on a black pedestal. It is mentioned in Vanderdoort's Catalogue of Charles the First's Collection. Le Soeur executed many other bronze or brass works in England, but they are now all lost or destroyed.

(Walpole, *Anecdotes of Painting, &c.; English Connoisseur.*)

SOFTNESS is a condition of solid bodies in which the particles are held together by a cohesive power of small intensity: in consequence of this, such bodies change their figures upon the application of a small degree of force; and they do not recover their previous forms upon its removal.

This condition is the opposite of hardness, in which the particles are held together by a power of cohesion so great that they cannot be separated by any force which it may be convenient to apply to them. No body in nature is known to possess either of these qualities absolutely; but in contemplating the mechanical actions of soft bodies, balls of wet clay are generally used, while blocks of wood acting against one another in the directions of their fibres are frequently used to illustrate the effects of hardness. Balls of glass or ivory, or steel springs, serve to show the mechanical actions of elastic bodies. [COLLISION OR PERCUSSION OF BODIES, P. C. S.]

SOLENI'TES, a finely leaved fossil plant from the Yorkshire coast, whose affinities are somewhat uncertain. Supposed to be Marsiliaceous. (Lindley.)

SOLIDA'GO (from *solido*, to make firm, on account of its supposed virtues), a genus of plants belonging to the natural order Compositae, the suborder Corymbiferae, and the tribe Asteroideæ. It has radiant heads of flowers, the florets of the ray pistilliferous ligulate in one row; those of the disk tubular, with stamens and pistils, the receptacle rather alveolate, the involucre imbricated, with a few scales on the peduncle; the pappus pilose in one row; the fruit terete. This genus closely resembles Aster, from which it is distinguished by its pappus in a single row, and its terete fruit.

S. Virgaurea, Golden Rod, has an erect, slightly angular stem, the leaves lanceolate, narrowed at both ends; the lower leaves elliptical, stalked, serrated; the raceme erect, simple, or compound; involucral scales, lanceolate, acute; the fruit downy. This plant is a native of the woods and thickets of Great Britain, and was formerly much used in medicine. Its leaves and flowers are said to be aperient, and it has been employed for internal hæmorrhages. It is astringent and tonic.

SOLIDITY. For the signification of this word in its strictest sense the reader is referred to IMPENETRABILITY, P. C.; but, as the word is frequently employed to designate a condition of material substance in contradistinction from liquidity, or a gaseous form, it may in this sense be defined to be a state of a body in which the force of cohesion between the molecules is such that these require a certain amount of force to separate them from one another; and, at the same time, they are subject to small variations only of their mutual distances by the application of any quantity of heat less than that which would reduce them to ashes or convert them into fluids. The expansion of solids by heat is noticed under HEAT, P. C.; see also SPECIFIC HEAT, P. C. S.

SOLIME'NA, FRANCESCO, Cavaliere, called l'Abate Ciccio, a celebrated Neapolitan painter, was born at Nocera de' Pagani in 1657. He was originally intended for the law, but having a decided taste for art, he was first taught by his father Angelo, who was the pupil of the Cav. Massimo, and studied afterwards at Naples under Francesco di Maria, and in the academy of Pietro del Po. Solimena was one of the best and most correct painters of his time; he had great versatility of talent and executed works in every style, and had also very great facility of execution. But his style in all its varieties belonged to the elegant and ornamental; his drawing is uniform, and in a great degree merely academical; his heads are only graceful, but his light and shade is effective; his works however want expression, sentiment, and dramatic vigour. He was a great admirer of Pietro da Cortona and the Bolognese painters, one or other of whom he generally made his model. He died at Naples extremely wealthy and in the enjoyment of a great reputation in 1747, at the very advanced age of ninety.

Solimena was the rival and at the same time the friend of Luca Giordano, by whose death in 1705 he was left without a rival, and he raised accordingly the price of his pictures, which however in no way diminished the number of his commissions. His works, both in oil and fresco, are very numerous; the principal of them are the frescoes of the sacristy of the Theatines of San Paolo Maggiore; others, in oil, in the Church of the Apostles, and those of the Chapel of San Filippo Neri in the church dell' Oratorio: there are likewise by him many great altar-pieces and other pictures in oil in the churches of Naples and in other cities of Italy. His portraits also are very numerous, including those of some of the principal kings and princes of his time. Solimena was also a poet; his sonnets have been several times published. He was never married; his large property, which besides estates amounted to 300,000 scudi, went to his nephews, the sons of his brother Tommaso Solimena, who was a distinguished lawyer. During his long life Solimena appears to have made only two short visits to Rome. Of his numerous scholars the principal were Sebastiano Conca, Giaquinto Corrado, Ferdinando Sanfelice, and Francesco de Mura.

(Dominici, *Vite de' Pittori, &c. Napolitani*; Lanzi, *Storia Pittorica, &c.*)

SOTHEBY, WILLIAM, was born in London, November 9, 1757. He was the eldest son of Colonel Sotheby, of the Guards, and Elizabeth, daughter of William Sloane, Esq., of Stoneham, in Hampshire. His father died when he was only seven years old, and he was placed under the guardianship of the Hon. Charles Yorke (afterwards lord chancellor) and of his maternal uncle Hans Sloane, Esq., and by them he was sent to Harrow School, where he remained till he was seventeen years of age. Instead of completing his studies at either of the universities, he entered the army, and purchased a commission in the Tenth Dragoons, from which he immediately obtained leave of absence, and passed several months at the military academy at Angers for the purpose of studying the principles of his profession, England at that time having no similar institution for military instruction. On leaving Angers he passed a winter and spring in Vienna and Berlin, and rejoined his regiment at the end of 1777, at Knaresborough, in Yorkshire, where, besides attending to his military duties, he studied, critically and assiduously, Shakspere and the other masters of English poetry. In 1780 he married Mary, youngest daughter of Ambrose Isted, Esq., of Ecton, in Northamptonshire; he immediately afterwards quitted the army and purchased Bevis Mount, near Southampton, where he continued to reside for the next ten years, amusing himself with poetical studies and writing. In 1788 he made a pedestrian tour through Wales with his only brother Admiral Sotheby, of which he published a poetical narrative under the title of 'A Tour through North and South Wales.' His mother died in 1790, and in 1791 he removed from Bevis Mount to London, where he afterwards chiefly resided, passing however a considerable part of every year at Fair-Mead Lodge, in Epping Forest, of which he was one of the master keepers. Soon after he settled in London he became a Fellow of the Royal Society, of the Antiquarian Society, and of the Dilettanti Society; and was in the habit of receiving at his house persons distinguished in literature and politics without any regard to party distinctions.

The language and literature of Germany had been for some time advancing in favour in England. Taylor, of Norwich, had chiefly contributed to this result; and Sotheby's friend Spencer had translated Bürger's 'Lenore' with more success than Taylor had done previously. Sotheby studied the language, and in 1798 published a translation of Wieland's 'Oberon,' which immediately became popular. In 1799 he published a short poem on the battle of the Nile, and in 1800 a translation of the 'Georgics' of Virgil. In 1801 he addressed Sir George Beaumont in 'A Poetical Epistle on the Encouragement of the British School of Painting.' In 1802 he published 'Orestes,' a tragedy, on the model of the Greek drama, accompanied by a mask, entitled 'Huon de Bourdeaux,' founded on the story of 'Oberon.' His next work, on which he was occupied the greater part of two years, and which appeared in 1807, was an epic poem, in blank verse, under the title of 'Saul.' In 1810 he produced 'Constance de Castille, a metrical Poem, in Ten Cantos,' in the style of the 'Lady of the Lake' and 'Marmion.' In 1814 he republished 'Orestes,' together with four other tragedies. Sotheby travelled through France, Switzerland, and Italy in 1816, in company with Mr. Elmsley and Professor Playfair. He returned through Germany to England at the close of 1817. In 1827 he published a corrected edition of his translation of the 'Georgics,' together with the original text, and the translations of De Lille, Soave, Guzman, and Voss, in folio; of which he presented copies to several of the sovereigns of Europe, and received medals from them in acknowledgment.

When he was in his seventieth year he commenced a poetical translation of the 'Iliad,' of which he completed a portion every day, even during a tour which he made to Scotland in the summer and autumn of 1829. On his return to London he pursued his task with unabated diligence, and completed the 'Iliad' in September, 1830. He immediately commenced the 'Odyssey,' which he finished in July, 1832.

He died December 30, 1833, in the seventy-seventh year of his age. His eldest son William, who was a colonel in the First Regiment of Guards, died in 1815, in consequence of injuries which his constitution had suffered in the Walcheren expedition and the war in Spain. His third son George, who was assistant-resident at Nagpoor, in Hindustan, was killed in repelling an attack of the Pindarees, November 27, 1817. Another son, Hans, who had been in the civil service in India, died in London, April 27, 1827.

Besides the works already mentioned, Sotheby published, in 1828, 'Italy, and other Poems,' fcap. 8vo., consisting chiefly of descriptions of Italian scenery, most of which were probably written while he was travelling in 1816-17, and a few other small compositions.

Sotheby's original poems made little impression on the public, and are now nearly forgotten. His thoughts are pleasing, but faint, and frequently indistinct, from the polished diffuseness of his style. He has little originality or strength of imagination, but he has great facility and elegance of diction and versification, and hence his poetical translations are among the best which have been made in English. His 'Oberon' is an excellent version of Wieland's romantic poem, tolerably close, and no bad substitute for the original to those who cannot read German. His version of the 'Georgics' seems to have been a favourite work, and to have occupied much time in correction and improvement, and is perhaps superior to any other which has been made in our language. The folio edition was published at five guineas, and is a splendid specimen of typography. His versions of the 'Iliad' and 'Odyssey' are closer than those of Pope, but have less animation and energy, and have certainly no chance of superseding Pope's. Of the English poetical versions of the 'Iliad' and 'Odyssey,' Cowper's blank-verse translation is the closest which has yet been made. Sotheby's is in rhyme. In 'Blackwood's Magazine,' April, May, July, and December, 1831, are four critical articles on Sotheby's 'Iliad,' written by Professor Wilson in his usual popular style, but with great skill, truth, and nicety of discrimination, in which the versions of Chapman, Pope, Cowper, and Sotheby are examined and compared, as well as the translation of the first book of the 'Iliad' by Dryden, and that (also of the first book) which was made by Tickell in rivalry with Pope. Sotheby receives a fair share of the praise as well as the blame which the critic deals out to the different translators; but Wilson's own specimens of literal prose versions exhibit Homer more truly than any of the others, and are probably to most readers more interesting, and even more delightful to read.

(*Annual Biography and Obituary for* 1835.)

SOULAMIA (Soulamion is the name of the tree in the Moluccas), a genus of plants belonging to the natural order Polyaleae. It has 5 sepals, the 3 outer ones very small, the 2 inner large and concave. The petal is concave. The capsule samaroid, indehiscent, compressed, corky, emarginate, and 2-celled.

S. amara, bitter Soulamia, is a shrub with crowded ovate leaves tapering to the base, quite entire, and veiny. It is native of the Moluccas, and has white racemose flowers, the size of those of the vine. The fruit is compressed, thin at the edges, dry, with 2 seeds in each cell resembling cucumber seeds, but smaller, each lying in a small cavity of the cell. The plant has not yet been introduced into gardens, and the mode of cultivating it is at present unknown.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

SOULS, CURE OF. [BENEFICE, P. C.]

SOUTH AUSTRALIA is a British colony, established on the southern shores of Australia. It extends, as fixed by the British government, from 132° to 141° E. long. From the coast, which at its western border occurs near 32° 30′, and at its eastern near 38° S. lat., its boundary line runs due north to 24° S. lat., which parallel constitutes its northern boundary. On all three sides it is encompassed by Eastern Australia, or New South Wales. Within its boundary are contained two large bays: Spencer's Gulf, and the Gulf of St. Vincent, and the lower part of the course and basin of the River Murray. Kangaroo Island, which lies before the entrance of the Gulf of St. Vincent, is also annexed to it. The area of the colony, according to a rough estimate, is about 320,000 square miles, and it is about 100,000 square miles larger than France.

The western portion of the territories is a mere waste. Near the western boundary-line the country along the sea-coast is low and barren, without trees or high bushes, but covered with scrub. It is almost entirely destitute of grass, and also of water, except during the rains and a few days after they have ceased, when small quantities of water remain in the flat depressions for a short time. This country continues as far east as Streaky Bay, south of which there is some improvement. The shore is skirted by low sand hummocks; and at the back of them is a belt a few miles wide, whose surface presents a succession of low hills, wooded and grassy, but very stony and destitute of water, except what is left by the rains in the depressions between the sandy hummocks and the stony hills. Behind the stony tract the country is a perfect level, and overgrown with scrub, consisting of the *Eucalyptus dumosa* and the Tea-Tree. Towards the southern extremity of the peninsula lying west of Spencer's Gulf, especially east of Coffin's Bay, the hills rise higher, and attain an elevation of between 600 and 800 feet; they consist of sandstone, and are covered with wood. The interior of the peninsula is low and barren, but interspersed with salt-lakes. Where the peninsula is connected with the main body of Australia, between Streaky Bay and the head of Spencer's Gulf, lies a mountainous tract, exhibiting a succession of lofty rugged ranges, one behind the other, running from east to west, but turning north-west at their western extremity. They are called Gawler's Range, and attain an elevation of about 2000 feet above the sea-level, but decrease as they advance farther east. These ranges are devoid of timber, and have a barren appearance, but are overgrown with prickly grass. There are no rivulets nor springs, but between the hills are small salt-water lakes, with salsolaceous plants growing round their margins; fresh water is only found after the rains in the clefts of the rocks. The country north of Gawler's Range has not been explored.

The country situated on the western shores of Spencer's Bay is of a much better description. It contains Port Lincoln, the most extensive and the best harbour in the colony. It consists of three basins: Spalding Cove, Port Lincoln, and Boston Bay, in each of which there is not less than ten or twelve fathoms water, with a bottom of muddy sand; they are capable of holding the navies of all Europe. Round these extensive sheets of water are many large tracts well wooded, and others grassy with single trees dispersed over them. It is calculated, that in the vicinity of Port Lincoln there are three millions of acres of land available for cultivation or pasture. The peninsula south of Port Lincoln is hilly, but well wooded, and has much good pasture ground, and also the country north of it to the distance of ten or twelve miles; but farther north the hills disappear and are followed by a low tract which extends along the shore, and is densely wooded with brush, among which are scattered a few small patches of grass. Water is only found near a few rocky elevations. At the back of this low and rather narrow tract is a moderately elevated table-land, whose edge is broken by deep gorges into portions resembling hills. The soil is a sandy red loam, greatly mixed with stones, and presents only here and there a little old withered grass. There are no high trees, but patches of scrubby bushes, and a few small pines. No water has been discovered.

The table-land just mentioned terminates at the head of Spencer's Gulf, where a rather narrow low tract separates it from Flinders' Range. This tract is quite level, and has a sandy soil almost without vegetation. Flinders' Range constitutes the western borders of a mountainous tract of considerable extent. It occupies in width a space more than sixty miles from west to east, lying east of Spencer's Gulf. It may be said that this mountain tract terminates on the south of the banks of Broughton River (33° 30′ S. lat.), where a higher summit occurs, Mount Bryan, 3000 feet high. From these parts it extends nearly due north, with a small declination to the east to Mount Hopeless (29° 20′ S. lat.). This region is traversed by a great number of ridges, which in general run south and north, but grow gradually narrower towards the north; for in 31° S. lat. the region is only thirty miles across, and still less towards its northern termination. In the southern portion of this mountain-region several summits attain an elevation of between 2000 and 3000 feet. The highest appears to be Mount Brown, not far from the head of Spencer's Gulf. Farther north, the mountains decrease in elevation. Between these ridges there are plains of considerable extent. The higher portion of the hills consists invariably of naked rock, generally sandstone, and without the least vegetation. The lower slopes are covered with dense brush, and the valleys with low shrubs, and occasional small patches of thin wiry grass. The plains are in general barren. Some of them have an undulating surface, and then it is found that the higher parts are quite destitute of vegetation, whilst the slopes and valleys are overgrown with scrub. In other parts the plains are level, and some of them are covered with salsolaceous plants. In a few places, patches of grass are found, but others are quite sterile. During the rains, and a short time afterwards, running water is found at a few places among the hills, but it does not appear that it reaches the plains at the foot of the hills.

This mountain-region, as already observed, terminates on the north near 29° 20′ S. lat. Its extremity is surrounded by a level desert, which when first seen appears to be covered with water and studded with islands. The first explorers of this region considered it to be a lake, and called it Lake Torrens. But it was found that these appearances were deceptive, being caused solely by an extraordinary mirage. Not a drop of water was found, and the islands turned out to be mere low sandy ridges, scantily clothed with stunted scrub on their summits. A salt crust is found at intervals on the surface of the sand, and a few pieces of what appear to be drift timber are lying about. Not a blade of grass or any species of vegetation is visible, and the sand is loose and drifting. This desert is about 300 feet above the level of the sea.

The river Broughton may be considered the southern boundary of the barren mountain-region just described. This river rises on the declivities of Mount Bryan, and appears to be a considerable river during the rains. In the dry season its upper course consists of extensive reaches of water connected by a strongly running stream, into which several chains of ponds discharge their water during the rains. Lower down, the Broughton winds through some broken hills of an open but barren description, and here the water is lost in the sands; only water-holes are found at intervals. Still further down, the channel, though very wide and deep, is quite dry. After the rains, however, the waters come down to Spencer's Gulf.

South of the Broughton a few high hills are found, as the Razorback (2900 feet above the sea), and the Lagoon Hill (2260 feet), but they soon sink much lower. The country between these hills and the shores of Spencer's Gulf presents open grassy downs, which are well adapted for sheep, and abundantly watered by ponds. With this part is connected Yorke's Peninsula, which separates Spencer's Gulf from the Gulf of St. Vincent. This peninsula is about a hundred miles long, with an average width of fifteen miles. It is a level country, rising gently towards the interior; the soil is a light sandy loam, and generally wooded in a park-like manner, except towards the eastern shores, where the woods are thick and have underwood. The surface is almost everywhere covered with grass. The most southern part of the peninsula is rather hilly, and very well wooded; there are numerous good timber-trees. On this part it appears that there is land fit for cultivation, but the remainder of the peninsula is better adapted to pasture.

The best portion of the colony is the country lying on the east of the Gulf of St. Vincent. The interior of this tract is hilly, but the hills do not attain a great elevation; the highest, called Mount Lofty, is about 1200 feet above the sea-level. This hilly tract lies nearer to the Gulf of St. Vincent than to the Murray River. The hills come down to the sea on the Gulf of St. Vincent, about three miles south of Holdfast Bay, and occupy the whole of the peninsula between the Gulf and Encounter Bay. They are mostly well wooded, with large timber trees, and between them are tracts of good land. Along the shores of the gulf are low sand-downs, on which only bushes grow. Between these downs and the hills, which are about ten miles distant, is an undulating country, which contains a great portion of land capable of cultivation. In its natural state it resembles a park, the single trees standing at considerable distances from each other.

In this part, the capital of the colony, the town of Adelaide is situated. It is built on the southern border of the Torrens, a river which rises in the hills about six miles east of the town. It can be called a river only in the rainy season, when the banks are full, and it runs with great velocity. In the dry season it consists of a number of expansions like small lakes, which are very deep and of considerable length, but rarely more than thirty or forty feet wide. These pools are connected with one another by shallow places, in which the water is hardly a foot wide and an inch deep. At these places hardly a current is perceptible in the dry season. The Torrens in that season does not reach the sea, but is lost in what is called the Reed-Bed, a swampy flat depression, overgrown with reeds, which is separated from the shores by the sandy downs. When the river is full, the surplus water finds its way to the sea by running from the Reed-Bed to the Creek. The Creek is an inlet, branching off from the Gulf of St. Vincent about twelve miles to the north-west of Adelaide. It runs about four miles eastward and then twelve miles southward, terminating not far from the Reed-Bed. Though there is a bank at the entrance of the creek, with only fourteen or fifteen feet of water over it, vessels of five hundred tons burden can sail up to Port Adelaide, which is only four miles from the town, and has a good landing-place and wharfs. As the water in the wells of Adelaide is brackish, that of the Torrens river is used for all purposes, and is even transported to Port Adelaide for the consumption of the people there, and for the vessels.

The Murray is the largest river in Australia, and its remotest tributaries rise in the mountains which are not far from the eastern shores of that continent. [AUSTRALIA, P. C., p. 121; WALES, NEW SOUTH, P. C., p. 13 and 14.] It enters South Australia near 34° S. lat., and flows for about eighty miles west, when it suddenly turns to the south, and runs in that direction to the sea; before entering into the sea it expands into a large lake called Lake Victoria. This navigable river runs in a bottom inclosed by higher ground, from twenty to forty feet above the bottom. The bottom is about four miles wide. As the river does not occupy the centre of the bottom, but inclines to either side according to its windings, the flats on its sides are of greater or less extent, according to the distance of the river from the base of the higher grounds. The bottom is level, and almost everywhere overgrown with high reeds. The soil is of the richest kind, being formed by an accumulation of vegetable matter, and as black as ebony; but as the destruction of the reeds would require much labour, no trial has hitherto been made to bring it under cultivation. Lake Victoria is about thirty miles long and fifteen miles across in the widest part. It has no great depth, and is united to Encounter Bay by three channels of little depth; the shortest of these channels is four miles long. From the southern side of Lake Victoria branches off a narrow channel, which after two miles gradually expands into another lake of smaller dimensions, called Lake Albert. This lake is not connected with the sea, but separated from it by a sandy neck of land and the Coorong.

The higher country between the Murray River and the hilly tract which forms the watershed between it and the Gulf of St. Vincent is rather hilly near the bend of the river, and overgrown with light woods; it appears to be adapted for sheep-walks. Nearer the sea the soil is sandy, and appears to possess only a small degree of fertility; but in the vicinity of Lake Victoria it is beautifully studded with cypress. The country east of the Murray is of a more barren description. The soil contains a much greater portion of sand, and it is covered in its natural state with low brush; large trees occur only at some spots. In some places it is covered with scrub, and in others the sandy surface does not present any indication of vegetation or water. The last-mentioned observation applies especially to the country which begins on the banks of the river, and extends to the eastern boundary of the colony.

The interior of the country, which, south of the parallel of Lake Victoria, extends from the sea to 141° E. long., is a desert; its surface being formed by a succession of low ridges destitute of vegetation, with wide valleys between them, in which only shrubby bushes grow. At the sea-mouth of the Murray begins a narrow arm of the sea, which extends along the shores and parallel to them over an extent of more than a hundred miles. It is called Coorong, and is separated from the open sea by a narrow strip of land covered with sand-downs of moderate elevation. At the back of the northern half of the Coorong there is a belt of grassy hills overgrown with casuarina, and between them numerous plains of moderate extent with a good soil; fresh water is found at a moderate depth under ground, rarely exceeding six feet. This belt is bordered on the north-east by the desert. At the back of the southern half of the Coorong there is a succession of salt swamps and low shrubby hills. A low range, called the Wambat Range, runs for twenty miles parallel to the Coorong, at a distance of about three miles. Behind this range is an extensive fresh-water swamp, several miles across, which appears to be subject to annual inundations. The soil of this swamp is similar to that of the flats of the river Murray. There are in the swamp many small sandhills, well wooded and grassed.

The Coorong terminates near 36° 30′ S. lat., but in the line of its continuation are a number of lakes, which are separated from the sea not by sand-downs, but by grassy flats. At the back of the lakes are several grassy plains with a good soil, and wooded hills. South of Cape Bernouilli (near 37° S. lat.) the country improves. It consists of several ranges of wooded hills, generally running parallel to the shores, which are separated from each other by low level grounds, a great portion of which is subject to inundation; but the soil is excellent, and in many places these flats are dry and available for pasturage or agriculture.

The south-eastern portion of South Australia will certainly become a very valuable country. A line drawn from Rivoli Bay nearly due east to the boundary-line divides it from the desert, which is farther north. Near the sea-shore low narrow ranges of wooded hills alternate with grassy plains and a few swamps. In approaching the higher country plains occur, which are of considerable extent, and covered with luxuriant forests, consisting of trees of great size, blackwood, gum, stringy bark, and mahogany. They extend to the foot of Burr Range, a mountain-tract divided into several ridges, which cover a great extent of surface, and are pretty well wooded. The highest point of this range rises to about 1000 feet above the sea. Between this range and the isolated mountains called Mount Gambier and Mount Schank lies a well-wooded tract with large timber-trees, and an excellent soil. The two last-mentioned summits are of volcanic origin. Three distinct craters are visible on Mount Schank, which is between 800 and 900 feet above the sea. Mount Gambier is higher, and has also a crater on its summit. The soil of this region is of the richest description, being mostly a black brown loam, and the vegetation luxuriant. The value of this country for settlers is still increased by having a good and safe harbour in Rivoli Bay.

Kangaroo Island, which lies before the entrance of the Gulf of St. Vincent, is about 80 miles long from east to west, and on an average about 20 miles wide, which gives an area of 1600 square miles. It rises gradually from the sea, and does not attain a great elevation, the interior being occupied by extensive plains. Close to the shore, within a quarter to half a mile from the sea, it is covered with a thick forest, but when this belt of wood is passed, an open country presents itself, which is covered with grass, and there are often hundreds of acres without a tree. In these plains are numerous ponds, and, near the shore, lagoons which are generally filled with fresh water, but some are salt. On the shores of Nepean Bay is a salt lagoon, on the banks of which large masses of crystallized salt are found. It would seem that nearly the whole of the island is available for agriculture or pasturage. On its north-eastern shore is Nepean Bay, where vessels may ride in perfect security during the western gales.

It is true that by far the greater part of the territory of South Australia will never produce any food for man or animals, but the rapid survey of the country shows that there are also several very good tracts of land. It is probable that one-twentieth of the whole will either be brought under the plough or used as pasture-ground for sheep and cattle. This would give an area of 16,000 square miles of available land.

As this country has only lately been settled, we are but imperfectly acquainted with its climate. No series of meteorological observations has reached us, and we must content ourselves with some general observations. The seasons are divided into dry and wet. The dry season begins at the end of August and continues to the end of March. In December and January, corresponding to our June and July, the heat is very great, and the ground so arid, that the least breeze raises clouds of dust. During the wet season, from the end of March to August, it rains frequently and sometimes very heavily. The long droughts, with which New South Wales is periodically visited, are not known in South Australia. It appears that the rain diminishes greatly as we proceed inland, and it is probable that it ceases entirely before it reaches the northern boundary-line of the colony. During the rains the wind blows from the west or south-west, and frequently in hard gales. In the dry season northern and north-eastern winds prevail. Frost has never been experienced, nor any fall of snow.

During the rainy or cold season a great number of whales visit the coasts of the colony, and are chased by British, American, and French vessels. The black whale is most frequent, but the sperm-whale also occurs. The native animals are the kangaroo, the wallobi, a smaller species of the same genus, the opossum, and the dingo, or Australian dog. Birds are numerous, and distinguished by their beauty. The emu, several kinds of parrokets, of cockatoos, partridges, and quails are common. The most common sea-fowl are pelicans, black swans, wild ducks, divers, waders, cormorants, and Cape-pigeons (Procellaria Capensis). Several kinds of fish are taken in the sea, as salmons, snappers, porpoises, and large and small sharks. There are several kinds of snakes and lizards; among the latter the iguana, which is eaten; among shell-fish, oysters and periwinkles are mentioned as plentiful.

The colonists have imported horses from Tasmania and New South Wales, and ponies from the island of Timor in the Indian Archipelago; cattle and sheep from the Cape, Tasmania, and New South Wales; hogs from New Zealand. Fowls are common, both the common species and the larger one from the countries of the Malays. The kangaroo-dog is a cross-breed of the bull-dog and greyhound, and used for chasing the emus and kangaroos; such a dog is often sold for 25 or 30 pounds sterling.

The woods of South Australia contain many large trees, but the timber is not much valued; and this article is imported from New South Wales and New Zealand. All kinds of grain have been introduced, and appear to succeed pretty well: maize grows well, and also potatoes; melons, water-melons, pumpkins, and cucumbers attain an uncommon size, and also cauliflowers. Onions are cultivated to a great extent in Kangaroo Island. Our fruit-trees do not appear to grow well, except the peach, and there is a small kind of lemon; for apples, pears, &c. the climate appears to be too hot and dry. The vine has not succeeded, but probably it will. No edible fruit is indigenous, except some berries, which are eaten by the natives.

It appears that South Australia is rich in minerals. Iron-ore has been found in many places, especially in the deserts; but it will probably never be turned to account, for want of fuel in these parts. Copper-ore has also been found at some places in the vicinity of the settlements; and a quantity has already been shipped for England. It is stated that this year (1846) gold has been discovered. Salt occurs in many places. There are numerous deposits of salt in the deserts; and there is also a salt-lagoon on Kangaroo Island, and others on the coast of the colony which lies to the east of Lake Victoria.

The natives of South Australia, like those of New South Wales, belong to that race which is called Negro Australian; but it appears they have not yet attained an equal degree of civilization with the native population of the eastern coast of Australia. This however may partly be the effect of the shorter duration of their communication with Europeans. When their hunger is satisfied, nothing can induce them to work, but when pressed by want of food they are ready to do any kind of labour for the colonist, especially carrying water or wood. It seems therefore that by able management they perhaps could be accustomed to some regular work, especially to guarding herds of cattle or flocks of sheep. Though it appears certain that all the natives of the southern and eastern coast of Australia speak the same language, a marked difference exists in the dialects spoken in different parts. Three such dialects are used within the territories of South Australia: one is spoken by the few isolated families which live in the eastern districts west of 136° E. long.; another by the tribes inhabiting the vicinity of Adelaide; and the third by those who wander about on the banks of the Murray River. A native of King George's Sound, in West Australia, who accompanied Mr. Eyre in his expeditions, did not understand the language spoken by the families on the Australian Bight.

The settlement of Adelaide was founded in 1835; but six or nine months previously some families had settled on

Nepean Bay, on Kangaroo Island, at a place called Kingscote. At first the emigration to this colony was very great: and in 1840 the number of the white population was estimated at 15,000. In 1838 the colonies of Port Phillip and New Zealand were founded; which offered greater advantages to the settler; and the current of emigration ran to these countries; and since 1840, very few have gone to South Australia. The white population at present probably does not exceed 20,000 individuals. The greater number of them are settled in the fertile country in the vicinity of Adelaide. A settlement exists at a place a little above the influx of Murray River into Lake Victoria, called Wellington. The settlement at Kingscote has been mentioned before. There is also another on Spencer's Gulf, at Port Lincoln.

SOUTH SEA BUBBLE. The original conception and establishment of the South Sea Company was a project of Queen Anne's minister, Harley (afterwards Earl of Oxford), soon after he came into power in August, 1710. The object was to provide the means for paying interest at 6 per cent. upon, and eventually discharging, certain arrears which had accumulated upon the navy, victualling, transport, ordnance, and other departments, amounting, together with a new loan of 500,000*l.*, to 9,471,325*l.* in all. For this purpose the crown was authorized by stat. 9 Ann. c. 21, entitled 'An Act for making good deficiencies and satisfying the public debts, and for erecting a corporation to carry on a trade to the South Seas, and for the encouragement of the Fishery,' &c., to incorporate all the persons interested in any of the bills, tickets, debentures, or certificates, or other public debts, deficiencies, or sums of money, intended to be provided for by the act, into a company; whose stock should consist of the said debts, or claims upon the public; and in which should be vested, from the 1st of August, 1711, for ever, 'the sole trade and traffic into, unto, and from all the kingdoms, lands, countries, territories, islands, cities, towns, ports, havens, creeks, and places of America, on the east side thereof, from the river of Aranoco to the southernmost part of the Terra del Fuego; and, on the west side thereof, from the said southernmost part of the said Terra del Fuego, through the South Seas, to the northernmost part of America; and into, unto, and from all countries, islands, and places, within the said limits, which are reputed to belong to the crown of Spain, or which shall hereafter be found out or discovered within the said limits, not exceeding 300 leagues from the continent of America, between the southernmost part of Terra del Fuego and the northernmost part of America, on the west side thereof; except the kingdom of Brazil, and such other places on the said east side of America as are now in the actual possession of the crown of Portugal, and the country of Surinam in the possession of the States-General of the United Provinces.' On the 8th of September, 1711, a charter was granted establishing the company by the name of 'The Governor and Company of the Merchants of Great Britain trading to the South Seas and other parts of America.'

The establishment of the South Sea Company went for a time under the name of the Earl of Oxford's masterpiece. It was anticipated that it would pour a continued stream of gold and silver into England from the mines of Mexico and Potosi. In point of fact however, the trade which the Company carried on was from the first extremely insignificant. 'By the peace of Utrecht,' says Coxe (*Memoirs of Sir Robert Walpole,* i. 127), 'Spain and the Indies being confirmed to Philip V., that monarch was too jealous to admit the English to a free trade in the South Sea; and, instead of the advantageous commerce which Oxford had held forth, the Company obtained only the Assiento contract [P. C., ii. 503], or the privilege of supplying the Spanish colonies of America with negroes for thirty years, with the permission of sending to Spanish America an annual ship, limited both as to tonnage and value of cargo, of the profits of which the King of Spain reserved one fourth, and five per cent. on the other three-fourths. But this disappointment was attempted to be counteracted by the declaration made by Oxford, that Spain had permitted two ships, in addition to the annual ship, to carry merchandise during the first year to the northern coasts of Spanish America, and a pompous nomination of the several ports where the Company had leave to trade and settle factories. But the grand benefits of this commerce were never realized. The first voyage of the annual ship was not made till 1717, and in the following year the trade was suppressed by the rupture with Spain. Their effects, factories, and servants were seized and detained, notwithstanding the agreement in the Assiento which allowed, in case of a rupture, eighteen months for the removal of their effects.'

This was the state of its affairs when, in the end of the year 1719 or beginning of 1720, the ministry of Sunderland and Stanhope secretly entered into arrangements with the Company for having the whole amount of the National Debt, amounting to above 30,000,000*l.*, transferred into its stock upon certain conditions. In conformity with what had been agreed upon between the parties, the Directors of the Company, on the 22nd of January, 1720, sent in their proposal to the House of Commons, engaging to pay 3,500,000*l.* for the liberty of increasing their capital by being thus constituted the sole national creditor. The ministers however were disappointed in their expectation of the scheme being at once assented to by the House. It was suggested that other proposals should be invited; and Walpole, who had already great weight in the House, having supported that suggestion, it was agreed after some debate that the matter should be thrown open to competition. In consequence, on the 27th the Bank sent in a proposal in which they offered to pay 5,500,000*l.* Upon this, at a General Court of the members of the South Sea Company, the Directors were instructed to obtain the preference *cost what it would;* and on the 1st of February they sent in a second proposal to the House of Commons offering to pay 7,567,500*l.* The Bank also sent in a second proposal on the same day, which was supported by Walpole; but on the representations of Aislabie, the chancellor of the exchequer, it was resolved that the proposal of the South Sea Company should be accepted. A bill to that effect was forthwith brought in, which, after several debates, passed the Commons on the 2nd of April, by a majority of 172 to 55, and the third reading of which was carried on the 7th in the Lords without a division. The same day it received the royal assent, and became the statute 6 Geo. I. c. 4.

The imaginary advantages accruing to the Company from this arrangement instantly produced a great rise in the market value of its stock. The profits of the scheme are enumerated by Coxe as being expected to arise from—'1, The exclusive advantages of the trade, which, although precarious, and depending on a peace with Spain, were stated at no less than 200,000*l.* a year; 2, The allowance for the charge of management, which was to be proportioned to the augmentation of their stock; 3, The difference of receiving five per cent. for the money expended in purchasing the public debts, when the usual interest was only four per cent.; 4, The great addition to their wealth from the constant rise in the price of the stock in consequence of the artifices used to enhance its value; on which the whole success of the scheme depended.' 'The promoters of the scheme,' adds Coxe, 'highly exaggerated the profits; rumours were at the same time spread that the Company, by monopolizing the fund of the whole national debt, would reduce Government to the necessity of applying to them for loans, which would be advanced on their own terms; and it was even insinuated that the proprietors would obtain, by the weight of their wealth, a majority in the House of Commons, and make and depose ministers.' The consequence was that the price of the stock, which at Christmas, 1719, had stood at 126, had risen by the 14th of April to 325, and by the end of August to above 1000. Meanwhile however a vast multitude of other projects had been started by the rage and fury of speculation which this rapid ascent of the Company's stock had excited; and all or almost all of these also, incredibly visionary and absurd as many of them were, were attended with a measure of temporary success. In Anderson's History of Commerce a list of nearly two hundred of these minor bubbles is given. About Midsummer it was calculated that the value of the stock of all the different companies and projects at the current prices exceeded five hundred millions sterling. Now however the South Sea Company, envious in the midst of its own prosperity of that of its rivals, procured writs of *scire facias* to be directed against certain of the other companies. The effect was instantaneous and universal. Alarmed by the apprehension of prosecutions by the law officers of the crown, the subscribers to the projects that had been specially attacked hurried to sell their shares for whatever they would bring, more eagerly than they had done to purchase them; the panic quickly spread through the whole extent of the share-market: the proprietors of stock, even in the legally incorporated companies, sobered by the general aspect of things around them, began to perceive that their stock too must have its point of highest elevation, from which it would as inevitably descend as would after a certain time a stone thrown into the air; and under this impression South Sea stock itself soon began to tumble down. By the 22nd of August it had fallen to 820; by the 30th it was at 780; by the 8th of September at 680; by the 20th at 410; by the 29th at 175. The bubble had burst.

It would require a great deal of space to tell the rest of the story of this remarkable financial infatuation and fever. A searching parliamentary investigation into the proceedings of the directors of the company followed in the next session, which produced many most scandalous disclosures, some of them affecting the most eminent persons in the country. The directors were all mulcted of the greater part of their fortunes; Aislabie, the chancellor of the exchequer, was expelled from the House of Commons; Craggs, the secretary of state, would probably have shared the same fate if he had not died of small-pox in the course of the proceedings, his son being carried off by the same disease about the same time; Sunderland was with difficulty saved by the influence of Walpole; Stanhope, who was not supposed to be implicated in the fraud and bribery, burst a blood-vessel while speaking upon the subject in the House of Lords, and expired the next day. Not only the royal mistresses, but the Prince of Wales, and even the king himself, were believed upon strong grounds to have profited largely by stock which they were favourably placed for selling at the most advantageous moment, and all or the greater part of which they had obtained without purchase.

The storm thus raised was weathered and allayed, and public credit restored, principally by the great financial talent of Walpole, who assumed the direction of affairs as first lord of the treasury and chancellor of the exchequer in February, 1721, and kept his post at the head of the government for the next twenty-one years. Even the affairs of the South Sea Company were by the measures which he adopted restored to some degree of real prosperity for a time; but its commercial operations never became of any consequence; and the members became at last mere government annuitants, till, all their claims having been satisfied, the company was finally dissolved only a few years ago.

It is not to be forgotten that the South Sea Bubble in England was coincident in point of time with the later stage of the famous Mississippi scheme of Law in France; but what real connection there may have been, if any, between the one and the other, may admit of question.

(Postlethwayt's *Historical State of the South Sea Company*; Anderson's *Chronological Deduction of Commerce*; Macpherson's *Annals of Commerce*; Craik's *History of British Commerce*; Coxe's *Memoirs of Walpole*; Malcolm's *History of London*; *Parliamentary History*; *Statutes at Large*, &c.)

SOUTHEY, ROBERT, LL.D. The little that there is to be told of the life of Southey beyond the account of his literary performances may most conveniently be given by itself in the first instance. He was one of several sons of a linen-draper in Wine-street, Bristol, where he was born, as the date is commonly given, on the 12th of August, 1774, but, according to the inscription on his tombstone, on the 4th of October in that year. His first teachers were, a Baptist clergyman named Foote, said to have been a man of no ordinary ability, to whose school he was sent when he was six years old; then a Mr. Flower, at Corston, near Newton St. Loe; then a Mr. William Williams, a Welshman (something dropped into his mind by whom, possibly, may have long after suggested the subject of his *Madoc*). At last, in 1788, he was placed at Westminster school, the expense of his education from this time, it is intimated, being borne by Mr. Hill, a brother of his mother, who in other accounts however is called a Rev. Dr. Herbert. His father, we suppose, was now dead. In 1792, leaving a distinguished reputation at Westminster, where however he had incurred censure for taking part in a rebellion against the head master, Dr. Vincent, in 1790, he was sent to Baliol College, Oxford, his uncle's intention being that he should enter the church. But it was almost unavoidable that his enthusiastic temperament should precipitate him into the so-called liberal opinions both in religion and politics which the French Revolution, yet in its morning of promise, had spread both in France and in this country; he went to the extreme of free-thinking on both subjects; and in 1794 he left Oxford. He and a fellow-townsman, a young Quaker named Robert Lovell, now, in this same year, published a volume of poems, under the names of Bion and Moschus. It was soon after this too that Southey became acquainted with Coleridge. Lovell had married a Miss Fricker, of Bristol; and in November, 1795, Southey and Coleridge on the same day united themselves to her two sisters. The three had formed a plan to go out together to the wilds of North America, and there to set up what they called a Pantisocracy, in which they were to live without either kings or priests, or any of the other evils of old world society, and to renew the patriarchal or the golden age. But this fancy was never even attempted to be carried into effect. Southey soon after set out for Portugal with his uncle, the Rev. Mr. Hill (or Herbert), who had been appointed chaplain to the English factory at Lisbon. He returned to Bristol in the summer of 1797; in 1798 he removed to London, and entered himself a student of Gray's Inn; but he never prosecuted the study of the law; and all that is further related of him for some years is, that he was again in the Peninsula in the years 1800 and 1801, and that on his return home in the latter year he went over to Ireland as private secretary to the Right Hon. Isaac Corry, Chancellor of the Irish Exchequer (other accounts say to Mr. Foster, that is, we suppose, the Right Hon. John Foster, who however did not become Chancellor of the Exchequer till 1804). He is stated to have retired from office with his patron, and then, returning to England, to have established himself at Greta, near Keswick, in Cumberland, where he spent the rest of his days. As Mr. Corry ceased to be Chancellor of the Irish Exchequer in August, 1804, this account agrees very well with the inscription on the monumental tablet commemorative of Southey in the church of Crosthwaite, which records that he had resided nearly forty years at Greta Hall in that parish. Wordsworth had, we believe, taken up his residence in this lake country before Southey; and they were soon after joined by Coleridge, who however left them in 1810, leaving Mrs. Coleridge with Southey, whose hospitable roof also sheltered his wife's other sister, Mrs. Lovell, now a widow.

Long before this time Southey had abandoned his democratic and half-deistical creed, and taken up with one diametrically opposite. For all the rest of his life, as is well known, he was an ardent, uncompromising, and somewhat intolerant monarchist and churchman, promulgating and maintaining doctrines, both ecclesiastical and political, which were in some respects even something beyond conservative.

In November 1813, on the death of Mr. Pye, Southey was appointed Poet Laureate; and in 1821 he received the degree of LL.D. from the University of Oxford. In 1835 a pension of 300*l.* a-year was bestowed upon him by the government of Sir Robert Peel. It is understood that he had before this been offered a baronetcy, and that he had also more than once declined being brought into parliament. Having lost his first wife, he contracted a second marriage on the 4th of June, 1839, with Caroline-Anne, daughter of the late Charles Bowles, Esq., of Buckland, North Lymington, a lady long well known in the literary world. But soon after this his hitherto incessantly active and probably overtasked mental faculties began to give way, and he sunk into a condition which gradually became one of deeper unconsciousness till death removed him, on the 21st of March, 1843. He left a son and three daughters, with property amounting to about 12,000*l.* in money, besides a valuable library, which was afterwards disposed of by auction in London.

Southey's publications are very numerous. The following list of those of them that appeared separately is probably not quite complete, although we have taken great pains to make it so; but it is, we believe, much the fullest that has been drawn up:—

In 1794, Poems, in conjunction with his friend Lovell (as stated above on the authority of the *Gentleman's Magazine*), under the names of Bion and Moschus.

In 1795 (according to Lowndes's *Bibliographer's Manual*), Poems, containing the Retrospect, Odes, Elegies, Sonnets, &c., by Robert Lovell, and Robert Southey, of Baliol College, Oxford, 2 vols. 8vo.

In 1796, Joan of Arc, an Epic Poem, 4to.

In 1797, Poems, 8vo.—Letters written during a short residence in Spain and Portugal, 8vo.

In 1799 and 1800, The Annual Anthology (a miscellaneous collection of poetry, of which he was the editor and principal writer), 2 vols. 8vo.

In 1802, Thalaba the Destroyer, a Metrical Romance, 2 vols. 12mo.

In 1803, Amadis de Gaul (a prose translation from the Spanish version by Garcia Ordoñez de Montalvo of that romance, which Southey contends to have been originally written in Portuguese by Vasco de Lobeira), 4 vols. 12mo.—The works of Thomas Chatterton (in conjunction with Mr. Amos Cottle, the Life, originally printed in the second edition of the Biographia Britannica, being by Dr. G. Gregory), 3 vols. 8vo.

In 1804, Metrical Tales, and other Poems, 8vo.

In 1805, Madoc, a Poem, in Two Parts, 4to.

In 1807, Specimens of the Later English Poets, with Preliminary Notices, 3 vols. 8vo.—Palmerin of England, translated from the Portuguese, 4 vols. 8vo.—Letters from England, by Don Manuel Velasquez Espriella (pseudonymous), 3 vols. 12mo.—Remains of Henry Kirke White, with an account of his Life, 2 vols. 8vo.

In 1808, The Chronicle of the Cid, Rodrigo Diaz de Bivar, from the Spanish, 4to.

In 1810, The Curse of Kehama, a poem, 4to.—The History of Brazil, vol. i. 4to.

In 1812, Omniana, 2 vols. 8vo.

In 1813, Live of Nelson, 2 vols. 8vo.

In 1814, Carmen Triumphale for the commencement of the year 1814, 4to.—Odes to the Prince Regent, the Emperor of Russia, and the King of Prussia, 4to.—Roderick, the Last of the Goths (a poem), 4to.

In 1816, The Lay of the Laureate; Carmen Nüptiale (a poem on the marriage of the Princess Charlotte), 12mo.—A Poet's Pilgrimage to Waterloo, 8vo.

In 1817, Wat Tyler, a Dramatic Poem (written, in a vein of ultra-Jacobinism, in 1794, and now surreptitiously published), 12mo.—A Letter to William Smith, Esq., M.P. (on the subject of the preceding publication), 8vo.—Morte Arthur (a reprint of Sir Thomas Malory's prose romance), with Introduction and Notes, 2 vols. 4to.—History of Brazil, vol. ii. 4to.

In 1819, History of Brazil, vol. iii. 4to.

In 1820, Life of John Wesley, 2 vols. 8vo.

In 1821, A Vision of Judgment (a poem in English hexameters), 4to.—The Expedition of Orsua and the Crimes of Aguirre (partially printed in 1812, in the Second Part of the Third Volume of the *Edinburgh Annual Register*, for 1810), 12mo.

In 1822, Letter to the Editor of the *Courier* Newspaper, dated Keswick, January 5th, and published in the *Courier* of January 11th (in reply to a note appended by Lord Byron to his tragedy of the *Two Foscari*).—Remains of Henry Kirke White, vol. iii. 8vo.—History of the Peninsular War, vol. i. 4to. (an expansion of what had been originally published in the *Edinburgh Annual Register*, 1810, &c.).

In 1824, The Book of the Church, 2 vols. 8vo.

In 1825, A Tale of Paraguay (a poem), 12mo.

In 1826, Vindiciae Ecclesiae Anglicanae, &c., 8vo.

In 1827, History of the Peninsular War, vol. ii. 4to.

In 1829, Sir Thomas More; or, Colloquies on the Progress and Prospects of Society, &c., 2 vols. 8vo.—All for Love, or The Sinner well Saved; and The Pilgrim to Compostella, or A Legend of a Cock and a Hen, 12mo.

In 1831, Attempts in Verse by John Jones; with Introductory Essay on the Lives and Works of our Uneducated Poets, 8vo.—Selections from the Poems of Robert Southey, Esq., LL.D., 12mo.

In 1832, Essays, Moral and Political, 2 vols. 8vo.—Selections from Southey, Prose, 12mo.—History of the Peninsular War, vol. iii. 4to.

In 1833, Naval History of England, vol. i. 12mo. (in Lardner's *Cabinet Cyclopaedia*); completed in 5 vols. in 1840.

In 1834, Dr. Watts's Poems, with a Life of the Author (in Cattermole's *Sacred Classics*), 12mo.—The Doctor (anonymous, and never acknowledged, but believed to be by Southey), vols. i. and ii. 8vo.

In 1835, The Doctor, vol. iii., 8vo.—The Works of William Cowper, with a Life of the Author, vol. i. 12mo.; completed, in 15 vols., in 1837 and 1838.

In 1837, The Poetical Works of Robert Southey, collected by himself, 10 vols. 12mo.—The Doctor, vols. iv. and v. 8vo.

Life of the Duke of Wellington, post 4to. (according to Lowndes, who however gives no date).

To these works, making in all above a hundred volumes of various sizes, are to be added numerous papers upon history, biography, politics, morals, and general literature, published in the Quarterly Review, to which he was a constant contributor from its establishment in 1809, till head and hand would work no longer. He also wrote for some years the historical portion of the 'Edinburgh Annual Register,' and contributed other matter to that work, which began to be published in 1810, and was discontinued in 1824. He was besides one of the most regular and voluminous of letter-writers; and large collections of his letters are understood to be in existence, which it is to be hoped will, ere long, be given to the world. Some have already appeared in Robberds's 'Memoirs of the Life and Writings of William Taylor, of Norwich,' 2 vols. 8vo., 1843.

As a poet, Southey cannot be placed in the first rank even of the poets of his own time. Wordsworth and Coleridge, Shelley and Keats, Byron and Scott, Moore and Crabbe and Campbell, whatever differences of opinion there may be as to their relative merits or their positions in reference to one another, will be generally admitted to have each and all evinced more or less of a *mens divinior* which was wanting in him. The light which was original and self-sustained in them, seemed, even when it shone the strongest, to be only reflected light in him. In mere fertility he was equal to any of them. But his mind, although a teeming, was not an inventive or creative one. It returned manifold the seed deposited in it, but communicated to it comparatively little of any new nature or quality. His imagination might even be said to be both opulent and gorgeous; still there was wanting the true spirit of life, that which distinguishes a real thing from a painted show. No natural human voice coming from the poet himself animated his verse; but rather an artificial sound, as from a flute or an organ. Such poetry may be both beautiful and majestic; but it fails permanently to interest, and will not live. For there is nothing so alien from and so fatal to poetry as any admixture of the mechanical. It acts like a dead substance imbedded in a living body. Witness such an instance as that of Darwin. There is much rhetorical splendour however in parts of Southey's poetry; especially in his 'Curse of Kehama,' and in his 'Roderick.' And some of his ballads and other shorter pieces, flowing on as they do in the easiest and purest English, are very happy.

In his prose writings the great merits of his style show to all advantage. It is essentially a prose style, and one unsuited to poetry, at least to poetry of any high order, by some of the very qualities that constitute its characteristic excellence. Its facility and fluency, running into some degree of diffuseness; its limpid perspicuity; its equability and smoothness; even its very purity, are unsuited for the passion, the rapidity, the boldness, the novel combinations of poetry. Both in its merits and in its defects Southey's style may be compared to glass, which perfectly transmits the light, but refuses to conduct the lightning. It does not often rise to any splendour of eloquence; it has little or no brilliancy of any kind; but whether for narrative, for exposition, or for animated argumentation, it was perhaps the most effective English style of the time. It combines in a remarkable degree a somewhat lofty dignity with ease and idiomatic vigour, and is equally pliable to the expression of sprightly and playful as of severe and indignant sentiment.

He certainly was not nearly so great a thinker as he was a writer. He had no subtlety of intellect, and he took rather a passionate than a reasoning view of any subject that greatly interested him. Much of his political and economical speculation is now probably regarded as altogether wrong-headed, even by the most ardent of his admirers. But there can be no question that he was thoroughly honest and in earnest in whatever opinions he at any time professed. He was, by the universal testimony of those to whom he was best known, of a sincere, generous, high-minded nature, and in all the relations of private life a man worthy of the highest estimation.

(Memoir in *Gent. Mag.* for June, 1843; *Dictionary of Living Authors*; Chambers's *Cyclopædia of English Literature*; *Literary Gazette*; *Athenæum*; and the works mentioned in the article.)

SOWENS. [AVENA, P. C. S.]

SPACE, POWER OF PENETRATING. [TELESCOPE, P. C., p. 163.]

SPALDING, SAMUEL, was born in London on the 30th of May, 1807. He furnishes an example of success attendant on the persevering pursuit of knowledge, in the absence of any remarkable ability or aptness for its attainment. According to the testimony of his friends, it was only by means of great labour that he could perform his daily tasks while at school; though his steady application, resulting very much even at this early period of his life from a sense of duty, the effect of moral and religious training, enabled him to acquit himself with great respectability; and the moderate estimate he always entertained of his own powers appears to have done much towards forming those habits of unremitting application which constituted one of the strongest features of his intellectual character. At a suitable age he was placed in a mercantile house; but his mind soon became too deeply interested in the study of theology to allow him to entertain the idea of spending his life in a secular profession. He now examined the evidences of Christianity with the most assiduous care, and the work of Dr. Chalmers on this subject, together with the splendid discourses of the same writer on the relation of revelation to the discoveries of modern astronomy, inspired his mind with such elevated views of the grandeur of Christianity and the expansive benevolence of its design, that he resolved to devote himself to the pastoral office in the religious connexion to which he belonged, that of the Congregational Dissenters. He consequently applied himself to study with fresh ardour, though he had to contend with a naturally feeble constitution, in which there is little doubt that the seeds of organic disease early existed. 'The chief feature in his moral character,' writes one of his near relations, 'was benevolence. In him it extended from the worm, which he would stoop to pick up lest it should be trodden on, to the highest order of beings. Whatever was capable of suffering or enjoyment excited his sympathy.'

With a view to promote his object of qualifying himself for the ministry, Spalding devoted his time, for two years, to the study of the Greek and Latin languages, in private; and afterwards entered as a student at University College, London, where he made himself an exact Greek scholar. During his academical course here he obtained, in addition to high certificates of honour in other classes, five first prizes in the classes of Hebrew, French, Natural Philosophy, and the Philosophy of the Mind and Logic. Of the last subject his pursuit was ardent, his diligence and ability, as manifested in his essays and examinations, being such as to mark him out as a student of unusual merit. In the year 1839, symptoms of incipient pulmonary disease induced him to try the effect of a warmer climate, and he spent the winter in the South of France. On his return he underwent tho examination for tho Master's degree in the University of London, in May, 1840. In the Transactions of the University, his name is mentioned with honour for his examinations in Animal and Vegetable Physiology, and in the Hebrew and Greek originals, and the History of the Holy Scriptures. He is also recorded as having 'passed a distinguished examination' in Logic, the Philosophy of the Mind, and Moral Philosophy. In consequence of this success he was urged by the examiners to write on some of these subjects; and this recommendation encouraged him to compose his work, entitled 'The Philosophy of Christian Morals.' In the autumn of 1840 Spalding went to Italy, where he remained nearly two years. It was during this period that the above-mentioned work was written, the subject of which however had occupied his mind for many years. On his return to England, in 1842, he purposed superintending the publication of his Treatise, but was prevented by the progress of his disease; and as a last resource he tried a sea-voyage, and went to the Cape of Good Hope, where he died on the 14th of January, 1843, about three weeks after his arrival. His work was published during the same year, by his friends, in one volume, octavo. We have not space for any criticism of Spalding's theory of morals: we must restrict ourselves to a bare summary of his principal doctrines. They are as follows:—Our primary notions of virtue and vice are derived from those feelings of moral approbation and disapprobation which we experience in viewing the conduct of others. These notions acquire new force and become more distinct in consequence of the emotions which we experience in the review of our own conduct. The objects of moral obligation are, first, virtue itself; and, secondly, the mode in which virtue ought to be displayed in the outward conduct. The great rule of action is the will of God, either as supernaturally revealed or as inferred from the end and object of the virtuous affections themselves. The notion of moral obligation is an immediate consequence of the testimony of our moral emotions. The great object of moral approbation is the principle of benevolence, chosen as the highest and most valuable principle in our nature. All other virtues are necessarily contained in this principle of benevolence; apart from which even sympathy itself is merely pathological, not moral. The moral character of volition depends entirely on the object of choice. In short, Spalding's theory may be characterized by its referring conscience ultimately to emotion, not to moral judgment; by its asserting the necessity of there being other moral agents in existence besides ourselves, before we can have the notion of virtue or of vice, and by its reduction of all the forms of virtue to the one principle of benevolence. Without pronouncing either one way or the other on the merits of this theory, we will only add that the work possesses considerable originality, and abounds with passages of genuine power and beauty; and that it is characterised throughout by an elevation of thought and sentiment which distinguish it even among books on ethical subjects. The author writes with the glowing warmth of one whose heart is in his work, sometimes with an intense ardour of feeling. Tho book is therefore of a popular cast, though it often discusses principles ably and profoundly. It exhibits also in a striking manner the real harmony subsisting between the Christian precepts and the genuine dictates of the moral faculty, notwithstanding apparent or supposed discordances. It is wholly free from all sectarian and party feeling, and exhibits very advantageously the benevolence which was a distinguishing characteristic of the author's mind.

SPARTI'NA, a genus of grasses belonging to the tribe Chlorideæ. It has upright 1-flowered spikes in racemes, the glumes unequal, the upper long and acuminate; the paleæ unequal, the outer boat-shaped, compressed, retuse; the styles elongated, united half-way up; the stigmas filiform, protruding at the summit of the floret. There are two British species, the *S. stricta* and *S. alterniflora*. The former grows in muddy salt-marshes, the latter has been found only on the mud-flats of the river Itchin at Southampton.

(Babington, *Manual of British Botany*.)

SPATHO'DEA (from σπάθη, a spathe, in reference to the form of the calyx), a genus of plants belonging to the natural order Bignoniaceæ. The calyx is spathaceous, cleft and toothed or entire on the other side. The corolla is funnel-shaped, with a 5-lobed rather unequal limb. The 4 stamens are divided into 2 long and 2 short, with tho addition of a fifth sterile filament. The capsule silique-formed, falcate, falsely 4-celled, and corky. The seeds are furnished with membranous wings. The species aro erect shrubs or trees, rarely climbing shrubs. The flowers somewhat panicled, orange-coloured, yellow, or purple.

S. Rheedii has downy impari-pinnate leaves, roundish downy leaflets, terminal erect racemes, and a much-curved slender corolla. The shoots are covered with a whitish down. The racemes the length of the leaves. The flowers white and pretty large. The limb spreading. The fruit about a foot long, pendulous, twisted in various forms.

S. Roxburghii has its leaves three in a whorl or scattered impari-pinnate. The leaflets from 4 to 5, in pairs, serrated and smooth. Tho panicles erect, terminal, dense, downy, and many-flowered. The fruit narrow and 4-celled. The calyx generally 2-parted, with the upper lip 2-cleft and downy. It is native of the Circars. The branches are very spreading. The back grey, with a few scabrous spots. The flowers large, rose-coloured, and delightfully fragrant. The limb of the corolla nearly equal, and elegantly waved at the edges. This species is remarkable on account of its serrated leaves. The wood is employed for many purposes by the natives.

S. longiflora is an arboreous plant, and has large spreading terminal panicles, a bilabiate corolla, long pendulous slender sub-cylindrical follicles, with sharp edges and variously curved. The flowers are large, yellow, and very fragrant. The follicles very long. The wood of this tree is high-coloured, hard, durable, and of much use amongst the inhabitants of the hills about the coasts of Coromandel and Malabar, where it is plentiful.

The species are splendid plants when in blossom. A mixture of loam and peat suits them best, and cuttings will strike readily in heat under a glass.

(Don, *Gardener's Dictionary*.)

SPATULARIA, a genus of fishes of the Sturgeon tribe, remarkable for the form of their snouts, which are enormously prolonged and leaf-like in form. The paddle-fish of the Mississippi is the type.

SPEAKER. [PARLIAMENT, P. C.]

SPECIAL OCCUPANCY. [OCCUPANCY, P. C.]

SPECIALTY, SPECIALTY DEBT, or debt by special contract, is a debt which becomes due or is acknowledged to be due by an instrument under seal. [DEED, p. 730.]

The nature of a debt by simple contract is explained under SIMPLE CONTRACT.

Blackstone (ii. 464) considers a debt of record, that is, a debt which appears to be due by the judgment of a court of record, as a 'contract of the highest nature, being established by the sentence of a court of judicature.' This is, however, an erroneous view of the matter. It is simply a rule of law that a debt for which the judgment of a court of record has been obtained has a priority over other debts.

SPECIFIC HEAT is the quantity of caloric which a substance of any kind absorbs, or which it gives out, when it undergoes a change of temperature; being determined, in a substance of any kind, with relation to the quantity which a substance of another kind, as water, absorbs or gives out in undergoing a like change of temperature. This designation, which is said to have been first used by the Swedish philosopher Wilcke, has nearly replaced the less proper one of *Capacity of Heat* which was given by Dr. Black, who first remarked that in order to bring different substances to equal temperatures different quantities of heat must be applied.

Dr. Black conceived that heat exists in all substances in two different states: one state he supposed to be that in which the heat is so united to the substance that it is insensible or inappreciable; and the other to be that in which the heat is sensible, or is capable of being made evident to the senses, and of being measured by the thermometer: the former is that which is now designated specific heat. The term capacity for heat is considered as objectionable, because it seems to imply that the heat existing in any substance is contained in the pores of the substance; and, if it were so, it should follow that the capacities of substances for heat are directly proportional to the porosities of the substances or inversely proportional to their densities, which is far from being the fact, though it is well known that the more dense substances contain smaller quantities of heat than those which are less so.

In determining the relative specific heat of substances, either the substances when heated to a certain temperature are plunged in cold water and the augmentations which they occasion in the temperature of the water are observed, or the instrument called a Calorimeter [HEAT, P.C., p. 89] is employed. With this instrument, since the ice surrounding the heated substances which are separately introduced in it continues at a temperature expressed by 32° (Fahr.) till it is entirely melted, it is evident that the quantities of water (at 32°) arising from the dissolution of part of the ice by the different substances, whose temperatures had been previously raised to equal heights, must be proportional to the caloric lost by those substances in the process of cooling; and thus the specific heats of the substances are determined. When, as is usual, heated water is one of the substances introduced in the calorimeter, the ratio between the specific heat of water and that of the substance may be obtained.

If the body whose specific heat is to be determined is a solid, it is first heated to any convenient number of degrees of temperature, suppose 212° Fahr.; it is then placed in the calorimeter, and allowed to remain there till it is reduced to the temperature of ice (32°): then the quotient arising from the weight of the water obtained from the melting of the ice surrounding the body, divided by the product of 180° (=212° − 32°) multiplied by the weight of the body, will express the required specific heat. The specific heat of water or any other liquid is determined by the calorimeter in a similar manner; the liquid heated to 212°, for example, being contained in a glass vessel, and care being taken to deduct from the total quantity of water produced by the melted ice that part of it which, by experiment, is found to depend on the cooling of the vessel containing the liquid.

The specific heats of solids and liquids are found to be greater at high than at low temperatures; and, from careful experiments made by MM. Dulong and Petit, the specific heats of different solids, that of water at 212° being unity, were found to be as in the following table:—

	(Between 32° and 212° Fahr.)	(Between 32° and 572°)
Platinum	0·0355	0·0355
Silver	0·0557	0·0611
Zinc	0·0927	0·1015
Copper	0·0949	0·1013
Iron	0·1098	0·1218

The difference between the specific heats at different temperatures is ascribed to the dilatations which the substances experience by an increase of heat: every change in the constitution of a substance is accompanied by a change of specific heat; a solid body, for example, has a smaller specific heat than the same substance in a liquid state. Thus the specific heat of water being unity, that of ice is 0·9.

With respect to liquids, Lavoisier and La Place have given a table of their specific heats, of which the following is an extract:—

Mercury	0·029
Sulphuric acid (spec. grav. = 1·87058)	0·334596
A mixture of sulphuric acid and water in the ratio of 4 to 3	0·603162
Nitric acid (spec. grav. = 1·29898)	0·661391
Water	1·0

The specific heats of gases are still subject to much uncertainty, though many attempts have been made by eminent philosophers to determine them. The method employed by MM. Delaroche and Bérard for this purpose was to transmit through the calorimeter a constant current of gas in a serpentine tube, the gas having been heated to the temperature of boiling water: the tube was surrounded by cold water in the instrument; and the gas, parting with its excess of sensible heat above that of the surrounding water, issued from the tube at the temperature of the water, the temperature of the gas at the entrance and exit being ascertained by means of thermometers. The following table contains the results of some of their experiments on different gases, the weights of the quantities of gas being equal and the specific heat of water being unity:—

Carbonic acid gas	0·2210
Oxygen gas	0·2361
Atmospheric air	0·2669
Nitrogen gas	0·2754
Olefiant gas	0·4207
Aqueous vapour	0·8470
Hydrogen gas	3·2936

The specific heats of volumes of the same gas, having equal weights, are found to vary with the density and elasticity of the gas.

SPECKTER, ERWIN, was born in 1806, at Hamburg, where his father, a native of Hanover, was settled as a merchant. During the siege of Hamburg, in the winter of 1813-14, his parents took refuge with their family in the house of the banker Dehn, in Altona, where there was a good collection of pictures, and where Erwin made the acquaintance of the painter Herterich, who was also living in the banker's house, and had a studio there. In this studio, in which he spent nearly all his time, Erwin Speckter acquired his first instruction in art, and his natural taste rapidly developed itself. In 1818 his father and the painter Herterich erected a lithographic press, the first which was established in North Germany, and young Speckter made some attempts in portraits, and in drawings to illustrate the old Reineke Fuchs, or Reynard the Fox.

In 1822 Von Rumohr returned to Hamburg from his second visit to Italy, and, being struck with admiration of the promising talents of Speckter, urged him on in his career, and particularly to study the monuments of art in and about the neighbourhood. This led to an artistic tour which he performed in 1823, with a brother and another artist friend, through Schleswig and the neighbouring country. The chief objects of this journey were the carved altarpiece of Hans Brügman at Schleswig (lithographed by Böhndel) and the picture of Memling at Lübeck, the latter of which Speckter and his brother Otto published in lithography. These early works gave Speckter's mind the peculiar bias which at that time characterised the majority of the younger artists of Germany, and the arrival of Overbeck's picture of Christ's Entry into Jerusalem, for the Marien Kirche of Lübeck, confirmed this tendency, and for a time enlisted Speckter among the young enthusiasts who appear to be devoted to the restoration of the sentimental symmetrical art of the renaissance in Germany, with the addition of academical drawing. Overbeck's picture has been lithographed by Otto Speckter. At this time Speckter's chief labours were indiscriminate studies from nature of every description, and portraits: his first oil-picture was a view of the town-house of Mölln. His adoration of Overbeck's picture seems to have kept him by a species of awe from attempting such high subjects himself; he was also always guided in his studies by Rumohr.

In 1825 he visited Munich, and placed himself under the direction of Cornelius, who expressed great admiration for his ability; and, after the completion of his cartoon of the Resurrection of Lazarus, allotted him one of the vaults or loggie in the corridor of the Pinacothek, which were to be painted in fresco with incidents from the lives of the greatest modern painters. Cornelius selected Fra Giovanni da Fiesole for Speckter, as peculiarly suited to his taste. Speckter, then about twenty-one years of age, received the commission with exultation, but he did not livo to execute it, for the Pinacothek was not ready for the frescoes until many years after this date.

In 1827 Speckter returned to Hamburg, chiefly to be in the vicinity of the above-mentioned work by Overbeck, while he painted his picture of Christ and the Woman of Samaria; but the deep impression made upon him by Overbeck's picture had a very prejudicial effect npon him, through his inordinate striving after abstract ideal representation. His own dissatisfaction with this work may be inferred from his immediate but still gradual change of manner; for in his next work, the Women at the Tomb, there is a far greater attention to dramatic probability, and a more prominent part given to colour. He painted at this time also several beautiful miniatures from sacred subjects. In 1830 he appeared in entirely a new character in his arabesqne and mythologic decorations of the house of the Syndicus Sieveking near Hamburg. In September of this year, after the completion of these decorations, he set out by Berlin and Munich upon his long-intended journey to Italy. The constrained taste which had hitherto possessed him, though it was gradually yielding to his own experience, was finally subjected by the contemplation of the great Italian works in the Museums of Berlin and Dresden, especially those of Fra Fillppo Lippi, Raphael, and the great Venetian masters.

Speckter arrived in Rome in January, 1831, after a short stay at Venice, from which is dated the first of his very interesting series of Letters from Italy, which, by the advice of Rumohr, have been recently published. He remained in Italy, chiefly at Rome and Naples, until the summer of 1834, when he was called to Hamburg to paint in fresco the villa of Dr. Abendroth, then recently constructed by A. de Chateauneuf. In Rome Speckter confined his labours almost exclusively to studies, and these are in the general spirit of Italian art, and quite in a different stylo from his early efforts. The only oil-paintings he painted in Rome were two of Albano Women, in ideal characters, and a large picture of Samson and Dalilah, which was purchased by Rumohr.

In the spring of 1835, though suffering greatly from asthma, Speckter commenced his frescoes; he had in the interim completed three of the principal cartoons: the subjects are from Grecian mythology, and the figures are half the size of life. The three subjects were—1, Minerva receiving the winged Pegasus from the Muses, and the Hippocrene fountain which sprung fom the kick of the horse (M. de Chateauneuf describes the nymphs or goddesses of this piece as the Graces, &c., and terms the spring the Castalian fountain); 2, the Graces, in a grove of laurels, decorate the bow and quiver of Cupid, and offer him a cnp of ambrosial drink; and 3, the Fates, lulled by the lyre of Cupid, have ceased their labours, and recline on cushions; the distance is concealed hy a curtain. The first of these designs, distinguished for the exquisite beauty of its forms, was completed in fresco, and the second was partly executed; the third was not commenced. His weak state forced Speckter to leave his work at the beginning of November, and he died on the 23rd of that month in 1835, deeply lamented by his friends, and by none more than Rumohr, who wrote a short account of the character of his genins, which is inserted in the biographical notice of him which precedes his letters. These letters, published in 1846, under the title of 'Letters of a German Artist from Italy' ('Briefe eines Deutschen Künstlers aus Italien,' 2 vols. 12mo., Leipzig, 1846), are full of interesting matter and reflections on art. Speckter's whole career is a remarkable instance of the power of nature over convention, where the love of art was real. The essential attractions of art itself gradually drew him from an abstract conventional system, in which art was only secondary to a peculiar sentiment independent of it, to the art itself, and for its own sake. Speckter's transition from convention to nature is not singular in the history of modern German art.

(*Briefe*, already mentioned.)

SPECTRUM, in optics, is a name applied to the elongated image of the sun which is formed on a screen in a darkened room when a slender beam of the sun's rays passing through a perforation in the wall or in a window-shutter has been afterwards transmitted through a prism formed of any transparent medium [DISPERSION, P. C.; and, for the dark lines observed in spectra, see FRAUNHOFER, P. C. S.]

If a prism of crown-glass, and one of flint-glass, have their refracting angles of such magnitudes that the spectrum formed by one shall be of the same length as that which is formed by the other; on combining them so that their refractions may be in contrary directions, the red and violet rays of the spectrum will be united so as to proceed parallel to one another in the emergent pencil, but the dispersions of the intermediate rays, though much diminished, will not be wholly corrected, and some colour will still remain in the image formed on the screen which receives the refracted pencil. This circumstance was first observed by M. Clairaut; and the coloured image was called by Dr. Blair a secondary spectrum.

When a spectrum is formed by a prism of crown-glass, the mean refracted ray meets the screen at the boundary-line between the blue and green spaces; but if a spectrum of equal length be formed by a prism of flint-glass, the mean ray, instead of being at that boundary, will be much nearer the red or least refracted end of the spectrum; consequently, with flint-glass, the rays which suffer the least refraction occupy a less, and those which experience the greatest refraction occupy a greater length in the spectrum than they, respectively, occupy in a prism formed of crown-glass. On the other hand, in a spectrum formed with a prism of rock-crystal the mean ray is nearer the violet end than it is in a spectrum formed with a prism of crown-glass, so that the least refrangible rays occupy a greater, and the most refrangible rays a less extent than they respectively occupy in the spectrum produced by the latter medium. Hence, if a pencil of white light be made to pass through two prisms, one formed of crown and the other of flint glass, their refracting angles being such that the red and violet rays of the spectrum are united, there will be formed on the screen a short or secondary spectrum, its upper part, or that which is near the violet end, consisting of the green light which remains uncorrected, and the lower part consisting of the light formed by the union of the red and violet rays. If the bar of a window-frame be observed through two such prisms combined together, the upper side will appear to be fringed with green and the lower side with a purple tint arising from the blending of the red and violet rays.

But if a pencil of white light be made to pass through two prisms, one formed of crown-glass and the other of rock-crystal, their refracting angles being such that the red and violet rays of tho first spectrum are united, there will be formed a secondary spectrum in which the lower part is green and the upper part purple: or, if the bar of a window-frame be viewed through two such prisms, the lower side will appear to be fringed with green and the upper with purple.

This dispersion of light, which remains after the rays have been refracted through an object-glass composed of two lenses (formed with crown and flint glass) is an insuperable obstacle to the perfection of what are called achromatic telescopes: the fact of the dispersion will be evident in any such telescope if the eye-piece be drawn out beyond the point at which a luminous object as the moon appears distinct, or be pushed nearer the object-glass than that point; for, in the former case, the object will appear to be surrounded by a bright margin of green light, and, in the other, it will be surrounded by a fringe of purple light. (Brewster, *Treatise on New Philosophical Instruments*, p. 358.)

Prisms of three different media might be formed which would unite the rays of three different colours; the uncorrected colours would then produce a spectrum much smaller than that which remains when two differently coloured rays only are united, and Sir John Herschel, in the 'Encyclopædia Metropolitana' (art. Light, No. 446), proposes to call it a tertiary spectrum. Spectra of higher orders might be formed by using a greater number of prisms, for the purpose of uniting with the former the rays of other colours; but the diminution of light caused by the employment of so many media would become an evil greater than that which it is proposed to correct.

Sir David Brewster has given the name of tertiary spectra to the images formed by the uncorrected colours which remain when the red and violet rays are united by causing a pencil of white light to pass through two prisms of the same medium, as flint-glass, with their refracting angles in opposite positions: in this combination the refracting angle of one prism is greater than that of the other, and the pencil of light is made to fall on the prism having the smaller angle with such obliquity to the surface as to render the dispersion of the red and violet rays in that prism sufficient to allow it to be exactly corrected by the contrary dispersion produced by the other prism. Sir John Herschel proposes to call spectra so produced subordinate spectra.

The celebrated Fraunhofer first observed that when a beam of light from the sun, after passing through a narrow slit (about $\frac{1}{100}$ in. in breadth) in the wall or in the window-shutter of a darkened room, and then through a still narrower aperture in an opaque screen placed a few inches from the object-glass of a telescope (the two apertures being parallel to one another), was allowed to fall on the object-glass; the coloured fringes produced by the diffraction of light at the edges of the aperture, being viewed through the telescope, assumed the appearance of spectra similar to those produced by the refraction of light through a prism of some transparent medium. To these images Fraunhofer gave the name of spectra of the first class; they are composed of variously coloured light, the tints melting into one another by insensible gradations, and they exhibit dark lines as in the usual prismatic spectra.

When there was placed before the telescope a grating consisting of many very slender wires parallel to one another and to the aperture in the wall, and having very narrow intervals between them, there appeared in the field of view a dark space on either side of the image of the aperture in the wall, and beyond this, on each side, a series of spectra each consisting of variously coloured spaces, of homogeneous light, separated from one another by dark lines; these he called spectra of the second class.

When two linear apertures only were made in the screen at the object end of the telescope, there appeared in the field, between the image of the aperture in the wall and the first of the spectra, on each side, what Fraunhofer designated imperfect spectra of the second class; these consisted of coloured spaces similar to those in the spectra of the first class, but without the dark lines; and when three linear apertures only were formed in the screen, there appeared, between the image of the aperture and the nearest imperfect spectrum of the second class, other spectra less distinctly formed than the latter, and, like them, without the dark lines; these he denominated spectra of the third class. No other classes of spectra than those which have been mentioned were observed on increasing the number of apertures in the screen.

Many beautiful varieties of spectra were observed by Fraunhofer when the light was transmitted through three or a greater number of small circular apertures in a metal plate, and also through two frames, each carrying a number of slender wires parallel to one another; the frames being placed so that the wires in one were at right angles to those in the other.

SPECULA'RIA (so called from Speculum Veneris, Venus's Looking-glass, the old name of one of the species), a genus of plants belonging to the natural order Campanulaceæ. It has a rotate corolla, a linear-oblong prismatical capsule opening by lateral pores between the calycine segments. In other respects this genus resembles that of Campanula, from which it has been separated by recent systematists. The species are small annual plants inhabiting the regions of the Mediterranean and the temperate parts of Europe. One species, the *S. perfoliata*, is a native of North and South America.

S. hybrida has a simple or branched stem, the leaves slightly crenate, wavy, oblong, sessile, the lower leaves spathulate; the calyx scabrous, the segments lanceolate, longer than the corolla, shorter than the ovary. This plant is a native of the corn-fields of Great Britain, and is found commonly throughout the region of the Mediterranean. There are several other species of this genus, all of which are worth cultivating on account of their showy flowers. The seeds should be sown in the open ground, where it is intended the plants should remain. By sowing the seeds in the autumn an early blossoming may be ensured in the following summer, and by successive sowings in the spring and summer they may be made to blossom for several months during the summer.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

SPENCER, JOHN CHARLES SPENCER, THIRD EARL, will be best remembered by the title of courtesy, Viscount Althorp, which he bore from his birth, through, it may be said, the whole of his public life, and until within a few years of his death. He was the eldest son of George John, second Earl Spencer, and Lavinia, eldest daughter of Charles Bingham, first Earl of Lucan; and was born on the 30th of May, 1782. Like his father, who was distinguished for his love of literature and his munificent expenditure in the collecting of rare books, he was educated at Harrow; whence he was sent to Trinity College, Cambridge, where he took the honorary degree of M.A. in 1802.

In April or May, 1804, towards the close of the second session of the second Imperial Parliament, Viscount Althorp entered the House of Commons as one of the members for Oakhampton. A vacancy appears to have been made for him by the resignation of James Strange, Esq. On the 11th of February, 1806, on the formation of the Whig ministry of Mr. Fox and Lord Grenville, in which his father Earl Spencer took office as Secretary of State for the Home Department, Lord Althorp was appointed one of the Junior Lords of the Treasury; and this appointment having vacated his seat, he offered himself for the University of Cambridge, which had been represented by the late premier, Mr. Pitt; the other candidates being Lord Henry Petty (now Marquess of Lansdowne), who was the new Chancellor of the Exchequer, and the present Lord Palmerston. The votes were, for Lord Henry Petty 331, for Lord Althorp 135, for Lord Palmerston 128.

To the next parliament, which met in December, 1806, Lord Althorp was returned at the head of the poll for the county of Northampton, after a severe contest. The numbers were, for his lordship, 2085; for the other member, William Ralph Cartwright, Esq., 1990; for Sir William Langham, Bart. (the defeated candidate), 1381. After this his lordship continued to be returned for Northamptonshire to every parliament down to the passing of the Reform Bill. In the first Reformed Parliament, which met in January, 1833, he sat as one of the members for the southern division of that county.

Lord Althorp, of course, lost his seat at the Treasury Board when the Grenville administration was dissolved in March, 1807; nor did he again hold office till the accession of Lord Grey and his friends to power in November, 1830. During all this interval, although he did not come forward in debate so frequently as some other members, he was regarded as one of the steadiest supporters of the Opposition in the House of Commons; and, while he was making his way to the highest place in the confidence of his party, it may be safely affirmed that there was no man on either side of the House whom the public generally held in greater respect for his universally admitted patriotism and freedom from the narrowness and rancour of faction. Yet he was no temporizer or half-and-half politician. On all the great questions of the day he took a decided part; and on most of the occasions on which his party made a stand against the government, he went as far with them as any other. In 1817, for instance, we find him supporting an address to the throne for a reduction of the number of the Lords of the Admiralty, and opposing the suspension of the Habeas Corpus Act, the maintenance of so large a standing army in time of peace, the continuation of the Alien Act, and the additional grant to the Royal Dukes; in 1819 moving for an inquiry into the State of the Nation; in 1823 moving for a repeal of the Foreign Enlistment Bill, and opposing the renewal of the Irish Insurrection Act; in 1824 moving for a Committee of Inquiry into the general state of Ireland; in 1825 opposing the Suppression of the Catholic Association; in 1828 moving the first reading of the bill to repeal the Test and Corporation Acts, and opposing the grant of 2000*l.* per annum to the family of the late Mr. Canning.

Lord Althorp was also prominent for several years, about this period, in a series of economical attacks upon the Tory administration, and his house was the resort of a powerful section of the Whig party, who considered him their leader in the House of Commons. There were few questions of public importance, over and above those already mentioned, in which he did not take a practical and useful share; and his sound judgment, under all the vicissitudes and excitement of Parliamentary affairs, amply justified the confidence and attachment with which he was regarded by the party. There was about him, indeed, so much reality of purpose, such unostentatious manners, a bearing and simplicity so characteristic of the English nation, that a few sentences from him were equivalent to eloquent orations from less consistent statesmen; and though he was not fortunate enough on all occasions to escape censure, we believe it may be truly said that such censure generally emanated from individuals whose views had been frustrated by his plain dealing; and that when he left politics, he was not less in charity with all men than they were in charity with him. 'Honest Lord Althorp' was the current phrase by which his Lordship was recognised by the House of Commons and the public for many years.

The House, it is true, has been often led by what are called abler men, and the Whig party in particular has never been wanting, any more than it was during his leadership, in distinguished talents and rare oratorical ability. We doubt however whether amongst the many distinguished persons who formed Lord Grey's administration, a single individual could have been selected who would have combined in the support of the great measures of the day so much popular confidence and support, and would have carried them through parliament with an industrious patience and an earnest equanimity equal to Lord Althorp. To the honour of the House of Commons, character in public men has an authority there which stands its possessor in lieu of more striking qualities; and no Englishman of our age need be ashamed, on being reminded of the great orators of the last generation, that for several years the public business was conducted by a gentleman whose language was as plain as his appearance, but who never spoke without effect, because his hearers well knew that he had no object but the honour and prosperity of his country.

In respect to the great questions which have risen into public importance and exercised so vital an influence for the last four years on the legislation and statesmen of the day, we mean those connected with the emancipation of trade and commerce, we have reason to know that Lord Spencer warmly sympathised with the progress of the principles of free trade; and there cannot be a doubt that his influence and support would have been given to the policy and measures of 1846.

It will be remembered that upon the address to the crown in the House of Lords in August, 1841, when the Whig budget and the stability of Lord Melbourne's government were at issue, he moved the address on that occasion, and emphatically declared himself in favour of free trade. There was an occasion also, within a short period of his death, when he lost the confidence of a portion of his agricultural friends by an open declaration in favour of a total repeal of the corn laws; and we question whether Mr. Cobden ever made greater progress amongst the middle or the upper classes of society than when he could appeal to the recorded sentiments of so devoted and so distinguished a farmer as Lord Spencer.

But to return to the narrative: In November, 1827, the Whig section of the Goderich cabinet fixed upon Lord Althorp to be chairman of a Committee of the House of Commons, which it was proposed to appoint to take into consideration the general state of the national finances, and the premier (the present Earl of Ripon) appears to have given a qualified assent to that arrangement. But it was defeated, after a communication had been made to Lord Althorp, and his lordship had signified his conditional acceptance of the intended nomination, by the opposition of Mr. Herries, the chancellor of the Exchequer. This affair led to the resignation of their offices both by Mr. Herries, and Mr. Huskisson, secretary for the colonies, and to the breaking up of the administration on the 8th of January, 1828. For full details the reader is referred to the 'Annual Register' for 1828, pp. 3-12.

On the accession to power of the Grey administration in November, 1830, Lord Althorp was appointed chancellor of the Exchequer. His position, and the sound ability which he evinced in the management of great political and economical questions, with the universal confidence in his integrity, made him the ministerial leader in the House of Commons. No man probably had ever filled the latter post who possessed less of the gift of oratory; but the clearheadedness and sound sense of Lord Althorp were considered amply sufficient to make up for that deficiency. Nor were the expectations of his friends disappointed. The task of carrying through the House both the Reform Bill and the Poor Law Amendment Bill devolved principally upon him; and not only the candour and patience and complete command of temper (often in very trying circumstances) which he never failed to evince, but his mastery of both measures in all their details, the readiness and accuracy of his recollection, and even the talent of exposition and advocacy which he displayed, produced a general conviction that the difficult work he had undertaken could hardly, looking to all considerations, have been placed in better hands.

The appointment of Lord Althorp to a high ministerial office in the House of Commons was attended with the serious drawback, that his father, Earl Spencer, having already attained to the age of seventy-two, Lord Althorp was very liable to be soon and suddenly called away both from the House of Commons and from his office, which could only be held by a member of that House. In point of fact, the death of Lord Spencer, which took place on the 10th of November, 1834, by occasioning this change, broke up the ministry. [WILLIAM IV.] When the administration of Sir Robert Peel and the Duke of Wellington, which succeeded, was obliged to resign in April following, and the Whigs came again into power under the premiership of Lord Melbourne, Lord Althorp, now Earl Spencer, was, as well as Lord Brougham, left out of the new cabinet. It was understood that he declined to take office again; and indeed that he had been reluctantly induced to resume the Chancellorship of the Exchequer after giving in his resignation when Lord Grey finally retired in July of the preceding year. There can be no doubt that in losing him, the remnant of the original Reform cabinet, now deprived also of Lord Durham, Lord Stanley, Sir James Graham, Lord Ripon, the Duke of Richmond, Lord Carlisle, Earl Grey, and Lord Brougham, lost one of its chief stays, notwithstanding that Lord Lansdowne, Lord Melbourne, Lord Palmerston, Mr. Grant (now Lord Glenelg), Lord Auckland, Lord Holland, and Lord John Russell still remained.

What is said of Lord Althorp by the writer of the Memoir in the 'Gentleman's Magazine' is the more valuable as the testimony of a political opponent:—'His sincerity was never doubted, nor the integrity of his motives. . . . Up to the hour of his quitting office, his honesty of purpose retained him the esteem of the House, if he did not support his popularity; and no minister ever retired into private life accompanied with warmer wishes for his happiness, or a more general feeling of good will.'

Earl Spencer had always been strongly attached to agricultural pursuits; and now that he was not only relieved from official occupation, but had nearly withdrawn altogether from politics and public life, he devoted his greater leisure with more eagerness than ever to practical farming, the rearing of cattle, the patronage of agricultural associations, and whatever promised to advance his favourite science. 'Regardless of expense and of personal inconvenience,' says the authority we have just quoted, 'he was almost invariably present at all the great agricultural meetings throughout the country.' Indeed he may be said to have been the father of many, as he certainly was the patron of all. He was for many years President of the Smithfield Cattle Club; and, in the year 1837, in the course of his address to its members, he suggested the formation of the Royal Agricultural Society. . . . . . Earl Spencer was the first President of this Society in 1838-9, when the meeting was held at Oxford, and again in 1844, when the meeting took place at Southampton. In the formation and operations of the Yorkshire Agricultural Society he also enacted a part no less prominent than useful—no less marked by zeal than by a sound discrimination. His Lordship was President of the Yorkshire Society when its meeting was hold at Doncaster in 1843.'

Lord Spencer was one of the original members of the Roxburghe Club (for the reprinting of rare and curious tracts), of which his father was the first President. He was also Vice-Chairman of the Council of the Society for the Diffusion of Useful Knowledge; and he was a liberal contributor to the fund raised for the 'Biographical Dictionary' which the Society commenced. Lord Brougham dedicated to him his 'Discourse on Natural Theology,' published in 1835, in an address in which he says, 'I inscribe the fruits of those studies to you . . . . . because you have devoted much of your time to such inquiries—are beyond most men sensible of their importance —concur generally in the opinions which I profess to maintain—and had even formed the design of giving to the world your thoughts upon the subject, as I hope and trust you now will be moved to do all the more for the present address. Lord Brougham's 'Dialogues on Instinct,' first published in his 'Supplement to Paley's Natural Theology,' in 1839, are also supposed to be carried on with Lord Althorp, neither whose political nor agricultural pursuits, he says, had 'ever at any time prevented him from cultivating a sound philosophy, in the study of which much of his leisure is always consumed.'

Lord Spencer died at his seat of Wiseton Hall, in Nottinghamshire, on the 1st of October, 1845. He had married, on the 14th of April, 1814, Esther, only daughter and heiress of Richard Acklom, Esq., of Wiseton; but she died on the 11th of June, 1818, without issue; and his lordship was succeeded in the peerage by his next surviving brother, Frederick, now Earl Spencer.

(*Memoir in Gentleman's Magazine for Nov.* 1845; *Annual Register; Private Communication.*)

SPHÆRA, a genus of Dimyarian fossil Conchifera, from the Cretaceous system of Kent. (Sowerby.)

SPHÆREDA, a fossil plant from the Yorkshire coast.

SPHÆROCOCCITES, a genus of fucoidal fossil plants, from tho oolitic series of the Yorkshire coast. (Presl.)

SPHÆ'RODUS, a fossil genus of fishes from the oolitic and cretaceous strata. (Agassiz.)

SPHÆRONITES, a group of fossil Echinodermata from the Silurian and Devonian strata. (Hisinger.) Von Buch includes them in his family of Cystidea.

SPHENACANTHUS, a fossil genus of fishes from the coal formation of Scotland. (Agassiz.)

SPHENONCHUS, a genus of fossil fishes from the lias and wealden series of England. (Agassiz.)

SPHENOPH'YLLUM, a fossil genus of plants from the coal formations of Europe and North America. (Brongniart.)

SPHYRÆ'NODUS, a genus of fossil fishes from the London clay. (Agassiz.)

SPIDER. [ARACHNIDA, P. C.] The habits of spiders have recently formed the subject of an interesting and valuable report drawn up at the request of the British Association for the Advancement of Science, by Mr. Blackwall. This report, which is printed in the Transactions of that body for 1844, is full of new and curious matter. It touches on many points in the economy of spiders hitherto mistaken or imperfectly understood. There are also some valuable memoirs on the same subject in the later volumes of the Linnean Transactions, and several papers on new forms in the 'Annals of Natural History,' by Mr. Adam White; also an important and elaborate account of the anatomy of some species by Mr. Tulk.

Of the discoveries of Mr. Blackwall the most interesting and extraordinary relate to the sexual intercourse of these animals, and to the purposes served by their palpi in aiding in the continuation of the species. The facts made known on this subject are among the most singular discoveries of late years. For them we must refer to the report mentioned. We shall quote only a passage respecting the reproduction of the amputated palpi:—

'When the palpi of male spiders which had been amputated before the penultimate moult are reproduced, the sexual organs, perfect in structure, are reproduced also. (See experiments 8, 10, 11, 14.) Unexceptionable evidence in support of this singular fact is to be found in their reduced dimensions and integrity of form; but it will scarcely be denied that the original germs of those organs must have been removed with the detached palpi. That the function of the sexual organs is not in the least affected by their reproduction there exists the most satisfactory proof. In the last of those experiments, having for their object tho determination of the seat of the sexual organs in male spiders, recorded in this report, the male Tegenaria civilis, stated to have possessed the right palpus only when introduced to the female, is identical with that which was the subject of experiment 8 in the foregoing series; consequently its sexual organs had been reproduced, yet the fertility of its mate bore ample testimony to the unimpaired efficiency of their generative agency.'

Mr. Blackwall adds some very curious facts respecting the reproduction of spiders' limbs generally:—

'Physiologists, in conducting researches relative to the reproduction of the limbs of spiders, seem to have limited their investigations to the legs of those animals; whereas in the experiments detailed above, the palpi and spinners, as well as the legs, were operated on; and all these parts are found to be renewed, and afterwards to have their dimensions enlarged at the period of moulting only; it appears also, that if a part of a limb be amputated, as the tarsus of a leg or the digital joint of a palpus, the whole is reproduced, all the joints of the new limb, though small, being proportionate to those of the corresponding limb on the opposite side, with the exception of the digital joint of the palpi of male spiders when tho sexual organs are not reproduced, which is usually somewhat modified in size and form by that circumstance.'

Tho following observations respecting the monstrosities occasionally presented by spiders, are of no small consequence in their bearing on specific determinations:—

'Variations in the colour and size of spiders of the same kind, resulting from differences in age, sex, food, climate, and other conditions of a less obvious character, as they conduce largely to the introduction of fictitious species, have long engaged the attention of arachnologists, while those arising from extraordinary organic modifications, in consequence perhaps of their less frequent occurrence, have been almost entirely overlooked. The importance which cases of the latter description possess, in relation to physiology and systematic arrangement, will be best illustrated by a few examples.

'1. A supernumerary eye, situated between the two small ones constituting the anterior intermediate pair, has been observed in an adult female *Theridion filipes*. The total number of eyes possessed by this individual was nine, and their arrangement symmetrical.

'2. An immature female (*Thomisus cristatus*) had the two lateral pairs of eyes only; the four small intermediate were altogether wanting, not the slightest rudiment of them being perceptible even with the aid of a powerful magnifier.

'3. A short but perfectly formed supernumerary tarsus, connected with the base of the tarsal joint of the right posterior leg on its outer side, has been noticed in an adult female *Lycosa campestris*.

'4. Deficiency of the right intermediate eye of the anterior row has been remarked in an adult male *Lycosa cambrica*.

'5. The left intermediate eye of the posterior row was perceived to be wanting in an adult female *Epeïra inclinata*, and the right intermediate row was not half the usual size.

'6. An adult female *Ciniflo atrox* was found to be without the left intermediate eye of the posterior row.

'7. The right intermediate eye of the posterior row in an adult female *Epeïra inclinata* had not one-eighth of the natural size, being merely rudimentary.'

SPIKENARD. [NARDOSTACHYS, P. C. S.]

SPILANTHUS (from σπῖλος, a spot, and ἄνθος, a flower, because of its dotted or speckled flowers), a genus of plants belonging to the natural order Compositæ and the suborder Corymbiferæ. It has a many-flowered head, either heterogamous with the florets of the ray ligulate, or homogamous with all the florets tubular and 5-toothed; the involucre is in two rows, appressed, shorter than the disk, the outer scales somewhat leafy, the inner rather membranous and folded up.

S. oleracea has a branched diffuse stem, opposite stalked broadly ovate leaves, obtuse at the base, truncate or somewhat cordate. The pedicels are one-headed, longer than the leaf. The heads thick, ovate, and discoidal. The achænia ciliated at the angles, bi-aristate or awnless. The whole plant, but especially the involucre and receptacle, acts as a powerful stimulant of the salivary organs.

(Lindley, *Flora Medica.*)

SPINELLI, PARRI, a celebrated old Italian painter, was the son of Spinello Aretino, and was born at Arezzo, apparently about 1388-90, though his father was then very old, upwards of seventy. This conjecture however rests only upon Vasari's statement respecting the age of Spinello, and the assertion that Parri died when he was fifty-six years of age, and on the date 1444, which is on the altar-piece of San Cristofano at Arezzo, which is attributed to him.

He was first instructed by his father, and was afterwards employed by Lorenzo Ghiberti in Florence as an assistant in preparing the celebrated gates of the Baptistery of San Giovanni, which were executed between 1402 and 1424. He painted chiefly in Arezzo, and Vasari enumerates many of his works, but few now exist. He returned to Arezzo, says Vasari, upon the death of his father, and after many years' absence, from which it would appear that the fathor lived further in the fifteenth century than is at present supposed: he is known to have been living in 1408, and his death is supposed to have happened about this time. Vasari's statement that he died in 1400 is probably a misprint as well as an error, as the account of Parri's assisting Ghiberti and returning to Arezzo at the time of his father's death and after many years' absence, is a complete contradiction to it.

Parri was an excellent colourist, and was the best practical fresco painter of his time; his draperies were also good, but his figures were too long in proportion; Vasari says some of them measured as many as eleven heads in height, and yet they were not ungraceful.

(Vasari, *Vite de' Pittori*, &c.)

SPI'RIFER, the earliest generic name assigned by Sowerby to a large group of fossil Brachiopoda, from the Palæozoic strata. (Delthyris, Orthis, &c., have since been dissevered from the group.)

SPIRITUAL COURTS [ECCLESIASTICAL COURTS, P. C. S.]

SPIRO'GLYPHUS, a genus of fossils from the mountain limestones of Ireland. (M'Coy.)

SPIRO'PORA. [Cricopora, P. C. S.]

SPONG'ARIUM, an undetermined probably Zoophytic genus of Silurian fossils. (Murchison.)

SPRANGER, BARTOLOMAEUS, a great mannerist, but a celebrated painter in his time, was born at Antwerp in 1546. His father was a wealthy merchant, and after he had received instruction from several masters at Antwerp, he visited Paris and Italy, where at Milan he placed himself with Bernardo Gatti, called Soiaro. From Milan he went to Rome, where he found a patron in the Cardinal Farnese, who introduced him to Pope Pius V., who commissioned Spranger to paint him a picture of the Last Judgment, gave him apartments in the Vatican, and appointed him his painter. This picture of the Last Judgment, which contained about five hundred heads, was painted on a large sheet of copper, and after the death of the pope it was fixed over his tomb in the church of Santa Maria Maggiore, but must have been long since removed.

In 1575 Spranger left Rome to enter the service of the Emperor Maximilian II., at Vienna, to whom he had been recommended by John of Bologna. After the death of Maximilian he remained in the service of Rudolph II., who ennobled him in 1588. He visited his native place in 1602, after an absence of thirty-seven years, and was treated with great distinction by his countrymen. He returned again to Prague, and died there about 1625, according to Von Mechel. There are nineteen pieces by Spranger in the gallery of Vienna, and many in other German collections. He painted with facility, but his figures are heavy, gross, and distorted; he was fond of allegorical and mythological subjects, which were utterly unfit for his style.

(Fiorillo, *Geschichte der Malerei*, &c.)

SQUALORA'IA, a genus of fossil fishes from the lias of Dorsetshire. (Riley.)

SQUARCIO'NE, FRANCESCO. This painter, celebrated for his superior acquirements as well as his great school and rich collections of works of art, was born of a good family at Padua, in 1394, and after performing many tours in Greece and Italy, lived there in great affluence and distinction until his death in 1744. His house was one of the chief attractions in Padua. He was the master of Andrea Mantegna, who lived some time in Squarcione's house. From his very numerous school (he had 137 scholars) he was called the father and primo maestro of painters. He appears to have been more engaged in teaching than in practising the art. [Venetian School of Painting, P. C., vol. xxvi. p. 212.] Vasari terms him erroneously Jacopo Squarcione.

(Ridolfi, *Vite de' Pittori Veneti*, &c.)

SQUATI'NA, a genus of cartilaginous fishes, of which the Angel or Devil Fish of our seas is the type. They differ from all the other sharks in the position of the mouth, which is cleft at the extremity of the snout, and not placed below, and in the position of the eyes, which, instead of being on the sides, are on the summit of the flattened head. The body is broad and flattened horizontally; the head is round. The dorsal fins are placed farther back than the ventrals, and there is no anal fin present.

STADE DUTIES are so called from Stade, in the kingdom of Hanover, a town situated on the right bank of the Schwinge, three or four miles from where it falls into the Elbe, and 22 miles west by north from the city of Hamburg. The name *Brunshausen Tolls* is now more commonly used, from the village of Brunshausen, at the mouth of the Schwinge, where there is a custom-house and a royal guard-ship, and where the duties are collected which are levied on vessels and merchandise passing up the Elbe. The original duties, which were regulated by a treaty made in 1691, were light, but were gradually increased by the Hanoverian government till they amounted to about 40,000*l.* a-year. The duties levied were about ½ per cent. *ad valorem*, more on some articles and less on others. British vessels by a proclamation of Geo. II., December 1, 1736, were allowed under certain regulations to sail directly up to Hamburg, without coming to anchor at the mouth of the Schwinge, as other foreign vessels were obliged to do.

By a convention between the King of Hanover and the other Elbe-bordering states (Emperor of Austria, King of Prussia, King of Saxony, King of Denmark, Duke of Mecklenburg-Schwerin, Duke of Anhalt-Cœthen, Duke of Anhalt-Dessau, Duke of Anhalt-Bernburg, Free and Hanseatic town of Lübeck, and Free and Hanseatic town of Hamburg), dated April 13, 1844, in conformity with articles 108 and 116 of Act of Congress of Vienna, of June 9, 1815, the Brunshausen Tolls were revised, regulated, and settled according to a Toll-Tariff agreed upon by the contracting parties.

By a treaty of commerce and navigation between the Queen of England and the King of Hanover, signed at London, July 22, 1844, British and Hanoverian vessels arriving at, remaining in, and departing from the ports of the two countries, are mutually subject to no other or higher dues or charges than those which are now or shall hereafter be imposed upon the national vessels of the two countries on their arrival at, remaining in, or departure from such ports. All articles of the growth, produce, or manufacture of Great Britain or Hanover, which are or shall be permitted to be exported or imported in British or Hanoverian vessels, are mutually allowed to be exported or imported in the vessels of either country, and no distinctions of duties or drawbacks shall be made. By article 6, 'From and after the 1st day of October, 1845, no other or higher duties or tolls shall be levied, as regards the tolls or charges known by the name of the Stade or Brunshausen tolls and charges, on British vessels passing up the Elbe to the point where the tolls of the Upper Elbe commence (that is to say, up to and including the town of Hamburg), or upon the cargoes of such vessels, than the tolls and duties which are specified in the convention between the Elbe-bordering states, which was signed at Dresden on the 13th of April, 1844, and in the separate articles, regulations, and five tables annexed thereto.' With respect, however, to the following articles of British produce and manufacture (that is to say, yarn, thread, manufactures of cotton, wool, and linen, tin and tin plates, articles of iron and steel, treacle or syrup, earthenware, copper and brass, and similar alloys of metals and manufactures thereof), it is agreed that the duty or toll to be levied, whether in British vessels or in vessels of any of the Elbe-bordering states, shall be only two-thirds of the duty or toll specified in the tables.

The treaty is to continue in force till January 1, 1854.

STAINING. [Dyeing, P. C., p. 225; Paper-Hangings, P. C., p. 215; Glass Painting, P. C. S., p. 654.]

STANHOPE, PHILIP, Captain, a brother of the celebrated James, Earl Stanhope [Stanhope, James, P. C.], was from early youth brought up to the sea-service, and in 1704 was appointed to the command of the Hastings frigate. From this vessel he was promoted to the Milford, in which ship he served under Sir Stafford Fairbourne at the siege of Ostend, and was chosen by that commander to bring home the news of the surrender of that fortress to the allies. He afterwards served in the Mediterranean, under the command of Capt. Carey, on which station he remained till the close of his life; he there earned the reputation of an active and intelligent officer. In August, 1708, it was determined in a council of war held on board the Elizabeth, at the request of Charles, who had taken the title of King of Spain [Succession, War of, P. C. S.], that the ships, the York and the Milford, should assist in conveying the transports, which had on board General Stanhope and a large body of Catalonian troops, to Minorca, the reduction of which island was an object of importance to the success of the allied cause. Capt. Stanhope, who was desirous of emulating his brother's glory, served as a volunteer in the expedition, and fell in the moment of victory at the assault of the Spanish lines at Port Mahon, Sept. 17, 1708. He is referred to in the Article Anne, P. C., under the name of Admiral Stanhope.

The details of his life are derived from Rees's 'Cyclopædia,' vol. xxxiii., London, 1819; Campbell's 'Lives of the Admirals,' vol. iv., p. 82, note; London, 1761; and Boyer's 'Life of Queen Anne,' p. 350, folio, London, 1735.

STANLEY, ST. LEONARD, a village, formerly a market-town (and described as still being one in the Article Gloucestershire, P. C.), in the lower division of Whitstone hundred, in the county of Gloucester, about 3 or 3½ miles W.S.W. of the town of Stroud, and about 12 S. by W. of Gloucester. The adjunct to its name, St. Leonard, serves to distinguish it from two other Stanleys in the county, namely, the adjacent parish of King's Stanley and the parish of Stanley Pontlarge, near Winchcombe, in the northern part of the county. The area of the parish is 910 acres; the population at the different enumerations was as follows:—1801, 590; 1811, 538; 1821, 757; 1831, 942; 1841, 864. The number of houses at the latest enumeration was 201, namely 182 inhabited, and 19 uninhabited. There were none building. The village consists of three or four small streets meeting at the church, which is dedicated to St. Swithin, and is an antient cross-church, with a tower at the intersection. The architecture is partly of the early English period, partly of later date. This church formerly belonged to a Benedictine priory founded here by the Berkeleys of Dursley, which afterwards became a cell to Gloucester Abbey. There are some remains of the conventual buildings, which have been converted to domestic purposes. St. Leonard Stanley was antiently of more consequence, and had a market: its decay was produced or accelerated by a fire which, in A.D. 1686, destroyed nearly the whole town: it has some share in the clothing manufacture of the district, and has two yearly fairs, but they are of little importance. The living is a perpetual curacy of the clear yearly value of 200*l.*, but without a glebe-house fit for residence, in the rural deanery of Stonehouse, in the Archdeaconry of Gloucester, in the diocese of Gloucester and Bristol. There were in the parish, in 1833, three small day-schools; one, with a small endowment, contained 14 children, the other two contained 42, giving a total of 56 children (25 boys and 31 girls), or only one in seventeen of the population, according to the census of 1831, under daily instruction. There were two Sunday-schools with 305 children, namely, 141 boys and 164 girls. The parish of St. Leonard Stanley is included in the parliamentary borough of Stroud.

(*Parliamentary Papers; Ordnance Map;* Fosbroke's *Gloucestershire.*)

STANZIO'NI, MA'SSIMO, Cavaliere, a celebrated Italian painter, was born at Naples in 1585. He was the pupil of Caracciolo, but became afterwards the imitator of the great Bolognese painters, especially Guido Reni; he was called the Guido of Naples, and is considered the most correct of the Neapolitan painters. He was an excellent portrait painter, and was also distinguished for his frescoes. There are several excellent works by Stanzioni in the church of the Cortosa, now an hospital, at Naples, especially the picture of St. Bruno presenting the rules of his order to his monks. In the same church is a picture of a dead Christ and the Marys, which, as it had somewhat darkened, Spagnoletto, through jealousy, persuaded the Carthusians to wash with a corrosive water, which completely spoilt it. Stanzioni, disgusted with the baseness of the act, would not restore it, preferring to leave it as a monument of Spagnoletto's meanness. Stanzioni died at Naples in 1650. He had a numerous school, and he left many notices of Neapolitan painters, which were used by Dominici.

(Dominici, *Vite de' Pittori Napolitani*, &c.; Lanzi, *Storia Pittorica*, &c.)

STARS, SHOOTING. [SHOOTING STARS, P. C. S.]

STA'TICE (from the Greek στατική, intended to be used in the active sense, 'to stop,' so named from its supposed property of restraining hæmorrhages), a genus of plants belonging to the natural order Plumbagineæ. It has spiked flowers with a 5-parted corolla, the calyx scarious above, the capsules not bursting.

S. caroliniana has narrow obovate leaves on long petioles, smooth, veinless, obtuse, mucronated, level, and flat on the margin. The scape is round, smooth, slightly scaly, and terminated by a panicle of numerous branches, which bear the flowers on the upper side only. The flowers are alternate, erect, mostly in pairs, but appear singly in consequence of one expanding before the other. The calyx is funnel-shaped, scarious, and pink at the edge, 5-angled, the angles ciliate, and ending in long sharp teeth. The petals are obtuse, longer than the calyx, and of a bluish purple colour. This species is a native of North America, where it is called the Marsh Rosemary. The root is a very powerful astringent, and is used as an application in aphthæ and similar affections of the mouth and fauces; it has been employed with success in cynanche maligna.

S. Limonium, Sea Lavender, is a British species, and has much divided corymbose branches curved outwards; the ultimate subdivisions short, unilateral, ascending, and densely flowered. The calyx segments entire, acute, with intermediate teeth, the outer bracts pointed and small. The roots possess astringent qualities.

S. rariflora is found near the sea in England and the coast of Galloway; it has oblong lanceolate stalked leaves, the branches divided, the panicle ascending or incurved, the ultimate subdivisions elongated with unilateral rather distant flowers; the calyx segments acute, denticulate, with intermediate teeth; the bracts obtuse, the outer ones large, the margins tinged with pink.

S. spathulata has spathulate leaves narrowed into a broadly winged stalk; the calyx segments blunt, entire, and without intermediate teeth.

S. reticulata has spathulate leaves narrowed into a flat stalk, mucronate behind the point; 3-ribbed below; the scape panicled almost from the base with numerous slender zig-zag much-divided branches, of which the lower are barren; the calyx segments acute, denticulate. It is found in muddy salt marshes in Norfolk.

(Babington, *Manual of British Botany;* Lindley, *Vegetable Kingdom.*)

STATUTE (*Scotland*). It would be difficult to explain the character of the older legislation of Scotland, the method in which it was sanctioned, or the constitution of the bodies by which it was passed. All the light that probably is to be obtained on the early history of the statute-law has lately been embodied by Mr. Innes, in his preface to the edition of the 'Scottish Statutes and old Laws,' published by the Record Commission. 'Whatever,' he says, 'may be the case in other countries, it is not easy in Scotland to distinguish the antient legislative court or council of the sovereign from that which discharged the duty of counselling the king in judicial proceedings. The early lawgivers, indeed, enacted statutes by the advice of the "bishops, earls, thanes, and whole community," or "through the common counsel of the Kynryk;" but during the reigns previous to Alexander III. we find the king also deciding causes in a similar assembly of magnates: while laws of the greatest importance, and affecting the interests of whole classes of the community, bear to be enacted by the king and "his judges."' It is probable that the practice of the assembly, legislative or judicial, of the principal barons, though irregular, was in general an imitation of the parliament of England. Before the war of independence the lands of the southern districts of Scotland had been in a great measure partitioned among Norman adventurers, some of whom owed a double allegiance to the crowns both of England and Scotland; and it was natural that they should bring with them the practices and opinions of the country with which they were earliest connected. A large proportion of the lowland population of Scotland were at the same time Saxon refugees from England. So early as the reign of David I. (1125) we begin to find that the municipal corporations had a voice in the ratification of the laws. 'The parliament,' says Mr. Innes, 'assembled by John Balliol at Scone, on the 9th of February, 1292, was probably the first of the national councils of Scotland which bore that name in the country at the time, although later historians have bestowed it freely on all assemblies of a legislative character. We have no reason to believe that any change in its constitution occasioned the adoption of the new term, which soon became in Scotland, as in England, the received designation of the great legislative council solemnly assembled. It was not till a few years later, on occasion of negotiating an alliance with France, that Balliol, probably at the desire of the French king, procured the treaty to be ratified, not only by the prelates, earls, and barons, but by certain of the burghs of his kingdom. That treaty was finally ratified at Dunfermline on the 23rd day of February, 1295; and the seals of six burghs were then affixed to the deed, along with those of four bishops, four monasteries, four earls, and eleven barons. Notwithstanding this very formal ratification, however, it may be doubted, both from the peculiar phraseology of the deed itself, and from the silence of historians as to any meeting of a parliamentary nature in which it could have been voted, whether the parties stated as consenting, and especially whether representatives of those six burghs, were actually present as in a national assembly of parliament.'

The acts which were thus sanctioned—sometimes, perhaps, by the separate adhesion of the principal interests of the country, sometimes in assemblies—were of a mixed character. Some were judgments in particular disputes, accompanied probably by the announcement of a principle on which such questions should thenceforth be decided; others were acts of executive authority: and others might be regulations having the character of fixed and general laws. When these proceedings related to matters of private right, the recording instrument would be put into the hands of the party interested. 'When the proceedings of the national council,' says the authority already cited, 'related to matters of a more public nature, such as negotiations with foreign states, its earliest records were probably of a similar kind, and consisted of nothing more than the indentures or other diplomacy which embodied the results of its deliberations. Perhaps the earliest instances of this kind that now remain are those important deeds of the reign of Alexander III., when, however, a more artificial system must have been beginning to prevail. It would be still more interesting to ascertain the modes in which the more general ordinances and laws of the realm were enacted and recorded; but on this head the loss of every original document had left us entirely to conjecture. Judging, however, from the mutilated and imperfect transcripts of a later age, and from the analogy of the other states of Europe, it would appear that the more important and general statutes were framed into snort capitulars, and ingrossed into a writ, addressed, in the name of the king, to the chief ministers of the law in the different districts of the kingdom, requiring the publication and observance of them. The laws of the burghs, the assizes of David I. and of William, and the statutes of Alexander II., as found in the old manuscript compilations of lawyers, seem to be the fragments of various capitulars of this kind.' The assizes of David I., 'Assisé Regis David,' are reported to be the oldest fragments of legislation in Scotland, and are partly, hut not entirely, traceable to so early a period as the reign of the king with whose name they are associated. The burgal laws, 'Leges Quatuor Burgorum,' constitute tho oldest systematic collection of laws. They too may be referred to the reign of David, and though historians give him the credit of having planned the whole system of the municipal corporations, it is more likely that this code of laws embodies the privileges and restrictions which had gradually come into existence with the growing influence of the burghs. The coincidence between these early vestiges of Scottish legislation and the old law of England is remarkable. Both in the assize, and In the burgh laws, technical phraseology is frequently nsed, which still helongs to the law and practice of England, but has long been disused in Scotland. Indeed, it is very clear that, before the attempt of Edward I. to be master of Scotland, there was much harmony in tone and spirit between the two nations, and that Scotland generally followed or accompanied England in all her constitutional progress. There is a still more remarkable coincidence of legislation in the celebrated *Regiam Majestatem*, or general code of the old laws of Scotland. It was, like the fragments mentioned above, attributed to David I., who had obtained the character of the Justinlan of Scotland; but It is undouhtedly of later date. In the sixteenth and seventeenth centuries it was very popular, as an undoubted early national code; hut it was subsequently discovered to have many features in common with the compilation 'De Legihus et Consuetudinibus Angliæ,' attrihuted to Ranulph de Glanvil, justiciar of England, and then it acquired the evil reputation of being a code prepared by Edward I., for the purpose of subjecting Scotland to the law of England. 'Upon an accurate collation of the books,' says Mr. Innes, 'it appears that the fourteen books of Glanvil contain in systematic arrangement, with some inconsiderable exceptions, the same matter, almost in the same words, which the compiler of the 'Regiam' has put into four books (in imitation of the Institutes of the Rŏman law), but divested of all systematic order. Many minute variations are found, and when these are intentional, they are plainly caused by a desire to snit the text of the English law-book to the local circumstances of Scotland; when they have happened accidentally, the vltiated or unintelligible text of the Scotch book is readily corrected by a comparison with the English author. There are, however, chapters in the 'Regiam' which are not in Glanvil. Part of these are extracts from the civil and canon law, and the remainder, joined inartificially to the surrounding text, appear to be genuine chapters of antient Scotch laws, most of which can be traced to their sources in the statutes of the early kings now collected.' Mr. Innes does not believe in the theory that the 'Regiam' was prepared under the authority of Edward I., but thinks its resemblance to the English compilation may be attributed to the spirit of imitation.

The 'Regiam Majestatem,' so named from the words with which it commences, is, with the burgh laws, and other vestiges of early legislation, printed in the first volume of the edition of the Scottish statntes issued by the Record Commission. None of the contents of this first volume, however, come within the description of the accepted statute law of Scotland. They are curious vestiges of constitutional hlstory; and If it be necessary for ascertaining the just application of any settled principle of law by a reference to its origin, these old collections are sometimes referred to; hut they are not admitted as direct authority in the substance of the law. In 1566 a commission was issued for the collection and puulication of the statute law, and they speedily published a series of statutes reaching from 1424 to 1564. It is at the former date that the statute law, properly speaking, commences, and It proceeds thence in a regular series to the Union with England. Several of the most important statutes still In force—as, for instance, that which secures to the agricultural tenant the continuance of his lease, notwithstanding the death of the landlord hy whom it may have been granted—date back to the earlier part of the fifteenth century. The Scottish acts are referred to hy the date of the parliament in which they are passed, and their numerical order; as, 'The Act 1424, c. 25;' 'The Act 1661, c. 16.' The early statutes are brief and sententious, and were admired by Bacon for 'their excellent brevity.' The following are two successive Acts of the Parliament of 1424, given in full:—

'Item, it is decreeted be the haill parliament, and forbidden be our soveraine lorde the king, that ony leagues or bandes be maid amongst his lieges in the realme; and gif onie has bene maid in time hygane, that they be not keeped nor halden in time to cum.'

'Item, it is ordained that na horse be sauld out of the realme, quhill at the least they be three yeir auld outgane, under the peine of escheitte of them to the king.'

From the date of the accesslon of Bruce, after the war with England, the Scots long entertalned a feeling of national jealousy and enmity towards England; and though some of the kings introduced Southern practices, we do not find that steady imitation and adoption of the constitutional movements of the English parliament which characterise the earlier period, but rather an isolated creation of, and adherence to national peculiarities. The Scottish parliament was not divided like the English into two houses, but the three estates—the clergy, the barons and other freeholders, and the burgesses—formed one assemblage. The method of conducting legislative business was very different from that which came into use in England. At the commencement of the sittings a commlttee was chosen, called Lords of the Articles, who had the duty of preparing and arranging the matters to be laid before the House for its approval. It thus appears to have generally happened that the full assemblage only met on the first and the last days of a session: on the former the lords of the articles were chosen; on the latter, the statutes or other proceedings prepared hy this committee were voted on, and sanctioned or rejected. The royal assent was given by touching the act with the sceptre; but some constitutional writers maintain that this was a mere court ceremony, and that an act which had passed the three estates became law without any sanction from the king. It became a principle which widely distinguished the legislation of Scotland from that of England, that in the former country statutes might cease to be law hy merely falling into desuetude. Of the statutes of the Scottish parliament, those only are now law which are said to be *in viridi observantiâ*. By this principle the statute law has silently modified itself to the character of the times; and, though not formally repealed, the barbarous laws of periods of bigotry or violence have ceased to be enforceable. Since the Union of 1707, it has been considered, in conformity with the English doctrine, that an act passed by the British parliament must be held as law, and judicially enforceable, until it is repealed.

The law of Scotland, the judicial and executive system, and the ecclesiastical polity, being quite distinct from the corresponding institutions of England, many statutes are from time to time passed by the British legislature solely applicable to Scotland, prepared by persons professionally acquainted with the institutions of that part of the empire. The revenue laws of Scotland were formerly distinct; but now, with few exceptions, one system embodied in one series of acts applies to the United Kingdom. In matters of national policy, and frequently in the criminal law and in legislation for internal economy, acts are made applicable both to England and Scotland at the same time. In these departments of legislation much confusion has arisen from its either heing left doubtful whether a statute applies to Scotland, or from terms being used which are not the proper technical phraseology of Scottish law. This uncertainty has heen a considerable source of litigation in Scotland; and the courts have been, from the want of uniformity in the composltion of the statutes, hitherto unablo to form any rule serving as a criterion for the extension of such acts to Scotland. In many cases—such as the Bankrupt Act, tho Tithes Commutation Act, &c.—the institutions to which the legislation refers distinctly limit its application to England. In other instances, however, general laws are made which are as applicable to Scotland as to England, while tho machinery by which the act directs them to be enforced is to be found only in England. In many instances these acts have only been capable of enforcement in Scotland by reading, instead of English institutions, those of Scotland, which most nearly correspond with them—as, by substituting 'The Court of Session' for 'The Courts of Record at Westminster.' The remedy for this evil appears to be, to incorporate with each act a clause stating the territorial extent of its application; and whenever it is intended that it shall apply to Scotland, to have clauses especially applicable to its enforcement in that part of the empire.

STATUTE (*Ireland*). [Parliament of Ireland, P.C.]

STATUTE OF FRAUDS. This name is applicable to any statute the object of which is to prevent fraud, but it is particularly applied to the 29 Car. II. c. 3, which is entitled 'The Statute of Frauds and Perjuries.' One object of the statute was to prevent disputes and frauds by requiring in many cases written evidence of an agreement. Before the passing of this statute many conveyances of land were made without any writing as evidence of the conveyance. An estate in fee-simple could be conveyed by livery of seisin, accompanied with proper words, and a use could also be declared by parol. No writing was necessary to convey any estate in possession, for such estate is technically said to lie in livery; but a reversion could only be conveyed by deed. The statute of frauds declared that all leases, estates, and interests of freehold or terms of years, or any uncertain interest in any lands or hereditaments, made by livery and seisin only, or by parol, and not put in writing and signed by the parties, &c., shall have the force of leases or estates at will only. But leases for not more than three years, whereon the rent reserved shall be two-thirds of the full improved value of the thing demised, are excepted by the statute. Further, no lease, estates, or interest either of freehold or terms of years, or any uncertain interest, not being copyhold or customary interest, shall be assigned, granted, or surrendered, except by deed or note in writing. Another section of the statute provides that all declarations or creations of trust or confidences of any land, tenements, or hereditaments, shall be manifested and proved by some writing signed by the party who is by law enabled to declare such trust, or by his last will in writing, or they shall be void. The 5th section of this statute declared that all devises of lands or tenements, as more particularly described in this section, should be in writing and signed in the manner here prescribed by three or four credible witnesses; and the 6th section related to the revocation of a devise in writing of lands or tenements. Both these sections are repealed by the last Wills' Act, 1 Vict. c. 26, which makes alterations in other provisions also of the Statute of Frauds.

There are several other important provisions in this statute, which may be omitted here, as the object is to show merely that the purpose of the statute is to prevent fraud by requiring the evidence of writing, which is a better kind of evidence than men's memory.

STATUTE MERCHANT. [Acton Burnell, Statute of, P. C. S.]

STATUTE STAPLE. [Staple, P. C.]

STEAM-VESSEL SCREW. While much has been done since the publication of the notices of screw-propellers under Screw of Archimedes, P. C., p. 111, and Steam Vessel, P. C., p. 510, in the practical application of such apparatus to steam-vessels, and results have been obtained which lead to the conclusion that this mode of propulsion is practicable upon a very large scale as well as in small vessels, and that it possesses some very important advantages over the use of paddle-wheels, the invention yet remains in too experimental a state to justify any attempt to deal with it as with a settled branch of science. Since the date of the articles referred to, in addition to vessels of more ordinary dimensions, the screw-propeller has been brought into use in the immense iron steam-ship now called the Great Britain, but which, while building, at Bristol, was sometimes referred to as the Mammoth, the dimensions of which, as given in the 'Athenæum' for 1845, p. 118, are 320 feet long and 50 feet broad in the widest part, drawing 16 feet water. Its capacity is about 3000 tons, and the engines, consisting of four cylinders of 88 inches diameter and 72 inches stroke, are of 1000-horse power. This great ship, by far the largest ever launched, was fitted, on her completion in 1845, with a screw-propeller 15½ feet in diameter, with six arms, mounted in the stern, and capable of being turned with great rapidity by means of a chain-wheel of 18 feet diameter, which was immediately connected with the engines, and communicated its motion through an endless chain to a much smaller wheel fixed on the shaft, which constituted the axis of the propeller. The propeller was thus turned with a velocity exceeding that of the crank-axis in a ratio determined by the relative diameters of the larger and smaller chain-wheels. Thus mounted, and furnished with six masts, five of which were stepped on deck so as to be removable at pleasure, with wire rigging, and with every requisite for taking advantage of favourable winds, the Great Britain sailed from Liverpool on the afternoon of July 26th, 1845, on her first trans-Atlantic voyage, and reached New York on the afternoon of August 10th. After her fourth voyage (the second homeward trip), during which she was left for some time wholly dependant upon her sails, in consequence of the shattering of the propeller, she was fitted with a new and much stronger propeller, weighing seven tons, of the same diameter as before, but consisting of only four arms or vanes; and she was at the same time fresh rigged, her number of masts being reduced to five, and the whole stepped upon the keelson. With these alterations, in an experimental trip made on the 30th of May, 1846, the Great Britain attained a speed of 11⅝ nautical, or about 13½ statute-miles per hour.*

An important discussion upon screw-propellers, suggested by an account of a new steam-vessel called the Liverpool Screw, submitted to that body, was carried on during three successive meetings of the Institute of Civil Engineers, in February, 1844. In the course of this discussion, of which a full report was published in the 'Mechanics' Magazine,' vol. xl. pp. 291-299, it was remarked by Mr. Rennie that the principal point to be obtained in a screw-propeller is a form which shall offer but little obstruction to the water, and yet act upon it so as to exert full power in propulsion; and that 'a large portion of a complete screw having no useful effect, had induced the introduction of propellers with several blades; thus doing away with the useless part of the surface.' A perusal of the discussion alluded to will show that the engineers who took part in it were not quite agreed in their views of the action of such propellers, especially with reference to what is termed the 'slip,' by which appears to be meant the amount of motion absorbed by the propeller cutting its way through the water, instead of pushing the water from it, or the difference between the speed of the vessel as it might be deduced from the number of revolutions made by the screw, and the actual way made through the water. Without attempting to unravel this somewhat difficult question, upon the true comprehension of which the best shape, size, position, and velocity of the propellers must depend, we may observe with Mr. Farey that while the advantageous action of ordinary paddle-wheels is greatly impaired by variations in the degree of immersion, the submersed screw propeller, being wholly under water at all times, does not appear to be sensibly affected by any such alterations in the depth of immersion as are likely to take place in the roughest waves, or the greatest variations of draught arising from changes in the lading of the vessel. 'When all circumstances were considered,' Mr. Farey observed, 'it might be safely concluded that vessels fitted with revolving submersed propellers would answer well for making regular sea voyages, either in winter or summer; and, on an average, he thought that their passage would be performed at least as well (if not better) than those of any steam-vessels now in use; and with an economy of fuel, arising from such vessels making a more advantageous use of their sails, and less of their engine-power.' The absence of the ponderous paddle-wheels and paddle-boxes of an ordinary steamer greatly improves the sailing qualities of a screw-propelled vessel, while the arrangement of the machinery may be such as to render the vessel far more commodious, and, if desired, to leave the upper decks open from end to end. These, among other advantages, recommend this mode of propulsion for steam-frigates, and other vessels of war. The Princeton, an American steam-frigate, launched about the commencement of 1844, and mounted with Ericsson's transversal screw-propeller, affords a good example of the advantages of the invention as applied to such vessels. This vessel, which, according to an account quoted in the 'Athenæum' for 1844, p. 205, from the 'New York Herald,' is of 700 tons burden and 250-horse power, has a submerged propeller making 36 or 37 revolutions per minute, and is capable of making its way through the water at the rate of 14 miles per hour, or even somewhat more, is said to have beaten the Great Western in speed, although drawing at the

* Since the above was written this noble vessel has run aground in the Bay of Dundrum, between Belfast and Drogheda. The accident occurred on her outward voyage, in the night of September 29, 1846; and though the spring-tides have since taken place, the vessel has not yet (Oct. 24, 1846) been got off.

time four feet more water, and exercising only two-thirds of her steam-power. The dimensions of the vessel are not given in the article quoted, but Mr. Braithwaite stated them, at the discussion above referred to, to be 164 feet long, 30 feet beam, depth of hold 22 feet 6 inches, and draught of water 17 feet 6 inches. He also, if the report we have quoted be correct, stated the power of the engines as 400 instead of 250 horses, and the velocity of the screw and speed of the vessel as rather less than we have stated. In the absence of proof as to which statement is correct, we may observe that while Mr. Braithwaite's would indicate a very unusually high proportion of power to tonnage, that of the 'New York Herald' shows about the common proportion for fast vessels. The engines, according to Mr. Braithwaite, are of peculiar construction, 'having two steam cylinders or chests, containing vibrating pistons or flaps, with cranks upon the ends of the suspending pivots;' these are coupled by connecting-rods to a main crank on the driving shaft, and the length of the first-mentioned cranks is so proportioned that their alternate vibrations shall give a rotatory motion to the main crank, and thus act directly upon the propeller, without the intervention of bands or gearing. In a subsequent stage of the discussion this point was reverted to by Mr. Galloway, the advantage of turning the propeller by the direct action of the engines being, he said, generally acknowledged; indeed, he added, 'the method of driving it was nearly the only problem remaining for solution, and that difficulty being once overcome, screw-propellers must necessarily, from their vast advantage over paddle-wheels, in every respect but that, be universally adopted.' Returning to the Princeton frigate, we may observe that it is evident, as stated in the 'New York Herald,' how greatly steam-vessels so mounted would have the advantage over those of the usual construction in active service; for in that vessel the whole of the machinery, cranks, boilers, and furnaces, as well as the propeller itself, are below the water line, the top of the highest plates of the boilers being as much as four feet below, and therefore pretty secure against injury from shot, while in the Great Western, and other steam-ships of the ordinary kind, the boilers and machinery, as well as the paddle-wheels themselves, are within destructive range. We may mention, although not directly affecting the use of the screw-propeller, that the Princeton is supplied with furnaces for burning anthracite, to avoid the production of smoke, and that she is ship-rigged, and so constructed that in favourable weather her screw may be unshipped, when she will sail well under canvas, a facility which can never be so perfectly attained with the use of paddle-wheels.

The Liverpool Screw, an account of which formed the basis of the discussion to which we have referred, is a small iron vessel, 65 feet long, 12 feet 6 inches beam, and drawing 3 feet 9 inches water. She was mounted originally with a screw of 3 feet 10 inches diameter, but it had been enlarged at three several times, and was, at the date of Mr. Grantham's account to the Institute, 5 feet 4 inches diameter by 20 inches long, of wrought iron, and consisted of four short arms whose united area amounted to 16 square feet, of which 13 only were immersed; a part of the propeller being constantly above the water. It was turned with a velocity of 95 revolutions per minute, by means of two high-pressure oscillating engines, working one crank upon the main driving shaft, without the intervention of gearing or bands; and the nominal power of the engines was 20 horses, though the effective power rarely exceeded 18½ horses. Though the proportions of this little vessel were not deemed favourable to a high speed, her length being only five times her beam, and her sectional displacement 28 feet, she was found, in a number of experiments, capable of beating all the steamers upon the Mersey, excepting the large sea-going vessels, and was proved to have a great superiority over other steamers in towing vessels out in a heavy sea.

Many observers have stated that the usual position of the screw-propeller, immediately before the stern-post, does not appear either to be disadvantageous for the application of the propelling power, or to interfere with the action of the rudder, and some have even contended that the propeller has the effect of increasing the efficiency of the rudder. Under the impression however that a contrary result takes place, it was proposed, in Maudslay's patent of 1843, to put the propeller behind the stern-post, in the position usually occupied by the rudder, and to employ two rudders, placed beneath the stern quarters, a little in advance of the propeller.

An important use to which screw-propellers have already been applied in a few instances, and for which it is highly probable that they may be extensively adopted, is as a mere auxiliary power, for occasional use during calms and contrary winds, to vessels which are ordinarily moved by sails alone, and which are not therefore to be regarded exactly as steam-vessels. An interesting example of this application is afforded by the new American packet-ship called the Massachusetts, which, though in all other respects a regular sailing vessel, fitted with conveniences of a very superior order, is provided with a small Ericsson propeller, 9½ feet in diameter, and has towards the stern of the vessel a steam-engine which can be set to work when required, of 170-horse power, capable of producing a speed of about 9 miles per hour in smooth water. The propeller is so constructed as to be raised out of the water when not in use. In sailing from Liverpool to America this vessel, in her voyage performed between October 22 and November 18, 1845, gained from five to thirteen days as compared with five other ships which sailed either on the same or on the following day. The cost of the motive power in this vessel was about two-sevenths of her total cost, which was about 16,000*l*. In a similar way an auxiliary screw-propeller is ordered to be fitted to the Amphion frigate, which was launched at Woolwich in January, 1846, and which, though she is to be furnished with a screw of 15 feet diameter, and engines of 300-horse power, which will render her quite efficient as a steam-vessel, has been built as a sailing ship, her construction having been commenced as long since as 1830. We believe the Amphion will be the first steam-vessel in the British navy with her machinery entirely below the water-line, as in the American frigate Princeton.

Those desirous of investigating the history of screw-propellers will find, in addition to much information in the report of the discussion which we have quoted, an ample chronological list of patents and inventions relating to the subject, from 1727, about which time a plan for propelling vessels up a river by means of a screw was contrived in France by M. Duquet, to the year 1843, in the 'Mechanics' Magazine,' vol. xxxix. p. 292, with addenda on pp. 340 and 360 of the same volume.

STEENHA'MMERA, a genus of plants belonging to the natural order Boragineæ. The calyx is divided into 5 deep segments. The corolla bell-shaped, with a short cylindrical tube with 5 minute protuberances in its throat. The stamens protrude beyond the throat, the filaments elongated.

S. maritima, the only British species, differs but little from *Lithospermum* except in habit. It has a procumbent branched stem, ovate, acute leaves, with rough, hard dots, glabrous, fleshy, and glaucous, having a taste resembling oysters. The nuts are smooth. The flowers in racemes and of a purplish blue colour.

(Babington, *Manual of British Botany*.)

STELLA, JACQUES, was born at Lyon, in 1596; his father, François Stella, who was also a painter, died when he was only nine years old. Notwithstanding the early age at which he lost his father, Stella is said to have had no other master. At the age of twenty he went to Italy, and at Florence he was employed by the Grand-Duke Cosmo II. to execute the decorations which were designed for the celebration of the marriage of his son Ferdinand II. Stella made many designs and painted several pictures for the grand-duke, who gave him apartments and allowed him a similar pension to that which he gave to Callot the engraver. After living seven years in Florence, Stella went to Rome, in 1623, and contracted a friendship with Poussin, of whom he became also an imitator.

While in Rome he was, by some treachery or misunderstanding, thrown into prison, and while in confinement he amused himself with drawing on the wall, in charcoal, the figure of the Virgin with the infant Jesus in her arms. A report of the excellence of the drawing reached the Cardinal Barberini, who went to see it, and from that time a lighted lamp was suspended over it and the prisoners performed their devotions before it.

In 1634 Stella returned by Venice and Milan to France, with the intention of visiting Spain. At Milan they offered him the directorship of the Academy with a view of retaining him in that city, but his object was to go to Spain, whither he had been invited by the king. Cardinal Richelieu however succeeded in detaining him in Paris; he procured him apartments in the Louvre, with the title of painter to the king and an annual pension of 1000 francs. In 1644 he was decorated with the cross of St. Michel and was elevated to the rank of principal painter to the king. He died at Paris in 1657.

Stella remained an imitator of the style of Poussin, but he did not go beyond the drawing and colouring of Poussin, and in the latter respect he exaggerated the defect of Poussin: many of his pictures are very red. He excelled in pastoral pieces, and in the sports of infants; he was also excellent in perspective and architecture. His chief defect was a want of expression. There are however several good pictures by him in some of the churches of Paris, and there are a few at Lyon.

The prints after Stella amount to several hundreds: his niece Claudine Stella has engraved fifteen pastoral pieces, fifty-two sports of infants, and three books of ornaments. Edelinck, the Poillys, Melan, and others have engraved some of his greater works. He etched five plates himself, which are very scarce, namely, the Descent from the Cross; a Madonna; a Saint George; a genre piece with infants dancing; and a large print of the ceremony of the Presentation of Tribute to the Grand-Duke of Tuscany, of the date 1621, which is very rare. Many woodcuts, apparently by P. Maupin, are marked 'Stella fecit,' but this alludes to the design, not the woodcut.

(Felibien, *Entretiens*, &c.; D'Argenville, *Vies des Peintres*, &c.; R. Dumesnil, *Peintre-Graveur Français*.)

STENEOSAU'RUS, a crocodilian genus of fossil Saurian animals from the Kimmeridge clay near Oxford. (Geoffroy.)

STENELY'TRA (Insects), the third family of heteromerous Coleoptera in the arrangement of Latreille. *Helops*, *Cistela*, *Dercæa*, and *Œdemera* are examples. They are usually oblong convex insects, with long legs and antennæ, which are thickened at their extremities. They live under the bark of old trees, or on leaves and flowers.

STERNBE'RGIA (Brongniart), the generic name for a singular group of fossil plants, supposed to be of the Palm tribe by Brongniart. Mr. Dawes has compared it to the interior of some tree stems in which the pith is transversely divided by diaphragms. It has been also named *Artisia* by Presl. It occurs in the coal formation.

STERNOPTYX, a genus of small fishes belonging to the order *Salmonidæ*, though very different in aspect from salmons or trouts. They have very elevated and much compressed bodies. They live in the warmer regions of the Atlantic Ocean.

STEWING is a process in cookery by which meat or vegetables are made fit for food by immersion in water of a high temperature for a considerable period of time. It differs from boiling by the temperature of the water not being allowed to reach 212° Fahr., and by being continued for a longer time. The effect is that of very thoroughly softening the substance used and the retention to a great degree of the flavour of the meat or of the spices added. These ends are accomplished by employing vessels with very closely fitting lids. The material of which these vessels is made is commonly copper; but for a small stew-pot silver is preferable, or the 'German enamelled stewpans, so safe, and so well suited, from the extreme nicety of the composition, resembling earthenware or china, with which they are lined, to all delicate compounds.' (Acton's *Cookery*.) Copper pans must be kept very clean, and the tinning always perfect. If this be rubbed off acid and saccharine liquids form poisonous compounds, which produce serious and occasionally fatal effects.

When several stews or made-dishes are prepared at the same time, a *bain-marie*, or water-bath, is the best apparatus. This is a flat vessel containing boiling water: all the stewpans are put into the water, which is to be kept always very hot, but it must not boil; the effect of this is to keep everything warm without altering either the quantity or the quality, particularly the quality.

'Gentle stewing is incomparably the best—the meat is more tender, and the soup better flavoured. By quick and strong boiling the volatile and finest parts of the ingredients are evaporated, and fly off with the steam, and the coarser parts are rendered soluble; so you lose the good and get the bad. The full flavour of the ingredients can only be extracted by long and slow simmering; during which, take care to prevent evaporation by covering the pot as closely as possible.' (Dr. Kitchener's *Cook's Oracle*.)

STICTA. [LIVERWORTS, P. C. S.]

STIEGLITZ, CHRISTIAN LUDWIG, was born December 12th, 1756, at Leipzig, in which city both his grandfather and father were persons of station, the former, who died in 1758, having been burgomaster, and the other holding the office of proconsul. Surrounded at home with objects of art, for his father possessed both a collection of pictures and a cabinet of medals and minerals, Stieglitz imbibed from them almost in his childhood those tastes which he so assiduously cultivated throughout life, although they were altogether remote from his other studies and occupations. Though he lost his father early (May 4th, 1772), in conformity with his wishes he applied himself to jurisprudence and other studies at the university of his native city, where he attended the courses of all the most eminent professors of that day, Ernesti, Winkler, Platner, &c.; and took his bachelor's degree in 1777, and in 1784 that of doctor of laws, on which latter occasion he produced his dissertation 'De Causis cur Jus Feudale Germanicum in Germania neglectum sit.' In the meanwhile he devoted all his leisure to literature and art, and in 1775 made his first essay in poetry, in which, if he did not distinguish himself, he continued occasionally to exercise his pen, for he contributed many pieces to a collection of Kriegslieder, or War Songs, published in 1778; and in 1801 he published 'Wartburg,' a poem in eight cantos, which appears to have attracted so little notice, that though bibliography has preserved its title, the production itself has obtained no permanent record in literary history. He also published some tales of romance and chivalry; but it was in a very different field from that of the poet or novelist that he gained his reputation and rendered essential service to a branch of literature which is more indebted to the labours of non-professional writers in it than of those who practise the art. It was in 1786 that he appeared, though then anonymously, as an architectural writer, with his 'Versuch über die Baukunst.' He next contributed to the 'Neue Bibliothek der Schönen Wissenschaften' several essays and minor treatises on various subjects relative to the æsthetics of architecture and decoration, one or two of which appear to have been also published separately. In 1792, the same year in which he was made a member of the Rathscollegium, or Council of Leipzig, he first brought out his 'History of the Architecture of the Antients' ('Geschichte der Baukunst der Alten'); and immediately afterwards engaged in a work of some extent, namely, his 'Encyclopædia of Civil Architecture,' in five volumes, the first of which appeared in 1792, the last in 1798. In the interim he brought out a work upon Modern Gardening, which came to a second edition in 1804. His next production was his 'Artistische Blätter' (1800), a collection of papers on Decoration. In 1804 he began to publish, under the title of 'Zeichnungen aus der schönen Baukunst,' a series of engravings, plans, and elevations, intended as select specimens of modern architecture; but though it was exceedingly well received—for not only did it come to a second edition, but there was also a French one—the choice compromised both his judgment and taste, the majority of the specimens partaking of that feeble and insipid mannerism which had just before prevailed in this country; and a great many of the subjects were taken from English publications—those, for instance, of Adam and Lewis—or showed English buildings, and among others such examples as the Trinity House, London, and the County Hall at Chelmsford. How he could reconcile them with his own theoretical principles is difficult to be understood.

Whether it was owing to his being satisfied with what he had then done for architecture, or afterwards dissatisfied with his last work, some years elapsed before he again published anything on the subject, turning in the interim to studies more professedly archæological; the fruits of which were an essay on 'Medals and Collections of Coins,' 1809, a treatise on the 'Pigments employed by the Artists of Antiquity,' 1818, and 'Archæologische Unterhaltungen,' 1820. In the same year with the last-mentioned publication came out his excellent work on 'Ancient or Mediæval German Architecture' (Alt-Deutsche Baukunst), which contributed not a little to direct attention to and inspire that taste for mediæval art and its monuments which has since struck root and grown up in Germany. His next work was his 'Geschichte der Baukunst,' a valuable compendium of the history of architecture from the very earliest periods, and among all nations; the first edition of which appeared in 1827, and the second, a greatly enlarged one, in 1837. Contrary to the opinion of Hirt [HIRT, P. C. S.], Stieglitz contends very strongly that Grecian architecture must have derived its principles and characteristics from an original construction of stone, and not of timber or wooden framing. The list of his literary labours is farther extended by his 'Distributio Nummorum familiarum Romanarum,' 1830, and his 'Beiträge zur Geschichte der Ausbildung der Baukunst,' 2 vols., 1834; and it would be prodigiously increased were it possible to enumerate all the various articles which he contributed to the 'Hermes,' the 'Kunstblatt,' and other journals; and to Ersch and Grüber's Encyclopædia. After having held the office of proconsul in the magistracy of Leipzig, and other appointments connected with the town government, Stieglitz retired from public duties in 1830, though he retained the title and distinction of proconsul; and in 1834 the '*jubilee*' or fiftieth anniversary of his obtaining his doctor's degree was celebrated by his townsmen, and a silver medal was struck and presented to him on that occasion. He died July 17th, 1836.

In Förster's 'Bauzeitung' for 1838 there is a portrait of Stieglitz accompanying a full memoir of him, which we have made use of for this article.

STIGLMAYER, JOHANN BAPTIST, the late distinguished director of the Royal Brass-foundry of Munich, was born October 18, 1791, at Fürstenfeldbruck, a small market-town near Munich, where his father carried on the business of a blacksmith. At Fürstenfeldbruck is an old convent founded by Ludwig the Strong, of Bavaria, in atonement for the hasty execution of his innocent wife Mary of Brabant, in 1250. This convent, which had undergone various changes, and had been at various times extensively decorated, was the school and academy of the barefooted blacksmith's son, though in his time it was a military stable for foals (Militär-fohlenhof). It contained stucco decorations by E. Asam, frescos by Appiani, statues by Roman Boos, and other works of the last century. This building, as already observed, was Stiglmayer's academy, and his collection of prints were the woodcuts of a book on natural history, which, with a catechism and prayer-book, constituted the whole library of his father. These woodcuts and the decorations of the convent were diligently copied by Stiglmayer, who, after many untiring visits (he was obliged to go daily for milk), at length ventured to introduce himself to the superintendent of the establishment, Herr Pfeiffer, who he had heard was not only himself a draftsman, but possessed also a collection of prints. Pfeiffer admired the boy's energy, and gave him some regular elementary instruction in design. After this he was placed by his parents with a goldsmith at Munich, of the name of Streissl, and he attended in the meanwhile the holiday school (Feiertagsschule), in which he obtained the first prize for industry and good conduct, amounting to 100 florins (8 guineas), by which he attracted the notice of M. Leprieur, the director of the Bavarian mint, who from this time took much notice of Stiglmayer, procured him admission into the academy in 1810, and became in a manner his patron. From the date of his admission into the academy, he pursued the regular course of study requisite for a statuary and sculptor, and at the same time practised seal and medal engraving. He was very successful in 1814 in a medal with Von Langer, the director of the Academy, on one side, and Moses making the water flow from the rock on the other, for which he was appointed one of the engravers of the mint, and he was sent in 1819, at the king's expense, to Italy to complete his studies.

It was in Rome that Stiglmayer's great patron, Ludwig, the present King of Bavaria (then crown prince), first became cognizant of his high abilities, and appears himself to have directed Stiglmayer's attention principally to metal-founding, in preparation for his own great undertakings already projected by him. In reference to this future occupation Stiglmayer repaired to Naples to witness the casting of the bronze colossal equestrian statue of Charles III., to be directed by Francesco Righetti and his son Luigi, from the model by Canova; tho Italian sculptor's reserve and jealousy however rendered Stiglmayer's journey in vain as regarded its principal object; he did not allow him to see the casting. But in another respect he was fully recompensed; after considerable trouble he obtained permission to erect a smelting-oven in his cellar, and having procured the assistance of Beccali, an experienced founder, then to be found in few even of the principal cities of Europe, he undertook the casting of several works himself. The first wholly failed, but the second, a cast from Thorwaldsen's bust of Ludwig I., then crown prince, was completely successful, so much so, that the journeyman, Pasquali, in his ecstacy kissed the lips of the bust before they were cool, and seriously burnt his own. After casting a few other works, and thus perfecting his practical acquaintance with the art, he left Naples for Germany, but on his road he had the misfortune to fall in with some banditti who robbed him even of his sketch-books. He returned to Munich in 1822, but was at this time employed chiefly in his capacity as engraver for the mint, and on some unimportant works of sculpture for the new Sculpture Gallery or Glyptothek then in progress. To the medals of this time belong that in commemoration of the marriage of the Queen of Prussia, for the minister Von Zentner, and the historical medal of the Royal family of Bavaria. Among his busts were those of King Maximilian I. and the Queen Theresa, Count Dörring, the ministers Baron Von Zentner, and Lerchenfeld, Bishop Streber, and others.

In 1824 he commenced preparations for his great series of metal castings, and from this time he was exclusively employed in founding the numerous monumental works which have been executed for Ludwig I., the present King of Bavaria, some of which are the most extensive castings of modern times. In order to be as well prepared as possible for his arduous tasks previous to casting any great monument, he visited Berlin in 1824, to witness the casting of Rauch's statue of Blücher, by Reisinger, who showed him everything in his power. Stiglmayer's great activity commenced with the reign of Ludwig I., in 1826, in the foundry established and afterwards much enlarged by the king, expressly for his own numerous undertakings in that important branch of art; and he left many, and the most considerable still unfinished, at his death. He was created in 1839 Knight of the Bavarian order of St. Michael.

The following is a brief summary of his labours:—from his own designs—the monument to the Brazilian children Juri and Isabella, and the reclining figure of the Fräulein Von Mannlich, in the cemetery at Munich; the monument of Maximilian I., in Bad Kreuth; and the monument of the parting of Otto, king of Greece, from his mother Theresa, queen of Bavaria, at Aibling: after Schwanthaler—the twelve colossal fire-gilded statues of the ancestors of the King of Bavaria, ten feet high, set up in the new throne-room of the palace of Munich; the statue of General Bekkers for his monument in Munich; the colossal monumental figures of Jean Paul in Bayreuth, Mozart in Salzburg, the Margrave Frederic of Brandenburg in Erlangen, and the Grand-Duke Ludwig of Darmstadt; and the gilt bronze pieces of table-service, with designs from the Nibelungen and Amelungen, for the crown-prince of Bavaria: after Thorwaldsen—the statue of Schiller at Stuttgardt, and the colossal equestrian statue of the elector Maximilian I. of Bavaria, at Munich: and, after Rauch, the monument of King Maximilian I. of Bavaria, before the theatre at Munich. He executed also the following architectural casts from models made in the foundry, chiefly from the designs of Von Klenze; the obelisk, 100 Bavarian feet high, in commemoration of the 30,000 Bavarians who fell in the Russian campaign of Napoleon in 1812; the bronze gates of the Glyptothek and the Walhalla; the great constitutional column at Gaibach; the interior pediments of the Walhalla, with the northern deities; the gilded candelabra in the new throne-room in Munich; the monument to the brave Oberländer, who fell at Sendling, in the cemetery at Munich; and the tomb of King Maximilian in the royal vaults (Fürstengruft) at Munich, after a design by the architect Ziebland. Besides the above works, which are completed, are the following important monuments which were in progress at Stiglmayer's death:—the colossal statue of Goethe, for Frankfort, after the model by Schwanthaler; and from the model of the same sculptor, the enormous colossal figure of Bavaria, nearly sixty feet high, to be placed before the Bavarian temple of Fame, or Ruhmeshalle (now in progress in the suburbs of Munich, and which will be completed in 1850). It is the largest statue in the world, measuring, with its pedestal, eighty feet; also, by Schwanthaler, tho monument of the late Grand-Duke of Baden, with a pedestal and four allegoric figures of the four circles of the dukedom; and the statues of Marshals Tilly and Wrede, for the new marshals' Loggia or Feldherrnhalle at Munich; and casts from Tenerani's models of the statues of Ferdinand, king of Naples, for Naples, and of Bolivar, for Bolivia, in South America.

Stiglmayer died March 2, 1844, on the day on which the statue of Goethe was cast by his nephew and assistant Ferdinand Miller. Stiglmayer had suffered from illness two years previous to his death, and many supposed it was owing to the unhealthy system of gilding by fire; but he died of cancer in the stomach, which Breslau, the king's physician, had previously declared to be the cause of his illness.

(*Kunstblatt*, 1844; Soeltl, *Bildende Kunst in München*.)

STIGMA'RIA, a genus of fossil plants allied to Lycopodiaceæ. Its dichotomous branches lie most frequently under beds of coal, whether Sigillariæ stand over these beds or not. It is most abundant in the lower parts of the true coal formation. (Brongniart.)

STILL, JOHN, the son of William Still, of Grantham, in Lincolnshire, was born in 1543, and became a student of Christ's College, Cambridge, where he took his degree as Master of Arts. In 1570 he was appointed Lady Margaret's Professor in the University: he afterwards held livings in Suffolk and Yorkshire, and was successively Master of St. John's and Trinity Colleges. In 1588 he was chosen prolocutor of the convocation; and, in 1592, he was raised to the bishopric of Bath and Wells, which he held till his death in 1607. Bishop Still is said by Fuller to have been 'one of a venerable presence, no less famous for a preacher than a disputant.' He left a large fortune, chiefly derived from lead-mines discovered in the Mendip Hills during his possession of the see. The historians of the drama concur in believing him to have been, in his youth, the author of a coarse but humorous play, which, till the recent discovery of 'Ralph Royster Doyster,' was held to be the earliest extant work known in England by the name of a comedy. It is called, 'A ryght pithy, pleasaunt, and merio Comedie, intytuled, *Gammer Gurton's Nedle:* played on stage not long ago, in Christe's Colledge in Cambridge. Made by Mr. S., Master of Art,' 1575. 'Gammer Gurton's Needle' is in Hawkins's 'Origin of the English Drama,' and in the second volume of Dodsley's 'Old Plays.'

STIPA, a genus of grasses belonging to the tribe Stipaceæ. It has stalked florets, the paleæ coriaceous, the inner entire.

S. *pennata*, the only British species, has a very long twisted feathery awn, with a glabrous base. It is a very beautiful plant, and is common in our gardens. Found on rocks in Long Seadale near Kendal.

(Babington, *Manual of British Botany*.)

STOCKADE, in Fortification, is the name given to a wall constructed by planting upright in the ground squared trunks of trees, or rough *piles* of timber, so as to inclose an area which is to be defended. The trunks or piles are planted close together; and at intervals of three feet from one another loop-holes are cut through them, or notches a few inches long are cut down, vertically, from the top, through which the defenders may direct a fire of musketry on the assailants. An inclosure of timber so planted is sometimes called a *Palanka*, from a name which is said to have been given by the Turks, when they first entered Europe, to their field-redoubts or small entrenched camps.

Stockades are still frequently constructed as temporary fortifications in countries which abound with timber, as in North America and the East Indies; and, among uncivilized nations, these, and rude parapets of earth, are the only kinds of fortification which have been executed. They were also, in general, the means employed by ancient armies while besieging towns, to protect themselves or to prevent the escape of the garrison. The walls with which the Peloponnesians surrounded Platæa during the siege and the blockade of that city were stockades consisting of palisades planted close together in a double line with a certain interval between the lines (Thucydides, ii. 75); and the fortresses of the Drilæ, a people inhabiting the shores of the Euxine Sea, are described by Xenophon (*Anab.* v. 3) as spaces surrounded by a ditch and embankment, on the latter of which were palisades and wooden towers.

The description of the Pahs, or Hippahs, of New Zealand, which is given in the accounts of Captain Cook's voyages, would nearly serve for the stockades within which the natives of that country very recently resisted the assault of a British force. It is stated that the works consisted of trunks of trees planted close together, with a small inclination towards the interior space; and that at intervals from one another, particularly at the angles of the works, there were scaffolds whose heights from the ground were three feet less than that of the top of the wall, so that the defenders were able to see the ground at the foot of the wall while they were concealed from the view of the enemy. In the interior there was usually a hollow place in which the women and children, with the provisions, were deposited. The pahs are generally on the summits of heights, and they are sometimes strengthened by outworks of a similar nature.

On the frontiers of the United States of North America, during a war, stockades consisting of roughly-hewn trunks of trees planted close together in upright positions and pierced with loop-holes for musketry, are very frequently constructed for the purpose of inclosing an area which is to be defended; and at each of the angles of the inclosure a sort of block-house, serving as a bastion to flank the stockade, is constructed with very thick logs of timber placed horizontally: these block-houses are sometimes formed with an upper story, the angles of which project over the sides of the lower one, so that by loop-holes in the projecting part of the floor a fire of musketry may be made upon the enemy when at the foot of the wall.

STOCKINGS. [WEAVING, P. C.]

STONE FOR BUILDING. The durability of stone may be examined in several ways, and results of much importance in the arts have been actually obtained by some late investigations set on foot for the purpose of determining on a proper stone with which to construct the New Houses of Parliament. In their natural repositories the surfaces of rocks are exposed to waste from chemical and mechanical agencies connected with the atmosphere and dependent on the climate. Rocks which are composed in any considerable degree of carbonate of lime or carbonate of magnesia—or which contain minerals into whose composition silicate of potash enters largely (as felspar),—are in general liable to be wasted by the solvent action on these substances of the carbonic acid gas in the atmosphere; and if such materials are transferred to buildings in great towns, the air, loaded with sulphureous and other acidulated vapours, is still less favourable to their preservation. Not only the feebly consolidated chalky rocks (like that of Mesterham), but the more solid Oolites of Bath and Portland, have failed to withstand the injurious atmosphere of London; nor is even the firmest mountain limestone of Derbyshire or half-crystallized and half-coralloid marble of Plymouth capable of preserving its edges and angles from slow decay and erosion, even in the pure air of the elevated and stormy Peak or the comparatively low and tranquil regions of Devonshire. Even the purest crystallized marbles of Attica or Carrara, which may endure in the sunny regions of their birth, cannot be exposed without injury to the moist and variable climate of Britain.

If, despairing to find a perfectly durable limestone, we turn our attention to other classes of rocks, we find other causes of decay equally influential on them. The most abundant of these is the class of sandstones which comprises every degree of bad quality, but scarcely the highest degree of good—the imperceptibly decaying millstone grit of the Druidical Pillars at Boroughbridge, and the rapidly mouldering red sandstone to which the architectural beauties of Carlisle, Chester, and Coventry have been unfortunately trusted.

Granite scarcely merits universally, nor even generally, the reputation of a very durable stone in Britain. Some of the Cornish and Devonian granite is of little permanence, much of that in Cumberland and the island of Arran is quite perishable, nor is all the stone of Killiney, near Dublin, free from the same reproach.

The decay of granite is usually ascribable to the unequal action of the atmosphere on its dissimilar and unequally resisting ingredients. The felspar often decays through the chemical action of carbonic acid on the potash, and then the powers of heat and cold, of alternate wetness and dryness, sunshine and shade, complete the disintegration. Similar remarks apply to many sandstones, for these often contain disseminated felspar, and in a state more easy to be acted on than that which is compacted with the quartz and mica of granite. The arenaceous rocks however yield with too much facility to the hygrometric and other changes of the atmosphere, and except we can obtain almost purely quartzose sandstones with almost confluent grains we cannot be confident of their durability. Now, such sandstones, like the harder granites, are unfitted for architecture, however useful for walls, paving, and other rough purposes.

STONE FIT FOR BUILDING must in general be freestone firm enough to sustain great pressure, and yet so aggregated as to admit of being worked with facility by ordinary tools, and of receiving correct surfaces in any direction. It must in general yield masses of great dimensions. Its colour is of consequence to the architect, who is necessarily attentive to this element of effect: and the colour which belongs to the stone is very often, indeed generally, modified in buildings by the growth of lichen, the access of moisture, and the change of oxidation of the contained iron. By so many conditions, indeed, is the choice of stone limited in a particular case, that very few samples can be really placed in competition.

In the great variety of limestones and sandstones which are adapted for building purposes, we remark, by the aid of the microscope, three principal modes of molecular aggregation: *mixtures* of grains; *segregated concretions* of grains; and *compacted* crystallizations.

To give an idea of the applicability of this classification, we may shortly review a small series of examples of limestones and sandstones arranged in a geological sequence. None are mentioned except such as have been extensively used. Those which are not really freestone or which have not been found tolerably durable are inclosed in parenthesis.

Geological age.	Sandstones	Limestones.
Cainozoic	Sarsen stone used in Stonehenge. A *mixed* mass. It hardens on the surface by exposure.	(The fresh water limestone of the Isle of Wight, and the crag of Suffolk are used, but are not freestone.)
Mesozoic	(The freestone of Surrey; a mixed mass. It has decayed in the churches of London.)	(The white chalk, though not durable, is used. It is a *mixed* mass.)
	The 'calcareous grit,' as it is called, of Yorkshire. It is a mixed mass (with little or no carbonate of lime). It is used at Duncombe Park; hardens by exposure.	The *concretionary* oolites of Purbeck and Portland, of very unequal quality; some durable, as the castle at Weymouth. Whitehall is an example of decay in Portland stone.
	The 'Kelloway' rock of Yorkshire: a soft mixed mass, very slightly calcareous; hardens by exposure. Durable in the vicinity of Hackness.	(The oolite of Oxford; concretionary, but not generally durable.)
	The ferruginous sandstone of the inferior oolite: a mixed mass; is much used in the Midland Counties, and is often found in old churches well preserved, *e. g.* Northamptonshire.	The oolites of Bath, the most purely *concretionary* of the class. Ketton stone, which appears durable, is a mass of globular concretions. Bath stone is partly even in texture, and partly 'rag' or uneven. The latter was used by the Romans, and is the most durable. Barnack stone is like it, and is very durable in churches near Stamford. Much of the oolite of Lincolnshire is very good, and its grains are immersed in clear calcareous spar. The Romans quarried it at Ancaster. The same spar cemented oolite occurs in other counties.
	The new red-sandstone of Penrith, mixed, durable in the old Castle, Giant's grave, &c. (Other specimens of finer grain are among the worst stones of the kingdom.) A light coloured sort, called 'Keuper,' quarried near the Malvern Hills, is durable.	
Palæozoic	(Few of the sandstones of the coal-formation are of much durability, though many are of great beauty.) In the lowest part of the coal strata are good firm, rather coarse-grained, mixtures, as near Leeds; and below these the well known millstone-grit, the base of the northern coal-fields. This stone was used by the Britons and Romans in the north of England. In the natural rocks of Brimham, the Devil's Arrows of Boroughbridge, and the abbeys of Kirkstall and Fountains, it has not well resisted the atmosphere; but its decay is slow.	The magnesian limestone, a *crystallized* mass, varies in its *compactness*. It varies also in texture, from a confused aggregation of crystallized grains, to a small cellular texture, the walls of the cells being composed of small crystals; and finally to a largely cellular mass, the interstices of the cells being either compactly crystallized or filled with a soft earthy mass. In fine examples of this stone, as those of Mansfield, Bolsover, Anston, Roche, and Huddersfield, the chemical constitution is nearly the same (one atom of carbonate of lime to one atom of carbonate of magnesia), and it is in the mode of aggregation that we are to seek the explanation of the very superior durability of these to nearly all the other magnesian limestones.
	In the series of strata above the mountain-limestone of Derbyshire, the sandstone in the vicinity of Chatsworth and Darley Dale is remarkable. Firm, of good texture and colour, and very extensively deposited; its use at Chatsworth and Buxton has made it well known. It is generally durable, but particular cases of failure occur. Stones of nearly corresponding age and of great durability have been much quarried near Barnard Castle and Bowes.	The thick beds of the mountain-limestone are often used for building, but seldom very tractable in ornamental work, except the processes of the marble-mason are adopted or imitated. It is one of the most durable of limestones, though generally only a mixture of grains. These are in a considerable proportion of organic origin. The magnesiferous varieties of Derbyshire have more the character of ordinary freestone than the other varieties.

In considering even the few cases here adduced, we find mixed, concretionary, and crystalline textures, some of which are durable, others perishing. Mixtures of very unequal or very dissimilar parts, as millstone-grit; concretions which have earthy textures in their interstices, as some oolitic limestones; crystallizations which do not produce compactness, as in some magnesian limestones,—are not in general durable. But equal mixtures, as the Sarsen sandstone, the Craigleith sandstone, and some mountain-limestones; concretions of adherent globules, as the oolite of Ketton; concretions of globules cemented by sparry interstices, as the oolite of Ancaster; and crystallizations with uniformly adherent grains, as in the magnesian limestone of Bolsover,—these appear to be durable. The microscope may determine in many cases between one class and the other. Additional evidence may be obtained by exposing masses of stone to frost and sunshine, rain and wind, to imbibition of salts which expand in crystallization, and to mechanical pressure. And there remains one further class of evidence more important than all the rest—and that is *experience*. By observing how the various sandstones and limestones have behaved in castles and abbeys, and churches, we may attain with the highest probability a correct estimate of their intrinsic durability.

The commissioners (Mr. Barry, Sir H. De la Beche, and Dr. W. Smith) who reported on the choice of stone for the construction of the New Houses of Parliament, have neglected none of these considerations, and their report, certainly the most valuable document which has ever appeared on this subject, embodies a great mass of valuable statistical information on the most famous quarries; accurate notices of the most remarkable buildings which were constructed from them; and chemical analyses and mechanical experiments on the stone. The strength of several sorts of stone, as measured by the weight necessary to be applied for breaking and crushing them, appears below:—

	Resistance to Fracture.	Resistance to Crushing.	Name of Stone.
Sandstones	60	111	Craigleith.
	88*	106	Darley Dale.
	56	107	Park Spring.
	48	70	Keaton.
	38	71	Binnie.
Oolites	50	127*	Ketton rag.
	30	55	Portland.
	22	57	Hambill.
	24	33	Ancaster.
	16	25	Barnack.
	18	21	Box.
Magnesian Limestones	70	117	Bolsover.
	36	74	Mansfield.
	34	61	Huddlestone
	24	55	Roche.
	20	23	Cadeby.

The asterisk is placed to two numbers. One refers to the sandstone of Darley Dale, which bore the greatest weight previous to the first fracture, and the other to the Ketton rag, which bore the greatest weight before crushing (this can hardly be an average specimen of the stone). Of sixteen specimens selected, the stone most absorbent of water was proved to be the Bath oolite from Box; that most injured by Brard's artificial process of disintegration was the Barnack stone: and that which was most easily crushed was the Bath oolite from Box. Generally speaking, sandstones were least absorbent, magnesian limestones least disintegrating; sandstones appeared to be strongest, though choice magnesian limestones (as that of Bolsover, finally recommended by the Commissioners) were fully equal in this respect, and were almost as little absorbent. (*Report of the Commissioners*, 1839.)

A few remarks on the appearance presented by stones in decay may be of service to guide further observation. Stones of uniform texture commonly decay by disintegration at the surface, losing grain by grain in proportion to time and exposure. But they sometimes suffer a singular change, as if *baked* at the surface. An external enveloping crust is thus formed, as at Stonehenge, where the interior is soft, but the exterior hard. This process appears to render such a stone durable. But if carried further, so as to produce a new texture of the surface, the external shell separates from the interior mass, desquamates and falls off, leaving a rough soft inner core. This happens even to moulded surfaces like those of balusters. Stones composed of parts unequally mixed suffer unequal waste in different parts. Shells, corals, concretions, and crystallized masses, thus appear prominent from earthy limestones, and indicate the general fact that, in proportion the force of molecular aggregation in the stone, is the resistance which it offers to decay.

Again, the circumstances under which a stone is exposed in a building influence its conservation. It is not the amount but the kind of exposure which governs the decay. The southern and western parts of our cathedrals yield, while the northern and eastern resist. Prominent cornices often are perfect, while below them the mouldings are reduced to shreds. The drip-moulding remains and is even hardened, while the parts which it was destined to protect have mouldered away. This has actually occurred to the observation of the writer in the space of only a few years. In fact since 1839 the same pieces of magnesian limestone remain perfect in the drip-moulding, showing every chissel-stroke, while the whole ornamented surface below is ruinously decayed.

STONE, NICHOLAS, master mason to Charles I., was born at Woodsbury, near Exeter, in 1586. He lived three years in London with one Isaac Jones, his master, and then went to Holland, where he worked for Peter de Reyser, whose daughter he married. He returned to England about 1614, and was for many years chiefly employed in making monuments for the nobility and gentry. In 1619, he was appointed master mason for building the new Banqueting House of Whitehall, on which he was engaged two years at 4 shillings and 10 pence per day; and in 1626, at the commencement of the reign of Charles I., he was appointed master mason of Windsor Castle. The patent is in Rymer's 'Fœdera,' vol. xviii. p. 675. The history of Stone's works is fully recorded by himself in a pocket-book, which was in the possession of a Mr. Hawksmore, and of which Vertue obtained a copy. This pocket-book contained a full account of the various monuments he had executed, with the sums of money he received for them, and the names of the persons for whom they were constructed.

According to this book, Stone erected in 1641 a monument to the Earl of Ormond, at Kilkenny, for which he received 400*l.* He received in the following year 500*l.* for a monument to Henry Howard, earl of Northampton, erected in Dover Castle. For a tomb made for Lucy Harrington, Countess of Bedford, 1616, he bargained for 1020*l.*, besides the charges for carriage and iron and setting up. This year he went to Scotland; and he gives the following account of his transactions there:—July, 1616, was I sent to Scotland, where I undertook to do work in the King's Chapple and for the King's Closett, and the organ, so much as came to 450*l.* of wainscot-worke, the which I performed and had my money well payed, and 50*l.* was given to drink, whereof I had 20*l.* given me by the king's command." He mentions drink-money on other occasions. Stone made several monuments for Westminster Abbey; among them one to Spencer, the poet, for which the Countess of Dorset paid him 40*l.*

In 1625, he made for the old Exchange of London four statues—Edward V., Richard III., Henry VII., and Queen Elizabeth, which was afterwards removed to Guildhall gate. For the three kings he received 25*l.* each, for the queen, 30*l.*; 25*l.* appears to have been Stone's ordinary charge for a statue, including the pedestal.

Stone received altogether nearly 11,000*l.* for the various monuments erected by him. The various sums for monuments noted in his pocket-book, amount altogether, according to his kinsman, Charles Stoakes, from whom Vertue acquired his information concerning Stone's family, to 10,889*l.* Walpole has given a list of the principal monuments, and mentions some architectural works by Stone. He died August 24, 1647, aged 61, and was buried in St. Martin's Church, where there is a slab to his memory with an inscription and his profile. His wife and his son Nicholas are buried in the same grave: they both died in the same year a few months after him. Stone had three sons, Henry, Nicholas, and John.

HENRY STONE, known as *Old Stone*, probably because he was the eldest, was a statuary and painter, but he was chiefly engaged in painting. He studied in Italy and the Netherlands, and made many excellent copies of celebrated Italian and Flemish pictures; there is a large copy at Hampton Court of the celebrated picture, by Titian, of the Cornaro Family, now in the possession of the Duke of Northumberland. He lived in Long Acre in the same house that was his father's, which he rented of the crown for 10*l.* per annum. He died in 1653, and was buried near his father; and the following inscription to his memory was placed in the church by his brother John:—"To the memory of Henry Stone of Long Acre, painter and statuary, who, having passed the greatest part of thirty-seven years in Holland, France, and Italy, atchieved a fair renown for his excellency in arts and languages, and departed this life on the 24th day of August, A.D. 1653, and lyeth buried near the pulpit in this church." Here follows some laudatory verses. Old Stone wrote a book, entitled the 'Third Part of the Art of Painting,' taken mostly from the ancients. Vertue, who saw this book, was uncertain whether the two former parts were composed by Stone, or by some other author.

NICHOLAS STONE, the second son, who was a statuary, also studied abroad and modelled many excellent copies of celebrated works. Mr. Bird, the statuary, says Walpole, had the 'Laocoon' and Bernini's 'Apollo and Daphne' in terra-cotta by him. He returned to England in 1642, and died in the same year as his father, as noticed above. Vertue saw a book of drawings by him of many buildings in Italy.

JOHN STONE, the youngest, was also a statuary, though he was originally designed for the church, and was educated at Oxford. In the civil war he entered the King's army, and narrowly escaped being taken. He concealed himself for a year in his father's house without his father's knowledge, and at length contrived to escape to France, where he probably took to the arts, as he was afterwards engaged in partnership with his brother Henry. He wrote a manual on Fortification, which he called 'Enchiridion'; it contained many small cuts etched by himself, but without his name. He died soon after the Restoration. In St. Martin's Church, below the inscription to Henry Stone, is the following addition, with the date June, 1699:—

'Four rare Stones are gone,
The father and three sons.

In memory of whom their near kinsman, Charles Stoakes, repaired this monument.'

(Walpole, *Anecdotes of Painting in England*, &c.)

STORM-SAILS. [SAILS, P. C. S.]

STORMS. [TORNADO, P. C.; WHIRLWIND, P. C.]

STORY, JOSEPH, a judge and juridical writer known to law students as Mr. Justice Story, was born on the 18th September, 1779, at Marblehead, in the State of Massachusetts, U.S. He received the rudiments of learning in his native town; entered Harvard University in 1795, and took a degree there in 1798. He commenced his law studies under Mr. Sewell, of the bar of Marblehead, subsequently chief justice of Massachusetts, and continued them under Mr. Putnam, of the bar of Salem, who became a judge of the same court. In 1801 he was called to the bar, and speedily obtained extensive practice. In an article in the 'Law Review,' the author of which enjoyed his friendship, it is stated that, 'from political considerations, he was very early engaged in important causes, in which he had to combat with the most eminent lawyers as his opponents; and, not unfrequently, he sustained the contest alone. His reputation at the bar has never been surpassed by that of any of the eminent lawyers of whom the United States can boast.' In 1805 he became a member of the State Legislature of Massachusetts, as representative of Salem. He continued a representative until his accession to the bench; and he then was elected to the office of Speaker. In 1809 he was chosen a member of Congress, as representative of the Essex South District. He acquired a high reputation as a politician and a forensic debater. In November, 1811, he was appointed an Associate Justice of the Supreme Court of the United States: 'The jurisdiction of this court,' says the authority already cited, 'both original and appellate, embraced an infinite variety of subjects. It had to administer, besides the municipal laws of the States, the common, and much of the statute law, as well as the system of equity jurisprudence of England; it had to administer parts of the law of Spain, and of the code civil adopted in the State of Louisiana. Again, it reviewed the final sentences of courts deciding questions of maritime and prize law. Its decisions, therefore, would be of still greater and more general importance, for they would contribute to the exposition of the law of nations. The peculiarities which in some important particulars distinguish the local laws of the different States also required a correct application of the principles which determined, when any case presented a conflict of those laws, the law which ought to be selected and govern the decision of the case.' These special advantages were an addition to the opportunities which the general character of the legal practice of America afforded, to one able to grapple with the subject, to treat the philosophy of international law with a wide view to its practical application. The American lawyers having to deal with a system of which the roots were diversified, although undoubtedly the law of England formed the principal proportion; requiring to adapt their practice to the mutual relations of the citizens of several states, each, to a great extent, entitled to make its own independent code of laws, while all were bound together by a mutual tie, and the usual means of finding redress where there were important legal conflicts—force—was inconsistent with the principles of their Union; inheriting, at the same time, that spirit of the strict interpretation of precedent which is so dear to English lawyers, and living among a free people, whose institutions could not easily be bent to meet expediency—it was clear that the American bar afforded the best opportunity for inquiries regarding international law on practical principles, whenever a genius sufficient for the task should there appear. It appeared in the person of Story, whose 'Commentaries on the Conflicts of Laws,' published in 1834, have passed through several editions, and have carried his reputation over all Europe. Even in England, where, owing to the vast extent of the domestic legal literature, that of other countries is less esteemed than in France, Germany, and Scotland, Story's work has obtained a high reputation; and on the occasion of his being expected to pay a visit to Britain, which bad health prevented, the masters of the benches of the inns of court in London resolved to invite him to a public entertainment. He wrote several other legal treatises—one on the law of Agency, in 1839; on the law of Partnership, in 1841; and on the law of Bills of Exchange, in 1843. In 1830, he was appointed to fill the newly founded chair of jurisprudence in Harvard University. It was during the time that he held this professorship that he wrote his numerous legal treatises; which besides those mentioned above comprehend a work on the Law of Bailments, one on Equity Jurisprudence, and a work on Equity Pleading. He died on the 10th September, 1845.

(*Law Review*, No. VI. 366-380; *American Almanac*, 1846.)

STOWELL, WILLIAM SCOTT, BARON, was the elder brother of Lord Chancellor Eldon, and the eldest son of Mr. William Scott, coalfitter, of Newcastle, by his second wife, Jane, daughter of Mr Henry Atkinson, who was of the same profession. [ELDON, EARL OF, P. C. S.] He was born on the 17th of October, 1745 (O.S.) at Heworth, a village on the Tyne, about three miles below Newcastle, and in the county of Durham, to which his mother had been sent a few days before, in the apprehension excited by the advance of the Scotch rebel army after the battle of Prestonpans. Egress in any common way being impracticable, they had been obliged, it is related, to hoist her in a sort of basket over the town wall, which then ran along the quay, separating Mr. Scott's house in Love Lane from the river, where a boat was in readiness to receive her. At Heworth she was safely delivered of twins; William, and a daughter, who was named Barbara and died in infancy.

William was educated with his two younger brothers, Henry and John, at the Royal Grammar-school of Newcastle, under the Reverend Hugh Moises. Moises is said to have been principally instrumental in getting both William and John sent to college. William entered the University of Oxford in February, 1761, standing for and obtaining a scholarship at Corpus Christi College, for which the circumstance of his having been born in the county of Durham rendered him eligible. Having taken his Bachelor's degree on the 20th of November, 1764, he was on the 13th of the following month elected a Probationary Fellow of University College; and it is remarkable that for his eligibility on this occasion likewise he was again indebted to the accident of his being a native of Durham. He was now also elected by the same society a College tutor in the room of the already celebrated linguist William (afterwards Sir William) Jones, who had recently left Oxford for the metropolis. In 1767 he took his master's degree; and in May, 1772, he proceeded B.C.L., having by this time determined upon following the profession of an advocate at Doctors' Commons. He had already, with a view to the study of the law, entered himself at the Middle Temple, in June, 1762. He was detained at the University however a few years longer than he otherwise would have been by being elected in 1774 by the members of convocation after a contest, to the office of Camden Reader of Antient History. The lectures which he delivered in this capacity attracted crowded audiences, and brought him into high and wide reputation. It is said that they still exist in manuscript.

At last, in 1776, he retired from the office of College tutor; but he still continued to reside at the University till after he had taken his degree of D.C.L., which he did in 1779. On this occasion, in the University phrase, he went out grand compounder, which means that he paid the higher fees exacted from graduates worth 300*l.* a-year. He had, no doubt, saved money from his income as Fellow, and his constantly increasing receipts during the twelve years that he held the office of College tutor; but it is to be remembered that he had also inherited a considerable property from his father, who died in 1776. It was probably the independence to which he was thus raised that determined him to resign his employment as a college tutor; but it appears that old Mr. Scott's wealth was not quite so great as it has been stated to be by Mr. Twiss in the first and second editions of his 'Life of Lord Eldon.' He left somewhat less than 20,000*l.*

He now entered at Doctors' Commons, and passed another year partly in Oxford, partly in London, the rule being that no one shall practise as an advocate till the expiration of that space of time after his admission, which accordingly is called his year of silence. Dr. Scott was called to the bar in February, 1780. He was admitted into the Faculty of Advocates at Doctors' Commons, according to Mr. Surtees in one place in November, 1779, in another place not till the spring of 1780 (*Sketch*, pp. 26 and 61). So early however as in December, 1778, he had been elected a member of the famous Literary Club, having been mainly indebted for that distinction to the favour of Dr. Johnson, to whom he had been introduced in University College by their common friend Chambers, afterwards Sir Robert, and now a judge in India. Scott soon became a favourite with Johnson, whom he had accompanied from Newcastle to Edinburgh, when the latter set out on his tour to the Hebrides, in the autumn of 1773. With the patronage of Johnson, and his own 'clubable' qualities, Scott rapidly made his way to distinction in the most intellectual society of the English capital.

His talents and learning, and the reputation he had brought from the University, brought him a large practice in his profession from his first entrance upon it. And his success as an Advocate in no long time led to promotion. In 1783 he was appointed to the office of Registrar of the Court of Faculties. In 1788 the Bishop of London appointed him Judge of the Consistory Court; and the Archbishop of Canterbury, his Vicar-General, or Official Principal. In the same year he was made Advocate-General, and knighted, and was also nominated a Privy Councillor. In 1790 he was nominated by the archbishop Mastor of the Faculties. Finally, in 1798, he was made Judge of the High Court of Admiralty.

Meanwhile, after having in 1780 been disappointed in his expectation of being sent into parliament as representative of the University of Oxford, and having been unseated on a scrutiny in 1784, when he had been returned for Downton, he had been a second time returned for that nomination borough, in 1790, through the influence of ministers with the patron, the Earl of Radnor. He was again returned for Downton to the next parliament, which met in 1796. At last in March, 1801, on a vacancy occurring by the retirement of Francis Page, Esq., he obtained the object of his early ambition by being elected member for his University; and that seat he retained as long as he continued a commoner.

He had had reason to expect that he would have been raised to the peerage in 1805; but some unexplained court intrigue interfered, and he was not ennobled till the 21st of July, 1821, when he was created Baron Stowell, of Stowell-park. He retained his place on the bench till Christmas, 1828. For the two last years of his life he was reduced to a state of mental imbecility; and he died at his seat of Early Court, Berks, after an illness of a few days, on the afternoon of Thursday, the 28th of January, 1836, in his ninety-first year. He had been twice married; first, in April, 1781, to Anna Maria, eldest daughter and co-heiress of John Bagnall, of Early Court, in the county of Berks, Esq., who died in September, 1809; secondly, on the 10th of April, 1813, to Louisa Katherine, Marchioness Dowager of Sligo (widow of the first Marquess and daughter of Earl Howe), his acquaintance with whom had originated, singularly enough, in the circumstance of his having presided in the preceding December at the Admiralty Sessions at the Old Bailey, on the trial of her son, the late Lord Sligo, for inveigling some seamen from one of the king's ships to serve on board his yacht (for which he was sentenced to pay a fine of 5000*l*., and to be imprisoned four months in Newgate). This last proved a very unsatisfactory connection; but the lady died in August, 1817. By his first wife Lord Stowell, besides a daughter who became the wife, first, of Thomas Townshend, Esq., secondly, of the late Viscount Sidmouth, had a son, William, who died at the age of forty-two, about two months before the death of his father.

Lord Stowell is the highest English authority in his own department of the law, including both ecclesiastical law and the law of nations, if not the highest of all authorities upon the particular questions which he had occasion to consider and decide; for, having produced no complete treatise upon either of the branches of jurisprudence which he administered, he must be distinguished from the great text-writers, between whom and him no comparison is properly admissible. His judgments in the Consistory Court have been reported very ably and carefully by Drs. Haggard and Phillimore; those delivered by him in the Court of Admiralty, in an equally superior manner, and, in part, with the advantages of his own revision, by Drs. Robinson, Edwards, Dodson, and Haggard. Their characteristics are the most complete mastery of all the learning of his subject, great comprehensiveness of view, a penetrating sagacity in the disentanglement of the essential points and governing principle of a case from the confusion and sometimes apparent contradiction of details and accessory circumstances, a remarkable faculty of luminous and striking illustration, and all this combined and set off with a diction generally of much precision, elegance, and expressiveness, though occasionally somewhat diffuse and rhetorical. Some of Lord Stowell's judgments may be called almost revelations of the law, being expositions of large and intricate questions which had never before been thoroughly investigated, but which he has completely cleared up and set at rest.

As a politician this distinguished lawyer was, like his brother, Lord Eldon, an uncompromising Conservative, shrinking from all change as only the beginning of universal ruin. Except, however, by giving his steady vote in support of his party and his principles, he very rarely took part in the proceedings of either House of parliament. During the first six years that he sat in the House of Commons, he only spoke once; of some two or three displays which he afterwards made, a speech of three hours' length, which he delivered on the 7th of April, 1802, on moving for leave to bring in a bill for amending the statute of the 21st of Henry VIII., respecting the non-residence of the clergy, was the most memorable. He was also instrumental, however, in carrying through the House several other measures having a reference to the established church, of which he was the supporter on all occasions, considering himself indeed as a sort of representative of the clergy, both in his quality of member for the University of Oxford, and from his office as an ecclesiastical judge.

(Memoir by Mr. Townsend in *Law Magazine*, No. xxxiii., reprinted, with some alterations and additions, in the *Annual Biography and Obituary* for 1837; article on Lords Stowell and Eldon in *Law Review*, vol. i.; Lord Brougham, *Historical Sketches of Statesmen*, second series; *Sketch of the Lives of Lords Stowell and Eldon*, by William Edward Surtees, D.C.L., 8vo. 1846; Anecdotes of Lord Stowell, in *Gentleman's Magazine* for October, 1846.)

STRATIO'TES, a genus of endogenous plants belonging to the natural order Hydrocharideæ. It has a 3-parted calyx and 3 petals. The male flower has 12 or more stamens surrounded by numerous abortive ones. The female has 6 deeply bifid styles. The berry is inferior, 6-celled, and many-seeded.

S. aloides, Water-soldier, has sword-shaped triangular ciliate spinous leaves. The root creeps extensively in the mud, and sends out rigid leaves like those of an aloe. The stalk is compressed, 5 or 6 inches high, with two leaves near its summit. The flower is white and delicate. It is a very ornamental aquatic plant, and is found in ditches in the east of England. It remains under water during the greater part of the year, but raises itself to the surface on special stalks during the season for fertilizing the seeds.

(Babington, *Manual of British Botany*; Burnett, *Outlines of Botany*.)

STRENGTH OF PILLARS. [FLEXURE OF COLUMNS, P. C. S.]

STREPSI'PTERA, a very extraordinary order of insects, remarkable for having the anterior wings transformed into a pair of short, slender, contorted appendages, whilst the posterior are very large and fold in the manner of a fan. The mouth is armed with two slender acute jaws and two 2-pointed palpi. The tarsi are 2- 3- or 4-jointed. The larva is vermiform and has no feet. The pupæ are inactive. They are all very small creatures, the largest not so long as a quarter of an inch. The larvæ are parasitic on the bodies of wasps and bees; the perfect insects are very short-lived, but very active.

These insects are the *Rhipiptera* of Latreille, the *Diptera Rhipidoptera* of Lamarck. Their systematic position has been much debated.

They were first observed by Mr. Kirby, who gives the following account of his discovery:—Observing acarus-like animals infesting the abdomens of various Andrenæ, he attempted to remove one, and to his surprise drew from the body of the bee a white fleshy larva a quarter of an inch long, the head of which he had mistaken for an acarus. 'How the animal receives its nourishment seems a mystery. Upon examining the head under a strong magnifier, I could not discover any mouth or proboscis with which it might perforate the corneous covering of the abdomen, and so support itself by suction; on the under side of the head, at its junction with the body, there was a concavity; but I could observe nothing in this but a uniform unbroken surface. As the body of the animal is inserted in the body of the bee, does that part receive its nutriment from it by absorption? After I had examined one specimen, I attempted to extract a second; and the reader may imagine how greatly my astonishment was increased when, after I had drawn it out a little way, I saw its skin burst, and a head as black as ink, with large staring eyes, and antennæ consisting of two branches, break forth and move itself briskly from side to side. It looked like a little imp of darkness just emerging from the infernal regions. I was impatient to become better acquainted with so singular a creature. When it was completely disengaged, and I had secured it from making its escape, I set myself to examine it as accurately as possible, and I found, after a careful inquiry, that I had not only got a nondescript, but also an insect of a new genus, whose very class seemed dubious.' (*Monographia Apium Angliae*, vol. ii. p. 111.)

Stylops and *Xenos* are the genera of this order. For full information consult the writings of Kirby, Curtis, and Westwood.

STRIGOCE'PHALUS, a genus of fossil Brachiopoda from the Devonian strata of Plymouth, the Eifel, &c. (Defrance.)

STROBILI'TES, a genus of fossil fruits from the Cretaceous and Oolitic strata of England. (Lindley.)

STROMATO'PORA, a fossil genus of corals from the Silurian and Devonian strata. (Goldfuss.)

STROMBO'DES, a fossil genus of corals from the Silurian, Devonian, and Carboniferous limestones. (Schwrigger.)

STRO'PHODUS, a genus of fossil fishes, including many species from the Oolitic and Cretaceous strata of England. (Agassiz.)

STUERBOUT, DIERICK commonly called DIRK VAN HAARLEM, was born at Haarlem, in the early part of the fifteenth century. He is perhaps the oldest of the Dutch painters, and one of the best of the early masters. The two large works by him in the Royal collection at the Hague are wonderful works for their time, and, independent of their age, are two of the most interesting pictures in the European collections. They were at one time attributed to Momling, whose works they somewhat resemble; their history however is now well known, as they and their master are mentioned in some MS. Annals and Antiquities of Louvain discovered by M. de Bast. The pictures were preserved at Louvain until 1827.

These pictures are called, in the catalogue of the gallery of the King of Holland, the first and second pictures of the Emperor Otho and the Empress Mary. Their subject is from a story of the old chronicles of Louvain, called the Golden Legend; the event took place in 985. The Emperor Otho III., on his return from a journey to Rome, condemned at Modena one of his courtiers, an Italian count, to death, in consequence of an accusation from the empress (which was false), that he had attempted her honour. The count was beheaded, but immediately afterwards his widow, with his head on one arm and a red-hot iron which she holds with impunity in her other hand (an infallible proof of her husband's innocence), on her knees supplicates the emperor for justice. The emperor, being convinced by the fire ordeal of the count's innocence, orders the empress to be burnt at the stake.

From this tradition Stuerbout painted two pictures for the Town-hall of Louvain in 1468, on wood, each 117 inches French, by 66; the figures are about the size of life. In the first picture the emperor is listening to the false accusation of the empress, and the count is being led out in his shirt to execution; the actual beheading is represented in the distance. In the second picture the widow is kneeling before the emperor with the head of her husband and the red-hot iron in her hand, and in the distance of this piece the empress is being burnt at the stake; in both pictures are various attendants. The execution is in the style of the Van Eyck school, and is extremely elaborate, especially in the second piece, which is superior to the first.

These pictures were fixed on the wainscoting of the Justice-hall at Louvain, and by each was a pannel containing an explanation of the subjects in the Flemish language, and in gold Gothic letters. They were very dirty, and fast approaching decay, when in 1827 they were purchased for a small sum by the late King of Holland, who presented them to the present king, then Prince of Orange. They were removed to and restored at Brussels, and were in the collection of the Prince of Orange there, until 1841, when they were placed in their present locality at the Hague.

In the above-mentioned MS. 'Annales et Antiquités de Louvain,' it is stated that Dierick Stuerbout painted these two pictures for the Council-hall in 1468, and that he was paid for them 230 crowns. In the same MS. it is stated that Stuerbout was on the 20th of May of the same year commissioned to paint a picture 26 feet long by 12 high, and another of the Last Judgment 6 feet high and 4 wide, both for the sum of 500 crowns. What has become of these pictures is not known: they have probably perished; but if Stuerbout died in 1470, the larger one was probably never painted; the other was completed, and for many years in the Town-hall. Van Mander mentions a picture by Dirk Van Haarlem which he saw at Leyden; in the centre was the head of Christ, and on two side-wings the heads of St. Peter and St. Paul. It was inscribed as follows in gold letters in Latin—'One thousand four hundred and sixty-two years after the birth of Christ, Dirk, who was born at Haarlem, made me at Louvain. Eternal peace abide with him.' From this inscription it is evident that the Dirk of Louvain mentioned by Guiciardini in his 'Description de tous les Pays-Bas,' Antwerp, 1568, is the same as Dirk Van Haarlem, though that writer mentions them as two painters. Vasari mentions Diric da Lovanio. Stuerbout must have resided some time at Louvain. He was also from his style probably a pupil of John Van Eyck, or of some of his scholars. These two great pictures prove that Stuerbout was a much better painter than many of the most celebrated of his followers; the proportions of his figures are better, his forms fuller and better modelled, and his heads are executed with less rigidity and sharpness of feature. M. Nieuwenhuys and others give 1410 and 1470 as the respective dates of Stuerbout's birth and death, but how the information is acquired is not stated; Van Mander, whose book was published in 1604, was not acquainted with either. They appear to have originated with Ottley, who makes some conjectures on the matter in his 'Early History of Engraving.'

(De Bast, *Messager des Sciences et des Arts*, Ghent, 1833; Passavant, *Kunstreise durch England und Belgien*, &c.; Nieuwenhuys, *Description de la Galerie des Tableaux de S. M. Le Roi des Pays-Bas*, 1843.)

STYLOPS. [STREPSIPTERA, P. C. S.]

SUBLEYRAS, PIERRE, a distinguished French painter, was born at Usez in 1699. His father, who was also a painter, was his first instructor, but at the age of fifteen he took his son to Toulouse and placed him with Antoine Rivalz, a painter of reputation in that part of France. In 1724 he went to Paris, and two years afterwards obtained the grand prize for painting given by the French Academy for a picture of the Brazen Serpent. He was accordingly sent in 1728 to Rome, with a pension from the then government, and he remained there the remainder of his life, and acquired a great reputation. In 1739 he married a Roman lady, Maria Felice Tibaldi, a distinguished miniature painter, and they were both a short time afterwards elected members of the academy of St. Luke. Subleyras was patronized by the popes Clement XII. and Benedict XIV., by several cardinals, and many of the Roman nobility. He painted Benedict's portrait, and was commanded by that pope to execute one of the altarpieces for St. Peter's, to be worked in mosaic. The picture, representing St. Basil celebrating mass before the Emperor Valens, who is seized with a fainting fit, was finished in 1745, and after being exposed in St. Peter's for three weeks, was removed to the mosaic offices, and completed in mosaic before the death of Subleyras. He died at Rome of pulmonary consumption May 28, 1749, aged fifty.

There are several fine pictures by Subleyras in Rome and in some other cities of Italy, and a few in France: there are eight in the Louvre. His execution was delicate, but he composed well, and was an agreeable colourist. He etched a few plates; among them three of the pictures which are in the Louvre—the Brazen Serpent, Mary Magdalen at the feet of Christ, and St. Bruno restoring an infant to life. There is also a Holy Family by him.

(D'Argenville, *Abrégé de la Vie des Peintres*, &c.; R. Dumesnil, *Peintre-Graveur Français*.)

SUBULA'RIA (from *subula*, an awl, from the form of the leaves), a genus of plants belonging to the natural order Cruciferæ and the tribe Subularieæ. It has an oval-oblong laterally compressed pouch, with boat-shaped valves.

S. aquatica, Awl-wort, is a little aquatic stemless herb, with fascicular simple white fibrous roots. The radical leaves are linear and awl-shaped, the scapes naked and few-flowered, the pedicels filiform and bractless. It is native of the colder parts of Europe, in ditches, lakes, and rivulets with a sandy or gravelly bottom. It is also found plentifully in the north of England, Scotland, and Ireland. Sir W. Hooker and Sir J. E. Smith agree in stating that the flowers always remain several feet under water, even during the time they are expanded, so that, contrary to the general rule, fertilization must take place in that element. This curious little plant only requires to be planted or sown in a pond or rivulet, with a sandy bottom, or it may be kept in a pot filled with sand or gravel, and then plunged in water.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*; Burnett, *Outlines of Botany*.)

SUCCESSION. This is a legal term derived from the Roman 'Successio,' which signifies a coming into the place of another, and Successor is he who comes into such place.

The Roman term signifies a coming into the place of another so as to have the same rights and obligations with respect to property which that other had. There might be successio either by coming into the place of a person living, or by becoming the successor of one who was dead. Gaius (iii. 77, &c.) gives instances of successio in the case of persons living, one instance of which is the Bonorum Cessio according to the Lex Julia. Succession was again either Universal or Singular. The instances of Universal succession (per universitatem) which Gaius (ii. 97) enumerates, are the being made a person's heres, getting the possessio of the bona of another, buying all a man's property, adopting a person by adrogatio, and admitting a woman into the manus as a wife; in all of which cases all the property of the several persons enumerated passed at once to the person who was made heres, or got the bonorum possessio, or bought the whole property, or adopted another by adrogation, or married the woman. An instance of singular succession is the taking of a legacy under a man's will.

The term Succession is used in our language. We speak of the succession to the crown or the regal dignity, and the term implies that the successor in all things represents the predecessor. Indeed, the king as a political person, never dies, and upon the natural death of a king the heir immediately succeeds. The English heir-at-law takes the descendible lands of his ancestor as universal successor; and the executor takes the chattels real and other personal property of his testator as universal successor. The general assignee or assignees of a bankrupt or insolvent take by universal succession.

Blackstone says that 'corporations aggregate consist of many persons united together into one society, and are kept up by a perpetual succession of members, so as to continue for ever.' It is true that when members of a corporate body die, others are appointed to fill up their places, but they do not succeed to the others in the Roman sense of succession—they simply become members of the corporation. But it has been established in some cases (2 B. & Ad. 840) that the use of the word 'successors' implies that the legislature meant to establish a corporation; and yet it is certain that a feoffment of land to a corporation aggregate without the word 'successors' is a valid grant. In a feoffment to a corporation sole the word 'successors' is necessary. The succession in the case of a corporation sole follows the nature of the Roman succession. In the case of a corporation aggregate there is no succession, and the rule that a corporation may be established by the use of the word 'successors' in a statute is founded on an erroneous understanding of the term 'successors.'

SUCCESSION, WAR OF, the name usually given to the war occasioned by the accession of the Duke of Anjou, grandson of Louis XIV., to the throne of Spain. Charles II. of Spain, the last male descendant of the Spanish branch of the House of Austria, having no issue nor brothers, the succession to the Spanish monarchy appeared to belong to Maria Theresa, Queen of France, the eldest sister of Charles, and to the children of her marriage with Louis XIV. She had however on her marriage renounced by a solemn covenant her right to the throne of Spain. The second sister of Charles was married to Leopold I., Emperor of Germany, and had not made on marriage a renunciation of her rights of succession; her daughter however, the Electress of Bavaria, had, previous to her marriage, been obliged to renounce her hereditary claims. The Emperor Leopold in consequence claimed the crown of Spain for his second son Charles, on account of Leopold's mother being aunt of Charles II. France and Bavaria, on the other hand, maintained that the renunciations alluded to could not prejudice the children, who held their right not by their mother, but by the fundamental law of Spain. Each of these powers endeavoured to influence Charles II. in their favour, and he was at length induced to name in his will Joseph Ferdinand, Elector of Bavaria, as his successor. The early death of this prince, in 1699, revived the contending claims of the Houses of Bourbon and Austria.

These different claims having excited the apprehensions of a general war, a treaty, called the second treaty of partition [PARTITION TREATY, P. C.], was concluded on 13th March, 1700, between France, England, and Holland, the details of which will be found in another part of this work. By this treaty the Archduke Charles, son of the Emperor Leopold, became the presumptive heir to the Spanish crown, while to the grandson of Louis was awarded the duchy of Lorraine, together with the kingdom of the Two Sicilies and the province of Guipuzcoa in Spain. This treaty however was rejected by the emperor, and the consequences of his rejection proved finally fatal to the cause of his son.

On the death of Charles II. (Nov. 1, 1700) a secret will was discovered which named the Duke of Anjou sole heir to the whole of the Spanish monarchy. Though Charles had been influenced in drawing up this will by the intrigues of Madame de Maintenon, carried on through the Marquis d'Harcourt, the French ambassador at Madrid, Louis, aware that a war, with Austria at least, must be the issue of his acceptance of the Spanish crown for his grandson, hesitated before availing himself of the offer, which was rendered the more pressing by the general feeling of the Spanish nation in favour of the House of Bourbon. A council which he summoned on the occasion gave its unanimous opinion in favour of acceptance, and induced the French king immediately to proclaim the Duke of Anjou as king of Spain and the Indies, under the title of Philip V.: to his assembled court he presented him with these laconic words:—'You see before you the king of Spain. Nature has formed him for it; the deceased king has nominated him, the people desire him, and I consent.' These words became the signal of a war which was one of the longest and most general in Europe. On the side of the emperor were the states of Germany, with the exception of Bavaria and Cologne. Most of the powers of Europe however acknowledged Philip V., who made his entry into Madrid on the 14th of April, 1701; and had Louis, at this time, prudently concerted his measures, he might have secured to his grandson the peaceable possession of the throne, or, at all events, prevented the war from extending beyond the limits of Germany. Peace was moreover of paramount importance to the French monarchy, drained as it was in its resources and weakened in its power by the war which had but lately been terminated by the treaty of Ryswick. [P. C. vol. xxvi. p. 174.] Age and infirmities had diminished the energies and damped the military ardour of Louis, while death had deprived him of many of the great statesmen and generals who have rendered his reign so illustrious in history; Louvois and Colbert had disappeared from the political stage, together with Turenne, Condé, Créqui, and Luxemburg.

England and the States-General, though they had acknowledged Philip V., entertained fears lest the balance of European power should be destroyed by the union of France with Spain. Louis, on the other hand, far from attempting to dispel these fears, with singular impolicy issued letters patent in favour of Philip, to the effect of preserving his rights to the throne of France. Another measure equally impolitic was the encroachments made at that time by the French in the Spanish Netherlands, and their consequent military approximation to the territories of the States-General. This latter measure gave an opportunity to William III. of Orange to excite the Dutch against France; but he found considerable difficulty in bringing over the English parliament to second his views. An event however soon occurred which removed these difficulties; it was the death of the exiled king of England, James II., and the recognition by Louis of his son as king of Great Britain. This was the immediate cause of the treaty drawn up at the Hague on September 7, 1701, and generally known under the name of the Second Grand Alliance. It was signed by the plenipotentiaries of the Emperor of Germany, the States-General, and the King of England. The principal objects of that treaty are detailed in another part of this work. [HAGUE, ALLIANCE OF THE, P. C. S., in which by an oversight the name of Charles III. is put for that of Philip V.] This alliance was afterwards joined by the Kings of Portugal and Prussia and the Duke of Savoy.

On the death of the King of England, his successor, Queen Anne, followed his policy in adhering to the alliance of the Hague [ANNE, P. C.], and three months had not elapsed after her accession before war was declared by the powers united by that treaty against France (4th May, 1702). At the commencement of the war the French for some time maintained the former glory of their arms, and defeated the Imperialists on the Upper Rhine, but the Earl of Marlborough [MARLBOROUGH, P. C.], who had been appointed to the command of the Anglo-Dutch army, made considerable progress in Flanders, while the combined fleets of England and Holland destroyed a French fleet in the Bay of Vigo. The fortress of Landau on the Rhine was also taken by the Imperial General Lewis of Baden. In Italy, Prince Eugene, who had the command of the German army, was unable, through the deficiency of his resources, to attempt any measure of importance. [EUGENE, P. C.]

The following year was spent by Marlborough in reducing the fortified places on the frontiers of the Spanish Netherlands. In Southern Germany the contest was more unfavourable to the allies. The French Marshal Villars [VILLARS, P. C.] had succeeded in crossing the Rhine and in uniting his forces with those of the Elector of Bavaria. In Italy and Alsace the French had likewise the advantage in arms. Their cause however was weakened during that year by the defection of the Duke of Savoy, who joined the allies, as did also the king of Portugal. The campaign of 1704 was more unfavourable to the French arms. Marlborough, having secured the safety of the Netherlands, determined upon marching into Germany to the aid of the emperor, whose capital was menaced on one side by the French and Bavarian armies, and on the other by the Hungarians, who had taken occasion of the war to attempt a revolt. A plan also was resolved upon by the allies to unite the forces under the three Generals—Marlborough, Eugene, and Lewis of Baden, while General Stahrenberg was to remain in Italy. The junction of their armies was effected at Heilbronn on the Neckar; it was agreed among them that Prince Eugene should direct his march along the Rhine, while the two other generals directed their course to the Danube. The passage of the Danube was bravely but unsuccessfully disputed by the Bavarians near Donauwerth. Advantage was taken of their success by the allies to offer peace on favourable terms to the elector, if he would withdraw from the alliance with France. The advance of Marchal Tallard with a French army of 30,000 men determined the elector upon refusing these proposals; at the same time Eugene had joined Marlborough with 20,000 men; the Prince of Baden, whose obstinacy it was feared might derange their plans, was sent to reduce Ingoldstadt. On the 13th August a decisive engagement took place, which terminated in the complete defeat of the French and Bavarians. The details of this important battle will be found in the articles Blenheim and Marlborough, P. C.

This disaster was followed by the loss of Bavaria, which was occupied by the Imperialists, and the elector was compelled to cross the Rhine with the French, and to take up his position at Brussels. In Italy and Spain the French obtained some advantages, which however were counterbalanced by the loss of the important fortress of Gibraltar, which fell into the hands of the English on the 24th July, 1704. [Gibraltar, P. C.]

The next year, 1705, the Emperor Leopold died, and was succeeded by his eldest son Joseph, whose character for energy and determination formed a favourable contrast with that of his father. After some hesitation, he decided upon vigorously pursuing the war in support of the claims of his brother Charles, who the year previous had proceeded to Spain, and had already been acknowledged as king in Aragon, Catalonia, and Valencia. Nothing however of importance occurred during the campaign of that year; the Prince Eugene was sent to Italy to reorganize the army, while Marlborough returned to Flanders to recruit his forces.

In 1706 fresh exertions were made by Louis to maintain an army in Germany, and to take the offensive in Savoy and Flanders. Accordingly he sent into Flanders one of the finest armies that had yet appeared in the war, and placed it under the command of Marshal Villeroi. The imprudent ardour of this general proved disastrous to his projects; he left a strong position which he had taken up at Louvain to give battle to Marlborough on the plains of Ramilies (May 22), which resulted in his complete defeat. [Ramilies, P. C.] The details of this great battle will be found in the article referred to; but the fact that it was fought almost on the site of Waterloo, by which name it has often been designated, may not perhaps be generally known. The victory at Ramilies secured to the allies the greater part of the Spanish Netherlands, while, to increase the misfortunes of Louis, his Marshal, Marsin, lost the battle of Turin against Prince Eugene (September 7); a defeat which was followed by the loss of all territories which had been occupied by the French in Italy. [Eugene, P. C.] In Spain they were also repulsed in an attack upon Barcelona; and the English and Portuguese entered Madrid, which city however they were unable to retain. At this juncture of affairs a suspension of hostilities was offered by Louis to the allies, but they were rejected chiefly through the influence of the pensionary Antony Heinsius.

In 1707 a considerable portion of the Spanish inheritance was in the possession of the Imperialists and their allies, while Lombardy and Flanders had already been secured to them by the battles of Turin and Ramilies. Louis at this time determined upon a diversion in his plan of attack, which was soon followed by important consequences. The large body of troops which had been forced to evacuate Italy he collected together, and, placing them under the command of the Duke of Berwick [Berwick, James Fitz-James, Duke of, P. C.], sent them into Spain to the support of his grandson. On the 26th April a most decisive victory was obtained by him over the English and Portuguese under the Earl of Galway and the Marquis Las Minas at Almanza. In this important battle the allies sustained a loss of 17,000 killed, wounded, and taken prisoners; their two generals were withdrawn from the field severely wounded, and 120 standards fell into the hands of the French. The victory of Almanza proved the prelude of further successes, which, joined to the popularity of his cause, finally ensured the throne of Spain to Philip V. Aragon and Valencia were reduced to his submission by the Duke of Orleans, and in the latter end of the year 1707 the only part of Spain retained by the Archduke Charles was Catalonia. The following year Prince Eugene once more formed a junction of his forces with those of Marlborough, and thus united gave battle to the French army under the command of the Dukes of Burgundy and Vendôme at Oudenarde (July 11, 1708), which terminated in the defeat of the French. [Oudenarde, P. C.] After this victory Eugene besieged and took the strong fortress of Ryssel and recovered Ghent and Bruges. In Spain and Italy the French obtained some success, but the islands of Sardinia and Minorca surrendered to the English fleet under Admiral Leake. A winter of unparalleled severity increased the difficulties under which the French king laboured in pursuing this war, and he once more made overtures of peace to the allies, offering to renounce Spain, India, Milan, and the Netherlands, if they would leave to his grandson Naples and Sicily. Still further concessions, however, were demanded of him, which were granted, and a peace was on the eve of being proclaimed when all hope of it was extinguished by a further proposition from the allies, to which it would have been dishonourable to Louis to have acceded; it was to the effect that, in the event of his grandson Philip refusing to resign the sovereignty of Spain, he should himself assist in expelling him from it by force of arms. This proposal was indignantly refused by the aged king, who once more rallied all the energies of his kingdom to prosecute this war. Thus a peace far more advantageous to the allies than that which was finally sanctioned at Utrecht was prevented by an ill-timed display of overbearing pretensions.

Part of the summer of the year 1709 was passed in these negotiations, and the allied generals hastened to take the utmost advantage of the remaining portion of the season. Their army, about 100,000 strong, was posted near Lille; Marshal Villars, with the French army of nearly equal strength, covered Douay and Arras. Eugene and Marlborough, instead of attacking him, marched against the important fortress of Tournay, of which they took possession. Their next operations were directed against Mons, which place Villars was desirous of protecting, and he accordingly encamped within a league of it in a strong position at Malplaquet. No time was lost by the allies in attacking him in his intrenchments; and, after a contest the most obstinate and sanguinary during the war, victory remained once more on the side of the allies (11 September). [Marlborough, P. C.] The surrender of Mons was the immediate result of this victory. Another campaign had terminated unfavourably to Louis; he again applied for peace, but the same dishonourable terms were proposed to him, and the cruel alternative was again presented to him of continuing a disastrous war or of waging one against his child; as before, he chose the former.

The campaign of 1710 was marked by the reduction of Douay and other strong places on the Netherlands frontier, and in Spain by the successes of Charles at Almenara and Saragossa, which enabled him to enter Madrid. Reverses, however, soon attended his arms; fresh troops arriving from France, the Spaniards cordially co-operated with them, and, under the able command of the Duke of Vendôme, all his possessions were re-conquered, and to Philip V. was secured the quiet enjoyment of his throne.

While, however, fortune favoured the cause of the French in Spain, their own country was reduced to a critical extremity by the victory of Malplaquet and the continued advance of the allies. In this untoward state of things, there happened a series of unexpected events, which so changed the aspect of affairs, that Louis was, from an humble suppliant for peace, soon placed in a condition which enabled him to dictate his own terms to most of the powers allied against him. Not the least important of these events was the death of the Emperor Joseph I. (11 April 1711), who fell a victim to small-pox at the early age of thirty-three. As he died without male issue he was succeeded by his brother Charles, who had for some time assumed the title of Charles III. of Spain. The balance of power, which it had been the object of this war to maintain, would have been destroyed if the new Emperor had added to the hereditary states of the German House of Austria the whole of the Spanish monarchy. Such a predominance appeared dangerous to the other powers, and thus by the accession of Charles VI. to the imperial throne a considerable difficulty in the way of an amicable adjustment with France was removed. [Balance of Power, P. C.]

Another event which tending to the same end was the change of ministry which took place in England. The Whig party, to which Marlborough and his friends belonged, had governed the state since the revolution of 1689. Their influence, in 1710, was somewhat suddenly superseded by that of the Tories. A new parliament was elected, in which the Tory party had a majority, and, as a means of depriving the Duke of Marlborough of his influence, measures of peace were strongly advocated. [ANNE, P. C.] Secret negotiations were set on foot between the Courts of England and France, which ended in a preliminary treaty of peace being signed in London on October 8, 1711. The conferences for a general peace were now opened, and Utrecht was selected as the place where they were to be held.

The conferences which took place at Utrecht in the early part of the year 1712 met with several interruptions, arising from the contending interests of the different powers who composed the grand alliance. The victory obtained by Marshal Villars over the Earl of Albemarle at Denain (24 July, 1712) [VILLARS, P. C.], and the consequent recovery of Douai and other strong places, increased the pretensions of the French, and rendered the allies more tractable. Peace was at length signed at Utrecht in the month of April, 1713, between France and England, the United Provinces, Prussia, Portugal, and Savoy: the Emperor alone refused to take part in it. A full detail of the terms of that treaty will be found in another part of this work [P. C. vol. xxv. p. 174]. The real gainer by it was undoubtedly the French King, who obtained nearly all the advantages which it had been the object of the war to prevent his acquiring; it was also productive of considerable odium against the English ministry. [HARLEY, P. C.]

The Emperor, now deserted by his allies, was compelled to negotiate alone a peace, which became important even for the security of his hereditary states. It was brought about by the moderation of the two great generals Eugene and Villars, who, though among the most distinguished in the war, proved themselves the most desirous of promoting peace. They commenced negotiations at the Castle of Rastadt in November, 1713, and a treaty was there concluded on the 7th March, 1714 [RASTADT, P. C.]; and the terms of it were definitely agreed upon on the 7th September following at Baden in Aarau. [BADEN, TREATY OF, P. C. vol. xxv. p. 174.] The King of Spain acceded to these treaties, and Europe once more enjoyed the privileges of peace.

For a more detailed account of this war, the following works may be referred to: Koch's 'Revolutions of Europe,' translated by Crichton, 3 vols., Edinburgh, 1828, vol. ii. p. 146-157; 'Outlines of History;' Lardner's 'Cabinet Cyclopædia,' p. 384-390; Koherausch's 'History of Germany,' translated by Haas, London, 1844, p. 532-547; Schlosser's 'History of Europe,' vol. iii. p. 17-84, translated by Davison, London, 1844; 'History of Spain,' Library of Useful Knowledge, London, 1833, book iii. chap. 1, 2, 3; Voltaire, 'Essai sur l'Histoire Générale,' &c., chap. 190-196; Lord Mahon, 'History of the War of Succession in Spain.'

SUCHET, LOUIS GABRIEL, Duke of Albuféra and Marshal of France, was a native of Lyon, where his father was a silk manufacturer. The year of his birth is stated by some authorities to have been 1770, by others 1772. On the breaking out of the French Revolution, he entered as a volunteer in the cavalry of the national guard of Lyon; shortly afterwards, he became captain of a volunteer company raised in the department of l'Ardèche, which he commanded during four months, when he was raised to the grade of 'chef de bataillon' in the troops of the above-named department. In this capacity, it is stated, he was compelled to be the active witness of many atrocities, committed in the name of the law by the deputy of the convention, Maignet. He was present at the siege of Toulon in 1793; from thence he was transferred to the army of Italy, and was attached to the brigade under the command of General Laharpe. In this campaign he specially distinguished himself at the combat of Loano (23rd November, 1795), where he captured three Austrian standards. He afterwards served with distinction in the same campaign under the Generals Augereau [AUGEREAU, P. C.] and Masséna [MASSÉNA, P. C. S.], and received several wounds. He was selected by Masséna to present to Bonaparte the standards which had been captured during the year 1797 by the brigade in which was his battalion. It was on the field of battle of Neumark (2nd April, 1797) that he was raised to the rank of 'chef de brigade.' He afterwards joined the army in Switzerland, where he was instrumental to the conclusion of a treaty with the cantons of Berne and Fribourg. This treaty did not prevent the war being soon after rekindled in Switzerland, and in it Suchet displayed considerable skill; it was there that he first gave proof of his talents as a tactician, which afterwards raised him so high in the estimation of Bonaparte. The important part he acted in this campaign was recognised by his chief, who deputed him to Paris to present to the Directory twenty-three standards taken from the enemy.

When the expedition to Egypt was determined upon, it was originally intended that Suchet should be included among the military commanders selected to act under Bonaparte; the disordered state, however, of discipline which prevailed in the army of Italy, and the representations of General Brune, who commanded it, caused him to be retained there with the rank of Major-General of Brigade. In his new command he made many strenuous endeavours to renew the antient discipline and to ameliorate the condition of the soldier; these endeavours were construed by the suspicious government at Paris into an attempt to introduce in the army an aristocratic rule. His recal was decided upon, in opposition to the strong remonstrances made on the subject by General Joubert, who was among the most popular and successful of the republican generals of that period. On his arrival at Paris, he succeeded in clearing himself of the charges which had been brought against him, and he was transferred to a command in the army of the Danube. He there rendered himself conspicuous by the able manner in which he seconded the skilful manœuvres of General Masséna in the Grisons. [MASSÉNA, P. C. S.] The successes which attended the French arms in Switzerland were counterbalanced by the disasters of General Schérer in Italy; these disasters necessitated the appointment of a more daring and vigorous commander, and Joubert was again intrusted with the chief command. On this occasion Suchet was recalled from the army of the Danube, and placed at the head of Joubert's staff. The campaign which ensued added greatly to his military reputation; the careful avoidance of error in his movements and manœuvres, the skilful disposition of his troops, whether acting independently or in conjunction with the main army, as they procured him important successes, soon attracted the notice of Bonaparte when he joined the Italian army, and he was appointed by him second in command to Masséna. In this capacity he particularly distinguished himself in the actions at San Bartolomeo and the bridge of Cezio (7th and 8th May, 1800). With a body of eight thousand men, advantageously posted, he checked the advance of General Mélas, who had five times his numbers, and for a long time harassed his army, whose retreat he had cut off; he thus afforded a powerful co-operation to the main army of the French, which, under the command of Bonaparte, was at that time crossing the Great St. Bernard. [BONAPARTE, P. C.] General Suchet, after these operations, rejoined Masséna on the plains of Alessandria, and was present at the battle of Marengo. When, in consequence of this decisive battle, the city of Genoa again fell into the hands of the French [MASSÉNA, P. C. S.], the government of it was given to Suchet. At the conclusion of the armistice of six months, which had been concluded between the French and Austrians, the command of the centre of the army of Italy was confided to him. In this command he was enabled to extricate General Dupont, so unfortunately known by his subsequent disasters at Baylen, in Spain [BAYLEN, P. C.], from a position of considerable danger, and, in conjunction with him, obtained a signal success over the Austrians, under General Bellegarde, at Pozzolo, in which action four thousand prisoners were made.

During the peace which was concluded in 1801 at Luneville between the Empire and France, General Suchet was employed in inspecting the troops stationed on the south and west frontiers; he was afterwards actively engaged in the superintendance of military works, and finally promoted to the governorship of the castle of Lacken, near Brussels, having been previously named member of the Legion of Honour.

On the opening of the campaign of 1805, Suchet was attached to the division of the army under the command of Marshal Lannes. [LANNES, P. C. S.] At the memorable battle of Austerlitz, he commanded the left wing of that division, and greatly distinguished himself by a manœuvre as daring as it was skilful. The following year, a few days previous to the battle of Jena (14th October, 1806), he obtained, at the head of his division, some important advantages over Prince Frederick Louis of Prussia, who commanded the advanced guard of the main army of the Prussians, at Graffenthal; in this engagement he captured thirty pieces of artillery; among the killed was the young and gallant Prince of Prussia. To this movement of Suchet Napoleon was indebted for the opportunity of attacking, without opposition, the rear of the main army of the Prussians. The following year, he materially contributed to the success obtained by Savary, Duke of Rovigo, over the Russian General Essen, who, with twenty-five thousand men, attacked the French on the banks of the river Narrew (16th February, 1807), and was repelled with considerable loss.

The reputation which Suchet had acquired in these engagements, as a brave soldier and a skilful tactician, induced Napoleon to intrust him with a separate command. An opportunity of doing so was afforded him by the war which broke out in Spain in 1808, and he gave him the command of the fifth division of the army, having previously raised him to the highest grade of the Legion of Honour [Legion of Honour, P. C. S.], with a pension of 20,000 francs, and the title of Count of the Empire. After assisting for a short time at the siege of Saragossa [Saragossa, P. C.; Lannes, P. C. S.], he was appointed to the important command of general-in-chief of the French army in the province of Aragon. This brings us to the most illustrious period of this general's military life; the campaigns which followed under his command, are among the most brilliant recorded in history, and it is to be regretted that sufficient justice has not been rendered to his merit by the English annalists of this war, previous to the time of General Napier. To this distinguished and impartial historian has been reserved the honourable task of raising the character of an enemy to the position he deserves in public estimation. When General Suchet was placed at the head of the forces in Aragon, he found the army so destitute of discipline that it almost amounted to disorganization. In applying the measures to restore this discipline, he evinced considerable discernment, prudence, and energy; no longer thwarted in his efforts by the factious opposition of mere theoretical statesmen, as he had been in the time of the Directory, he speedily effected this important purpose. 'Suchet,' says the historian above referred to, 'was no ordinary man; and with equal vigour and prudence he commenced a system of discipline in his corps, and of order in his government, that afterwards carried him, with scarcely a check, from one success to another, until he obtained the rank of marshal for himself, and the honour for his corps of being the only one in Spain that never suffered any signal reverse.' (Napier, *History of the Peninsular War*, vol. ii. p. 97.) In 1810 General Suchet received orders from Madrid to lay siege to the strong fortress of Lerida, the approaches to which were covered by the Spanish General O'Donnell and a strong body of Catalonian troops. The defeat of this general was followed, after a gallant and obstinate resistance, by the surrender of the fortress which he had protected (14th May, 1810), in which were found five hundred pieces of artillery. The fall of Lerida was followed by that of Mequinanza (8th June, 1810), and Tortosa (2nd January, 1811). These successes were followed by one still more important, the taking of the city of Tarragona (28th June, 1811), which was defended by a garrison of eighteen thousand men; the city fell into the hands of the French after a siege of two months, or rather, as Suchet himself expressed it, after a succession of three sieges and five assaults; they found in it, according to the French accounts, five thousand cannon and abundant munitions. [Tarragona, P. C.] The sanguinary nature of this siege may be judged from the fact that upwards of nine thousand Spaniards of the garrison are said to have perished. The occupation of Mont-Serrat, a place of such great strength that it was deemed impregnable, followed soon after the capture of Tarragona. These brilliant services were justly appreciated by Napoleon, who rewarded them by raising Suchet to the dignity of a Marshal of the Empire. In the latter end of the year 1811 Suchet directed the operations of his army against Murviedro, the antient Saguntum [Hannibal, P. C.], the fortifications of which had latterly been reconstructed at considerable expense; the defeat of General Blake and thirty thousand men under its walls, was followed, after about a month's siege, by the fall of this important fortress. A reinforcement of fresh troops having arrived from Navarre, Suchet next proceeded to invest the city of Valencia, which surrendered to him by capitulation on 10th January, 1812. The fall of this city, and of some fortresses in its neighbourhood, was followed by the occupation of the entire province of which it was the capital. Albuféra, which had been the scene of his last successes, became the title of the dukedom to which he was raised by Napoleon, who added to this title an extensive and valuable domain. But he obtained a higher title to the respect and admiration of posterity by the general expressed feeling of the Spaniards under his rule, that he mitigated the horrors of war by his humanity, and dealt equal justice to the conquerors and to the conquered. 'The mission imposed upon him had been to conquer and to subdue: he was required to provide for the expenses of the war by the successes of war; the mission, however, which he imposed upon himself was to augment his power by his skill, and to diminish opposition by his justice.' (Translated from *Le Journal de la Méditerranée*, du 7 Janvier, 1826.) Marshal Suchet pursued the same system of government in the province of Valencia that had answered so well in that of Aragon; he placed it in the hands of a commission composed of enlightened and respectable men. He called together an assembly of persons of every class of society, and who represented various interests, to vote the expenses of the war and equitably to divide its burdens; and to them he rendered a faithful and detailed account of the manner in which these taxes were employed. He manifested the same spirit of confidence and justice towards the soldiers under his command, and found it productive of the most beneficial results.*

The success which attended the British arms under Lord Wellington, and the decisive victory which he obtained at Vittoria, compelled a large portion of the French army to retreat beyond the Pyrenees, and, in consequence, Suchet found himself under the necessity of abandoning the eastern provinces of Spain, and to fall back upon Catalonia, where he maintained himself for some time. Obliged at length to evacuate this province, and to retreat towards the frontiers of France, he effected this retreat in the attitude of a conqueror, and secured his army from the reverses usually incident upon such an operation. On reaching Narbonne, he signified, on 14th April, 1814, his adhesion to the decrees of the senate directed against Napoleon. Employed to receive Ferdinand VII. [Ferdinand VII., P. C.], who had been released from Valençay, and to present him to the Spanish army, he was publicly thanked by the king for the manner in which he had carried on the war against his subjects. The gratitude of the Spanish nation towards the administration of this marshal was further evinced by the general testimony which was borne to his justice and humanity, when, in 1823, the French again occupied the scene of his exploits. The correct view taken by Suchet, with respect to the release of Ferdinand, will be seen by reference to Montholon, *History of the Captivity of Napoleon*, vol. ii. p. 350.

The speedy adhesion of Suchet to the Bourbons was rewarded by his being created a member of the new peerage, and his appointment to the command of the tenth military division, of which the head-quarters was Strasbourg. On the return of Napoleon from Elba, though he maintained his fidelity to the Bourbons so long as Louis XVIII. remained in France, he renewed his allegiance to his former chief, and accepted the command of the army of the Alps, with which he obtained several important successes over the Piedmontese and the Austrians. His army was composed of only ten thousand men, and on the approach of the main body of the Austrians, nearly one hundred thousand strong, he was compelled to fall back upon Lyon, for which city, by his judicious management, he obtained an honourable capitulation; one of the conditions in it being that all the valuable munitions of war contained in that city should be respected by the enemy.

On the second restoration of the Bourbons, he remained for some time in disgrace, and was deprived of his civil though not of his military honours. He was however restored to his position in the peerage by a royal ordinance, dated the 5th of March, 1819. That he entirely recovered the favour of the king may be presumed from the fact that he was chosen to assist at the birth of the present Duke of Bordeaux. On the French expedition to Spain, in 1823, it was generally expected that Marshal Suchet would have been selected to accompany the Duke of Angoulême, as his principal adviser, but he was already suffering severely from the disease to which he shortly afterwards fell a victim. He died at Marseille on the 7th of January, 1826, leaving behind him a young widow and several children. During the latter years of his life he was occupied in composing a memoir of his campaign in Spain, which has since been published. (*Mémoires de Suchet*, 2 vols., Paris, 1826.)

* 'The corps under the command of Marshal Suchet,' says Napoleon, 'which occupied the kingdom of Valencia, never suffered a want of anything; the country, being well governed by the marshal, supplied all the necessities of the army; the contributions were regularly paid, and war was carried on, as it would have been in Germany, and all this because the marshal set an example of severe probity, and maintained discipline among his troops. Had all the other marshals done the same, the war would have been reduced to the chances of a battle.' (Montholon, *Hist. of the Captivity of Napoleon*, vol. ii. p. 342.)

The reputation of Suchet stands deservedly high amongst the generals of Napoleon. His military career was unstained by any of the excesses which have disgraced so many of his most distinguished colleagues in command. Brought up in the school of Masséna, he rivalled his military skill without imitating his vices. It is true that his entrance by storm into Tarragona was marked by the rapine and inhumanity of his soldiers; but the same excesses were committed by our own army at Badajos and St. Sebastian, and it would be unjust to throw the odium of them on its illustrious commander. The inability of a chief perfectly to restrain the frenzied violence of his soldiers on such terrible occasions is a melancholy fact which the history of all ages has established. We have already dwelt upon his qualities as a military and a civil ruler. The high opinion entertained of Suchet by Napoleon has been recorded by O'Meara and Las Cases. On the question being asked him by the former, who, in his opinion, was the first of his generals? he replied, 'I think that Suchet is probably the first. Masséna was; but you may say that he is dead' (1817), alluding to the complaint under which that marshal was fast sinking. On another occasion, at St. Helena, Napoleon remarked, 'that if he had had two such field-marshals as Suchet in Spain, he should not only have conquered, but kept the Peninsula. His sound judgment, his governing yet conciliating spirit, his military tact, and his bravery had procured him astonishing success.' (*Court and Camp of Bonaparte*, p. 419.)

SUCHOSAURUS, the name given by Owen to a fossil Saurian of the Wealden formation of Tilgate.

SULPHURATION, or SULPHURING, is the process of bleaching employed to give whiteness to silk and woollens by exposing them to the fumes of burning sulphur. For this process a detached chamber, without a chimney, is made use of, but so constructed that, when required, a current of air may be passed through it.

According to Berthollet, 100 pounds of silk, stretched on perches, are placed at a height of nearly seven feet, and about two pounds of sulphur, reduced to coarse powder, are put into an iron pot, containing a small quantity of ashes; the sulphur is fired in several places, and the chamber well closed to prevent the loss of sulphurous fumes: afterwards the windows are opened to let them escape and to dry the silk. In winter, after the smell of the sulphurous vapour has ceased, the windows are shut, and charcoal is burnt in the chamber, in order that the silk may be dried. By this operation the silk becomes perfectly white, and is rendered fit for subsequent operations. Woollen cloths are treated nearly in the same manner.

SURGEONS, COLLEGE OF. [SURGEONS, COLLEGE OF, P. C.] A new charter was granted to the College of Surgeons in the 7th year of Victoria, by which it is declared that the name of the college shall henceforth be The Royal College of Surgeons of England; and that a portion of the members of the said college shall be fellows thereof, by the name of The Fellows of the Royal College of Surgeons of England. The charter declares that the present president and two vice-presidents and all other the present members of the council of the said college, and also such other persons, not being less than 250 nor more than 300, and being members of the said college, as the council of the college, at any time before the expiration of three calendar months from the date of the charter, shall elect and declare to be fellows in manner by the charter directed; together with any such other persons as the council of the said college, after the expiration of the said three calendar months and within one year from the date of the charter, shall appoint in manner by the charter authorized, shall be fellows of the said college. But no person, except as hereinbefore named, is to become a fellow unless he shall have attained the age of twenty-five years, and complied with such rules as the council of the college shall think fit and by a by-law or by-laws direct; nor unless he shall have passed a special examination by the examiners of the said college. Every person admitted as a fellow, as last mentioned, is to become a member of the College by such admission, if he is not already a member. Henceforth no member of the College who is not a fellow is to be eligible as a member of the council. There are also (10) some other restrictions as to eligibility. The present members of the council are to continue life members as heretofore; and the number of members of council is to be increased from twenty-one to twenty-four, and all future members are to be elective, and to be elected periodically, in the manner prescribed by the charter (12) when the number of elective members of the council shall be completed and made up to twenty-four. Three members shall go out annually, but they may be re-elected immediately. The members of council are to be elected by the fellows, including the members of the council as such, in the manner prescribed by the charter (15); and the election is to be by ballot (17). There are various special provisions as to the eligibility of fellows, for which we refer to the charter. There are to be ten examiners of surgeons for the college, and the present examiners are to continue for life; and all future examiners are to be elected by the council, either from the members of the council or from the other fellows of the college, or from both of them; and all future examiners of the College shall hold their office during the pleasure of the council. The charter contains other regulations, and confirms the powers of the college and the council, except so far as they are altered by the charter; and it declares that no by-law or ordinance hereafter to be made by the council shall be of any force until the crown shall have signified its approval thereof to the College under the hand of one of the principal secretaries of state, or otherwise as in the charter stated (22). 'The by-Laws and Ordinances of the Royal College of Surgeons of England' contain the regulations as to the candidates for the fellowship (sect. 1), for the examination of candidates for the fellowship (2), admission of fellows (3), election of members of council (5). By section 1 it is required that every candidate for the fellowship, among other certificates, shall produce a certificate, satisfactory to the court of examiners, that he has attained a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics. The subjects of examination for the fellowship are Anatomy and Physiology on the first day, and Pathology and Therapeutics and Surgery on the second day. The examination is to be by written answers to written or printed questions; but any candidate may be interrogated by the examiners, on any matter connected with the questions or answers. In the anatomical examination the candidate must also perform dissections and operations on the dead body in the presence of the examiners.

The members of the College are admitted by diploma after examination before the court of examiners, and their diploma confers upon them the right of practising surgery in any part of the British dominions.

The council of the College have at various times required certain qualifications of age, education, &c. from candidates for examination. The regulations last issued are dated October, 1841.

The examinations of members are conducted *vivâ voce*, or, if the candidate desire it, in writing. The questions are almost exclusively anatomical and surgical; and the examination of each candidate occupies about an hour and a half, during which time he is usually questioned by four of the examiners in succession.

According to the financial statement (June, 1843), the receipts of the College for the previous year were as follows:—

	£	s.	d.
Court of examiners; fees for diplomas, at 20 guineas each, exclusive of stamps	14,093	11	0
Rent	12	10	0
Incidental sale of lists, catalogues, &c.	160	6	6
Dividends on investments in government securities, &c.	1,499	0	4
	£15 765	7	10

And the disbursements were as follows:—

	£	s.	d.
College department, including council, court of examiners, auditors, &c.	7,402	19	1
Museum department, including catalogues, specimens, spirits, salaries, &c.	3,653	0	10
Library department, including the purchase and binding of books, salaries, &c.	1,120	12	7
Miscellaneous expenses, taxes, rent, &c.	698	18	1
Repairs and alterations	253	10	6
Hunterian oration, lectures, &c.	264	4	0
	£13,393	5	1

SUSSEX, AUGUSTUS FREDERIC, DUKE OF, a Prince of the United Kingdom, the sixth son of George III., was born on 27th January, 1773. After having been some time under a private tutor, he travelled abroad, and studied at Göttingen. From an incident connected with his early history, a very curious question regarding the law of marriage and legitimation arose. In April, 1793, he was privately married at Rome to the Lady Augusta Murray, daughter of the Earl of Dunmore. Independently of other questions, it was thought that there might be an objection to the validity of this marriage on the ground of its being celebrated by a Protestant clergyman in a place where by the law of the state a marriage by such a person is invalid, and where there was no British representative to make a special domicile. Accordingly the ceremony was repeated in St. George's, Hanover Square, London, on 5th December, 1793. The ground for questioning the validity of their union was the Royal Marriage Act, 12 Geo. III. c. 3, which prohibits every descendant of George III. from contracting matrimony without the consent of the crown, and provides that every marriage contracted without this consent being first obtained, 'shall be null and void to all intents and purposes whatsoever.' There is no doubt that, so far as respected England, the English marriage came under this act. But there were reasons for supposing that the marriage at Rome might be capable of being declared valid in other parts of the kingdom, of which the Duke, as a prince of the blood, was as much a citizen as he was of England. With regard to Scotland, the statute was so much connected with the English Marriage Act, that it is questioned if it extends to that part of the kingdom; and as to Ireland, that country was not united to England when the act passed. It was supposed that the question might come to be considered in relation to the succession of the throne of Hanover, but the birth of a nearer heir has rendered such an event unlikely. His first wife having died in 1834, he married in 1840 the widow of Sir George Buggin, without conforming with the Marriage Act. On 30th November, 1830, he became President, after a pretty warm contest, of the Royal Society, but he resigned this office before his death. He was a great friend of literature and art, and a warm supporter of every liberal measure in politics. His manners were popular, and his disposition kind. He was a great collector of rare books, and left behind him a magnificent library. It consisted in 1827 of 50,000 volumes, 14,000 of which were theological. He died at Kensington Palace on 21st April, 1843, and was buried in Kensall Green Cemetery.

(*Biographical Dictionary of the Society for the Diffusion of Useful Knowledge.*)

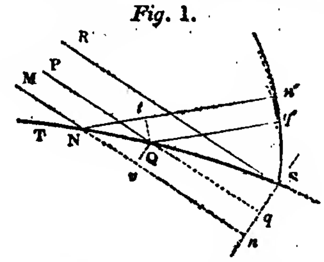
SUSTERMANS, JUSTUS, a distinguished Flemish painter, was born at Antwerp in 1597. He was the pupil of William de Vos. He is little known in Flanders; he lived chiefly in Florence, where he was appointed his court painter by the Grand-Duke Cosmo II. He was favoured also by Ferdinand II., whose portrait he painted, and who ennobled him. His master-piece is a large picture of the Florentine nobility swearing allegiance to Ferdinand upon his succession. He died at Florence in 1681. There are several portraits by him in the Pitti Palace at Florence. Rubens is said to have pronounced Sustermans an honour to his country.

(Descamps, *La Vie de Peintres Flamands*, &c.; Lanzi, *Storia Pittorica*, &c.)

SWIFTEST PROPAGATION, PRINCIPLE OF, in the undulatory theory of light, is the expression of the fact that the front of a wave, after reflexion or refraction, passes through a given space in the least possible time; the velocity after reflexion being the same as before it, and after refraction being that which depends on the medium in which it moves.

In the article UNDULATORY THEORY, P. C., the equality of the angles of incidence and reflexion was proved only for the case in which the reflecting surface is a plane; but it is easy to prove that the equality subsists whatever be the form of the reflecting surface. For let the curve NQS be a section through the axis of a reflecting surface, and, if

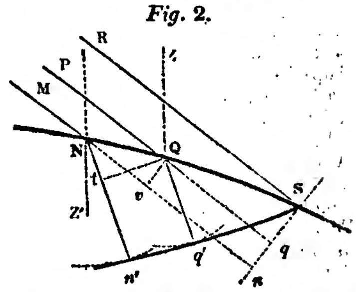
Fig. 1.



the radiant point be infinitely remote, let MN, PQ, RS be rays of right, or lines parallel to the direction of the incident wave; or, if the radiant point be at a finite distance, let those lines diverge from such point so that in either case they may be perpendicular to the general front of the wave: also let that front have the position nqS at a certain time if the reflecting surface be not interposed. Then N, Q, S being the centres of the partial waves produced by reflexion, let the curve at n' be part of the surface of the wave originating at N; its radius Nn' being equal to Nn, since the velocity before and after reflexion is the same: and let the curve at q' be part of the surface of the wave originating at Q, so that $Qq' = Qq$. Imagine partial waves to be formed in like manner from every point in the curve surface NQS; then a curve surface touching all the spheres, as at n' and q', will be the general surface of the reflected wave, at the time that the surface of the direct wave would have been at nqS. Next, imagine Q to be very near N, and let fall Qt, Qv, perpendicular respectively to Nn' and Nn; then Nt may be considered as the difference between Nn' and Qq', and Nv as the difference between Nn and Qq; therefore these differences are equal to one another: hence, NQ being considered as part of a straight line touching the curve NQS at N, the angle QNt is equal to QNv or MNT: consequently the angle of reflexion (the complement of QNt) is equal to the complement of MNT, or the angle of incidence.

Again, in the article UNDULATORY THEORY, P. C., it is proved that, when light is refracted at a plane surface, the sine of the angle of incidence is to the sine of the angle of refraction in a constant ratio, which is that of the velocities of the waves previously and subsequently to the moment of incidence, and the same law may be proved to hold good whatever be the form of the refracting surface. For let

Fig. 2.



NQS represent a section through the axis of a transparent medium bounded by a curve surface, and let MN, PQ, RS be rays or lines perpendicular to the surface of a general wave; also let Sqn represent the position of that surface at a certain time if the refracting medium be not interposed. Next, N, Q, S being the centres of refracted waves, let spherical surfaces at n', q', be the surfaces of such waves at the same time, and imagine partial waves to be formed in like manner from every point in the curve surface NQS: then a curve surface represented by $Sq'n'$ touching all those spherical surfaces will be the general surface of the refracted wave.

Now I and R representing the velocities of the incident and refracted waves respectively, by the principles of the undulatory theory we shall have

$$\mathrm{I} : \mathrm{R} :: Nn : Nn' \left(= \frac{\mathrm{R}}{\mathrm{I}}\, Nn\right)$$

and

$$\mathrm{I} : \mathrm{R} :: Qq : Qq' \left(= \frac{\mathrm{R}}{\mathrm{I}}\, Qq'\right):$$

Next, imagining Q to be very near N, let fall Qv perpendicularly on Nn, and Qt perpendicularly on Nn'; then

$$Nv = Nn - Qq, \text{ and } Nt = Nn' - Qq';$$

or, substituting the values of Nn' and Qq',

$$Nt = \frac{R}{I}(Nn - Qq);$$

therefore $\quad Nv : Nt :: I : R.$

Now NQ being considered as a straight line, it is a common hypotenuse to the right-angled triangles NQv and NQt; hence

$$Nv : Nt :: \sin. NQv : \sin. NQt.$$

But ZQ and NZ′ being perpendiculars to the refracting surface, NQv is the complement of PQN, and is therefore equal to the angle (PQZ) of incidence at Q or N; also NQt is the complement of QNt, and is therefore equal to the angle ($Z'Nt$) of refraction at N:—thus $Nv : Nt ::$ sine of incidence : sine of refraction; and it follows that

sine of incid. : sine of refraction :: I : R;

or since, by the principles of the undulatory theory, the ratio of I to R is constant in the same medium, the sine of incidence bears a constant ratio to the sine of refraction.

It may now be shown that a wave is propagated from the radiant point to any other point in the line of its direction, subsequently to reflexion or refraction, in the least possible time.

Thus, with respect to reflexion, if the waves diverging from N and Q (*Fig.* 1) with velocities equal to that of the incident wave were to take any other directions than those of Nn' and Qq', which are perpendicular to the front $Sq'n'$ of the general wave, it is evident that a curve surface passing through S and touching the surfaces of the several waves would fall between Sn' and SN: such surface would then be the front of the reflected wave; and thus the front would, in a given time, have passed through a less interval from the reflecting surface (or from the radiant point) than it actually passes through in consequence of the partial waves taking the directions Nn' and Qq'. In like manner with respect to refraction: if the waves diverging from N and Q (*Fig.* 2) with velocities which bear to the velocities before refraction the ratio of R to I were to take any other directions than those of Nn' and Qq, it is evident that a curve surface passing through S and touching the surfaces of the several waves would fall between Sn' and SN: such surface would be the front of the refracted wave; and the conclusion corresponds to that which has been stated for a reflected wave. Therefore in both cases the time, reckoning from the moment of setting out from the radiant point, or from the reflecting or refracting surface, during which the general wave arrives in any given position, as $Sq'n'$, will be the least possible.

SWITHIN, ST., seventeenth Bishop of Winchester, was born in the early part of the ninth century, but the exact year is not ascertained. He was ordained priest in 830 by Helmstan, Bishop of Winchester, and was soon after appointed by King Egbert his chaplain, and tutor to his son Ethelwulf. In the reign of the latter he became chancellor, and was intrusted with the education of Alfred, whom he accompanied to Rome. [ALFRED, P. C.] The services rendered by Swithin to Ethelwulf in the direction of the ecclesiastical affairs of his kingdom were rewarded by his elevation in 852 to the see of Winchester, vacant by the death of Helmstan. He is supposed to have been the originator of the payment of 'Peter-pence' to Rome, though there is much reason to believe that this tribute had an earlier origin [PETER-PENCE, P. C.], and also to have procured the first act of the Wittenagemot for enforcing the universal payment of tithes.

William of Malmesbury says of St. Swithin that 'he was a rich treasure of all virtues, and that those in which he took most delight were humility and charity to the poor.' He adds that he built several churches, and devoted himself exclusively to the spiritual administration of his diocese; in his frequent visitations of it, he travelled with his clergy on foot, and for the most part by night, in order to avoid the suspicion of ostentation. He died in the reign of Ethelbert, on the 2nd July, 862. His last request was that he should be buried in the churchyard of Winchester, 'ubi cadaver et pedibus praetereuntium et stillicidiis e coelo rorantibus esset obnoxium.' Within a century afterwards, his name having been admitted into the calendar as that of a canonized saint, it was resolved to transfer his remains to the cathedral, and to place them in a magnificent shrine prepared for the purpose by King Egbert. The translation, which was to have taken place on the 15th of July, was delayed for forty days in consequence of the severe rainy weather which occurred, and hence arose the well-known tradition of which the prevailing notions are thus expressed in a Scotch proverb:—

> 'Saint Swithin's day, gif ye do rain,
> For forty days it will remain;
> Saint Swithin's day, an ye be fair,
> For forty days 'twill rain nae mair.'

In France the day of the festival of St. Gervais (19th June) is marked by a similar superstition:—

> 'S'il pleut le jour de Saint Gervais,
> Il pleut quarante jours après.'

These superstitions are not however altogether unfounded on facts, experience having shown that whenever a wet season sets in about the end of June to the middle of July, it generally continues for a considerable period, and that, in a majority of our summers, a rainy season of about forty days comes on nearly at the time indicated by the tradition of Saint Swithin. (See an interesting paper on the subject in the *Penny Magazine* for 1832, p. 149.)

The festival of St. Swithin in the Roman Martyrology is the 2nd of July, the day of his death, but in England it was celebrated on the 15th of July, the day appointed for the translation of his relics to the Cathedral of Winchester. [WINCHESTER, P. C.]

(Alban Butler, *Lives of the Saints*; Fleury, *Histoire Ecclesiastique*. b. xlix. c. 29; Lord Campbell's *Lives of the Lord Chancellors and Keepers of the Great Seal of England*, first series, 3 vols. 8vo., London, 1845.)

SYCO'CRINUS, a genus of fossil Crinoidea from the mountain limestone of Yorkshire. (Austin.)

SYDENHAM, CHARLES EDWARD POULETT THOMSON, LORD, was the son of John Poulett Thomson, Esq., of Waverley Abbey and Roehampton in Surrey, the head of the mercantile firm of J. Thomson, T. Bonar, and Co., which had been long one of the most eminent houses engaged in the Russian trade. Mr. John Thomson, who assumed the name of Poulett by sign-manual, in 1820, in memory of his mother, married, in 1781, Charlotte, daughter of Dr. Jacob of Salisbury, and by her he had a family of nine children, of whom the subject of the present notice, born at Waverley on the 13th of September, 1799, was the youngest. There were two elder sons, Andrew and George, of whom the latter, now George Poulett Scrope, Esq., is the present member for Stroud, and the author of 'Principles of Political Economy,' 12mo., 1833, and of 'The Life of Lord Sydenham,' 8vo., 1843.

Charles is stated by his brother to have been remarkable in his infancy for his grace and beauty; but the story which he tells of the child, who had attracted the notice of George III. at Weymouth, in the summer of 1803, having been placed by his majesty in the arms of Mr. Pitt, cannot be correct in all respects; for Mr. Pitt was not then prime minister, as is assumed, and could not have been in attendance upon the king in that capacity. It seems unlikely indeed that he should have been with his majesty at all in that year.

Lord Sydenham was never at any public school or university; and he left his native country at the age of sixteen, to be placed in his father's house of business at St. Petersburg, then under the chief direction of his eldest brother He returned to England in ill-health in 1817; then made a tour to the south of France, Switzerland, and Italy; after which he took his place in his father's counting-house in London, in the summer of 1819. In the spring of 1821 he was again sent out to St. Petersburg, this time as a partner in the firm; and here he remained for two years. The greater part of the winter and spring of 1823-4 he spent in Vienna; whence returning by Paris to England, he assumed, in conjunction with his brother Andrew, the chief conduct of the business in London.

Sanguine, ambitious, and self-confident, he involved himself to some extent in the American mining speculations of 1825. Meanwhile he had become intimate with the late Mr. Bentham and Mr. James Mill, with Mr. Warburton, Mr. Hume, Dr. Bowring, and Mr. M'Culloch, and had set his heart upon entering public life. He obtained a seat in parliament for Dover, after an expensive contest, at the general election in the summer of 1826. His rise from this date was very rapid. Voting steadily with the extreme section of the Opposition, he spoke but seldom, and almost exclusively upon commercial questions. On the first occasion however on which he delivered himself at any length, in a debate on the state of the shipping interest, on the 7th of May, 1827, he made a very favourable impression on the House, and had the gratification of being warmly complimented by Mr. Huskisson. After this, whenever he rose he was listened to with attention. He was again returned for Dover in 1830; and when the Whigs came into power, in November of that year, he was appointed to the offices of Vice-President of the Board of Trade and Treasurer of the Navy. He was returned again for Dover after his acceptance of office, and also to the succeeding parliament, which met in June, 1831. At the general election in December, 1832, he was returned both for Dover and for Manchester; he elected to sit for the latter place; and continued to represent Manchester as long as he remained in the House of Commons. Meanwhile on the reconstruction of the ministry in June, 1834, occasioned by the secession of Lord Stanley and Sir James Graham, Mr. Poulett Thomson was made President of the Board of Trade, in the room of Lord Auckland, who was removed to the Admiralty; and on the recovery of power by his party in April, 1835, after Sir Robert Peel's short administration, he resumed that office with a seat in the cabinet. So early as in the beginning of the year 1836, if there be no misprint of the date in Mr. P. Scrope's narrative, it had been in contemplation to remove him to the House of Lords, in order to relieve him from the fatigues of the long night sittings in the Commons, under which his health was already beginning to break down; but circumstances, it is added, for a time put a stop to this plan. At last, towards the close of the session of 1839, on the elevation of Mr. Spring Rice to the peerage, he was offered his choice between the chancellorship of the exchequer and the government of Canada; and accepted the latter. He was sworn into his new office before the Privy Council on the 29th of August; he left England on the 13th of September, and landed at Quebec on the 19th of October. Of his administration in Canada, which was highly successful, Mr. Scrope has published a very full narrative, which was drawn up by Mr. Murdoch, the civil secretary. In August, 1840, the governor-general was raised to the peerage by the title of Baron Sydenham, of Sydenham, in Kent, and Toronto, in Canada. But on the 4th of September, 1841, while in a weak state of health, he had the misfortune to be thrown from his horse, which stumbled and fell upon him, and to sustain a fracture of the principal bone of his right leg, besides other serious injuries; and his death followed on Sunday the 19th of the same month. The most remarkable quality that Lord Sydenham possessed was great decision of character, arising from clear-headedness and self-reliance. His activity, zeal, and extensive information also made him an excellent man of business, and his very attractive manners added to his value as a partisan.

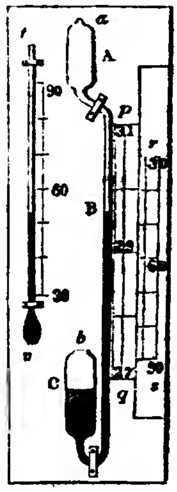
(*Memoir*, by G. Poulett Scrope, Esq., M.P.)

SYE'NE. [EGYPT, P. C.]

SYLVESTER, JOSHUA, was born in 1563. He appears to have engaged in mercantile pursuits, and was a member of the company of merchant-adventurers at Stade, for whose secretaryship he was a candidate in 1597, recommended by the Earl of Essex. He seems to have always remained a poor man, and to have been of a roving disposition. In the latter part of his life he emigrated to Holland, and died at Middelburg in 1618. Both in his opinions and in his choice of friends he was strongly puritanical; and those numerous versified works, chiefly translations from the French, to which he owed his literary reputation, show a warmly devotional and serious tone of feeling. He was not however remiss in courting the patronage of the great. To King James VI. he addressed many adulatory dedications; and it was probably in compliment to him that he selected the topic of one of his original poems, which is thus entitled: 'Tobacco battered, and the Pipes shattered (about their Ears that idly idolize so base and barbarous a Weed, or at leastwise over-love so loathsome a Vanitie), by a Volley of holy Shot thundered from Mount Helicon.' He is chiefly known now on account of the obligations said to have been incurred by Milton to his principal translation, that of the 'Divine Weeks and Works' of Du Bartas. [BARTAS, DU, P. C.] There are two collected editions of Sylvester's works, both in folio, and commencing with the translation of Du Bartas. Their dates are 1633 and 1641. The second of them contains a supplement of posthumous poems; among which is that tasteless alteration of the 'Soul's Errand,' which caused this fine poem to be erroneously attributed to Sylvester.

SYMPIESO'METER (from συμπιεσις, *compression*, and μέτρον, *measure*), is an instrument which was invented by Adie, of Edinburgh, in 1819, to serve as a barometer, for the purpose of measuring the pressure of the atmosphere, or of exhibiting the variations of its density near the earth. An account of its construction is contained in the first volume of the 'Edinburgh Journal of Science.'

It consists of a glass tube B about eighteen inches long and seven-hundredths of an inch in diameter internally: at the upper extremity is a cylindrical vessel A half an inch in diameter internally and two or three inches long; and the lower extremity, being turned upwards, terminates also in a vessel C of an oval form horizontally. The vessel A and the upper part of the tube B are filled with an elastic fluid, as hydrogen gas, while the vessel C and the lower part of the tube contain almond-oil tinctured with some colouring matter, as anchusa root.



In order to introduce the gas and oil, the extremities a and b of the vessels A and C being open, and the former extremity being drawn in the form of a slender tube, the instrument is quite filled with mercury; when, being held in a horizontal position with the orifice b covered by the finger, that the mercury may not run out, the slender pipe at a is put in communication with the gasometer. The hydrogen gas entering at a, and the instrument being now brought to a vertical position, on removing the finger from b the mercury will flow out till its upper surface is at the same level in the tube B and the vessel C, the gas occupying its place in the former. The extremity a is then hermetically sealed, and, the instrument being inverted, the mercury in C runs out, while that which remains in the tube B prevents the gas from escaping. The instrument being afterwards returned to its former position, the vessel A uppermost, the oil is poured into the vessel C: then, the gas being heated, by its expansion it drives the mercury in B into the vessel C; and, the instrument being now held in an inclined position, the oil is by the pressure of the atmosphere forced into the tube B in proportion as the gas by cooling becomes contracted in volume. The remaining mercury is lastly poured out of the vessel C; and the end b being left open, the pressure of the atmosphere on the oil is, the instrument being again put in a vertical position, a counterbalance to the weight of the column of oil in B and to the expansive force of the compressed gas which is in the upper part of the tube and in the vessel A.

In order to form a scale for the sympiesometer, the instrument, together with a good barometer and a thermometer, must be placed in a glass receiver in which, by proper syringes, the air may be rarefied or condensed at pleasure: then, on bringing the air in the receiver successively to such states, with respect to density, that the top of the column of mercury in the barometer may stand at 27, 28, 29 and 30 inches, and marking the points on the tube or frame of the sympiesometer at which the top of the column of oil stood when the air was in those states, the distance between every two of these points being divided into one hundred equal parts, the scale $p\,q$ of the instrument is constructed. The particular graduation at which, on the scale, the top of the column of oil stands at any time should indicate the number of inches and hundredths of an inch at which the top of the column of mercury in a barometer would stand at the same time in the same place.

But the volume of the hydrogen gas changes in consequence of variations in the temperature of the atmosphere; and therefore a correction, depending on the amount of the variation in the volume of gas for given increments of heat, should be applied to the number of the graduation on the scale of the sympiesometer in order to obtain the true height of the mercurial column in a barometer.

But, to avoid the trouble of computing and applying this correction, the scale $p\,q$ of the sympiesometer is made to slide on one side of a scale $r\,s$ which is graduated like that of a thermometer, by communicating different degrees of heat to the vessel A while the pressure of the atmosphere on the upper surface of the oil in C remains the same (suppose that which corresponds to 29½ inches on the scale of a barometer) and observing the points at which the top of the column in B stands: these points on the scale $r\,s$ are numbered so as to express, in degrees, the temperature of the gas; and the scale $p\,q$ being moved till its index (at 29½ inches) coincides with the degree of the scale $r\,s$ corresponding to the temperature of the atmosphere, expressed by the degree of a thermometer $t\,v$ attached to the instrument, the graduation on $p\,q$ corresponding to the top of the column of oil in B expresses the height of a column of mercury in a barometer.

Dr. Robert Gordon, the writer of the article Meteorology in the 'Edinburgh Encyclopædia,' having made a series of observations for the purpose of comparing the indications of the sympiesometer with those of a barometer, found that the former stood higher than the latter by quantities varying between 0.03 inch and 0.017 inch, the temperature varying between 42°.3 and 62°.6 (Fahr.): he found at the same time that, in general, the difference between the indications of the two instruments increased as the temperature and pressure diminished. The excess of the indications given by one instrument over those given by the other may be conceived to have arisen from some inaccuracy in the construction of the sympiesometer: but the variation of the excess is not so easily accounted for; it may, however, be supposed to be caused in part by the expansions of the gas not being exactly proportional to the increments of heat, a circumstance which is assumed in the subdivisions of the scale *r s*, between each of the complete inches, being made equal to one another, and in part from some absorption between the oil and the gas. It is inferred, therefore, that the indications of the sympiesometer cannot always be relied on as accurate measures of the density of the atmosphere; but, since it has been observed that the instrument is frequently affected by changes in that density, which are too small to be perceived on the scale of a barometer; and since it is well known to be less deranged than the latter instrument by the motion of a ship at sea, it follows that, in these respects, it possesses great advantages as a marine barometer in indicating the approach of gales of wind.

SYMPLOCARPUS, a genus of plants belonging to the natural order Araceæ. It has a cucullate spathe, a short spadix covered with tetrandrous floscules. The ovaries are one-celled, with one ovule in each and a minute stigma. The berries are consolidated, the seeds without albumen.

S. fœtidus, Skunk-weed or Skunk-cabbage, has a large abrupt tuber with numerous crowded fleshy fibres. The spathe is præcocious, ovate, turgid, various in width, spotted, and sometimes covered with dull brownish purple. The spadix is oval, on a short peduncle covered with perfect tetrandrous flowers, and of the same colour as the spathe. It has 4 fleshy wedge-shaped sepals, truncate at the top, and edges inflated; the 4 stamens are opposite the sepals with subulate filaments equal in length to the calyx. When the spathe decays, the spadix continues to grow, and every part of the plant, excepting the anthers. Within the spadix at the base of each style is a round fleshy seed as large as a pea, white, tinged with green and purple, and invested with a separate membranous coat, and with a prominent embryo situated in a depression at the top. The leaves spring up some time after the flowers; they are numerous, large, crowded, oblong, heart-shaped, and on long channelled petioles. The plant emits an offensive odour; its tubers are acrid, but when dried and powdered, are antispasmodic.

It is considered an excellent remedy in asthma, catarrh, and chronic coughs, and has also been employed in dropsy, rheumatism, and epilepsy.

(Lindley, *Flora Medica.*)

SYNBATHO'CRINUS, a genus of fossil Crinoidea from the mountain limestone of Bolland forest. (Phillips.)

SY'NOCHUS and **SY'NOCHA**, forms of fever recognised by most of the older and many recent writers on the practice of medicine. Sauvages defined Synochus to be a fever which lasted more than a fortnight without materially weakening the pulse; whilst Cullen used this term to express a fever which combined the two forms of inflammatory and putrid fever, that is, a fever which at its commencement was inflammatory and at its close putrid. The inflammatory form of fever which was characterised by running its course rapidly, and marked by high excitement of the heart and arteries, was called Synocha by Cullen. A putrid and low form of fever was called Typhus. The latter term is now however applied to all continued contagious fevers, and the former terms are not often used at all.

INDEX TO THE LETTER S.

VOLUME II.

T.

TABLE. Since the article TABLE, P. C., appeared (in 1842) we have kept an eye upon it, with a view to its correction and amplification in this supplement. We were obliged to take much of our article from the description of other writers: though we had ourselves seen a majority of the books we cited. We have since seen many more, and have found several errors in our sources of information; but not more than, in the general laxity of bibliographical description, we were prepared to expect. We shall take the subjects in the same order as in the article above referred to; and when a table is merely mentioned by the author's name in the present article, it will be found in the former one with fuller description.

The restoration of the old numerical type, namely, that in which all the figures except 0, 1, 2, have a head or a tail, and in which the thickness does not vary sensibly from one part to another, was adopted and recommended by the Astronomical Society at the end of 1842; but it had previously been used by Mr. Baily in his detail of the Cavendish experiment, which forms one volume of the Memoirs of that Society. The writer of this article, who first suggested the revival of the old figure (and caused it to be employed in Taylor and Walton's five-figure logarithms, in their reprint of Barlow's tables, and in his own work on Arithmetic, before any one else had used it) is decidedly of opinion that one more change is yet wanting, the substitution of dull and rather dark paper for the bright and shining material now in general use, which dazzles the eye too much. Tables should not be hot-pressed, and not even pressed at all. The mischiefs of pressure are two-fold; first, the smooth surface thereby created makes the page a kind of mirror, which has a bright image in one place, whereas rough paper dissipates the light equally in all directions; secondly, the other side of the leaf shows through much more after pressure than before. It is also a mistake to suppose that great blackness in the ink, combined with great whiteness in the paper, is favourable to the reader. Every increase of the contrast, over and above what is necessary to perfect legibility, is injurious to it: jet upon snow would in time destroy the strongest eyes. Of all the things which are meant to be read, a black monumental inscription on white marble in a bright light is about the most difficult: one would suppose, to look at our specimens of expensive printing, that such an inscription was the model which it was intended to imitate, and if possible to surpass. We are satisfied, after many trials and comparisons, that a dull paper, of a whitish brown character, too thick to be seen through, and an ink which is of a dull-brown black, as it were the very deepest shade of the colour of the paper itself, are the things which are permanently agreeable to most eyes. Those who try it should remember that the first page read is not so good a test as the hundredth.

One of the most legible books we know of is the trade edition of Gibbon's 'Decline and Fall,' &c., in twelve volumes octavo, London, 1820. It is considered by the booksellers themselves to be very badly executed. But printers and publishers are too much in the habit of forgetting that a book is a book and not a line engraving. They look at the page as a whole, and if the individual lines stand out and make their separate existences too perceptible, they pronounce it ugly. Accordingly, the uglier they hold it to be the more legible the reader will pronounce it.

We regret to see that, just as we are beginning to abandon the use of the thick even-sized figures, the Germans are taking strongly to them. Most of the modern German tables have these illegible characteristics.

§ 1. *Tables of Multiplication.*—We were wrong in calling the anonymous table, London, 1775, by the name of Riley. This table, which goes up to 10,000 × 10, is 'Tables of Products . . . London, printed for J. Plummer.' But Riley's table, published in the same year, under exactly the same form, is 'Riley's Arithmetical Tables . . . . London, printed for G. Riley.' It is imperfect in all the copies we have seen, ending abruptly at the multiplicand 5280. The numerals are of the same form and size as in Plummer, but the headings and lines are different. We suspect that some writer of more than usual research on the quarrels of authors, or some hunter of old injunction cases, might find something about the history of these two books.

Cadet's 'Table,' Paris, 1797, goes to 10,000 × 100; misprinted 1000 × 100 in our article.

Bretschneider, 'Producten-Tafel,' Hamburg and Gotha, 1841, goes up to 100,000 × 10.

There is a compression of this kind: in finding, for example, the multiples of 62873, the reader must look into the page headed 2800, and there, in one part of the page, opposite to (6) 28, he finds the first three figures, and in another part, opposite to 73, the last three figures. The first part belonging to 628 is repeated twice, once for the cases in which the following numbers are less than 50, and once for those in which they are above it; and an asterisk in the last part of the table occurs when it is necessary to add a unit to the preceding figures. This arrangement brings the table into ninety-nine pages octavo, and is very ingenious: but there is more risk of error in using it than we like. Again, multiplying five figures by one is not so difficult an operation that it need be avoided by using a table which requires us to look attentively at three distinct things. Lambert's table (1770), presently mentioned, contains the nine multiples of sin x for every degree, to six figures; and multiples of primes to those of 313.

The Munich table, mentioned in our last article, is 1610, J. G. Herwart, 'Tabulæ Arithmeticæ Προσθαφαιρέσεως* Universales,' a folio containing all products up to a thousand thousand.

In the Royal Society's Library is a table by J. J. Centnerschwer, 'Neu-erfundene Multiplikations- und quadrat-Tafeln,' Berlin, 1825. The earliest table we have seen mentioned (by Lipenius) is—Thomas Finck, 'Tabulæ Multiplicationis ac Divisionis,' Copenhagen, 1604 (oblong form). There is also, by the same author, 'Tabulæ quotidiano numerandi usui accommodatæ,' Copenhagen, 1615, 16mo.

As Finck is an author of some interest in the history of tables (as will presently appear), we have made some inquiry about these works,† and we find that they are not in the library at Copenhagen; but that Mollerus (*Cimbria Litterata*, vol. iii. p. 254) gives them as follows. It seems they were not intended for scientific purposes.—

'Tabulæ Multiplicationis et Divisionis, seorsim etiam Monetæ Danicæ accomodatæ,' Hafniæ, 1604; fol. obl.

'Tre Tabeller, indrettet til daglig fornöden Regning;' Copenhagen, 1615, 16mo.

Under this head we ought to mention John Bernoulli (the younger), 'Sexcentenary Table,' London, 1779, and Michael Taylor's 'Sexagesimal Table,' London, 1780, intended to save the use of logistic logarithms; the former having 10′ for the first term, and the latter 1°. Both were published by the Admiralty.

§ 2. *Tables of division and of prime numbers.*—Chernac's table gives not merely the lowest divisor as stated, but every divisor, for all the numbers under 1020000 which are not divisible by 2, 3, or 5. It is accordingly a larger (and we think a more useful) work than that of Burkhardt.

Branker's translation of Rhonius, mentioned in our preceding article, is of London, 1668, 'much altered and augmented by D. P.': this D. P. is Dr. Pell. The table of primes, &c. to 100000 is computed under Pell's advice and direction. But there is preserved in several places the title of a work of Pell which we have never seen, and which we take from Lipenius: 'Tabula decem millium difficilium Numerorum, eorum nempe omnium qui ab 0 ad centum Milliones [mille?] habent difficultates,' English, London, folio, 1666. This looks like a table of prime numbers, and the number of primes under a hundred thousand is about ten thousand. But we must leave it to those who can see the work, if it still exist. Branker's table was reprinted in the

* Prosthaphæresis is a word compounded of prosthesis and aphæresis, and means addition or subtraction. Astronomical corrections, sometimes additive and sometimes subtractive, were called prosthaphæreses. The constant necessity for multiplication, in forming proportional parts for the corrections, gave rise to this table, which therefore had the name of its application in the title-page.

† From Professor Werlauff, Royal librarian at Copenhagen, through the kindness of Professor Schumacher.

second volume of Harris's 'Lexicon Technicum,' London, 1710.

Murhard mentions the *first part* of a table (by A. Felkel) of the factors of all numbers not divisible by 2, 3, or 5, from 1 to *a hundred million*, Vienna, 1776. We presume if this work had got as far as either Burkhardt or Chernac, we should have heard of it.

§ 3. *Tables of squares, cubes, square roots, cube roots, and powers in general.*—Perhaps the oldest printed table of squares is that in p. 30 of Pacioli's *Summa*, &c. [VIETA, P. C., p. 318], printed in 1494 and again in 1523, which however goes only to 100^2. Cosmo Bartoli, 'Del Modo di misurare le Distantie,' &c., Venice, 1564, has squares up to 661^2. Maginus's 'Tabula Tetragonica,' Venice, 1592, is not a separate work, but a chapter in his work on triangles, presently mentioned: it gives squares up to 10100^2, but not cubes. It was however published separately, at the same time with the work on triangles, as well as in it: the only difference being that the separate publication has its headings and explanations Italian instead of Latin. The number of so-called books, which are only chapters of other books, is large enough to make a big catalogue.

Lipenius mentions 'Tabulæ numerorum quadratorum decies millium,' Londini, 1672, which is Pell's table, though it has not his name. It has also an English title, contains the first ten thousand squares, and also the number of pairs, triads, and quaternions (1044 in number) of figures with which a square can end. Henischius, 'Arithmetica perfecta,' Augsburg, 1609, begins with squares and cubes of all numbers up to 360. Heilbronner (p. 627) mentions a *tabula Calviana* which gives squares up to 1000^2. Detached tables of powers are given in various works. John Hill's Arithmetic, of which the seventh edition bears London, 1745, has all the powers of 2, up to the 144th, for the purpose of solving questions about chessboards and horseshoe-nails. We have also the title G. C. Sartorins, 'Cubische tabellen,' Eisenach, 1827.

Maseres, at the end of the tracts on Combinations, London, 1795, has reprinted Hutton's square roots 0(1)1000 to ten decimals, and reciprocals to seven. We believo that Hutton first gave them in his 'Miscellanea Mathematica,' 4 vols. 12mo. 1775. In Jonas Moore's Arithmetic, 1650, there are the squares and cubes of all numbers up to 1000, the fourth powers up to 300, and the fifth and sixth up to 200. These were reprinted in the edition of 1660.

Rogg mentions 'Art gantz nen-entdeckte,' &c. Dessau, 1755, 8vo., containing the cubes of all numbers up to 100,000, or at least professing in the title-page to give the cube root of every number under a thousand millions of millions: perhaps the cubes went to that of 10,000, with a rule for the fifth figure. And here we may mention that we have been several times deceived by a title-page stating, not the extent of the table, as it ought to do, but the extent to which operations of interpolation will be effective.

§ 4. *Pure Decimal Operations.*—An anonymous work, 'Tafeln zur Verwandlung aller Brüche, &c.' Oldenburg, 1842, gives every fraction less than unity whose denominator does not exceed three figures, nor its numerator two, to seven places of decimals. This is a useful table. We may also mention (but not as having seen it) W. F. Wucherer, 'Beyträge zum allgemeinen Gebrauch der Decimalbrüche, &c.' Karlsruhe, 1795, 8vo.

Tho oldest table we have found printed in English is in 'This boke showeth the maner of measurynge of all maner of lande, as well of woodlande, as of lande in the felde, and comptynge the true nombre of acres of the same. Newlye invented and compyled by Syr Rycharde Benese Chanon of Marton Abbay besyde London. Prynted in Southwarke in Saynt Thomas his hospitall by me James Nicolson.' There is no date, but Nicolson's dated works run from 1536 to 1538. There is another edition (which omits the tables) printed by Thomas Colwell, who printed from 1558 to 1575. They aro double-entry tables of the rudest character, for finding the number of acres in a given length and breadth, and for casting up payment at per perch, per acre, &c.

§ 5. *Pure Trigonometrical Tables.*—The bibliographical history of the early part of this subject is so incorrectly given, as well as ambiguously, even by the best authorities, that it will be worth while to collect the several heads, distinguishing between what we know from the books themselves and what we are obliged to take from other sources, by putting the name of an authority (of which we have usually two or three) to the latter. Much confusion has arisen from the double meaning of the word *publication* in the century following the invention of printing, when it was applied equally to the issue of a printed book and of a manuscript. We are here only concerned with the former; and it is sometimes difficult to distinguish between the two.

That ALBATEGNIUS [P. C. S.] had substituted sines for Ptolemy's chords,—that he had also used versed sines and tangents—that Purbach and Regiomontanus had constructed and issued (in manuscript at least) tables of sines to two separate radii, 6,000,000 and 10,000,000—are historical facts of notoriety. Our question is, what tables were first *printed?* On the books which Regiomontanus actually printed, out of the long lists of those which he published and intended to publish (as set forth in his own 'Index Operum, &c.' printed at Nürnberg by himself), his historians, Doppelmayer, De Murr, Weidler, &c., are either not very clear, or somewhat at varianco. In the vague manner in which books and their contents are frequently described by professedly mathematical writers, a good resource is often found in the catalogues of general bibliographers.

The 'Tabulae Directionum Profectionumque' of Regiomontanus were published by himself at Nürnberg (without date, probably about 1475), and were reprinted at Venice in 1485. But we cannot ascertain that either of these contained tables of sines. But Hain (*Repert. Bibliogr.*), who gives their titles, gives that of the next edition (Augsburg, Ehr. Ratdolt, 1490, 4to.) in a fuller manner: from which it appears that there is appended to it a table of sines to minutes, in words which would imply that Regiomontanus had not given such a table in the former edition: they are, 'Tabella Sinns recti: per gradus et singula minuta divisa. Ad Tabulas Directionum Mag. Joh. de Regiomonte necessarias.' But from the description it is clear that this table does not belong to the work, since it follows even the printer's insignia. And Hain also met with it as a separate work; being, as appears from his description of the lineation, pages, &c. absolutely the same as that which was appended to the Tabulæ Profectionum. Accordingly, until something earlier or more definite is produced, we must say that the first known printed table of sines is an anonymous table, to minutes, in quarto, without date, but before 1500, stated (with *necessarias* when it ought to be *necessaria*) to be necessary to the tables of Regiomontanus, and implying that sines had not then been printed with those tables. From the next-mentioned edition of the Tabulæ Directionum (this we have seen) we should suppose that these tables were to a radius of 600,000, as in that edition, which is of Venice, 1504, 4to. In it we find a minute-table of sines, beaded 'Incipit tabella sinus recti,' and with a column containing differences for ten seconds. Delambre and others mention Regiomontanus as having given the first tables of tangents in this work under the name of *tabula fæcunda*. It is in the edition of 1504, and was reprinted by Gemma Frisius in his book 'De Radio Astronomico,' Antwerp, 1545. It is to degrees only, and to a radius 100,000; and is a table of cotangents, not of tangents. Delambre mentions an edition of the work, edited by Gauricus, in 1524, as containing a table of sines to every ten minutes: of this we can find nothing. As yet we have no sines calculated to the now ordinary radius of 10,000 &c. Of these the earliest that we have seen (and we find no earlier ones mentioned) are those of Peter Apian in the 'Introductio Geographica, &c.' Ingoldstadt, 1533, folio. They are minute-tables to a radius of 100,000, and were reprinted the next year in the same author's 'Instrumentum primi Mobilis,' Nürnberg, 1534, folio. Apian states that they are of his own calculation, and this is to us a strong presumption that no such tables had been previously printed; for Apian was a great reprinter of the writings of others at his own press, and very unlikely to have recalculated any table which he knew to exist already. The statement that the work of Regiomontanus on triangles (Nürnberg, 1533, folio) contains tables of sines, is incorrect: we know it from examination of two perfect copies. As we are now contradicting our own previous assertion [TABLES, P. C.], we will point out how we were misled. Lalande (*Bibl. Astron.*) says that the first edition of the work, Basle, 1536, has in the title-page 'una cum tabulis sinuum.' Now the fact is that Lalande, who had only seen the second edition (*Basle*, no date, known to be of 1561), which *does* contain tables of sines, took the liberty of presuming that the first edition was the same in contents, title, and place; in all of which he was wrong, and in the date also.

In 1542, Rheticus, the most laborious of all the table computers, made his first appearance as the editor of a work of Copernicus: 'De Lateribus et Angulis Triangulorum,' &c., Wittemberg, 4to. (Weidler and Kastner). This contains a minute-table of sines to a radius of ten millions, being the first-published seven-figure table. The table which appeared in the following year, in the great work of Copernicus [Copernicus, P.C.], is an abridgment of the preceding; going only to every ten minutes, and to a radius of 100,000.

In 1541 appeared one of the tables which have obtained most celebrity: being the 'Tractatus Geo. Purbachii super propositiones Ptolemæi de Sinubus et Chordis, item compositio Tabularum Sinuum per Joannem de Regiomonte. Adjectæ sunt Tabulæ Sinuum duplices per eundem Regiomontanum,' Nürnberg, 1541, folio (Kastner, &c.). The two tables of sines are both minute-tables, with radii of 6 millions and of 10 millions. The table of tangents to every degree is repeated again under the name of *tabula fœcunda*.

Rheticus, in the meanwhile, was pursuing the route of analogy, which suggested to him the formation of a table giving *all* the ratios which exist between the sides of a right-angled triangle: by which he was led to the invention of what were afterwards called secants, to the completion of the trigonometrical canon, and to its arrangement in the form which it has ever since preserved. His rights in this matter have long been forgotten; and it is only very recently indeed that the work which established them has received any notice in modern times. (See the *Notices of the Astron. Soc.*, vol. vi. p. 213, and *Phil. Mag.*, June, 1845.) In 1551, the year following that in which he was placed in the *Index* as a forbidden author, he published his 'Canon Doctrinæ Triangulorum,' Leipzig, 4to. This is a complete canon to every ten minutes, and to a radius of 10 millions (or, as we should now say, to seven decimals) with differences, so arranged that the matters connected with each angle also belong to its supplement, in the manner so familiar to those who can use any modern table. This arrangement may be called *semi-quadrantal*, as opposed to the older *quadrantal* arrangement in which the sines are carried direct from 0 to 90°. Accordingly the page of Rheticus has both a head and foot description, as in modern tables. So completely is he bent on the idea of a register of the proportions of right-angled triangles, that he rejects the use of the word sine. In the place of the sine and cosine, he has the perpendicular and base to an hypothenuse of ten millions; in that of the tangent and secant he has the perpendicular and hypothenuse to a base of ten millions; in that of the cotangent and cosecant, he has the base and hypothenuse to a perpendicular of ten millions. The same description is adopted in his larger work, of which we shall presently speak.

In 1554 Erasmus Reinhold (who had been the colleague of Rheticus* in teaching mathematics at Wittemberg) published the 'Liber Tabularum Directionum,' Tübingen, 4to. In this work, for the first time, occurs a *canon fœcundus* (not yet called a table of tangents) carried to every minute. Both sines and tangents were computed to a radius of 10 millions. This work of Reinhold, though founded upon Regiomontanus, must not be confounded with his professed edition of the 'Tabulæ Directionum' of Regiomontanus himself, which had tangents only to every degree, and was printed several times, the last edition being in 1606. (We have not thought it worth while to catalogue reprints.)

In 1558 (Delambre) Maurolycus published his edition of Theodosius, Menelaus, &c. (Messana, 4to.), containing the three tables, that of sines, the tabula fœcunda, and the *tabula benefica* (as he called the present table of secants). This table goes only to degrees (except that tangents and secants are given for 15, 30, 45, 55, and 59 minutes of the last degree of the quadrant) and is to a radius of 100,000. Delambre, &c. suppose that these are the first tables of secants which were published, and they accordingly attribute the invention to Maurolycus. But we have seen that it is due to Rheticus: and Finck (presently mentioned), who lived close to these times, states expressly that Maurolycus borrowed this table from Rheticus.

In 1562 a pupil of Rheticus published a table of sines to every minute, and to a radius of ten millions. This was Samuel Eisenmenger (or Siderocrates, as he wrote himself), in his 'Libellus Geographicus,' Tübingen, 4to. And there was, as we find stated in various quarters, a table of sines in the work on dialling of Hermann Witekind, 'Conformatio Horologiorum,' of which the first edition is said to be of Heidelberg, 1576, 4to.

The first complete canon *to every minute* (that of Rheticus in 1551 being to every ten minutes) was Vieta's 'Canon Mathematicus, seu ad Triangula, cum Adpendicibus,' Paris, 1579, folio. We have described this work in Vieta, P. C., p. 316, and shall here only make a few additions. Besides the three title-pages there mentioned, there must have been a fourth; for in the title of that which Delambre examined was the motto *Dura et quiesce*, which certainly was not in either of the three seen by us. The work has well obeyed the direction given: it has lasted in silence, having never been described in catalogues or histories till modern times. Copies seem to have been rare in Germany; neither Weidler, Heilbronner, nor Kastner mentions it. Hutton never saw but his own copy; Montucla (in France!) never saw more than two, one in the royal library, and one sold at the Soubise sale (but it is not in the catalogue of that sale), which the historian would fain have bought, had not a *curieux* bid too high. And this was only by the time Montucla's second edition was written, for by the mention of it made in the first edition it is clear that the author had never seen it. We have examined in London at least eight copies. We have mentioned [Vieta, P. C.] the complaints which the author had to make against the printers: Montucla states that he bought in as many as he could.. There are several signs of something odd having taken place in the printing: and the following is worth mention:—To one of the copies we have seen (as well as to one of those in the Museum) is appended one folio sheet, in correction of a mass of errors in one sheet of the collection of formulæ: this sheet is a separate publication, with the date (1579) and printer's name on it.

Vieta imitates Rheticus in his method of heading the tables, but in addition uses the word sine, and calls the table of tangents *fœcunda*, and that of secants *fœcundissima*. He complains that elegant names have not been found, and states that he gets his denominations from certain *Raphsodi* (as he calls them; it is not often that mathematical tabulators are called rhapsodists) whom he does not name. In a later work, the *Responsa*, &c. [Vieta, P. C., p. 315], published in 1593, he names and objects to the words tangent and secant, which by that time he had seen. And he proposes to call the tangents *prosines* or *amsines*, and the secants *transsinuous* lines.

As to the matter of Vieta's tables, it is worth notice that they must have been made by independent calculation. They do not exhibit the errors in the last tangents and secants which appear in all writings prior to the more correct publication of Rheticus by Pitiscus. On the additions made by Vieta to the theory of trigonometry we have not here to speak: but we may simply say that they made the computation of a trigonometrical canon a much easier thing than it had theretofore been. Delambre is quite right when he observes that the 'Trigonometria *Britannica*' of Briggs is altogether French in all that relates to the non-logarithmic part of it. Had he known a little more of Vieta, he could have reinforced his assertion. For the method of solving equations which he describes (evidently not understanding it) as an obscure mixture of division and extraction of roots, was the slightly amended form of Vieta's numerical exegesis, to which we have referred in Involution and Evolution, P. C. S., p. 104. And as, by Gellibrand's account, we trace the commencement of Briggs's labours to shortly after the time when Vieta first published this exegesis, it is by no means an unlikely conclusion that the power of trisection and quinquisection given by this mode of solving equations, first put it into his head to construct the table.

Purbach and Regiomontanus had seen the advantage of adopting decimal tables, though their use of the radius 600, &c. was a remnant of sexagesimalism. It was reserved for Maurice Bressius to show himself a century behind his time, by publishing in his 'Metrices Astronomicæ Libri Quatuor,' Paris, 1581, folio, sexagesimal tables to every minute of sines, tangents, and secants, or as he calls them, *sines*, *adscripts*, and *hypothenuses*. Thus, the radius being 60°, the sine of 57° 20′ is given as 50° 30′ 34″; and the adscript and hypothenuse as 1 sex. 33° 34′ 46″, and 1 sex. 51° 9′ 44″; 1 sex. meaning 60°. Accustomed as we are to look upon sexagesimal division as sacred to angular and horary measure, we are apt to forget that the time was when other subdivisions were rarely used in Europe.

* Reinhold taught the higher branches, and Rheticus the lower. It is very illustrative of the neglect into which the prohibition (with other circumstances afterwards noted) caused the writings of Rheticus to fall, that Weidler, himself of the university of Wittenberg, writing and printing his History of Astronomy there, giving minutely the dates of Rheticus's degrees from the register, and stating that from the time when he and Reinhold were colleagues it had always been customary to have two teachers of mathematics—is as ill-informed as any one about the writings of Rheticus, and in particular knows nothing of the publication of 1551, of which we may therefore be pretty sure there was not a copy in the library.

As yet we do not find the modern names of *tangent* and *secant*. These were introduced in 1583 by a young man of twenty-two years, Thomas Finck, of Flensborg in Denmark, in his 'Geometriæ Rotundi Liber XIV,' Basle, 4to. His part in the matter was quite forgotten, and has been recently revived (see *Phil. Mag.*, May, 1845). He introduces the words with expressions which cannot be interpreted otherwise than as a proposal of his own, to which it must be added that no earlier use of these words has ever been brought forward. The tables of sines, tangents, and secants, so called, which Finck has introduced in his work, are to every minute, and to a radius of 10 millions. Finck deserves a much higher name than he has got, for the contents of this work alone: there are other writings of his, which we have not seen. He calculated his own secants by a theorem which answers to the formula

$$\text{Sec }\theta = \tan\theta + \tan\left(45^\circ - \frac{\theta}{2}\right).$$

In 1585-6 Clavius published at Rome, in quarto, his edition of Theodosius, to which is appended a treatise on triangles, and a table of sines, tangents, and secants, under those names. They were reprinted in the folio collection of his works, Mayence, 1611. It is clear, on inspection, that these tables are, as far as tangents and secants are concerned, a reprint of those of Finck, in their preliminary theorems, in their arrangement, in their omissions, and in their errors, as well as in the new terms with which they are headed. The name of Finck is suppressed as well as that of Rheticus; both of them were Protestants, and Clavius was a Jesuit, high in favour at Rome. Delambre expresses his astonishment that Clavius, in recapitulating the names of celebrated writers on dialling, should have omitted Sebastian Munster. The fact was, that Munster followed Luther. We are not quite certain that a greater than Clavius was altogether exempt from this laughable weakness. When Vieta suppresses the names of his authorities, as above noted, calling them merely *rhapsodists*, we may almost suspect that he wanted to avoid speaking of Rheticus and Reinhold; for he was very intolerant.

In 1591, Philip Lansberg published 'Triangulorum Geometriæ Libri Quatuor,' Leyden, 4to.: and in 1592 Magini published 'De Planis Triangulis Liber Unicus,' Venice, 4to. Both these are copied from Clavius: but Magini at least, who goes beyond Clavius in historical reference, wilfully suppresses the name of Finck.

We at first thought ourselves unable to give a date to the tables of Stevinus, except within a few years, and conjecturally. That he published his Arithmetic in 1585, and that Snell* collected his works in Latin in 1605-8, are the facts which are supposed to mark out the known limits of his career. The tables must have been published after 1593, since Vieta's names for the tangent and secant are mentioned; probably long after, for Vieta's works were of very slow travel. We ourselves believe fully that the Cosmographia, which contains the tables, was never published until it appeared in what is called Snell's collection (in 1608). These tables are to every minute, to a radius of 10 millions, and they are copies of Finck, Clavius, &c. We are informed that recent researches in Belgium have made it appear that Stevinus was born in 1548, and died in 1620, which puts our opinion beyond dispute. The mistake about Snell seems to have originated with Gerard Vossius.

In 1588, Nic. Raymar, Ursus Dithmarsus, published 'Fundamentum Astronomicum, id est nova Doctrina Sinuum,' &c., Strasburg. We cannot make out from the descriptions, whether this work contains tables or not: probably it did.

Who published the first English trigonometrical table is a point which we have never seen examined: and we must investigate it in the best way we can from rather scanty materials. We cannot find the word *sine* mentioned in the works of Recorde, nor in the English works of either Digges, father or son, nor in those of John Dee; nor indeed in any work written in English before Blundeville, except that of Burroughs presently cited. In the 'Alæ, seu Scalæ Mathematicæ' of Thomas Digges, London, 1573, 4to., trigonometrical processes are required for which allusion is made to Copernicus and Regiomontanus, and the tables of Rheticus are often cited (the ten-minute canon, of 1551). In John Dee's 'Parallacticæ Commentationis Praxeosque Nucleus quidam,' London, 1573, 4to., there are also solutions of triangles, and the tables referred to are those of Regiomontanus with the radius 60,000, before mentioned. But neither of these writers makes the smallest allusion to any tables published in England. We have examined the libraries of more than one diligent collector of English works of the sixteenth century, without finding anything which at all controverts our decided impression that Blundeville* was the real introducer of a complete canon of sines, tangents, and secants.

Blundeville's 'Exercises,' London, 1594, 4to. (it is said sometimes that 1597 is the date of the first edition, but incorrectly), were commenced, as he informs us, about seven years before. He alludes to Regiomontanus, Copernicus, and Clavius, from whom he took his tables. And he informs us that Regiomontanus is in folio, and that Clavius is in quarto, and published in 1586, at Rome. We rely much on this in our conclusion that his were the first tables: for to mention the form of a book, or the date of publication, is very rare with the writers of his time; and it is most likely that so precise a person would have noticed any previous work of the same kind in his own country. The tables, being copies of Clavius, have already been described. These 'Exercises' went through seven editions at least: the seventh, now before us, has the tables corrected from Pitiscus, by Robert Hartwell, the editor; it is London, 1636, 4to.

It must be noticed however, that though Blundeville gave the first English canon complete, a table of sines *only* had been printed four years before. It is at the end of the 'Horologiographia, the art of Dialling,' by Thomas Fale, London, 1593, 4to. (reprinted in 1652). The sines are to minutes, with a radius of 100,000. This then is the earliest table, but it is of sines only. We have seen that Digges used sines, but he is a Latin writer, and refers to a foreign table. Perhaps the first writer who *used* them in English (but still with foreign tables) is the well-known W. Burroughs, in his 'Discourse on the Variations of the Compasse,' published in 1581. In the preface he apologises for introducing rules 'wrought by the doctrine of signes and triangles, which may seem strange in our English-Tongue,' and all he gives on tables is in the following passage:—'In these examples I have used the abridged table of 100,000 the whole sine, which though it give some ease in the working, yet it is not so exact as that of 10,000,000 of *Erasmus Reinholdus*. Unto the which, with his *Canon fœcundus*, answerable to the same, if the third *Canon* of the *Hypothenusæs* were annexed, wee should have an entire Table for the Doctrine of Triangles, that might worthily bee called *The Table of Tables*. Which thing, though *Georgius Joachimus Rheticus* have well begunne, and framed it orderly, from ten Minutes to ten: yet is it left very rawly, for such as desire the exacte truth of things. I have therefore for mine owne ease and use, Calculated the complement of this Table, and almoste ended it, for the whole Quadrant, from minute to minute: which if in the mean time before I have finished, I shall not finde it extant by any other, I will publish it for the commoditie of all such as shall have occasion to use the same for navigation and cosmographie.' But this table was never published, and accordingly the editor of the edition of 1614 refers the reader to Ralph Handson's tranlation of Pitiscus, and the very tables of that work are annexed to the end of the edition of 1614. They are tables to every minute, and to a radius of 100,000. We cannot describe the first edition of Handson's work, having only seen the second, which is London, 1630, quarto. (Wilson, in the preface to his Navigation, says it was in 1614.) In 1609, John Speidel, afterwards well known in the history of logarithms, began his career by publishing, in quarto, 'Certaine verie necessarie and profitable Tables: *viz.* A Table of Sines, Tangents, and Secants, &c.' This tract of sixteen pages contains a canon to every ten minutes, and to a radius 1000, with some tables subsidiary to astronomy.

In 1610, Arthur Hopton published 'Baculum Geodæticum sive Viaticum, or the Geodæticall Staffe,' London, 4to. The seventh book of this is called 'Trigonometria, containing Longimetria, and Altimetria, performed by Synnicall supputation, with a Canon for the Dimension of tryangles.' The canon (from Pitiscus) is complete for every five minutes and

* It can be made very obvious that Stevinus *was alive* throughout the whole of the printing of these two volumes (or five volumes bound in two). In the very *last page* of the *last volume* (Index excepted), the author excuses himself for not fulfilling certain announcements, because he had not made up his mind about the subjects of them; and the printer could not wait. And this after referring to the places of the several matters in the very volumes which are supposed to be the collection of the editor. Besides, Snell, the reputed editor, was only seventeen years old when the work was published.

* This is the same as the Blundeville who wrote on Horsemanship. A few months ago (it is now October, 1846) a patent for a horseshoe was upset in Chancery, upon proof that Blundeville had described it before 1600.

to a radius of 100,000. Peculiar to this table is a heading by which the sine, tangent, secant of the complement, or defect from 90°, are also made to belong to the excess above 90°; thus at 10° tho sine, tangent, and secant of 80° are made to be those of 100°.

The history of the rest of the works of Rheticus was, till lately, very inaccurately told, and there is still some confusion about it. After Rheticus had published his ten-minute canon, already noticed, in 1551, he was occupied till his death in 1576, in what is, beyond a doubt, the most laborious work of calculation that any one man ever undertook: a complete trigonometrical canon to every ten seconds, and to ten places of decimals, sines to every ten seconds, and to fifteen decimals, with the first and last degree to every second, and tangents and secants to every minute, and to fifteen decimals. It is to be remembered that he wanted the abbreviations which might have been introduced, if he had known what Vieta had done. At his death, he had finished this work, within a mere trifle: what little remained to do, was done by his pupil Valentine Otho, and part of it was published at Neustadt* in the Palatinate, 1596, in folio (sometimes bound in two volumes, from its thickness). The title of the book, which was published at the expense of the Emperor Maximilian, is 'Opus Palatinum de Triangulis a Georgio Joachimo Rhetico cœptum: L. Valentinus Otho Principis Palatini Frederici IV. Electoris Mathematicus consummavit.' The contents are (after prefaces) three books *de Fabrica Canonis*, on the construction of the Canon, by Rheticus; one book on plane triangles, and four books on *right-angled* spherical triangles, by the same; five books on oblique-angled spherical triangles by the editor, Otho; three subsidiary astronomical tables called *meteoroscopia;* the great table, in 540 folio pages, giving, under the titles already alluded to, the sines, tangents, and secants, for every ten seconds, with a radius of 10000 millions, or, as we should now say, to ten places of decimals; a list of errata; and lastly, a second table of cotangents and cosecants for the first half of the quadrant, to every ten seconds as before, and to a radius of 10 millions. The appearance of the last table is merely the editor's want of judgment; it is clearly nothing but a previous attempt, made before the larger plan was resolved on, and is much less accurate than the great table to ten places.

Within a short time after the *Opus Palatinum* was published, it was found (by whom or how we are not told) that the tangents and secants towards the end of the quadrant became more and more erroneous, and at the extreme end were very erroneous indeed. All persons who know anything of trigonometry are aware that, to calculate the tangent or secant of an angle near to 90° true to any number of decimal places, requires that the cosine should be calculated to a greater number of places. Rheticus seems to have foreseen this, and to have provided sines true to a larger number of places than those which were published. When the defect was discovered, the advisers of the Elector Palatine, Frederick IV., to whom the work was dedicated by Otho, caused him to intrust the superintendence of the corrections to Bartholomew Pitiscus of Grünenberg, in Silesia, who had been his own teacher, and who was still in his service as chaplain: we suppose this means that Pitiscus himself was the adviser. Pitiscus applied to Otho, then an old man, for the larger tables of sines which Rheticus was known to have calculated: Otho was never able to find them; but at his death they were found among his papers. Pitiscus accordingly made *two* publications; but so confused are the statements respecting them, that some of our readers may almost doubt the fact. These two publications were as follows: 1,—He corrected all that part of the great table of the *Opus Palatinum* in which the tangents and secants are sensibly erroneous, being the first 86 pages. These be reprinted, and joined his reprint to the 540—86, or 454 remaining pages of the great table. He then cut away all the *Fabrica Canonis*, the books on triangles, the *Meteoroscopia*, and the small table of cotangents, &c., and added to his own 86 pages and Otho's 454 a short description, or *commonefactio*, as be calls it. This of course gives a thin folio. But we collect from Delambre's account of Prony's copy, tbat besides this, there were such things as complete copies of the *Opus Palatimum*, with tbe 86 correct pages substituted for the incorrect ones. And we presume that to these the separate title of tbe *commonefactio* was not appended, being printed only for the separated table. For Prony, Delambre, and all the rest of the French savans (to whom the subject was particularly interesting, on account of its connection with the *Tables du Cadastre*, then preparing) missed the date of the correction, which nevertheless appears on the separate title-page of the *commonefactio*. The person who is used to accurate descriptions of books might possibly, without this warning, throw away the thin folio we are speaking of, under the idea that it could not be in any sense an edition of the Opus Palatinum: which in fact it is not, though it is an edition of all that was corrected. The 86 pages of reprint are easily distinguishable by the inferiority of paper and type.* The title-page of the thin book is a sort of fly-title, without date &c., on the first page, as follows:—'Georgii Joachimi Rhetici magnus canon doctrinæ triangulorum ad decades secundorum scrupulorum, et ad partes 1 00000 00000. Recens emendatus a Bartholomæo Pitisco Silesio. . . . Addita est brevis commonefactio de fabrica et usu hujus Canonis . . . . . Canon hic, una cum brevi commonefactione . . . . . etiam separatim ab opere Palatino venditur. In bibliopoleio Harnischiano.' And the *commonefactio* has a title-page of its own, as follows: 'Bartholomæi Pitisci Grünbergensis Silesii Brevis et Perspicua commonefactio de fabrica et usu magni canonis doctrinæ triangulorum Georgii Joachimi Rhetici. Neostadii Typis Nicolai Schrammii MDCVII.' It thus appears that the date is 1607, which no one has yet noted, except Kastner, copying an older description, apparently without any distinct separate knowledge of what he was describing. 2, Pitiscus published, Frankfort, 1613 (misprinted on two of the titles 1513, by omission of a C) folio, the tables of Rheticus by which himself was enabled to make the preceding corrections, under a long descriptive title beginning with *Thesaurus*† *Mathematicus*. The contents, described in modern language, are:—sines to every ten seconds and to fifteen decimals, with first, second, third, and sometimes more differences; those of the first and last degrees, also to fifteen places, and to every second; the fundamental sines, from which the rest were calculated, to twenty places: the sines of every 10th, 30th, and 50th second in the first 35 minutes to 22 places (this last table was done by Pitiscus himself). Pitiscus died in July, 1613, very shortly after the publication of the *Thesaurus*.

When we come to reflect, we find that the tables of Rheticus did not make such an epoch in the history of these things as might have been expected. The ten-minute canon (1551) which we have described, and of which the memory was almost lost, introduced the secants, completed the system, and suggested to Vieta both the extension and its form. Had Rheticus published his own large table before his death, in 1576, it might have been otherwise: but deferred as this publication was, partly till 1596, seventeen years after Vieta's Canon had appeared, and partly till 1613, the year before the publication of logarithms, it turned out that the impulse had already been given from other quarters. The next great tables of sines which were produced were the work of Briggs, who was, as we have seen, exclusively the follower of Vieta in this part of the matter. The labours of Rheticus became little more than a tradition, though Vlacq used the last half of his quadrant in the construction of logarithmic sines. Vossius (1650) knew nothing definite of the tables except the Thesaurus, and that only in time to insert it in the additions to his work. Sherburne (1675) has not a word of tables. Briggs hardly mentions Rheticus; his biographers not at all. The Jesuit Blancanus omits him as a condemned writer; and it is to be noticed that he was, as to this matter, worse off than Copèrnicus himself; and the absolute prohibition against all his writings must have tended to the oblivion into which his name fell. Weidler (1741), writing in the University of Wittemberg, in which Rheticus taught, had not seen the Opus Palatinum, and knew nothing of what Pitiscus had

* Weidler, copied by Montucla, gives Heidelberg, 1594; and Lalande reconciles them by taking *Neostadium* to be Latin for Heidelberg! The Neustadt here mentioned is now part of Bavaria, lat. 49° +, long. 11° –.

* The corrected copies of the work, thick or thin, may be distinguished from the uncorrected ones in a moment, as follows:—Look at the bottom of page 7, at the running titles of the columns. The uncorrected copy will have, as it ought to have,

Basis Differentia Hypothenusa.

But the *corrected* copy (*quis custodict ipsos custodes?*) will have, as it ought not to have,

Hypothenusa Differentia Basis.

† The copies of the two works, the *Opus Palatinum*, and the *Thesaurus*, which belonged to Delambre, were bought at the sale of his books by Mr. Babbage. The copy of the *Thesaurus* is curious: it once belonged to De Thou, and was bequeathed to Delambre by Lalande. It sold at the sale for eleven pounds sterling. Mr. Babbage has also a copy of the corrected table (the thin volume). He informs us that, in 1828, Reuss, the librarian at Göttingen, and the indefatigable editor of the *Repertorium Commentationum*, &c., the most complete digest of scientific transactions which exists, was altogether ignorant of the existence of any corrections of the Opus Palatinum. This is a truly singular instance of the slowness with which bibliographical information spreads.

done. In the Berlin Memoirs for 1786, John Bernoulli (the younger) revived the knowledge of the *Opus Palatinum* and the *Thesaurus*; and Lalande had previously come at some statement to the effect that Pitiscus had once received instructions to correct the former. But Bernoulli knew nothing of these corrections, and nothing was known until chance threw a copy of the corrected Opus Palatinum into the hands of Prony, who described it in a paper printed in the fifth volume of the Memoirs of the Institute (1804). Delambre gave an accurate account at the beginning of the second volume of the 'Histoire de l'Astronomie Moderne.' Montucla had given nothing but mistakes. Hutton knew as much as Bernoulli. Kastner (1796, who would have got much more credit if he had given a proper name to his work of bibliography, instead of calling it a history of mathematics) has a detailed account of all the matter, except the corrections of the Opus Palatinum, on which he could only quote from a periodical of 1789.

In 1599 Pitiscus published his own work on Trigonometry, with tables, generally to seven places, and having intervals which may be described in the notation of our former paper as 0 (1″) 1′ (2″) 10′ (10″) 1° (1′) 45°. The edition of 1608, now before us, has of course the corrected tangents and secants. It was reprinted again in 1612, and Dechales mentions a reprint, by Henrion, in 1623.

Pitiscus will always be remarkable as the priest who wished that all his brethren were mathematicians,* to make them manageable and benevolent.

Among the non-logarithmic tables, which were published after the invention of Napier turned all the calculators another way, we have mentioned in our former article Schooten's Table, Amsterdam, 1627. Lipenius says this was reprinted in 1638 (?) and we know there is an edition of 1672 at Rouen, and of 1683 at Brussels. Editions are mentioned of 1640 and 1664, and also a Spanish edition, Brussels, 1683. Joh. Meyer's tables, Strasburg, 1619, contain sines, tangents and secants, squares, and cubes. Those of Adrian Metius, 1633, give a complete canon, to minutes, to seven decimals. In 1627 Snell published his 'Doctrina triangulorum canonica,' Leyden, containing a complete canon to every minute, and to seven places. Cruger's 'Synopsis Trigonometriæ,' Danzig, 1612, gave a five-decimal canon, to minutes. Albert Girard's 'Tables des sinus,' &c., Hague, 1626, are to five decimals; there was a Dutch reprint in 1629. Adrian Romanus gave tables (Delambre, *Astr. Mod.*, vol. ii. p. 35) in 1609; they were taken from Clavius. The contents of this paragraph are taken from different sources, and not from the books themselves. We might mention some anonymous tables from various catalogues, but anonymous works of this kind are so rare that we always suspect them.

Alsted's Encyclopædia (1649), the earliest work which has bulk enough to be compared with modern works of the same name, gives nothing more than a canon to degrees and seven decimals, with another to ten minutes and five decimals. The name only of logarithms is mentioned, and an insufficient definition given.

§ 6. We shall now add something to our account of logarithmic tables, including a fuller description of a few of those mentioned in our former article. The date and name, when unaccompanied by a title, will serve as a reference to that article.

1614. Napier. It must be specially noted that the logarithms which Napier himself published are not precisely those which are now called Naperian; that is, they are not the simple logarithms to the base $\epsilon=2{\cdot}7182818\ldots$ As the sines increase, his logarithms decrease. As he uses no decimal point, both his sines and logarithms are integers, the former to a radius of 10 millions. And if N be a sine and L the logarithm of it, as they stand in Napier, the equation connecting them is

$$N = 10{,}000{,}000 \;\; \epsilon^{-\frac{L}{10{,}000{,}000}}$$

Delambre proposes to call them *Naperian* logarithms, and to restrict tho term *hyperbolic* to the *modern Naperian* or ϵ logarithms.

1618. Benjamin Ursinus. The *Magnus Canon*, besides going to every ten seconds, has one place more than in Napier. It was partially reprinted by Schulze, as presently mentioned.

1619. John Speidell. These 'New Logarithmes' are the first *modern Naperian*, or *hyperbolic* logarithms. The second edition was in 1620, not 1627, as we stated (from others) before we had seen it. The reason of the mistake is that the 'Briefe Treatise of Sphæricall Triangles,' which is frequently prefixed, has 1627 on its title-page.

Taking decimals it stands thus:—If $m:n$ be the sine of an angle, and if λ represent the logarithm to the base ϵ, the *figures* of the Naperian logarithm are found in

$$\lambda n - \lambda m.$$

Thus, the sine of 19° 38′ is ·336, very nearly. And we have

$$\begin{aligned}\lambda\ 1000 &= 6{\cdot}9077552\ldots\\ \lambda\ \ 336 &= 5{\cdot}8171111\ldots\\ \hline &\ \ 1{\cdot}0906441\end{aligned}\qquad \text{Napier has } 10906448.$$

The figures of Speidell's logarithmic sine are found in

$$10 + \lambda m - \lambda n$$

thus for 19° 38′ he has 890936. But he leaves the 10 out of all the secants and the last half of the tangents. His logarithms of numbers, 0 (1) 1000, are modern hyperbolic to six decimals, as we should now say, but without the decimal point; thus at 770 he has 6646388 not 6·646388. To each logarithm he gives its difference, its arithmetical complement, and the halves of all three. Also an additional column which shows that he means to use his table in calculation by feet, inches, and quarters. Thus the number 775 has 16.1.3 opposite to it, there being 775 quarter inches in 16 feet 1 inch 3 quarters. At the bottom of each page he puts the logarithm of 100 and of 1000, for help in decimal fractions.

Speidell, as we have seen, first published in 1619; Baron Maseres reprinted from the 'tenth impression,' dated 1628; Hutton mentions the seventh, dated 1624; the Royal Society has one of 1623; Murhard gives the third impression of 1621, and we have the second, dated 1620. And it appears that Speidell was not the only person who reprinted it. In his 'briefe treatise' above mentioned, Speidell mentions, and naturally complains of, those * who had printed his work without an atom of alteration, and yet dispraised or undervalued it in their prefaces for want of alterations which themselves either could not or would not make. This he attributes to his not having been at Oxford † or Cambridge. These ten editions give a very large idea of the progress which the use of logarithms had made: but (whether for his own reason or not) Speidell's name was very ‡ little known. The Continental writers rarely mention him; Wallis knew nothing of him; and even his own son, Euclid Speidell, when he published his 'Logarithmotechnia,' in 1688, has no accurate information on his father's writings; for he says, 'I do find my father printed several sorts of logarithms, but at last concluded that the decimal or Briggs's logarithms were the best sort for a standard logarithm, and did also print the same several ways.' This must have been merely a mistaken tradition, arising from Speidell's not having printed the same logarithms as Napier: we may safely say he did not print any decimal logarithms. In addition to this testimony as to the rapid spread of logarithms in England which Speidell gives, we may state that their advantages were immediately seen by the practical mathematicians. Aaron Rathborne, in his 'Surveyor,' London, 1616, recommends the use of the 'tables and more than admirable invention of logarithmes by that divine and noble writer the Lord Marchiston, whose name and honour will never out.'

1643. F. B. Cavalieri, 'Trigonometria plana et sphærica,' Bologna. Seven-decimal Briggs's logarithms 0 (1) 1000, with interscript differences; also sines, tangents, secants, and their logarithms, 0 (10″) 1° (1′) 45°. But the decimal point is not used.

1620. J. B. [Justus Byrgius], 'Arithmetische und Geometrische progresse Tabulen,' Prague. This is the title given

* In his preface he says, 'Mansuetudo autem, bone Deus, quantum et quam rarum est Theologorum ornamentum! Et quam optandum esset hoc seculo, omnes Theologos esse mathematicos, hoc est, homines tractabiles et mansuetos.' Perhaps the union of the characters of divine and mathematician gives a peculiar right to speak well of the latter; for Barrow says, 'Tenerrimæ frontis et stomachi robustissimi, aut si mavis, pudentissimum undique patientissimum genus hominum sunt mathematici.' We accept the *si mavis*, for there is no saying how the moderns might translate the first epithets.

* To them he speaks as follows, in the introduction:—

'To the M. C. Z.
If that thou canst amend it,
So shall the Arte increase:
If thou canst not: commend it,
Else, preethee hould thy peace.'

† 'Yet to satisfie in part the learned, that I can giue a reason for what I doe, I will set downe the making of there 2. last Theorems, whereby they may (if so they please) suppose I can doe as much for the rest, and whether some of them doe or no, I passe not greatly, for that they are sorry I can doe so well, not hauing seene one of the Vniuersities' (p. 27).

‡ There is not now a copy of any edition in the British Museum. Hutton happens to say that there is in the seventh impression (being the one he had before him) a table of logarithms of numbers. Hence in the *Encycl. Brit.* this is translated into an assertion that the table was not added until the seventh impression.

by Montucla, and the history of the book is as follows:—Kepler had stated that Byrge had invented the very same logarithms as Napier many years before the latter published anything on the subject. And Bramer, author of a German work on perspective (Cassel, 1630), says that his brother-in-law and teacher, Justus Byrgius, had, twenty years before that time, made a table of progressions with differences of 10, calculated to nine figures, which he had published without text at Prague in 1620. This announcement obtained no notice, until Kästner informed Montucla (how, Montucla does not state; probably by private communication, or perhaps Montucla ought to have cited the 'Forsetzung der Rechenkunst,' 1783) that this passage of Bramer had led him to look at some old tables which he had bought, and which had lain by neglected. And in these old tables he says he found the above work of Byrgius. This occurs in the second edition of Montucla's History, vol. ii. p. 10; see also Kästner's History, vol. ii. p. 375, and vol. iii. p. 14; and Delambre, Hist. de l'Ast. Mod., vol. i. pp. 560-566. It will be noticed that Byrgius did not publish till six years after Napier; so that in all probability Napier is first in point of invention as well as publication. His system begins with 0 as a logarithm and 10^9 as a number; for every increase of the logarithm by 10, the number is multiplied by 1·0001; so that $10m$ has for its number $10^9\,(1{\cdot}0001)^{m-1}$. This is undoubtedly a rude table of logarithms, or rather of numbers to logarithms: and since Byrgius carried it up to 230270, the number to which is 999999999, he certainly secured the main advantages of logarithmic calculation.

1624. John Kepler, 'Chilias Logaritbmorum,' Marpurg, and 1625, 'Supplementum . . . continens Præcepta de eorum Usu.' These were reprinted by Maseres, in vol. i. of the *Scriptores Logarithmici*. See a very full account of them also in the first volume of Delambre's History of Modern Astronomy. The logarithms are strictly *Naperian*, 0(1)1000, but four ciphers are put to the end of each number, to make the radius ten millions. There are five columns, of which this is a specimen—

44° 30′ 26″ | 7010000 | 16^h 49^m 26^s | 3552474 | 42° 4′

The number here is 701, and the sine being 7010000 the angle is 44° 30′ 26″. The logarithm is 3552474. And if 1000 represent 24h, then 701 represents 16^h 49^m 26^s: while if 1000 represent 60°, 701 represents 42° 4′. We were wrong in saying that it was this set of logarithms that was republished in 1700, as will presently appear.

1626. Wingate. 'Arithmétique Logarithmique.' Under this head, in our last article, we mentioned the difficulty about the date of the book by which Wingate introduced Briggs's logarithms into France. We have since found a copy dated 1625, and we are satisfied, from the date of the 'privilège' and other things, that this was the first edition. That date is November 4, 1624, and the printing is stated as having been finished April 4, 1625. This edition and that of 1626 are from the same types, except in their title-pages, and a page or two of the postfixed explanations. The latter has also a further appendix on some points of explanation. It has also additional (perhaps, for the same thing may have been torn out of our copy of 1625) a folding sheet of mean proportionals between 10 and 1. The contents are,—seven-decimal logarithms of numbers 0(1)1000 with interscript differences; and 0(1′)45° logarithms of sines and tangents. This is the introduction of Briggs's logarithms into France; that of Napier's was made, as noted, by B. Vincent. But the dates should have been 1619 for the *Descriptio*, and 1620 for the *Constructio*.

1626. Henrion. In our former article we left this work in doubt. All we can learn is from Dechales, who states that Henrion wrote on the proportional compasses in 1623 (reprinted in 1681) and on the rule of proportion (which we take to be Gunter's scale) in 1626; and that this last work contains logarithms of numbers up to 2000.

1626. 'Tables des Logarithmes pour les nombres d'un à 10000, composées par Henry Brigge. A Goude. Par Pierre Rammaseyn.' The negligence of a bookbinder enables us here to take up a thread or two from our former article, in rather a singular manner. It will be seen that we have (p. 498) noted Sherwin as stating that he examined his table by one of Vlacq's, in large octavo, printed at Gouda in 1626, of which table we find no other mention. The table before us corresponds in every respect, except that there is no author's name: but no one except Vlacq can be mentioned, who was in the least likely to have printed logarithms at *Gouda* in or about 1626. And this we have no doubt is the real first edition of the series of small logarithms called Vlacq's, which will occur several times in our list. Again (p. 498) in speaking of Gellibrand's 'Institution Trigonometricall,' we have noted the table at the end of Well's 'Sciagraphia,' which we had seen, and which seemed to resemble the description of Gellibrand's tables, which we had not. Now this table, Gouda, 1626, having the title above described (and which we have also seen with a Dutch title and preface), *is* the table which is always bound up at the end of 'Sciographia, or art of Shadowes . . . . by T. W., Esq.,' London, 1635, large octavo. That the book was intended to have these logarithms bound at the end is evident from every page of it. Now the fact stands as follows:—A sufficient number of copies of the logarithms having been procured from abroad, the binder was directed to cancel the title-page of the logarithms, and to append them to the work. Accordingly, most copies have no title to the logarithms, which look quite like part of the work. But in some copies the binder has not cancelled as required; we have obtained two (since our first article was written) and there is another in the library of the Royal Society. But in all three copies the title of the logarithms is cut half way up with knife or scissors, as a direction to the binder to cancel it. One of our copies has this Dutch title-page to the tables 'Henrici Briggii Tafel van Logaritbmi voor de Ghetallen van een tot 10000. Ter Goude . . . 1626.' And the work (though the same impression as before) has a different title-page and date, namely, 'The Compleat Art of Dyalling . . ., by T. Wells of Deptfort, Esq.,' London, 1637.

This first edition of Vlacq (1626), as we will call it (being certainly the first *small* table published under Vlacq's name), contains logarithms of numbers 0 (1) 10,000, to ten decimals, and a complete canon (of logarithms only) to every minute and to seven decimals. But the terms cosine, cotangent, cosecant, are not yet introduced.

The 'Institution Trigonometricall' of Henry Gellibrand, London, 1635, contains logarithms, sines and tangents (not secants), from 1 to 10,000, a minute-canon of logarithms, and a complete minute-canon of sines, &c. all to seven decimals: but without differences. It has also some subsidiary tables for astronomy and navigation: and it has the name of Briggs prefixed to the logarithms of numbers only. All this, the subsidiary tables excepted, is most literally the description of the celebrated small work of Vlacq, of which we shall mention five editions, one of which is called the twentieth. Now it is stated in VLACQ, P. C., that his first edition of the small table which goes by his name was published in 1636; which is confirmed by Dechales, who describes the book in a manner which completely identifies it. If this be correct, of which we can be by no means certain, for early * editions are often nearly lost to history, then the celebrated tables of Vlacq (in their later and usual form) are certainly Gellibrand's, in every point which distinguishes them from preceding tables. But in all probability Gellibrand took his plan from the Vlacq of 1626, or at least the idea of publishing small tables: and it is most likely that neither of these two men, the undoubted successors of Napier and Briggs, would have thought there was much, either to claim or to take, in the way of scientific merit, from the smaller publications with which they indulged those who were unwilling to face their folios.

1630. Bartschius. The tables which Bartschius published independently of his father-in-law (Kepler) had fallen into oblivion, when Eisenschmidt found a copy and republished them with Kepler's *last* tables under the title of 'Joh. Kepleri et Jacobi Bartschii Tabulæ manuales logarithmicæ,' Strasburg, 1700, 12mo. What the titles and dates of the original works were, we can find only from Lipenius, who gives them as follows:—

> Jac. Bartschii 'Tabulæ Novæ Logarithmico-logisticæ,' Leipzig, folio, 1635; and 'Trichil. Hexacosias Logarithmi.' Sagan, 8vo., 1630.

Whether the first was an original edition we do not know: if so, it was posthumous. The reprint by Eisenschmidt contains, according to Delambre (*Astr. Mod.* i. 530), *Naperian* logarithms of sines and tangents to ten seconds, but only to five decimals. The *Trichil-Hexacosias* is in fact a table of what we *now* call logistic logarithms for every second of the first degree, 1° being the first term of the proportion. It is to six figures.

1630. J. Faulhaber, 'Ingenieurs-schul, Erster Theyl, Frankfort. This work contains logarithms, according to Scheibel, who does not give a description.

* Witness the first edition of Smart's tables, hereinafter mentioned, which seems to be wholly unknown to all the modern writers on interest.

1633. J. B. Morin, 'Trigonometriæ Canonicæ Libri Tres,' Paris. Seven-decimal Logarithms; of Numbers 0 (1) 1000, with interscript differences; of Sines and Tangents 0 (1′) 45°. The decimal point is not used.

1634. Cruger. Kästner gives Dantzig as the place. The logarithms are Naperian, according to him.

1651. Vincent Wing, 'Harmonicon Coeleste,' London. The logarithms have separate title-pages, and might, if torn out, pass for separate works. They have the decimal point and are to six decimal places. Sines and tangents 0 (1′) 45°; numbers, in decads, 0 (1) 1010, without characteristics. Wing was a much more learned man than his reputation (which is that of an almanac-maker) would imply.

1668. John Newton, 'The Scale of Interest, or the use of Decimal Fractions.' Here is a table of logarithms to six decimals 0 (1) 10000 arranged in lines of decads, with a separate table of proportional parts.

1681. Vlacq, 'Tabulæ' Sinuum, &c., Amsterdam: also 1683. Vlacq, 'Tables de Sinus,' &c., Amsterdam; and 1689, Vlacq, 'Tabellen der Sinuum, &c.,' Amsterdam. A great many small tables of logarithms bear the name of Adrian Vlacq. Those before us, which have the same introduction, one in Latin, the other in French, the third in German, have sines, tangents, secants, and logarithms of sines and tangents, to every minute and to seven decimals. Also, seven-decimal logarithms from 1 to 10,000, headed 'H. Briggii Tabula Logarithmorum.' See above, at the year 1626.

1685. Ozanam, 'Tables des Sinus,' &c., Paris. This is really Vlacq in every particular as to the tables, though his name is not mentioned.

1690. Dechales, 'Cursus seu Mundus Mathematicus.' The first volume has seven-decimal tables; logarithms of numbers 0(1)10000; of sines and tangents 0(1′)45°, and the sines and tangents also.

1690. Wm. Leybourn, 'Cursus Mathematicus.' This book has internal evidence of having been written before 1660. Seven-decimal logarithms of numbers 0(1)10000; six-figure logistic logarithms 0(1″)1° and 1°(1′)1°12′; *signs*, tangents, and secants, &c., 0(1′)45°; the names cosine and secant not used.

1699. John Wing (nephew of Vincent), 'A compleat Body of Surveying, formerly publish'd by Vincent Wing,' London. Five-decimal logarithms of sines and tangents, 0(10′)45°; of numbers, 0(1)1000.

1704. J. H[arris], Table of Logarithms, quarto, mentioned in Hutton's sale catalogue.

1705. (Second edition.) Anonymous, 'A Table of Logarithms for Numbers increasing in their natural order, &c.,' London. Six-decimal logarithms of numbers 0(1)10000. The trigonometrical part has a separate title, 1704, 'A Triangular Canon Logarithmical,' London. Six-decimal logarithms of sines, tangents, and secants 0(1′)45°. As far as appears, this table was got up by J. Seller and C. Price, mathematical-instrument makers, who seem to have desired to sell their own table of logarithms as well as their own quadrants.

1710. John Harris, 'Lexicon Technicum,' vol. ii. This volume contains seven-decimal tables of logarithms 0(1)10,000, and a complete canon (including versed sines), 0(1′)45°, both natural and logarithmic. There is also a table of proportional parts for every integer from 44 to 4320. These tables, except the last, seem to be taken from Sherwin.

1721. In this year was printed at Pekin, by command of the Emperor Kang-Hi, in Chinese type and in three folio volumes, Vlacq's logarithmic tables of sines, &c., to ten seconds, and of numbers to 100,000. (Brunet, from Vega, who had seen it at Vienna.)

1741. Deparcieux, 'Nouveaux Traités de Trigonométrie Rectiligne et Sphérique,' Paris. Deparcieux is so much better known by his tables of annuities, that his other writings * are neglected. The tables are all to seven decimals (though the decimal point is not used). There are logarithms of numbers 0(1)20000; sines, tangents, and secants, &c., 0(10″)5°(1′)45°, and logarithms of sines and tangents. This is the earliest table we remember to have seen in which the argument of degrees, minutes, and seconds accompanies the logarithms of numbers. The book is also distinguished by its gnomonical tables, and by the excellence of its solid diagrams.

* When a person is distinguished by one particular work, his other, and particularly his previous, writings, even on the same subject, go out of notice. How many persons, for instance, know that Laplace published (separately from the Memoirs of the Academy) a small work on the elliptic motion and on the figures of the planets, in 1784? (See Lalande, Bibl. Astron. ann. 1784.) And how many biographical accounts of Laplace mention it?

1742. J. F. Gleditschen, 'Des vollständigen Mathematischen Lexici zweyter Theil,' Leipzig. Here we have squares and cubes 0(1)10,000; seven-decimal logarithms of sines, tangents, and secants 0(1′)45°; logarithms of numbers 0(1)20000; sines, tangents, and secants 0(1′)45° to seven decimals; factors of odd numbers not ending with 5, to 10,000.

1743. Rivard, 'Tables des Sinus, &c.,' Paris, with the official 'approbation' of Clairaut. Seven-decimal logarithms of sines, tangents, and secants 0(1′)45°; sines and tangents to five decimals; secants in a separate table; logarithms of numbers 0(1)20000: all with characteristics and no decimal points.

1770. J. H. Lambert, 'Zusätze zu den Logarithmischen Tabellen,' Berlin. This is a miscellaneous collection of tables and formulæ, containing—Primes, and least divisors of all odd numbers which do not divide by 3 or 5, up to 102,000; first ten multiples of all prime numbers up to 313; primes alone up to 102,000; powers of 2 as far as the 70th, and of 3 and 5 as far as the 50th; hyperbolic logarithms, seven decimals, 0(1)100, and 1(·01)10; numbers which divide by 2, 3, 5, or 7 only (except those which divide by 2 or 3 only), up to 10,000; 27-decimal arcs 0(1°)100°(20°)120°(30°)360°, and for minutes and seconds; five-decimal sines and nine multiples 0(1°)90°; seven-decimal sines, tangents, and secants, and logarithms of sines and tangents 0(1°)90°; tables for facilitating cubic equations; sines and cosines of *hyperbolic trigonometry*, the only table of the kind we have met with; squares and cubes 0(1)1000; figurate numbers to the 12th order, 30 of each; eight decimal powers of fractions 0(·01)1 to the 11th power; seven-decimal square roots 0(1)100. There is another edition of this useful miscellany, Lisbon, 1798.

1775. Douwes 'Tafellen bebelzende de Sinussen.... als mede de Logarithmen,' &c., Amsterdam. A complete minute-canon to seven decimal places; followed by logarithms to seven places; versed sines and logarithms on the same scale to 90 degrees; logarithms of numbers from 1 to 101000; and traverse tables.

1778. J. C. Schulze, 'Neue und erweiterte Sammlung logarithmischer . . . Tafeln,' Berlin. Also 'Recueil de tables logarithmiques . . . .' The titles and preliminary explanations are both in French and German. This is a valuable and original collection. It contains the usual seven-figure tables 0 (1) 101000; a page of multiples of ·434 . . . and its reciprocal to 48 places, and powers of 2·718 . . . to 28 figures; *Wolfram's** hyperbolic logarithms of all numbers from one to 2200, and from thence to 10,000 for all numbers not divisible by any single digit, all to *forty-eight decimal places;* common logarithms to seven decimals of sines and tangents 0 (1″) 2°; logistic logarithms 0 (1″) 1°; a complete canon 0 (10″) 3° (1′) 45° containing sines, tangents, and secants to seven decimals, common logarithms of sines and tangents to seven decimals, *Naperian* logarithms of sines and tangents to eight decimals; first nine multiples of sines of every degree to five decimals; lengths of arcs 0 (1°) 360° to twenty-seven decimals; ditto 0 (1′) 1° and 0 (1″) 1′; powers of fractions 0 (·01) 1 as far as the eleventh, to eight decimals; squares and cubes 0 (1) 1000; square and cube roots 0 (1) 1000 to seven decimals; factorials 0 (·01) 1 to six factors; a table for the fall of bodies, of rational right-angled triangles, and small tables of specific gravities and of weights and measures. Half-a-dozen of Wolfram's logarithms which were accidentally missing in consequence of an illness, are supplied in the Berlin Ephemeris for 1783, p. 191. The *Naperian* logarithms of sines and tangents are an abbreviation of Ursinus, who carried them to ten seconds all the way through the quadrant.

1783. Vega 'Logarithmische Trigonometrische und andere . . Tafeln und Formeln,' Vienna. This was Vega's first work, and we have never met with it. (Octavo.)

1783. Callet, 'Tables Portatives de Logarithmes, publiées à Londres par Gardiner,' &c., Paris. This first edition of Callet, as it is called, and which we have said was substantially that of Gardiner, was actually and formally so 'aug-

* This table was the work of Lieut. Wolfram, of the Dutch artillery, and took six years of hard labour. It is one of the most striking additions to the *fundamenta* of the subject which has been made in modern times. Delambre (*Hist. Astr. Mod*, v. i. p. 501, &c.) introduces his comparisons of Napier and Wolfram so abruptly, and so many pages elapse before the reader can find out who the latter was, that most probably many have inferred that the two were contemporaries. But this is Delambre's way, and is often liable to confuse a reader who has no warning on the subject. With a work before him from which he is drawing his materials, he perhaps never mentions it till the end of his remarks, or perhaps casually in the middle, though until such mention is made, all he says is very liable to be misunderstood.

mentées et perfectionnées dans leur disposition par M. Callet.' Callet added as much of each kind of table as would leave no white in his last page, and, from Mouton, completed the single-second table of sines and tangents up to 2°. Here also first occurs the broken line at the change of tho third figure. On this edition Hutton says 'it is but justice to remark the extraordinary spirit and elegance with which the learned men and the artisans of the French nation undertake and execute works of merit:' and the compliment is well deserved by the beauty of the type and the general accuracy of the work.

1784. M. Robert, curate of 'St. Geneviève à Toul,' sent Lalande (*Ency. Meth.* 'Tables,') a manuscript volume containing sines to every second, to how many places he does not say; shortly afterwards he sent the tangents. Lalande gives a hint that the approaching publication of Taylor's logarithms prevented any steps being taken to print these. He also states that there was in the library of the Academy of Sciences a manuscript of Mouton, giving the logarithmic sines and tangents of 0 (1″) 4° to eleven figures; we suppose he means to ten places of decimals. M. Robert's manuscript came into Delambre's possession, and was bought at the sale of his books by Mr. Babbage, in whose possession it now is. It is in two large folio volumes, the figures (to seven decimals) being written in printed skeleton columns. Some corrections of Callet, discovered by means of this manuscript, were printed in one of the Nautical Almanacs.

1794. George Vega, 'Thesaurus Logarithmorum completus,' Leipzig, folio. There is also a German title-page, and the explanations are both in German and Latin. This is, no doubt, up to this time, *the* table of logarithms; the one of all others to which ultimate reference should be made in questions of accuracy. Its contents are,—a *ten*-decimal table of common logarithms 1 (1) 101000, distributed in the common manner, a decad in each line, with the differences arranged in the same way, and tables of proportional parts for the first three figures of the differences. Logarithmic sines and tangents to 10 decimals, 0 (1″) 2° (10″) 45°. Sines 0 (1″) 12′ to ten decimals. Lengths of arcs to 11 decimals. Wolfram's *hyperbolic* logarithms above described, reprinted from Schulze.

1794. J. J. Girtanner, 'Logarithmische Tafeln zur Abkurzung kaufmannischer Rechnungen,' Commercial logarithms. The plan is to have logarithmic tables for integers and different sorts of fractions, among which eighths, tenths, sixteenths, and sixtieths are conspicuous. But it will not do: Mohammed must go to the mountain. When coinage, weights, and measures, are decimalized, the use of logarithms will follow as a matter of course. It is useless trying to bring logarithms to ordinary fractions.

1799. J. P. Hobert and L. Ideler, 'Nouvelles Tables Trigonométriques calculées pour la Division décimale du Quart de Cercle,' Berlin. Delambre speaks highly of this table; but he is wrong in saying it subdivides the quadrant as minutely as those which himself and Borda published. Meaning by 1° the hundredth of the right angle, and 1′ being 0°·01, and so on, Hobert and Ideler's division of the quadrant is 0 (10″) 3° (1′) 50°; but Delambre and Borda's, which is not given correctly in our last article, is 0 (10″) 5′ (1″) 3° (10″) 40° (1′) 50°. The Berlin table gives sines and tangents and their logarithms, through the quadrant; the Paris table gives logarithms only. The former has no logarithms of numbers except 0 (1) 1100 and 999980 (1) 1000021, all to 36 decimals.

1802. J. R. Teschemacher. 'Tables calculated for the Arbitration of Exchanges, both Simple and Compound,' London. This is a book of commercial *logarithms*, though the author wisely avoided frightening the merchant by mentioning the word in any part of his book. There is one table of logarithms for the exchange between London and each other place: the tables average about a page each. With this limited range, the logarithms are really effectively applied to commercial purposes, and operations are very much simplified. We are fully of opinion that such a work might be very useful.

1806. Thomas Whiting. 'Portable Mathematical Tables,' London. Six-figure logarithms. This book is a striking proof that in the old figure, the reduction of the thickness of the type very much increases the legibility. This is a very easy book to read, and would exactly suit those who want a large type in a small book.

1808. Ebert. 'Adriani Vlacq Tabulæ Sinuum,' &c. Leipzig. The contents are as before described. This is a new (and apparently the last) edition of Ebert's, whose preface is dated 1790. Besides the contents above described there are squares and cubes of all integers up to 1000.

1809. George Douglas. 'Mathematical Tables,' Edinburgh. A long preface; followed by seven-decimal logarithms from 1 to 10,000, ten in a line, in the usual way, without differences. Two supplemental tables, with the same from 10,000 to 11,000, and from 100,000 to 101,000. A complete logarithmic canon for minutes, to seven decimals. A corresponding canon of natural sines, &c. Natural and logarithmic versed sines, the latter continued to 180°. A table to convert sexagesimals into decimals; and logarithms from 1 to 180, to 15 decimals. A different arrangement from the usual one in several respects.

1812. In Zach's *Monathliche Correspondenz*, vol. xxvi. page 498, Gauss proposed his logarithms for the finding of log $(a \pm b)$ from log a and log b [LOGARITHMS, GAUSS'S, P. C. S.], with a specimen. He stated that he had been in the habit of using five-figure tables of his own construction. Gauss has given a short review of Pasquich's tables (next mentioned) in the 'Gottinger gelehrte Anzeigen,' 1817, No. 158.

1817. J. Pasquich, 'Tabulæ Logarithmico-Trigonometricæ contractæ,' Leipzig. Title and explanations in both Latin and German. Five-decimal logarithms of numbers 0 (1) 10,000; logarithms of sines and tangents 0 (10″) 56 (20″) 1°; five-decimal logarithms of sines and tangents, with a table of the *squares* of sines and tangents 0 (1′) 45°; *Gauss's logarithms.* [LOGARITHMS, GAUSS'S, P. C. S.] A ranging as follows, 0 (·001) 2 (·01) 3·40 (·1) 5. This trigonometrical canon of squares is, we suppose, almost unique.

1817. E. A Matthiesson, 'Tabula ad expeditiorem Calculum Logarithmi Summæ vel Differentiæ duarum Quantitatum,' Altona. This is hitherto the most extensive set of tables of Gauss's logarithms in existence. It is to seven decimals, and A proceeds as follows: 0 (·0001) 2 (·001) 3 (·01) 4 (·1) 5 (1) 7.

1821. Nordmann, 'Adriani Vlacq Tabulæ,' &c. The explanations are given in Latin and German. To the contents of Ebert's edition are added square and cube roots to seven decimals for all integers up to 1000. This is called the *twentieth edition*, which very likely it is; but it was the editor's duty to have stated what the other nineteen editions were.

1821. Westphal's tables, Leipzig, contain Gauss's tables, to five decimals, with proportional parts.

1823. Matthiessen, 'Gemeine Logarithmen,' &c., Altona. *Stereotyped.* This tablo has five-figure logarithms from 1 to 10,000, with a supplemental table of proportional parts, arranged on the two sides of a folding sheet, on canvas.

1828. 'Encke's four-figure Tables of Logarithms,' &c., Berlin, contain Gauss's tables. See '1842, Warnstorff,' &c. below.

1832. J. P. Gruson, 'Bequeme Logarithmische .. Tafeln,' Berlin. A school-book. Seven-decimal logarithms 0 (1) 10,000; squares and cubes, square and cube roots 0 (1) 1000; arcs of the circle; logarithmic sines and tangents 0 (1′) 5° (10′) 45°

1832. H. G. Köhler, 'Tables de Logarithmes,' &c. An edition of Lalande which gives Gauss's logarithms.

No date, (stereotyped,) Moritz von Prasse, 'Logarithmische Tafeln,' edited by Mollweide, and then by Jahn, Leipzig. Five-decimal logarithms of numbers 0 (1) 10,000; of sines and tangents 0 (1′) 45° put together in a new way, so as to separate the common figures, as in the logarithms of numbers, and to get five degrees into a double page, sacrificing the differences; Gauss's tables, A having 0 (·001) 2 (·01) 3·40 (·1) 5; and a modification of Gauss's table, in which log x is the argument, and log $\left(\frac{x-1}{x+1}\right)$ the tabular result, x going through ·382 (·001) 2 (·01) 3·6 (·1) 5·5. An edition of Von Prasse was published by Halma, at Paris, in 1814; and the last-mentioned table was published separately by Weidenbach, Copenhagen, 1829.

1838. G. B. Airy, 'Appendix to the Greenwich Observations, 1837,' London. A table of sines and cosines, with the arguments given *in time*, 0 (10^s) 24^h and the signs marked. There is a separate table both of sines and of cosines, each of which is therefore a transformation of the other. And each again is the table from 0 to 6^h repeated, with transformation, four times; so that the pair of tables is an eight-fold repetition of one table. It is to five decimals, without differences

1839. Anonymous (Useful Knowledge Society). After the first *tirage*, the following addition was made:—One page, for example, begins and ends with the numbers 5220 and 5310, and with the logarithms ·71767 and ·72509. According, at the corner of the page, so as to catch the eye on opening the book, is

5220	·71767
5310	·72509

in full. This plan ought to be adopted in all tables, instead of the abbreviations which are frequently employed as headings.

1840. (Second edition.) Moritz Rühlmann, 'Logarithmisch-Trigonometrische . . . Tafeln,' Dresden and Leipzig. Six-decimal logarithms of numbers 0 (1) 10080; logarithmic sines and tangents 0 (1′) 45°; sines and tangents 0 (10′) 45°; arcs of circles.

1840. Hülse's edition of Vega, Leipzig, stereotyped. This contains Gauss's tables to five decimals with proportional parts, in six columns, the additional three (which contains a peculiar mode of treating the proportional parts) having been also suggested by Gauss. The most recent tirage of this excellent work (1846) contains seven-decimal logarithms of numbers 0 (1) 108000; logarithmic sines and tangents 0 (0″·1) 1′ (1″) 1° 32′ and 0 (10″) 6° (1′) 45°; angles to eleven decimals; five-decimal Gauss's tables A being 0 (·001) 2 (·01) 3·4 (·1) 5, with the proportional parts above alluded to.

1845. Warnstorff's edition of Schumacher's 'Sammlung von Hülfstafeln' (first published in 1822), Altona. This is a well-known and valuable astronomical collection. What we have here to do with is the republication of Encke's four-figure logarithms, 0 (1) 1000, and 0 (4′) 10° (10′) 45°, and Gauss's logarithms 0 (·01) 1·80 (·1) 4.

1846. R. Sheepshanks, 'Tables for facilitating Astronomical Reductions,' London (also issued two years before, without title, preface, or author's name). This is the most complete *four-figure* table we know of, and will do for the purpose oftener than our orthodox septenarians are aware of. Logarithms 0 (1) 1000, with proportional parts, in decads; logarithms of sines and cosines, *the angle being in time*, 0 (1^m) 24^h, with proportional parts for 10^s, and 0 (10^s) 1^s; table for converting sidereal into mean solar time; logarithmic sines, tangents, and secants 0 (1′) 6° (10′) 45°; constants for precession; tangents and secants 0 (10′) 80° (1′) 86°, with a rule for the rest; Bessel's refractions; Gauss's tables, thus arranged, log x as an argument gives log $\left(1+\frac{1}{x}\right)$ as a tabular result, and log $\left(1-\frac{1}{x}\right)$ as another, log x being 0 (·001) ·909 (·01) 2 (·1) 4 in the first table, and 0 (·001) 1 (·01) 3 (·1) 4 in the second; log. $\sin^2 \frac{1}{2}$ hour angle, in time 1^h (1^m) 9^h; numbers to logarithms 0 (·001) 1.

1844. Captain Robert Shortrede's 'Logarithmic Tables to seven places of decimals, containing logarithms of numbers from 1 to 120,000, numbers to logarithms from 0 to 1·00000, logarithmic sines and tangents to *every second* of *the circle*, with arguments in *space and time*, and new astronomical and geodesical tables,' Edinburgh, stereotyped. We do not yet know enough of this table to form an opinion. It is printed at the whole expense of the framer, an enterprising officer attached to the Indian survey. The types were cast for the work, and being of the old figure, we wish of course that they had not been so; but we must say that they look better than any existing figure of the old form could have done in so heavy a page, and also that the uniformity of the type used in logarithms of numbers with that of the trigonometrical ones is a great advantage. It is a most public-spirited undertaking.

Among the titles of tables which we might have said something on if we had seen them, collected from different sources, are those of—John Lauremberg, Leyden, 1628, 8vo.; Lubert Middendorff, Cologne, 1648, 12mo.; Henry Phillips, London, 166?, 8vo.; Institutio Mathematica, London, 166?, 12mo.; Strauchius, Witteberg, 1662, 12mo., and Amsterdam, 1700, 8vo.; D. R. Van Merop, Harlingen, 1671; Chr. Grüneberg, *Tabulæ Mathem.*, Berlin and Frankfort, 1690 (oblong form); Chr. Grüneberg, *Pandora Mathem.*, Berlin and Frankfort, 1700, 8vo.; Chr. Wolff, Magdeburg, 1711, 8vo.; J. G. Leibknecht, Giesa, 1726, 8vo.; Raph. Levi, Hanover, 1747, 4to., and supplement in 1748; J. C. Nelkenbrechers, Leipzig, 1752, 4to; J. Melitaó da Mata, Lisbon, 1790, 8vo.

To our old tables of interest we have to add the following. Stevinus, in the 'Practique d'Arithmetique,' appended to his Arithmetic, Leyden, 1585, reprinted by Albert Girard in Stevinus's collected works, 1626, gave the first tables of compound interest and annuities. They precede the famous tract *La Disme*, in which decimal fractions were first proposed. And as this *Practique* should rather have been at the beginning than at the end, if rational arrangement had been studied; and as the *Disme* again should have preceded it, on the same supposition; we must infer it to be most likely that the tracts were placed in the order in which they were written. If this be the case, then it is pretty certain that these tables of compound interest *suggested decimal fractions*, the account of which speedily follows them. They are constructed as follows:—Ten millions being taken as the base (or *root*, as Stevinus calls it), and a rate, say five per cent., being chosen, the present value of ten millions due at the end of 1, 2, &c., up to 30 years, are put in a column, to the nearest integer. By their sides are the sums of their values, which give the present values of the several annuities of ten million, as follows:—

Table d'Interest de 5 pour 100.

1	9523810	9523810
2	9070295	18594105
3	8638376	27232481
4	8227025	35459506
. . .	. . .	. . .
. . .	. . .	. . .
30	2313774	153924494

The rates are from 1 to 16 per cent., and also for 1 in 15, 1 in 16, &c., to 1 in 22; or, as the French say, denier quinze, denier seize, &c. At the end is a direction to dispense, when convenient, with some of the last figures.

There is thus a virtual use of decimal fractions preceding the formal one. The same thing happens in the tables of Richard Witt, mentioned in our former article, which we believe to be the first English tables of compound interest, and the first English work (except a translation of the *Disme* of Stevinus) in which decimals were used; the use* of them being something more than the virtual use by Stevinus in the *Practique*. The next English writer who gave tables of compound interest, Robert Butler, in his 'Scale of Interest,' London, 1633, makes a rather more decided use of these fractions than Witt, and uses the phrase *decimal fractions*, which had then hardly found its way into books. It should be noted that both Witt and Butler give real half-yearly and quarterly tables, as well as yearly ones.

Mr. Pocock, in his Bibliography of Annuities, &c. (Familiar Explanation . . . . of Assurances upon Lives, London, 1842), gives the following works, which we do not remember to have seen:—'Tables of Leases and Interest . . . ,' London, 1628, 12mo; and William Purser, 'Compound Interest and Annuities, containing the Art of Decimal Arithmetic,' London, 1634, 8vo.

In Newton's 'Scale of Interest,' mentioned in the list of logarithms, is a set of tables for six per cent., then the maximum legal rate. There is here what we never met with elsewhere—a common almanac, with months, dominical letters, and fixed saints' days; having, in lieu of astronomical information, simple and compound interest and discount tables, telling for each day the amount of one pound from the beginning of the year, or the present value for the end.

The first edition of Smart's tables, the original of all our large tables of compound interest, is 'Tables of Simple Interest and Discount at 3, 4, 5, 6, 7, 8, 9, and 10*l.* per cent. per Ann.; also tables of compound interest at the same rates, whereby,' &c. By John Smart, at the Town Clerk's Office, London: London, 1707, 4to. (duodecimo size). The second edition, of 1726, is as large, compared with the first, as it is possible its author 'John Smart of Guildhall, Gent.' may have become, compared with the subordinate at the town clerk's office. The first edition (which we did not know of when we wrote our last article, and we find all† modern writers knew as little), besides a smaller range of rates, has not the half-years, and has only six decimal places. The tables of simple interest are also of very little extent. This set of tables was incorporated (with acknowledgment) in the article *Interest* in the second volume of Harris's 'Lexicon Technicum,' London, 1710. There was an abridged edition, with some of the rates and of the half-years left out,

* See the Bibliography of Arithmetical works, by the author of this article, intended for the 'Companion to the Almanac' for 1848.

† Since this was written we find that Mr. Farr (*Reg. Gen. Rep.* 1844, p. 559) mentions the edition of 1726 as the second edition.

but still to eight figures, 'Tables of Interest, &c., abridged for the use of Schools, in order to instruct young gentlemen in the use of Decimal Fractions,' by John Smart, &c. London, 1736, quarto (octavo size).

Commercial tables of any real power are rendered impossible in practice by the use of shillings, pence, and farthings, except by an extent of matter which makes them very expensive. If, indeed, the rule for decimalizing the parts of a pound [COMPUTATION, P. C. S.] were well learned and properly used, some of the older tables, which have fallen entirely into oblivion, would certainly be revived with effect. Two of those mentioned in our former article will certainly be reprinted when the time comes; Brown's 'Arithmetica Infinita,' and Webb's 'Tables for buying and selling Stocks.' The main part of the former is the first nine multiples of the decimal, which expresses any number of farthings in a pound. Thus, under 7*s.* 8¾*d.* are ·3854166... and its multiples up to nine times. The latter has the multiples necessary to find the quantity of stock which answers to any sum of money, and *vice versâ*, at different prices. These are both pocket tables, and their places are supplied at present by works of much greater bulk and less extensive use.

We go a littlo out of our way to mention Mr. Edward Sang's 'Assurance and Annuity Tables,' Edinburgh, 1841, folio, a most extraordinary work. The author learnt to print that he might set it up with his own hands, and caused the distribution of the types before printing to be done with the care used in composition. It contains for a single life, and for the Carlisle tables at 3 per cent., *every thing.* All annuities and assurances, temporary or deferred, or for the whole life; all values of policies, whenever made, for every subsequent period; all the yearly risks of such policies; assurances at increasing or decreasing premiums; five-figure logarithms and antilogarithms, &c., &c., &c. And every result has its logarithm set down by its side ready for use. Why it is so coldly looked at hy the assurance offices, those who study the human mind will be at no loss to decide. The typography is so beautiful, the paper and type so luxurious, that a century hence a copy will he an object of competition to the Hebers and Spencers of that day. We believe it to be a work of great accuracy.

In the preceding articles [TABLES, P. C. and the present one] we have described, we believe, all the tables of note, whether in history or practice, as far as general tables of pure mathematics are concerned. We have omitted those which relate only to astronomy, life contingencies, or any other special application of mathematics. Altogether, we have hrought forward about 318 tables, of which 221 have been taken from actual inspection, and the remainder from various authorities, very few indeed from one only. In Lalande's *Bibliographie Astronomique* there are 208 tables mentioned, *including astronomical ones.* In the Royal Society's Library the entries under tables, of every sort, mathematics, astronomy, navigation, geography, meteorology, &c. are 536 in number, including from the merest tide-table for one year up to the largest body of logarithms. And upon looking at the appearances which the different catalogues present, we do not find one in which 200, or even 100, tables of pure mathematics are mentioned as having undergone the actual inspection of the compiler. It would not, then, we suspect, he a very extensive undertaking to make as complete a list of tables of all kinds as can now be recovered; and the undertaker of it might expect to be able to verify about two out of three from inspection.

TACK is the technical term in Scotland for a lease, whether of lands or edifices; the rent is called the tack-duty, and the tenant tho tacksman. The Scottish system of leases having lately attracted some attention, and being intrinsically important, a separate sketch of its more prominent peculiarities seems to be requisite. The Scottish lease, however long its duration, is purely a contract, and does not partake—at least in questions betweon landlord and tenant—of the peculiarities of the feudal system. In early times it is possible to trace something like an inferior system of vassalage in the nature of the agriculturist's tenure. He held not as party to a contract, but by a unilateral conveyance from the landlord, called assedation. In Scotland, however, there was no permanent interruption of the legitimate system of subfeuing; and thus all descriptions of permanent estates could bo constituted in the land by the pure adaptation of the feudal usages. There was no temptation to convert the contract for the limited occupation and use of the land into a means of constituting a semi-proprietary right in it—of supplying with a lessee the place of a sub-vassal; and the system of leases, as one of mere letting and hiring, took its principles from the Roman contract of *locatio conductio.* The right of the lessee or tacksman was so purely personal that it was ineffectual against a party acquiring the lands by purchase from the lessor; and so early as 1449 a statute was passed, preserving the rights of 'the puir people that labouris the ground' against new owners. Leasehold rights, however, in questions of succession, and in the form of attachment, employable by creditors, have by usage come into the position of real or heritable property. In the times of rapid agricultural improvement, when farms were frequently taken on leases of fifty-seven years at a low rent, a virtual estate was created, the succession to which might for the time be more important than that of the ownership of tho land. Unless there be any specification to the contrary in the lease, such successions follow the rules applicable to landed property. It has been matter of much regret, that the system by which feudal rights in land may be subjected to real burdens, has not been extended to this species of property, so as to enable valuable leases to be burdened with a security for borrowed money, or a guarantee fund for provisions for children. The system of granting and recording public feudal titles not being available for this species of property, all attempt to accomplish this object, by the tenant assigning the lease and retaining possession as the assignee's sub-tenant, have been ineffectual against the rights of creditors. It has been frequently proposed to pass an act creating a system of registration of leases, and of burdens affecting them.

It is unnecessary to state very minutely the title which a person must have to enable him to grant a lease, the parties who may hold leases, or the nature of the titles which constitute an ordinary lease, as these hear a generic resemblance to the corresponding features of English law. Long leases however being the prominent feature of the Scottish system, those cases in which there is a restriction on granting them may be noticed. A person who has a life-rent interest is, in the general case, not entitled to grant a lease to last beyond his own life. Persons having the absolute administration of property, as trustees, corporations, &c., are entitled and bound to grant leases for such a period as is deemed necessary to good husbandry; and this period has, by usage, in the ordinary case, been fixed at nineteen years. There have been many questions as to the extent to which persons holding under entails may grant leases, because in many instances attempts have been made in this form to alienate a considerable estato in tho property, which have been challenged by successors. In the celebrated Queensberry case, leases granted for ninety-seven years, on a grassum (that is, a sum of money paid by the tenant on entering, like a fine in England), were found to be struck at by the entail as an attempt to alienate part of the property (2 Dow, 90). In later cases, leases of forty and thirty-one years have been found ineffectual. A lease of twenty-one years is the longest that has heen sanctioned by the courts where an heir of entail has shown that he has an interest to impugn the contract.

Writing is necessary to constitute a lease, although possession during the part that may remain over of a year begun, may ho held as a right from sufferance and acquiescence in its commencement. The proper form of the written agricultural lease has been an object of much attention by conveyancers, and there is a considerable degree of uniformity in the practice throughout the country. There are usually nineteen clauses, as follow:—1. *The Description of Parties.* 2. *The Destination,* in which the extent to which assigning or subletting is permitted or prohibited is set forth, and provision is made for the arrangements in case of the tenant's decease. 3. *Clause of Possession,* describing the subject let. 4. *Duration.* 5. *Reservation,* if there be any rights such as that to minerals or game reserved by the landlord. 6. *Landlord's Meliorations,* containing such obligations to improve the subject as the landlord undertakes. 7. *Warrandice,* or guaranteo of the title given to the tenant. 8. *Rent clause.* 9. *Tenant's Meliorations,* setting forth such improvements as the tenant undertakes. 10. *Preservation,* containing the tenant's obligation to keep the building, fences, &c. in repair. 11. *Insurance,* in which the tenant becomes bound to insure the buildings, crops, &c. against fire. 12. *Thirlage.* This clause, a remnant of feudal usages, is now comparatively rare—it binds the tenant to grind his corn at the mill of the over-lord. 13. *Management.* 14. *Bankruptcy,* providing in general for the landlord's resumption of the lease if the tenant becouo bankrupt. 15. *Removal,* by which the tenant engages to evacuate the premises at the prescribed term. 16. *Reference*, providing for arbitration of disputes. 17. *Mutual Performance*, indicating penalties to be paid by the party failing. 18. *Registration* for execution. [REGISTRATION, P. C. S.] 19. *Testing clause*, containing the formalities of the execution of the contract. Of these, the clause of management is the most important. It is now much doubted how far it is good policy to bind the tenant to the observance of a particular course of agriculture. In the highly improved districts, where very scientific farming is expected, the tenant is generally more capable than the landlord of estimating the value of improved systems. Agricultural chemistry, and other means of increasing the produce of the soil, are at present the object of much attention among farmers, and where tenants cannot alter a fixed routine without the risk of a law-suit, an embargo is laid on the practical application of improvements. The landlord's chief interest in any routine being followed, is simply the preservation of the land from deterioration towards the conclusion of the lease. On the subject of the usual provisions for management, Mr. Hunter says, 'In those districts where agriculture is best understood, the following are the ordinary rules of management during the currency of the lease:—1. White corn crops ripening their seeds shall never be taken from the same land in immediate succession. 2. A certain proportion shall be under turnips or plain fallow every year, and be sown to grass with the first corn crop after turnips or fallow. 3. No farm-yard dung or putrescent manure made from the produce of the farm, nor straw nor hay made from the natural herbage, shall ever be carried off the farm. It is sometimes added, that no turnips or rape or hay of any kind shall ever be removed or sold. And upon weak soils, it is sometimes required that no less than half of the turnips shall be eaten by sheep on the ground where they grow. 4. If the soil is not such as to admit of being ploughed and cropped every year, it is stipulated that a certain part or proportion shall be always in grass, and that land laid down to grass shall be, before being broken up again, two or more years in pasture. 5. During the first five or six years of a lease, the conditions are sometimes more special, obliging the tenant to have so much more in fallow or turnips every year, and so much more in grass, and also to leave the farm in a particular shape, so as to admit of the incoming tenant pursuing a correct rotation of cropping from his very entry. Or, 6. What is approved of by some agriculturists, it may be agreed that the lessee shall cultivate the lands according to the rules of husbandry, but with the addition of specific regulations applicable to the four or five last years of the lease. 7. Adherence to the course prescribed may be enforced by conditioning for payment of additional rent in the event of contravention, besides damages, and with a power to prevent further contravention, for which purpose power to make a summary judicial application is occasionally taken. Or, 8. Liberty may be given to the lessee to deviate from the prescribed course upon payment of an additional rent specified, which may be declared to be pactional and not penal, and not liable to judicial modification. 9. In some districts, though seldom in the most improved, there is occasionally a stipulation that the lessee shall himself reside upon and manage the farm.' (i. 369-370.)

(*A Treatise on the Law of Landlord and Tenant, with an Appendix containing Forms of Leases*, by Robert Hunter, Esq., Advocate, 2 vols. 8vo. 1845.)

TÆNIOI'DES, a family of Acanthopterygious fishes nearly allied to the Mackerels. The species comprising it are all long flattened fishes, with very small scales. The following are among the principal genera.

Lepidopus, tænioid fishes with elongated snouts, a wide gape, projecting under jaw, and strong sharp cutting teeth. The ventral fins are reduced to small scaly plates. The tail is well formed. The *Lepidopus argyreus* or scabbard-fish is an example. It is of a bright silver colour, and attains a length of six feet. It is one of the rarest of British fishes.

Trichiurus resembles the last genus in the character of the head, but has neither ventral nor caudal fins, the tail being represented by a long slender compressed filament. The *Trichiurus lepturus* of Linnæus, an inhabitant of the Atlantic, attains a length of more than 12 feet and resembles a beautiful silver riband.

Gymnetrus, the Deal fish, has a very small protractile mouth with small teeth. It has no anal fin, and the caudal is composed of few rays. The *Gymnetrus arcticus* is between four and six feet in length, but does not exceed a table-knife in thickness. An original description of it may be found in Dr. Fleming's 'British Animals.'

Cepola, the Ribbon or Band-fish, is a well known Mediterranean genus. The snout is short, the gape oblique, and the teeth well developed. The dorsal and anal fins are both long, and reach to the base of the caudal. The ventrals are moderately developed. The *Cepola rubescens*, a beautiful little fish about a foot long, and of a subpellucid carmine hue, is occasionally found on the southern coasts of Britain.

The genus *Lophotes* of Giorna has a short head with a bony crest bearing a long and stout spine. The caudal fin is distinct, but very small. The *Stylephorus* of Shaw is allied to *Gymnetrus*, but has the tail prolonged into a slender filament, exceeding the length of the body.

TÆNIO'PTERIS, a group of fossil ferns with broad ribband-like leaves. In the Oolitic series of Yorkshire and Scania. (Brongniart.)

TAGORE, DWARKANATH. [RAMMOHUN ROY, P. C. S.]

TAILZIE, in the law of Scotland, is the technical term corresponding with the English word Entail, which now generally supersedes it in colloquial use, even in Scotland. The early history of Entail law in Scotland in some respects resembles that of England, but in later times they diverged from each other. In Scotland there was no early effort, such as the statute of Westminster the Second (13 Edw. I.) favouring deeds appointing a fixed series of heirs, nor does there appear to have been on the part of the judges that inclination to permit perpetuities to be defeated by fictions which was shown in England. Devices however of a very similar character to those of the English statute were adopted to defeat attempts by holders under entail to use their lands as if they were absolute proprietors. The first and simplest restriction laid on the destined heirs of an entail was in the form of a mere prohibition, against contracting debt which might occasion the attachment of the estate by creditors, selling the property, altering the order of succession, and the like. A provision of this character, called the 'Prohibitive clause,' was however quite insufficient to accomplish the end; because if a creditor had really attached the estate for debt, or a person had bonâ fide purchased it, it was no ground for wresting the title out of his hands, that the proprietor was under a prohibition against permitting such occurrences. A second provision was added, called an Irritant clause, by which any right acquired contrary to the provisions of the entail was declared to be null. Still this did not effectually intimidate the holder under the entail from making efforts to break it, and did not give the next in succession a sufficient title to interfere. A third provision was added called the 'Resolutive clause,' by which the right of the person who contravenes the prohibition 'resolves' or becomes forfeited. It was provided by statute (1685, c. 22) that all entails should be effective which contain Irritant and Resolutive clauses, are duly recorded by warrant of the court of session in Registers of Entails, and are followed by recorded saisins containing the Prohibitory, Irritant, and Resolutive clauses. No attempts were made to counteract the Entail system by fictions of law, which are not in accordance with the genius of the law of Scotland, and it became a permanent feature in the institutions of the country. A sort of judicial war has however been carried on against Entails individually, which has been productive of a vast amount of litigation and strife, has occupied much judicial time, and has tended to place the titles of property in a precarious and doubtful position. An Entail is excluded from the favourable interpretation of the law. The interpretation of its clauses is to be what is termed *strictissimi juris*. The intention of the framer is never to be contemplated: every blunder is to be given effect to, and nothing is to be explained by reference to the context, if its own meaning as a sentence is doubtful. Thus, in a late case, those who held under an Entail were prohibited among other things from contracting debt to the effect of the estate being attached. The Irritant clause proceeded to say, 'if the heirs shall contravene the premises, by breaking the Tailzie, contracting of debts,' &c. (enumerating other contraventions), it was provided that 'then and in any of these cases, the said venditions, alienations, dispositions, infeftments, alterations, infringements, bonds, tacks, obligements, made to the contrair' should be null. It was found that proceedings by creditors to attach the estate for debt were good, because they were not by name enumerated among the things that should be null, though they were prohibited, and mentioned among the things which, if coming to pass, should cause a nullity. (*Duffus's Trustees* v. *Dunbar*, 28*th January*, 1842, 4 *D. B. M.* 523.) Some statutory enlargements have been made on the powers of persons holding under entail to provide for widows and younger children: but the system is still productive of great domestic inequality, and it is to be hoped that in no long time it will be swept away as an impediment to the improvement of the country and an injustice to the mercantile classes.

TAJURRAH is a sea-port in Africa, situated at the most western corner of the Gulf of Aden, in 11° 47′ N. lat. and 43° E. long. It is built on the northern shore of a bay, which extends several miles farther west, and is called the Bay of Tajurrah. The anchorage is of moderate extent, and large vessels must remain at some distance from the shore. It is secure, except during the north-western monsoon. The town lies at the base of a group of hills of moderate elevation, which run north and south, and are furrowed by narrow glens, which during the rainy season bring down a great volume of water. It contains about 300 houses and a population of 1200 or 1500 inhabitants. The houses are built of wooden framework, covered with matting. There are only a few stone houses in the town, and two mosques. As no cultivation is carried on in the vicinity of the town, the inhabitants are principally engaged in the trade in slaves and salt. The salt is obtained from the lake of Assal [ADAL, P. C. S., v. i. p. 34], and the slaves are brought to the place by the Dankali, or tribes that inhabit the country between the sea-port and Shoa. [ABYSSINIA, P. C. S., p. 20.] These articles go chiefly to Mocha and Hodeida; to Aden wool, sheep, goats, and butter are sent. There is no bazar in Tajurrah, but the common necessaries of life may be obtained in exchange for beads, buttons, fish-hooks, and tobacco. Water is plentiful, but grass is scarce, and fodder for horses is obtained with difficulty. The climate is very hot; during the last days of May the thermometer at noon ranges between 96° and 98°, but the heat is rendered less oppressive by the sea-breeze, which generally sets in about eleven o'clock of the morning. Almost all the inhabitants belong to the Dankali, and the governor of the town, who is styled sultan, is considered the chief of the whole nation. None of the Dankali tribes pay obedience to his orders, but they send him annually a present of two hundred head of cattle and camels. As this town is the nearest port to Shoa, and the British have entered into a closer connexion with the sovereign of that country since their occupation of Aden, it is hoped that Tajurrah will soon rise to greater importance. The British have also made a treaty with the Dankali and Somauli, and have acquired two larger islands, situated near the entrance of the Bay of Tajurrah, and a smaller one which lies farther within the bay; but we do not know if they are actually taken possession of and settled.

(Isenberg and Krapf's *Journals, detailing their proceedings in the Kingdom of Shoa*, &c.; Kirk's *Report on the Route from Tajurrah to Ankóbar; The Friend of Africa*, 1841.)

TALBOTYPE. [PHOTOGRAPHY, P. C. S.]

TALLOW (French, *suif;* German, *talg;* Italian, *sevo, sego;* Russian, *salo, toplenoe;* Spanish, *sebo*) is animal fat [FAT, P. C., p. 204] melted and separated from the fibrous or membranous matter which is naturally mixed with it. When pure, tallow is white, and nearly tasteless; but the tallow of commerce usually has a yellow tinge. It is divided, according to its qualities, into various kinds, of which the best are used for the manufacture of candles, and the inferior for making soap, greasing machinery, and some other purposes. Much tallow is used in the dressing of leather.

A very large proportion of the tallow used for making candles in this country is of home production, and, according to a paper on 'Artificial Light from Solid Substances, and the Manufacture of Candles,' published by Arthur Aikin, Esq., in the fifty-second volume of the 'Transactions' of the Society of Arts (part ii. pp. 123-127), is fitted for use by the *renderer*, who chops into pieces the fat and suet received from the butchers, and boils it in water, by which operation the greater part of the fat is melted out from the membranes, and floats to the top, whence it is removed by skimming. The remaining fat is subseqnently squeezed from the membranes by a powerful press, leaving the membranous matter in the form of a cake or block, of a dark colour, which is called *graves*, and which, when macerated in warm water, softens and swells, and becomes a wholesome and palatable article of food for poultry, dogs, and other domestic animals. It is said to be extensively used in fattening poultry for the market. Dr. Ure, in noticing this subject in his 'Dictionary of Arts,' &c., art. 'Candle,' styles the refuse membranous matter *cracklings;* states that the operation of rendering should he performed as speedily as possible after the removal of the fat from the carcass, because the fibrous and fleshy matter mixed with it tend to promote putrefaction; and directs that the liquid tallow be strained through a sieve into a second copper, and there treated with water at a boiling temperature to wash it.

Almost all our imported tallow is brought from Russia, where this article is produced in enormous quantities. Kohl, in his work on that empire, gives a graphic account of this great branch of industry, from which (using the abridged translation, published in Chapman and Hall's 'Foreign Library,' 1842, pp. 501-503), we condense the following particulars: — The exports of St. Petersburg, he states, are estimated to amount to about 120,000,000 of rubles (the ruble being, according to MONEY, P. C., p. 325, worth 3*s.* 1*d.*) annually, of which one-third consists of tallow; while the value of the exports of this article from other Russian ports is probably about 30,000,000 more. For these 70,000,000 of rubles about 250,000,000 of lbs. of tallow are furnished to the rest of the world, providing the chief supply of soap and candles to England, France, Germany, Scandinavia, Italy, and the other countries of Europe; and this is all in addition to the large quantity consumed by the Russians themselves. Nearly the whole of this enormous quantity is furnished hy the Pontine steppes, in the southern part of European Russia. 'At present,' observes Kohl, 'the large tallow-manufactories, or *Salgans*, as they are called, are exclusively in the hands of the natives of Great Russia, who have their establishments in all parts of the steppe.' They huy the cattle by hundreds and thousands, and after fattening them for a season, drive them to the salgans to be slaughtered; and Kohl states, that if the season proves tolerably moist, so that the cattle may fatten well, the speculation is productive, but that a long-continued drought is ruinous in its consequences, the tallow-boilers remaining empty, and the meagre oxen having nothing but their skins wherewith to remunerate the speculators. 'After such a season,' he adds, 'the owners of the salgans usually close their books, and declare themselves insolvent, for they are seldom possessed of much capital, and generally carry on their operations with the money advanced by the merchants of the sea-port towns.'

The salgans, to which the tallow-boilers usually begin to drive their oxen in small numbers towards the close of summer, generally consist of a spacious court-yard surrounded by the buildings necessary for the manufacture, embracing shambles for slaughtering the oxen, houses containing enormous boilers to boil down the flesh, places for salting the hides, and counting-houses and dwellings for the workmen. In the summer these establishments are untenanted, excepting by dogs and birds of prey, which hover about all the year round, attracted by the nauseous smell, which, however alluring to them, is described as being infinitely disgusting to a visitor, and evidently distressing to the oxen. They seem, according to our informant, as if conscious of their approaching fate, and become so restless as they approach the salgan, that it is often necessary to drag them to it by main force, notwithstanding the device of mixing with the herd, as decoys, a few tame oxen accustomed to the place, and trained to the service. About a hundred oxen are driven into the court-yard at once, and of these twenty or thirty are conducted immediately to the slaughterhouse, where six or eight hutchers are kept constantly at work, in the midst of stench and filth which Kohl describes as exceeding anything that the mind can imagine. The business is generally carried on during the rainy season; and, owing to the utter absence of provision for cleanliness, 'the whole salgan is soon converted into a swamp of blood and mud,' the smell of which is never removed by the rigours of the winter or the storms of the spring. It appears also that the actual slaughtering is performed in so rude and unartificial a manner as to occasion much needless suffering to the beasts.

After the carcasses are skinned, three or four poods of flesh are cut off from the loins and back, for sale in the bazaar as meat, there being little fat in those parts of the body; but owing to the barbarous method of slaughtering, this meat is so much injured that none but the poor will buy it. The remainder of the carcass is cut up, and everything, excepting the intestines, which are given to the pigs (of which a considerable number are always kept at the salgan to fatten during the season), is thrown into the boilers, of which there are from four to six in every salgan, each large enough to contain the flesh of ten or fifteen oxen. A little water is put into the boiler, to prevent the 'soup,' as its contents are termed, from burning. The fat, as it collects at the top, is skimmed off with large ladles; and before it is quite cold it is poured into the casks in which it is afterwards shipped. The first fat which comes off is the best, and is quite white, while that which follows has a yellowish tinge. When there are not sufficient casks at hand, the hides of the slaughtered oxen are sewn up, and the tallow is poured into them, 'till,' our author observes, 'the whole assumes again a form something like that the animal wore when living. Of these tallow-stuffed oxen,' he adds, 'a large number are usually seen standing about the salgans.'

A further supply of fat, but of very inferior quality, is subsequently obtained by subjecting the mash of bones and flesh to huge presses. This tallow, which is rarely exported, is of a dark brown colour, and is used for greasing wheels and for other coarse purposes.

An ox in good condition, it is stated, will yield from seven to eight poods (250 to 290 lbs.) of tallow, which is generally worth from eleven to fifteen rubles a pood. The article is always so greatly in demand, that the merchants often pay part of the price for it while the oxen are yet grazing on the steppes; and the singular appearance of the salgans is heightened by the number of merchants and their clerks in attendance upon them; while the steward of the estate on which the oxen have fattened comes to receive his rent; the workmen for their wages; cattle-dealers to contract for further supplies of oxen, while perhaps some merchant is standing by, eager to secure and advance money for the tallow to be produced by them; and 'a colonist comes in to bargain for the fattening of some 200 hogs, which he afterwards receives back walking masses of hog's-lard, too yellow and coarse however for the market, till the grunters have been a little refined by sundry good feeds of corn.' Sometimes a wealthy nobleman, possessing oxen, but no tallow-making establishment of his own, makes his appearance to farm a salgan for a few weeks, while other persons visit the place to buy the refuse-meat for feeding pigs on the steppe, or to bargain for the horns and hides. 'The Turkish captains come eagerly to obtain the tallow in its greatest purity at the fountain-head, for tallow is too much esteemed by the gourmands of Constantinople to be idly wasted in enlightening their darkness; in short, however busily death may be at work, there is, meanwhile, no want either of life or bustle in the salgan.'

Notwithstanding the nature of the employment, there are always plenty of hands found to seek engagements in the salgans, the wages being high. The workmen usually earn about 70 or 80 rubles per month during the season, which lasts about twelve or thirteen weeks. In the neighbourhood of Odessa, Kohl states, there are seven salgans, in which probably 25,000 oxen are killed every year, besides countless numbers of sheep. In the vicinity of Kherson, Taganrog, Nikolayeff, Saratoff, Kisheneff, and other places, he adds, they will be found on an equally large scale.

From details quoted in M'Culloch's 'Dictionary of Commerce,' from a work by Borrisow on the commerce of St. Petersburg, it appears that the merchants of that city divide the tallow which they receive from the interior into white and yellow candle-tallow, and common and Siberian soap-tallow; the latter, which is considered the best tallow for soap-making, being brought by several rivers from Siberia to the lake Ladoga, and thence to the Neva by the canal of Schlusselburg. An *ambare*, or warehouse, is appropriated to the reception of the tallow on its arrival, in which it is selected and assorted (or *bracked*) according to quality, after which the casks are marked with the quality, the date of the selection, and the name of the *bracker* or selector. The white tallow is usually brought in conical casks, 2½ feet in diameter at the largest and 1½ at the smallest end; but the yellow tallow is commonly in casks of the more usual shape. 'Yellow candle-tallow, when good,' according to this authority, 'should be clean, dry, hard when broken, and of a fine yellow colour throughout. The white candle-tallow, when good, is white, brittle, hard, dry, and clean. The best white tallow is brought from Woronesch.' Soap-tallow however is said to be better the more greasy and yellow it is. M'Culloch states that 120 poods of tallow, gross weight (of which the cask is usually about 10 per cent.), make a Petersburg last, and 63 poods an English ton.

In his account of the candle-manufacture, referred to at the commencement of this article, Mr. Aikin refers to the practice of mixing different kinds of tallow together according to the quality of candles required, but does not give any directions for the mixture; but it is stated in the article 'Candle,' in the 'Encyclopædia Britannica,' that one-half of sheep's and one-half of bullock's tallow should be used, and that hog's tallow should be avoided, because it would make the candles gutter, give an offensive smell, and produce a thick black smoke; and Dr. Ure states that 'mutton-suet, with a proportion of ox-tallow, is selected for mould candles, because it gives them gloss and consistence. When weighed in due proportions, and cut up into small pieces that it may melt the more readily, the tallow is, according to Aikin's account, put into a boiler with some water, which tends to prevent its becoming over heated, and melted at a temperature of about 90°. Some water is then sprinkled upon it, which has the effect of causing such dregs and impurities as may have escaped the skimmer to sink to the bottom, after which the clear tallow is let out by a cock into suitable vessels, and when sufficiently cooled, but while yet retaining its perfect transparent fluidity, it is fit for use. Different kinds of tallow melt and retain their fluidity at very different degrees of temperature; the fat which is deposited about the kidneys being, in all animals, harder than that found in the cells of the bones, and especially than the half-oily fat found in the muscles and other soft parts; while the fat of some animals is harder than that of others—that of the sheep and deer, for example, congealing much sooner than that of the ox or horse. According therefore to the different kinds of fat which may enter into its composition, tallow will be found to vary considerably in fusibility; but 92° is the heat generally given as its melting-point, though Aikin states that he had seen a boiler-full of tallow perfectly fluid at 72°, and even then not sufficiently cooled to be made into candles; nor was this case, he observes, considered remarkable; 'whence we may conclude that tallow, made into candles and exposed to the air, loses much of its fusibility.' The author of the article above referred to in the 'Encyclopædia Britannica,' observes that no water should be mixed with the tallow for the first three dips, lest the candle-wicks, being quite dry, should imbibe it, and thus cause the candles to sputter in burning. He adds that in removing the melted tallow from the boiler to the tub or vessel in which the candles are dipped, it may be passed through a coarse horse-hair sieve, to purify it the more perfectly; and that it may be used after standing three hours, and will continue fit for use about twenty-four hours in summer and fifteen hours in winter.

The mode of manufacturing both dip and mould candles being described under CANDLE, P. C., p. 236, we need only, upon this subject, refer to a fuller account of the process, illustrated with engravings of some of the machinery employed in an extensive candle-factory, including one by which the operation of dipping is so facilitated as to enable a man and a boy to make nearly 26,000 candles, of twelve to a pound, between six o'clock in the morning and four in the afternoon, in the 'Penny Magazine,' No. 631, description of 'A Day at a Soap and Candle Factory.'

'A recently made candle of good quality,' observes Aikin, 'is of a yellow colour, is soft, and will be found to spit or sputter when set fire to, and to give a comparatively feeble light, the two latter qualities showing that it contains a little water.' 'If kept three or four months,' he proceeds, 'in a box placed in a cellar (for the presence of the sun's light is by no means necessary), the candle will be found bleached both inside and outside, will be harder than at first, and will now burn with a clear flame undisturbed by any sputtering. It is evident therefore that the water has been evaporated, and it is also extremely probable that the water, or the air which the water holds in solution, has acted chemically on the tallow, bleaching and at the same time hardening it.' 'This bleaching process,' he adds, 'goes on slowly in a cold and damp atmosphere; it being found that autumn-made candles hardly ever bleach to a good colour, although in three or four months they are fit for use. Candles made in March bleach the best of any, for the three or four months during which they are kept in the manufacturer's store are usually dry and warm.'

Tallow-lamps, as well as some recent improvements in candles and candle-lamps, are treated of under LIGHTS, ARTIFICIAL, P. C. S., p. 203.

TANACE'TUM, a genus of plants belonging to the natural order Compositae and the sub order Corymbiferae. The florets of the disk hermaphrodite, the involucre hemispherical imbricated, the receptacle naked, the fruit oblong and angular, with a large epigynous disk crowned with a slight membranous border.

T. vulgare, Tansy, has pinnatifid leaves and serrated leaflets. The heads in a terminal corymb. The florets of a bright yellow. The fruit with an entire crown. The stem is from 1½ to 3 feet high, erect, and rather angular. The root moderately creeping. Every part of the plant is bitter, and emits a strong but not unpleasant scent. It is considered tonic and cordial, and has been administered as a medicine in cases of worms and hysteria. It is also said to be of use in gout. It does not however suit every stomach. Withering says if meat be rubbed with tansy leaves the flesh-fly will not touch it. This plant is found by roadsides all over Europe and the Crimea.

(Lindley, *Flora Medica;* Babington, *Man. Brit. Botany.*)

TARA'NTULA, the *Aranea tarantula* of Linnæus, a species of spider of the genus *Lycosa* of Latreille. It is one of the largest of European spiders, and is found in the countries bordering the Mediterranean, where its bite is dreaded, and believed to be curable only through the effects of music. In reality, however, its venomous powers have been greatly exaggerated. According to Walckenaer, several distinct species have been confounded under the name of *Tarantula*.

TARIFF, a table of duties payable on goods imported into or exported from a country. The principle of a tariff depends upon the commercial policy of the state by which it is framed, and the details are constantly fluctuating with the change of interests and the wants of the community, or in pursuance of commercial treaties with other states. The British tariff underwent six important alterations from 1772 to 1842; namely, in 1787, in 1809, 1819, 1825, 1833, and 1842. The act embodying the tariff of 1833 is the 3 & 4 Wm. IV. c. 56. Its character has been described in the Report of a Committee of the House of Commons in 1840, on the Import Duties, as presenting 'neither congruity nor unity of purpose. No general principles seem to have been applied. The tariff often aims at incompatible ends: the duties are sometimes meant to be both productive of revenue and for protective objects, which are frequently inconsistent with each other. Hence they sometimes operate to the complete exclusion of foreign produce, and in so far no revenue can of course be received; and sometimes, when the duty is inordinately high, the amount of revenue becomes in consequence trifling. An attempt is made to protect a great variety of particular interests at the expense of the revenue and of the commercial intercourse with other countries.' The schedules to the act 3 & 4 Wm. IV. c. 56, contain a list of 1150 articles, to each of which a specific duty is affixed. The unenumerated articles are admitted at an *ad valorem* duty of 5 and of 20 per cent., the rate having previously been 20 and 50 per cent. In 1838-9, seventeen articles produced 94½ per cent. of the total customs' duties, and the remainder only 5½ per cent., including twenty-nine, which produced 3$\frac{9}{10}$ per cent. The following table of the tariff of 1833, showing the duties received in 1838-9, is an analysis of one prepared by the inspector-general of imports for the parliamentary committee to which allusion has been made:—

	No. of Articles.	£
1. Articles producing on an average less than 24*l*.	349	8,050
2. Ditto less than 240*l*.	132	31,629
3. Ditto less than 713*l*.	45	32,056
4. Ditto less than 2,290*l*.	107	244,933
5. Ditto less than 22,180*l*.	63	1,397,324
6. Ditto less than 183,864*l*.	10	1,838,630
7. Ditto less than 2,063,885*l*.	9	18,575,071
		Excess of drawback
8. Articles on which no duty has been received	147	5,398
	862	22,122,095

In 1840 Mr. Porter, of the Board of Trade, in his evidence before the Parliamentary committee on import duties, showed that out of a total amount of 22,962,610*l*. of Customs-duties received in 1839,

17 articles produced 94½ per cent. or	£21,700,630
29 articles produced 3$\frac{9}{10}$ per cent. or	898,661
46 articles produced 98⅖ per cent. or	£22,599,291

In 1842 Sir Robert Peel effected some improvements in this system, which were carried into effect by 5 & 6 Vict. c. 47. This act reduced the duty on about 750 different articles on which the receipts had amounted to about 270,000*l*. The general principle of the measure was to reduce the duty on raw materials to about 5 per cent., to limit the highest duty on partially manufactured materials to 12 per cent., and on complete manufactures to about 20 per cent. The number of articles in the tariff was now reduced to 813. Foreign horned cattle, sheep, goats, swine, salmon, soles, and other fish, and fresh beef and pork, which had been prohibited formerly, were admitted on paying a duty under the tariff of 1842. In 1844 the duty on foreign wool was abolished. In 1845 Sir Robert Peel effected further improvements in the tariff by abolishing the duty on cotton wool (about 680,000*l*.), and on 430 other articles, on which the duty amounted to 320,000*l*. By this plan expenses of warehousing are saved [WAREHOUSING SYSTEM, P. C.], and a number of troublesome accounts and impediments to business are got rid of; but for statistical purposes the customs department retains the power of examining articles which do not pay duty. The paramount object of the tariff reform of 1845 was to encourage the abundance and cheapness of raw materials of manufacture. In the same year, by an act (8 Vict. c. 7) 'to repeal the Duties of Customs due upon the Exportation of certain Goods from the United Kingdom,' the duties on the exportation of coals, culm, &c. are wholly repealed.

Caps. 84 to 94 of the 8 & 9 Vict. are all acts relating to Customs, Trade, and Navigation, and they all came into operation on the 4th of August, 1845. Cap. 84 is 'An Act to repeal the several Laws relating to Customs,' by which 26 acts were repealed. Cap. 85 is 'An Act for the Management of Customs,' and regulates the appointment and duties of officers, the taking of land for warehouses, &c. Cap. 86 is 'An Act for the general Regulation of Customs,' and relates to landing, warehousing, and custom-house entries. Cap. 87 is 'An Act for the Prevention of Smuggling,' and specifies the acts which constitute smuggling, and the penalties. Cap. 88 is 'An Act for the Encouragement of British Shipping and Navigation,' giving, with exceptions which are specified, certain privileges to British ships over foreign ships. Cap. 89 is 'An Act for the Registering of British Vessels.' Cap. 90 is 'An Act for granting Duties of Customs,' and imposes duties upon certain articles. (These duties are referred to in the preamble of the Tariff Act (9 & 10 Vict. c. 23) hereafter mentioned.). Cap. 91 is 'An Act for the Warehousing of Goods.' Cap. 22 is 'An Act to grant certain Bounties and Allowances of Customs,' which is confined however to refined sugar. Cap. 93 is 'An Act to regulate the Trade of British Possessions abroad.' Cap. 94 is 'An Act for the Regulation of the Trade of the Isle of Man.'

On the 26th of June, 1846, the royal assent was given to Sir Robert Peel's last tariff, which carries out still farther the principles of free trade by a total repeal of several important duties, and by a great reduction of numerous others. It is entitled 'An Act to alter certain Duties of Customs' (9 & 10 Vict. c. 23).

On the same day (June 26, 1846) the royal assent was given to the act for repealing the duties on the importation of foreign corn. It is entitled 'An Act to amend the laws relating to the Importation of Corn' (9 & 10 Vict. c. 22). By this act certain reduced 'sliding scale' duties are substituted for those of 1842, and they are to continue till Feb. 1, 1849, when all duties on the importation and entry for home consumption of corn, grain, meal, and flour, in the United Kingdom and in the Isle of Man, are repealed, with the exception of 1*s*. per quarter on all wheat, barley, bear or bigg, oats, rye, peas, and beans, merely for the purpose of registration of the quantities imported. The duties on all wheat-meal and flour, barley-meal, oat-meal, rye-meal and flour, pea-meal, and bean-meal are to be 4½*d*. for every hundred-weight.

The sliding-scale duties of 1842 (5 & 6 Vict. c. 14) are given under WHEAT, P. C., p. 305. The duties of 9 & 10 Vict. c. 22 are as follows:—

	s.	*d.*
Wheat, per quarter, under 48*s*	10	0
48*s*. and under 49*s*.	9	0
49*s*. and under 50*s*	8	0
50*s*. and under 51*s*.	7	0
51*s*. and under 52*s*.	6	0
52*s*. and under 53*s*.	5	0
53*s*. and upwards	4	0
Barley, bear, or bigg, per quarter, under 26*s*.	5	0

	s.	d.
Barley, 26s. and under 27s.	4	6
27s. and under 28s.	4	0
28s. and under 29s.	3	6
29s. and under 30s.	3	0
30s. and under 31s.	2	6
31s. and upwards	2	0
Oats, per quarter, under 18s.	4	0
18s. and under 19s.	3	6
19s. and under 20s.	3	0
20s. and under 21s.	2	6
21s. and under 22s.	2	0
22s. and upwards	1	6

On rye, peas, and beans the duty is equal in amount to the duty payable on barley. But there appears to be some blunder here, for the duty on rye, peas, and beans being regulated by the duty on barley, is regulated by the price of barley, and not by the price of rye, peas, and beans. The consequence of this is that when barley is under 26s. the quarter, and is paying 5s. duty, rye, peas, and beans will pay 5s. dnty, whatever their respective prices may be; and they will only pay the lowest duty of 2s. per quarter when barley is 31s. and upwards the quarter. (See 'Economist' Newspaper, Juno 4th and 11th, 1846.) The duties payable on all flour and meal, as above enumerated, until the 1st February, 1849, are enumerated in the schedule to the act. The average price, both weekly and aggregate, of all British corn is to continue to be made up according to 5 & 6 Vict. c. 14.

Of the exemptions from duty and reductions of duty made by the last tariff act (9 & 10 Vict. c. 23), it will suffice to mention a few of the most important.

No duties are chargeable on the following living animals:—oxen and bulls, cows, calves, horses, mares, geldings, colts, foals, mules, asses, sheep, lambs, swine and hogs, sucking-pigs, goats, kids.

No duties are chargeable on bacon, beef fresh or slightly salted, beef salted, not being corned beef, meat fresh or salted, not otherwise described, pork fresh or salted (not hams), potatoes, all vegetables not otherwise enumerated or described, hay, hides, and some other articles slightly wrought, and a few wholly manufactured.

Of the reduced duties the following are the most important: —ale and beer of all sorts, 1*l.* the barrel; arrow-root, 2*s.* 6*d.* the cwt., and if from a British possession 6*d.* the cwt.; pearled barley, 1*s.* the cwt., and if from a British possession, 6*d.* the cwt.; buckwheat, 1*s.* the quarter; butter, 10*s.* the cwt., and if from a British possession 2*s.* 6*d.* the cwt.; tallow-candles, 5*s.* the cwt.; cheese, 5*s.* the cwt., and if from a British possession 2*s.* the cwt.; cured fish, 1*s.* the cwt.; hams of all kinds, 7*s.* the cwt., and if from a British possession 1*s.* 6*d.* the cwt.; men's hats, 2*s.* each; men's boots, 14*s.* the dozen pairs; men's shoes, 7*s.* the dozen pairs; women's boots and shoes, from 4*s.* 6*d.* to 7*s.* 6*d.* the dozen pairs, according to kinds, as described; maize or Indian corn, 1*s.* the quarter; potato flour, 1*s.* the cwt.; rice, 1*s.* the cwt., and if from a British possession 6*d.* the cwt.; sago, 1*s.* the cwt.; tallow, 1*s.* 6*d.* the cwt.

The duties on manufactured goods of brass, bronze, china-ware, copper, iron, and steel, lead, pewter, tin, woollen, and cotton, are 10*l.* for every 100*l.* value. On silk manufactures the duties are about one-third higher, or 5*s.*, 6*s.*, and 9*s.* the lb., according to kinds, as described, or 15*l.* on every 100*l.* value.

The duty on foreign spirits of proof strength is 15*s.* the gallon.

The duty on foreign solid timber, from and after April 5, 1847, is 1*l.* the load of 50 cubic feet; from and after April 5, 1848, the duty is 15*s.* the load. On deals or boards, the duty, from and after April 5, 1847, is 1*l.* 6*s.* the load; from and after April 5, 1848, it is 1*l.* the load. Tho Tariff of 1842 is not altered with respect to timber imported from a British possession, which is still 1*s.* the load of solid timber, and 2*s.* the load of sawn timber.

The dnties on coffee and tea are not altered by the tariff.

Sugar Duties.—On the 18th of August, 1846, the royal assent was given to an Act (9 & 10 Vict. c. 63) 'for granting certain Duties on Sugar and Molasses.' By this Act the previous distinctions between free-labour and slave-labour are abolished, the former duties on sugar and molasses are repealed, and the following duties levied:—

From and after the passing of the Act,—

On sugar or molasses the growth and prodnce of any British possession in America, or of any British possession within the limits of the East India Company's Charter, into which the importation of foreign sugar is prohibited, and imported from thence, the duties following:—

	£.	s.	d.
Candy, brown or white, double refined sugar, or sugar equal in quality to double refined, per cwt.	1	1	0
Other refined sugar, or sugar rendered by any process equal in quality thereto, per cwt. . .	0	18	8
White clayed sugar, or sugar rendered by any process equal in quality to white clayed, not being refined, per cwt.	0	16	4
Brown sugar, being Muscovado or clayed, or any other sugar, not being equal in quality to white clayed, per cwt.	0	14	0
Molasses, per cwt.	0	5	3

And from and after the respective days next hereinafter mentioned,—

On Sugar or Molasses the Growth and Produce of any other British Possession within the Limits of the East India Company's Charter:—

—	From passing of Act to 5 Joly, 1847.	5 July, 1847, to 5 July, 1848.	5 July, 1848, to 5 July, 1849.	5 July, 1849, to 5 Jaly, 1850.	5 July, 1850, to 5 July, 1851.	From and after 5 July, 1851.
	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.	
Candy, brown or white, double refined sugar, &c., per cwt.	1 8 3	1 5 8	1 4 4	1 3 3	1 2 0	The same Duties as on Candy, Sugar, and Molasses, the Produce of other British Colonies.

Molasses, per cwt. . .	0 7 10	0 7 6	0 6 11	0 6 4	0 5 9	

And also from and after the passing of this Act,—

On all foreign sugar or molasses not otherwise charged with duty, the duties following:—

	£.	s.	d.
Refined sugar, or sugar candy, per cwt. . .	3	3	0
Brown Muscovado or clayed sugar, not being refined, per cwt.	2	2	0
Molasses, per cwt.	0	15	8

TARRUNTE'NUS PATERNUS, a Roman jurist, was Praefectus Practorio under Commodus, by whom he was put to death. (Lamprid., *Commod.* 4.) He wroto four books De Re Militari, from which there are two excerpts in the Digest. He is mentioned by Vegetius (*De Re Militari*, i. 8).

TARTASH TAGH, or TARTASH-I-LING, is the Turkish name for that mountain-system, which, by the Chinese, is called Thiung-ling, and on our maps Bolor Tagh or Beluth Tagh. These mountains separate Chinese Turkistan, or the province of Thian-shan-nanlu, from Uzbeck Turkistan, or Turan. At their southern extremity they are connected with the two mountain-systems of the Himalaya and Hinducoh Range, and the point where the Tartash-i-ling branches off from them is considered as the place where the two last-mentioned ranges are separated from each other. This place occurs near 35° N. lat., and between 74° and 75° E. long., between Chitral and Gilgit, where a high mountain-mass, the Tutucan Mutcani, rises to nearly 18,000 feet above the sea-level, and some thousands above the snow-line. From this point the mountain-mass extends in a north-by-west direction to 45° N. lat., where its northern prolongation is known by the name of Kosy-urt; it lies between 70° and 71° E. long.

This mountain-mass is of great width, occupying between the parallels above mentioned all the countries which lie between 70° and 75° E. long. But we are not exactly acquainted with the places where its declivities terminate in the plains on the east and west, as these countries are very difficult of access to Europesn travellers, a few of whom only have reached them. A great portion of these mountains appears to be elevated above the snow-line. This is especially the case with an immense snow-region, which occurs between 35° 30′ and 36° 30′ N. lat., and which goes by the name of Puschtikur. It is considered one of the most extensive snow-regions on the surface of the globe. North of this remarkable region is a depression in the range, in the middle of which is a large alpine lake, called Sir-i-kol, in which the river Oxus originates; it runs out from its western extremity. This lake has the form of a crescent, and is about fourteen miles long from east to west, with an average width of one mile. On three sides it is bordered by swelling hills, about five hundred feet high, but along its southern banks they rise into mountains 3500 feet above the lake. As the lake is 15,600 feet above the sea-level, their summits attain more than 19,000 feet. North of this lake lies an immense table-land, which is called Pamir, or, in the emphatic language of the natives, Bam-i-Dúniah (the Roof of the World). In these parts several large alpine lakes are stated to occur, but we are not acquainted with their true position, nor with their extent. In 41° N. lat., the Bolor Tagh crosses the mountain range, which is called Thianshan, and which runs from west to east. That portion of the last-mentioned range, which lies west of the Bolor Tagh, is called Asferal Tagh, or Ak Tagh, and that on the east Tereck Tagh. In these parts the Bolor Tagh appears to be less elevated, so as to permit a passage over it, which connects Chinese Turkistan with Turan; but the mountains even here are always covered with snow. It is also stated that several snow-capped summits occur in the northern prolongation of the range, the Kosy-urt.

In the numerous valleys which open into the adjacent plains, and generally run east and west, different kinds of grain are cultivated. In the valley of Wakhan (37° N. lat.) wheat is grown at an elevation of 10,000 feet above the sea-level, whilst in the Alps it does not succeed in Engadin, at a height of 6000 feet. These valleys are inhabited on the western declivity of the mountain system by Tadjicks, or descendants of the ancient Persians. On the eastern declivity they are in possession of a population of Turkish origin, the Kirghiz. They are of the same stock as the numerous tribes which, under the name of Kirghiz Kaisak, wander about in the wide desert plains which lie on the east and north of the Aral and Caspian seas. They appear also to be closely allied to the Uzbecks, as, according to the statement of Lieut. Wood, their language differs only in a trifling degree from that spoken in Kunduz. This bold traveller describes these mountaineers as being of a middle size, varying between five feet two inches to five feet five and a half inches in height. Their countenance is disagreeable. The upper part of the nose sinks into the face, leaving the space between their deeply seated and elongated eyes without the usual dividing ridge; the brow immediately above the eye is protuberant, but slants back more abruptly than in Europeans; their cheeks, large and bloated, look as if pieces of flesh had been daubed upon them. They have little beard, and with those individuals who have a more luxuriant growth of hair, both beard and whiskers have a close natural curl. Their persons are not muscular, and their complexion is darkened by exposure to weather rather than by the sun. The women are rather good-looking, having a small and delicate form and fair complexion. The Kirghiz roam about in this mountain-region with their herds and flocks, like the Laplander, descending during the winter to the lower parts, and visiting in summer the upper declivities of the mountains. Their wealth consists of sheep, camels, and yaks. The camels have two humps, and Lieut. Wood thinks that this mountain-region is the true native country of these animals, which are called Bactrian camels. The yaks still less than the rein-deer cannot bear a considerable degree of heat, and live always near the places which are covered with snow. The Kirghiz of this mountain-region acknowledge allegiance to Kokand, and pay a nominal tribute to its ruler, but with China and Tibet they are constantly at feud, and they rob all parties from both countries.

We know very little of the mineral wealth of the Bolor Tagh. Gold and silver are said to be found. In the sand of the Oxus gold is found in abundance, and in some parts of its lower course it is washed; it is probably brought down from this region. In Shagnan, a country lying on the western declivity of the mountains, are rich mines of rubies, and deposits of salt occur at many places.

Two commercial roads cross this mountain-region from east to west, connecting Chinese Turkistan with Turan. They enter into the western plains by the valleys of the two great rivers Oxus and Jaxartes (Sir-Diria). The southern unites the Chinese town of Yarkand with Kunduz and Balkh. Leaving Yarkand it gradually ascends the valley of one of the tributaries of the Yarkiang-osteng river, and after passing the crest of the mountains near the lake of Sir-i-kol it descends through the valleys of Wakhan [WAKHAN, P.C.S.] and Badakshan to Kunduz. This road does not appear to be much frequented. The northern road runs from Kasghar in Chinese Turkistan to Kokand and Taschkand. After leaving the first named place it follows the valley of the Kasghar-diria, or river of Kasghar to its source, then turns northward, passing over the crest of the Tereck Tagh to Osch, in the valley of the Sir-diria, and crossing again the northern prolongation of the Bolor Tagh, it reaches Kokand. Numerous caravans pass along this road, and exchange the goods of Chinese Turkistan for those of Bokhara and the other countries of Turan.

(Elphinstone's *Account of the Kingdom of Cabul and its Dependencies*; Burnes' *Travels into Bokhara*; Wood's *Journey to the Source of the River Oxus*; and Humboldt's *Central Asia*.)

TAXATION, LOCAL. There was published, under the direction of the Poor-Law Commissioners in 1846, a valuable work entitled 'The Local Taxes of the United Kingdom, containing a Digest of the Law, with a Summary of Statistical Information concerning the several Local Taxes in England, Scotland, and Ireland.' England includes England and Wales. It is remarked in the Introduction that 'these local taxes are of two kinds: the rates raised in defined districts; and the tolls, dues, and fees paid for particular services or on certain occasions. But those rates only will be here noticed which are authorised by general statutes or the common law; excluding such as derive their origin from special or local Acts.' The rates are divided into three classes:—I. Rates of independent districts, on the basis of the poor-rate. II. Rates of independent districts, not on the basis of the poor-rate. III. Rates of aggregate districts on the basis of the poor-rate. No. I. comprehends—1, the Poor Rate; 2, the Workhouse Building Rate; 3, the Survey and Valuation Rate; 4, the Jail Fees' Rate; 5, the Constables' Rate; 6, the Highway Rates (three); 7, the Lighting and Watching Rate; the Militia Rate. No. II. comprehends—1, the Church Rates (three); 2, the Sewer* Rate; 3, the General Sewers' Tax; 4, the Drainage and Inclosure Rates; 5, the Inclosure Rate; 6, the Regulated Pasture Rate. No. III. comprehends—*Counties:* 1, the County Rate; 2, the Police Rate; 3, the Shire Hall Rate; 4, the Lunatic Asylum Rate; 5, the Burial Rate. *Hundreds:* 6, the Hundred Rate. *Boroughs:* 7, the Borough Rate; 8, the Watch Rate; 9, the Jail Rate; 10, the Prisoners' Rates; 11, the Lunatic Asylum Rate; 12, the Museum Rate. *Counties and Boroughs:* 13, the District Prison Rates.

The head of Tolls, Dues, and Fees, comprehends—1, Turnpike Tolls; 2, Borough Tolls and Dues; 3, Light Dues; 4, Post Dues; 5, Church Dues and Fees; 6, Marriage Fees; 7, Registration Fees; 8, Justiciary Fees.

The following statement is given in the work published under the direction of the Commissioners, as an approximate summary of the present annual amount of the local rates in England and Wales (p. 178):—

The Parish Rates:—	
Poor-rate, including the Workhouse Building Rate, and the Survey and Valuation Rate.	
Relief of the Poor	£4,976,093
Other objects	567,567

* The 3 & 4 Wm. IV. c. 22, the chief provisions of which act have been stated under SEWERS, P.C., was amended by 4 & 5 Vict. c. 45.

Contributions to County and Borough Rates	See below
The Jail Fees' Rate	Unknown
The Constables' Rate	do.
The Highway Rates	£1,312,812
The Lighting and Watching Rate	Unknown
The Militia Rate	Not needed
The Church Rates	406,812
The Sewer Rate, and the General Sewers' Tax—	
In the Metropolis	82,097
In the rest of the country	Unknown
Drainage and Inclosure Rates, The Inclosure Rate, The Regulated Pasture Rate	Unknown
The County Rates, The Hundred Rate, The Borough Rate } Contributed from the Poor-Rate	1,356,457
	£8,801,838
Tolls, Dues, and Fees	2,607,241
	£11,409,079

Some of the taxes are regularly increasing, and the produce of some, as appears from this table, is not known. It is assumed that the Local Taxation of England and Wales may be in round numbers twelve millions; but this estimate, as already shown, does not include the sums raised under special or local acts, of the amount of which sums no estimate can be formed.

A century ago the poor-rate was about 700,000*l.*; it is now about 7,000,000*l.* In 1818 it was 9,320,000*l.* But the sums levied under the name of the poor-rate are expended on various purposes besides the relief of the poor.

The work published under the direction of the Poor-Law Commissioners contains a chapter on the Local Taxes of Scotland, written at the request of the Poor-Law Commissioners, by J. Hill Burton, Advocate, Edinburgh.

The Local Taxes in Scotland are distributed by Mr. Burton under the following heads:—

I. Administration of Justice, which includes Criminal Prosecution, Court-Rooms and County Buildings, Rural Police, Town Police, Prisons. II. Internal Transit, which includes Commutation Roads, Turnpike Roads, Highland Roads and Bridges. III. Navigation. IV. Civic Economy, which includes Direct Municipal Taxes, Petty Customs, Miscellaneous Burdens. V. Relief of the Poor. VI. The Church and Education, which includes the Church of Scotland Education. VII. Miscellaneous Taxes.

Mr. Burton observes 'that the money expended on the ecclesiastical establishment and on education, partakes, in some respects, of the nature of a tax.' The amount of money annually levied by local taxation in Scotland is not accurately known. The sum of 956,678*l.* is the approximate amount given by Mr. Burton.

The local rates levied in Ireland are distributed under the following heads in the work published under the direction of the Poor-Law Commissioners:—

I. Grand Jury Cess (in all the counties, including counties of cities and towns).

II. Poor-rates (in 130 Unions, comprising every townland and denomination of land in Ireland).

III. Lighting, Cleansing, and Watching Rates (in all cities, towns, and boroughs which may adopt the provisions of the statute).

IV. Borough Rates (in certain Boroughs).

V. Pipe Water Rates (in every city and town, except Dublin, Cork, and Limerick, which gives title to a bishop or archbishop).

VI. Parish Cess (in all parishes, unions of parishes or chapelries in Ireland).

VII. Rates for deserted children (in all parishes in Ireland, except those in the city of Cork).

VIII. Ministers' Money (in cities and towns corporate in Ireland).

IX. Board of Health Rates (in parishes in which the lord lieutenant shall direct officers of health to be appointed).

'Besides the above rates leviable under general acts of parliament, there are rates leviable under special acts in many places, as Dublin, Cork,' &c. No account is given in the work here referred to of the provisions of these special acts, but the amount of the sums levied under them, which is considerable in some places, is given so far as it has been obtained.

The rates for Ireland are given at	£1,631,818
Tolls, Dues, and Fees	199,469
	£1,831,287

The amount of annual local taxation of Great Britain and Ireland accordingly amounts to 14,197,044*l.* But it is observed that if the deficient information were supplied, it would appear to be at least 15,000,000*l.* a year: and this, as already observed, does not include the local taxes raised in particular places under special acts of parliament. The sum raised by general taxation in the United Kingdom for the year ended 5th January, 1846, was 51,719,118*l.* The amount of the local and general taxation is accordingly about 67,000,000*l.* a year. The public expenditure for the year ending 5th January, 1846, was 49,061,411*l.*, of which sum 28,253,872*l.* was paid on account of the Funded and Unfunded Debt. This leaves somewhat under 21,000,000*l.* for the rest of the general public expenditure. Accordingly the present amount of the local taxation, 15,000,000*l.*, is nearly equal to three-fourths of the public expenditure after deducting the payments on account of the Funded and Unfunded Debt. It is well remarked in the work from which these facts are derived (p. 190), 'When the Local Taxes are brought under review in this collective amount, it then at once becomes manifest how really deserving of serious consideration are the modes of raising and expending them, so as to secure the most efficient and economical management of a revenue so large and important: a revenue, indeed, which derives its importance not only from the largeness of its aggregate sum, but from the extent of the property and the number of persons affected by it, and from the numerous and diversified public objects to which it is applied.'

TAXICORNES. The second family of the heteromerous coleoptera, in Latreille's arrangement of insects. They have no corneous tooth on the inner side of the maxillæ. They are all winged insects with nearly square bodies, and a thorax which conceals or receives the head. They have short antennæ and legs adapted for walking only. They live in fungi, beneath the bark of trees, or on the ground under stones. This family is divided into two tribes, of which the genera *Diaperus* and *Cossyphus* are respectively the types.

TAXITES, a coniferous fossil genus of plants from Stonesfield. (Brongniart.)

TAXO'CRINUS, the last generic name assigned by Phillips to the group of Encrinites analogous to Taxocrinus (Poteriocrinus) Egertoni. It has several synonyms. (Morris's Catalogue.)

TAYLOR, WILLIAM, was born at Norwich, in the year 1765. He was the only child of an eminent merchant of that city. He first studied under a Swiss refugee, and afterwards became a pupil of Mr. Rochemont Barbauld, the Unitarian minister, at Palgrave, a tutor chiefly selected on account of his religious opinions, which were those of Mr. Taylor and his family. To Mrs. Barbauld, better known as Miss Aikin, Taylor was indebted for much assistance in his early studies; aided by her assiduous care, he soon acquired a correct knowledge of the principles of English composition, and, in after life, he gratefully acknowledged his obligations to this celebrated woman, whom he styled 'the mother of his mind.' On leaving the house of Mr. Barbauld, at the age of fourteen, he was placed by his father in his counting-house at Norwich, who was desirous that he should succeed him in his large and prosperous business. Shortly afterwards he was sent on the Continent, under the care of one of the partners of the firm, for the purpose of perfecting himself in the French and Italian languages, which were of importance to the proper conducting of his father's business. Before leaving England, he had already evinced considerable facility in acquiring knowledge of languages; and he had been but a short time abroad when his letters to his parents, in English, French, and Italian, at the early age of fifteen, gave the promise of that eminence as a writer to which he afterwards rose. On his return to his native city, he was encouraged in the prosecution of his studies by the fond admiration of his parents and friends; and for the two years he remained there, he appears to have given the tone to its literary circles. A second tour to the Continent was resolved upon; and he proceeded to Germany with the view of acquiring a familiar acquaintance with its language and literature. A residence of a year with a clergyman at Paderborn was sufficient for this purpose. Under the influence of his preceptor he imbibed a taste not only for the literature of Germany, but for the philosophy of that country: a taste which ever afterwards characterized his writings. On his second return to Norwich, at the age of eighteen, his parents perceived that their son had an imagination too lively, and a taste too decided for literary pursuits, to allow him to devote himself to the mercantile profession. The affluent circumstances of the father, added to the gratification which he enjoyed of seeing his son arrived at so early an age to a high distinction in letters, induced him to forego the strict accomplishment of his favourite project, and to put no restrictions to the youth's inclinations. The time of young Taylor was now chiefly occupied in making various contributions to the periodicals, and to translations from the best German writers.

When the French revolution had convulsed the Continent of Europe, it extended its influence over no small proportion of the English nation; of this influence the mind of Taylor was adapted to fee the force, and he soon became ambitious to add to his other distinctions that of being a prominent political character. The quiet of the study was now exchanged for the noisy meetings of political debaters.

Taylor allowed himself to be enrolled as secretary of a democratic club established at Norwich. His political activity however, so far from interfering with his desire to obtain literary distinction, served as a stimulus to bring his writings before the public, and thus to extend his reputation beyond the narrow sphere of his native place.

A poetical translation of the 'Lenore' of Bürger was the first publication by which he became generally known. This translation, which preceded that of Spencer, still maintains a high reputation for elegance and accuracy. It contains some variations from the original; that of the most importance being the liberty he has taken to transfer the scene of the poem, which in Bürger is towards the end of the Seven Years' War, to the time of the Crusades; in this he has been followed by Sir Walter Scott, to whom the public is also indebted for a translation of 'Lenore.' This work was soon after followed by several other poetical translations from the same author. Specimens of the other German poets, by him, also appeared in various magazines and periodicals. These he afterwards collected together, with explanatory observations, and published in 1830, in three large volumes, under the title, 'Survey of German Poetry.' The peculiar metre to which he has adapted many of these translations, and a homely and too familiar style of expression, have exposed him to some severe criticisms.

In the year 1798 he became acquainted with Southey, whose political opinions in early life were similar to his own; an interesting collection of their correspondence will be found in the biography of Taylor, referred to at the end of this article. In one of them he describes his first interview with Sir James Mackintosh and Dr. Parr; and vividly, though not perhaps impartially, delineates their manner and peculiarities (vol. i. p. 295).

Severe losses, consequent upon the war of the French Revolution, induced Mr. Taylor to retire from the management of his father's business: a circumstance which enabled him to devote a greater portion of his time to his favourite studies. Magazines and Reviews still continued to be the principal vehicles by which his writings came before the public. As a reviewer, he was remarkable for his close attention and extensive information on the subject he reviewed. Though not profound as a classical or an Oriental scholar, he in a great measure supplied his deficiency in that respect by his intimate acquaintance with the German translations of the classics, and the commentaries upon them. The style, however, of his prose writings was so peculiar, that it was disrelished by many of his readers; and it became a source of constant altercation between him and the editors of the works to which he contributed. 'Were I reviewing my own reviewals,' he writes to Southey, 'I should say this man's style has an ambitious singularity, which, like chewing ginseng, displeases at first, and attaches at last. In his pursuit of the "curiosa felicitas" he often sacrifices felicity to curiosity of expression. With much philological knowledge, and much familiarity among the European classics of all sorts, his innovations are mostly defensible, and his allusions mostly pertinent; yet they have both an *unusuality* which startles, and which, if ultimately approved, provokes at least an anterior discussion that is unpleasant.' A pleasing feature in the reviews of Taylor is the enthusiasm with which he entered into his subject, but which led him occasionally to hazard assertions which, on cooler reflection, he often disavowed. Thus it is stated that in one of his papers on the prose of Milton, he expresses the conviction that it is superior to his poetry.

In 1802, on his return from a visit to Paris, Mr. Taylor accepted the management of a weekly local paper, 'The Norwich Iris,' after having used his endeavours to induce Southey to undertake it. This paper became the organ of the party to whose political opinions he was attached; its success however was not equal to his anticipations, and it was given up after two years. He then applied himself anew to his reviewing labours, the changes which had taken place in his family circumstances affording him an additional motive for literary exertion. The Monthly Review, under the editorship of Dr. Griffiths, was the work in which the greatest number of his contributions appeared. In 1806 he gave to the public his version of Lessing's 'Nathan the Wise;' which was severely criticized in the Edinburgh Review. A succession of pecuniary losses which soon after occurred, rendered the position of Mr. Taylor's family, if not one of privation, at least of diminished comfort. His adversity, however, was cheered by the kindly sympathies of his numerous friends, and by several unexpected offers of assistance, which, though not accepted, were sensibly felt and gratefully responded to. At the same time increase of years and premature infirmities diminished his energies, and his later productions have not added to his fame. Among his last works was a collection of short essays on English Synonyms, which, though incomplete and frequently fanciful, are calculated to assist the philological student, and to lay the foundation of a more complete undertaking. The last years of his life were embittered by the loss of the aged parents, to whom he had proved himself a devoted and affectionate son, and by the decay of his mental powers. He died in the month of March, 1836; his remains were deposited beside those of his parents, in the cemetery of the Octagon Chapel at Norwich.

Mr. Taylor's chief claim to literary celebrity consists in his valuable translations from the German; it was through him that the English first became acquainted with the modern literature of Germany. If his talents as a poet were unequal to the task of producing such a translation as the Wallenstein of Coleridge, to him at least must be assigned the merit of having been the first in the field, and perhaps to have laboured in it more assiduously than any other English writer. A good translation does not only require a perfect knowledge of the two languages, but also the power of approaching in some degree to the style of the original. Hence in poetical translations it is necessary that the translator should be a poet also. 'We know,' says a high authority on this subject, 'the remark of Denham, that the subtle spirit of poesy evaporates entirely in the transfusion from one language into another; and that, unless a new or an original spirit is infused by the translator himself, there will remain nothing but a "caput mortuum." Thebest translators of poetry therefore have been those who have approved their talents in original poetical composition.' (Tytler's *Essay on the Principles of Translation*, p. 373.) These remarks will account for the chief and perhaps only defect of Taylor as a translator.

Memoir of the Life and Writings of the late William Taylor, of Norwich, &c., by T. W. Robberds, F.G.S., of Norwich, 2 vols. 8vo., London, 1843; *Quarterly Review*, vol. lxxxiii. p. 27-68.)

TECO'MA (from Tecomaxochitl, the Mexican name of the species), a genus of plants belonging to the natural order Bignoniaceæ. It has a campanulate 5-toothed calyx, a short-tubed corolla with a campanulate throat, and a 5-lobed bilabiate limb, four didynamous stamens with a sterile filament of a fifth, a bilamellate stigma, a silique-formed 2-celled capsule having the dissepiments contrary to the valves; the seeds winged, disposed in two rows. The species are erect trees or shrubs or scandent plants, with unequally pinnate or digitate simple leaves with terminal panicles yellow or flesh-coloured flowers. They are natives of the Old and New World in tropical and subtropical climates. They are all elegant plants and well worthy of cultivation.

T. radicans is a climbing glabrous plant with rough rooting branches, 9 ovate acuminated coarsely serrated leaflets, the racemes of flowers terminal corymbose on long peduncles, the tube of the corolla 5 times longer than the calyx. This is a hardy plant in our climate. It is a native of North and South Carolina, of Florida, and Virginia. This plant has been a great favourite in this country. It grows against a wall by throwing out roots from its branches in the same manner as ivy. The flowers grow from the ends of the branches in large bunches, and the tube of the corolla gradually swells out in the form of a trumpet; hence this and some of the species of Bignonia have been called trumpet-flowers.

T. stans is a small tree with somewhat tetragonal glabrous branches; ovate-lanceolate, acuminated serrate and glabrous leaflets, the racemes terminal simple. This plant is a native of various parts of South America, the West Indies, and Mexico. The roots of this plant are reputed diuretic.

Several other species of Tecoma have reputed medicinal virtues. *T. speciosa* is said to be a useful diuretic, also a cathartic. *T. impetiginosa* and *T. Ipe* contain large quantities of tannin, and decoctions of the bark are used by the Brazilians as external applications in rheumatism and a gargle in ulcers of the throat. The leaves are milder and are employed in affections of the eyes. In cultivation the species of Tecoma may be treated in the same general way as recommended for the species of Bignonia. (Bignonia, P. C. S.)

(Lindley, *Vegetable Kingdom;* Don, *Gardener's Dictionary.*)

TEESDA'LIA (named after Robert Teesdale, author of a catalogue of plants growing about Castle Howard), a genus of plants belonging to the natural order Cruciferae and the sub-order Angustiseptae. It has a roundish notched pouch, boat-shaped valves, their backs keeled below, narrowly winged above; the seeds two in each cell; the petals either equal or the two outer ones larger. The species are small annual smooth herbs with stalked expanded vertical leaves. The flowers usually small and white.

T. nudicaulis is the *T. Iberis* of De Candolle. It has unequal petals and numerous leaves spreading on the ground. The stamens with remarkable scales within, the pouch emarginate. It is found in sandy and gravelly places in England, France, Germany, Denmark, and Sweden. It is the only British species.

T. lepidium is a native of Europe, particularly of Spain. It differs but little in general characters from the former species; there are two varieties of it.

If the seeds of these little annuals be sown on rockwork or in dry sandy places they will scatter themselves and increase rapidly.

TELEGRAPH, ELECTRIC. The electric telegraph, although it has only begun to attract the attention of the public from a comparatively recent date, has nevertheless not originated in any sudden but happy idea. The possibility of such an application of electrical power had long been imagined; and from the commencement of the present century, the attempts to render one or other of the phenomena of electricity subservient to such a purpose, have been numerous and interesting. In the sequel we have endeavoured to trace briefly some of the most remarkable of these inventions, of which any authentic account exists. We have arranged them as far as possible, in their proper order of succession, down to the period when the invention assumed that form which it at present retains in England; omitting those subsequent stages of the invention, which have related rather to the improvement of details, than to the adoption of any new principles of construction.

With this subject the Electric Clock is so far interwoven, that we have introduced a short description of its mode of action.

From the earliest date which we can assign to the existence of an electric telegraph, its essential parts have been the same. These are, the source of electrical power; the conducting material by which this power is enabled to travel to the required locality; and finally, the apparatus by which at the distant end of the line, the existence of this power, its amount, or the direction of its action is made known to the observer. In the earlier stages of the invention, the investigations of its promoters were confined to the latter of these three essentials; and so long as the illustration of the idea was confined to the lecture-table of the philosopher, or to the scientific museum, this part justly claimed an undisputed pre-eminence. But with the proposed application of the principle to purposes of general utility, there arose the necessity for an equal, nay, almost for a greater degree of attention to the two former requisites. We shall see, in our brief retrospect of the history of this invention, how this fact developes itself.

The experiments of Dr. Watson and others, about the middle of the last century, and the humorous display of electrical phenomena which Franklin mentions as having been exhibited on the banks of the Schuylkill, at the same period, may possibly have suggested some notions of the conveyance of information, by means of electricity. The earliest authenticated instance of any attempt to reduce this idea to practice, appears to have been that of Mr. Lomond, in 1787. His apparatus was, however, of the simplest possible construction. He employed, as an indicator, a pair of pith balls, which were suspended from one end of an insulated wire, at the other end of which the operator took his station, provided with an electrical machine. On charging the wire with electricity, the pith balls would exercise mutual repulsion, and diverge from one another; but on removing the electrical charge from the wire by the contact of some conductor, the balls would collapse. It is evident that certain numbers of successive divergences might be made to denote particular preconcerted signals. No account is, however, preserved of the manner in which the inventor intended to apply these indications. Subsequently to this, the phenomenon of the spark was used for the transmission of signals. It is well known that on the passage of electricity through an interrupted conductor, a brilliant spark of light is seen, at all the breaks in the continuity of the conducting material. This fact is well known in its application to various electrical toys in the present day. We allude to the outlines of birds, animals, or stars, which are formed of small pieces of tinfoil, attached to plates or strips of glass, at such distances asunder, that an electrical charge may be readily passed through the whole series. When this is done, the figure becomes luminous for an instant, as the electricity leaps across the small intervals between the successive pieces of tinfoil. Were the various letters of the alphabet formed in this manner, upon a table, and connected each one with a distinct and insulated wire, any particular letter might be rendered visible in a darkened room, by passing an electrical charge through the appropriate wire. This in fact constituted the Telegraph of Reizer, invented in 1794.

A somewhat simpler form of apparatus, involving the same principle, was constructed by arranging the several wires in succession, with a single break in each. The various wires bore the names of the different letters or figures, and any required signal was indicated by passing the charge through the proper wire, when the spark visible at the interruption of the circuit would denote the letter to the observer at the farther end.

This was the point to which the invention had progressed, at the commencement of the present century. The discovery by Volta, of the battery which bears his name, forms the commencement of a new era in electro-telegraphs, although no immediate application of the phenomena of the galvanic current appears to have been made. One or two points present themselves for our consideration, before proceeding to the later periods of our history.

In reference to the relative adaptability of the electricity derived from the ordinary machine, and that from the Voltaic battery, to the purposes of electric telegraphs, we may add a few words. The researches of philosophers have established the identity of the force in both cases, and have shown that, in operating with the electrical machine or the Voltaic battery, we are dealing with the same powerful agent, only under different forms. Machine or Frictional electricity presents us with phenomena which indicate its high degree of tension. It possesses the power of passing visibly in the form of a spark, through a greater or less space, even when present in small quantity, so that a slight break in the conductor is not sufficient to prevent its passage. The Voltaic current, on the contrary, unless its intensity be exalted to a high degree, is unable thus to leap across more than a very minute interval. From this difference would arise the necessity for a much more perfect state of insulation, in the wire destined to convey the former, than is requisite in the conductor for the latter. When, therefore, the extension of these conductors over many miles of distance becomes necessary, it will be sufficiently obvious to our readers, that the impediments to the use of the former current were and are almost insuperable, from the difficulty of maintaining through so great a length, the requisite degree of insulation. With the galvanic current, on the contrary, provided that the continuity of the conductor be insured and its capacity be sufficient, a much less perfect insulation will suffice. Another point to which it appears desirable to allude here, is the actual transmission of the electrical force. It is well known, that with respect to the Leyden jar, the shock caused by the passage of the electricity through the body is not experienced, until the circuit between the outside and inside coatings of the jar is completed, by touching them both at once; or by so nearly completing the circuit, that the electricity may leap across the interval in the form of a spark. When we present our knuckle to the conductor of an electrical machine, and take a spark from it, the mode of completion of the circuit is less apparent, though the necessity for it is not less absolute. The body in fact forms the communication between the prime conductor and the earth, from which latter inexhaustible reservoir of electricity the machine draws its constant supply. To extend this same principle farther, if we conceive two wires extended parallel to one another, to any length, and put in connection with the two ends or poles of a Voltaic battery respectively, no indications of the passage of the electric fluid through either can be found. But if the wires be brought in contact at any point, or if a sufficiently good conductor be made to connect them, and thus complete the circuit, the passage of the fluid from one pole of the battery to the other through the extended wires will take place immediately. If this connection be made at any distant point, by an apparatus fitted for such indications, the direction and amount of the current may be appreciated, as certainly as they could be, were the circuit completed between the battery poles by this apparatus only. To use the words of the late Professor Daniell, 'the journeyings of this force must be in a circle, and the arrangements must be made in such a way, that the impulse may return to the point from which it set out; it must *circulate*.' It will be seen how important an influence this necessity exercises upon the construction of the electric telegraph.

We may now return to the point whence we have digressed at so great a length. In 1807, Sömmering at Munich proposed to construct an electric telegraph, on the principle of the decomposition of water by the Voltaic current, as discovered in 1800 by Nicholson and Carlisle. The form of his apparatus was the following:—In a glass trough containing water, thirty-five gold pegs or pins were arranged vertically, this number of pegs corresponding to the letters of the alphabet, together with the nine digits. Each of these pins was connected with a wire, which extended to the place whence the signal was to be transmitted. At this point they terminated in brass strips, arranged in a frame side by side, but like the wires and pins, insulated from each other. Each brass strip bore the name of the letter or figure which belonged to the pin to which it was connected. The operator, when wishing to send any communication, connected the two poles of the battery, with the brass strips bearing the names of the two first letters required. Decomposition of the water in the trough at the distant end, was instantly indicated by the evolution of bubbles of gas, from the two gold pins thus rendered the two electrodes or poles of the battery. The letters forming any communication were to be in this manner denoted in pairs, the inventor ingeniously availing himself of the different quantities of the two gases evolved, to point out the relative position of the letters in each pair. The hydrogen which made its escape in the largest quantity was always employed to indicate the first letter, and of course the operator had to bear this rule in view in making his connection with the battery.

In 1816, Mr. Ronalds of Hammersmith invented an electric telegraph, in which he recurred to the use of frictional electricity. This telegraph, which was shown to several scientific men, at the date above given, was fully described by the inventor, in a work published by him in 1823. Mr. Ronalds employed the divergence and collapse of a pair of pith-balls as the telegraphic indication, in which respect the principle was the same as that adopted by Mr. Lomond; but to this simple apparatus, a distinct contrivance was appended, which would render the communication more rapid and easy. A single wire perfectly insulated by being suspended from silken strings, or buried in glass tubes, surrounded by pitch, and protected by wooden troughs, was extended between the two stations. From the end of this wire were suspended in front of the dial of a clock a pair of pith-balls, so that while the wire was charged the balls would remain divergent, but would instantly collapse, when the wire by contact with the earth, or with the hand of the operator, was discharged. A person at one end, having therefore an electrical machine, by which he could maintain the wire in an electrified state, and the pith-balls at the farther extremity, consequently in a state of divergence; had it of course in his power to give an instantaneous indication to an observer at that farther extremity by touching the wire with his hand, which, discharging the electricity, would allow the balls to collapse for an instant. But instead of merely employing the successive movements of the pith-balls to denote the various signals, Mr. Ronalds added another apparatus for this purpose. Two clocks, very accurately adjusted to the same rate of going, carried, instead of the ordinary seconds hand, light discs, on which the various letters of the alphabet, the figures, and other required signals were engraved. These discs turned with a regular step by step movement, behind a screen of metal, in which was made a small opening, sufficient to allow of one letter at a time being seen. As the discs turned round, each letter in succession would be visible through this space; and it is evident that if the clocks were started with the same signal visible, the movement of the discs would bring similar signals into view at the same time. One of these instruments was situated at each end of the communicating wire. The operator who was about to transmit any communication, watched the dial of his clock until the letter he required was visible, and at that instant discharged the wire. The momentary collapse of the balls at the distant end would then warn the observer to note the letter visible on his instrument, which would form a part of the intelligence to be received. The successive letters or signals constituting any message were denoted in this manner as the clock dials continued to turn round. In order to avoid the necessity for constant attention on the part of the observer, an arrangement was adopted by which a pistol could be fired by the spark at the farther end, to summon the attendant to his instrument. Various signals were also concerted beforehand, by the use of which, the time necessary for the transmission of any intelligence was lessened. These experiments of Mr. Ronalds' were made with the intervention of several miles of wire, carried backward and forward across his grounds.

Mr. Ronalds, in his work on electricity, published in 1823, informs us that an electric clock was constructed in 1815 by Buzengeiger.* A very light pendulum was suspended, with its bob or weight midway between two brass balls, forming the extreme ends of a De Luc's Pile. Having been once set in motion, the pendulum would continue to oscillate between the balls, receiving at the end of each vibration an impulse, from the attraction of the opposite ball to that which it had just touched. The upper end of the pendulum was made to cause the revolution of a small ratchet wheel, by means of the alternate action of two catches, or pallets, one on either side of the wheel. To many of our readers the construction and action of the Dry Pile or column of De Luc may be familiar. It may not however be amiss to add, that it consists of many hundreds, or even thousands, of small discs of silver and zinc foil, piled up in regular order, with the intervention of writing-paper discs between the succeeding pairs. They are then usually enclosed in a glass tube, and pressed firmly together, by means of screw-caps or ends of brass. The ordinary hygrometric moisture of the paper is sufficient to excite weak voltaic effects in the pile, which are manifested by the two ends exhibiting constantly opposite electrical states. The bob of the pendulum in Buzengeiger's clock, after touching one of these ends, received a minute electrical charge; in consequence of which it was repelled by this ball, and attracted by the other. These actions, though very feeble, are long continued, and might suffice to maintain a movement in a very light train for months. In the opticians' windows at the present day, slender frames are often seen revolving, with paper figures of chariots and horses, under the influence of two or more of these Dry Piles.

In 1819, Professor Œrsted of Copenhagen made his great discovery of the action of the galvanic current upon a magnetic needle. He observed that when a galvanic current is passed along a wire, placed parallel and near to a magnetic needle, free to turn on its centre, the needle is deflected to one side or the other, according to the direction in which the current is transmitted. He further noticed that the position of the wire, whether above or below the needle, had an equal influence with the direction of the current in determining the side to which the deflection took place. The power of a single wire in causing this deviation of a needle is very small, but within a short time after Volta's discovery, Professor Schweiger invented the multiplier, as he called it, in which the needle, being surrounded with many successive coils of insulated wire, is acted upon by the joint force of all. This instrument, commonly known in England as the Galvanometer, has been of the most signal use to the philosopher; as it

* Ronalds' Description of an Electric Telegraph, &c., p. 89. Translated from the Stutgard *Morgen-blatter*, September 23rd, 1815. In the same work (page 67) Mr. Ronalds, quoting from Schweiger's Journal, vol. 13, p. 379, states that M. Ramis at Munich, and M. Strelzig at Verona, had each constructed an Electric clock, which received motion from a Dry Pile.

enables him by its extreme delicacy not merely to discover the existence of feeble currents, but also to measure their force and direction with extreme accuracy. Under a somewhat different form, this discovery now forms the basis of the Electric Telegraph, which has spread so extensively over England.

Very shortly after this important discovery had been made, Œrsted, Arago, Davy, and others, succeeded in rendering iron magnetic, by the passage of a galvanic current through a wire coiled around the iron. It was found that, provided the iron to be magnetized were perfectly soft and pure, the magnetic property remained only during the actual transmission of the electricity, and was lost immediately on the interruption of the electric circuit. If the iron which was exposed to the influence of the galvanic current were combined with sulphur, carbon, or phosphorus, the magnetic power became to a greater or less extent permanent in it.*

These two principles have, since their discovery, formed the groundwork of almost all the electric telegraphs which have been proposed, and certainly of all which have hitherto been found practicable. Far be it from us, however, to assume that these principles must henceforward bound the inventive genius of men of science, or that no further progress can be made. Much has been already done, but far more, as yet latent and unknown, may be before us.

M. Ampère suggested the employment of the discovery of Œrsted as early as 1830, and this suggestion was acted upon by Professor Ritchie, in a model Telegraph exhibited by him at the Royal Institution.† Ampère's plan however was far from possessing the simplicity, so essential in an instrument designed for practical use. Not less than thirty pairs of conducting wires were necessary, according to his scheme, for maintaining a Telegraphic communication.

M. Schilling also in 1832, following the idea originated by Ampère, proposed a similar form of telegraph, in which there were as many of these galvanometers, each with its appropriate circuit, as there were letters or signs to be used in the various communications. The momentary deflection of any one of these needles, by the completion of the galvanic circuit with its wires, denoted the required letter or sign. The same plan, to a certain extent, seems to have been followed by M. Alexander, in his telegraph, described about the end of the year 1837. In this instrument a distinct needle was employed for the indication of each letter, as in M. Schilling's apparatus, these needles bearing at one end light screens of paper, which concealed from view a letter or figure, until by the deflection of the needle the screen was removed, and the letter brought into sight. M. Alexander however effected one great improvement, in substituting a single return wire, to which one end of all the coils was joined for the several distinct return wires existing in the previous invention of M. Schilling.‡ At a later period this latter gentleman undertook a series of experiments, with a view to the establishment of a communication by means of a single wire; but some mechanical difficulties appear to have arrested his progress, previous to his death, which occurred while he was engaged in the prosecution of his investigations. In both of these telegraphs all that was requisite, in addition to the indicating apparatus and conducting wires, was a contrivance by which the connection of the voltaic batteries could be made with any pair of wires in the former, and with any single wire and the return-conductor in the latter of the two inventions. In M. Alexander's instrument, a set of keys resembling those of a pianoforte, and corresponding to the number of needles, were arranged on a frame or table. One pole of the battery being connected to the return or common wire, the other pole was joined to a plate of metal, or to a trough of mercury, extending beneath all the keys. On depressing any key, the wire belonging to it, which was continued to the end over the battery connection, was brought into contact with this bar or trough. The current would then flow along the conducting wire, around the multiplier-coil in the distant instrument, and return by the common wire to the voltaic battery. The keys bore the same letters as the needles to which they were connected, so that the operator communicated any letter by pressing down the corresponding key.

* Thomson's *Lectures on Heat and Electricity*, p. 512.

† See Froriep's *Notizen*, &c., vol. 27, p. 88.

‡ In this and other parts of this article, when treating of the transmission of an electric current through a conductor, it is necessary, in order to simplify the description, to represent the electricity as starting from one end or pole of the battery, and returning after its circuit to the other. Theory however warrants us in regarding the phenomena of the circuit as due rather to force developed at once at both ends of the battery, than to any power acting in one direction only.

In these two instruments no use was made of the power which exists, of determining the deflection of the needle, to either side, by merely reversing the connections of the battery. In a telegraph recorded as the invention of MM. Gauss and Weber, the varied deflections of a single needle appear to have formed the code of signals. From the use of a telescope and scale however, to read off the different signals, it is to be inferred that the indications wanted precision and distinctness.

In June, 1837, the experiments of Messrs. Cooke and Wheatstone, which had been progressing for more than a twelvemonth, appeared so far successful as to induce them to apply for a patent for their inventions.* The principal points of novelty in this patent were the use of a much smaller number of needles to denote all the required signals, the employment of the temporary magnetism excited by the current, in soft iron, to ring an alarum, either directly or indirectly, by the means of suitable machinery; and the reciprocal arrangement by which the invention was rendered practically applicable to a long line of communication. The telegraphic instrument shown in the drawings annexed to their specification, and which was brought into use on the Great Western Railway shortly after the date of the patent, contained five needles, arranged with their axes in a horizontal line. The needles when at rest hung vertically, by reason of a slight preponderance given to their lower ends. Each coil was connected with one of the long conducting wires at one end, and was united at the other with a common rod of metal, which joined together the similar ends of all the coils. The current was transmitted from the opposite end of the wires (where an appropriate set of five pairs of finger-keys, for making the connections with the battery, was placed) through two of the wires at once. That is to say, one of the wires, of which one key was pressed down, served to convey the current from one pole of the battery to the distant instrument, while the key of a second wire being brought into contact with the other pole, the current returned by the rod of metal connecting the coils and the second wire to the battery again. Two needles were in this manner deflected at once, and it will be obvious that the current would pass in opposite directions around their coils, and consequently that the deflections must be in contrary directions. The needles would therefore converge, either above or below their line of centres, as one or other of the pair of keys belonging to each wire was depressed. Fixed stops were so placed on each side of the needles as to limit their motion, and when resting against them, the needles were parallel to two converging lines, at the point of intersection of which, a letter was placed. This was the signal indicated by the movement of the needles. In a similar manner, as lines were drawn diverging from the centre of each axis, mutually crossing one another, a number of points of intersection were formed, at each of which was a letter or signal. Any of these letters could be indicated by the simultaneous movement of two needles, so that a communication could be carried on with rapidity and certainty. At the same time a plan was recognised, by which the number of wires requisite for maintaining a communication might be reduced, by using one of them at times as a return wire only, there being no needle in connection with this one. One needle could by the use of this wire be deflected by itself either to the right or left, and thus of course each would furnish two signals, in addition to those formed by its simultaneous deflection with any other. The instruments at the two stations were always rendered reciprocating; that is, at each

* It appears desirable here to add a few words explanatory of the actual origin of the Electric Telegraph. Mr. Cooke first had his attention directed to the subject by some experiments of Professor Moencke, at Heidelberg, which he had the good fortune to witness. Thoroughly impressed with the practicability of the oft-attempted scheme of employing Electricity in the conveyance of intelligence, he at once applied his mind wholly to the prosecution of this idea. In the early part of 1837, after having been engaged nearly a twelvemonth in the construction of various Telegraphic instruments, and in efforts to bring them into use on some of our Northern Railways, Mr. Cooke became acquainted with Professor Wheatstone, whose attention had been already directed to the same subject, and whose experiments and researches in Electricity were of the highest interest and importance. The first patent was taken out in the joint names of these two gentlemen, as were several which succeeded at various intervals. The relative connections of Mr. Cooke, and of Professor Wheatstone, with this invention, to the success of which both have contributed, is well expressed in the following words of Sir M. I. Brunel, with which this note may be appropriately concluded:—'While Mr. Cooke is entitled to stand alone, as the gentleman to whom this country is indebted for having practically introduced and carried out the Electric Telegraph, as an useful undertaking, and Professor Wheatstone is acknowledged as the scientific man, whose profound and successful researches had already prepared the public to receive it as a project capable of practical application; it is to the united labour of two gentlemen, so well qualified for mutual assistance, that we must attribute the rapid progress which this important invention has made since they were associated.'

end of the line were placed an instrument, a set of finger-keys, and a voltaic battery, so that either station could transmit or receive a signal. By a beautiful arrangement, the keys, on being released after depression, were made to resume by themselves the position necessary to enable that which had been the signalling station to become the recipient. By this means messages and answers, or words and their acknowledgments, could follow one another without the necessity for any intervening adjustment of the instruments.

The bell or alarum which was to be rung, when the attention of the clerk at the distant terminus was required, was either direct or indirect in its action. In the first case the attraction exercised by a horse-shoe piece of soft iron, rendered temporarily magnetic by the galvanic current, was made to draw an armature, likewise of soft iron, towards it, and by this action impel a small hammer against a bell. In the second form of alarum, the movement of the armature merely released a detent or catch from a train of clock-work driven by a spring or weight. This clock-work, by the intervention of a scape-wheel and pallets, rang the bell in the manner well known in common alarums.

In the early part of 1838 Mr. Cooke obtained a patent for some further improvements of this apparatus. Of these the most prominent was the mode of introduction of the intermediate apparatus. Before the date of these patents, the two stations at the extremities of a line of telegraph had alone been put in communication with each other; but Mr. Cooke devised means, by which any number of intermediate instruments might be introduced between the two terminals, and any intelligence rendered simultaneously visible in all or in any of them, as required. Furthermore any one of these instruments could be put in communication with the rest, either generally or in part only; and by an admirable contrivance, the same mechanical adjustment which limited the connection of any intermediate instrument to one part of the line, placed its bell in the circuit of the other part. Thus if, while intelligence was being transmitted in one direction from an intermediate station, some message of importance were required to be sent from the terminus, or any other station on the excluded side, the ringing of the bell at the communicating station would warn the attendant to restore his instrument to its intermediate position, and thus leave the line clear throughout.

In the same patent were included some important improvements on the mode of protecting and insulating the wires, which were to be laid beneath the earth, in tubes or troughs of wood, iron, earthenware, or other material; and also in the expedients for detecting the exact position of any accident or derangement, without the necessity of uncovering the whole length. Two needles were also shown to be sufficient for carrying on a complete communication with ease and rapidity.

In the course of the ensuing year (1839) Messrs. Cooke and Wheatstone's telegraph was brought into actual operation upon the Great Western Railway, where its capabilities were tested severely.* The results of this trial were most gratifying to the inventors, and demonstrated that the undertaking, yet in its early infancy, was eminently successful, and that the question of the practicability of the electric telegraph, so long at issue among scientific men, was set at rest for ever. Within less than two years from the date of the existence of the invention of Messrs. Cooke and Wheatstone, the severe test of practical application was borne, not merely without lessening the value of the invention, but in a manner which justified increased admiration in those who witnessed the experiments.

We must here go back a little, to take notice of Dr. Steinheil's telegraph, which was erected between Munich and Bogenhausen in 1837.† In his instrument, two needles or magnetic bars were placed within an elongated coil of fine wire. These bars were suspended on axes passing transversely across the coil, and in their quiescent position lay parallel to one another and to the sides of the coil. They had their poles placed the same way, so that when a current was transmitted along the wire, they had a tendency to move in the same direction, remaining still parallel to each other. Against the outer end of each needle or bar a stop was placed, which checked its motion on one side, but left it free to turn to the other. The opposite poles of the two bars were therefore prevented from moving out from the coil, under the influence of the deflecting current; and the effect of this arrangement was, that the two bars could not move simultaneously, but only alternately. Both were acted upon alike, but when the inner end of one was free to move outward, the other bar remained pressed against its stop, and was fixed: and on reversing the current, the effects upon the two needles were also reversed; that which was before stationary, now moved forward, while the other was fixed. In order to bring back the needles to their ordinary position, a permanent magnet was fixed near to each at the back of the coil, by the attraction of which the needles were again rendered parallel after the cessation of the deflecting power of the coil. The inner ends of these bars carried each a light brass arm, terminating in a cup furnished with a small perforated beak or spout. These cups were filled with printing-ink, which oozed through the beak, and formed a minute bead or drop at its point, which, from its viscid consistence, did not drop off. These beaks were arranged so as to be in the same horizontal line, and at a distance from each other a little less than the width of a strip of paper, which was placed before them. If then a galvanic current were passed through the wire of the coil, so that the right-hand needle tended to pass, with the end bearing the cup, out from the coil towards the paper (the cup on the other needle receding as far as the stop would allow, and then remaining fixed), the little beak would just touch the paper, and leave a minute dot of ink on its surface. By reversing the current the other needle would approach and leave a point of ink on the opposite edge of the strip of paper. By the varied number and arrangement of these dots, on one or both edges of the paper, the various letters of any communication were denoted. The paper used in this apparatus, being obtained in a very long strip or ribbon, and coiled upon a roller, was made to pass slowly lengthwise before the printing points by a simple and obvious application of a weight and cord, which as the printing was effected gradually wound the ribbon upon a second drum or reel. This instrument was also adapted to give audible signals, by the substitution of small knobs for the ink-cups, and of two bells of different tones for the ribbon of paper. One bell being so placed as to be sounded by the first needle, and the other by the second, the pre-concerted combinations of their sounds might indicate various letters to a listener.

In the construction of his telegraph, Dr. Steinheil availed himself of the conducting power of the earth, whereby he was enabled to reduce the cost of erection. The earth in fact occupied the place of the return wire, which has been already spoken of. All that is necessary to enable this to be effected, is that the wire which connects the two ends of the metallic conductor with the earth, shall be carried to a sufficient depth below the surface to be always in contact with moist earth or with water; and that it shall be at this point attached to a plate or other piece of metal, of about two or three feet superficial. For the ordinary Voltaic battery, Dr. Steinheil substituted the magneto-electric machine; in which, according to Faraday's great discovery, the electric current was derived by induction from a permanent magnet.

The electric telegraph invented by Prof. Morse, of America, and which was exhibited by him in September, 1837, was essentially a registering instrument, the various signals being traced on a strip of paper. The plan appears to have been the following:—an electro-magnet was so placed as to be within attracting distance of an armature fixed to the shorter arm of a lever, of which the longer end carried a pencil projecting sideways from it, and pressed lightly against a sheet of paper. This paper, by a contrivance analogous to that of Dr. Steinheil, was made to travel slowly beneath the pencil. So long as no attractive power was exerted by the electro-magnet, the pencil would continue to trace a straight line as the paper moved onwards; but on momentarily making the circuit with the battery, the armature was drawn to the electro-magnet, and the pencil, carried by the arm of the lever upwards, made an angular mark, like the letter V reversed, on the paper. These angles might either be joined in groups, by rapidly succeeding completions of the circuit, or they might be separated by longer or shorter spaces of straight line. The nine digits were represented by corresponding numbers of angles, and these were combined so as to form all possible numbers. A short space intervening between two or more successive groups, denoted that they must be taken together to form a total of two or more places of digits; while a longer space showed the actual completion of one number and the commencement of the next. All the necessary words were represented by various numbers, as arbitrary signs, a previously arranged

dictionary being used for their interpretation. This plan had also been proposed by Mr. Ronalds, to simplify the working of his telegraph.

In the telegraph erected by Prof. Morse, in 1844, between Baltimore and Washington, a different mode of recording the signals was adopted. The use of the pencil was found objectionable, from its so frequently requiring fresh pointing, and from the risk of breakage. The same arrangements were retained in regard to the paper, bnt it was made in its course to pass under a roller having a groove around it. The long arm of the lever carried a blunt steel point, standing out from its upper surface, vertically under the groove in the roller. When therefore the arm of the lever was elevated, by the attraction of the magnet upon the armature, the steel point pressed the paper into the groove, and produced an indentation. If the attraction were momentary, a depressed point was produced; but if the action were continued for a longer time, a lengthened depression was the result, as the paper was drawn on. The combinations of these two kinds of marks denoted the various letters and figures.

In his first instrument, Mr. Morse produced the requisite groups of angles by means of type having as many projecting ridges or teeth as there were to be angles. These being arranged in a frame, as required for the message, made the successive contacts with the battery as they were drawn under a lever or spring. Subsequently however a single key was used, by depressing which with the finger the circuit might be completed when necessary. The first plan had the advantage of requiring no exertion of memory on the part of the operator, after the message had been set up properly; but nevertheless in practice, the second, in which all depended on the skill and recollection of the person transmitting any signal, was preferred.

In the year 1837 Mr. Davy of London obtained a patent for an electric telegraph. The actual principles of his invention were three: first, the employment with each wire (of which three were to be used) of two magnetic needles, each moveable in one direction, but stopped in the other, in a manner analogous to that in Steinheil's telegraph; secondly, the use of a supplementary battery, to effect the registration of the signals, the connection of this second battery being made by the deflections of the needles; thirdly, the method of registering or recording the various communications, by causing the current of the supplementary battery to pass through a ribbon steeped in a solution of iodide of potassium and starch. The salt being decomposed by the current, a blue spot was produced by the combination of the iodine with the starch, and the position of one or more of these spots across the breadth of the ribbon, determined the nature of the signal transmitted. The action of the two needles in each circuit was exactly similar to that of the bars in Dr. Steinheil's telegraph, in respect to their alternate deflections, according to the direction of the current. Instead however of carrying a cup for ink, each needle bore a small metallic arm on its axis, which, when the needle was deflected away from the fixed stop, came in contact with a brass pin or stud, and thus completed the circuit of the supplementary or registering battery. The stud belonging to each needle was connected with one of a series of platinum rings placed at equal distances asunder around a light drum. The edges of these rings bore lightly upon the prepared ribbon, as it passed over a metallic cylinder driven by a weight and cord. Instead however of allowing the ribbon to move at a uniform speed wholly independent of the rate of signalling, Davy ingeniously connected the two parts of the apparatus together, by such means that the transmission of each signal caused the revolution of the cylinder bearing the ribbon through a small space; so that the successive registrations forming any communication were placed at regular intervals apart upon the fabric. This was done by introducing a small electro-magnet into the circuit of the registering battery, so that whenever this circuit was completed an armature was attracted, and one tooth or division of the cylinder released from a catch or pallet. The ribbon itself was divided into squares by transverse and longitudinal lines, in such a manner that each platinum ring pressed upon the fabric, in the centre between two longitudinal lines, while the space through which the cylinder turned, at each release, corresponded to one of the transverse divisions. Thus successive squares were brought in turn under each ring, as the ribbon passed onwards, receiving the registrations as it moved. If we now suppose one pole of the supplementary battery to be connected with the metallic cylinder bearing the cloth, and the other with the axes of all the magnetic needles, the action of the apparatus will be readily rendered apparent. When a current was transmitted from the communicating station, so as to cause the deflection of the first needle of the first wire (the second needle of the same wire then being pressed against its stop and fixed), the arm of this needle coming in contact with the brass pin or stud, would complete the supplementary circuit in the following manner: supposing the current to start from the end of the registering battery in connection with the needle axis, it would pass from the axis of the deflected needle along its arm to the brass pin, from thence to the first platinum ring, through the ribbon (decomposing the iodide in its course) to the metallic cylinder, and to the pole of the battery joined thereto. When the current from the signalling station was reversed, the second needle would be deflected, and a similar supplementary circuit formed with the second platinum ring, and so on with the others. After each signal the ribbon would be advanced one division, so that the successive registrations would take place in succeeding transverse divisions of the fabric. The person who is to communicate has an apparatus, in which, by depressing different keys, he can transmit the electricity in one or other direction through any wire, making it return either by a spare wire or by the earth; or he can employ another of the signalling wires to return the current. In the first case, he would produce a single spot on the ribbon from one ring only; while in the second, spots from two rings would be produced simultaneously. By the use of the various simple and combined indications, a sufficient number of variations to express the necessary letters and signs could be obtained.

In the beginning of 1840 Professor Wheatstone patented his electro-magnetic telegraph, in which the indicating power was the magnetization of soft iron by the electric current. The object of the invention was to produce, by excitation and cessation of the magnetic power in pieces of soft iron, certain determinate and definite movements of rotation, in dials or indicators; by which movement signals might be given, of various kinds and in various modes. The first part of the apparatus which claims attention is the Communicator. A thin disc of wood, turning horizontally upon a pillar or axis, has its circumference divided into equal spaces, alternately filled up with metal or ivory. The metal divisions communicate with the central column, and through it with one pole of a battery, of which the other pole is connected with the return wire or with the earth. Against the circumference of the disc rests a spring, from the foot of which proceeds a wire going to the line or long conductor. As the disc is revolved on its centre, the spring rests alternately on metal and ivory, and were there no break in the circuit at the distant station, the current from the battery would be transmitted or intercepted accordingly. Over each division of the circumference is placed a letter or figure, so that by bringing one letter after the other opposite to a stop fixed near the disc, the galvanic circuit would be opened and completed alternately with each succeeding letter. For the ease of turning the disc it is provided with spokes or arms radiating around its upper surface. The telegraph which is operated upon by this Communicator, possesses great simplicity both in its principle and construction. Opposite and near to the poles of a temporary or voltaic magnet is placed a small armature of soft iron. When the iron is rendered magnetic the armature is attracted to it, but on interrupting the galvanic circuit the magnetism of the iron ceases, and a small reacting spring throws the armature back to its original position. The armature itself turns on an axis, which carries a pair of pallets, taking into the teeth of an escapement-wheel. In the instrument first constructed according to this patent the recurrence of the attraction and release of the armature actually formed the motive power of the machinery, the two pallets alternately moving the escape-wheel onward, one tooth at a time. For this arrangement another was afterwards substituted, in which a common spring barrel and fusee were employed to turn the escapement-wheel, and the pallets, actuated as above, merely controlled its revolutions like the same parts in a common clock. In either case the object was the same, that is, to communicate to a light paper or mica dial, bearing letters around its circumference, a step by step motion, wholly under the control of the operator at a distant station; so that he might bring any figure or letter on the dial to a small opening in a screen, through which it would be visible to an observer. The number and order of the signals upon the paper disc corresponded with those on the Communicator previously described. Supposing for instance that the letter A were opposite to the fixed stop in the Communicato , and that the same letter were visible through the opening in the screen of the telegraph ; if while in this position the spring of the communicator rested on an ivory division of its circumference, no current would be passing from the battery. But if the communicator were moved one division forward, so that B came to the fixed stop, then the spring would rest on a brass division of the circumference, and the current would flow freely through the circuit and the coil of the electro-magnet. The armature being attracted, the pallets would, by their motion with it, let one tooth of the escape-wheel pass, and the following signal B would appear through the opening in the screen. The movement to C on the communicator, breaking the circuit, would release the armature; and another tooth of the escapement would be let go, bringing round C also on the telegraph. In this manner by turning the communicator round steadily with the finger, until any required letter came opposite to the fixed mark or stop, the same letter could be brought into view on the telegraph dial. A momentary pause would then be made, before continuing the movement to another signal, so as to enable the observer to note each letter in succession as it appeared. The same plan was obviously applicable to causing the rotation of a hand or index around a fixed dial, so as to point to any required letters or signals, one after the other. It is indeed unimportant whether a dial be made to move behind a screen having an opening in it, or, the dial being fixed, a hand travel round so as to indicate any requisite letters upon it. In this, as in the needle instrument, the communicating stations would have a mutual and reciprocal power of sending or receiving signals. From this arrangement another very marked advantage arises. The operator sees upon his own dial or instrument the signals which he makes upon his correspondent's apparatus; so that he is at once aware of any accidental error in signalling, and is prepared to rectify it forthwith. Still further to reduce the chance of an error, each word as it is completed is acknowledged by the recipient by a single preconcerted signal, before the next word is commenced. This telegraph requires only a single wire for its use, the return of the current being provided by the earth.

Several applications of the principle forming the basis of this Invention presented themselves to Professor Wheatstone. Of these we will describe two of the most prominent. It is evident that if the operator were to move the communicating part of the apparatus, step by step, in accordance with the beats of a clock pendulum, a hand upon the telegraph at the distant station would rotate exactly as if attached to the clock, and show precisely the same time. But that the clock itself might be made to do this samo duty, and thus telegraph its own time to any number of distant stations, was an idea which did not long fail to occur to the inventor. This was effected simply by attaching a small communicator-disc to the arbor of the escapement-wheel of the clock; a spring being placed so as to make and break the circuit, as the divisions of the disc passed under it. These electric clocks were either constructed so as to derive their motion wholly from the action of the current, as in the form of electro-magnetic telegraph first alluded to; or the movements of the armature were employed only to control the power of an ordinary spring or weight. It is evident that any number of secondary 'telegraph clocks' might thus, if connected by a single wire, receive their motion from one governing chronometer at a central point. In allusion of Professor Wheatstone's scheme for thus regulating all the clocks of the metropolis, by means of wires passing under the streets, and connecting the subordinate instruments with one central chronometer, an eminent artist aptly remarked, that 'he proposed to lay on Time through the streets of London, as we now lay on water.'

The second application above mentioned to which Professor Wheatstone turned his attention, immediately after having completed the details of the electro-magnetic telegraph, is that of enabling the machine to print its intelligence, instead of rendering it visibly, or to do both at the same time. To effect this it was only necessary to replace the paper dial by a light metallic disc, cut in radiating lines so as to form a circle of delicate springs. On each of these, instead of a visible character only, was placed a small type. The type-disc was then made to rotate, precisely as the paper dial or the index would do, in front of a cylinder covered with white paper; there being interposed between the type and the cylinder, a sheet of the copying or transfer paper well known as the Carbonic ink paper. Any requisite type could therefore, by the same action which brought the various letters into view in the signal telegraph, be placed in the proper position for being impressed on the paper of the cylinder. Immediately that any one was so placed, a small hammer, acting by a train of wheel-work precisely similar to the striking train in a clock, struck the end of the type, and by means of the interposed transfer-paper impressed the letter on the cylinder. The succeeding signals were similarly impressed, one after the other. The train giving motion to the printing-hammer was released by the same armature which moved the type-disc; and by an arrangement sufficiently obvious, this train was made, after each impression of a letter, to move the paper cylinder round through a small space, in readiness to receive the next signal. The cylinder did not turn on a simple axis, but on a screw; so that the words of any communication were arranged in spiral lines around it. When the paper was unwrapped, to be replaced by a fresh piece, the message would be found printed in slightly sloping lines from one side to the other. The action of this instrument was very perfect, and it appeared to possess every requisite which could be demanded in a registering telegraph. There were however some very obvious impediments to its being brought into use, in the increased cost of the apparatus, and the slowness with which signals would be rendered, as compared with the needle instrument.

Towards the end of 1840 Mr. Bain, in conjunction with Mr. Barwise, patented a clock which was to be set in motion by electricity. It was proposed by the inventors to employ the magnetic power of the current, in giving an impulse to the pendulum of a clock, at the end of its oscillations, in the following manner:—An electro-magnetic coil formed the bob of the pendulum, having its ends so placed as to come very near to the ends of two permanent magnets, when at the two extreme points of its swing. On reaching these points, the pendulum itself, by coming in contact with a slender spring, completed the circuit of the galvanic current through the coil, in such a way, that the end of the coil then nearest to the magnet on the side to which the pendulum had oscillated, was momentarily endued with the same polar force as the magnet itself. The result was a mutual repulsion of the coil and magnet, and the former, being free to move, receded from the latter with a small impulse, sufficient to carry the pendulum to the opposite end of its oscillation. The same effects then took place, in respect to the other fixed magnet at that side. A small force was thus communicated to the bob of the pendulum, at each extremity of its arc, which was sufficient to maintain its vibrations undiminished; and at the same time to put in motion, by means of the ordinary arrangement of a scape-wheel and pallets, the works of the clock acting upon the minute and hour hands. By causing the circuit to be completed by the primary pendulum, not merely through its own clock, but through the similar coils of other instruments at distant stations, connected by appropriate wires, a series of such clocks might be made to work together with absolute accuracy.

In July, 1841, Mr. Bain exhibited at the Polytechnic Institution in London an electric printing telegraph, and in the following year he proceeded to patent an improved form of the apparatus. The essential principles of this contrivance are two. First, the employment of type, mounted on the periphery of a disc or wheel, capable of revolving with its edge carrying the type very near to a cylinder covered with white paper, between which and the type-wheel a piece of transferring paper or ribbon was placed. The cylinder had a small movement in a spiral direction communicated to it, after each impression of a signal. The action of this part of the apparatus will be readily understood, from the brief description of the printing telegraph of Professor Wheatstone, already given. It is only necessary to particularize, that in Mr. Bain's machine the type were arranged on the edge of the disc or wheel, radiating from its centre; and that the printing of any one upon the cylinder was effected by the movement forward of the entire type-wheel and its axis, by a crank and connecting gear in the printing train, instead of one punch or type only being struck down by the printing-hammer, in impressing a signal. The second principle is that of the use of two clocks at the two communicating stations, to rotate the type-wheels with a uniform motion. These clocks, having been adjusted to exactly the same rate, and being started from the same signal, would bring continually, at each station, similar type opposite to the paper cylinders at the same moment. The action of this part of the apparatus is exactly analogous to that of Mr. Ronalds, already described. A hand or index revolving on a dial in front of the machine, at the same rate as the type-wheel, indicates to the operator the signals which are successively in a position ready for printing in his own instrument, and therefore, if the clocks go accurately together, in a similar position in his correspondent's instrument. At the same time this hand, by coming in contact in its revolution with a pin, placed by the operator opposite to any signal that he wishes printed, completes the electric circuit at this moment, and by so doing stops the type-wheel, and releases the printing train at each station. A similar figure having thus been impressed on the cylinder at the two ends of the line, the operator removes the pin, and replaces it opposite the next signal he requires to send. The moment the pin is removed, and the circuit therefore broken, the hands and type-wheels at each station resume their revolutions, which are again checked by the contact of the hand and pin as before.

Mr. Bain's single-index telegraph, which was the instrument proposed by him for practical use, consisted of two hollow cylindrical coils of wire, placed horizontally a short distance apart, with their axes in the same line. Between them a small bar magnet was fixed across a delicate spring, which in front passed through the dial-plate of the instrument, and was turned up to form an index. The two coils were connected, so that an electric current entering from the line wire would pass through both. When this was the case, the bar magnet would be attracted towards one coil, while at the same time it would be repelled by the other. These actions tended to carry the magnet to the same side, as far as the spring to which it was attached and a fixed stop would allow of its moving. The reversal of the current inverted the effects of the coils, and the magnet would then pass to the other side. The combinations of these two movements represented the various letters and signals, being denoted to the observer by the index on the dial of the instrument. The movement of the index to the left denoting the letter I, and to the right the letter V, this instrument obtained the name of 'I and V Telegraph.'

In the autumn of the following year (1842) Mr. Bain patented his proposed plan for working an electric telegraph 'without any galvanic battery whatsoever,' or, more correctly speaking, with a peculiar form of battery. At one end of the line he buried in moist earth a large plate of zinc, and at the other end a plate of copper, iron, or other substance such as coke or charcoal, which might act the part of a negative plate to the zinc. Then on connecting these distant plates with a wire insulated from the earth, a current of electricity would constantly pass from the one plate to the other. Indeed the distant plates connected with the wire, as above described, may be regarded merely as a battery of one pair of plates, separated by a very wide interval of exciting material, represented by the earth. It was at first supposed by Mr. Bain that this current would be applicable to all telegraphic purposes, but subsequent experiments showed that it was available only for a few miles of distance; its intensity being insufficient to enable it to travel through any great length of wire. In some cases, where a constant current of low intensity is required, this earth battery would become very useful and important.*

In the early part of the year 1843, Mr. Cooke specified his patent for what has been probably the most important part of the invention, regarded in a commercial point of view. This was in reference to the mode of extending the wires between distant places, so that their insulation from one another, and from the earth, might be maintained without the heavy expense and unavoidable difficulty hitherto incurred. Before this period, the wires having been covered with cotton and insulated by coating them with shell-lac, resin, or pitch, had been laid down in tubes or pipes of wood or iron. This method had been adopted on the Blackwall line, in 1840, and has not since been altered. On the Great Western Railway it was superseded by the new and improved mode of insulation. Mr. Cooke now proposed to insulate the wires by suspending them in the air upon posts or standards of wood or iron; the wires not coming in actual contact with any part of the standard, but passing through rings of porcelain or earthenware. The standards were usually fixed at from forty to sixty yards asunder, and at each quarter of a mile a stouter post was placed, to bear the winding or straining apparatus. This was a simple winding-reel, connected with a ratchet-wheel and click to prevent its recoil, after the wire had been strained up by its means. The intermediate posts within each quarter of a mile only supported the wire, without reference to its tension, which depended solely on the winding posts. Instead of the copper wires hitherto employed, iron wires of a larger size were now used. By the adoption of this method of extending the conducting wires, the cost of construction of an electric telegraph was reduced nearly one-half, and at the same time the risk of imperfect insulation was diminished.* So long as the wires were buried in tubes beneath the ground, it was always deemed prudent to add a return wire, extending from one end of the line to the other; as it was found very difficult to render the insulation sufficiently good to enable the earth itself to be used as half of the circuit. The tendency of the electric fluid to escape from the wires in the tubes, to the earth, was much greater than to another wire lying in the same tube, so that the latter plan was always adopted. But when the suspended conductors came into operation, the insulation was rendered so complete, that the earth was subsequently in all cases used to return the current, by which means an economy of one wire throughout the whole line was effected. In addition to this, another very decided advantage was gained by the suspension of the wires, in the facility with which accidental errors or injuries were discovered and rectified. While the tubes were in use, it was necessary to supply at about each quarter of a mile along the line, a proving or testing post, within which the wires were brought up to a box, so as to afford the means of examining any of them as to their insulation and conducting power. For this purpose Mr. Cooke had invented an instrument called the 'Detector,' by which the perfect state of each wire could be tested, and the position of any error or fault discovered with considerable accuracy. Still with all these appliances, the detection and repair of any derangement of the wires demanded considerable skill, and led to no small expense. But when the wires were in sight throughout, any contact or fracture was at once visible, and was easily and quickly repaired.†

Having traced the invention through a few of its most remarkable stages, up to the time when it assumed the form it at present retains in England, we may add a few words on the method of applying it to the purposes of a railway. Mr. Cooke's first plan was one of admirable completeness in all its details. We can do little more than indicate its outline, as the full description would occupy far too much space. He proposed to divide the entire line of a railway, if necessary, into portions including each from four to six stations, and to make the traffic and communications within each of these divisions wholly independent of those on any other portion. The stations where these partitions occurred were termed Division Stations, and might be regarded each as the terminus to its adjacent portions of the line. At the same time a general system of telegraph connected all the divisions with each other, and with the actual termini of the line, so as to bind the whole of the subordinate parts into one series, and thus maintain the correspondence between the most distant points. Each station possessed a wire of its own, extending from one to the other terminus of its division, and including at every station a coil and needle. The apparatus necessary for transmitting signals by any wire and system of needles, was provided at each point, so that the most ample means of correspondence was secured between all the stations. Each needle was used to denote the condition of that part of the line which was under the control of its own station; and by its means the movements of all trains upon this portion of the railway were made known to the other stations in the same division. As the signals made by any needle were simultaneously visible by the corresponding needle at all the stations, and as all information respecting the arrival or departure of trains, state of the line, accidental impediments, &c. was immediately indicated by known signals upon the telegraph, the station master at any point had only to turn to his instrument, to perceive at a glance the existence of any circumstance which might influence the working of the line. Nothing was left to

* For an account of some experiments with earth batteries see 'Electrical Magazine,' pp. 279, 393, 521.

* Although the plan of enclosing the conducting wires in tubes beneath the ground, when put in practice on a long line, presents many difficulties, it is nevertheless perfectly safe and practicable for a short distance. Combined with some improvements in the method of insulating and protecting the wires, it is now in course of extensive adoption for the purposes of a general commercial system of telegraph throughout England.

† In the preceding paragraphs we have not included an account of all, nor even of the greater number of inventions, having reference to the transmission of intelligence by the aid of electricity. Only a few of the most remarkable have been described, and these examples have been selected with a view rather to the general illustration of the subject, than to a regular and detailed history of the successive steps.

be surmised or inferred, all was evident and visible, and in fact, in the words of Mr. Cooke, the clerk at every station possessed in his telegraph a constant bird's-eye-view of the whole of his division. In addition to these 'line' wires, as they may be termed, two others were in every case to be extended throughout the line, with instruments at each station, so as to afford the means of verbal communication, whenever this might be necessary. The result of such a complete system could hardly fail to be most beneficial, and experience has now proved how accurately and justly all Mr. Cooke's measures were planned beforehand.*

The Blackwall line absolutely depends upon this instantaneous means of communication, not only for its safety, but for the very possibility of its being worked. On this railway however the telegraphic system is different, inasmuch as from its peculiar locomotive plan, the stations do not require any communication between themselves, but only with the two terminal.

Even on railways possessing a double line of rails, so complete a means of information as that described in reference to the Yarmouth and Norwich line, would tend much to the prevention of accidents and increased safety of travelling. To prove this it is hardly necessary to recall to mind the disasters which have occurred, and still do occur at times, from the want of intelligence as to the unexpected approach of a train, or its undue delay on a particular part of the journey. Where there does not exist however an absolute necessity for such a system, its unavoidable expense would be unfavourable to its adoption. In order therefore to meet the requirements of the railway in as economical a mode as possible, a modified system has been adopted. The same plan of divisions and of 'through' communication is still adhered to, but the line-needles are dispensed with, and merely the ordinary telegraph retained at the subordinate stations. Usually the instrument possessing two needles and requiring two wires, is preferred for both the general and the divisional telegraph, as experience has shown that it is, taking all things into account, far superior to any other. The single-needle instrument, with one wire, is sometimes used for the small stations; but where the messages are either of frequent occurrence or of considerable length, it has been found that it cannot be used with advantage, from the diminished rapidity of signalling, as compared with the double needle.

It is evident that in the system above described no subordinate station can communicate directly with another station beyond its own division. Intelligence therefore referring to a distinct portion of the line, would be sent in the first place to one or other of the terminal stations of the division, and from thence would be forwarded again as required.

In England, up to the present time, the electro-magnetic or mechanical telegraph (as it is called in contradistinction to the needle-telegraph), of Professor Wheatstone, has not been adopted; the needle-instrument, from the great rapidity with which messages can be sent, and from other causes, having obtained the preference. It will however become very valuable with particular systems of working a line of railway, and also in some cases for the transmission of political or commercial intelligence, where secrecy is required. It is now in use in France, and has been entirely approved of. Within this last year or two a great and important improvement has been effected in the mechanical instrument, by the use of the electric current derived by induction from a permanent magnet, instead of the voltaic battery. This plan is not applicable to the needle instrument, but is peculiarly so to the electro-magnetic telegraph; while at the same time a permanent and unalterable source of electric power is substituted for the galvanic battery. Although the batteries now employed for telegraphic purposes are singularly constant in their action,† yet this is a most important advantage, obviating as it does all necessity for change or renewal of the source of electrical power.

It may not be uninteresting to our readers to learn the extent to which the electric telegraph has been adopted in England, at the present time. We therefore subjoin the following statement of the lines of telegraph in actual operation:—

		Miles
South-Western		99
South-Eastern		88
,,	Ramsgate branch	30
,,	Maidstone	10
,,	Tunbridge Wells, &c.	12
Blackwall		5
Eastern Counties:	Colchester line	51
,,	Thames junction	3
,,	Cambridge line	88
,,	Hertford branch	7
,,	Ely and Peterboro'	29
Norfolk Railway		38
,,	Yarmouth and Norwich	20
,,	Lowestoff branch	10
Wolverton and Peterboro'		57
Eastern Union		17
Midland Counties:	South line	49
,,	West line	41
,,	North line	73
,,	Derby and Lincoln	41
,,	Sheffield branch	5
York and North Midland		23
Hull and Selby and Milford Extension		40
York and Scarborough		43
Great North of England:	York and Darlington	45
,,	Richmond branch	9
Newcastle and Darlington		39
,,	Durham branch	2
,,	Sunderland ,,	6
,,	Shields ,,	3
Preston and Wyre		20
Great Western		19
South Devon		20
	Total	1041

This list does not include several lines on which the telegraph is yet only in partial operation or now being erected Among such may be specified the Leeds and Bradford, Leeds and Manchester, Syston and Peterboro', Newcastle and Berwick, North British, Hull and Bridlington, &c.

TELLUR-BISMUTH. [TELLURIUM, P. C.]

TEMNOPLEURUS. Some fossil echinida of the Suffolk crag are referred to this genus by Mr. S. V. Wood.

TEMPERATURE OF THE SEA. [SEA, P. C.]

TENT, MILITARY, is a temporary dwelling-place made of canvas, which is supported by one pole, or more, and distended by means of cords, which are made fast to pickets driven into the ground: tents are set up when an army is encamped in the field either for actual service or for the purpose of performing military exercises.

The tents of the private soldiers, whether infantry or cavalry, are of a conical form with circular bases, the supporting pole or *standard* of each being planted vertically in the ground, in the centre: the standard is 10 feet 3 inches long, and the whole diameter of the tent, between two opposite pickets, is 17 feet 3 inches; but from the lower extremity of the cone, at about 2 feet from the ground, the canvas hangs down vertically and forms a cylindrical *wall*, therefore the diameter of the tent within the canvas is 13 feet 3 inches. Fifteen infantry, or twelve cavalry soldiers occupy such a tent. The round tent of an officer is 12 feet 6 inches in diameter within the walls. The marquees of officers, as well as the hospital and laboratory tents, are of oblong forms on the plan; and, in these, the canvas is supported by two standards, which are connected together at their tops by what is called a *ridge pole* 6 or 7 feet long. The length of an officer's marquee is 19 feet, and the breadth 13 feet, both dimensions being taken within the walls: tents of the two other kinds are still greater.

For the rules of modern castrametation, or the dispositions of tents in an encampment, see ENCAMPMENT, P. C.

TENTACULITES, (Schlottheim), a beautiful group of small annulated pointed shells, fossil in the Silurian strata. They have been recently referred by Mr. Salter to the Annulosa. (Reports of British Association for 1845.)

TENTO'RI, CRISTO'FORO, born in 1745, in Spain, of a Venetian family, studied first in his native country, and afterwards removed to Venice, where he spent the greater part of his life. He is known chiefly for his historical works concerning Venice. He published, in 1785, his first work, 'Storia Civile e Politica della Repubblica di

* The Yarmouth and Norwich Railway was provided with this system of telegraphs, in 1844, and has been since that period absolutely free from all accidents arising from trains meeting or overtaking one another, although it is a single line of twenty miles in length, and trains are constantly started from the two ends at the same time.

† This battery, known as the 'sand-battery,' is the result of an accidental discovery of Mr. Cooke, subsequently improved upon and perfected. The metallic elements are zinc and copper, and the exciting substance clean sand moistened with dilute sulphuric acid. When well charged they will last in action for three or four months, with only an occasional addition of a small quantity of dilute acid to replace what is lost by evaporation, &c.

Venezia, con una Descrizione Corografica e Topografica de' suoi Stati,' Venice, 12 vols. 8vo. This was the first condensed history of Venice, being a kind of abridgment of the many and voluminous historians of that republic, and especially of Sandi's 'Storia Civile e Politica,' with the important addition of a topographical and statistical description of all the dominions of Venice. Tentori's second work is a continuation and completion of the first, being an authentic narrative of the destruction of the republic of Venice by the French in 1797: 'Raccolta Cronologico-Ragionata di Documenti inediti che formano la Storia Diplomatica della Rivoluzione e Caduta della Repubblica di Venezia, corredata di Critiche Osservazioni,' 2 vols. 4to., 1799, published without the author's name from prudential motives. Tentori consulted the secret state archives when they were first opened to the public after the fall of the old government, and there he found full evidence of the iniquitous arts by which the catastrophe had been effected. He gives the text of the documents in order of time, and accompanies them with a brief narrative of the events. The perusal of this work is absolutely necessary to form a correct idea of those transactions, and to counteract the erroneous impression produced by the garbled accounts published in France and in Italy; among the rest by an anonymous contemporary work entitled 'Storia degli ultimi Otto Anni della Repubblica,' which was falsely attributed to Tentori himself. [VENICE, REPUBLIC OF, P. C.]

Tentori wrote about the same time an elaborate investigation of the true character of the famous insurrection of Baiamonte Tiepolo and the two Querini in 1309, which had been ignorantly asserted by the modern democrats of Venice to have been a movement in favour of popular liberty, whilst in reality it was a conspiracy of disappointed patricians against heir own order, and for the purpose of supplanting their personal enemy, the Doge Gradenigo: 'Il vero Carattere politico di Baiamonte Tiepolo, dimostrato dall' unanime Consenso degli Storici Veneti ed Esteri,' Venice, 1798. The other works of Tentori are—'Della Legislazione Veneziana sulla Preservazione delle Lagune,' 8vo., Venice, 1792; 'Dialogo sulla vera Regolazione del Fiume Brenta, con una Appendice di Riflessioni sopra il medesimo, corredata di una Carta Idrografica,' Venice, 1790; 'Errata-corrige sulle Memorie Venete del Gallicioli;' 'Osservazioni sulle Memorie suddette,' Venice, 1797. Gallicioli was a contemporary compiler of Venetian history.

Tentori lived and died poor. He filled in the latter years of his life the office of preceptor in the patrician family of Tiepolo at Venice. As a native of Spain he was required by Napoleon's police in 1808 to swear fidelity to the intrusive king Joseph, which having refused to do, he was kept under arrest for a long time, and his papers were inspected by the gendarmes. He died in 1810 at the country residence of the Tiepolo family, at Carbonera.

(Tipaldo, *Biografia degli Italiani Illustri*; Moschini, *Della Letteratura Veneziana*.)

TERATI'CHTHYS, a fossil fish from Sheppey. (König.)

TEREBELLA'RIA, a genus of fossil Milliporidæ from the Bath oolite rocks. (Lamouroux.)

TEREBRA'TULA. This genus has been divided, according to the suggestion of Phillips ('Palæozoic Fossils of Devon'), into Epithyris and Hypothyris. (Morris.)

TERENTIUS CLEMENS, a Roman jurist, whose period is uncertain, but he lived after Julianus, or was at least his contemporary, for he cites him. (*Dig.* 24, tit. 6, s. 6.) He wrote twenty books 'Ad Legem Juliam et Papiam,' from which there are some excerpts in the Digest. He is not cited by any jurist in the Digest.

TERMS, ATTENDANT AND SATISFIED. As the assignment of satisfied terms on the purchase of property was frequently accompanied by great difficulty and expense, it was deemed adviseable to remedy this increasing evil. In the 8 & 9 Vict. an act was passed intituled 'An Act to render the assignment of Satisfied Terms unnecessary.' It provided that every satisfied term on the 31st December, 1845, attendant upon the inheritance, should on that day cease, except that such term, although thus made to cease, should afford the same protection as if the same still subsisted, if it had not been dealt with after the 31st December, 1845. And, by s. 2, That every term of years subsisting or after created, and becoming satisfied after the day mentioned above, and which should after that day become attendant on the inheritance, should immediately on becoming so attendant cease and determine.

The benefit of these provisions will be seen by referring to VENDOR AND PURCHASER, P. C. With respect to the provisions of this Act all must admit that they are beneficial. The principle that by a subtlety a subsequent purchaser might obtain a priority over a prior bonâ fide purchaser was unjust, and would only have been resorted to by judges if the legislature had not left the laws of property in an incomplete state. This devise of assignments of outstanding legal interests was but a clumsy and imperfect substitute for a general registry, with this addition, that it protected one innocent purchaser at the expense of another. There are, in the opinion of many, some technical objections to the statute, which we cannot here enter on, but which it is probable will be removed.

TERRITORIES OF INDIA. The information which was promised, in the article BENGAL, P. C., p. 232, to be given under the head BRITISH INDIA, is given under that of EAST INDIA COMPANY, P. C.

The area of Hindustan, from the Brahmapootra to the Indus and from the Himalaya Mountains to Cape Comorin, has been estimated at about 1,200,000 square miles, and the population at from 130,000,000 to 140,000,000. If the British possessions from the Ganges eastward to the frontiers of Birma be included, the entire area may be estimated at 1,270,000 square miles, and the entire population at 140,000,000.

The following tables are given, in the deficiency of official returns, merely as approximations, in order to afford such a general view as may be useful, though not accurate, of the areas, population, and possessors of the territories of Hindustan:—

BRITISH POSSESSIONS.	Square Miles.	Inhabitants.
Bengal Presidency	320,000	47,000,000
North-west Provinces	100,000	20,000,000
Madras Presidency	140,000	15,000,000
Bombay Presidency	70,000	8,500,000
Sinde	70,000	1,500,000
	700,000	92,000,000
DEPENDENT STATES.		
Hydrabad (The Nizam)	95,000	9,000,000
Berar, or Nagpoor (Raja)	45,000	2,200,000
Mysore (Raja)	27,000	3,500,000
Gwalior and Malwa (Raja)	34,000	4,000,000
Gujerat, &c. (The Guicowar)	25,000	2,000,000
Oude (King)	20,000	4,000,000
Lahore, or Panjab (Raja)	60,000	3,000,000
Cashmere States (Raja)	20,000	1,000,000
Seik Hill States (Chiefs)	20,000	1,000,000
Bundelcund States (Chiefs)	8,000	1,000,000
Rewah (Raja)	7,000	600,000
Bhopal (Raja)	6,000	500,000
Indore (Raja)	8,000	600,000
Dhar (Raja)	500	30,000
Sattara (Raja)	8,000	1,500,000
Colapoor (Raja)	3,000	600,000
Sawuntwarree (Raja)	1,000	30,000
Bhurtpoor (Raja)	2,000	500,000
Travancore (Raja)	5,000	600,000
Cochin (Raja)	1,500	200,000
Sikim (Raja)	2,000	140,000
Bikaneer	14,000	
Bahwulpoor	12,000	
Jessulmeer	9,000	
Joudpoor, or Marwar	25,000	
Jypoor	14,000	
Oodipoor, or Mewar — Rajpootana (Rajas)	10,000	10,000,000
Cutch (Rao)	7,000	
Sirohi	3,000	
Kotah	4,000	
Boondee	2,000	
Dholpoor, Tonk, &c.	2,000	
	500,000	46,000,000
INDEPENDENT STATES.		
Nepaul (Raja)	45,000	1,500,000
Bootan	25,000	500,000
	70,000	2,000,000
British Possessions	700,000	92,000,000
Dependent States	500,000	46,000,000
Independent States	70,000	2,000,000
	1,270,000	140,000,000

The Bengal Presidency comprises the provinces of Bengal, Bahar, Benares, Allahabad, Orissa, Cuttack, Gundwana, the Ceded Districts on the Nerbudda, and the British territory east of the Ganges to the frontiers of Birma.

The North-West Provinces comprise the territory of the late Agra Presidency, which was established by an Act, 3 & 4 Wm. IV. c. 85 (August, 1833), but suspended by a subsequent Act, 5 & 6 Wm. IV. c. 52 (August, 1835), which empowered the Governor-General to appoint a lieutenant-governor of the North-West Provinces, and also from time to time to declare and limit the extent of the territory placed under him, and the extent of the authority to be exercised by him. The North-West Provinces extend at present from Allahabad west and north so as to include the Delhi Doab, and the countries to the west and north of the Delhi Doab; and probably include also the Jullindar Doab and hill-country connected with it, which is added to it in our Table.

The Madras Presidency comprises the Northern Circars, the whole of the Carnatic, and extends westward across the peninsula so as to include all the British territory (Malabar, Canara, &c.) south and west of Mysore.

The Bombay Presidency comprises all the British territory on the west side of Hindustan from Canara northward, the Concan, South Mahratta country, Deccan, Candeish, Surat, &c. The Bombay Presidency will probably be made to include Sinde, which was annexed to the British territory in March, 1843, and is yet (1846) under a separate governor.

The late conquest of Lahore has added to the British territory a portion of the Lahore territory on the east banks of the Garra and Sutlege, and the Jullindar Doab, between the Beas and the Sutlege, with a considerable portion of hill-country which extends north-east towards the upper part of the Indus. By the treaty of peace with the Maharaja of Lahore, the British assume the control, in respect to tolls and ferries, of the Beas and Sutlege, the Garra, and the Punjnud to the confluence of the Indus at Mithunkote, and the control of the Indus from Mithunkote to the borders of Beloochistan.

Each Presidency is divided into Collectorates for purposes of revenue and administration, but accounts are not published of the extent and revenues of the Collectorates separately. A general statement of revenue is published for each Presidency. The last actual statement (not an estimate) is for the year 1843-4, as follows:—

Bengal Presidency		£7,328,500
North-West Provinces . . .		4,195,433
Madras Presidency		3,601,996
Bengal Presidency . . .		2,046,728
		17,172,657
Receipts from assets in England and China		1,131
Total Income . . .		£17,173,788
Total charges in India .	£15,668,843	
Total charges in England .	2,944,073	
		18,612,916
Deficiency		£1,439,128

The total amount of the public debts of the Presidencies, on the 30th of April, 1844, was 37,639,829*l.*, bearing annual interest amounting to 1,781,522*l.*

British India, strictly speaking, comprises only the territory which is actually in the possession of the British government, but the whole of Hindustan, from the Indus to the frontiers of Birma, with the exception of Nepaul and Bootan, is under British superintendence and control, and in fact forms one great body politic, of which the British government is the head. Some of the states are subsidiary, some are tributary, some are feudatory, and some are restricted, according to the circumstances and treaties under which they became dependent. The new Cashmere state is feudatory. Gholab Sing is to give to the British government annually one horse, twelve perfect shawl-goats (six male and six female), and three pairs of Cashmere shawls, as an acknowledgment of the supremacy of the British government. The government of Lahore is left independent, except that the regular army is limited by the new treaty to 25 battalions of infantry, consisting of 800 bayonets each, and 12,000 cavalry. If a larger army should be necessary in any emergency, it may be increased with the concurrence of the British government; and the limits of the Lahore territory are not to be changed without a similar concurrence. All the dependent states are prohibited from making treaties of alliance with each other. The Portuguese still possess Goa, with a small territory around it, and the port of Damaun; the French, Pondicherry, Mahé, and Carrical. Serampore and Tranquebar have been recently purchased by the British government from the Danes.

The circumstances which led to the annexation of Sinde to the British territory are stated in the article SINDE, P. C. S.

The late ruler of the Panjab, Runjeet Sing, always remained on terms of amity with the British government in India, and had not only extended his territories, but had collected before his death a powerful army and large stores of arms and ammunition. He was succeeded by his son, who having since died, and the present Maharaja, Dhuleep Sing, who succeeded, being very young, his mother the Ranee was declared regent. The Sikh army however became mutinous and ungovernable, and the result was that the Lahore government, in order to extricate themselves from the dangers to which they were constantly exposed from the violence of the soldiers, secretly gave its sanction to the leaders of the Sikh troops in making an attack on the British frontier. The Sikh army began to cross the Sutlege, Dec. 11, 1845, and, after investing Ferozepore on one side, took up an intrenched position at the village of Ferozeshah, about ten miles in advance of Ferozepore, and about the same distance from the village of Moodkee. In this camp the Sikhs had placed 108 pieces of cannon, and a force of upwards of 50,000 men, in order to intercept the British force which was advancing from Umballah to the relief of Ferozepore, which had been attacked without provocation or declaration of hostilities. The British army, under Sir Hugh Gough, commander-in-chief, after a rapid march of 150 miles, reached Moodkee, Dec. 18, and on the evening of the same day repulsed an attack of the Sikh army and captured 17 guns. On the following day the army was concentrated at Moodkee, and on the 21st moved towards Ferozepore; and having on the march formed a junction with Major-General Sir John Littler, who had with him 5000 men and 21 guns, Sir Hugh Gough formed the army in order of battle, and attacked the enemy's intrenched camp, and on the evening of Dec. 21 and the morning of Dec. 22 captured 74 pieces of cannon, took possession of the camp, with large quantities of ammunition and warlike stores, and compelled the enemy to retreat to the west side of the Sutlege. The British force on this occasion consisted of 16,700 men, and 69 guns, chiefly horse artillery. The Sikh forces were variously estimated at from 48,000 to 60,000 men, with 108 pieces of cannon of large calibre and in fixed batteries. Sir Henry Hardinge, governor-general of India, was engaged in this battle as second in command. The total killed of the British was 694, the total wounded 1721; in all 2415. The British took 91 pieces of cannon. The loss of the Sikhs must have been very large.

Major-General Sir Harry Smith having with much difficulty and loss of some baggage formed a junction with the troops at Loodiana, who were hemmed in by a formidable body of the enemy's troops, the Sikh army then retreated, and took up an intrenched position at Budawal, from which they were also compelled to retreat down the Sutlege, but having been reinforced by about 4000 regular troops, 12 pieces of artillery, and a large force of cavalry, from the right bank, they advanced towards the British forces in order to intercept their communication with the main army, intrenching themselves near the village of Aliwal. The Sikh camp was carried by storm on the 28th of January, 1846, the whole of the enemy's cannon and munitions of war captured, and his army driven headlong across the Sutlege by a difficult ford. Fifty-six guns were taken by the British, and 11 others were sunk in the river. The total of British killed was 151, the total wounded 413, total missing 25; in all 589. The commander at the battle of Aliwal was Sir Harry Smith.

The result of this second victory was the evacuation by the Sikh garrisons of all the forts previously occupied by detachments of Lahore soldiers on the left bank of the Sutlege, and the submission of the whole of the territory on that side of the river to the British government.

Meantime the main body of the Sikh army had taken a position on the left bank of the Sutlege near Sobraon, had formed a good bridge of boats across the Sutlege, and had constructed a strong battery and intrenchments on the left bank, which Sir Hugh Gough did not deem it prudent to attack till the siege train and ammunition had advanced from Delhi, which having arrived on the 8th, and the army of the commander-in-chief having on the same day been reinforced by Sir Harry Smith with the victorious army of Aliwal, the attack on the Sikhs was made on the 10th of February. The enemy's camp, strongly intrenched, defended by 35,000 men, and 67 pieces of artillery of large calibre, with a considerable camp and some artillery on the opposite bank of the river, was stormed by the British army under Sir Hugh Gough, and after two hours of desperate resistance on the part of the Sikhs, they were driven into and across the river with immense loss, 67 guns having been captured by the British. Sir Henry Hardinge, though suffering from the effects of a fall, was also in this battle. The loss of the enemy is supposed to have been from 8000 to 10,000 men. The loss of the British was 320 killed, 2063 wounded; in all 2383.

After this the remains of the Sikh army retreated from the west bank of the river, having been defeated in every action, with the loss of a vast number of men and 220 pieces of field artillery. The British army crossed the Sutlege, entered the Panjab, and the Maharaja having delivered himself up to the Governor-general, he was conducted back, and restored to his palace in the city of Lahore on the 20th of February, 1846. A treaty of 'perpetual peace and friendship between the British government on the one part, and Maharaja Dhuleep Sing, his heirs and successors, on the other,' was concluded at Lahore, March 9, 1846. A similar treaty was concluded with the Maharaja Gholab Sing at Umritsir, or Amritsir, March 16, 1846.

Sir Henry Hardinge has since been created Viscount Hardinge, with an annuity of 3000*l*., and Sir Hugh Gough has been created Lord Gough, with an annuity of 2000*l*., the annuities to descend to the two next surviving heirs male of the body of each who may succeed to the respective titles; but the Court of Directors of the East India Company having granted to Sir Henry Hardinge an annuity for life of 5000*l*., payable out of the territorial possessions of the East India Company, it was enacted that the government annuity of 3000*l*. should not be paid to Viscount Hardinge till after the annuity of 5000*l*. terminates; and an annuity for life of 2000*l*. having in like manner been granted by the East India Company to Sir Hugh Gough, it was enacted that only one-half of the government annuity should be paid to Lord Gough till after the East India Company's annuity terminates. The two annuities granted by the East India Company commence from the date when the British troops arrived at Lahore. Viscount Hardinge has therefore 5000*l*. a-year, and Lord Gough 3000*l*. a-year. Their two next surviving heirs male of the body of each will have respectively the government annuities of 3000*l*. and 2000*l*.

(*Parliamentary Papers, Maps*, &c.)

TERTULLIANUS, Jurist. [TERTULLIANUS, P. C.]

TERWESTEN, AUGUSTYN, was born at the Hague in 1649. He became at about twenty years of age the pupil of N. Wieling and W. Doudyns; before this time he had maintained himself by working and chasing for goldsmiths. In 1673 he went to Italy, where he studied chiefly in Venice and Rome, and visited France and England; and after an absence of six years returned in 1678 to the Hague, where he distinguished himself by his historical and mythological compositions, sacred and profane, but his favourite author was Ovid. He restored the Academy of the Hague, which had declined to a very inefficient state; and in 1690 he was invited by the Elector of Brandenburg, afterwards King of Prussia, to Berlin, and was appointed his court painter. He contributed chiefly to the establishment of the Academy of Berlin, of which he was made director. He died at Berlin in 1711. He painted with remarkable rapidity and freedom; there are a few etchings by him.

TESSELATED PAVEMENTS. [TILES AND PAVEMENTS, P. C. S.]

TEST ACT. [BOROUGHS, &c., P. C., p. 202.]

TESTE OF A WRIT. [WRIT, P. C.]

TESTELIN or TETTELIN, LOUIS, was born at Paris in 1615, and was a pupil of Vouet. He was elected one of the original members of the French Academy, though he was only thirty-three years of age at its establishment in 1648. His presentation picture was an historical portrait of Louis XIV. In 1650 he was appointed one of the professors of the academy. Testelin's picture of the Resurrection of Tabitha by St. Paul, painted in 1652, is considered one of the master-pieces of the French school of painting, and is compared with Le Sueur's celebrated picture of Paul Preaching, and the Burning of the Books at Ephesus; it is in the church of Notre Dame; there is a print of it by Bosse and Picard le Romain. There is another celebrated picture by Testelin in the church of Notre Dame—the Flagellation of St. Paul and Silas, which was painted in 1655, the year of his death. St. Louis attending a sick man, in the Hospital de la Charité, is likewise a distinguished work by Testelin. As he died at the early age of forty, his works are necessarily scarce. Le Brun and Testelin were great friends. Testelin had great theoretical knowledge, and he and Le Brun frequently conversed on the principles of art. Testelin never was in Italy, but on one occasion the subject of their argument was the comparative merit of the Roman and Venetian schools, taking their abstract characteristics as their subject, Roman design, and Venetian colour and light and shade, Le Brun advocating the Roman, and Testelin the Venetian. After arguing the whole night through, Le Brun rose, saying, 'My friend, you have charmed me by your profound knowledge; the victory is yours; certainly no man is better instructed in the great maxims of his art.'

(D'Argenville, *Abrégé de la Vie des Peintres*, &c.)

TETRAGONO'LEPIS, a remarkable and numerous genus of fossil ganoid fishes, chiefly from the lias strata of Dorsetshire. (Agassiz.)

TETRA'NTHERA, a genus of plants belonging to the natural order Lauraceæ. The flowers are diœcious, some hermaphrodite, involucrated. The calyx 6-parted, the segments nearly equal or wanting. The fertile stamens generally about 9, in the petaloid flower from 12 to 21. The leaves are variable, with pinnate veins.

T. Roxburghii is a variable plant, a native of the mountains of India and China. The leaves are ovate, oblong, acute at the base, smooth and shining above, more or less downy beneath. The umbels rather compound and nearly white. The fruit is globose, black, and about the size of a pea, yielding a kind of greasy exudation from which the Chinese manufacture candles of a bad quality, and which serves as a basis for salves. This fixed oil is supposed to constitute the principal part of the fruit of *Persea gratissima*, so much esteemed in the West Indies under the name of Avocado Pear.

(Lindley, *Vegetable Kingdom*; Lindley, *Flora Medica*.)

TETRA'ODON. [GYMNODONTES, P. C. S.]

TETRA'PTERUS, a genus of fossil fishes from the Cretaceous and Tertiary strata. (Agassiz.)

TEXAS. This country lately formed a portion of the territory of Mexico. The revolution through which it became separated, arose from the permission given to immigrants from the United States to receive grants of lands. The first permission of this kind was conceded to Moses Austin in January, 1821, which on his death was extended to his son, Stephen Austin, and confirmed by the Mexican Cortes, April 14, 1823. These and other similar concessions were made on condition of bringing into the country from 500 to 200 families as the consideration of each grant of land.

Texas formed part of the State of Cohahuila in the confederation of the Mexican States. It was established as a state August 15, 1824, and the State Constitution was promulgated in March, 1827.

In 1830, the first collision between the Mexican troops and the American settlers occurred. This was followed by various conflicts; and at last the independence of the country was proposed, when Stephen Austin advised that no limits of territory should be mentioned, and that the field should be left open to extend beyond the Rio Grande to Chihuahua and New Mexico.

On the 2nd of March, 1836, a declaration of independence was issued; and, on the 17th, a constitution was proclaimed, founded on the model of those of the southern states of North America. The law of slavery, which Mexico had abolished, was re-instituted—the legislature was denied the power to emancipate slaves—the presence in the country of free coloured persons was interdicted, and the privileges of citizenship were denied to all Africans, and the descendants of Africans and Indians.

On the 21st of April, 1836, the battle of San Jacinto was fought between the Mexican and Texan forces, when the president of Mexico, General Santa Anna, was taken prisoner by General Houston. This event terminated all Mexican authority in the country.

In 1837 the Committee of Foreign Affairs at Washington reported to the House, that the independence of Texas ought to be recognised. This recommendation was laid upon the table—but at the last hour of that session of Congress and of the Presidency of General Jackson, an amendment to the General Appropriation Bill was carried, for the payment of the outfit and salary of a diplomatic agent to Texas when the President should receive satisfactory evidence that Texas was a independent power. Immediately after this bill was signed by the President, the nomination of a Chargé d'Affaires of Texas was sent by him to the Senate and consented to by it—and thus it was, that the Republic of Texas was recognised by the United States. To have effected this recognition by treaty, a majority of two-thirds of the Senate would have been requisite, and such a majority could not then have been obtained. A mere majority was sufficient to confirm the nomination of a chargé d'affaires.

On September 25, 1839, a treaty was signed between France and Texas, and was ratified at Austin, Jan. 18, 1840. This was the first recognition of the independence of Texas by a European power. On Nov. 16, 1840, a treaty between Great Britain and Texas was signed, which was ratified at Austin in Feb., 1841. But no treaty was made between the governments of the United States and Texas; and in consequence of no such treaty being required as a condition precedent to the recognition of Texan independence by this country, the annexation of Texas to the United States was greatly facilitated.

The government of Mexico persisting in its refusal to acknowledge the independence of the country, proposals were made to annex the republic to the United States. The trade and security of the people settled in the western district were constantly disturbed—marauding incursions were common, and the government had not pecuniary resources sufficient to enable it effectively to carry on a war. It had been hoped that the influence of France or of Great Britain would have checked the evils arising from the obstinacy and weakness of the Mexican authorities. Seeing that this did not happen, public opinion became favourable to a union with the United States, and this feeling was further stimulated by the efforts of Presidents Tyler and Polk, both of whom strongly urged upon the Congress of the United States the policy of taking advantage of the opportunities afforded by the political condition of Texas. On the passing of an Act by the Texan Congress to surrender its independence, in December, 1845, an Act of Congress of the United States declared Texas to be one of the States of the North American Union. The boundary between Texas and the United States was fixed by the Florida Treaty of 1819. The Congress of Texas declared the western limits of Texas to extend to the Rio Grande, including the department of New Mexico, which had never formed part of the State of Texas or Cohahuila, and was settled by the Spaniards as early as 1595. The government of the United States, since the annexation of Texas, appears to make a claim to the same extent of territory, and there is also every probability that one of the results of the pending war with Mexico will be to extend the authority of the United States over the entire province of California.

(*Address of J. Q. Adams to the Electors of Braintree*, September 12, 1842; Kennedy's *Texas*; *Congressional Documents of the Senate of the United States*, 1846; Falconer *On the Discovery of the Mississippi*, 1844.)

THAW is the reduction of ice or snow to a liquid state in consequence of an increase of temperature. This effect is produced on the surface of the earth or in the atmosphere during the spring season by the return of the sun to the hemisphere of the observer, the solar rays then falling in greater abundance than before on a given extent of ground; or it is produced by accidental currents of warm air which pass over a frozen mass. The dissolution of the particles of ice in the atmosphere is the cause of the humidity which accompanies a thaw.

As the conversion of a liquid into ice always commences at the surface of the former, and about the sides of the vessel containing it, or about those of a solid body immersed in it, so in ice surrounded by air which has acquired a higher temperature than the ice has, the process of liquefaction commences at the sides and extends gradually from thence inwards; ice being a bad conductor of heat, the central parts of it are the last which are dissolved. It is observed that when solid bodies, whose temperatures are equal to one another and higher than that of ice, are applied to the latter, the ice is dissolved most rapidly by those which have the greatest power of conducting caloric: thus a piece of ice being laid on a plate of polished metal, and a piece of equal magnitude on wood, the ice on the metal will be dissolved before that which is laid on the wood, not only when the temperature of the metal and wood are equal, but even when the temperature of the wood considerably exceeds that of the metal, the latter conveying more abundantly to the ice the calorie which it is continually receiving from the atmosphere.

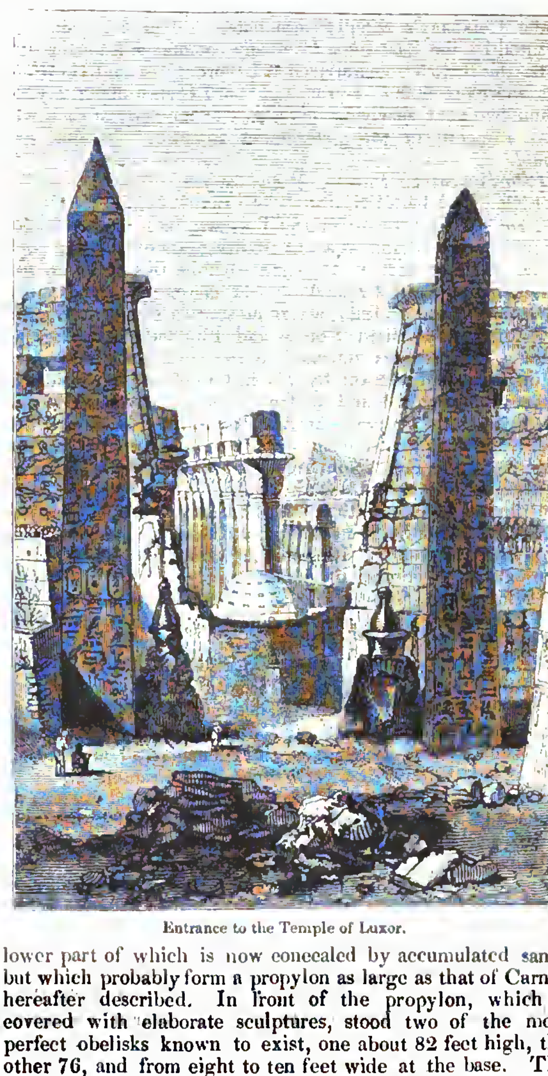
A severe and long-continued frost abstracts so much caloric from terrestrial bodies, as the walls of buildings which are not exposed to the sun, that these are often cooled below the temperature of freezing water; and while in this state, if a current of warm air pass over their surfaces, the water which the air holds in solution deposits itself on the walls, where it is converted into ice or snow: it remains thus frozen for a time after a thaw has commenced, but at length, the temperature increasing, the ice is melted and the walls are then covered with moisture.

It is often remarked that at the time of a thaw taking place there is felt a degree of coldness greater than that which is experienced during the continuance of the frost; this is apparently caused merely by the evaporation of the moisture which is then on the skin, for the thermometer at the same time indicates an elevation of temperature in the atmosphere.

The overflowing of rivers by the dissolution of the snow and ice on the mountains about their sources is well known, and to the liquefaction of the ice formed by the previous congelation of water which has introduced itself in the fissures of rocks is to be ascribed the occasional severance of large masses from the sides of mountains; the expansion of the water in freezing having destroyed the cohesion, so that the parts are only held together by the ice, and on the liquefaction of this the disunion is complete.

THEBES. The writer of the article THEBES, P. C., has, owing to a misapprehension, given references to CARNAC and LUXOR, instead of describing them under the article Thebes. We now supply the omission.

On the site and amongst the ruins of the antient city of Thebes stand four principal villages, Carnac and Luxor on the eastern bank of the Nile, Gournou and Medinet-Abou on the western bank. At Luxor, near the river, are the remains of a temple, the entrance to which is through a magnificent propylon, or gateway, consisting of two pyramidal moles, the



Entrance to the Temple of Luxor.

lower part of which is now concealed by accumulated sand, but which probably form a propylon as large as that of Carnac hereafter described. In front of the propylon, which is covered with elaborate sculptures, stood two of the most perfect obelisks known to exist, one about 82 feet high, the other 76, and from eight to ten feet wide at the base. The smaller obelisk has been removed by the French, and now stands in the Place de la Concorde at Paris. A ship constructed expressly for the purpose of transporting the obelisk sailed from Toulon in March, 1831. The smaller obelisk was selected as not only lighter, but in a better state of preservation than the larger. This obelisk was found to have been placed on a higher pedestal than the other, and somewhat more forward, so as to make the difference of size less observable by the spectator. The obelisk was lowered, conveyed to Paris, and erected Oct. 25, 1836. The cut on the preceding page presents a view of the two obelisks with the propylon seen behind them, and a portion of the ruins of the interior of the temple.

But the remains of Carnac, about a mile and a quarter lower down the river, are still more wonderful than those of Luxor. An irregular avenue of sphinxes, 2180 yards in length, connects the southern entrance of Carnac with the northern entrance of the temple of Luxor. Carnac is about 830 yards from the east bank of the Nile, and is surrounded by a wall of unburnt bricks about 5300 yards in circuit, or more than three miles. An adequate idea of the extent of the remains in this inclosure could only be given by a plan on a large scale. The largest of them, which some have thought to be a temple and some a palace (it may have been both) is 1215 feet in length, 360 feet in its greatest width, and 321 feet in its least width. The entrance to it (the western entrance) fronts the Nile, with which it is connected by an alley of crio-sphinxes (sphinxes formed of the body of a lion and the head of a ram). This alley conducts to a propylon, without sculpture, 360 feet long and 148 feet high, with a great doorway in the centre 64 feet high; passing through which a large court is entered having a range of pillars on the north and south sides, and a double row of lofter pillars down the middle, which terminate opposite two colossal statues in front of a second propylon. A flight of twenty-seven steps then leads to an enormous hall, which has been called the Great Hypostyle Hall of Carnac. It is 338 feet by 170½ feet, and comprises an area of 57,629 square feet. The roof, which is flat, and when perfect was formed of very large slabs of stone, is supported by 134 columns, the largest of which are about eleven feet in diameter and the smallest nearly nine feet. Four churches of the size of that of St. Martin's in the Fields, London, might stand side by side in this vast hall without occupying the whole space. The interior propylon, pillars, and walls are covered with sculptures. Four beautiful obelisks form the entrance from the hall to the adytum, or sacred place, which consists of three apartments, all of granite, and the central room, or sanctuary, is adorned with sculptures, and painting and gilding. Beyond the adytum are porticoes and galleries, which were probably continued to another propylon at the eastern end.

Four propyla, with colossi in front of them, form the entrance on the south side, at the end of the long avenue of sphinxes leading from Luxor; and there was probably a similar entrance on the north side.

(*Library of Entertaining Knowledge*, 'Egyptian Antiquities,' vol. i.; *Penny Magazine*, 1837.)

THEOTOCOPU'LI, DOMINICO, called EL GRECO, was painter, sculptor, and architect. He is said to have been the scholar of Titian. In 1577 he was residing in Toledo, where he appears to have settled, though from his name and his surname of El Greco, the Greek, he was doubtless a native of Greece. He painted many pictures in Toledo, and acquired a great reputation in Spain. El Greco made the marble decorations of the altar (retablo), and the altarpiece of the Parting of Christ's Raiment before the Crucifixion, for the old sacristy of the cathedral of Toledo, on which he was occupied from 1577 until 1587, when he was paid for the whole work 319,600 maravedis, of which 119,000 were for the picture; about 100*l.* sterling altogether, but owing to the change in the value of Spanish money it is now perhaps impossible to calculate the sum accurately. He was however not engaged exclusively on this work all this time; he painted other works in the meanwhile, and for Philip II. an altarpiece of the Martyrdom of St. Maurice for the Escorial, which however Philip was dissatisfied with. It is now in the chapel of the college; a picture by Romulo Cincinnato was substituted for it over the altar of the chapel of St. Maurice in the Escorial. The objections to this picture were a certain hardness of colour and extravagance of design which El Greco is said to have introduced to prevent the picture being mistaken for a work of Titian, which it seems had been the fate of some of his best paintings.

As an architect he designed the Casa del Ayuntamiento or mansion-house, of Toledo, and the churches of La Caridad and of the convent of the bare-footed Franciscans at Illescas; and he executed also a great part of the paintings and sculptures of these churches. In 1590 he designed the church of the Augustines at Madrid, called de Donna Maria de Aragon, and painted the principal altarpiece of their college. He designed also several monuments, which are among his best works. He died at Toledo in 1625, according to Palomino, seventy-seven years of age; and was buried with great pomp in the church of St. Bartholomew.

El Greco's pictures were still very numerous at the end of the last century; Cean Bermudez enumerates a great many in Toledo, Illescas, Escalona, Bayona, in Segovia, La Guarda, Mostoles, Casarrubios, Siguenza, Medina Celi, Valencia, Leon, at the Escorial, and in Madrid. Many have probably since been removed. Mr. Ford, in his 'Handbook of Spain,' notices only three pictures by this painter—Christ bearing his Cross, and a Nativity, and an Adoration, in the Salon de la Sacristia al Toledo.

Richard Cumberland speaks in high terms of the pictures of El Greco, especially the Preparation for the Crucifixion and the Parting of Christ's Raiment in the cathedral of Toledo, already mentioned; and the entombment of Don Gonzalo Ruiz, Count Orgaz, in the church of Santo Tomé at Toledo, which he considers his masterpieces. The first he terms a grand composition so entirely in the style and manner of Titian, that his reputation could have suffered no injury by its adoption. The burial of the Conde de Orgaz was painted in 1584 for the archbishop of Toledo, Cardinal Don Gaspar de Quiroga, for the great sum of 2000 ducats according to Cumberland. The Count Orgaz was the founder of the Augustine convent of San Estevan at Toledo, and this picture was painted in honour of the foundation—the saints Augustine and Stephen are represented depositing the count in his tomb, and the picture contains the portraits of many distinguished persons of the time.

His son, George Manuel Theotocopuli, was also a sculptor and architect of eminence. He was appointed sculptor and architect to the chapter of the cathedral of Toledo in 1625: he died at Toledo in 1631. He was the architect of the ochavo of the cathedral: it is an octagon decorated with precious marbles and a painted dome, and is used as the treasury-house of the Virgin, where her splendid dresses are kept, as well as many precious relics.

THE'LODUS, a fossil fish from the upper Silurian strata of Ludlow. (Murchison.)

THEONO'A, a genus of fossil Zoophyta from the secondary and tertiary strata. (Lamouroux.)

THIBAUT, ANTON JUSTUS FRIEDRICH, a celebrated German jurist, was born on the 4th of January, 1772, at Hameln in Hanover. In 1792 he went to Göttingen to study the law; he continued his studies at Königsberg; and he finished them at Kiel, where he became acquainted with Niebuhr. In this university he took the degree of D.C.L., and in 1796 was admitted as a junior teacher of the law. He soon rose to eminence, and at the age of twenty-seven was appointed ordinary professor of civil law. In 1802 he went in the same capacity to Jena, where he published his 'System des Pandekten-Rechts,' the first systematical attempt of the kind that was written in the German language, the former works on that subject having been written in Latin. The merits of this excellent work were generally acknowledged, and Thibaut was chosen by the Emperor Alexander one of the foreign members of the commission of legislation for Russia, and in 1805 he was invited to the university of Heidelberg, where he remained till his death. Though scarcely passed thirty, he was considered to be the first civilian in Germany after Hugo, Savigny having not yet attained his great reputation. Twice Thibaut was chosen prorector of the university of Heidelberg, and nine times he filled the office of dean of the faculty. He was also chosen deputy of the university in the first chamber of the States of Baden, but as his new duties interfered with those of a teacher, he resigned the office. In 1826 he was made a privy councillor. His fame and his popularity among the students led to his receiving invitations from other universities, as for instance from Leipzig, where the place of professor primarius of law was offered to him with a very large income, besides a prebend in the chapter of Merseburg; but nothing could induce him to leave Heidelberg. In 1830 he was knighted by the Grand-Duke of Baden, his former pupil, who in 1834 appointed him judge for the grand-duchy, in the newly established tribunal of arbiters for the domestic affairs of Germany. In 1837 he was chosen Membre correspondant de l'Académie des Sciences Morales et Politiques, for the section of legislation and jurisprudence. Thibaut died on the 28th of March, 1840, with the well-deserved reputation of being equal to Savigny as a civilian, and superior to him as a teacher and a practical jurist. The great object of Thibaut was to distinguish clearly between the obsolete portions of the Roman law, and those which were of real practical use. In his private life Thibaut was most amiable; to many a poor student he proved a kind father; to many who had talent, a wise friend. His house was open to all his pupils, whether introduced to him by others or by themselves; but he showed particular attention to those who, besides their legal knowledge, showed proficiency in music, of which he was a profound judge. His little work on Purity of Music quoted below is a specimen of his refined taste in this respect.

The principal work of Thibaut is his 'System des Pandekten-Rechts,' mentioned above, of which the eighth edition was published at Heidelberg in 1834, 2 vols. 8vo., and a ninth edition since the author's death, by Professor Buchholtz, Jena, 1846. This work is in the hands of nine out of ten lawyers in Germany, but though of the highest value, it is rather a difficult book to beginners. The following are the other works of Thibaut according to the date of their publication:—1, 'De genuina Juris Personarum et Rerum Indole veroque hujus divisionis Pretio,' Kiel, 1796, 8vo., is a dissertatio inauguralis which brought the young author the honour of being attacked by Hugo. 2, 'Juristische Encyklopädie und Methodologie,' Altona, 1797, 8vo. 3, 'Versuche über einzelne Theile der Theorie des Rechts' ('Essays on several Branches of the Theory of the Law'), Jena, 1798-1802, 2 vols. 8vo.; 2nd edit., 1817, translated into French by De Sandt et De Chassat, Paris, 1811. 4, 'Ueber Besitz und Verjährung' ('On Possession and Prescription'), Jena, 1802, 8vo., a work which caused a great sensation, but was afterwards thrown into the shade by Savigny's work on Possession. 5, 'Civilistische Abhandlungen' ('Essays on Civil Law'), Heidelberg, 1814, 8vo.; 2nd edit., 1822. 6, 'Ueber Reinheit der Tonkunst' ('On Purity of Music'), Heidelberg, 1825, 8vo.; 2nd edit., 1826. 7, 'Ueber die Nothwendigkeit eines Allgemeinen bürgerlichen Rechtes in Deutschland,' Heidelberg, 1814, 8vo. ('On the Necessity of a Common Code of Laws for Germany'). This work placed its author at the head of a great legislative movement, and a short explanation is necessary in order that the reader may understand it. Antient German laws and a large portion of the Roman law exist there together, the former referring principally to landed property, entailed estates and others called 'noble estates,' the different hereditary and temporal tenements of the peasantry, the succession to such estates, the legal consequences of marriage inasmuch as it effects complete communion of property, personal and real, between husband and wife, further the remnants of feudal institutions, and others; while contracts, the common succession to personal property and to land, except entailed estates either noble or villain, testaments (in a great measure) and many other things are regulated by the Roman law. In some parts of Germany the German and Roman elements of the law are knitted together by modern legislation into a regular code, civil and criminal, as the Austrian code; the Prussian, which is in force in the greater portion of the kingdom of Prussia; the Bavarian criminal code, the work of Feuerbach, in Bavaria and Oldenburg. But the civil law in the latter two countries and nearly the whole of Germany, except Austria and Prussia, is that compound of Roman and German elements which has been mentioned above. Besides the 'Common Law,' by which is meant the Roman-German compound aforesaid, there is a variety of provincial and local laws, among which the laws of the cities of Magdeburg, Hamburg, and Lübeck deserve a particular attention, especially the law of Lübeck, since it is not only shaped into the form of a code, but is the common law of nearly all the towns of North-Eastern Germany as well as those in the adjacent provinces of Eastern Prussia and the so-called German provinces of Russia, Courland, Livonia, and Esthonia. To augment the difficulties, the French code became the common law in the Rhenish provinces and in the grand-duchy of Baden.

This sketch, however imperfect, may be sufficient to show that the administration of the law in Germany is no easy matter; and that the difficulties increase in proportion to the extent of the jurisdiction of the different courts; and hence the strange, yet under such circumstances necessary fact, that the faculties of law in the various universities were, and partly still are, so many courts of justice before which cases used to be brought which require more learning, especially historical learning, than is generally possessed by the members of the common courts of justice. Thibaut's proposal was to fashion this legal chaos into a general code, as was done in France; and although he admitted that the task would be very difficult, he maintained that what had been done in France would diminish the difficulty. His plan became soon popular, but he also met with decided adversaries, among whom Savigny took the lead, who contended that Germany was not yet ripe 'for a common legislation; that the idea itself was good, but that there were so many scientific (rather theoretical) differences among the jurists concerning the most important points, that every attempt would prove abortive till matters had previously been settled scientifically.' Savigny also could refer to an example, the Prussian code (*Landrecht*), which, though only an experiment upon a portion of Germany, is yet considered to be a failure: he avoided to speak of the Austrian code. At present the opinion of Thibaut has more adherents than that of Savigny; and since the latter's views depend merely upon an eventuality which cannot but take place, however soon or late it may be, it is to be presumed that the period when Germany will enjoy a common code is not so very distant. Thibaut has entered into many details concerning that important question in several of his numerous essays, dissertations, and treatises in the principal legal reviews of his country. He was the founder of the 'Civilistisches Archiv' and the 'Heidelberger Jahrbücher.'

(*The Life of Thibaut*, in *Heidelberger Jahrbücher*, year 1840.)

THIN PLATES. [Colours of Plates, P. C. S.] We take this opportunity of correcting an accidental mistake in the article referred to. It is there stated (p. 395, col. 2) that the thicknesses of the air at the most and least luminous parts of the rings are proportional to the 'semi-diameters of the rings;' whereas they are proportional to the *squares* of the semi-diameters of the rings.

THLASPI (from θλάω, to compress; seeds compressed), a genus of plants belonging to the natural order Cruciferæ, and the sub-order Angustiseptæ. It has a roundish notched pouch, boat-shaped valves winged at the back; the seeds are numerous, the petals equal, the flowers white.

T. arvense, Penny-cress, has oblong toothed leaves and erect stems, an elongated fruit-bearing raceme, orbicular pouches with a longitudinal wing. It is native throughout Europe and in England. The flowers are small and white, and the whole plant when bruised has a somewhat alliaceous odour.

T. perfoliatum has obcordate pouches, the stem-leaves cordate, oblong, the petals equal in length to the calyx. It is a native of Europe and is found in England on a chalky soil.

T. alpestre is found on limestone mountain pastures throughout Europe and England; the leaves are entire, the radical ones ovate, stalked, the cauline ones sagittate and stem-clasping; the petals nearly as long as the calyx, the pods obcordate, from 8- to 12-seeded.

The species of this genus are hardly worth cultivation except in general collections or in botanical gardens. They succeed best in a light sandy soil.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

THORWALDSEN, BERTEL (*Albert*), was born November 19, 1770, at Copenhagen. He was the son of Gottschalk Thorwaldsen, a carver in wood, and his wife Karen Grönlund, the daughter of a priest of Jütland. Gottschalk was a native of Iceland, and was in very poor circumstances when his son Bertel was born. Bertel assisted his father in his work at a very early age, and when only eleven years old he attended the free school of the Academy of Arts at Copenhagen, and made such progress in two years that he was enabled to improve his father's carvings; and himself undertook to execute the head-pieces of ships. At the age of seventeen he obtained the silver medal of the academy, for a bas-relief of Cupid reposing; and in 1791, when he was only twenty years of age, the small gold medal for a sketch of Heliodorus driven from the temple. Two years later he obtained the principal gold medal of the academy, and with it the privilege of studying for three years abroad at the government expense. Before setting out, however, he devoted a year or two to preliminary general study, for scholarship was not one of his acquirements, and he had much to read and much to learn. On the 20th of May, 1796, he set out for Italy in the Danish frigate Thetis, and he arrived at Naples in the end of January of the following year, in the packet-boat from Palermo. The Thetis cruised in the North Sea until September; in October it touched at Algiers; it then performed quarantine at Malta, made a voyage to Tripoli to protect Danish commerce, and performed quarantine a second time at Malta, when Thorwaldsen left it in a small sailing boat for Palermo, where he took the packet-boat to Naples.

At Naples, wholly unacquainted with the Italian language, and for the first time entirely separated from his own countrymen, Thorwaldsen's heart failed him, and he longed to return to Denmark, which according to his own account he would have done if he had found a Danish vessel about to leave the port at the time. However, in a little time he found courage to engage a place in the coach of a vetturino for Rome, where he arrived March 8, 1797.

Thorwaldsen brought letters of introduction to his distinguished countryman Zoëga, who however did not give the young sculptor much encouragement, nor did he estimate his ability very high. When Zoëga was once asked what he thought of him, three years after his arrival, he answered with a shake of the head, 'There is much to find fault with, little to be contented with, and he wants industry.' Up to this time Zoëga was right, except in the last particular. Thorwaldsen was industrious, but fastidious, and often destroyed what had cost him much labour. This was the fate of a statue of Jason with the Golden Fleece which he had modelled to take back with him to Copenhagen at the expiration of his term of three years allowed by the Academy. He however made a second attempt at the same figure, and this statue satisfied even the difficult Zoëga, with whom Thorwaldsen was about to return to Denmark; and Canova exclaimed, 'This work of the young Dane is in a new and a grand style.' By the assistance of a Danish lady, Frederika Brun, who gave him the necessary funds, which he had not, and praised the statue in song, it was cast in plaster, and Thorwaldsen prepared for his return home: but when on the point of starting and about to step into the vehicle of the vetturino, one of his companions, the Prussian sculptor Hagemann, found that his passport was not in order, and he was obliged to put off his journey until the next day. Thorwaldsen determined to wait with him, the vetturino started without them, this delay was followed by another, and it eventually happened that Thorwaldsen did not return to his native country until 1819, after an absence of twenty-three years. The liberality of Thomas Hope was the immediate cause of Thorwaldsen's finally settling in Rome. The words of Canova upon the statue of Jason were repeated in the artistic circles of Rome, and echoed by the professional ciceroni of the place. One of these ciceroni took Mr. Hope in the year 1803 to the studio of the young Dane to see the statue which the great sculptor had praised. The English connoisseur stood long before the plaster figure, then inquired what Thorwaldsen required for a marble copy of it: '600 ducats,' was the answer; 'You shall have 800,' was the generous reply of the Englishman.

From this time the star of Thorwaldsen was in the ascendant; the statue was however not finished until many years afterwards, but many celebrated works were done in the meanwhile; as the bas-reliefs of Summer and Autumn, and the dance of the Muses on Helicon; Cupid and Psyche; and Venus with the apple. His fame spread far and wide, and Christian, the present king (then crown-prince) of Denmark, wrote him a pressing invitation to return to Copenhagen, communicating at the same time the discovery of a white marble quarry in Norway. Thorwaldsen was eager to return, but commission upon commission rendered it impossible; he could not leave the papal city.

During this busy time Thorwaldsen recreated himself in the summer seasons at Leghorn, in the beautiful villa of Baron Schubart, the Danish minister at Florence: he executed also some of his works here.

In 1812, when arrangements were being made for Napoleon's visit to Rome, the architect Stern, who superintended the preparations, happened to sit next to Thorwaldsen at one of the assemblies of the Academy of St. Luke, and asked him if he could get ready a plaster frieze for one of the large apartments of the Quirinal Palace, in three months. Thorwaldsen undertook the commission, and in three months the plaster sketch of his celebrated bas-relief of the Triumph of Alexander was completed. The immediate subject was Alexander's triumphal entry into Babylon: the length of the frieze is 160 Roman palms, its height five palms: it has been twice executed in marble, with slight variations, and is engraved in a series of plates by S. Amsler, of Munich, after drawings by Overbeck and others.

In 1815 Thorwaldsen modelled, in a single day, two of his most popular works, the bas-reliefs of Night and Day; but he had done nothing whatever for weeks and months before.

In July, 1819, he started in the company of two friends on his first visit to his native land, and he arrived at Copenhagen on the 3rd of October of the same year: his parents had died some years before. His fame was now so well established, that even through Italy and Germany his journey was a species of triumphal passage, and at its termination he was lodged in the palace of Charlottenburg and entertained with public feasts. In about a year he left Copenhagen and returned to Rome through Berlin, Dresden, and Warsaw, where he received several commissions, and made a bust of the Emperor Alexander.

He executed his principal works after his return to Rome,—as Christ and the Twelve Apostles; the group of St. John in the Wilderness; and the monuments to Copernicus, Pius VII., Maximilian of Bavaria, the Poniatowski monument, and others. In 1823 he had a narrow escape of his life: a boy, the son of his landlady, contrived to get hold of one of his pistols, which he had carelessly hung up loaded; the boy, ignorant of the danger, pointed it and discharged it at Thorwaldsen, but the ball, after grazing two of his fingers, lodged in his dress without doing him any further injury.

In 1838 the Christ, the St. John preaching, and the Apostles,—the principal works for the cathedral or church of Our Lady at Copenhagen—and other works for the palace of Christiansburg, on which Thorwaldsen had been many years engaged, were completed, and the Danish government sent the frigate Rota to carry them and their sculptor to Copenhagen. Thorwaldsen was received with enthusiasm by his countrymen; and he remained among them on this occasion about three years, and chiefly at Nysö, the seat of his friend the Baron Stampe, where a studio was built for him; and he finished here some of his last works—the frieze of the Procession to Golgotha, for the cathedral; the Entrance into Jerusalem; Rebecca at the Well; his own statue; and the busts of the poets Oehlenschläger and Holberg.

In 1841, finding the climate disagree with him, he felt compelled to return to Italy, and he executed at this time his group of the Graces for the King of Würtemberg. He returned however to Denmark and Nysö in the following year, and executed two other works, bas-reliefs, which are among his last productions – Christmas Joy in Heaven; and the Genius of Poetry, which he presented to his friend Oehlenschläger. He intended to return to Rome in the summer of 1844, but he died suddenly in the theatre of Copenhagen, on March 24th, in that year, aged seventy-three: he died of disease of the heart. He lay in state in the Academy, and was buried with extraordinary ceremony beneath his own greatest productions in the cathedral church of Copenhagen.

Thorwaldsen's will bears much resemblance to Sir F. Chantrey's: he bequeathed all works of art in his possession, including casts of his own works, to the city of Copenhagen, to form a distinct museum, which was to bear his name, on the condition that the city furnished an appropriate building for their reception. This building was nearly completed before the death of Thorwaldsen; 60,000 Danish dollars were subscribed already in 1842, and the museum fast approaches its completion. Besides casts of the numerous works of Thorwaldsen, which would alone constitute an imposing collection of its class, it contains many works of ancient and modern sculpture, numerous paintings by old and recent masters, casts, vases, engraved gems, cameos, terracottas, bronzes, medals, curiosities, engravings, prints of all descriptions, books on the fine arts, and drawings. With the exception of 12,000 dollars to each of his grandchildren, and the life-interest of 40,000 dollars to their mother Madame Poulsen, his natural daughter, to descend to her children, the whole of his personal estate is to be converted into capital, and to be added to the 25,000 dollars already presented for the purpose by Thorwaldsen, to form a museum perpetual fund, for the preservation of the museum and for the purchase of the works of Danish artists, for the encouragement of Danish art, and to add to the collections of the museum. His daughter, now a widow, resides in Rome, where she was born.

Thorwaldsen's unfinished works are to be completed by Professor Bissen, of the Academy of Copenhagen, and he is superintendent or keeper of the Thorwaldsen Museum; the government is under five trustees, two are always to be professors of the Academy, one a magistrate of Copenhagen, and one a lawyer. The president of the council is to be the senior trustee, and all questions are to be decided by a majority of voices. The trustees themselves will supply all vacancies as they occur. There are at present six, but the perpetual number is fixed at five.

Thorwaldsen is considered by his admirers the greatest of modern sculptors, and many have not hesitated to place him far above Canova, and to compare him with the antique. This is however hardly the rank he will hold with posterity; his style is uniform to monotony, though many individual figures are bold, solid, and of beautiful proportions. His *beau-idéal* appears to have been something between the Antinous and the Discobolus of Nancydes, as it is sometimes called; but as his subjects are seldom heroic, he seldom required more than a moderate expression of heroic vigour or robust strength and activity: in this respect, and in execution generally, he was much surpassed by Canova; but still more so in the grace of the female form, in which Thorwaldsen certainly did not excel. His females are much too square in the frame, the head and shoulders being generally heavy; and in no instance do we find in his female figures, in full relief, that beautiful undulation of line and development of form characteristic of the female, which is displayed in the antique, in the works of Canova, and in those of some other modern sculptors; as, for instance, the Ariadne of Dannecker. Basso-rilievo was a favourite style with Thorwaldsen, and a great proportion of his works are executed in this style. Of this class some of his minor works are the most expressive; but the principal are—the Triumph of Alexander, and the Procession to Golgotha, which is the frieze of the cathedral church of Copenhagen, immediately below the numerous group of John preaching in the Wilderness, in full relief, in the pediment: in the vestibule are the four great Prophets; Christ and the Twelve Apostles are above and around the altar. The Triumph of Alexander, of which there is a copy in marble in the palace of Christiansburg (the first marble copy was made for Count Somariva's villa on the Lake of Como), is a long triumphal procession in two divisions, one meeting the other. In the centre, Alexander, in the chariot of Victory, and followed by his army, is met by the goddess of Peace, followed by Mazæus and Bagophanes with presents for the conqueror. The subject is taken from the work of Quintus Curtius. Much of the frieze is symbolical: perspective is nowhere introduced. The whole arrangement is beautiful, especially that portion which comes from Babylon, comprising the General Mazæus with his family; female figures strewing flowers; Bagophanes placing silver altars with burning incense, musicians, and attendants leading horses, sheep, wild animals, and other presents for the conqueror; next to these are symbolic representations of the river Euphrates, and the peaceful occupations of the Babylonians. The human figures of this work are admirable, as is also the management of the costumes; but the horses are below mediocrity both in design and modelling, especially that of Alexander himself, Bucephalus, which is led following the chariot of Alexander; it is a complete distortion. None of the horses of Thorwaldsen are successful. The colossal animal of the Poniatowski monument at Warsaw, and that (of smaller proportions) of the monument to Maximilian of Bavaria at Munich, are heavy and graceless, and wanting in the finer characteristics of form which belong to the horse. The works of Thorwaldsen do not display extraordinary power or fertility of invention—Flaxman's distinguishing faculty. Flaxman's outlines belong not the less to the province of sculpture from the circumstance of their not having been executed in marble; most of them are designed and well adapted for basso-rilievo.

Many years ago some admirers of Lord Byron raised a subscription for a monument to the poet, to be placed in Westminster Abbey. Chantrey was requested to execute it, but on account of the smallness of the sum subscribed, he declined, and Thorwaldsen was then applied to, and cheerfully undertook the work. In about 1833 the finished statue arrived at the custom-house in London, but, to the astonishment of the subscribers, the Dean of Westminster, Dr. Ireland, declined to give permission to have it set up in the Abbey, and owing to this difficulty, which has proved insurmountable, for the present dean was of the same opinion as his predecessor, it has remained for upwards of twelve years in the custom-house, and has recently (1846) been removed to the library of Trinity College, Cambridge: it was previously taken to the studio of Sir Richard Westmacott. The poet is represented of the size of life, seated on a ruin, with his left foot resting on the fragment of a column; in his right hand he holds a style up to his mouth; in his left is a book, inscribed 'Childe Harold:' he is dressed in a frock-coat and cloak. Beside him on the left is a skull, above which is the Athenian owl. The execution is not of the highest order; both face and hands are squarely modelled; thus fineness of expression is precluded through want of elaboration. The likeness is of course posthumous.

(H. C. Andersen, *Bertel Thorwaldsen, eine biographische Skizze. Aus dem Dänischen übertragen von Julius Reuscher*; *Kunstblatt*, 1844; *Art-Union Journal*, 1845.)

THRINCIA, a genus of plants belonging to the natural order Compositæ and the suborder Cichoraceæ. It has an oblong involucre in one row, with a few additional scales at the base. The receptacle is punctured, the fruit beaked. The pappus in two rows, the outer row setaceous deciduous, the inner one longer, feathery and dilated at the base. The marginal row of fruits enveloped in the scales of the involucre.

T. hirta, the only British species, has lanceolate leaves, sinuate dentate, hispid or hairy. The leaves are all radical, sometimes nearly or quite entire, occasionally runcinate. It is found chiefly in gravelly soil.

(Babington, *Manual of British Botany*.)

THUNBERGIA (in honour of Charles Peter Thunberg, M.D., professor of botany in the university of Upsal), a genus of plants belonging to the natural order Acanthaceæ. It has a double calyx, the outer one 2-leaved, the inner about 12-toothed. The corolla is campanulate; the capsule beaked and 2-celled. The species are handsome climbing plants with a fragrant odour.

T. fragrans has a climbing stem, with cordate acuminate leaves somewhat angular at the base.

T. grandiflora has large flowers with no inner calyx; the leaves are angular cordate; the anthers bearded and spurred. This and the former species are natives of the East Indies.

(Loudon, *Encyclopædia of Plants*.)

THUYITES, a genus of fossil coniferous plants from the oolite of Stonesfield, Collyweston, Gristhorpe, and Solenhofen. (Brongniart.)

THYNNUS, the subdivision of the genus SCOMBER (Mackerel) to which the fish called the Tunny belongs. The Tunnies differ from the Mackerels in the position of their first dorsal fins, which, instead of being separated from the second by a wide interval, are prolonged close to them. Round the thorax they have a corslet of larger scales, a character which is wanting in the subgenus *Scomber*. The Tunny and Bonito are the best known examples. The former fish has nine spurious finlets above and below; the latter has eight above and seven below.

The general form of the tunny resembles that of the mackerel, but it is thicker in proportion to its length. The back is black with a tinge of blue; the corslet and sides of the head are whitish; the belly is grey, with silver spots; the fins variously coloured; the first dorsals, pectorals, and ventrals are dusky; the tail is rather paler, the second dorsal and anal more or less flesh-coloured, and the spurious finlets sulphur-yellow, edged with black. The tunny grows to more than seven feet in length, and when of those dimensions weighs more than four hundred and sixty pounds.

The following interesting account of the modes of fishing the tunny in the Mediterranean is given by Mr. Yarrell in his 'History of British Fishes:'—

In the months of May and June, when seeking a proper situation near the shore upon which to deposit their spawn, the adult fish rove along the coast in large shoals and are known to be extremely timid, easily induced to take a new and apparently open course to avoid any suspected danger. Advantage has been taken of these peculiarities to carry on a most extensive fishery against them at various places, which is as valuable as it is destructive. Cuvier and M. Valenciennes have described the two most common modes of effecting their capture. When the look-out sentinel, posted for that purpose on some elevated spot, makes the signal that he sees the shoal of tunnies approaching, and the direction in which it will come, a great number of boats set off under command of a chief, range themselves in a line forming part of a circle, and joining their nets form an inclosure which alarms the fish, while the fishermen drawing closer and closer, and adding fresh nets, still continue driving the tunnies towards the shore. When they have reached the shallow water, a large net is used, having a cone-shaped tunnel to receive the fish, which is drawn towards the shore, bringing with it all the shoal. The fishermen carry out the young and small tunnies in their arms, the larger are first killed with poles. This fishery, practised on the coast of Languedoc, sometimes yields many hundredweight at each sweep of the nets.

Another mode of taking tunnies is by the madrigue, or, as the Italians call it, tonnaro. This is a more complicated engine, and somewhat expensive to set up. It consists of a series of long and deep nets fixed vertically by corks at their upper edges, and with lead and stones at the bottom. These are kept in a particular position by anchors, so as to form an inclosure parallel to the coast, sometimes extending an Italian mile in length: this is divided into several chambers by nets placed across, leaving narrow openings on the land side. The tunnies, which in their progress proceed along the coast, pass between it and the tonnaro: when arrived at the end, they are stopped by one of the cross nets, which closes the passage against them, and obliges them to enter the tonnaro by the opening that is left for them. When once in, they are driven by various means from chamber to chamber to the last, which is called the chamber of death. Here a strong net, placed horizontally, that can be raised at pleasure, brings the tunnies to the surface, and the work of destruction commences. Sailors who have come off in boats for the purpose, give unequal battle on all sides, striking the tunnies with poles and all sorts of similar weapons. This imposing spectacle, which attracts a great number of curious people to witness it, is one of the great amusements of rich Sicilians, and at the same time one of the most considerable branches of the commerce of the island. When Louis XIII. visited Marseille, he was invited to a tunny-fishing at the principal madrigue of Morgion; and found the diversion so much to his taste, that he often said it was the pleasantest day he had spent in his whole progress through the south.

The tunny is occasionally taken in the British seas, but it can scarcely be regarded as more than a straggler. In the seas of the South of Europe, and especially in the Mediterranean, it is very abundant.

The Bonito (*Scomber pelamys*) of Linnæus, is also an occasional visiter to the coasts of England, but its true realm is in the tropics. It is a very beautiful fish of a fine blue colour, with four dark lines extending from the pectorals along the side of the belly to the tail. It rarely exceeds thirty inches in length. The Bonito of tho Mediterranean, a fish of equal beauty, is a distinct species, and is the *Pelamys Sarda* of Cuvier. Its back and sides are marked by dark oblique transverse bands. It has much stronger teeth than the Bonito of the tropics.

THYSANU'RA, apterous insects, with six legs and peculiar organs of motion on their sides, or at the extremity of the abdomen. They undergo no metamorphosis. They have been grouped by Latreille under two families, of which *Lepisma* and *Podura*, two Linnæan genera, are the respective types. In the first we have a number of brilliant silvery little insects, covered with small scales, which are used as tests for the powers of microscope glasses. They have long setaceous many-pointed antennæ, distinct palpi to the mouth, and moveable false feet on the sides of the abdomen; the body is terminated by articulated setæ, three of which are especially conspicuous. The *Podurellæ* have 4-pointed antennæ, indistinct palpi, an abdomon terminated by a forked tail, which is folded under the belly when the animal is at rest, and serves to aid it in leaping. They are little, long, soft insects. The *Lepismenæ* and *Podurellæ* livo chiefly among wood or under stones.

TICO'REA, a genus of plants belonging to the natural order Rutaceæ. It has a small 5-toothed calyx, a monopetalous funnel-shaped corolla with a long tube, and a 5-cleft limb, either equal or unequal. The stamens are from 5 to 8, of which from 2 to 6 are often sterile. The disk is cup-shaped, surrounding the ovary; the stigma 5-lobed. *T. jasminiflora* is a shrub from seven to eight feet high, a native of Rio Janeiro. The leaves are ternate and stalked; the leaflets lanceolate, from one to six inches long, tapering to the base, acuminate, obtuse, deep green with pellucid dots. Tho calyx is rather downy, the corolla white, downy, glandular with pellucid dots. A decoction of the leaves is drunk by the Brazilians as a cure for framboesia. *T. febrifuga* differs but littlo in its character from the last species, but in its stem being generally arborescent, its panicles contracted, its flowers not more than half the size, the bracts more numerous and foliaceous, and tho style more protruded. The bark is intensely bitter, astringent, and is regarded as a febrifuge. (Lindley, *Flora Medica.*)

TIDAL HARBOURS. On the 5th of April, 1845, ten Commissioners were appointed by the Queen for the purpose of inquiring into the state and condition of the tidal and other harbours, shores, and navigable rivers of Great Britain and Ireland; and to ascertain what changes have taken place in any of such harbours, shores, and rivers, as respects bars, entrance, depth of water, extent and amount of scour, or otherwise; and what encroachments have been made upon them, or upon the waters above such harbours and rivers, by enclosures of lands, embankments, wharfs, piers, or other works; and by whom and by what authority such encroachments have been made; what effect they have produced, or may hereafter produce; and also what injury may have been done or may accrue, by the removal of shingle, rock, soil, or other materials, from any shores, or by the emptying ballast or other materials into or near any such harbours and rivers, or in consequence of wreck not being removed; and what measures are necessary and expedient to remedy and prevent any injury that may have resulted or may be likely to result therefrom; and also whether there are sufficient powers for enforcing such remedy; and whether any and what further powers are necessary. The Commissioners are also authorised to inquire into the state of the law, as regards the powers of the Commissioners who execute the office of Lord High Admiral, for the conservation of all harbours, shores, and rivers of the kingdom; and how the powers given to bodies corporate, commissioners, trustees, local authorities, or other persons, supersede or interfere with the powers vested in the Commissioners who execute the office of Lord High Admiral; and whether any and what legislative or other measures are necessary to confer the necessary powers on that office. The Commissioners are also empowered to inspect personally such harbours, &c., and to employ engineers and others to make surveys; and to call persons before them in order to obtain evidence, and to administer oaths for that purpose; and the Commissioners may from time to time make a report of their proceedings.

The First Report of the Commissioners is dated July 8, 1845. After stating that the labours of the Commissioners had been, in some measure, anticipated by returns from 260 harbours and havens, which had been made by order of the House of Commons in 1844, the Commissioners state that they have determined to confine their inquiries, in the first instance, to a few specific cases, having special reference to the necessity of some legislative measure to be taken without delay, in order to remedy the injuries which they found had already taken place, and which were daily increasing.

The Commissioners select as examples the rivers Clyde and Tay, and harbour of Montrose, in Scotland, and Southwold, Harwich, and Rye, in England. They find that great and increasing injury to the best interests of the country has accrued from negligence of the several authorities in permitting the improper removal of soil and beach, as well as by embankments, weirs, and other obstructions, which check the free flow of the tide, impair its strength, and thus permanently diminish the general depth of the river; and that, on the other hand, when the aid of experience and science have been called in, and a duo vigilance exercised, a proportionate improvement has been the invariable result.

In addition to the above examples, which the Commissioners examine and report upon in detail, numerous instances of encroachments, of neglect, and of want of efficient control, came before them in the course of their inquiries, several of which they mention.

The Commissioners next examine into and report upon the state of the law, and find that in numerous instances the jurisdiction of the Lord High Admiral, which is by prescriptive right and is recognised by statute, has, by charters and acts of Parliament, been superseded, to the great detriment of the public service.

The Commissioners then recommend that a Board of Conservancy be established, for the superintendance and protection of all the tidal harbours and navigable rivers of the United Kingdom of Great Britain and Ireland; that it be in connection with the Admiralty; and that it be permanent. They then explain in detail the powers which they are of opinion should be given to the Board, and its mode of operation in conjunction with the Admiralty.

They recommend, in the last place, that accurate plans and surveys, on a sufficient scale, of all the ports and navigable rivers in tho United Kingdom, should be made with as little delay as is practicable.

The Report is accompanied by Minutes of Evidence, an appendix of matters relating to the inquiry, and by plans of the rivers Clyde and Tay, Southwold Harbour and the river Blyth, Harwich Harbour, and Rye Harbour.

The Second Report of the Commissioners is dated March 20, 1846. It is printed separately, as well as with the Minutes of Evidence, the whole forming a very bulky volume, with numerous plans.

The Commissioners state that a more extended inquiry has fully confirmed the views which the limited examination of the previous year led them to. They find that there is not only a general want of control over the management and revenue of the ports, but that such control, in every one of the numerous cases which came before them, would have been the means of saving unnecessary outlay, of preventing encroachments which can now scarcely be remedied, and of preventing the execution of works which it is now expedient to remove. The income of the various ports of the United Kingdom considerably exceeds 800,000*l.* a year, the whole of which is levied by charters and acts of Parliament, or otherwise, from dues on shipping and on goods borne by shipping, but over the expenditure of which Parliament has not at present the slightest control. After explaining the causes of the misapplication of much of this money, the Commissioners detail their proceedings since the First Report.

They state that they have examined the chief ports on the east coast of England from the river Thames to the Tyne; that on the west coast they have inspected the rivers Lune, Wyre, Ribble, and Dee, and the ports of the Isle of Man; that in Ireland they have visited most of the ports and fishing-piers around the coast, and have been strongly impressed by the great value of its natural harbours, their depth and capacity, and the extent and capability of improvement of its fisheries, which, even in their present state, with the fishery-piers often in ruin from neglect, afford employment to 19,880 vessels and boats, and 93,000 hardy fishermen.

The commissioners next point out in detail the injuries which have arisen, partly from neglect and partly from mismanagement, and which an efficient control would have prevented, in the harbours of Dublin, Wexford, Waterford, Cork, Limerick, Galway, Sligo, Londonderry, Belfast, Newry, Dundalk, and Drogheda. They point out the damage which several of the breakwaters have suffered owing to bad construction, and the distress which has been occasioned by the neglect of repairing many of the fishing-piers. They cite as instances of neglect the injury done to Bantry Harbour, Skerries, and Larne, by discharging ballast and stones into them.

After adverting to the necessity for additional lights and beacons on the Isle of Man, they proceed to animadvert on the rivers and harbours of England:—On the north-west coast, the river Lune and the port of Lancaster, Fleetwood-on-Wyre, the river Ribble and port of Preston, the river Dee and port of Chester; on the south coast, Salcombe, Dartmouth, and Exeter; on the north-east coast, the river Tyne and port of Newcastle with North and South Shields, Sunderland, Hartlepool, Stockton-on-Tees, Whitby, Scarborough, Bridlington, Kingston-upon-Hull, Grimsby, Great Yarmouth, Norwich, Lowestoft, Beccles on the Waveney, Blackney and Cley on the north coast of Norfolk, Wells, near Blakeney, and Harwich Harbour.

It appears, from Parliamentary Returns, that the aggregate debt of the several ports of the United Kingdom, exclusive of docks in the port of London, exceeds 4,000,000*l.* and that consequently one-fourth of the whole harbour-income of 800,000*l.* must be annually appropriated to pay the interest of this debt. This large sum, though borrowed with the sanction of the legislature, has been entirely laid out by the several local boards without the least parliamentary or other special control.

The Commissioners then animadvert on the obstructions and shoals which so seriously impede and endanger the navigation of the Thames between London Bridge and Gravesend, arising from neglect occasioned by the conflicting claims of the Admiralty, the Trinity House, and the corporation of the city of London. The Commissioners finally again urge the necessity of establishing a Board of Conservancy for the superintendence and control of the management of all the tidal harbours of the United Kingdom. The proceedings of the Harbours of Refuge Commission are briefly stated under Refuge, Harbours of, P. C. S.

(*Tidal Harbours Commission—First and Second Reports*, 1845, 1846.)

TIDES. [Acceleration and Retardation of Tides, P. C. S.]

TILES AND PAVEMENTS. The subject of tessellated pavements being already partially treated of under Mosaic, P. C., p. 427, the principal object of this article is to notice some recent improvements by which the revival of this elegant and durable kind of architectural decoration has been facilitated. In doing so we may refer our readers for fuller information to the literary portion of a beautifully illustrated thin folio volume published in 1842 by Mr. Blashfield, a gentleman who has done much for the promotion of this long neglected branch of art, under the title of 'Designs for Mosaic and Tessellated Pavements, by Owen Jones, architect; with an Essay on their Materials and Structure, by F. O. Ward;' or, for a pretty full popular notice of the subject of ornamental pavements generally, to the 'Pictorial Gallery of Arts,' vol. i. pp. 182, 183.

Decorated paving tiles of baked pottery, commonly called encaustic tiles, which were much used in the pavements of churches and other ecclesiastical buildings of early date, have been recently brought into use again with excellent effect in the Temple Church, London, and many other buildings; and improvements in their manufacture introduced by Messrs. Chamberlain, of Worcester, and Mr. Minton, of Stoke-upon-Trent, have, by the aid of great pressure, rendered them much harder and less porous than old tiles of the same character, and therefore even more durable. The process of making these encaustic, or, as they are called from their resemblance to mosaic work, tessellated tiles, as practised at the Royal Porcelain Works at Worcester, is described by an eye-witness in No. 700 of the 'Penny Magazine,' from which we condense the following particulars:—These tiles are formed of two, or, if need be, more, differently coloured clays, one imbedded in the other. The body of the tile, which is about an inch thick, is moulded in stiff clay, of the quality required to form the ground colour of the device, which is frequently brown, in a mould which, in addition to giving the tile its required form, produces depressions about a quarter of an inch deep wherever another coloured clay is required; the process of moulding being effected under pressure by means of a fly and screw. The second coloured clay, which, instead of being made stiff like the first, is mixed to about the consistence of honey, is then applied so as to fill in all the depressions or cavities, it being carefully plastered in with a knife or trowel. Much care and skill are necessary in the selection of the clays, that they may be of such quality as to contract together in baking as if they were one, although they are of such different consistence when moulded. In order the better to guard against injury from irregular shrinking, the tiles are laid aside for about eight weeks to dry slowly, after which the surface is scraped to remove all that may be superfluous of the softer or second clay, and to bring it to a perfectly even face, and they are then baked or burnt in a similar manner to porcelain. Like porcelain also, they may be subsequently coated upon the upper surface with a liquid glaze, which is fixed and vitrified by a second burning. Such tiles may be imbedded in cement, and such holes or other cavities may be formed in their lower surface as will, by affording increased hold for the cement, render it almost impossible to disturb them from their bed.

Among other recently invented methods of imitating the antient Roman tessellated pavements, which are so called from being composed of small pieces termed tesseræ or tessellæ [Tessera, P. C., p. 245], Mr. Ward, in the Essay above referred to, notices a patent obtained early in the present century, by Mr. C. Wyatt, for producing ornamental pavements by inlaying stone with coloured cements; but both these and pavements formed by a combination of cements with terra-cotta appear to have failed from the unequal hardness of the materials used. More recently, according to this writer, Mr. Blashfield has constructed some pavements which have answered pretty well for indoor purposes, though they would not bear exposure to weather, of cements coloured with metallic oxides; and, but with less success, he has tried bitumen coloured in like way. In 1839 a patent was obtained by Messrs. Alfred Singer and Henry Pether for a method of forming tesseræ of pottery or porcelain by cutting them out of sheets of clay, and, after baking, combining them into slabs suitable for laying down to form pavements by means of Roman cement, of which a complete layer is formed at the back of the tesseræ. This plan has been followed, among other places, in a large pavement in the saloon of the Reform Club-house. Under ordinary circumstances it is proposed to form the tesseræ, which may be of any required colour, about an inch square, and to combine them into slabs of about eighteen inches square before laying down. In 1840 Mr. Prosser, of Birmingham, obtained a patent for a method of producing a substance similar to, but very much harder and less porous than common porcelain, by subjecting a mixture of pulverized felspar or flint and fine clay, in as dry a state as possible, to immense pressure between steel dies, so as to condense the powder into about one-fourth of its natural bulk, and then baking it. This process was first applied to the manufacture of a kind of button which has in a great measure superseded those of hone and mother-of-pearl; being, when well made, beautiful in appearance, and cheaper and far more durable than common buttons. Mr. Blashfield perceived the peculiar fitness of this process for making tesseræ for pavements, and the manufacture has been commenced by Mr. Minton with every prospect of success. These compressed tesseræ are made by a simple but powerful machine, which condenses the material from a thickness of about an inch and one-eighth to three-tenths of an inch, and are then baked in an oven; and it was stated by Mr. Blashfield in an explanatory lecture before the Society of Arts (reported in the 'Athenæum' of 1843, p. 266), that they had been found to bear a pressure of forty tons, and to be proof against injury by frost, some having been tried by plunging them in boiling water and immediately exposing them to a freezing temperature. Blue and green colours are imparted by metallic oxides during the baking process; but other colours are mixed with the materials before submitting them to pressure. By this process tesseræ are produced of such perfect regularity and uniformity in size and shape, that when fitted together they unite much more perfectly than those used in antient pavements, in which the beauty is often impaired by broad and irregular lines of cement. In constructing pavements with them, the tesseræ are arranged, face downwards, upon a smooth level surface, and, when a convenient portion of the design has been thus adjusted, a stratum of Roman cement is laid upon the back, and worked into the joints. The compound slabs thus produced are laid down upon the prepared foundation in the same manner as already described in the case of Singer's plan. This mode of producing tessellated pavements possesses many advantages over the antient plan, in which, a level foundation having been prepared by cramping stones together, or forming a thick floor of stucco or concrete, a layer of plaster was spread to receive the tesseræ, which were laid one by one while the plaster continued soft. This method required much time and care to preserve the level, and as that could not be done perfectly, much additional labour was involved in the subsequent rubbing down and polishing of the surface, an operation which, in the case of vitrified tesseræ, would have the further disadvantage of destroying their hard surface. Owing to the imperfect fitting of the antient tesseræ it was also necessary to spread cement upon the surface of the pavement, in order to fill up the joints and crevices, and afterwards to scrape it off again.

By Prosser's process, with the power supplied by an hydraulic press, bricks and other larger articles may be produced, among which may be mentioned slabs, inlaid with coloured devices, for chimney-pieces and other architectural decorations.

An extensive collection of specimens of Roman tessellated pavements, in a very large atlas folio, published by William Fowler early in the present century, together with specimens of antient stained glass, is worthy of the attention of those engaged in the revival of this elegant species of decoration, which, though necessarily expensive, has been so much reduced in cost by the introduction of the compressed tesseræ, that in some cases they have superseded the use of oil-cloth in the covering of halls, the substitution being made on the score of economy, although sanctioned by a refined taste.

TIMBER, PRESERVATION OF. Whatever other causes may combine to promote the decomposition of wood by dry-rot [Dry-Rot, P. C., p. 163] or other forms of decay, there can be no doubt that imperfect seasoning, by leaving in the pores of the timber a large portion of the fermentable juices always found in recently-felled timber, is one of the most important, and therefore that good seasoning is as essential in promoting the durability of wood as it is in lessening the tendency to those changes of form and bulk which so greatly increase the difficulties of the carpenter and joiner. The process of seasoning usually consists simply in the exposure of the timber to the action of air in a dry situation, in stacks or piles so constructed as to allow the free circulation of air in contact with as much as possible of the surface of each piece of timber, until the sap or vegetable juices shall have dried up so far as to offer no facility for the germination of the microscopic fungi which constitute various kinds of rot. In order to the success of this operation it is important that the pile of timber be so far elevated from the ground as to allow the circulation of air beneath as well as through and around it; and also that, if exposure to rain be not entirely avoided, care be taken to prevent the lodgment of moisture in any place where it would be likely to remain long. Great improvements in this respect have, of late years, been introduced in our dockyards, in the stacking of timber upon elevated supports of iron or stone, and the building of ships beneath spacious roofs, which protect their timbers from rain, while they allow an unimpeded current of air around them. In the article House, pp. 53 and 54 of this volume, we have noticed a very simple, though not unimportant, improvement upon the common method of seasoning flooring-boards. Kiln-drying, and the expulsion of sap by charring or scorching the surface of the timber, have also been tried, but without success, as substitutes for the tedious operation of natural seasoning.

Another process, which may seem at first sight very unlikely to succeed, and respecting which indeed the most contradictory opinions are given by writers on the subject, consists in the dissolving and washing out of the fermentable juices by lengthened immersion in fresh or sea water, and subsequent drying. Immersion in sea-water especially has been extensively practised of late years; and it is stated that in some cases where dry-rot had already made its appearance, this treatment has arrested it, the action of the sea-water appearing to destroy the vitality of the fungi. Some authorities however state that ships built of timber which has been so immersed, are unhealthy in consequence of the hygrometric properties acquired by the absorption of salt.

The protecting power of metallic oxides, when applied to the surface of wood in the form of paint, is well known; and many abortive schemes for the preservation of timber have been devised to act upon the same principle, which is that of excluding such external influences as might promote decay. To imperfectly seasoned timber however such applications are worse than useless, because by filling up the pores they impede the natural drying of the vegetable juices, and therefore rather promote than check internal decay. Far more efficient than these are the numerous modes of protection which involve the impregnation of the timber with some antiseptic substance, or with such matters as, by pre-occupying the pores, may render the reception and germination of destructive fungi mechanically impossible. Historical notices of many processes of this character are given in a paper in the 'Mechanic's Magazine,' vol. xxxix. pp. 346-350, extracted from a report made in 1843 by a committee of the Franklin Institute, on the best method of paving highways; and in a previous volume of the same work (vol. xxxvi., p. 406, &c.) is a report of an interesting conversation on the subject, at a meeting of the Institute of Civil Engineers, in 1842, when several of the principal modern inventions were discussed.

Of plans for protecting timber by impregnation, perhaps none has attained such general celebrity as Mr. Kyan's, which was patented in 1832, and has been very extensively practised under licences granted by the Anti-Dry-Rot Company. The preservative agent in this process is bi-chloride of mercury, commonly called corrosive sublimate, which is dissolved in water, and forced into the pores of the timber, in closed tanks, by means of force-pumps, and which combines with the albumen of the wood, and converts it into a compound capable of resisting the ordinary chemical changes of vegetable matter. The idea of using corrosive sublimate for this purpose does not appear to have originated with Mr. Kyan; that substance having been tried and recommended as an anti-dry-rot application by Sir Humphry Davy many years previously. The alleged failure of the precipitate formed by Kyanization to protect timber when exposed to the action of sea-water, led Sir William Burnett, physician-general to the navy, to patent a method for preserving timber by impregnation with chloride of zinc, which process, like Kyan's, is also applicable to canvas, cordage, &c., and to which the name of *Burnetization* has been given. Sir John Barrow has recommended the application of creosote, obtained from the distillation of tar, and applied in the form of gas, by which it may be made to penetrate to the heart of the largest logs. This treatment renders the wood exceedingly hard, so much so indeed as to render it difficult to work. An oil extracted from chips and refuse wood was used for the same purpose by Mr. Mackonochie in 1803. He applied it by placing the timber in a steam-tight chamber, expelling all air and gases from the pores of the timber by the admission and subsequent condensation of steam; and, after repeating this process as often as needful, plunging the timber into the oil, which filled the exhausted pores. Mr. Bethell's more recent invention, of which an account is given under 'Wood-Preserving,' in the 'Supplement' to Dr. Ure's 'Dictionary of Arts,' &c., appears to be somewhat similar, although the impregnation is effected by withdrawing the air and gases by air-pumps, and forcing the injected fluids into the pores by hydrostatic pressure. Dr. Ure mentions the application by this process of oil of tar and other bituminous matters containing creosote, and also of pyrolignite of iron, which holds more creosote in solution than any other watery menstruum. For railway sleepers, piles, posts, and fencing, this process has been extensively and most successfully employed, as timber protected by it is not affected by exposure to alternate wetness and dryness; while the commonest and cheapest Scotch fir is rendered superior to the best and hardest wood in an unprotected state. In the discussion at the Institute of Civil Engineers above alluded to the efficiency of coal-tar in preserving ship-timbers was particularly mentioned. It was stated to be very superior to vegetable tar, and its efficacy in resisting the worm was attributed to its containing sulphocyanic or sulpho-prussic acid, which is highly destructive to animal and vegetable life. Piles protected with coal-oil were stated to have resisted the attacks of the teredo better than those protected by Kyan's process. It is necessary however to observe that the coal must be deprived of its ammonia, which would produce immediate decay if thrown into the timber. In Mr. Bill's method, tried about 1822, some large logs were impregnated with asphaltum; and a five years' immersion in the dry-rot pit at Woolwich showed that timber thus prepared would withstand the fungus-rot, while unprepared timbers were destroyed in one-fifth of the time. M. Pallas, in 1779, proposed to mineralize wood by steeping it to saturation in green vitriol, and precipitating the vitriol by means of lime-water; and in Payne's recent process it is proposed, by the application of both exhaustion and pressure, to impregnate wood with metallic oxides, alkalis, or earths, and, by decomposing them in the pores of the wood, to form new and insoluble compounds. The writer has seen specimens of wood which appeared to be almost silicified or fossilized by this treatment, by which the softest woods may be rendered harder and denser than the hardest in their natural state, apparently indestructible by any ordinary process of decay, and, for all practical purposes, incombustible. In addition to its anticipated utility as a means of preserving timber, this process may probably be useful in increasing the value of many soft and rapidly growing woods, by rendering them applicable where hitherto none but costly woods could be employed. In 1840 Dr. Boucherie presented a memoir to the French Academy of Sciences on the application of pyrolignite of iron (which had been previously used in this country by Mr. Bethell, as above mentioned), or of other metallic salts or earthy chlorides, by a process which he terms *aspiration*, which consists in immersing the lower end of the tree, as soon as it is felled, in the solution, which is thereby drawn into the pores by what may be considered as a continuation of the natural process of circulation. Unless performed immediately after felling, the process will not answer, as the power of absorption becomes very shortly impaired. Other plans have been tried for effecting impregnation from one end of the timber, in some cases by attaching a water-proof bag containing the fluid to the upper end, and thus causing the preserving liquid to trickle down through the substance of the wood, until it drops from the lower end. In connection with all such schemes it is well to remember a fact which has been pointed out as indicative of a valvular structure in wood, namely, that if a trunk be exposed to a running stream, with its butt end towards the current, its vegetable juices will be much sooner washed away than if it be laid in the opposite direction. Dr. Boucherie proposed by his process to infuse such liquids as might prevent dry-rot, warping, and splitting, such as should reduce the inflammability of timber, or such as should impart any desired colour or odour; and it is evident that the same objects might be effected by many of the other modes of impregnation which have been suggested. Mr. Bushell, for example, proposed, in order to render wood fire-proof, to use silicate of potash, or soluble glass, which when heated would melt, and form a protecting film or glaze, impervious to the further action of fire.

A popular article on the preservation of timber, in which several of the above methods are noticed, was given in the 'Penny Magazine' for 1844, p. 135; and much information on the subject is contained in the article 'Ship-Building,' and some other articles of the same kind, in the seventh edition of the 'Encyclopædia Britannica.'

TIME. A reference has been made to this head from the word FUTURE. Time as expressed by the different forms of verbs is considered in the article CONJUGATION, P. C.

TISSUES, ORGANIC. SECTION I.—*General Organic Substances.* In the present section we propose taking a brief sketch of the chemical physiology of the organic kingdom. We commence with the consideration of the origin of those substances which are common both to plants and animals, or which exist in one of them only. The first division contains protein; the second embraces cellulose in plants, and gelatin in animals. We shall show that these substances and their derivatives yield the foundations of the animal and vegetable kingdoms.

Protein is undoubtedly the most important of all known substances in the organic kingdom. It is present in all parts of plants, in roots, stems, leaves, fruits, and in their several juices; in the animal body it is the chief constituent of the blood, the muscles, and many other parts, and is the original source of numerous other compounds. In plants it assumes three different forms, being soluble in water, insoluble in water, or soluble in alcohol; in animals it may be either soluble or insoluble in water. For the mode of obtaining it see CHEMISTRY, P. C. S., p. 349. It is one of the substances directly prepared for the food of plants, and is found in the youngest roots; whether it is only *formed there*, and afterwards conveyed to the other parts, or whether it is produced in any other part of the plant, is uncertain. Its property of being readily soluble in water facilitates its transference to the various organs. It may however assume the solid state and become deposited in cells; in this form it occurs in many seeds, occasionally being their principal constituent. This deposition is effected in a very simple manner. Most acids render it insoluble, and therefore the mere presence of an acid is usually sufficient to accomplish the transformation: again, the insoluble protein may be redissolved by alkalies, and hence, after it has been deposited in the cells in a solid state, it may be removed to another part of the plant through the medium of an alkaline solution.

Whether protein can be formed within the animal body is uncertain, but it cannot be doubted that the protein compounds in vegetables are imparted to animals in their food, and as these compounds form the principal component parts of the animal body, this constituent must be supplied either wholly or in part by plants.

The protein-compounds existing in plants were till quite recently known as soluble albumen, coagulated albumen, legumin, and gluten; Liebig has however applied to the three first the names vegetable albumen, vegetable fibrin, and vegetable casein, asserting that they are identical in their physical properties and in their chemical compositions with the corresponding principles in the animal kingdom. Mulder, the discoverer of protein, denies the accuracy of this statement. 'The special character of these animal substances is,' he remarks, 'determined by the small portions of sulphur and phosphorus they contain, by which they differ from each other and from pure protein. The proportions of sulphur and phosphorus in the three vegetable substances are still unknown; and therefore the names proposed by Liebig cannot be applied to them. Moreover both vegetable albumen and legumin differ so much from animal fibrin and casein, both in form and appearance, that they ought not to have a similar name.' We shall retain the former names, representing by *legumin* the substance which is precipitated in white flocks, when the infusion of crushed peas or beans in warm water is mixed with an acid.

By *soluble vegetable albumen* we mean to designate that substance which, being soluble in water, is precipitated from the juices of plants by heat, alcohol, or acids. It is soluble in weak alkaline fluids, from which it is precipitated by acids, and, independently of the sulphur and phosphorus, has the same composition as protein. By *coagulated* vegetable albumen we mean the compound of protein, sulphur, and phosphorus which is insoluble in water; it exists in the seeds of the cerealea, in almonds, &c. By *glutin* we understand the substance which can be extracted by alcohol from the ordinary *gluten* obtained by washing away the starch from flour. It is the same substance as is described in the article CHEMISTRY, P. C. S., as gliadine. Its composition according to Mulder is 10 (C_{40} H_{31} N_5 O_{12}) + S_2, or 10 $\overline{Pr}$ + S_2 if we take $\overline{Pr}$ as an arbitrary symbol for protein.

The protein-compounds contained in the animal body, as far as we yet know, are the following:—

Fibrin from blood is composed according to the formula 10 (C_{40} H_{31} N_5 O_{12}) + S P, or 10 $\overline{Pr}$ + S P; that is to say, every atom or equivalent of fibrin contains 10 atoms or equivalents of protein with one each of sulphur and phosphorus. *Albumen* from eggs has a similar composition.

Albumen from the serum of the blood is represented by 10 (C_{40} H_{31} N_5 O_{12}) + S_2 P, or 10 $\overline{Pr}$ + S_2 P; that is to say, it differs from fibrin in containing one atom more of sulphur.

Casein from cow's milk, 10 (C_{40} H_{31} N_5 O_{12}) + S, or 10 $\overline{Pr}$ + S.

Crystallin, the substance that forms the principal constituent of the lens, 15 (C_{40} H_{31} N_5 O_{12}) + S, or 15 $\overline{Pr}$ + S.

These are all the protein-compounds of the animal body yet known. The muscular fibre is for the most part composed of a protein-compound, fibrin, which likewise exists in the circulating fluids; and albumen occurs in the brain, liver, kidney, and many other organs, as well as in the blood. The above compounds of protein enter into some very important combinations, a few of which, from their physiological bearings, we shall here notice. The combinations of the leading protein-compounds, fibrin, albumen, and casein, with alkalies, acids, and salts, are especially remarkable. Protein is soluble in weak alkalies, and according to Mulder it exists in the blood as a proteate of soda with sulphur and phosphorus. Enderlin and the Giessen school, on the other hand, deny that it exists in that fluid as proteate of soda. They assert that the cause of the alkalinity of the blood is the presence of the ordinary tribasic phosphate of soda—a salt which has the power of dissolving the protein-compounds: the question whether Mulder or Enderlin be correct is still undecided.

On neutralizing a weak alkaline solution of protein by an acid, its solubility is greatly diminished; a fact which Mulder regards as elucidating the medical properties of certain acids. The sulphuric and phosphoric acids for instance possess the property of stanching blood; acetic acid, on the contrary, by which protein is readily dissolved, is destitute of that property. Very dilute hydrochloric acid occurs in the stomach, and as it possesses the property of dissolving protein, it doubtless renders the food (at least the portion consisting of protein-compounds) tender, and thus assists digestion. Some acids enter into combination with the protein-compounds, producing comparatively insoluble bodies. For this reason certain acids (sulphuric and hydrochloric) are very efficacious in putrid fevers, scurvy, &c. As an illustration of the combinations of the protein-compounds with salts, we may notice that of bone-earth with casein. Bone-earth is a phosphate of lime whose composition is represented by the formula 3 P_2 O_5 + 8 Ca O. In casein, and therefore in milk, it exists in great quantity, and this seems to supply a large amount of earthy matter to the tender bones of young animals.

In addition to albumen and fibrin, a third protein-compound exists in the blood, constituting the cell-wall of the corpuscles. It is termed *globulin*. Its real composition is unknown: Simon regards it as casein. All these protein-compounds contain more or less phosphate of lime, which thus finds its way to the bones.

Two other very important protein-compounds exist in the animal body, namely the binoxide and tritoxide of protein. They both exist to a large amount in the blood in inflammatory diseases, and to a small amount in healthy blood. The latter is soluble in water, the former is not. (For the mode of obtaining them in a state of purity, and for the fullest account of them in the English language, we must refer to Dr. Day's Introduction to Simon's 'Animal Chemistry,' published by the Sydenham Society, London 1845.) At every respiration a small amount of them is produced in the blood, and Mulder (who must be regarded as the highest authority in all that relates to protein) believes that they form around the blood-corpuscles a thin layer having the same composition as the buffy coat or inflammatory crust.

The above sketch is sufficient for our purposes at present. In a later part of this article we shall have occasion to return to the protein-compounds. We now turn to the second group, commencing with the consideration of *cellulose*, or the cellular substance of plants. As the morphology of vegetable cells has been fully discussed in the article TISSUES, VEGETABLE, we shall confine our observations to the chemical characters and metamorphoses of this substance.

This cellular substance may be procured from all the parts of plants without exception, by dissolving (by certain re-agents) the other substances associated with it. Pure cellulose is easily obtained from the pith of the elder-tree, or from very young roots. The substances most commonly associated with it are, starch, gum, fats, resins, vegetable alkalies, salts, sugar, and the peculiar woody matter termed by Payen *matière incrustante*. After the removal of these substances by extraction with alcohol, ether, dilute potash, hydrochloric acid, and water, the cellulose, which was previously solid and dense, assumes a spongy appearance. As a proof of its constant composition, it is worthy of mention that the following substances, previously purified in this manner, gave similar results, viz. the ovula of almonds, of apples, of the Helianthus annuus, the sap of cucumbers, the tissue of the cucumber, the pith of the elder-tree, the pith of the Æschynomene paludosa, cotton-wood, the leaves of endive and of Aylanthus glandulosa, the tracheæ of the Musa sapientum, films from the pith of oak-trees, cellulose from cow-dung (the cow fed with meadow-grass), the internal tissue of the leaves of Agave Americana, the skeleton of a wasp's nest, the perisperm of the Phytelephas, extracted lichen, membranes of the Chara, &c. From these and various other substances, the purified cellulose always gave a result approximating to the formula C_{24} H_{21} O_{21}. It is thus apparent that the proper tissue of all plants leaves a substance which is identical for all of them,—a substance which contains carbon and the elements of water, which is isomeric with inulin [CHEMISTRY, P. C. S., p. 345], and therefore easily convertible into starch and sugar; and that in its turn it may easily be produced from dextrin [CHEMISTRY, P. C. S., p. 343], the change consisting only in the loss or gain of the elements of water. It has been recently shown by Von Baumbauer (in Mulder's Laboratory) that sulphuric acid or diastase will convert cellulose into dextrin. Hence the cellular substance is closely allied to starch, dextrin, gum, and sugar, causing their production in the vegetable kingdom, and no doubt being itself produced from one of them, namely from dextrin. It is therefore of great importance to the animal body. It explains the nourishing power of those plants in which the incrustation of the cellulose is prevented by artificial means, as of greens, endive, sea-kale, &c. The cellulose of these plants, being easily converted into dextrin, may fairly be reckoned amongst the substances which are most serviceable in maintaining the vital functions of animals.

Further, as cellulose exists ready formed in the youngest parts of plants, it belongs, together with protein, to the first vegetable products of the food of plants; and, further, it follows, that from cellulose, or from vegetable substances similarly formed, especially from one soluble in water, namely dextrin, starch, gum, and sugar are occasionally formed. In many parts of plants we find starch, especially in the lichens, which consist for the most part of cellulose. In many fruits containing a large proportion of cellulose, there is much sugar. These different substances may be produced from the same cellulose, simply by a change in its physical character and a new chemical arrangement of its constituents. On the other hand, we observe that fleshy fruits, from being sugary, become mealy when kept through the winter; this being a converse change of sugar into cellulose. Hence, as Mulder remarks, 'we may consider the cellular plants as consisting chiefly of cellulose and of protein-compounds; the vascular plants containing, in addition, the incrusting or real woody matter. These together are the most indispensable constituents of plants; they are found everywhere and in all their organs. Cellulose is to plants what gelatin is to animals; they form together the cells in these two kingdoms. In the cells both of plants and animals protein-compounds are either deposited in solid particles or are dissolved in the liquids with which their organs are permeated. In plants the cell-walls are thickened by the woody matter; in animals, the cells contain fat and other substances; in animals, as well as in plants, the cellular substance is the chief agent in connecting all the other existing organs.'

Mohl and Schleiden have shown that the cellular membrane of many parts of plants is coloured blue by iodine, just as if it contained starch. This apparent identity of re-action would lead us to infer that cellulose can often be modified as it were into starch, though still retaining the appearance of cellular membrane. The similarity of the chemical constitution of these two substances renders their conversion apparently easy.

For 1 eq. cellulose (C_{24} H_{21} O_{21}) = 2 eq. starch (C_{24} H_{20} O_{20}) + 1 eq. water (H O). Hence, by a separation of water and a re-arrangement of the molecules, cellulose may be converted into starch; and conversely, by the absorption of water, starch may be converted into cellulose.

Starch exists in three separate forms: common starch, lichen-starch, and inulin. The first is intermediate between dextrin and cellulose; the second, between dextrin and common starch; and the third, between common starch and sugar.

Common starch occurs in the form of globules, which are found in the most different parts of plants, and present varying forms in consequence of having to adapt themselves to the shape of the cells in which they have been deposited. It has been frequently observed that starch-globules, after being deposited, again disappear under the influence of growth; that is to say, they become dissolved and carried away to other parts by the sap, and give origin to new products. In young parts of plants, such as the extremities of the radicles, no starch is present, but only cellulose and protein-compounds; hence, it is not formed till after the parts in which it has to be deposited have obtained a certain growth. Payen could not detect any starch-globules either in the vessels or in the intercellular canals; hence, if starch is present, it must occur in a dissolved state, or in a modified or changed condition. It is further worthy of remark, that in those bulbs in whose scales there is much starch, it disappears either in part or altogether on exposure to light; that is to say, it becomes converted into other substances. This is the reason why much less starch is to be found in the parts of a plant which are above-ground than in the roots; and that in plants whose stalks contain starch it is found chiefly in the pith. We have already mentioned that starch-globules may be dissolved wholly or in part during the growth of the plant. According to Payen the products of this metamorphosis are dextrin and sugar, and the cause of the action diastase, a substance the effect of which on starch separated from plants is now well known. This is the change which frozen potatoes undergo when all the starch is converted into sugar. It also takes place in the growth of new potato-plants; all the starch disappearing from the tuber, and being replaced by sugar. According to De Candolle, the quantity of starch in potatoes increases during their ripening almost in the same degree as it afterwards diminishes. In August, 100 lb. of potatoes gave 10 lb. of starch; in September, 14·5 lb.; in October, 14·75 lb.; in November, 17 lb.; it remained constant till the end of February; in April it had diminished to 13·75 lb.; and in May, to 10 lb.

There is still considerable mystery regarding the formation of starch. We have undoubted evidence that it gives rise to the formation of dextrin and sugar, and it is just as certain that the same substances may, under different circumstances, form starch. In addition to its uses in forming dextrin and sugar, it is likewise the efficient agent in the production of fat and of chlorophyle.

Lichen-starch. The starch of the cryptogamic plants has been examined by several chemists, especially by Vogel and Dietrich. It is coloured green by iodine, instead of blue, and in several other points differs from ordinary starch.

Inulin is a modification of starch, very abundant in the dahlia, helenium, and taraxicum, but found also in many other plants. [CHEMISTRY, P. C. S, p. 345.] It is very readily converted into sugar, and as it combines with this sugar and carries it with it, it is obvious that ultimate analyses of inulin from different plants must vary. Possessing apparently the same composition as starch, it differs in not being changed into a jelly by hot water; nor does it turn blue with iodine, but yellow. It may as well be termed a variety of sugar insoluble in cold water and destitute of taste, as a variety of common starch. From the facility with which it may be converted into sugar, it must, like dextrin, be placed between sugar and common starch. In many plants dextrin is a transition substance from common starch to sugar, as is the case when either sulphuric acid or diastase [CHEMISTRY, P. C. S., p. 343] acts on it. In other plants inulin seems the transition between starch and sugar, without the formation of dextrin. As its composition is the same as that of cellulose, it is probably produced from that substance and not from starch.

From starch we are led to the consideration of a very important constituent of plants, *dextrin*, which is obtained by treating starch with *diastase.* [CHEMISTRY, P. C. S., p. 343.] Mulder has shown that *dextrin* may also be obtained from cellulose both by sulphuric acid and by diastase. The quantity of diastase required is extremely minute; if too much be used, or the process continued too long, grape-sugar is produced. It is by these or similar means that nature converts cellulose into dextrin, and dextrin or starch into sugar. As in malting barley diastase is naturally produced from starch, there is no reason why it should not in a similar manner be produced in the growing plant, and thus convert the cellulose into dextrin.

The sap of nearly all plants contains a certain amount of dextrin, which, having the same chemical composition (C_{12} H_{10} O_{10}) as gum, and in many other points resembling it, has been in most analyses put down as gum. If one equivalent of water (H O) be taken from one equivalent of cellulose (C_{24} H_{21} O_{21}), two equivalents either of gum or dextrin [2(C_{12} H_{10} O_{10})] are formed. Thus a part of the cellular membranes may be converted into dextrin by catalysis [CHEMISTRY, P. C. S., p. 341] without destroying the cells, if the vegetable sap, while passing through them, contains only a very minute quantity of diastase, or of a substance resembling it.

We have already mentioned that gum and dextrin have been frequently confounded. The most important difference between them is, that the latter may be changed into grape-sugar by sulphuric acid or diastase, while the former is incapable of undergoing that change.

Dextrin belongs to the nutrient matters; all the starch taken as food being converted by the gastric juice into it. The gums are mere excretions, and are apparently of little or no importance.

There seems every reason for believing that dextrin is the source of the cellular matter, for it is a universal constituent of all parts of plants. We are justified in assuming that the sap of plants must contain the elementary matter of cellulose in a state of solution, so as to be able to penetrate through the cell-walls, and to supply new substance to increase the number of cells. No material but dextrin is fitted for this office, though in young plants sugar also contributes to it. By the production, during germination, of dextrin and sugar, we are led to believe that the cellulose of the young plant is really formed from this dextrin and from the sugar in the germinating cotyledons. Whilst many full-grown plants do not contain sugar, all contain dextrin, so that the use of the latter in the formation of cells cannot be doubted.

Dextrin is not merely a source of cellulose, but likewise of starch, sugar, gum, and perhaps other vegetable substances; it is almost as valuable to plants as protein is to animals, for it is a constituent from which their organism derives its most important products. The composition* of dextrin being C_{12} H_{10} O_{10}, the formation of cellulose is accomplished by every two equivalents of dextrin taking up one equivalent of water. Thus

$$2\,(C_{12}\,H_{10}\,O_{10}) + H\,O = C_{24}\,H_{21}\,O_{21} = \text{cellulose.}$$

Starch and gum contain the same elements in the same proportions as dextrin, and hence for their production require merely a re-arrangement of the molecules.

Sugar, as we shall immediately show, requires only the addition or subtraction of water from the elements of dextrin.

The different species of sugar, as far as they are yet known, are—

1 Milk-sugar	. .	$C_{24}\,H_{19}\,O_{19} + 5\,H\,O$
2 Cane-sugar	. .	$C_{12}\,H_{9}\,O_{9} + 2\,H\,O$
3 Grape-sugar	. .	$C_{12}\,H_{12}\,O_{12} + 2\,H\,O$
4 Eucalyptus-sugar	.	$C_{24}\,H_{19}\,O_{19} + 9\,H\,O$

Milk-sugar is an integral constituent of the milk of the mammalia, and has very rarely been met with anywhere else. It has recently been detected in eggs during the process of incubation; but this observation requires to be confirmed. Cane-sugar is the most closely related to starch and dextrin, differing from them merely by one equivalent of water. It is not by any means so widely distributed as grape-sugar, being found in very few plants besides the sugar-cane, beet, and maple. Grape-sugar is identical with the sugar in honey and in diabetic urine, and with the glucose or fruit-sugar of the French chemists. The uncrystallizable sugar which is obtained during the decomposition of many plants, and which is yielded by starch acted on by diastase or sulphuric acid, has the same composition as grape-sugar.

Eucalyptus-sugar is a species of manna produced in Van Diemen's Land by various species of eucalyptus. Whether it

* The formula C_{24} I 10 O_{10} in the article CHEMISTRY, P. C. S., p. 343, is obviously a misprint.

is the natural sap spontaneously escaping, or whether it is the sap extracted by the locust and afterwards excreted, is uncertain. Its properties have been carefully examined by Professor Johnston of Edinburgh.

There is obviously an intimate connexion between these different kinds of sugar, as well as between cellulose, starch, dextrin, and gum. They all contain carbon, in combination with the elements of water. As they all contain C_{12} or a multiple of it, they are produced from each other by a simple change depending on catalytic force. [CHEMISTRY, P. C. S., p. 341.]

If sulphuric acid is allowed to act on gelatin, a species of sugar containing nitrogen, and termed *glycicoll* or *gelatin sugar*, is formed. Its formula is $C_8\,H_9\,N_2\,O_7$; and it is worthy of remark that if from two of its equivalents we deduct one equivalent of cane sugar, we obtain the elements of two equivalents of urea, or

$$2\,(C_8\,H_9\,N_2\,O_7) - C_{12}\,H_{10}\,O_{10} = 3\,(C_2\,H_4\,N_2\,O_2).$$

This relation leads to the belief that sugar is a component part of the gelatinous tissues, and when separated from them it may be presumed to discharge the same functions as when either cane or grape sugar is supplied with the food. In other words, there exists in the substances yielding gelatin a primary matter which exists also in cane-sugar. If then substances or tissues containing gelatin are employed in effecting the metamorphosis continually occurring in the animal body, this primary matter may serve the same purpose as cane-sugar when supplied to feed the body. On these grounds Mulder considers that gelatin-sugar should be classed amongst the nourishing substances. If gelatin be formed in the animal body, then sugar, either derived directly from the food or produced from starch in the alimentary canal, may be used for this purpose.

It is not known in what part of the plant sugar is formed. Mr. Knight states that birch sap contains more sugar the farther from the root it is collected; this seems to prove that the sap, which probably contains much dextrin, is changed into sugar as it passes through the cell-walls. When sugar accumulates in certain parts of a plant, it almost always remains in solution; it is however found crystallized in some few instances, as in the nectary of Fritillaria imperialis.

Closely allied in its chemical composition to sugar is a peculiar substance to which the term *mucilage* is given. Although insoluble in water, it assumes the appearance of a mucilaginous mass when immersed in that fluid. It sometimes accumulates largely in certain parts of plants, as in the perisperm of quince-seed, lint-seed, &c.; it is the chief constituent of the gums tragacanth and Bassora, and is abundant in various roots, as for instance the mallows. According to Mulder's analysis it must be represented by the formula $C_{24}\,H_{19}\,O_{19}$. It has been shown by Schmidt that mucilage when digested with dilute sulphuric acid is converted into sugar. Hence it supplies a link to the following series of analogous substances:

Grape-sugar and fruit-sugar . .	$C_{24}\,H_{24}\,O_{24}$
Cellulose and soluble inulin . .	$C_{24}\,H_{21}\,O_{21}$
Starch, dextrin, gum, insoluble inulin, and lichen-starch	$C_{24}\,H_{20}\,O_{20}$
Mucilage, milk-sugar, and eucalyptus-sugar	$C_{24}\,H_{19}\,O_{19}$
Cane-sugar	$C_{24}\,H_{18}\,O_{18}$

In its physical characters the product of the mucous membrane of the animal body resembles vegetable mucilage. Owing to their insolubility in water, both these substances serve to cover denuded parts of animals, and thus they are both suited to lessen or prevent the influence of acrid matters on the tender parts of the animal frame. It is for this reason that the mucilage of salep, tragacanth, &c. may be made, in certain diseased conditions, to supply temporarily the want of animal mucus. In chemical composition they are perfectly distinct, as animal mucus contains nitrogen. The mucus of the animal body seems however to differ according to the organs by which it is produced. (Day's edition of Simon's *Animal Chemistry*, vol. ii. p. 78, note.)

We now arrive at a peculiar group, occurring both in the vegetable and animal kingdoms—*the fats.*

Stearin, margarin, and olein are the most widely distributed fats in the organic kingdom, but they are not the only ones. They were formerly regarded as salts formed by fatty acids with glycerin [CHEMISTRY, P. C. S., p. 344]; recent investigations have however shown that this view requires a slight modification. Berzelius thinks that glycerin does not exist ready formed in the neutral fats, but that it is a product of the formation of soap; and he considers the base of the neutral fats to be the oxide of a radical ($C_3\,H_2$) which he terms lipyle. Glycerin is then formed from two equivalents of the oxide of lipyle, with three equivalents of water: $2\,C_3\,H_2\,O + 3\,H\,O = C_6\,H_7\,O_5$. (If to this we add one equivalent of water, we obtain the formula given in CHEMISTRY, P. C. S., p. 344.)

According to this view, which is supported by Redtenbacher, Varrentrap, and Mulder, the base of every neutral fat yielding glycerin is a compound which is represented by $C_3\,H_2\,O$.

The most important of the fatty acids are:—

Stearic acid . .	$C_{68}\,H_{66}\,O_5 + H\,O$
Margaric acid . .	$C_{34}\,H_{33}\,O_3 + H\,O$
Oleic acid . .	$C_{44}\,H_{40}\,O_4 + H\,O$

These are universally diffused in plants and animals; and, combined with the oxide of lipyle ($C_3\,H_2\,O$), they form the neutral fats—stearin, margarin, and olein; and this is the form in which they most commonly occur in the organic kingdom. Sometimes however a more powerful base (potash, soda, &c.) removes the oxide of lipyle, and there are then formed compounds of the fatty acids with alkalies.

In connexion with this subject, Mulder observes that 'when salad-oil is conveyed into the stomach, it may pass unchanged into human fat, for both consist of margarin and olein, although in different proportions; and as margarin and olein are found in many vegetables used for food, nothing is more simple than to assume that these substances are directly transferred, without change, into the fats of the animal body.

'But if these same vegetables are eaten by a sheep, the olein and margarin must undergo some change in the body of the animal, since mutton-fat contains a large amount of stearin. In this case the change is easily understood, for 2 eq. margaric acid ($C_{68}\,H_{66}\,O_6$) = 1 eq. stearic acid ($C_{68}\,H_{66}\,O_5$) + 1 eq. oxygen. Thus, from two equivalents of margaric acid, one equivalent of stearic acid is produced, and one equivalent of oxygen is given off. In all probability, such a deoxidation of the margaric acid in the food of the sheep is really effected; and on the contrary, when mutton-fat is used for food by man, stearic acid is most probably converted into margaric acid by the absorption of oxygen.' It is now believed by our first physiologists, that the neutral fats taken as food do not directly form fatty tissue, but that they enter the blood in a saponified state. In fact the alkaline character of the bile as it enters the duodenum renders it impossible for the fat to enter the blood without undergoing this change. If it is saponified, we readily understand how compounds of fatty acids and soda should exist in the blood and in various parts of the body. When a soda-soap however exists in the blood, it cannot form a neutral fat, such as margarin or olein, without combining with glycerin. This leads to the inquiry, in the first place, whether these soaps meet with glycerin; and secondly, if they do, whether the glycerin would combine with the fatty acids and form neutral fats. There is good reason for believing that both these questions may be answered in the negative, for the glycerin set free when the soda-soap is formed, is most probably at once decomposed; and further, glycerin will not remove the soda from the fatty acid and form a neutral fat.

It has been suggested by Mulder, that although glycerin will not enter into this combination, the oxide of lipyle in a nascent state may do so, and that in this manner the fatty acids may be converted into neutral fats and deposited in the cellular tissue and other parts of the body. We have already shown that (according to the opinion of Berzelius) glycerin is the oxide of the radical ($C_3\,H_2$) lipyle. The second oxide of this radical exists in lactic acid, which is supposed by the great majority of chemists to be present in most parts of the body. When lactic acid ($C_6\,H_5\,O_5$) is sublimated, we obtain a white sublimate, the composition of which is $C_3\,H_2\,O_2$; while the composition of the oxide of lipyle is $C_3\,H_2\,O$.

It may happen that there are causes of deoxidation at work in the system, by which some of the substances usually converted into lactic acid are made to produce oxide of lipyle, which in the nascent state unites with the fatty acids, forming neutral fats.

Hence in all probability the neutral fats are not deposited directly and unchanged in the cellular tissue, but are first saponified, and entering the blood as margarate and oleate of soda, are again reduced to neutral fats by the influence of lactic acid.

In many parts of plants, especially in the perisperms of some fruits, a fatty matter (popularly known as *wax*) occurs. It has been known to exist in plants, but it has only recently been shown that bees can prepare it from honey, which does not contain any wax at all. It is the wax that gives to grapes and plums their beautiful purple bloom; it abounds in the skins of apples, and is a component of the green colouring matter of leaves (chlorophyle), of which we shall presently speak. Avequin has analyzed the crystalline wax which collects on the surface of the sugar-cane, and to which he has given the name *cerosia*. He mentions an important peculiarity in connexion with it, namely, that those kinds of sugar-cane which contain much sugar have but little cerosia; while conversely, those which contain much cerosia have but little sugar. From this we should infer, that either wax is used in the plant to produce sugar, or sugar to form wax. That the latter is the case seems definitely proved by the following experiments of Gundlach. He fed bees with a solution of sugar-candy in water, and saw them producing wax. Thus the sugar-cane and bees are both enabled to convert sugar into wax, that is, into a fatty matter.

There are some animals, just as there are some plants, which contain peculiar fats; there are even separate organs in which certain fats are formed.

In butter we find the following acids, chiefly in combination with oxide of lipyle: margaric and oleic acids, and

Butyric acid . . .	$C_8\ H_8\ O_4$
Caproic acid . . .	$C_{12}\ H_{12}\ O_4$
Capryllic acid . . .	$C_{16}\ H_{16}\ O_4$
Capric acid . . .	$C_{20}\ H_{20}\ O_4$

Butyric acid is occasionally present in the urine, the gastric juice, and the sweat; the others occur only in hutter.

Cetine, occurring in a particular portion of the cavity of the skull of the Physoter macrocephalus; *phocenine*, in the fat of Delphinus phocena; *cholesterin*; *ambrain*, in amber; and the hrain-fats known as *eleencephol*, *cerebrot*, *cephalot*, and *stearoconot*—are illustrations of this class.

It is worthy of observation, that both in the vegetable and the animal kingdom there seems a connexion between the protein-compounds and fat: when we find solid protein-compounds deposited in plants, we often find at the same time a large quantity of fat, as in numerous seeds; the brain and milk serve as illustrations of the same point in the animal kingdom.

The next question for our consideration is *the formation of fat*—a subject which has given rise to much angry and intemperate discussion between the leading chemists of France and Germany. Dumas, who may be regarded as the representative of the French school, maintains that all the fat of animals originates in and is obtained from plants; while Liehig, on the contrary, maintains that a portion of it is formed hy the animal itself, from starch, sugar, and gum. The goose was the animal respecting which the dispute originated. When fattened with Indian corn, the starch must, according to Liebig, have been changed into fat, because he had found but a minute quantity (about 1 part in 1000) of fat in that kind of grain. Dumas however extracted 9 per cent. of fat from Indian corn (or ninety times as much as Liehig), and thus he found in the food which the goose had eaten much more fat than had to be accounted for. The actual fact is, that the amount of fat in this grain is so variable that no conclusion can be drawn from the experiment. Liebig quotes many examples of snbstances which, although they contain little fat, are well known hy experience to be especially fit for fattening the animal body. Rice, peas, beans, and potatoes are all known to possess this property; yet rice gives only 0·2 to 0·8 per cent. of matters soluble in ether (the ordinary means of determining the amount of fat); peas 1·20 to 2·1; beans 0·70, and dried potatoes 0·35 per cent. Thus any animal that has eaten 1000 pounds of one of these substances may ohtain from them 2 to 8, 12 to 21, 7, or 3½ pounds of fat respectively. He makes the following calculations:—Three pigs to be fattened in thirteen weeks require 1000 pounds of peas, and 6825 pounds of boiled potatoes, the latter being equal to 1638 pounds of dry potatoes. These contain in all 26 pounds of fat, the peas yielding 21, and the potatoes 5 pounds. One fattened pig gives on an average 50 to 55 pounds of fat, the three yielding 150 to 165 pounds. Each pig before fattening contains on an average 18 pounds of fat—that is, 54 pounds for the three. If to these 54 pounds be added 26 pounds contained in the food, we get 80 pounds; and if we suhtract these from 150 to 165 pounds, there is a remainder of 70 to 85 pounds of fat produced from the starch, &c., of the food. Liebig's opinion is further strengthened hy the circumstance that some fats are undouhtedly produced in the body, as, for instance, the fats peculiar to the brain, cholesterin, cetine, phocenine, &c. To obtain these from other fat requires just as much a new arrangement as if they were produced from starch; hence, in a scientific point of view, there is nothing improhable in the supposition that animals are able to produce fats.

With regard to the formation of fat in plants, it is worthy of observation that all seeds which yield oil on pressure—as the castor-oil seed, hemp seed, &c.—contain starch in their early stages, this starch disappearing as the oil increases, and when the seed is completely developed not a trace of the starch remaining. This renders it probable that these fatty matters are formed from starch. From their ultimate composition it is ohvious that whenever fats are produced from any substance there must be produced at the same time either highly oxidised compounds, or else that oxygen must be itself liberated. Liehig observes that if from the formula for starch, $C_{12}\ H_{10}\ O_{10}$, we take 9 equivalents of oxygen, there will remain in 100 parts—

C_{12} . . .	79·4
H_{10} . . .	10·8
O . . .	9·8

The empirical formula for fat which comes nearest to this is $C_{11}\ H_{10}\ O$, which gives in 100 parts—

C_{11} . . .	78·9
H_{10} . . .	11·6
O . . .	9·5

According to this formula an equivalent of starch, in order to be converted into fat, would lose one equivalent of carbonic acid and seven of oxygen, or (expressed in symbols) $C_{12}\ H_{10}\ O_{10} = C_{11}\ H_{10}\ O + C\ O_2 + 7\ O$.

The same point is also clearly shown by contrasting the ultimate composition of starch and fat.

	Starch.	Human fat (Chevreul).
Carbon . .	44·91 .	79·00
Hydrogen . .	6·11 .	11·42
Oxygen . .	48·98 .	9·58

As we are not acquainted with any constituent of plants which can take up the oxygen thus liberated in the formation of fat, we must regard this as one of the sources of the oxygen given off by plants. Mulder has given the following scheme as illustrative of the mode in which starch may possihly be converted into fat or oil, in the vegetahle kingdom:—

	C	H	O
To 7 equiv. of starch . . .	84	70	70
Add 8 equiv. of water . . .		8	8
And we have	84	78	78
Which are equal to			
1 equiv. of margaric acid . .	34	34	3
1 equiv. of oleic acid . . .	44	40	4
2 equiv. of oxide of lipyle . .	6	4	2
69 equiv. of oxygen			69
Making as before	84	78	78

There is a substance almost universally diffused through plants, which we must here notice, and that is, the green colouring matter of the leaves—the substance termed *chlorophyle*. For the following account of this substance we are almost entirely indehted to the investigations of Mulder. It is a striking fact that young leaves have a much lighter green colour than those which are older, showing that the quantity of chlorophyle increases with the age of the leaves. If chlorophyle were a substance poor in oxygen, and were derived from substances rich in oxygen, this fact alone would be sufficient to explain the power which the green parts possess of separating oxygen. This however is not the case; chlorophyle is rich in oxygen. Nevertheless the leaves give off oxygen not *because* they *are* green, but *whilst* they are *becoming* green.

When green leaves are digested with ether the liquid becomes green. On evaporating the etherial solution, and treating the residue with hot alcohol, a considerable amount of white fatty matter (wax) separates on cooling, while the green colouring matter remains in solution. Before proceeding to the consideration of the green colouring matter, it will be expedient to say a few words respecting the mixture it forms with the wax.

In a physiological or botanical sense this mixture has the name of chlorophyle; in a chemical sense the term is restricted to the actual green pigment. To prevent confusion the former is designated as B. chlorophyle, and the latter as C. chlorophyle; B. indicating the botanical, and C. the chemical signification of the word.

We find similar mixtures of a waxy fat, and colouring matter, in other external parts besides the leaves, namely in the skins of fruits, especially of such as are coloured; and on digesting them in ether we obtain a large quantity of waxy matter in solution, varying in tint according to the colour of the skin; being gray when obtained from apples, and of a beautiful orange colour when obtained from the berries of the mountain ash.

The degree in which the action of light contributes to the change of colour in the C. chlorophyle which exists in the perisperms, and to the production from it of the colouring matter of the skin of ripe fruits may be obviously inferred from the green colour which such fruits retain if they do not receive a sufficient supply of solar light, or from the difference of colour exhibited by the opposite side of the same fruit, as well as from the fact that leaves when deprived of the action of light become colourless, while if completely exposed to its action they secrete a considerable amount of B. chlorophyle.

This apparently anomalous difference in the action of light on the skins of fruits and on leaves is dependent on the same cause as the change of colour in the leaves during autumn: namely, that light can only produce B. chlorophyle when there is a sufficient supply of materials for its renewed formation as often as the existing quantity is decomposed by the influence of the light; and that as soon as this supply is exhausted the green colouring matter is itself decomposed, and other compounds are formed from it.

Light acts powerfully in keeping plants green, and likewise exerts a powerful decomposing action upon all colouring matters, the C. chlorophyle not excepted; thus asparagus, potatoes, young leaves, &c., become green whenever they are exposed to light, and hence there must be a substance widely diffused through plants, which causes the production of chlorophyle. The change takes place not merely on the surface, but beneath it as far as light can penetrate through the semi-transparent parts. All plants however are not coloured green; some have no colour at all, while others are speckled or spotted, or of a colour entirely different from green. Hence we conclude that in these plants or parts of plants, the materials yielding chlorophyle are absent. We may sometimes observe, in summer, one single spot of a green leaf coloured red by the action of insects or by being injured by hail; the green colouring matter is at the spot decomposed by the light; no new portion is formed, and the spot acquires the same colour which the whole leaf would have assumed in autumn. From this we infer that the change of colour in the leaves during autumn is simply dependent on a chemical alteration of the green colouring matter by light.

Mulder, after showing from a large number of facts that wax along with a green colouring matter exists in leaves and unripe fruits,—wax with a red colouring matter, in the red leaves which appear in autumn, and in the red fruits,—and wax with a yellow colouring matter, in the yellow leaves of autumn, and in the yellow fruits, gives a lengthened chemical description of chlorophyle, for an account of which we must refer to the original work.

From Mulder's experiments, and those previously instituted by Berzelius, it appears that the green colouring matter of the leaves is readily decomposed into three different substances, one yellow, another blue, and a third black; and that according to the proportion of these three mixed with the green, a different kind of green must be produced. Hence the difference in the green colour of different leaves depends not only on the presence of more or less chlorophyle, but also on the different mutual proportions of these three colouring matters.

The quantity of pure C. chlorophyle contained in the leaves is exceedingly small; according to Berzelius, it is not more than the amount of pigment in dyed cotton.

If a tincture of pure chlorophyle be exposed to the action of the sun, the green colour becomes in a few hours converted into a yellow. When a solution of pure chlorophyle in ether and hydrochloric acid was kept for five months in a bottle half full, the green was entirely changed into a yellow. From these experiments we learn, first, that the green colouring matter is decomposed and a yellow one left, both with and independently of the influence of light; and secondly that in all probability a similar decomposition (accompanied by a reproduction) of green colouring matter and green leaves is constantly going on under the influence of light. Mulder conceives that the continual decomposition of the green colouring matter may be in part the origin of the wax, since the quantity of the latter is found to have increased when the same leaves are analyzed later in summer. In consequence of the continuance of this reproduction the leaves remain green; when it stops, the leaves become yellow, as in autumn.

It is worthy of notice that decomposed chlorophyle yields a blue colouring matter; it is this which is no doubt present in the skins of many fruits, as for instance those of the grape; the exact nature of the chemical change is not clearly understood.

It is very obvious that the influence of light will convert starch into chlorophyle. Every part of an amylaceous root becomes green on exposure to light. The parts of plants which become green (all without exception) contain starch; and in autumn as this green colour decreases, the starch also decreases, and finally cannot be detected by the iodine-test. Hence starch ceases to form B. chlorophyle under the influence of light; the B. chlorophyle being a complex substance consisting chiefly of wax. The change of starch into botanical chlorophyle may be explained in much the same manner as its conversion into fat.

The wax contained in the leaves and other parts of plants may be chemically represented by the formula $C_{15}\ H_{15}\ O$. Now if no other products be simultaneously produced we may suppose the wax obtained from the starch in the following manner:

5 equiv. of starch .	$C_{60}\ H_{50}\ O_{50}$
With 10 of water . .	$H_{10}\ O_{10}$
Make	$C_{60}\ H_{60}\ O_{60}$
And 4 of wax . .	$C_{60}\ H_{60}\ O_{4}$
Leaving to be given off ·	O_{56}

That is to say, 5 equivalents of starch yield 4 equivalents of wax, and give off 56 equivalents of oxygen. This fully explains the phenomenon why plants *while becoming green*, evolve oxygen, and further indicates the use of starch in the leaves.

Mulder has, as far as we are aware, made only one ultimate analysis of pure C. chlorophyle—that from poplar leaves; from this analysis he calculated the formula $C_{18}\ H_{9}\ N\ O_{8}$.

'Properly speaking,' Mulder observes, 'the green colouring matter in the leaves has nothing to do with the evolution of oxygen; on the contrary, the colourless C. chlorophyle, which seems to be every where present, becomes green by the *absorption of oxygen*. Hence a small portion of the oxygen produced from the conversion of starch into wax is employed for this purpose, and is not mixed with the atmosphere. But this is just the reason why C. chlorophyle is not *formed* by the exhalation of oxygen; it only becomes green instead of white, as it previously was. This can only happen when there is an abundance of oxygen, and this we have seen to be the case when starch is converted into wax. We may therefore assume as proved that white chlorophyle diffused throughout the whole plant, will become green in proportion as starch is converted into wax; because it is enabled, in such proportion, to take up oxygen—to become oxidised, just like white indigo.

'Now, the probable composition of green chlorophyle,—$C_{18}\ H_{9}\ N\ O_{8}$ shows that pure white chlorophyle is not produced from starch. It is necessary that an azotized body in a liquid state, should penetrate into the globule of starch, which during this transformation into wax is converted into $C_{18}\ H_{9}\ N\ O_{8}$. We do not know yet what that substance is, but it is certain that it must be one which is diffused throughout the plant like starch; hence it is probably protein, which is changed into a most beautiful violet-coloured substance by the influence of hydrochloric acid and oxygen.'

We now return to the animal kingdom, and have a few remarks to offer on *gelatin*, a substance yielded by most parts of the animal body. Amongst the component parts of organized bodies, the most frequent is the *cell*. Modified in an infinite variety of ways, it gives rise to the innumerable varieties exhibited both by plants and animals, in the external form, the structure, and consequently the functions of their organs. In the vegetable kingdom the substance employed in the construction of these cells is *cellulose* combined usually with a little protein. In the animal kingdom the case is very similar, although the elementary form of the tissue and its chemical characters are different. In animals we must distinguish between the persistent and the original cellular substance. The original in all probability varies in different cases, while the persistent exhibits a constant and general character. The persistent tissue is consequently a secondary product, and in this respect differs from the cellular substance in plants which is a primary or original one; neither has it an actual cellular form like the latter. There is however a resemblance between the two in several points, especially in relation to the large proportions in which they both exist, and to the several functions which they perform.

Gelatigenous substance is so widely diffused over the body that it would exhibit the entire shape of the principal organs, even if all other constituents were separated. It constitutes the skin, the serous membranes, the cellular sheaths of the muscles, the organic portion of bone, and many other substances. It is insoluble in cold water; acetic acid renders it transparent and bulky; tannic acid renders it solid and prevents its putrefaction; and when boiled it forms a jelly. It is in consequence of the last property that it has received the name of gelatin. The gelatigenous substance (skin, areolar tissue, serous membranes, &c.) is insoluble in cold water, and on boiling is merely physically and not chemically altered. In the process of boiling nothing is taken up and nothing separated; the alteration being similar to that undergone by starch when heated in water.

The composition of gelatin is represented by the formula

$$C_{13} H_{10} N_2 O_5$$

whether obtained from hartshorn, from isinglass, or from silk. Both boiled and unboiled cellular tissue (after its conversion into glue) combine with tannic acid, and produce compounds which are insoluble in water and resist putrefaction; hence the power of all medicines containing this substance to heighten the tone of the system. The protein-compounds in a similar manner form hard and coherent compounds with tannic acid. Peruvian and willow bark, catechu, and many other astringent medicines produce compounds of this nature in the organism.

On boiling gelatin in water for a long time we obtain a hydrate of gelatin which no longer gelatinizes; its composition is 4 ($C_{13} H_{10} N_2 O_5$) + aq.

This peculiarity should be remembered, for the compound is likely to be formed in the preparation of broth, and in the application of Papin's Digester to cooking; and it is regarded by Mulder as doubtful whether this hydrated gelatin can be again converted in the organism into nutrient matter, and whether it may not produce noxious substances in the body.

As gelatin has never yet been discovered in the vegetable kingdom, there is every reason to believe that it is produced in the animal body. It is most probably formed from the decomposition of the protein in the blood, through the action of the alkali in the serum, and the oxidising influence of the atmosphere.

We are likewise imperfectly acquainted with the products of the decomposition of the gelatigenous tissues in the body. Out of the body we know that by the influence of oxidation on gelatin prussic acid is formed, and that, by the action of alkalies, gelatin-sugar, leucin, and extractive matters are produced, while ammonia is disengaged, and an alkaline carbonate formed. Finally, when boiled in dilute sulphuric acid, it yields extractive matters with either gelatin-sugar or leucin. Since leucin is also produced from albumen when decomposed by potash, we perceive an intimate connexion between that protein-compound and gelatinous matters.

Besides the gelatin obtained from cellular tissue and serous membranes there is another kind which has many of its properties, but differs from it in composition. It was first described by Müller under the name of *chondrin*. It is obtained from the cornea, and from those cartilages which do not ossify, by boiling them in water.

Its composition* is 10 ($C_{32} H_{26} N_4 O_{14}$) + S.

The preceding observations on the *general organic substances* which exist in the two great departments of the organic kingdom are sufficient for the clear understanding of the forms and properties of the elementary parts of plants and animals. Both kingdoms however contain an immense number of additional substances. In plants there are acids, bases, colouring matters, oils, and resins; in animals there are the various secretions. As these vegetable products have been fully treated of in many of the articles of the PENNY CYCLOPÆDIA, our attention will in the future part of this article be chiefly confined to the animal products.

According to Schwann, all organic tissues, however different they may be, have one common principle of development as their basis, namely, the formation of cells; that is to say, molecules are never united immediately into a fibre, a tube, and so forth, but always (or almost always) in the first instance into round cells, which subsequently become connected so as to form the various primary tissues as they present themselves in the adult state. The formation of the elementary cells takes place, in the main points, in all the tissues, in accordance with the same laws; their further transformation varies in the different tissues.

SECTION II.—*Microscopic Character of Tissues.*

All organic beings, according to the cell-theory, are composed of a number of minute parts, which in their leading characteristics are identical in the two kingdoms, but which are combined in different ways, and whose products are therefore distinct not only in the animal and vegetable world, but likewise in the different organs of the same animal or plant. These minute parts, which are invisible to the naked eye, although identical in form and development, differ extremely in their combinations and functions. All the tissues that we meet with both in the animal and vegetable world are nothing more than groups of these elementary parts; their functions depending on the nature of the grouping.

The elementary forms which organic matter on becoming organized assumes, are for the most part, if not always, minute vesicles which can only be distinguished by the microscope. These have received the names of *elementary*, *nucleated*, or *primary cells*. They are most easily observed in vegetable and animal tissues in the process of development. They usually contain a fluid, but granules are also not unfrequently observed in them. The vesicle is formed of a thin membrane wherein a *nucleus* is often observable. This nucleus is almost invariably present in animal cells, whilst it can only be distinguished in the young cells of plants. From these simple cells, or slight modifications of them, all organized bodies are constructed; we find them in the blood (as blood-corpuscles), in the lymph, in mucus and pus, and in nearly every solid portion of the animal body; even the germ of the future being (the ovum) is nothing more than a nucleated cell. As the cell-theory in relation to the vegetable kingdom has been already noticed in the article TISSUES, VEGETABLE, P. C., our observations will be entirely confined to the cellular formation and structure of the animal world.

On the addition of acetic acid the cell-wall dissolves while the nucleus remains unacted on; hence the nucleus is a distinct body. It is named by Schleiden the *cytoblast* (κυτος, *a cell*, and βλαστάνω, *I cause to bud*), being supposed by that physiologist to be the originator of the cells. In the nucleus we can usually observe one or more dark spots which have received the name of *nucleoli*. The nature of these nucleoli is unknown; we cannot tell whether they are cavities, vesicles, or solid particles. They lie on the inner part of the nucleus.

The nucleus itself is regarded as a minute cell; it is connected with the cell, and is an essential constituent of it.

The cells are surrounded by a fluid whose consistence increases with the age of the tissue, and which finally becomes solid, forming intercellular substance. The formation of cells takes places in the following manner. In an amorphous, semifluid, sometimes almost gelatinous mass which is named the *cytoblastema*, and wherein the substances necessary for cell-formation are contained, there are formed minute, roundish granules (nucleoli), around which is deposited a layer of granular matter, which gradually becomes thicker and forms the nucleus. On the surface of this nucleus a vesicle arises, resembling a segment of a sphere. This vesicle is thin and transparent, at first smaller than the nucleus, but rapidly enlarges, and when it has attained its full size, the nucleus is seen as a minute body attached to its inner wall. The substance necessary for the formation of the vesicle is yielded by the cytoblastema. The earliest trace of organization is coincident with the appearance of the nucleolus, which gives rise to the formation of a deposit of granular matter around it, and in this way to the production of the nucleus.

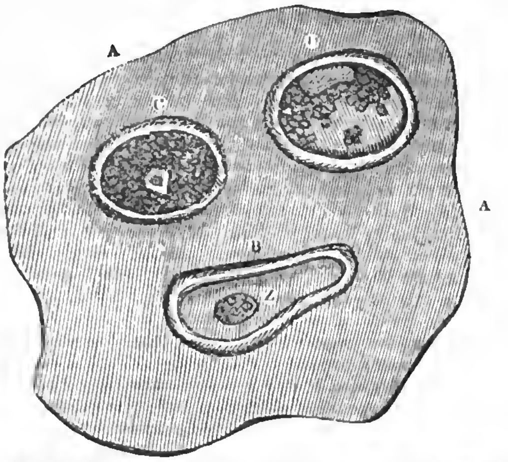
This theory of cell-formation, which is supported by Schleiden and Schwann, proceeds on the assumption that in cells there is always a pre-existing nucleus. It is objected to by Henle and others, on the grounds that there are many classes of cells in which there is no nucleus, or in whose nuclei there are no nucleoli; as for instance in the cryptogamia; and according to Meyen also in many phanerogamia. Similar observations have been made on certain cells in the animal organism, but Schwann combats the objection by the assertion that the nucleus or nucleoli become absorbed during the development of the cell.

According to Schleiden, the membrane of the cell grows from the nucleus, which latter remains as a persistent part of

* Liebig has recently found that albumen, fibrin, and casein contain more sulphur than is generally admitted, albumen containing about 2 per cent., and gelatin containing ½ per cent. of sulphur. This is very nearly the amount of sulphur yielded by the formula for chondrin given in the text, and which is deduced by Mulder from his own analyses.

the cell-wall; Mohl opposes this view, asserting that the nucleus lies within the cell at some distance from its mem-

Fig. 1.



An ideal figure illustrating the formation of a cell. In an amorphous substance (A A), the *cytoblastema*, lie three ideal cells (B, C, D). The cell B appears oval; in its interior we observe an elliptic body (Z), the *nucleus* or *cytoblast*; and within this, round dark corpuscles, the *nucleoli*. The space between the cell-wall and nucleus, the cavity of the cell, is filled with a fluid which escapes observation.

The cell C is round; it contains a nucleus with a single nucleolus in its centre; the cavity is filled with dark granular matter.

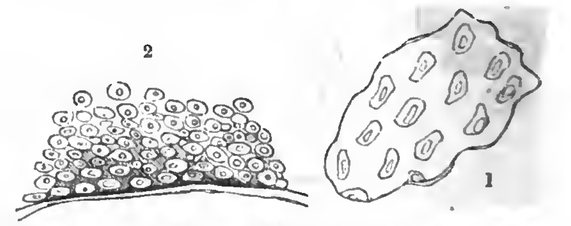
In the cell D the nucleus lies on the inner surface of the cell-wall; no nucleolus is observable. The contents of this cell are granular in the vicinity of the nucleus, but fluid and invisible in the remainder of the cavity.

brane. Valentin has also made similar observations in many of the animal tissues. He has observed cases in which the nucleus was not directly connected with the cell-wall, except by a few radiating fibres. Hence the function of the nucleus in relation to cell-formation is still obscure.

Whenever cells are formed, numerous pre-existing nucleoli are always present. They serve to form the contents of the cell, while the cell-wall is probably formed from the delicate connecting medium which unites these minute granules. These granules, which are the most minute organised particles with which we are acquainted, must be regarded as the most elementary form of all organic structures, since they are a necessary condition for cell-formation: there can be no doubt that they contain a protein-compound, since in the most recent structures in the animal and vegetable world protein is never absent, and indeed appears to be essential to organization. The very simplest form of fungi (such as the common mould-plant) which are produced in non-nitrogenous bodies, such as lactic or tartaric acid under the influence of the atmosphere (and therefore of nitrogen) and of water, contain protein from the first moment of their existence.

Before proceeding to the description of the various forms of cells, we must notice certain delicate membranous expansions in which no definite structure can be detected. They have been especially described by Bowman and Goodsir, the former terming them *basement*, and the latter *primary* or *germinal* membranes. This structure receives the former name from its being the foundation or resting-place for the epithelium-cells which cover its free surface, whilst the latter appellation was selected because it is 'a form of the primary cells of glands, and the source of secondary or secreting-cells.' Bowman considers it to be simple or homogeneous. This is true as far as it contains no blood-vessels, and as regards its external and attached layers; but as in its original condition it consists of cells, and when perfect contains nuclei at equal or variable distances, it must not be considered as simply molecular. 'Germinal membranes,' observes Goodsir, 'are only met with on the free surface of parts or organs. One surface of the membrane is therefore attached, and is applied upon a layer of areolar texture, interspersed with a more or less rich net-work of capillary vessels; while the other surface is free, and it is only on it that the developed or secondary cells of its germinal spots are attached. These secondary cells are at first contained between the two layers of the membrane, these layers being the opposite walls of each of its component cells. When fully developed, the secondary cells carry forward the anterior layer which is always the thinnest, leaving the nuclei or germinal centres in the substance of the posterior layer, in close contact with the blood-vessels.' To show the generality of the primary membrane, it may be observed that it constitutes the outer layer of the true skin; it lines all the cavities formed by mucous membrane, and is prolonged into all the ducts, and ultimate follicles and tubuli of the glands connected with them; it likewise forms the innermost layer of the serous and synovial membranes, and lines the blood-vessels and lymphatics, forming the sole constituent of the walls of their minutest division. The primary membrane must be regarded as a *transitional* rather than a *persistent* structure; furnishing the germs of all the cells which are developed on its surface, as well as the nutriment which they require for their support, its *free* surface must be continuously undergoing disintegration, and must be as continuously renewed at the side in connexion with the blood-vessels.

Fig. 2.



1. A portion of the germinal membrane of the human intra-glandular lymphatics, with its germinal spots or nutritive centres diffused over it.
2. Shows along one edge the thickness of the germinal membrane, and upon it the thick layer of glandular epithelia.
(Taken from Goodsir.)

We now proceed to notice the *history and functions of isolated animal cells*. It is only during the last three or four years that any correct ideas have been maintained regarding the importance of *simple isolated cells* in the animal economy; each of these cells grows and lives independently of all the others, deriving its support from the general nutrient fluid of the part in which it exists.

The animal cell in its simplest form originates from a reproductive granule, previously formed by some other cell; this granule attracts to itself, and assimilates and organizes the particles of nutrient fluid in its neighbourhood, converts some of them into the substance of the cell-wall, whilst it draws others into the cavity of the cell; in this manner the cell gradually increases in size, and whilst it is itself approaching the term of its life, it usually makes preparation for its renewal by the development of reproductive granules in its interior, which may become the germs of new cells when set free from the cavity of the parent. This mode of production and growth is almost identical with that occurring in the vegetable cell; there is however an important difference in their powers. The latter possesses the power of forming organic compounds from inorganic matters; while the former has no productive power of this nature, but can merely transform one compound into another. The best illustrations of simple isolated animal cells are afforded by the corpuscles occurring in blood, lymph, and chyle. There is a certain uniformity in their general character. They are only found in albuminous fluids, and they do not vary very much in size, averaging about the 3000th of an inch in diameter. They are known as lymph or chyle corpuscles, or as the *white* corpuscles of the blood. These white corpuscles have only of late years attracted much attention, though they had been described as far back as the time of Hewson. In man and the mammalia they are often larger than the red corpuscles; they may be recognised by their granular appearance, their peculiar coutour, and the irregular shading of their figure. (*Fig.* 3, parts 4 and 5.) They are also to be distinguished from the red corpuscles by their different actions towards chemical re-agents; they are not attacked by water, but remain in it for a long time without apparent change; they are not rendered transparent, and dissolved by acetic acid; they only become more decidedly granular under its action, and a kind of nucleus is developed in their centre. As they are in all respects similar to those of lymph and chyle, and as they have the same chemical relations, they have been regarded by many as the corpuscles of the lymph mingled with the blood, and have hence been termed *lymph corpuscles* (Hewson, Müller); others have viewed them as globules of coagulated fibrin (Mandl, Weber); and others again as blood-corpuscles in progress of solution or disintegration. They may be seen in the capillary system of living animals (in transparent structures, as for instance in the frog's foot) swimming with the ordinary blood-corpuscles, but not so much moving rapidly in the great current of the blood, as progressing in close contact with the walls of the vessels in a slower stream. They are not elastic, like the ordinary corpuscles, and seem to stick to each other. The exact functions of these corpuscles are still unknown, but there are many facts which seem to indicate that there is a decided relation between them and between the nutritive or organic life of the tissues.

Fig. 3.

1. Red corpuscles of human blood, exhibiting their flattened surfaces
2. The same, adherent by their flattened surfaces so as to form rolls.
3. Red corpuscles of frog's blood.
4. Colourless corpuscles of human blood.
5. The same, enlarged by the imbibition of water.

On examining a drop of blood under the microscope, we find, in addition to these cells, which are comparatively rare, an immense number of what are termed *red corpuscles*, but which usually present a yellow appearance. These red corpuscles have been already noticed in the article Blood, P. C. The following are the most important additiona made to our knowledge of them since the publication of that article. The blood of numerous animals has been submitted to microscopic examination by Nasse, Wagner, Gulliver, and other observers. In the article Blood it is stated that the 'red particles of the blood have a circular form in all animals constituting the class mammalia.' A remarkable exception to this rule has been shown by Mandl to occur in the corpuscles of the camel tribe. The mean long diameter of the blood-corpuscles of the dromedary be found to be the 3254th of an inch, while the mean short diameter was only the 5921st of the same standard. In the paco (Auchenia paco) and guanaco (Auchenia glama) the blood-corpuscles scarcely differed in form and size from those of the dromedary, whilst in the vicugna they were slightly smaller. In structure and magnitude however these oval corpuscles of the Camelidæ belong entirely to the mammiferous type; they have no perceptible nucleus, like those of birds, and they are not much more than half the size of even the smallest that have been observed in birds or reptiles.

The difference of size in the corpuscles of different mammalia is also worthy of notice. The averago diameter of those of man, according to Mr. Gulliver, is the 3300th of a inch, but the average diameter of those of the elephant, according to the same observer, is as much as the 2745th of an inch (which were the largest he observed amongst the mammalia), whilst those of the Napu musk-deer were no more than the 12,325th, and some were as small as the 16,000th of an inch in diameter. There is also an exception to the general statement that the corpuscles of fishes are oval; in one class, namely the Cyclostomi, or lamprey tribe, they are circular. Neither is the statement now correct that the corpuscles of the skate are the largest known; those of certain reptiles, as for instance the *syren* and the *proteus*, are considerably larger, and are even visible to the naked eye as very minute specks.

There can be no doubt that the red corpuscles go through the same course as other cells. We have undoubted evidence of their rapid regeneration in cases where much blood has been lost, and of the peculiar power which chalybeate medicines have in forwarding their production. The precise method in which they are developed is however not exactly known.

With respect to the chemical composition of the blood-corpuscles, we have already stated that the *globulin* of which the walls are formed seems undoubtedly to be a protein-compound. The red colour is due to a pigment which has received the name of *hæmatin*, and is enclosed in the vesicles of globulin. It has been generally assumed that this substance exists in two distinct states in arterial and venous blood, having in the former an excess of oxygen, and in the latter an excess of carbon or carbonic acid. Mulder has however shown that its elementary composition is the same whether obtained from arterial or venous blood, and that it may be represented by the formula $C_{44}\,H_{22}\,N_{3}\,O_{6}\,Fe$; the following being the analyses from which he deduced it:—

	1	2	3	4	5	According to the formula.
C	66·49	65 91	66·20	65·73	65·90	65·84
H	5·30	5·27	5·44	5·28	5·27	5·37
N	10·54	..	10·46	10·57	10·61	10·40
O	11·01	..	11·15	11·97	..	11·75
Fe	6·66	6·58	6·76	6·45	..	6·64

1, 2, and 3, were arterial, and 4 venous ox-blood; 5 was the mixed blood of a sheep.

It may be shown by conclusive experiments that the red colour is not dependent on the iron, for that constituent may be removed from the hæmatin without materially altering its tint, although it is very firmly combined with the four organic elements. The condition in which the iron exists in hæmatin—whether as an oxide, a carbonate, a carburet, or in the metallic state—has long been disputed. According to Liebig the iron of the hæmatin is the most essential constituent of the blood in relation to the respiratory process. The following is his view of the theory of respiration:—'During the passage of the venous blood through the lungs, the globules change colour, and oxygen is absorbed from the atmosphere. Further, for every volume of oxygen absorbed, an equal volume of carbonic acid is, in most cases, given out. The red globules contain a *compound of iron*, and no other constituent of the body contains iron.' Whatever change the other constituents of the blood undergo in the lungs, this much is certain, that the globules of venous blood experience a change of colour, and that this change depends on the action of oxygen. Now we observe that the globules of arterial blood retain their colour in the larger vessels, and lose it only during their passage through the capillaries. All those constituents of venous blood which are capable of combining with oxygen, take up a corresponding quantity of it in the lungs. Experiments made with arterial serum have shown, that when in contact with oxygen it does not diminish the volume of that gas. Venous blood in contact with oxygen is reddened, while oxygen is absorbed, and a corresponding quantity of carbonic acid is formed. It is evident that the change of colour in the venous globules depends on the combination of some one of these elements with oxygen; and that this absorption of oxygen is attended with the separation of a certain quantity of carbonic acid gas. This carbonic acid is not separated from the serum; for the serum does not possess the property, when in contact with oxygen, of giving off carbonic acid. On the contrary, when separated from the globules, it absorbs from half its volume to an equal volume of carbonic acid, and at ordinary temperatures is not saturated with that gas. Arterial blood, when drawn from the body, is soon altered; its florid colour becomes dark red. The florid blood, which owes its colour to the globules, becomes dark by the action of carbonic acid, and this change of colour affects the globules, for florid blood absorbs a number of gases which do not dissolve in the fluid part of the blood when separated from the globules. *It is evident therefore that the globules have the power of combining with gases.* The globules of the blood change their colour in different gases; and this change may be owing either to a combination or to a decomposition. Sulphuretted hydrogen turns them blackish green and finally black; and the original red colour cannot, in this case, be restored by contact with oxygen. Here a decomposition has obviously taken place. The globules darkened by carbonic acid become again florid in oxygen, with disengagement of carbonic acid. The same thing takes place in nitrous oxide. It is clear that they have here undergone no decomposition, and consequently they possess the power of combining with gases, *while the compound they form with carbonic acid is destroyed by oxygen.* When left to themselves out of the body, the compound formed with oxygen again becomes dark, but does not recover its florid colour a second time by the action of oxygen. The globules of the blood contain a compound of iron. From the never-failing presence of iron in red blood, we must conclude, that it is unquestionably necessary to animal life; and since physiology has proved that the globules take no share in the process of nutrition, it cannot be doubted that they play a part in the process of respiration. The compound of iron in the globules has the characters of an oxidized compound; for it is decomposed by sulphuretted hydrogen, exactly in the same way as the oxides or other analogous compounds of iron. By means of diluted mineral acids, peroxide (sesqui-oxide) of iron may be extracted, at the ordinary temperature, from the fresh or dried red colouring matter of the blood. The characters of the compounds of iron may perhaps assist us to explain the share which that metal takes in the respiratory process. No other metal can be compared with iron for the remarkable properties of its compounds. The compounds of protoxide of iron possess the property of depriving other oxidized compounds of oxygen; while the compounds of peroxide of iron, under other circumstances, give us oxygen with the uttermost facility. Hydrated peroxide of iron, in contact with organic matters destitute of sulphur, is converted into carbonate of the protoxide. Carbonate of protoxide of iron, in contact with water and oxygen, is decomposed; all the carbonic acid is given off, and by absorption of oxygen it passes into the hydrated peroxide, which may again be converted into a compound of the protoxide. Not only the oxides of iron, but also the cyanides of that metal, exhibit similar properties. Prussian blue contains iron in combination with all the organic elements of the body; hydrogen and oxygen (water), carbon and nitrogen (cyanogen). When it is exposed to light, cyanogen is given off, and it becomes white; in the dark it attracts oxygen, and recovers its blue colour. All these observations, taken together, lead to the opinion that the globules of arterial blood contain a compound of iron saturated with oxygen, which in the living blood loses its oxygen during its passage through the capillaries. The same thing occurs when it is separated from the body and begins to undergo decomposition. The compound, rich in oxygen, passes therefore, by the loss of oxygen, into one far less charged with that element. One of the products of oxidation formed in this process is carbonic acid. The compound of iron in the venous blood possesses the property of combining with carbonic acid; and it is obvious that the globules of the arterial blood, after losing a part of their oxygen, will, if they meet with carbonic acid, combine with that substance. When they reach the lungs, they will again take up the oxygen they have lost; for every volume of oxygen absorbed, a corresponding volume of carbonic acid will be separated; they will return to their former state, that is, they will again acquire the power of giving off oxygen. For every volume of oxygen which the globules can give off, there will be formed (as carbonic acid contains its own volume of oxygen without condensation) neither more nor less than an equal volume of carbonic acid. For every volume of oxygen which the globules are capable of absorbing, no more carbonic acid can possibly be separated than that volume of oxygen can produce. When carbonate of protoxide of iron by the absorption of oxygen passes into the hydrated peroxide, there are given off, for every volume of oxygen necessary to the change from protoxide to peroxide of iron, four volumes of carbonic acid gas. But from the one volume of oxygen only one volume of carbonic acid gas can be *produced*. And the absorption of one volume of oxygen can only cause directly the *separation* of an equal volume of carbonic acid; consequently the substance or compound which has lost its oxygen during the passage of arterial into venous blood, must have been capable of absorbing or combining with carbonic acid; and we find, in point of fact, that the living blood is never, in any state, saturated with carbonic acid; that it is capable of taking up an additional quantity without any apparent disturbance of the functions of the globules. Thus, for instance, after drinking effervescing wines, beer, or mineral waters, more carbonic acid must necessarily be expired than at other times. In all cases where the oxygen of the arterial globules has been partly expended otherwise than in the formation of carbonic acid, the amount of this latter gas expired will correspond exactly with that which has been formed; less however will be given out after the use of fat and of still-wines than after champagne. According to the views now developed, the globules of arterial blood in their passage through the capillaries yield oxygen to certain constituents of the body. A small portion of this oxygen serves to produce the change of matter, and determines the separation of living parts, and their conversion into lifeless compounds, as well as the formation of the secretions and excretions. The greater part, however, of the oxygen is employed in converting into oxidized compounds the newly-formed substances which no longer form part of the living tissues. In their return towards the heart, the globules which have lost their oxygen combine with carbonic acid, producing venous blood; and when they reach the lungs, an exchange takes place between this carbonic acid and the oxygen of the atmosphere. The organic compound of iron, which exists in venous blood, recovers in the lungs the oxygen it has lost, and in consequence of this absorption of oxygen the carbonic acid in combination with it is separated.'

Mulder is strongly opposed to this theory; he denies that the iron takes any essential part in the respiratory process; and he refers the process entirely to the oxidation of the protein-compounds. He alleges the following grounds against the probability of the correctness of Liebig's views:—

1. The iron is so intimately connected with the other elements of hæmatin, that it cannot be removed even by long digestion of this constituent in dilute hydrochloric or sulphuric acid. If these re-agents cannot effect its oxidation, it is highly improbable that it should be oxidized in the lungs. Respecting Liebig's assertion that dilute acids remove iron from dried blood, Mulder proves that this fact is valueless in relation to his theory, because other constituents of the blood besides the hæmatin contain this metal, apparently in an oxidized state.

2. If, as Liebig asserts, peroxide of iron exists in arterial blood, and carbonate of protoxide of iron in venous blood, almost any dilute acid would be capable of removing it. But this is not the case. Hæmatin, properly prepared, may be digested with dilute hydrochloric or sulphuric acid for many days without the least diminution in the quantity of the iron. From hæmatin treated in this manner Mulder obtained by combustion 9·49 per cent. of peroxide of iron, which is the constant quantity always left after the combustion of well-prepared hæmatin.

3. The probability that the iron exists in a *metallic state* is strongly supported by the observation that hydrogen is evolved when a clot of blood is digested in sulphuric acid, and water is added. Mulder suggests that it occurs as an integral constituent of hæmatin in just the same manner that iodine occurs in sponge, sulphur in cystin, or arsenic in the cacodyl series.

4. The amount of hæmatin in the whole mass of the blood is far too inconsiderable to carry a due supply of oxygen to the whole system.

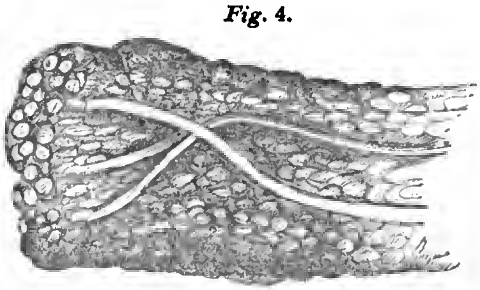
Having thus shown the principal objections to which Liebig's celebrated theory is open, we shall endeavour briefly to explain the rival theory of Mulder. We have at an early part of this article shown that the protein-compounds are capable of undergoing oxidation when in contact with the oxygen of the air. When a protein-compound becomes oxidized, it assumes a plastic character, that is to say, it has a tendency to become solid and to adhere to solid substances. Now we have already mentioned that the blood-corpuscles are cells, of which the wall consists of a protein-compound named *globulin*. When a respiration is performed, the exterior layer of such of the corpuscles as are exposed in the lungs to the action of the air, becomes converted into oxidized protein; it becomes whitish and less transparent. This is the state in which the corpuscles exist in arterial blood. As they reach the capillary system, this white exterior layer is employed in the change of material of the body, and is in that way consumed. Having lost this white layer, they again become transparent. The dark colouring substance in the corpuscles of arterial blood, shining through a white layer, must necessarily appear of a bright red tint, as may be shown by pouring dark red blood into a vessel of milky glass.

The preceding observations have been made with the view of showing the utility of these isolated animal cells—the blood-corpuscles—in the *respiratory process*. (We shall revert again to the distinctions between the characters of venous and arterial corpuscles in our remarks on the *colour of the blood*.)

In our remarks on various tissues we shall often again have to notice the functions of isolated cells. We shall now give another illustration of their utility, namely, their importance in the *process of nutrition*. Mr. Goodsir has recently shown that there is a continual development of cells at the extremity of each villus in the small intestine, and that these cells are the agents by which the *secretion* of the nutritious fluid is accomplished, and by which it undergoes its first preparation for the purposes it is subsequently to fulfil. The process is so singular and interesting, that we give Mr. Goodsir's observations in his own words, omitting those portions which do not bear specially on the point.

'As the chyle begins to pass along the small intestine, at increased quantity of blood circulates in the capillaries of the gut. In consequence of this increased flow of blood, or from some other cause with which I am not yet acquainted, the internal surface of the gut throws off its epithelium, which is intermixed with the chyme in the cavity of the gut. The cast-off epithelium is of two kinds,—that which covers the villi, and which, from the duty it performs, may be named protective epithelium; and that which lines the follicles, and is endowed with secreting functions. The same action then, which in removing the protective epithelia from the villi prepares the latter for their peculiar function of absorption, throws out the secreting epithelia from the follicles, and thus conduces towards the performance of the function of these follicles. The villi, being now turgid with blood, erected, and naked, are covered or coated by the whitish-grey matter already described. This matter consists of chyme, of cast-off epithelia of the villi, and of the secreting epithelia of the follicles. The function of the villi now commences. The minute vesicles which are interspersed among the terminal loops of the lacteals of the villus, increase in size by drawing materials from the blood through the coats of the capillary vessels, which ramify at this spot in great abundance. While this increase in their capacity is in progress, the growing vesicles are continually exerting their absorbing function, and draw into their cavities that portion of the chyme in the gut necessary to supply materials for the chyle. When the vesicles respectively attain in succession their specific size, they burst or dissolve, their contents being cast intn the texture of the villus, as in the case of any other species of interstitial cell. The debris, and the contents of the dissolved chyle cells, as well as the other matters which have already subserved the nutrition of the villus, pass into the looped network of lacteals, which, like other lymphatics, are continually employed in this peculiar function. As long as the cavity of the gut contains chyme, the vesicles of the terminal extremity of the villi continue to develop, to absorb chyle, and to burst, and their remains and contents to be removed along the lacteals. When the gut contains no more chyme, the flow of blood to the mucous membrane diminishes, the development of new vesicles ceases, the lacteals empty themselves, and the villi become flaccid. The function of the villi now ceases till they are again roused into action by another flow of chyme along the gut. During the intervals of absorption, it becomes necessary to protect the villi from the matters contained in the bowel. They had thrown off their protective epithelium when required to perform their functions, just as the stomach had done to afford gastric juice, and the intestinal follicles to supply their peculiar secretions. In the intervals of digestion the epithelium is rapidly reproduced.'

Fig. 4.



Extremity of a villus with its absorbent vesicles distended with chyle, and the trunks of its lacteals seen through its coats. Very highly magnified.

The researches of Mr. Goodsir have likewise thrown much light on the general process of secretion. He shows, by an admirably selected series of observations (chiefly on the lower animals), that secretion is a function of the nucleated cell.

If the membrane which lines the secreting portion of the internal surface of the ink-bag of *Loligo sagittata* (Lamarck) be carefully freed from adhering secretion by washing, it will be found to consist almost entirely of nucleated cells, of a dark brown or black colour. These cells are spherical or ovoidal. Their nuclei consist of cells grouped together in a mass. Between these composite nuclei and the walls of their containing cells is a fluid of a dark brown colour. This fluid resembles in every respect the secretion of the ink-bag itself. It renders each cell prominent and turgid, and is the cause of its dark colour.

The dilated terminal extremities of the ducts in the liver of *Helix aspersa* (Müller) contain a mass of cells. If one of these cells be isolated and examined, it presents a nucleus consisting of one or more cells. Between the nucleus and the wall of the containing cell is a fluid of an amber tint, and floating in this fluid are a few oil-globules. This fluid differs in no respect from the bile as found in the ducts of the gland. The liver of *Modiola vulgaris* (Fleming) contains masses of spherical cells. Between the nucleus and the wall of each of these cells a light-brown fluid is situated, bearing a close resemblance to the bile in the gastro-hepatic pouches. The nucleated cells which are arranged around the gastro-hepatic pouches of *Pecten opercularis* are irregular in shape, and distended with a fluid resembling the bile. The hepatic organ which is situated in the loop of intestine of *Pirena prunum* (Fleming) consists of a mass of nucleated cells. These cells are collected in groups in the interior of larger cells or vesicles. These nucleated cells are filled with a light-brown bilious fluid. The hepatic organ situated in the midst of the reproductive apparatus, and in the loop of the intestine of *Phallusia vulgaris* (Forbes and Goodsir), consists of a number of vesicles, and each vesicle contains a dark-brown bilious fluid.

The hepatic cæca in the liver of *Patella vulgata* contains vesicles enclosing a body which consists of a number of nucleated cells, full of a dark fluid resembling the bile. The kidney of *Helix aspersa* (Müller) is principally composed of numerous transparent vesicles. In the centre of each vesicle is situated a cell full of a dead-white granular mass. This gland secretes pure uric acid. The ultimate elements of the human liver are nucleated cells. Between the nucleus and the cell-wall is a light-brown fluid with one or two oil-globules floating in it. The vesicular cæca in the testicle of *Squalus cornubicus* contain nucleated cells, which ultimately exhibit in their interior bundles of spermatozoa. The generative cæca of *Echiurus vulgaris* (Lamarck) contain cells full of minute spermatozoa. *Aplysia punctata* secretes from the edge and internal surface of its mantle a quantity of purple fluid. The secreting surface of the mantle consists of an arrangement of spherical nucleated cells. These cells are distended with a dark purple matter. The edge and internal surface of the mantle of the *Janthina fragilis* (Lamarck), the animal which supplied the Tyrian dye, secretes a deep bluish purple fluid. The secreting surface consists of a layer of nucleated cells, distended with a dark purple matter. If an ultimate acinus of the mammary gland of the bitch be examined during lactation, it is seen to contain a mass of nucleated cells. These cells are generally ovoidal, and rather transparent. Between the nucleus and the cell-wall of each a quantity of fluid is contained, and in this fluid float one, two, three, or more oil-like globules, exactly resembling those of the milk.

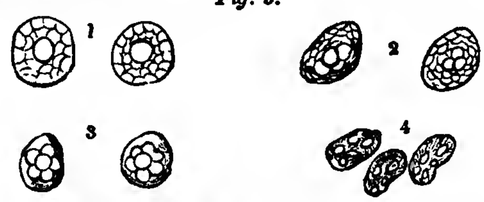
The secretion within a primitive cell is always situated between the nucleus and the cell-wall, and would appear to be a product of the nucleus.

The ultimate secreting structure then is the primitive cell, endowed with a peculiar organic agency, according to the secretion it is destined to produce. Mr. Goodsir names it the *primary secreting cell.* It consists, like other primitive cells, of three parts—the nucleus, the cell-wall, and the cavity. The nucleus is its generative organ, and may or may not, according to circumstances, become developed into young cells. The cavity is the receptacle in which the secretion is retained, till the quantity has reached its proper limits, and till the period has arrived for its discharge. Each primary secreting cell is endowed with its own peculiar property, according to the organ in which it is situated. In the liver it secretes bile; in the mamma, milk, &c. The primary secreting cells of some glands have merely to separate from the nutritive medium a greater or less number of matters already existing in it. Other primary secreting cells are endowed with the more exalted property of elaborating from the nutritive medium matters which do not exist in it. The discovery of the secreting agency of the primitive cell does not remove the principal mystery in which this function has always been involved. One cell secretes bile, another milk; yet the one cell does not differ more in structure from the other, than the lining membrane of the duct of one gland from the lining membrane of the duct of another. The general fact however, that the primitive cell is the ultimate secreting structure, is of great value in physiological science, inasmuch as it connects secretion with growth, as phenomena regulated by the same laws. The force, of whatever kind it may be, which enables one primary formative cell to produce nerve and another muscle, by an arrangement within itself of the common materials of nutrition, is identical with that force which enables one primary secreting cell to distend itself with bile and another with milk.

Instead of growth being a species of imbibing force, and secretion on the contrary a repulsive, the one centripetal, the other centrifugal, they are both centripetal. Even in their latter stages the two processes, growth and secretion, do not differ. The primary formative cell, after becoming distended with its peculiar nutritive matter, in some instances changes its form according to certain laws: and then, after a longer or shorter period, dissolves and disappears in the intercellular space in which it is situated; its materials passing into the circulating system if it be an internal cell, and being merely thrown off if it be an external cell. The primary secreting cell, again, after distension with its secretion, does not change its form so much as certain of the formative cells, but the subsequent stages are identical with those of the latter. It bursts or dissolves, and throws out its contents either into ducts or gland-cavities.

The general fact of every secretion being formed within cells, explains a difficulty which has hitherto puzzled physiologists, namely, why a secretion should only be poured out on the free surface of a gland-duct, or secreting membrane. We have attempted to illustrate Mr. Goodsir's views by the accompanying figure.

Fig. 5.

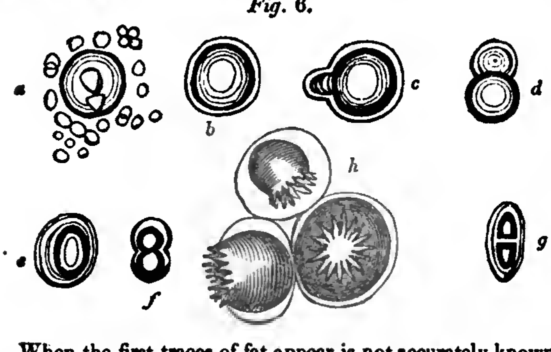


1. Cells from the kidney of *Helix aspersa;* the contained secretion is dead-white and presents a chalky appearance.
2 Cells from the ink-bag of *Loligo sagitta.*
3. Cells from the liver of the *Patella vulgata.* In this instance the bile is contained in the cavities of the secondary cells, which constitute the nucleus of the primary cell.
4. Cells from the mamma of a bitch. In addition to their nuclei these cells contain milk-globules.

Persistent tissues. We now proceed to the histological and chemical investigation of the most important constituents of the human organism.

1. *Adipose tissue* is usually associated with *areolar tissue* (which see), the two being generally known collectively as *cellular tissue.* It must be distinguished from *fat*, the former being a membrane of extreme tenuity in the form of closed cells or vesicles, while the latter is the material contained within them. The membrane of the adipose vesicle does not exceed the 20,000th of an inch in thickness, and is quite transparent; it is moistened by watery fluid, for which it has a greater attraction than for the fat it contains. Each vesicle is a perfect little organ, varying, when fully developed, from the 300th to the 800th of a line; minute capillaries may be observed on their external surface. When fat-vesicles are deposited together in large numbers, as is usually the case, they assume a more or less regular polyhedric form from their mutual pressure.

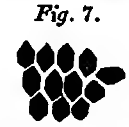
Fig. 6.



When the first traces of fat appear is not accurately known. In a well-formed five-months human fœtus Valentin found in the subcutaneous cellular tissue of the sole of the foot not merely fat-cells, such as occur in adults, varying from the ordinary size to the 125th or 100th of a line, within and around which were numerous small vesicles (*Fig.* 6, *a*), but other forms which threw more light on their structure and development. In some the surrounding cell-membrane was much more distinct than as it occurs in adults (*b*). In others there appeared to be a deposition of fat, not occupying the whole space of the cell (*c*); the remainder of the cell having often a striped or streaky appearance, and forming a lateral projection; this is seen in *c*, and in a more marked degree in *d* and *e*. In other fat-cells there were observed to be two vesicles, separated by a septum, against which they were partially flattened by pressure (*g*), or merely separated by a constriction in the external walls, as in *f*. This form leads us to conclude that fat-cells increase by division. For the chemistry of this constituent we must refer to the article Fat, P. C., and to an early part of the present article. It is sufficient here to remark that the fat-vesicle of the human subject contains *margarin*, a solid, and *olein*, a fluid fat. These sometimes separate spontaneously, presenting a very beautiful microscopic appearance. The margarin collects in a spot on the inner surface of the cell-membrane, and presents the appearance of a small star, whilst the olein occupies the remainder of the vesicle, unless when the quantity of fat in it is rather smaller than usual, in which case we may observe a little aqueous fluid between the olein and the cell-membrane. We have attempted to depict this separation in *h*.

2. *Pigment.*—In certain parts of the animal organism we meet with definite and well-marked colorations, not dependent on any peculiar arrangement of fibres, &c., but on the presence of *pigment-granules* of various colours. These granules are usually inclosed in cells, termed *pigment-cells.* In all races of men we find a most remarkable development of these cells on the inner surface of the choroid coat of the eye, where they form several layers known as the *Pigmentum nigrum.* They are probably always mingled with the epidermic cells, giving rise in the dark races to the deep colour of the skin; and presenting themselves in the white races in the form of freckles, the areola round the nipple, &c. The pigment-cells are usually flat and laterally compressed into the polygonal form. The granules in their interior are extremely minute, retain their dark colour under high magnifying powers, but exhibit various forms. In the choroid membrane of the human eye their form is very regular; in the adult no nucleus

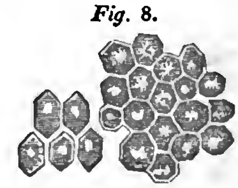
Fig. 7.



Cells from the choroid coat of an adult.

can be seen, a structure which is obvious in corresponding cells from the fœtus. The pigment-cells have not always a simple rounded or polygonal form; they sometimes

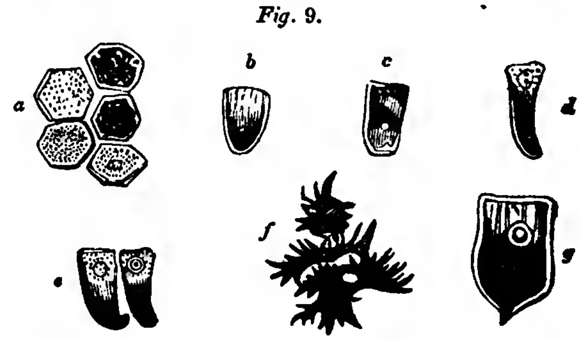
Fig. 8.



Similar cells from a fœtus at the third month.

present remarkable stellate prolongations and other singular shapes, which we have attempted to depict in *Fig.* 9, repre-

Fig. 9.



senting pigment-cells from a frog. *a*, *b*, *c*, *d*, *e*, and *g*, *Fig.* 9, are representations of various pigment-cells from its choroid coat, while *f* is intended to exhibit the stellar shape in which these cells occur on the skin of that animal. The nucleus is sufficiently obvious in one of the cells in *a*, in *c*, *d*, *e*, and *g*.

Little is known of the chemistry of the animal pigments. Scherer has made three analyses of the black pigment from the eye of the ox, from which he concludes that it consists of

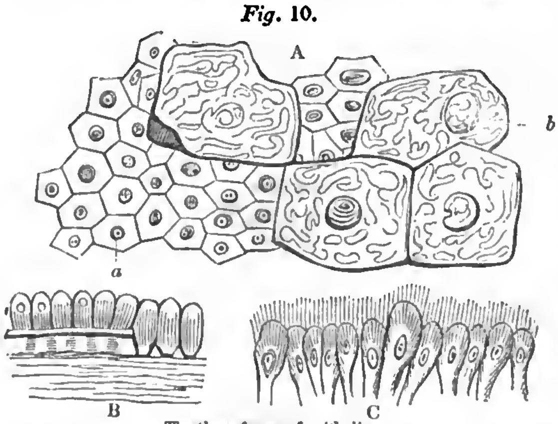
Carbon	58·284
Hydrogen	5·918
Nitrogen	13·768
Oxygen	22·030

From these analyses it appears probable that the black pigment contains a larger amount of carbon than any other constituent of the animal body.

3. *Horny tissues.*—Under this general name are included not only true horns, but feathers, hairs, cuticle, the various forms of epithelium, and the crystalline lens. We shall confine our observations to the microscopic characters of *epithelium* and *hair*, and then briefly advert to the general chemical characters of the class.

The *epithelium* may be regarded as a delicate cuticle covering the free *internal* surfaces of the body, just as the epidermis (to which it is closely allied) invests the external surface. Some of the uses of the epithelial cells have been already noticed in our remarks on isolated cells, in addition to their obvious use in protecting the surfaces on which they are placed. This structure was first investigated by Henle (in Müller's 'Archiv,' 1838), and has been since carefully examined by Bowman (art. 'Mucous Membranes,' in Todd's 'Cyclopædia of Anatomy and Physiology,' 1842), Goodsir, and others. From the forms presented by the epithelial particles they have received different names. Henle divided them into *pavement or tessellated epithelium*, *cylinder epithelium*, and *ciliated epithelium*, and although they frequently run in one another, yet on the whole these distinctive terms are serviceable.

Fig. 10.



The three forms of epithelium.

The *pavement epithelium* consists of broad flattened particles, or scales, having an angular outline and a nucleus; these scales form layers of extremely variable thickness. *Fig.* 10, A, shows very clearly how they are superimposed over one another, forming an effectual protection to the basement membrane beneath them. As a general rule the nucleus is large in proportion to the youth of the cell. In this figure we have attempted to exhibit these cells in two stages, a recent and a mature stage. In the young cells marked *a* the nucleus is relatively much larger than in *b*. This figure is intended to represent the epidermic scales of the frog; the larger cells, *b*, lying above the younger and smaller cells, *a*.

This form occurs on all synovial and serous membranes, and on most of the mucous membranes.

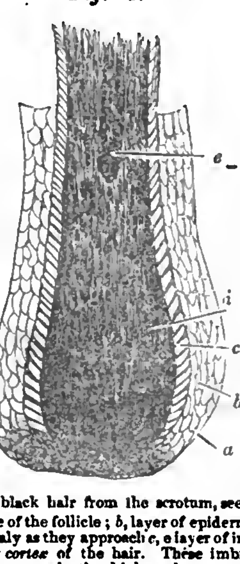
In the *cylindrical epithelium* the particles have the shape of small rods disposed endways on the basement membrane in a single layer. In consequence of their mutual compression they usually assume a prismatic rather than a cylindrical form, and hence Bowman applies the term *prismatic* to this form of epithelium. This form is perhaps best seem on the villi of the small intestine, or the conjunctival surface of the cornea of the eye. We have attempted to depict the latter in *Fig.* 10, B.

The *ciliated epithelium* is little more than cylinder epithelium on whose free surface numerous cilia or delicate filaments are observed in actual motion (*Fig.* 10, C). When in motion each filament appears to bend from its root to its point, returning again to its original state like corn moved by the wind. The motion of the cilia is not only quite independent of the will of the animal, but seems even to be independent of the life of the rest of the body; it has been seen after the death of the animal, and proceeding with perfect regularity, in parts separated from the body. Dr. Carpenter states that ciliary movement has been observed fifteen days after death in the body of a tortoise. The motion may be readily observed in the oyster or muscle. In the human subject this form of epithelium exists in the air-passages with their various offsets, as the nasal cavities, eustachian tube, lachrymal ducts, &c., and in the upper part of the vagina, the uterus, and the fallopian tubes. Its purpose is evidently to propel fluids over the surfaces on which it occurs.

Hair. The *shaft* of the hair is that portion which is fully formed and projects beyond the surface. On examination we find it lodged in a follicular involution of the basement membrane (*Fig.* 11, *a*), which usually passes through the cutis into the subcutaneous areolar tissue. This *hair-follicle* is bulbous at its deepest part, like the hair which it contains. Its sides have a cuticular lining, *b*, continuous with the epidermis, and resembling the cuticle in the rounded form of its deep cells and the scaly character of the more superficial ones, which are here in contact with the outside of the hair, *c*. The hair grows from the bottom of the follicle, and the cells of the deepest stratum, there resting on the basement-membrane, are very similar to those which in other parts are transformed into scales of cuticle. A gradual enlargement occurs in these cells as they mount in the soft bulb of the hair, which indeed owes its size to this circumstance. If the hair is to be coloured, the pigment-grains are also here developed, for the most part in scattered cells, which may send out radiating processes; at other times, in a diffused manner around the nuclei of the cells generally. It frequently happens that the cells in the axis of the bulb become loaded with pigment at one period, and not at another; so that, as they pass upwards in the shaft, a dark central tract is produced of greater or less length, often only in irregular patches, and the hair appears here and there to be tubular, *e*. The shaft is much narrower than the bulb, and is produced by the rather abrupt condensation and elongation into hard fibres of the cells, both of those which contain pigment and those which do not. The granules of pigment assume a linear arrangement between the fibres, which are firmly united into a solid rod by a material similar, it may be supposed, to that which cements the scales of the cuticle.

The human hair has a proper bark, or cortex, formed in the following way:—A single layer of the cells immediately surrounding those about to form the fibrous tissue of the shaft are seen near the bottom of the follicle to assume an imbricated arrangement (*Fig.* 11, *c*), and gradually to mount on the hair, becoming more compressed against it in their ascent, until they form upon its surface a thin transparent colourless film, in which the overlapping of the delicate cells is still exhibited by elegant and exceedingly fine sinuous

Fig. 11.

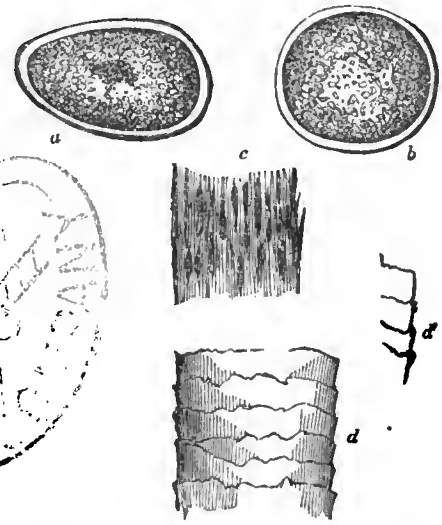


Bulb of a small black hair from the scrotum, seen in section.

a, basement-membrane of the follicle; *b*, layer of epidermic cells resting upon it and becoming more scaly as they approach *c*, a layer of imbricated cells forming the outer lamina or *cortex* of the hair. These imbricated cells are seen more flattened and compressed, the higher they are traced on the bulb. Within the cortex is the proper substance of the hair, consisting at the base, where it rests on the basement-membrane, of small angular cells, scarcely larger than their nuclei. At *d* these cells are more bulky and the bulb consequently thicker: there is also pigment developed in many of them more or less abundantly. Above *d* they assume a decidedly fibrous character and become condensed. *e*, a mass of cells in the axis of the hair, much loaded with pigment.

cross lines (*Fig.* 12, *d*, *d'*). The fibrous interior and this peculiar cortex together compose the shaft of the hair. By the continual emergence of fresh portions of the shaft from the follicle, fragments of the cuticular lining of the latter are apt to be drawn up upon the hair, aided probably in this by the imbrication of its surface, and are often found clinging around it for some way; but they are not to be regarded as any part of the hair itself. From the preceding description it will be evident that the fibrous part of the hair is a peculiar development of the cuticular cells resting on the bottom of the follicle, that the imbricated cortex is formed by a single series differently developed at the circumference of these, and that beyond this series comes the cuticular lining of the follicle, so that the hair is neither covered nor underlaid by cuticle, but it is in fact the modified cuticle of the bottom of the follicle.

Fig. 12.



a, Transverse section of a hair of the head, showing the exterior cortex, the fibrous tissue with its scattered pigment, and a central space filled with pigment. *b*, a similar section of a hair at a point where no aggregation of pigment in the axis exists. *c*, longitudinal section, without a central cavity, showing the imbrication of the cortex, and the arrangement of the pigment in the fibrous part. *d*, surface showing the sinuous transverse lines formed by the edges of the cortical scales. *d'*, a portion of the margin, showing their imbrication.

The figures and the description of the structure are copied from Todd and Bowman's 'Physiological Anatomy and Physiology of Man,' vol. ii. p. 418.

The chemistry of horny tissues has been specially investigated by Scherer and Van Laer. The following analyses of various tissues of this class have been analyzed by the former chemist (Liebig and Wöhler's 'Annalen,' vol. xl. p. 53) :—

	Buffalo horn.	Nails.	Cuticle from sole of the foot.	Hair of the beard.	Hair of the head.	Calculated C_{48}, H_{39}, N_7, O_{17}.
Carbon . .	51·162	51·089	51·036	51·522	50·622	51·718
Hydrogen . .	6·397	6 824	6·801	6·687	6·613	6·860
Nitrogen . .	17·284	16·901	17·225	17·936	17·936	17·469
Oxygen } Sulphur } . .	24·959	25·186	24·938	23·848	24·829	23·953

From the analyses of Van Laer it appears that the average amount of sulphur in human hair is 5 per cent. From a series of well-devised experiments he concludes that 'the hair consists essentially of –

'1. A connecting medium consisting of a tissue yielding gelatin, and represented by the formula $C_{13}\ H_{10}\ N_2\ O_5$;— and

'2. Of bisulphuret of protein, $C_{40}\ H_{31}\ N_5\ O_{12}\ S_2$

'The large amount of sulphur is the cause of its colour being affected by various metallic salts. As there is no constant difference to be observed in the results obtained by the analysis of hair of various tints, it is to be presumed that the colour is dependent on peculiar arrangements of the ultimate particles.' Hair further contains about 0·4 per cent. of peroxide of iron, which is supposed by Van Laer to be chemically combined with the protein.

4. *Fibrous and Areolar tissues.—Fibrous tissue* is now usually considered under two heads, namely as the *white* and the *yellow* tissue.

White fibrous tissue occurs in ligaments, tendons, and membranes requiring great strength. On carefully dissecting away the areolar tissue with which it is associated, it seems, when examined under the microscope, to consist of extremely delicate fibrillæ running parallel to one another, and taking an undulating course. There is however reason to believe it does not in reality consist of a bundle of fibrillæ, but that it is simply a mass with longitudinal parallel streaks, and which has a tendency to split up in a longitudinal direction (*Fig.* 14, *a*).

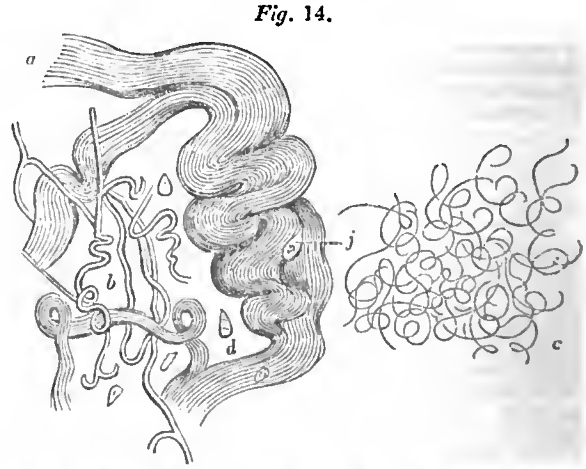
Yellow fibrous tissue differs in many essential points from the preceding form. It is remarkably elastic, is of a yellow colour, and is arranged in bundles or fibres, invested by a thin sheath of areolar tissue. In man we find it extended between the laminæ of the vertebræ, in several other ligaments, and in the transversalis fascia of the abdomen. It forms the *ligamentum nuchae* of animals. Examined under the microscope it is seen to consist of fibres varying in diameter from the 5000th to the 10,000th of an inch. They bifurcate or even divide into three, and freely anastomose with each other.

Fig. 13.

Yellow fibrous tissue showing the curly and branched disposition of its fibrillæ.

Areolar tissue is dispersed over almost every portion of the body, being the substance most commonly (but incorrectly) termed *cellular tissue*. The following are the microscope characters of this tissue, as described by Bowman and Todd :—When a fragment is examined, it presents an inextricable interlacement of tortuous and wavy threads, intersecting one another in every possible direction. They are of two kinds. The first are chiefly in the form of bands of very unequal thickness, and inelastic. Numerous streaks are visible in them, not usually parallel with the border, though taking a general longitudinal direction. These streaks, like the bands themselves, have a wavy appearance, but can be rendered straight by being stretched. The streaks seen have more the marks of longitudinal creasing than a true separation into threads ; for it is impossible to tear up the band into filaments of determinate size, although it manifests a decided tendency to tear lengthways. The larger of these bands are often as wide as the 500th of an inch ; the smaller can only be detected with high powers. These are the *white fibrous element*. The others are long, single, elastic, branched filaments, with a dark, decided border, and disposed to curl when not put on the stretch. They interlace with the others, but appear to have no continuity of substance with them. They are most commonly about the 8000th of an inch in diameter. These form the *yellow fibrous element*.

Fig. 14.

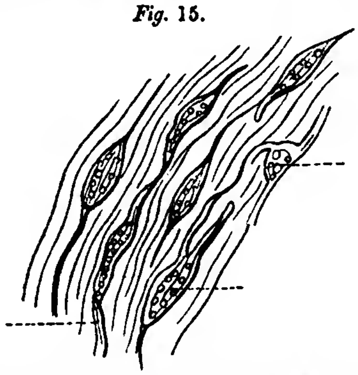


The two elements of Areolar Tissue in their natural relations to one another. *a*, the white fibrous element, with cell-nuclei, *j*, sparingly visible in it ; *b*, the yellow fibrous element, showing the branching or anastomosing character of its fibrillæ ; *c*, fibrillæ of the yellow element, far finer than the rest, but having a similar curly character ; *d*, nucleated cell-nuclei, often seen apparently loose.

These two tissues may be most easily discriminated by the addition of a drop of dilute acetic acid, which at once swells up the former and renders it transparent, whilst it produces no change in the latter. It thus brings into view corpuscles of an oval shape, which are probably the nuclei of the cells from which the bands have been originally produced. Oval corpuscles (*Fig.* 14, *d*), either altogether isolated or having very delicate prolongations with the adjacent threads, are sometimes noticed. They seem to be either advancing or receding stages of the tissue.

In *Fig.* 15, which represents the areolar tissue from beneath the skin of a five-months fœtus, we can perceive the cells elongating into fibres.

Fig. 15.



In a chemical point of view the leading difference between the white and yellow tissues is, that the former is acted on by acetic acid in the manner already described, and yields a considerable amount of gelatin in boiling; while the latter resists the action of acetic acid, and yields little or no gelatin.

5. *Nervous Tissue.*—In a microscopic point of view nervous tissue may be separated into two elements, the *vesicular* and the *fibrous*. The vesicular nervous matter is grey or cineritious in colour and granular in its texture, containing nucleated nerve-vesicles, and being largely supplied with blood. The fibrous nervous matter is, on the other hand, usually white, and composed of tubular fibres, although in some parts it is grey, and consists of solid fibres; it is also less vascular than the preceding. The former is more immediately associated with the mind, and is the originating seat of the force manifested in nervous actions; while the latter is simply the propagator of impressions made on it. The union of these two kinds of matter constitutes a *nervous centre*, and the threads of fibrous matter which pass to or from it are called nerves. The smaller nervous centres are termed *ganglia*; the larger ones are the *brain* and *spinal cord*.

Two species of primitive fibre have been observed by microscopists in the fibrous matter; they have been named the *tubular* fibre, or the *nerve-tube*, and the *gelatinous* fibre; the latter is comparatively rare, and is seldom found except in the sympathetic system.

The *tubular fibre* is a tube composed externally of a fine transparent homogeneous membrane, very much resembling the *sarcolemma* of muscle, which will be presently noticed. Nucleated cells may however be occasionally seen in it, as in *Fig.* 16, which represents a portion of the sciatic nerve of a frog. This may be termed the *tubular membrane* of nerve. The

Fig. 16.

contents of this tube consist of a soft, semi-fluid, whitish, pulpy substance, which is readily pressed out of its cut extremity. This is termed by Schwann the *white substance*, since the white colour of the nerve-tubes is dependent on it. Within this and occupying the centre of the tube is a transparent, somewhat flattened band, which is extremely delicate, and in which it seems impossible to recognise any more definite structure. Hence the tubular fibre consists of three distinct elements.

The tubes when quite fresh are perfectly cylindrical; but very slight pressure or almost any disturbing influence gives rise to swellings or enlargements in the course of the fibre, causing it to assume a varicose appearance. Two conditions seem to favour the production of this change; namely, a feeble power of resistance in the tubular membrane, and a semi-fluid state of the contained nervous pulp. In the nerves of the special senses the tubes are very delicate in structure, and are very apt to exhibit this change of form, and in the brain and spinal cord they present the same tendency. We mention this appearance because Ehrenberg formerly supposed that these varicosities were natural and existed during life, and that they furnished a valuable morphological character of the nerves of the spinal senses and the cerebro-spinal centres.

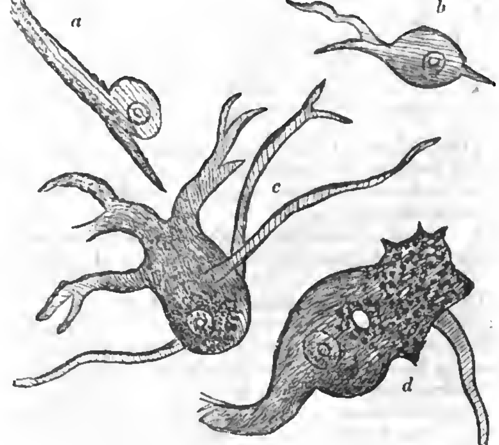
In point of size the nerve-tubes present considerable variety even in the same trunk; and in the different classes of animals the differences are well marked.

In man and other mammalia they vary from the 1625th to the 6500th of an inch; in birds, from the 2000th to the 3000th of an inch; in reptiles—in the frog—from the 1260th to the 2280th of an inch; in fish—in the eel—they are the 1043rd of an inch, and in the optic nerve of the cod-fish they are the 650th of an inch. These primitive tubules present no subdivision or branching. Whatever be the connexion which each primitive tubule forms with the nervous centre and with the textures to which it is distributed, it passes from one point to the other without any change, save perhaps in size, and without any communication with neighbouring tubules, beyond possibly investment by a common sheath.

The *gelatinous nerve-fibre* is a term applied by Henle to certain fibres occurring principally in the sympathetic nerve, and which may be regarded as its distinctive element. They are flattened, soft, and homogeneous in their appearance, bearing a considerable resemblance to unstriped muscular fibres; and like them, they contain numerous cell-nuclei, which are frequently arranged in a tolerably regular manner. These nuclei are brought in view by acetic acid, which dissolves the rest of the fibre, leaving them unchanged. These fibres contain nothing analogous to the white substance of Schwann, and hence are devoid of that whiteness which characterizes tubular fibre. It seems that the grey colour of certain nerves depends chiefly on the presence of a large proportion of the gelatinous fibres. Hence they are sometimes termed *grey fibres*. They are usually smaller than the tubular fibres, their diameter ranging between the 6000th and the 4000th of an inch. Both classes of fibres appear to run continuously from one extremity of the nervous cord to the other, without anything like union or anastomosis; each ultimate fibre probably having its distinct office which it cannot share with the other.

We now proceed to the consideration of the *vesicular nervous matter*, which in its normal form may be regarded as globular (*Fig.* 18, A, *a*, and B, *a*). This form is however liable to great variation, and from the compression to which these *nerve* or *ganglion-globules*, as they are termed, are exposed, they may become oval or polygonal, or they may extend

Fig. 17.



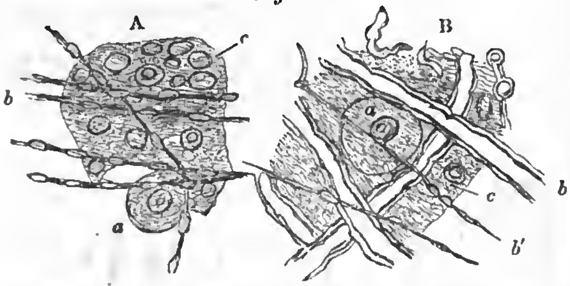
Ganglion-globules with their processes, nuclei and nucleoli.

a, From the deeper part of the grey matter of the convolutions of the cerebellum. The larger process is directed towards the surface of the organ. *b*, Another from the cerebellum; *c*, *d*, others from the posterior horn of grey matter of the dorsal region of the cord. These contain pigment which surrounds the nucleus in *c*. In all these specimens the processes are more or less broken. Magnified 200 diameters. From Todd and Bowman.

into one or more long processes, giving them a caudate or star-like aspect.

The wall of each vesicle consists of an exceedingly delicate membrane, containing a soft but tenacious finely granular mass. The *nucleus* is generally eccentric, much smaller than the containing vesicle and adherent to some part of its interior. Its structure is apparently the same as that of the outer vesicle. The *nucleolus* is a minute, remarkably clear, and brilliant body, also vesicular, enclosed within the nucleus. The processes to which we have alluded contain the same granular matter as the cells, with which they seem to be continuous. They are extremely delicate, and generally break off close to the nucleus; sometimes however they may be traced to a considerable distance, and will be found to divide into two or three branches, which undergo further subdivision. It is most probable that they either serve to connect distant vesicles or that they become continuous with the flattened bands occurring in the centre of the tubular element. In most situations where vesicular matter is found in the nervous centres, tubular fibres and sometimes both varieties of fibre are also present. We have attempted to depict this union in *Fig.* 18.

Fig. 18.



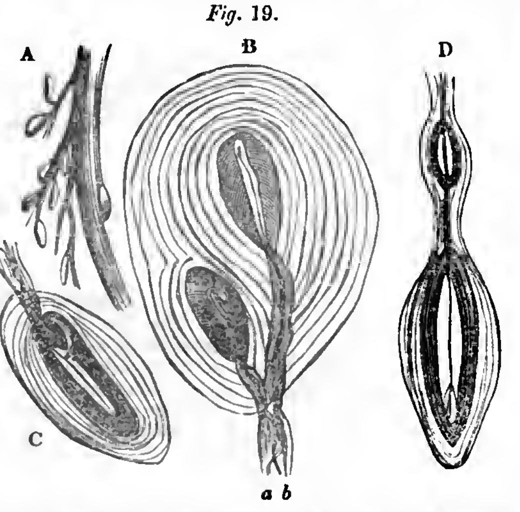
A, vesicular and fibrous matter of the laminæ of the cerebellum. *a*, ganglion-globule; *b*, very minute nerve-tubes traversing a finely granular matrix, in which are numerous rounded nuclei, *c*.

B, blending of the vesicular and fibrous nervous matter in the dentate body of the cerebellum; *a*, ganglion-globule with its nucleus and nucleolus; *b*, nerve-tube, slightly varicose, in close contact with the ganglion-globule; *b'*, a smaller nerve-tube. These parts all lie in a finely granular matrix interspersed with nuclei, *c*. From Todd and Bowman.

Chemistry of Nervous tissue. In the 'Annales de Chimie,' for 1841, there is a memoir by Fremy on this subject. From the fatty matter of the brain, which usually amounts to 5 or 6 per cent., he isolated several secondary compounds; namely, 1, Cerebric acid; a white substance in the form of crystalline grains, abounding in carbon, and containing a minute proportion of phosphorus. 2, Cholesterin; 3, Oleo-phosphoric acid, a peculiar fatty acid containing about 2 per cent. of phosphorus in the form of phosphoric acid; and 4, Traces of olein, margarin, and fatty acids. The following table has been drawn up by L'Heretier from his own researches. The numbers in each instance represent the mean of six analyses:—

	Infants.	Youths.	Adults.	Aged Persons.	Idiots.
Water . . .	82·79	74·26	72·51	78·85	70·93
Albumen . .	7·00	10·20	9·40	8·65	8·40
Fat . . .	3·45	5·30	6·10	4·32	5·00
Osmazome and salts	5·96	8·59	10·19	12·18	14·92
Phosphorus . .	0·80	1·65	1·80	1·00	0·85

Fig. 19.



A, nerve from the finger, natural size, showing the Pacinian corpuscles; B, unusual form from the mesentery of the cat, showing two included in a common envelope; *a*, *b*, are the two nerve-tubes belonging to them; C, another from the same, showing an offset from the central cavity, containing a branch of the nerve; D, rare form from the mesentery of the cat, showing two corpuscles placed in succession on a single stalk, and furnished with the same nerve-tube, which resumes its white substance in the interval between them. From Todd and Bowman.

The varying amount of phosphorus has been supposed to stand in some connexion with the mental powers; this view must however at present be deemed merely hypothetical. The nerves according to L'Heretier contain more albumen, less solid and more soft fat, than the brain.

Pacinian Corpuscles. These bodies, so called from Pacini their discoverer, are found in the human subject in great numbers in connexion with the nerves of the hand and foot, but they also exist sparingly on other spinal nerves and on the plexuses of the sympathetic, though never on the nerves of motion. In the mesentery of the cat they may be almost always detected by the naked eye, being pellucid oval grains rather smaller than hemp-seeds.

A gives a correct idea of their relation to the nerves in the palm and sole. In the human subject they vary from the 10th to the 20th of an inch. The structure of these bodies is highly singular. They consist, first, of a series of membraneous capsules, from thirty to sixty or more in number, enclosed one within the other; and, secondly, of a single nervous tubular fibre enclosed in the stalk, and advancing to the central capsule, which it traverses from end to end.

Fig. 20.

Pacinian corpuscle from the mesentery of a cat; intended to show the general construction of these bodies. The stalk and body, the outer and inner system of capsules, with the central cavity, are seen.

a, Arterial twig, ending in capillaries, which form loops in some of the intercapsular spaces, and one penetrates to the central capsule. *b*, The fibrous tissue of the stalk, prolonged from the neurilemma. *n*, Nerve tube advancing to the central capsule, there losing its white substance, and stretching along the axis to the opposite end, where it is fixed by a tubercular enlargement. Todd and Bowman.

In the above figure, which exhibits the general structure, the ten or fifteen innermost capsules may be observed to be in contact with one another, while the rest are separated by a clear space containing fluid.

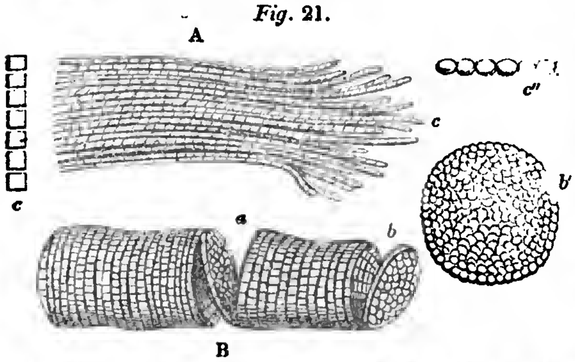
Respecting the *function* or *use* of these corpuscles no satisfactory account has yet been given. Pacini is himself inclined to believe that they may be concerned in the phenomena of what is called animal magnetism.

6. *Muscular tissue.* There are two forms of muscular fibre, differing extremely in their microscopic characters. The fibres of the voluntary muscles, as well as the fibres of the heart and some of those in the œsophagus, are *striped* or *striated*; while all other muscles, including those of the alimentary canal, the uterus, and bladder, all of which are involuntary, are *unstriped* or *non-striated*. [MUSCLE. P. C.]

. The elementary fibres of the voluntary muscles are arranged in sets parallel to one another, whilst those of the involuntary muscles usually cross at various angles, and interlace, forming membranous organs, enclosing a cavity which their contraction serves to constrict.

The *striated fibres* are usually of about the same length as the muscle to which they belong. In the sartorius they often exceed two feet in length, while in the stapedius (in the middle ear) they are not two lines. They vary in diameter from the 60th to the 1500th of each inch, being largest in crustacea, fish, and reptiles, where their irritability is most enduring, and smallest in birds, where it is most evanescent. In man their average diameter is the 400th of an inch. The fibre always presents upon and within it longitudinal dark lines, along which it subsequently splits up into fibrillæ; but it is by a fracture alone that these fibrillæ are obtained; they do not exist as such in the fibre. Sometimes, on the application of violence, cleavage takes place in a different manner, in a plane at right angles to the long axis of the fibre. In this case discs, and not fibrillæ, are obtained; and the cleavage is just as natural as the former, though less frequent.

Fig. 21.

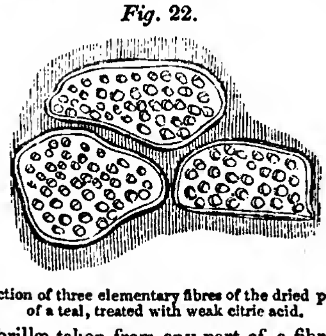


Fragments of elementary fibres, showing a cleavage in opposite directions.
A, Longitudinal cleavage. The longitudinal and transverse lines are both seen. *c*, Fibrillæ separated from one another by violence at the broken end of the fibre, and marked by transverse lines equal in width to those on the fibre. *c'*, *c''*, represent two appearances commonly presented by the separate single fibrillæ (more highly magnified) At *c'* the borders and transverse lines are all perfectly rectilinear, and the included spaces perfectly rectangular. At *c''* the borders are scalloped and the spaces bead-like. When most distinct and definite the fibrilla presents the former of these appearances. B, Transverse cleavage. The longitudinal lines are scarcely visible. *a*, incomplete fracture following the opposite surfaces of a disc, which stretches across the interval and retains the two fragments in connexion. The edge and surface of this disc are seen to be minutely granular, the granules corresponding in size to the thickness of the disc, and to the distance between the faint longitudinal lines. *b*, Another disc, nearly detached. *b'*, Detached disc more highly magnified, showing the sarcous elements. Bowman in Todd's Cyclopædia.

Hence tho fibre must be regarded neither as a bundle of fibrillæ nor a pile of discs, but as 'a mass in whose structure there is an intimation of the existence of both, and a tendency to cleave in the two directions.' The same particles compose the disc and the fibrilla, and they have received the names of the *primitive* or *sarcous* elements. Tho cross stripes of the fibre are formed, according to the views of almost all the best observers of the day, by the apposition, side by side, of the dark points seen on the separated fibrillæ. That they are not caused by a structure distinct from the fibrillæ, and present only on the surface of the fibre, is evident, according to Todd and Bowman, from the following facts:

1. That a transverse section of a fibre shows it to be solid and not hollow, and that the ends of tho fibrillæ, as seen on its section, exist throughout its interior, just as on its surface.

Fig. 22.



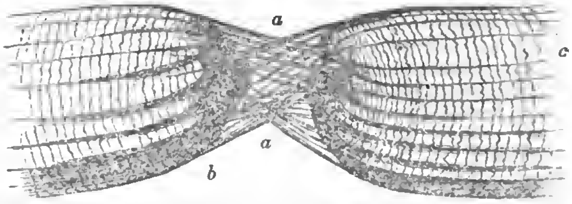
Transverse section of three elementary fibres of the dried pectoral muscle of a teal, treated with weak citric acid.

2. That fibrillæ taken from any part of a fibre are marked with light and dark points, corresponding in distance and force with the transverse stripes of the fibre

3. That with a high magnifying power applied to a thick fibre we may bring all parts of its interior into focus in succession, and perceive throughout the same kinds of stripes.

The *Sarcolemma*, or tubular sheath enclosing the striated fibre, consists of a transparent, very delicate, but tough and elastic membrane, which isolates the fibre from all other tissues. It most commonly has no appearance of structure, but occasionally small corpuscles, the remains of cell-nuclei, are observed in it.

Fig. 23.

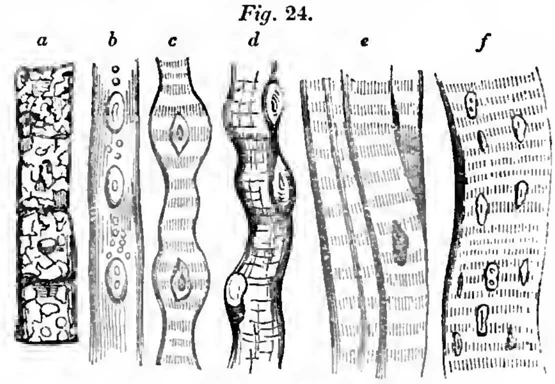


Fragments of the elementary fibre of a skate held together by untorn but twisted sarcolemma.

If the fibre be immersed in acid, it swells, bursts the sheath, and forms small protrusions or herniæ.

The researches of Valentin and Schwann have thrown much light on the development of muscular tissue in the embryo. In its earliest stage, muscle consists of a mass of nucleated cells which first arrange themselves in a linear series, and then unite to form the elementary fibres.

Fig. 24.



Stages of development of striated muscle fibre.
a, Arrangement of the primitive cells in a linear series.
b, The cells united, the nuclei separated, and some broken up; longitudinal lines becoming apparent. From a fœtal calf, three inches long.
c, *d*, Transverse stripes apparent. In *c* the nuclei are internal and bulge the fibre; in *d* they are prominent on the surface. From a fœtal calf, two months old.
e, Transverse stripes fully formed and dark; nuclei disappearing from view. From the human infant at birth.
f, Elementary fibre from the adult, treated with acid, showing the nuclei *a* From Schwann. The rest from Bowman.

As the cells unite, a deposit of contractile material gradually takes place within them. The deposition assumes a granular form, the granular or sarcous elements being of the same size as in the perfect muscle; for this reason the transverse stripes resulting from their apposition are of the same width as in the adult. Muscles grow by an increase, not of the number, but of the bulk of their elementary fibres.

The *unstriped or non-striated* fibres consist of flattened bands, generally of a pale colour, bulged at intervals by oval or elongated corpuscles. Their texture seems to be homogeneous. By transmitted light they have usually a soft and very finely mottled aspect; their ordinary diameter varies from the 3000th to the 2000th of an inch.

Chemical characters of Muscle.—In consequence of the difficulty that exists in separating muscular fibre from areolar tissue, vessels, and nerves, it is impossible to speak with certainty regarding its behaviour towards re-agents. Playfair and Boeckmann have analyzed the dried muscular flesh of the ox, and found it to be identical in its composition with dried blood. For analyses of the flesh of man and of various animals we refer to Simon's Chemistry, vol. ii. p. 422-425.

7. *Cartilaginous Tissue.*—The simplest form of cartilage consists merely of nucleated cells, and closely resembles the cellular tissue of plants. This kind is found in the rudimentary spinal column of the early embryo; it also exists in the chorda dorsalis of the cartilaginous fishes. In other kinds of cartilage the cells are embedded in an *intercellular* substance, presenting certain varieties of appearance.

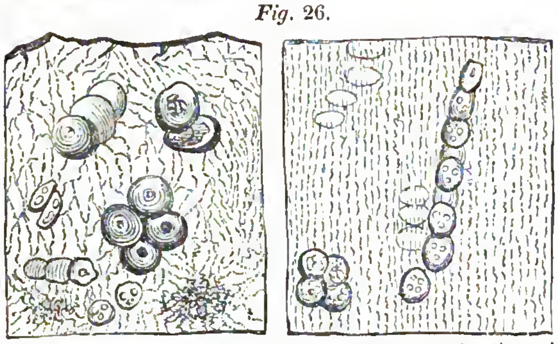
Fig. 26.

A



B

Articular cartilage from the head of the humerus. Vertical sections: A, section close to the surface; B, section far in the interior.

In articular cartilage the cells are oval or roundish, dispersed in groups through a nearly homogeneous intercellular substance. The cells measure from the 1300th to the 900th of an inch. In the interior part of the incrusting cartilages the cells usually assume a more or less linear arrangement. In the different cartilages the cells vary in size and form. For the chemistry of cartilage, see Simon, vol. ii. p. 415.

8. *Osseous Tissue* has, during the last few years, been examined closely, with much success. These examinations have increased our knowledge of the nature of bone, as regards both its minute structure and its development. We must here confine ourselves to the former point.

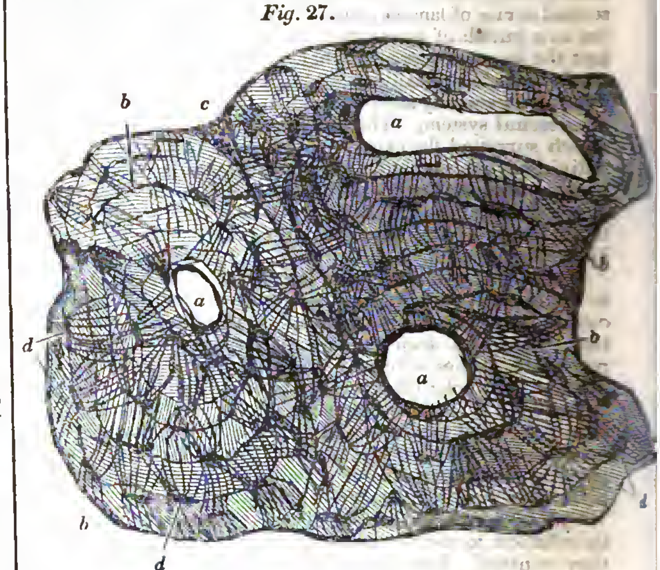
The canals which are everywhere found traversing variously the substance of bone, and giving passage to the blood-vessels for the nourishment of the tissue, are called *Haversian Canals*, a name given them in consequence of Clopton Havers having been the first who gave a full account of them. The parietes of these canals have a laminated arrangement. The laminæ themselves are numerous and placed concentrically; the internal lamina, that which is in immediate contact with the vessel or vessels, being the most distinctly marked, and each succeeding one having a less distinct outline.

Besides the concentric laminæ, there are others which surround the exterior of the bone, and may be known as the superficial laminæ. In connexion with both the concentric and superficial laminæ are a third set, which cannot belong to either of the other orders, but which are placed between them, and form the bond of union between each system.

Much has been lately written on the *bone-corpuscles*. These are small cells, of oval form, placed between the laminæ, and having numerous distinct tubes running from them in almost every direction. They have been sometimes compared to a spider with many legs. The corpuscles, or, as they are occasionally called, the calcigerous cells, have a definite relation to the Haversian canals and to each other.

The Haversian Canals, the osseous laminæ, and *the bone-corpuscles* are therefore the leading points to be mentioned in treating of the structure of the bone. Upon a closer view, however, it will be seen that it is only the laminæ which are bone; the canals and corpuscles are spaces existing in bone, and are not really necessary to the existence of osseous tissue, though they are requisite where the amount of substance is appreciable to the unaided senses.

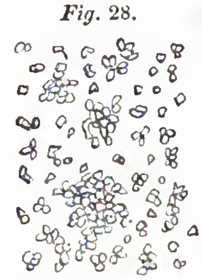
Fig. 27.



Transverse section of the dense portion of the femur.
a, Haversian canals; b, Concentric laminæ; c, Laminæ of connexion; d, Corpuscles with their system of tubes.
The parts marked a, b, and d, constitute an Haversian system.

Of the substance of Bone, or Hyalitic Substance.—The substance of bone has been considered, with but one or two exceptions, as homogeneous, and without appreciable structure. If it be examined however under advantageous circumstances, with high magnifying powers, there will be no difficulty in detecting a very definite though delicate structure. A very small portion of a thin plate of bone should be taken for the purpose of examination; such may be found in the ethmoid bone of small animals, as of the rat. If the piece is properly chosen it will be found to contain no Haversian canals nor corpuscles, but will be extremely thin and transparent. A piece of this kind will present a delicate granular aspect with the surface nodulated. This granular appearance proceeds from the substance of the bone being composed of minute irregularly spherical granules. This structure may be traced without much difficulty in any specimen of bone, although it varies much in distinctness in different specimens. The object should be placed between two slips of glass with a little plain water for examination. A delicate spiculum from the point where ossification is going on illustrates the granular tissue exceedingly well. The granules may be obtained separated from each other, so that each individual may be examined independently of the others.

Fig. 28.



Ultimate osseous granules, obtained by depriving bone of its animal matter.

When seen in this manner they exhibit a tolerably regular character, being mostly spherical, though a few have an oval form. In a few specimens the oval form predominates.

Of the Laminæ.—The form assumed by the osseous tissue is that of laminæ, and these laminæ have a definite arrangement, so much so that three distinct systems are recognised, namely: laminæ of the Haversian canals; secondly, the laminæ which connect the Haversian systems; and, thirdly, the laminæ which form the surface of the bone, and enclose the two previous orders. The laminæ of the Haversian canals have a concentric arrangement, and when divided transversely present a series of more or less distinct and perfect rings.

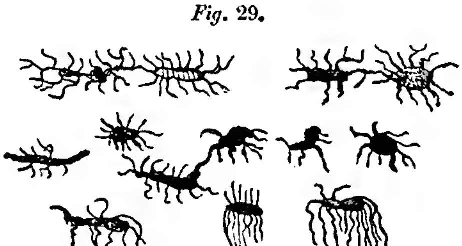
They vary very much in number, but the most common amount is ten or twelve. Of these, the internal lamina, that which forms the parietes of the Haversian canal, is most distinctly marked, while each succeeding one as we proceed outwards becomes less distinct. Connecting these Haversian systems is a second series of laminæ, without which the former would exist but as a bundle of loose tubes (*Fig.* 27, *c*). In this substance we find the laminated arrangement less distinct, far less regular, and the laminæ individually subject to great irregularity of thickness. They are generally more transparent than either the Haversian or external system. The last division consists of those laminæ which surround the exterior of the bone. These have greater individual extent, but are the least numerous. They are continuous with the laminæ of the Haversian system whenever the latter arrive at the surface of the bone; the external laminæ in this case being continuous with the inner laminæ of the Haversian system.

The effect of madder upon the osseous system, when given to an animal with its food, may here be noticed, since the colour is imparted to the laminæ. By introducing madder into the stomach, a deep red tinge is very soon observed: in a pigeon the bones were rendered brilliantly red in twenty-four hours. A similar effect was produced on a young pig in three weeks. On making sections of bone so affected, the colour is found to be present in the external laminæ of the bone, and in the inner laminæ of the Haversian system, thereby proving that the action of colouring takes place upon those surfaces which lie in contact with vessels.

Of the Haversian canals.—These canals must be considered in relation to their number, their size, and the parts which they contain. The number of canals in a given space vary perhaps a little, but this variation will be regulated in some degree by the situation of the bone, but more especially by its age. Thus the transverse section of the femur of a human fœtus of seven months will present many more canals than a section of equal measurement from the femur of an adult. The size of the Haversian canals takes a considerable range, varying from the 300th to the 500th of an inch. The Haversian canals undoubtedly give passage to blood-vessels, this being their principal if not only purpose.

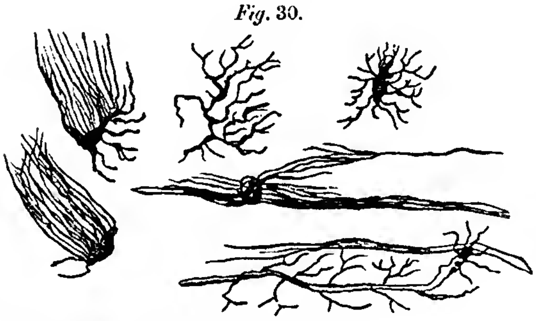
The corpuscles or cells of bone cannot be described as having any definite unvarying shape or size. The general form is a compressed oval, though not unfrequently they are circular. Again, they are sometimes almost triangular in their outline, while in other instances they approach n linear shape. These are the most common varieties of outline to which the bone-cells are subject, as they occur in the bones of man and the higher animals. In the four great classes of animals,

Fig. 29.



The forms assumed by the bone-cells in man.

Fig. 30.



Various forms of bone-cells found in the bone of the boa-constrictor.

namely mammalia, birds, reptiles, and fishes, it has been shown by Mr. Quekett that there are certain characters connected with these cells by which a bone of one class may be distinguished from that of another. He has shown that they are smallest in birds, a little larger in mammals, and largest of all in the reptiles; while in fishes they are altogether unlike those in the preceding classes. The importance of this observation in relation to fossil osteology is obvious. Connected with the cells are numerous delicate branching tubes, which are slightly dilated as they enter the cells. The number arising from each cell does not allow of any very definite enumeration, since no two cells will be found possessed of a like number of branching tubes. The general arrangement of the tubes is radiate, as regards the cells which form their common centre. The connexions are so numerous between the tubes and between the cells through the tubes, that a fluid introduced into one cell in a bone, may enter every other cell in that bone. The cells are situated between the laminæ, or on their surface; but where concentric laminæ occur, as in the Haversian system, the cells are placed in circular lines between the laminæ, each line of cells having the Haversian canal as an exit common to it and the connecting laminæ. When the canals for vessels are in great abundance, the bone-cells are more rarely met with; indeed in some cases they are almost entirely absent. When the cells are seen by transmitted light, particularly in a transverse section of bone, they are frequently opaque. There is no doubt that the bone-cells perform the function of circulation.

The Chemistry of Osseous Tissue has recently met with much attention from Valentin, Lehmann, Marchand, and more especially Von Bibra. From the bones of a man aged forty years, who committed suicide, Lehmann obtained—

	Humerus.	Femur.
Phosphate of lime and fluoride of calcium	56·61	58·93
Carbonate of lime	9·20	9·28
Phosphate of magnesia	1·08	1·09
Chloride of sodium	0·37	0·40
Soda	1·35	1·04
Organic matter	31·52	28·81

For a full account of the chemistry of bone we must refer to Simon's 'Chemistry,' vol. ii. pp. 396-414, or Von Bibra, 'Chemische Untersuchungen der Knocken,' &c., Schweinfurt, 1844.

9. *Tooth.*—The structures entering into the composition of the teeth are three: *dentine*, or *tooth-substance; enamel;* and *cement*, or more properly *tooth-bone*. The enamel invests the more prominent parts of the crown, from which points it gradually diminishes in thickness, till it terminates in a line on the neck of the tooth. The cement, or dental bone, is thickest at and near the end of the root, and gradually becomes thinner as it advances towards the crown of the tooth. In a tooth that has been used for some little time, the cement terminates where the enamel commences, but there is reason to believe that a thin layer is continued over the enamel. Of these tissues, dentine, as forming the great bulk of the tooth, and thereby becoming the most important, will first demand our attention. The pulp-cavity occupies the centre of the dentine, and on its surface are superimposed the enamel and the tooth-bone, the former investing the crown and the latter the surface of the fang. These two tissues form a layer of variable thickness in different parts of the teeth. This layer, however, is soon worn off when the tooth comes into use. If the enamel and cement be removed from a tooth, and the dentine alone allowed to remain, the tooth still retains much of its original shape, losing most at the two extremities, while in point of size the loss sustained is comparatively slight; thus showing the dentine to constitute by far the greater portion of the tooth.

The dentine is made up of two distinct parts: first, dentinal tubes; secondly, intertubular tissue. The tubes have distinct parietes, equal in thickness to their calibre. In some instances they appear to contain a minute granular matter, but in many, perhaps in the majority of cases, they are perfectly free from solid contents. If a vertical section, passing through the pulp-cavity, be taken for examination, the dental tubes may be traced from their commencement on the surface of the pulp-cavity, to their termination at the junction of the cement, and the dentine on the enamel of the latter, or they may be seen passing into these external structures. The tubuli commence at a right angle with the surface of the pulp-cavity, and proceed outwards towards the surface of the tooth, giving out in their way numerous small branches, which, meeting with other similar branches from neighbouring tubes, anastomose with them, or meeting with simple cells in the intertubular tissue, there terminate. Towards the surface of the dentine it is not uncommon to see a tube alter its course, and by joining another, form a loop. The tubes all commence in the pulp-

cavity, and pass outwards towards the surface of the dentine. Their course, as regards each other, is divergent, so that the proportion of the intertubular tissue increases relatively as their distance from the pulp-cavity is greater or less. This preponderance of the intertubular over the tubular tissue near the periphery of the tooth is, however, in a considerable degree lessened by the more frequent branching of the tubes, and by the occurrence of cells near the surface of the dentine. If a single tube be traced through its whole extent, it will be found to make two undulations; and in addition to these, which are called the primary curves, a number of smaller undulations. In examining this structure a thin section may be taken from the fang, and, with the aid of the microscope, viewed by transmitted light. A tube will then appear as a very definite dark line pursuing its tortuous but definite course towards the surface, giving out numerous minute branches on its way, and at last dividing into two terminal branches, which end either by passing into a cell of the intertubular tissue, or by anastomosis with a collateral tube, or by passing into the cement. If a section of the dentine and enamel be taken, then the tubes will be seen to give out comparatively few branches till they come near to the latter, when they divide and anastomose freely, and some few terminal branches may be traced entering the enamel. It is by no means uncommon for a tube in its course to suddenly dilate and give out branches from the dilatation, then again contract, and pursue its original course. In such a case the dilatation forms a cell in every way similar to the bone-cell. The point of the greatest diameter of the dental tubes is at their commencement on the walls of the pulp-cavity, though in their course previous to the division of the trunk into two terminal branches they suffer but little loss in calibre. In tracing this structure in the teeth of various animals, we find every form of branching; sometimes the branches are few, in others extremely numerous; in some instances they are given out from one side of the tube only, in others from each side; but whatever the modification in the number or form of the branching given out, the primary tube always commences by an open extremity on the walls of the pulp-cavity, or upon the walls of a canal for a blood-vessel; and the direction taken by the tubes is invariably towards the periphery of the tooth, always anastomosing in their way by the numerous branches. In the temporary, and not unfrequently in the permanent teeth, the tubes, instead of presenting an uninterrupted line, present on their surface numerous indentations, just as though they were composed of a series of hollow beads, which were united and made to communicate with each other.

The second part composing the dentine is the intertubular tissue, which occupies the spaces between the tubuli, everywhere surrounding and investing them, and thereby contributing greatly in rendering tho whole dentine a solid dense mass, the area of the tubes and cells being the only hollow portion. In a favourable specimen of this tissue Mr. Tomes observed that it was composed of very minute granules, united to each other on all sides, thus forming a solid mass, of which, in character of formation, oolite would give a coarse illustration. The granularity is best seen near the external surfaces of perfect dentine, or in tho tissue when developing. In the intertubular tissue, hemispherical or elliptical cells are found, especially near the surface of the dentine of the fang, where they form a layer joining the cement.

Structure of the Enamel.—The enamel is the hardest of the dental structures, being composed of dense semi-transparent fibres, placed side by side, and closely united. Their form is an approximation to a six-sided prism, and their size is tolerably uniform, being about the $\frac{1}{4000}$th of an inch in diameter. The direction taken by the enamel-fibres is for the most part vertical to the surface of the dentine upon which they rest; those therefore which proceed from the flat surface of the crown will rise vertically, while those from the lateral surface of the tooth will be horizontal. When the coronal surface of the dentine is concave, the enamel fibres of the opposite sides of tho concavity form with each other angles, and meet at their external ends. This juncture is frequently imperfect, and leaves a fissure, under which the dentine, being less protected from external influence than on tho other parts of the crown of the tooth, is more frequently attacked by disease. The fissures on the crown of the molars are often subject to this defect of development. The ends of the enamel fibres are received into shallow hexagonal depressions in the coronal surface of the dentine, from whence in their course they frequently describe curves. The direction taken by neighbouring fibres is not however at all times perfectly parallel; indeed, they often diverge or cross each other at considerable angles. The curves also seem less regular than those formed by the dentinal tubes.

The Bone or Cement.—Where the enamel ceases to encase the dentine, the cement commences in a layer, gradually increasing in thickness to its termination at the apex of the root, although a very thin (rudimentary) layer is continued over the crown, investing the enamel. The histological characters of this structure are so completely identical with those of ordinary bone that we need offer no additional remarks on them.

For the importance of the microscopic investigation of the teeth in tho classification of existing and the determination of extinct species of vertebrated animals, we must refer to Professor Owen's 'Odontography,' one of tho most splendid works ever published.

Chemistry of the dental Tissues.—Von Bibra has instituted numerous analyses of the teeth of man and the lower animals. We select the following by way of illustration:—

	Molar tooth of a woman aged 25 years.		Molar tooth of an adult male.	
	Enamel.	Osseous portion.	Enamel.	Osseous portion.
Phosphate of lime, with a little fluoride of calcium	81·63	67·54	89·82	66·72
Carbonate of lime . . .	8·88	7·97	4·37	3·36
Phosphate of magnesia .	2·55	2·49	1·34	1·08
Soluble salts	0·97	1·00	0·88	0·83
Cartilage	5·97	20·42	3·39	27·61
Fat	a trace	0·58	0·20	0·40

The osseous portion includes the dentine and cement.

We have thus taken a brief survey of the microscopical and chemical characters of the most important structures entering into the composition of the human body. In addition to, and perfectly distinct from these are numerous morbid products—the results of disease. In this class we must place pus, granular cells, the various forms of morbid tumours, cancer, tubercle, scrofulous deposits, &c. These however hardly fall within the scope of this article; and for information regarding them we must refer to Vogel's 'Pathological Anatomy of the Human Body,' an English translation of which has recently appeared by Dr. Day.

Section III.—*Nutrition and the Secretions.*

We shall here notice those points in the chemistry of the blood—*the general nutrient fluid*—which the labours of recent investigators have evolved since the publication of the article Blood, P. C., and adopt a similar course in relation to the various secretions yielded by it.

We shall, in the first place, however, offer a few remarks on *nutriment* in connexion with *nutrition*, with tho view of bringing the article Food, P. C., up to the present state of our knowledge on that subject. The classification of foods in that article is not at present adopted by chemists and physiologists.

There are very strong reasons for believing that foods containing nitrogen are alone capable of conversion into blood, and of forming organised tissues; hence Liebig has termed them the *plastic elements of nutrition*. The *non-nitrogenous foods* are, according to Liebig, incapable of transformation into blood, and are therefore incapable of forming organised tissues. They are, however, not without their use; their function being, according to Liebig, to support the process of respiration, by yielding carbon and oxygen, whose oxidation is attended with the development of heat. These latter foods he terms the *elements of respiration*.

Nitrogenous Foods, or Plastic Elements of Nutrition.	Non-nitrogenous Foods, or Elements of Respiration.	
Vegetable fibrin.	Fat.	Pectine.
Vegetable albumen.	Starch.	Bassorine.
Vegetable casein.	Gum.	Wine.
Animal flesh.	Cane-Sugar.	Beer.
Animal blood.	Grape-Sugar.	Spirits.
	Sugar of Milk.	

Liebig believes that a second use (an abnormal rather than a natural one) of the second group is, in relation to the formation of fat (p. 636). Moreover, the statement contained in the article FOOD, that 'gelatin is a highly nutritious principle,' requires some notice. Liebig has established it as a law that 'no nitrogenized compound, the composition of which differs from that of fibrin, albumen, or casein, is capable of supporting tho vital processes in animals.' 'The animal organism,' he observes, 'unquestionably possesses the power of forming from the constituents of its blood, the substance of its membranes, as of cellular tissue, of the nerves and brain, of the organic part of cartilage and bones. But the blood must be supplied to it ready formed in everything but its form—that is, in its chemical composition. If this be not done, a period is rapidly put to the formation of blood, and consequently to life.' For this reason gelatin, which, as we have already shown (p. 639), is not a protein-compound, cannot form blood, and therefore will not support the vital processes. The two following facts seem however to show that it has a use in the economy:—1. When in the body of a starving or sick person the fat disappears, and the muscular tissue again takes the form of blood, we find that the tendons and membranes retain their natural condition, and the limbs of the dead body retain their connexions, which depend on the gelatinous tissues.—2. On the other hand, the gelatin of bones devoured by a dog entirely disappears, whilst only the bone-earth is found in the excrements. The same is true of man when fed on food rich in gelatin; as, for example, strong soup. The gelatin is not to be found either in the urine or in the fæces, and consequently must have undergone a change, and have served some purpose in the animal economy: in other words, it must have been expelled from tho body in a form different from that in which it was introduced. From these facts Liebig inclines to the belief that gelatin is serviceable in the formation of cellular tissue, membrane, and cartilage; and that it may tend to the reproduction of such parts of those tissues as have been wasted, and for their growth. 'And when the powers of nutrition in the whole body are affected by a change of the health, then, even should the power of forming blood remain the same, the organic force by which the constituents of the blood are transformed into cellular tissue and membranes must necessarily be enfeebled by sickness. In the sick man the intensity of the vital force—its power to produce metamorphoses—must be diminished as well in the stomach as in all other parts of the body. In this condition, the uniform experience of practical physicians shows that gelatinous matters, in a dissolved state, exercise a most decided influence on the state of the health. Given in a form adapted for assimilation, they serve to husband the vital force, just as may be done in the case of the stomach, by due preparation of the food in general. Brittleness in the bones of the graminivorous animals is clearly owing to a weakness in those parts of the organism whose function it is to convert the constituents of the blood into cellular tissue and membrane; and if we can trust to the reports of physicians who have resided in the East, the Turkish women, in their diet of rice, and in the frequent use of enemata of strong soup, have united the conditions necessary for the formation both of cellular tissue and of fat.' Whether this be the mode in which gelatin acts or not, no one who has seen much medical practice will deny to it a place amongst useful nutritive substances.

We now proceed to make those additions to the chemical portion of the article BLOOD which the labours of the last ten years havo rendered necessary.

We have already (in our remarks on isolated cells) noticed the additions that have been recently made to our knowledge regarding the blood-corpuscles of various animals. Numerous observations have also been made on the changes in form which the corpuscles occasionally undergo in various diseases (Simon's 'Animal Chemistry,' translated, with additions, by Day, vol. i. p. 103, London, 1845; published by the Sydenham Society); also on the effects of various medicines and re-agents on the corpuscles ('An. Ch.,' pp. 107-112). Additional information on the acceleration or retardation of the coagulation may be found in Hamberger's Thesis on that subject, published at Berlin in 1839, and in Simon, 'An. Ch.'

With regard to the chemical composition of the blood, we may regard it as usually containing the following ingredients:—

1.	Water.
2. Protein-compounds	Fibrin. Albumen. Globulin. Binoxide and tritoxide of protein.
3. Colouring matters	Hæmatin. Hæmaphæin.
4. Fats	Cholesterin. Serolin. Red and white solid fats containing phosphorus. Margaric acid. Oleic acid.
5.	Iron. Albuminate of soda (?). Phosphates of lime, magnesia, and soda. Sulphate of potash.
6. Salts	Carbonates of lime, magnesia, and soda (?). Chlorides of sodium and potassium. Lactate of soda (?). Oleate and margarate of soda (?).
7. Gases	Oxygen. Nitrogen. Carbonic acid.
8.	Urea—a trace.
9.	Sugar—a trace (?).

It will be observed that there are notes of interrogation to several of the salts: the presence of these constituents is denied by Enderlin and Liebig's school generally. Their objection is founded on the circumstance, that if these salts were exposed to a red heat, they would become converted into carbonates; and that the ash obtained from the incineration of blood, if examined directly after the operation, does not contain those salts. As these experiments have been performed under Liebig's personal observation, and have been published in his journal, and as further they apply equally to almost all the other fluids of the animal body, we shall give the leading grounds on which the presence of alkaline carbonates in the ash is disproved, and its alkalinity is otherwiso accounted for:—

1. The ash does not effervesce on the addition of an acid.
2. Hot water poured over the ash becomes alkaline; it holds in solution alkaline phosphates and sulphates, chloride of sodium, and sometimes chloride of potassium, but no other salts.

a. On the addition of a neutral solution of nitrate of silver to this fluid, there is a yellow precipitate which is partly soluble in nitric acid; a portion however consisting of chloride of silver remains undissolved. The addition of nitric acid causes no effervescence. On neutralizing the acid filtrate with ammonia, a yellow precipitate of tribasic phosphate of silver ($3\,AgO,\,P_2O_5$) is thrown down.

b. On treating the aqueous solution of the ash with a solution of chloride of calcium, there is a copious gelatinous precipitate of phosphate of lime ($3\,CaO,\,P_2O_5$) which dissolves in nitric acid without effervescence. On treating this acid solution with nitrate of silver, and neutralizing with ammonia, the tribasic phosphate of silver is precipitated as before. The addition of the chloride of calcium neutralizes the previously alkaline fluid. From 1, we see that the alkaline reaction is not due to the presence of alkaline carbonates; and 2 shows it is not dependent on the presence of free potash or soda, for otherwise the fluid would not be neutralized by the chloride of calcium. Hence the albumen in the blood cannot exist as a soda compound (albuminate of soda); neither can there be alkaline lactates, acetates, nor fatty-acid salts in that fluid: and on the above grounds Enderlin conceives that we are justified in assuming that the alkaline reaction of the ash is dependent on the presence of tribasic phosphate of soda ($3\,NaO, P_2O_5$); and as this is the only salt that remains tribasic at a red heat, he concludes that the alkalinity of the blood, as well as of the ash, is dependent on it. The manner in which he accounts for the occurrence of carbonates in the analyses of other chemists is very plausible. On exposing $3\,NaO, P_2O_5$ to the atmosphere, it becomes converted into $2\,NaO, HO, P_2O_5$ and NaO, CO_2, or phosphate of soda in which one atom of the base is replaced by an atom of water, and carbonate of soda.

This question regarding the salts actually occurring in the blood is however far from settled, Ludwig having during the last few months positively denied Enderlin's statements. (See Day's 'Report on the Progress of Chemistry,' in Ranking's 'Half-yearly Abstract of the Medical Sciences,' vol. iii., 1846.)

Generally speaking it is only requisite in the analysis of the blood, to determine a few of the most important constituents; as, for instance, the water, fibrin, blood-corpuscles (globulin and hæmatin), and the solid residue of the serum (the organic portion and the salts). For this purpose we may adopt the following simple plan lately published by Figuier. It is based on the fact made known many years ago by Berzelius, that after the addition of a solution of a neutral salt to defibrinated blood, the globules do not (as before) pass through filtering paper. On the addition of two parts of a solution of sulphate of soda of specific gravity 1130 to one of blood, Figuier found that the whole of the corpuscles remained on the surface of the filter. The following are the steps of his analysis:—The fibrin is removed by stirring, dried, and weighed; the weight of the corpuscles is ascertained by the method indicated, and that of the albumen by coagulating by means of heat the filtered solution. The proportion of water is known by evaporating a small known weight of the blood. The filter containing the corpuscles should be dipped in boiling water, which removes any sulphate of soda that may be present, and at the same time renders the corpuscles insoluble. Separate and frequently difficult processes are requisite to detect those ingredients which occur in small quantity or only in morbid conditions.

Distinctions between Arterial and Venous Blood.—We have already (p. 642) noticed the circumstance that the external envelop of the blood-corpuscles becomes converted during the act of respiration into oxidized protein, and that the bright red colour of arterial blood is owing in part to the modifying influence of the white investing membrane. But there is yet another mode in which it acts. The buffy coat which is frequently observed on the upper part of the clot in inflammatory diseases is very apt to curl up and become concave. Now this buffy coat consists, for the most part, of the oxides of protein—of the very same matter with which the blood-corpuscles become invested. For this reason the form assumed by the two laminæ on both sides of the little flat body—the corpuscle—must resemble that of the buffy coat. The tendency to contract and become bi-concave is so strong, that the central portion of the crust becomes entirely depressed. In this form the corpuscles reflect a great deal more light than when, in consequence of the removal of the buffy coat in the capillaries, they have a less bi-concave form.

From four analyses of the blood of horses, Simon deduces the following rule regarding the chemical differences of arterial and venous blood. 'Arterial contains less solid residue generally than venous blood; it contains less fat, less albumen, less hæmatin, less extractive matter and salts, than venous blood. The blood-corpuscles of arterial blood contain less colouring matter than those of venous blood.' The arterial blood was taken from the carotids, and the venous from the jugulars.

Composition of healthy human venous Blood.—In a medical point of view the composition of venous blood is the most interesting, because it is from the veins that blood is almost always taken in disease, and because venous blood can naturally only be compared with venous blood for the purpose of ascertaining any deviations that may occur. The following table represents the mean composition of human venous blood without reference to sex:—

Water	795·278
Solid constituents	204·022
Fibrin	2·104
Fat	2·346
Albumen	76·660
Globulin	103·022
Hæmatin	6·209
Extractive matters and salts	12·012

100 parts of blood-corpuscles contained 5·7 of hæmatin.

Hence the blood contains about 20 per cent. of solid constituents, much more than 0·2 per cent. of fibrin, and about an equal quantity of fat; the blood-corpuscles considerably exceed the albumen in quantity, and contain about 5 or 6 per cent. of colouring matter.

The space within which we are limited precludes us from noticing the various modifications which the blood undergoes in different forms of disease. The extent of these variations is obvious from the following table, drawn up from Simon's 'Animal Chemistry,' vol. i., p. 246.

The water may vary from	915·0	to	725·0
The solid residue ,,	275·0	to	85·0
The fibrin ,,	10·8	to	a trace.
The fat ,,	4·3	to	0·7
The albumen ,,	131·0	to	55·1
The globulin ,,	106·6	to	30·8
The hæmatin ,,	8·7	to	1·4
The extractive matters and salts	16·5	to	7·6

Lymph and Chyle.—Closely allied to the blood are the lymph and chyle. These fluids have only recently been submitted to correct chemical examination. In Simon's 'Chemistry' the reader will find recent analyses of the former by Marchand and Colberg, l'Heretier, Rees, and Nasse; and of the latter by Simon, Rees, and Nasse.

From the consideration of the blood we naturally turn to that of the various secretions yielded by it.

The *saliva* has been analysed by Simon, L'Heretier, and Wright. The following is Dr. Wright's account of healthy saliva. It varies considerably in specific gravity, being always denser after a meal than during fasting. Healthy saliva has mostly the specific gravity of 1007·9. When above 1010 or below 1003 it may be considered morbid. Healthy saliva is either alkaline or neutral, generally the former. He believes in the existence of the principle termed *ptyalin*, although he separates it from the saliva by a new process, which is 'to pass saliva through ordinary filtering paper, and after filtration shall have been accomplished to exhaust the residue with sulphuric ether: the ethereal solution contains a fatty acid and ptyalin. It is to be allowed to evaporate spontaneously, and the residue left by evaporation is to be placed upon a filter and acted on by distilled water, which dissolves the ptyalin and leaves the fatty acid.' On evaporating this solution to dryness the ptyalin will be obtained in a pure state. In relation to the presence of sulpho-cyanogen Wright remarks that it is a constant ingredient of the saliva. 'The proportion,' he observes, 'is temporarily augmented by local stimulation of the salivary glands, as by smoking, chewing sialogogues, &c. It is also increased by the internal use of prussic acid and salts of cyanogen, and remarkably so by the use of sulphur.' The occurrence of this substance in the saliva is equally interesting in a physiological and in a medico-legal point of view. The circumstance that it forms with the per-salts of iron a beautiful cherry-red of the same colour as the meconate of iron, must not be overlooked in examining the stomach in a case of suspected poisoning by opium.

L'Heretier has recorded the mean of 10 analyses of the saliva of healthy persons made while fasting:—

Water	986·5
Organic matter	12·6
Inorganic matter	0·9

The ptyalin formed 2·5 of the 12·6 parts of organic matter.

Mialhe has recently (April, 1845) announced the discovery in the saliva of an active principle analogous in its physical and chemical characters to diastase. It is solid, white or greyish white, amorphous, insoluble in alcohol, but soluble in water and in weak spirit. The directions for obtaining it are the following: filter saliva and treat it with five or six times its weight of absolute alcohol, adding it as long as any precipitate occurs. This animal diastase falls in white flocks, which when dried constitute 0·2 per cent. of the saliva.

The Bile.—It would take up far more space than we could devote to the subject to notice all the additions that have been recently made to the chemistry of the bile. In the year 1838, Demarçay announced that bile consisted essentially of an organic acid combined with soda. He termed the acid *choleic*, and obtained it in the following manner: bile, from which the mucus had been precipitated by alcohol, was evaporated on the water-bath, and 10 parts of the dried residue were dissolved in 100 of water, to which 10 of hydrochloric acid had been added. Allowing evaporation at a moderate temperature to proceed, it was observed that a dark green oil collected on the surface, while at the same time the fluid became turbid. On removing the oil and allowing the fluid to rest for some time, it gradually became clear, with the precipitation of a green deposit. This dark green bitter precipitate is Demarçay's choleic acid, and is regarded by him as constituting nine-tenths of the solid constituents of the bile. It is still mixed with margaric acid, cholesterin, pigment, &c. After their removal it forms a yellow spongy matter, which rapidly absorbs oxygen from the atmosphere, is very bitter, slightly soluble in ether, soluble in water, and very soluble in alcohol. The *choleate of soda*, obtained by adding an alcoholic solution of soda to an alcoholic solution of choleic acid, and then passing a current of carbonic acid through it to remove the excess of soda, possesses all the characters of bile; it yields on evaporation a brown resinous mass, and is soluble in water and in alcohol.

When choleic acid is boiled with hydrochloric acid it yields ammonia, taurine (see TAURINE, P. C.), and choloidic acid; the latter being insoluble is deposited. The formulæ usually assigned to choleic acid, taurine, and choloidic acid are, $C_{42} H_{36} N O_{12}$, $C_4 H_7 N O_{10}$, and $C_{72} H_{56} O_{12}$.

But it has been recently shown by Redtenbacher that the formula for taurine should in reality be $C_4 N H_7 O_6 S_2$; since it contains no less than 25·6 per cent. of sulphur which had been previously altogether overlooked (Liebig and Wöhler's 'Annalen der Chemie und Pharm.,' Feb. 1846). Hence there can be no doubt that the formula for choleic acid also requires considerable modification. For further information on the recent history of the chemistry of the bile we must refer to Simon's 'Animal Chemistry,' vol. i., pp. 45-49, and vol. ii., pp. 17-27; Day's 'Reports on the Progress of Animal Chemistry,' in Ranking's 'Half-yearly Abstract of the Medical Sciences,' vols. ii. and iii.; and Platner's 'Ueber die Natur und den Nutzen der Galle,' Heidelberg, 1845. The following description of the microscopical and chemical character of healthy human bile is condensed from a series of papers on the subject by Frerichs (*Hannov. Annal.*, i. and ii., 1845).

In colour it is always a deep brown, but when seen in thin layers it has a brownish-yellow tint. It is very fluid, being viscid only in new-born infants. The specific gravity varies from 1032 to 1040. On examining with the microscope bile from the gall-bladder, with which, of course, a certain amount of mucus is mixed, there are observed:—1. Transparent or greyish round vesicles, about the 700th of a line in diameter; they disappear on the addition of alcohol or ether, and are removed by filtration. 2. Conical yellow bodies, about the 140th of a line in length, and about the 300th or 400th of a line in breadth, apparently devoid of nuclei; these are epithelial cells from the gall-bladder. 3. Here and there irregular dark granules, which disappear on the addition of a solution of potash, apparently pigment cells. 4. Occasionally minute crystals of cholesterin, occurring as colourless rhombic tablets.

The chemical characters are shown in the two following analyses. The bile in these cases was obtained from healthy men, killed by severe accidents:—

	1.	2.
Water	86·00	85·92
Solid constituents	14·00	14·08
Choleate of soda	10·22	9·14
Cholesterin	0·16	0·26
Margarin and olein	0·32	0·92
Mucus	2·66	2·98
Chloride of sodium	0·25	0·20
Tribasic phosphate of soda	0·20	0·25
Basic phosphate of lime / " " magnesia	0·18	0·28
Sulphate of lime	0·02	0·04
Peroxide of iron	traces	traces.

Platner has recently succeeded in obtaining choleic acid and choleate of soda in a crystallized form.

That the bile is not merely an excrementitious fluid, intended to remove effete matter from the blood, but that it is a secretion essential to the animal economy, was rendered almost certain by the experiments of Berzelius, Theyer, and Schlosser, which showed that the human fæces contained much too small a quantity of a substance resembling bile, to justify the idea that it is evacuated in this manner. A further proof that the bile is absorbed and not excreted is afforded by an examination, made by Enderlin, of the ash yielded by the contents of the different portions of the intestinal canal of a hare. He found that the ash from the contents of the duodenum *alone* effervesced on the addition of an acid, thus showing that the choleate of soda (which yields the carbonate on incineration) is absorbed before reaching the jejunum. Schwann has recently established this opinion beyond a doubt, by a series of well-devised experiments on dogs. He tied the ductus choledochus, and at the same time formed a fistulous opening in the gall-bladder, by which the bile escaped externally. His most important conclusions are, 1st, that when the bile does not get into the bowel its absence is generally perceptible in dogs about the third day, by a marked diminution in weight; and, 2ndly, that unless the channel for the conveyance of bile to the duodenum is re-established symptoms of deficient nutrition, wasting, debility, &c. ensue, and death is the ultimate consequence.

The chemistry of the *gastric juice* is still very unsettled; it has been recently made the object of especial study by Blondlot, Bernard and Barreswil, Melsens, and Dr. R. D. Thompson, who have obtained very contradictory results.

The *milk* has been recently examined by Simon, Clemm, and Dumas. The reader will find a copious account of the chemistry of this secretion in Simon's 'Animal Chemistry,' vol. iii. pp. 42-69.

The *urine* has, since the publication of the article URINE, P. C., been made an object of especial investigation by Liebig. The most important fact that has been discovered is that *hippuric acid* is, although in small quantity, a constant ingredient of this secretion. The acid reaction of this secretion depends in a great measure, according to that chemist, on the property that uric and hippuric acids possess of combining with the potash or soda of the alkaline phosphates, and thus forming an acid phosphate of soda.

The brief space necessarily allotted to this article has rendered it imperative on us to omit the consideration of many points of very high physiological importance.

For further information on the subjects contained in the preceding pages we must refer to the following works:—

On the Structure of Animal Tissues—Henle's 'Allgemeine Anatomie;' the article 'Tissue' (Gewebe) in Wagner's 'Handwörterbuch der Physiologie;' Bowman and Todd's 'Physiological Anatomy and Physiology;' the works of Dr. Carpenter; Goodsir's 'Anatomical and Physiological Observations;' the articles 'Mucous Membrane,' 'Muscle,' and 'Osseous Tissue,' in Todd's 'Cyclopædia of Anatomy and Physiology;' and Mr. Tomes's Lectures on Dental Surgery in the 'Medical Gazette' for 1845-6. The best account in the English language of vegetable tissues is given in Henfrey's 'Structural and Physiological Botany.'

On the Chemical Department of this article we must refer to Simon's 'Animal Chemistry;' to Dr. Day's Reports on the 'Progress of Physiological and Pathological Chemistry,' in Ranking's 'Half-yearly Abstract of the Medical Sciences;' to Liebig's 'Animal Chemistry,' translated by Gregory; to Mulder's 'Versuch einer Allgemeinen Physiologischen Chemie;' to Lehmann's 'Lehrbuch der Physiologischen Chemie;' and to L'Heretier's 'Traité de Chimie Pathologique.'

TLEMSEN. [ALGIERS, P. C., p. 330.]

TOD, JAMES, Lieutenant-Colonel in the service of the East India Company, was born in 1782, in England, but educated in Scotland. He went out to India in 1800, and obtained a commission in the 2nd Bengal European regiment; thence he volunteered for the Moluccas, was transferred to the marines, served as a marine on board the Mornington, and, in 1805, was attached, under his friend Mr. Græme Mercer, to the embassy sent at the close of the Mahratta war to the camp of Sindia in Mewar, where the embassy arrived in the spring of 1806. Rajpootana, of which Mewar is one of the states, thenceforward became the scene of his official labours, as well as of the geographical, historical, and antiquarian investigations by which he distinguished himself. He began to make surveys of Rajpootana soon after his arrival in the country, and the result of those surveys was the magnificent map which is given at the commencement of his 'Annals of Rajast'han.' The map was completed in 1815, and was presented to the Marquis of Hastings, then governor-general of India, and it was of great use in forming the plan of operations in 1817, the previous maps of the country having been very imperfect and erroneous. In 1817 he was appointed political agent, with the entire control of five of the states which had just then placed themselves under British protection, Mewar, Marwar, Jessulmeer, Kotah, and Boondee. The results of his investigations into the geography, history, and antiquities of Rajpootana are given in his 'Annals of Rajast'han.'

In 1822 the impaired state of his health rendered it necessary that he should return to the more congenial climate of his native country. Previously however to his departure from India, he made a circuit of nearly the whole of Rajpootana, including Gujerat, which he completed at the close of 1822, and in the beginning of 1823 he sailed from Bombay, and arrived safely in England.

After his return to England his time was chiefly devoted to literary pursuits. He officiated for a while as librarian to the Royal Asiatic Society. In 1834 he went to the Continent for the relief of a complaint in the chest, and remained abroad twelve months. He returned to England in September, 1835. While at Rome he was occupied with a work to be entitled 'Travels in Western India,' the result of the journey which he made previous to his return to England, and especially his observations in Gujerat. The last chapters of the work were written in October, 1835, while residing with his mother in Hampshire, and the MS. is said to have been left nearly fit for publication except filling up a few blanks and the completion of the engravings; but it has not yet been published. On the 16th of November, while transacting business with his bankers in London, he had an attack of apoplexy, and lay without consciousness for twenty-seven hours. He died November 17, 1835, at the age of fifty-three. He left a widow, the daughter of Dr. Clutterbuck, and a young family.

Bishop Heber, who travelled through Mewar and the adjoining Rajpoot states, in 1825, on his way to Gujerat, bears testimony to the affection and respect borne to Colonel Tod by the upper and middling classes of society in various towns through which the bishop passed. He says, 'Here and in our subsequent stages we were continually asked by the cutwals, &c. after Tod Sahib (Captain Tod), whether his health was better since he returned to England, and whether there was any chance of seeing him again. On being told it was not likely, they all expressed much regret, saying that the country had never known quiet till he came among them, and that everybody, whether rich or poor, except thieves and Pindarees, loved him. He, in fact, Dr. Smith told me, loved the people of this country, and understood their language and manners in a very unusual degree.' Bheelwara, a commercial town, which had contained 12,000 families, had been entirely ruined by the depredations of the Mahrattas at the time when Colonel Tod was appointed political agent. He set himself to restore it, and in less than a year there were seven hundred prosperous and peaceful families in it. Colonel Tod, in a letter to a friend, says, 'Regarding Bhilwarra, the work of my hands, in February, 1818, there was not a dog in it; in 1822 I left 3000 houses, of which 1200 were bankers and merchants. An entire street, arcaded, was built under my directions and with my means. The merchants from Calcutta, Jessulmér, Delhi, Surat, from every mart in India, had their correspondents, and in fact it was becoming the chief mart of Rajast'han. The affection of these people a thousand times repaid my cares.' Bishop Heber, after describing the prosperous state in which he found the town in 1825, says, 'The place had been entirely ruined by Jumsheed Khan, and deserted by all its inhabitants, when Captain Tod persuaded the Rana to adopt measures for encouraging the owners of land to return, and foreign merchants to settle. He himself drew up a code of regulations for them, and obtained them an immunity from taxes for a certain number of years, and sent them patterns of different articles of English manufacture for their imitation. He also gave money liberally to the beautifying of their town. In short, as one of the merchants who called on me said, "It ought to be called Todgunge, but there is no need, for we shall never forget him."'

The 'Annals of Rajast'han' were published in London, in 2 vols. royal 4to., vol. i. in 1829, and vol. ii. in 1832.

(*Annual Biography and Obituary*, 1836; *Gentleman's Magazine, February*, 1836; Bishop Heber's *Narrative of a Journey through the Upper Provinces of India*, 1824, 1825.)

TODD, REV. HENRY JOHN, was born in 1763, and educated at Hertford College, Oxford, where he proceeded M.A. in 1786.

He became a minor canon of Canterbury Cathedral soon after being ordained. In 1792 he was presented by the Dean and Chapter of Canterbury to the vicarage of Milton, near that city; and some years after, by the same body, to the rectory of Allhallows, Lombard Street, London, on which he fixed his residence in the metropolis. In November, 1803, he was appointed, by the Archbishop, Keeper of the Manuscripts at Lambeth. In 1820 he was withdrawn from London, by being presented by the Earl of Bridgewater to the rectory of Settrington, in Yorkshire, of the value of 1045*l.*; in 1830 he was collated by the Archbishop of York to the prebend of Husthwaite, in that cathedral church; and, finally, in 1832 he was appointed Archdeacon of Cleveland.

His first publication was 'Some Account of the Deans of Canterbury, from the new foundation of the Church by Henry VIII.,' 8vo., 1793. This was followed by an edition of Milton's 'Masque of Comus,' with notes and illustrations, from a manuscript belonging to the Duke of Bridgewater, 1798; 'The Poetical Works of John Milton,' with notes and a life, 6 vols. 8vo., 1801, for which he received 200*l.* from the booksellers, and of which there was a second edition in 1809, a third in 1826, and a fourth in 1843, and the portion of which consisting of the Life and the Verbal Index has also been published separately; 'A Catalogue of the Library of Christ Church, Canterbury,' 8vo., 1802; 'The Works of Edmund Spencer,' with notes and a Life, 8 vols. 8vo., 1805, reprinted in 1845; 'Illustrations of the Lives and Writings of John Gower and Geoffrey Chaucer,' 8vo., 1810; 'A Catalogue of the Archiepiscopal Manuscripts in the Library at Lambeth Palace,' fol., 1812 (100 copies privately printed); a new edition of 'Dr. Johnson's Dictionary of the English Language, with corrections and additions,' 4 vols. 4to., 1814, &c., and again in 3 vols. 4to., 1827; 'The History of the College of Bonhommes, at Ashridge, folio, 1823 (privately printed for the Earl of Bridgewater); 'Original Sin, Free Will, Regeneration, Faith, Good Works, and Universal Redemption, as maintained in certain Declarations of our Reformers,' &c., 8vo., 1818; 'A Vindication of our Authorized Translation and Translators of the Bible' (in reference to Bellamy's new translation), 8vo., 1819; 'Observations on the Metrical Version of the Psalms, by Sternhold, Hopkins, and others,' 8vo., 1819; 'Memoirs of the Life and Writings of the Right Rev. Brian Walton, Bishop of Chester,' 2 vols. 8vo., 1821; 'An Account of Greek Manuscripts of the late Professor Carlyle, now at Lambeth,' 8vo., 1823 (privately printed); a new edition of 'Archbishop Cranmer's Defence of the Doctrine of the Sacrament', 8vo., 1825, with a Vindication of Cranmer, reprinted in 12mo. in 1826; 'A Letter to the Archbishop of Canterbury, concerning the Authorship of Icôn Basilikè,' 8vo., 1825 (assigning the work to Bishop Gauden); 'A Reply to Dr. Lingard's Vindication of his History of England, as far as respects Archbishop Cranmer,' 8vo., 1827; 'Bishop Gauden the Author of Icôn Basilikè further shown, in answer to Dr. Wordsworth,' 8vo., 1829; 'Life of Archbishop Cranmer,' 2 vols. 8vo., 1831 (an enlargement of the 'Vindication'); 'Authentic Account of our Authorized Version of the Bible,' 12mo., Malton, 1834. We have omitted a few theological pieces of inferior importance. He was also, in the early part of his literary career, a frequent contributor to the 'Gentleman's Magazine;' and he is stated in Hasted's History of Kent, to have assisted largely in the preparation of that work.

Archdeacon Todd, who was a Chaplain in Ordinary to her Majesty, died at Settrington, on the 24th of December, 1845. From his will, an abstract of which is given in the 'Gentleman's Magazine' for June, 1846, he appears to have left several daughters.

Archdeacon Todd, though the editor of Milton and Spencer, had no pretensions to either poetical talent or poetical taste; nor was even his acquaintance with our old poetry, or with our old literature in general, very extensive or intimate. His annotations, accordingly, are rather dry. At the same time, if they do not overflow with much variety of knowledge, and rarely display any remarkable ingenuity, they do not annoy the reader by any kind of superfluous disquisition. He is certainly not a very animated narrator; but his facts may generally be depended upon. His most useful services, perhaps, have been rendered in the field of bibliography.

(Memoir in *Gentleman's Magazine* for March, 1846.)

TOFIELDIA, a genus of plants belonging to the natural order Colchicaceæ. It has a 6-parted perianth, the anthers bursting longitudinally. The three capsules, connected to above the middle, are 1-celled and many-seeded.

T. palustris, the only British species, has pedicels naked at the top, but with a 3-lobed bract at the base. The stem is from 4 to 8 inches high, the leaves sword-shaped, about 2 inches long, in 2-ranked radical tufts. The flowers are in a dense spike, at first sessile, afterwards slightly stalked with a bract at the base of the stalk, but none under the perianth.

(Babington, *Manual of British Botany*.)

TONICS. [ANALEPTICS, P. C.]

TONNAGE. [SHIP-BUILDING, P. C.]

TOPES. [AFGHANISTAN, P. C. S.]

TORDYLIUM (τορδύλιον of Dioscorides, 3. 56), a genus of plants belonging to the natural order Umbelliferæ. The calyx consists of 5 awl-shaped teeth, the petals obcordate with an inflexed lobe, the outer ones radiant. The fruit has a thick wrinkled margin, the pericarps with very slender ribs, the 3 dorsal ribs at equal distances, the 2 lateral ones contiguous to the thickened margin or covered by it. The species are herbs, with pinnate leaves and ovate leaflets deeply toothed. The flowers white.

T. maximum, Great Hart-wort, has a scabrous or hispid stem, pinnate leaves, and lanceolate leaflets deeply notched and clothed with fine bristly hairs. The flowers are reddish, the outer petal having 2 equal lobes, the two next with extremely unequal ones. It is native of the middle and south of Europe, and England, in corn-fields.

T. officinale, Officinal Hart-wort, has a branched furrowed stem, clothed with soft deflexed hairs; the leaves are pinnate, rough, and hairy; the leaflets ovate, cut, and crenate. The 2 outer petals are radiant, each with 2 very unequal lobes, which are sometimes reddish. It is the Σέσελι of Hippocrates, 'Vict. Acut.,' 387, and of Theophrastus, 'Hist. Plant.' 9. 18. The *Seseli* of Pliny, 25. 8. The seeds of these species only require to be sown in an open border in the spring; a light soil suits them best.

(Don, *Gardener's Dictionary;* Babington, *Manual of British Botany.*)

TORILIS, a genus of plants belonging to the natural order Umbelliferæ. The calyx has 5 teeth; the petals are obovate, emarginate, the outer ones radiant and bifid; the fruit slightly and laterally compressed; the carpel with bristly primary ridges, the secondary hidden by the numerous prickles which occupy the interstices; the flowers white, those in the disk of the umbellules male and sterile.

T. anthriscus has bipinnate leaves, the leaflets ovate, lanceolate, inciso-serrate; the umbels on long peduncles, the leaves of the involucre awl-shaped, the fruit covered with bristles; the flowers are small, reddish or white. It is native of Europe and Caucasus, and is plentiful in Britain.

T. infesta has an erect much-branched stem, the leaves bipinnate, the leaflets deeply cut, ovate, lanceolate. The fruit is densely prickly, the flowers small and reddish. It is found on fields and waste places in Europe and Great Britain.

T. nodosa has nearly sessile dense umbels, the outer carpels with hooked bristles, the inner often covered with dense whitish shining granulations; the lower leaves are bipinnate, the upper ones pinnate; the leaflets deeply, narrowly, and uniformly pinnated. It is native of Europe and the Levant, and is plentiful in Britain.

The seeds only require to be sown in the open ground.

(Don, *Gardener's Dictionary;* Babington, *Manual of British Botany.*)

TORTOISE-SHELL. This beautiful substance, or at least the best kind of the material which goes under the name, is procured from a marine tortoise called the Hawk's-bill turtle, or *Testudo imbricata* [TORTOISES, P. C., pp. 76, 77], the Latin name of which is derived from the mode in which the scales upon its back are arranged, overlapping one another like the tiles upon the roof of a house, one kind of which were called by the Romans *imbrices*. In most other tortoises the several scales of which their covering is composed adhere to one another by their edges, like inlaid work. Each animal furnishes thirteen principal plates, five along the centre of the back, and four on each side; and twenty-five smaller scales or plates, which constitute the margin of the shell. 'The size and thickness of the plates,' observes Mr. Aikin, in a paper on Horn and Tortoise-shell, in the 'Transactions' of the Society of Arts, vol. lii., part ii., pp. 343-347, 'depend on the magnitude and age of the animal, a fresh layer being produced every year; and at the margin of the large plates may be seen distinctly the edges of the layers as they thin off in succession.' 'Sometimes, however,' he adds, 'large plates are met with, so thin as to consist, apparently, of only a single layer;' and he observes that 'some of the dealers in this article have an opinion that these thin plates are the produce of full-grown tortoises that have been stripped of their plates the year before, either purposely or by accident.' The horny plates which constitute true tortoise-shell are separated from the bony foundation which forms the shell or covering of the animal by the application of heat; the whole shell being commonly placed over a fire until the plates begin to start from the bone, and the separation being completed by the aid of a slender knife. The shell varies much in value, being frequently injured by barnacles, limpets, and other shell-fish, adhering to the turtles while alive, and interfering with the growth of the shell where they attach themselves. Occasionally plates of a uniform yellow colour are met with, and such, Mr. Aikin states, are in great request among the Spanish ladies, who will give at least twice as much for a comb of plain tortoise-shell as for a mottled one. The belly-plates of the tortoise are yellow, and sometimes they are found sufficiently clear for use.

The mode of manufacturing tortoise-shell so nearly resembles the working of horn, described on pages 46 and 47 of this volume, as to need little further notice; but owing to the very high value of the material (about three guineas per lb. was the price of fine shell when Aikin wrote in 1832), it is economised as much as possible. Before working the shell needs to be softened or *tempered*, which is usually done by dipping it for three or four minutes, or longer if it be very thick and brittle, in boiling water, which, according to Aikin, should have a little salt mixed with it, because pure water abstracts much of the colour. Too much salt however renders the shell brittle; and too long boiling injures it by turning it nearly black, and covering the surface with an opaque white film. According to Holtzapffel, in whose work on 'Turning and Mechanical Manipulation,' vol. i. pp. 128-135, is a very full and interesting account of the manufacture of tortoise-shell into various articles of taste and utility, some manufacturers flatten and temper their shells with hot flat irons, similar to those used by laundresses; the tortoise-shell being, in the course of the operation, frequently dipped in cold water to prevent scorching. Holtzapffel remarks that generally the less the shell is heated and pulled about the better, because from its apparent want of grain or fibre it is apt to become very brittle. Being also less fusible than horn, tortoise-shell cannot be made soft enough to be moulded without some injury to the colour; and accordingly, Aikin states, 'the manufacturers, at least in England, never attempt to produce tortoise-shell combs with ornamental open work by means of dies.' Such work is produced by pasting a piece of paper over the tortoise-shell, drawing the pattern upon it, cutting it out with drills and fine saws, and, after the paper has been removed by steeping in cold water, finishing the ornaments with the graver. The cutting or *parting* of the teeth of combs by machinery is described under COMB, P. C. S., p. 398; but we may here notice another mode which is occasionally followed, and which illustrates the convenience arising from the flexibility of the material when warmed. A piece of tortoise-shell large enough to make two combs, with their teeth interlaced, is bent or bowed, in the direction of the length of the teeth, to such a degree of convexity that they may be cut with a straight bow-saw without cutting through either of the edges of the pieces of shell, which are required to form the top or back portions of the combs. The shell is then flattened and the ends or points of the teeth are separated with a narrow chisel or *pricker*, after which the combs are finished with files and scrapers, and bent to any required curvature upon wooden moulds. The same method of cutting is resorted to in making the frames for eye-glasses, which are usually formed out of narrow slips of shell in which slits are cut with a saw, the slits being subsequently, while the shell is warm, *strained* or *pulled* open, until they form circular or oval apertures, by the insertion of tapering triblets of the required shape. The same yielding or flexible property is made use of in the manufacture of boxes; a round flat disc of shell being gradually forced by means of moulds into the form of a circular box with upright sides. The union of two or more pieces of shell may be effected by carefully scraping the parts that are to overlap, so as to render them perfectly free from grease, even such as might arise from being touched by the hand, softening them in hot water, pressing them together with hot flat tongs, and then plunging the joint into cold water.

In veneering with tortoise-shell, by which very beautiful work may be produced, it is usual to apply fish-glue, mixed with lamp-black, vermillion, green, chrome, white, or other colouring matter, at the back of the shell, both to heighten its effect and to conceal the glue or cement by which it is secured to the wooden foundation. In making knife-handles and some other ornamental work metallic foils are put beneath the tortoise-shell veneer with excellent effect.

Aikin refers to the luxurious taste of the Romans of the Augustan age for couches and other articles of furniture veneered or inlaid with tortoise-shell; and in Dr. Smith's 'Dictionary of Greek and Roman Antiquities,' p. 585, it is stated that the lyre is sometimes called by Greek writers χέλυς or χελώνη, and in Latin *testudo*, because it was occasionally made of tortoise-shell.

TOWNLEY, JAMES, REVEREND, the second son of a merchant, was born in London in 1715. He was educated at Merchant Tailors' School, elected thence to St. John's College, Oxford, and took orders. After having held two lectureships in London, he was appointed, through the interest of his wife's family, to the living of St. Bennet, Gracechurch Street. Afterwards he was grammar-master in Christ's Hospital, and in 1759 was appointed head master of Merchant Tailors' School, and held that office till his death in 1778, which happened soon after he had been presented to a living in Wales. He is said to have been admired as a preacher: and some single sermons of his are in print. But he is chiefly known on account of his intimacy with Hogarth and Garrick. To the former he and Morell gave material assistance in the composition of his 'Analysis of Beauty;' and he got the credit of having much assisted the latter in his dramatic works. The popular farce of 'High Life Below Stairs,' first played in 1759, was at length owned by him. He was also the author of two other farces, which were unsuccessful; but one of them, 'False Concord,' contains both characters and dialogue which were borrowed in Garrick and Colman's comedy of 'The Clandestine Marriage.' The closeness of Townley's connexion with Garrick is further evidenced by the fact that he received from Garrick, and held for some years, the living of Hendon.

TOXOTES, a genus of Acanthopterigious fishes of the family *Squamipennes*, the species of which are remarkable for having the power of spirting out drops of water even to a height of three or four feet with such accuracy of aim as to bring down the insects upon which they feed from the aquatic plants frequented by their prey.

TRACHE'LIDES, the fourth family of heteronomous Coleoptera in Latreille's arrangement of insects. The head is more or less triangular or pedicled, and cannot be retracted. They have soft bodies, smooth flexible elytra, often short, and maxillae, which are not hooked. They mostly live on leaves and flowers. Many of them simulate death when seized. *Lagria*, *Pyrochroa*, *Mordella*, *Notoxus*, *Floria*, and *Meloe* are types of tribes in this family.

TRACHIU'RUS. [TÆNIOIDES, P. C. S.]

TRADER. [BANKRUPT, P. C.]

TRANSFER OF REAL PROPERTY. During the last few years various statutes have been passed for the purpose of facilitating the transfer of Real Property.

The first of these was one passed in the 4th & 5th of Victoria, intituled 'An Act for rendering a Release as effectual in the conveyance of Freehold Estates, as a Lease and Release by the same parties.' It enacted that every deed or instrument of release of a freehold estate executed after the 15th of May, 1841, and expressed to be made in pursuance of the Act, should operate in all respects, both in law and in equity, as if the parties thereto had also executed the usual lease for a year, providing at the same time that such release should be subject to the same stamp duty as the lease and release would have been liable to under the Acts relating to the Stamp Duties.

In consequence of the terms used in this Act, it was thought necessary that all releases made under it should recite the title in order to give them full effect. To obviate the difficulties often arising from the loss of the lease for a year, it was enacted by the second section, that the recital or mention of a lease for a year in a release executed before the passing of this act, should be evidence of the execution of such lease for a year.

The next Act on the subject was the 7th & 8th Vict., c. 76, intituled 'An Act to simplify the Transfer of Property.' This Act having been found in many respects objectionable, it was in the following year repealed by the 8th & 9th Vict., c. 106, whereby several of the provisions of the former have been re-enacted in an improved form. This Act is intituled 'An Act to amend the Law of Real Property,' and, as its provisions will have a great effect upon the Transfer as well as the Law of Real Property, it will be necessary to consider them separately.

After repealing all the clauses of the former Act from the 1st of October, 1845, except those which related to contingent remainders, which were repealed as from the commencement of the former Act, it provides: That after the 1st of October, 1845, all corporeal tenements and hereditaments shall, as regards the conveyance of the immediate freehold, be deemed to lie in grant as well as in livery, that is to say, shall pass by the delivery of the deed of conveyance, as incorporeal hereditaments and reversions and remainders of corporeal hereditaments have heretofore passed, the stamp-duty chargeable on every deed to be effectual as a grant, being the same as if the same had been a release founded on a lease for a year, and also with the stamp-duty (exclusive of progressive duty) with which such lease for a year would have been chargeable. For the conveyance of a fee simple or any less estate, the only operative word now necessary to be used is 'grant.'

By section 3, a feoffment (unless made under custom by an infant) is to be void unless evidenced by deed; and a partition and exchange, or lease required by law to be in writing, an assignment of a chattel interest, a surrender in writing of an interest which could not be made at law without writing, of or in any tenements or hereditaments not being copyhold, is to be void at law unless made by deed. The only effect of this section with respect to most of the matters comprised in it, is to assimilate the law to the practice, and with respect to others, to make a formal instrument, called a deed, necessary where by the Statute of Frauds a writing only was required. Feoffments are required to be evidenced only, while partitions, &c. are required to be made by deed. The reason of this distinction seems to be that in the feoffment the essential part is not the execution of the deed, but the delivery of the possession or seisin from the feoffer to the feoffee.

A feoffment is not to have any tortious operation, and an exchange or partition is not to imply any condition in law; and the word 'give' or 'grant' is not to imply any covenant in law beyond what it already has under any Act of Parliament, (section 4). This provision points to the old common law doctrines, that a feoffment, though made by a person having no title but possession, had the tortious effect of passing the fee, and that warranty was implied from the use of the technical words 'exchange,' 'give,' and 'grant.' A saving clause has been rendered necessary by the introduction into certain Acts of Parliament containing short forms of conveyance, and providing that, to save expense, the word 'grant' shall imply the usual covenants for title.

By sect. 5 it is enacted that under an indenture an immediate estate and the benefit of a condition or covenant may be taken, although the taker be not named a party; and a deed purporting to be an indenture is to have the same effect as an indenture, although not indented. This abolishes the distinction between an indenture and a deed-poll, whereby a person not a party to an indenture could not take under it except by means of the Statute of Uses; whereas any person might take under a deed-poll, which is addressed to all the world. The latter clause of the section merely expresses what has long been understood to be law.

By sections 6 and 7, contingent interests, possibilities coupled with an interest and rights of entry, whether immediate or future, and vested or contingent, in tenements and hereditaments of any tenure, may be disposed of by deed; but no such disposition is to defeat or enlarge an estate tail. These provisions extend to married women, who are likewise enabled to disclaim by deed, but all deeds executed by them must be made conformably to the provisions of law with respect to dispositions by married women. One object of the first of these clauses is to remedy a deficiency in the Act for the Abolition of Fines and Recoveries, which provides for the conveyance of contingent estates tail, but omits to mention any other species of contingent estate. Under this clause also the assignee of a right of entry has power to enter for a breach committed before the assignment. The second clause is also intended to remedy an omission in the Fines and Recoveries Act.

By sect. 8 a contingent remainder existing at any time after the 31st December, 1844, is to be, and if created before the passing of this act, is to be deemed to have been, capable of taking effect notwithstanding the determination by forfeiture, surrender, or merger of any preceding estate of freehold, in the same manner as if such determination had not happened. As that part of the 7 & 8 Vict. c. 76, relating to contingent remainders, was repealed as from its commencement, it was necessary to provide for those cases in which property had been limited under the provision there contained. This is effected by making the clause in question relate as well to those contingent remainders existing at any time after 31st December, 1844, as to those created before the passing this act. The force of this clause will be understood by referring to Remainder, P. C. The practical effect of this section will be the omission in settlements of the limitations to trustees to preserve contingent remainders.

By sect. 9, where the reversion on a lease shall, after the 1st October, 1845, be surrendered or merged, the estate which shall for the time being confer as against the tenant the next vested right to the possession shall, for the purpose of preserving the incidents to and obligations on the same reversion, which, but for the surrender or merger, would have subsisted, be considered the reversion expectant on the lease. The object of this section is to do away with the rule that the covenants of and remedies against a lessee, and the obligations on the lessor, being incident to the immediate reversion, cease as regards the land on the merger of that reversion in another estate.

In the 8 & 9 of Vict. two acts were passed which had for their object the reducing the length of conveyances of property and leases. The first, the 8 & 9 Vict. c. 119, is entitled 'An Act to facilitate the Conveyance of Real Property;' and the second, the 8 & 9 Vict. c. 124, 'An Act to facilitate the granting of certain Leases.' The provisions of the two acts are analogous, and their place is that of providing, that where the words in the first column of the schedule attached to the act are used in a deed, they are to have the same effect as if the words in the second column had been employed. The schedule here spoken of contains in the first column a short clause, and in the second the long covenant for which the first may be substituted. The acts also contain provisions for making slight alterations in the wording of the clauses according to the circumstances of the case. It seems doubtful whether these acts will be of much practical application.

All the acts here considered relate to England and Ireland, but not to Scotland.

TRANSIT, RAILWAY. In an article intended to be supplementary to that given under Railway, P.C., pp. 245-267, and to treat especially upon matters which have risen into importance during the six years that have elapsed since that article was written, many topics which might seem to claim attention must be passed over, or treated very briefly. Excepting in the simply historical portion of the subject, almost every page of the article referred to presents matter upon which something might be said indicative of the rapid progress of mechanical improvement, or of the results of extended experience; but our attention must be confined to a few only of the more important points relating to railway legislation, and to the construction, working, and management of railways, together with statistical notices of the progress of the railway system in the United Kingdom, whence it is rapidly extending over the whole face of Europe, and of the civilized world. To facilitate reference we shall, as far as the natural dependence of one subject upon another will allow, follow the order of arrangement adopted in the article Railway, so that the reader may readily trace the connection between the original and the supplemental matter. The principal deviations from this course are in the bringing together, under the general head of Railway Legislation, all matters relating to the obtaining of railway acts, originally noticed under Railway, pp. 251, 252, and such as relate to government control, taxation, &c., which were noticed in pp. 260, 261 of that article; and in the incidental notice in connection with the important question of gauge, of various matters relating to general principles of railway construction, working, and management.

Railway Legislation.—The growth of Railway travelling in this country has been so sudden, and its consequences, in relation to the interests of the public, were so little foreseen at its commencement, that until very recently it has advanced without control, and, it may be said, almost without the notice of the government.

There are two opposite principles of administrative policy which may be pursued in reference to undertakings of public utility. By the one all such works are executed either directly by the government or under government superintendence; by the other they are the result of private enterprise, and government has no further concern with them than to give or withhold the legal powers necessary for their execution. In countries where capital is not abundant, nor the spirit of commercial enterprise very active, the former principle is often essential for the promotion of public works, and it has accordingly been adopted by the governments of France, Belgium, and Germany; but where the speculative energy and resources of capitalists are so remarkable as in England, no encouragement is needed from the government, and its interference is required only for the protection of public interests. The circumstances of this country, therefore, would naturally have dictated the policy of permitting the employment of capital in public undertakings, with as little restraint as possible; and our free institutions, and the generally passive character of our government, have favoured politically a principle which would appear to be economically expedient. It may be doubted, indeed, whether this principle has not been carried too far; and whether capital would not have been invested more beneficially under a surer and more provident system of legislation.

The following is a sketch of the proceedings which have been necessary for carrying out a scheme of railway communication. The parties who have planned it obtain subscriptions to the undertaking, and having made the necessary surveys and satisfied themselves of the profitable character of the speculation, they determine to apply for an Act of Parliament to incorporate a company for executing the works, and to give them the powers required for that purpose. The most important power to be obtained is that of taking lands and houses without the consent of the parties interested in them; and in the early period of railway legislation, the only opposition encountered by railway companies was that of the landowners, who were either unwilling to sell their land or dissatisfied with the price which had been offered them. If this opposition was overcome or conciliated, the bill was allowed to pass. If no such opposition was offered, and if there were no competing lines, no means were taken by Parliament to inquire whether the line was the best that could have been suggested for the district through which it was intended to pass; but the evidence adduced by the promoters was held to establish the public utility of the undertaking; and it was authorised. The executive government took no part in the investigation; and Parliamentary Committees composed of members locally interested can scarcely be said to have inquired into the merits of lines except when an inquiry was forced upon them by the opposition of private parties. Little or no security was taken for the public interests, and so little was the character of railway communication understood, that in fixing the tolls and charges, parliament at first named a *maximum* for the tolls, as in the case of canals, but imposed no limit upon the charges for the conveyance of goods and passengers. As the companies undertook the entire traffic of their own lines, no tolls were payable, and thus the *maximum*, which was intended for the security of the public, was wholly inoperative. This oversight has since been rectified, and every railway act of 1845 and 1846, whether for a new line or for the amendment of acts, under which existing lines were constructed, contains a clause which reserves to Parliament the right of revising the fares and charges; and in most of the recent acts the *maximum* charges are moderate. In 1836 committees were required to give more detailed reports concerning the bills committed to them, but their proceedings were improved by this regulation in form rather than in substance. In 1839 the constitution of the committee was improved by the admixture of "selected members," who were not locally interested: and since 1844, the committees have been composed exclusively of members who have had no local interest in the lines referred to their consideration. But however these tribunals may have been improved, the same system of legislation has practically prevailed. Unopposed lines have, almost without exception, been sanctioned upon the *ex-parte* evidence of the promoters; and opposed lines have been granted or refused according to the relative wealth, influence or perseverance of the contending parties.

It is undeniable that more vigilance ought to have been exercised in investigating the merits of lines, and in securing the best terms for the public which were consistent with justice and fairness; while, on the other hand, the promoters of railways ought to have been protected against the ruinous waste of capital which has been occasioned by vexatious forms of procedure, and by ill-regulated and too often incompetent tribunals.

But notwithstanding admitted defects in the system of railway legislation, and the abuses which have arisen from it, the principle of allowing free scope to the operations of private enterprise and capital has been eminently successful, and more railways have been constructed in the last fifteen years, and more science and skill have been devoted to their improvement, than a government could have called forth in half a century. Nor have the public interests otherwise suffered so materially as might have been anticipated; for the conditions, for the public good, which might have been made the subject of express stipulation, have in great measure been secured by the operation of the same principle. The charges upon goods and passengers, for example, which might have been regulated more strictly, have shown a continual tendency to decrease. The competition of canals and steam-boats, the profits to be secured by the encouragement of increased traffic, the dread of competing lines, the example of other lines which meet with public favour, and other circumstances, have already caused a very general reduction of railway charges, and may eventually lead to still more extensive reductions.

This acknowledgment is due to the spirited and able capitalists, who, under a defective system of legislation, and without any aid or direction from the government, have done so much for the country. But it has been impossible to overlook many serious evils which have arisen from the want of a uniform administration of railway affairs:—1st. Parliamentary committees, however well conducted, are independent of one another, are guided by no uniform principle, have no peculiar experience, and are devoid of all means of obtaining any other information but that which is offered by the parties themselves. 2ndly. Great powers are required by companies for executing their works and conducting their traffic, in granting which considerable caution is necessary. 3rdly. When the acts for incorporating companies have been passed, it is desirable that some supervision should exist to prevent the law from being exceeded, or exercised injuriously. The whole traffic of the country is rapidly being absorbed in railway communication, and so enormous a public interest needs the utmost care of the government. To guard the public safety and convenience is quite compatible with a respect for the freedom of capital.

Having stated these general principles in reference to railway legislation, we may proceed to a brief analysis of the various measures which have been passed, from time to time, for the supervision of railways and for other purposes connected with the general administration of railway affairs. The objects for which they were passed are not always analogous, but it will be convenient to offer a consecutive view of them, as, however imperfect they may be, they constitute, in effect, our whole railway code.

The first step towards a control of railways by the government was taken in 1840, when an act was passed to place them under the supervision of the Board of Trade (3 & 4 Vict., s. 97). By this act it was provided, that no railway should be opened until a month's notice had been given to the Board of Trade; that returns should be made by all railway companies of their traffic, of accidents, and of their tolls, rates, and charges; that the Board of Trade should be authorised to appoint inspectors to examine railways; and that all bye-laws should be submitted to the Board, who may disallow them. These and other matters provided for by this act, at once disturbed the independence under which the railway system had hitherto grown up, and placed the affairs of all the railways under the immediate supervision, and, in some degree, under the control of government.

By the act 5 & 6 Vict., c. 55, power was given to the Board of Trade to postpone the opening of any railway not considered safe by their inspectors: notice of accidents attended with serious personal injury was required to be given to that board within forty-eight hours after their occurrence, and the Board were further empowered to direct returns to be made of all accidents, whether attended with personal injury or not. With a view to the public safety, disputes between railway companies having a common terminus, or using a portion of the same line of rails in common, were to be decided by the Board of Trade; and all powers, under existing acts, of making branch communications with railways, and of running locomotive engines upon them, were submitted to their regulation. They were also authorised to enforce the alteration of level crossings which appeared to endanger the public safety.

The same act required all railway companies to convey Her Majesty's Forces and the Police Force at such prices and upon such conditions as may be contracted for by the secretary at war.

The provisions of these acts were mainly directed to the ensuring of the public safety; but in 1844 a more important act (7 & 8 Vic. c. 85) was passed with a view to secure, as far as possible, the interests of the public from being sacrificed to the independent privileges granted by parliament, in perpetuity, to railway companies. With this object the following securities, amongst others, were provided. If after twenty-one years from the passing of the act for the construction of any new line of passenger railway the clear annual profits divisible upon the paid-up capital shall have exceeded 10 per cent. upon the average of the three preceding years, the Treasury may revise the scale of tolls and charges as they think fit, so as to reduce the profits to 10 per cent.; with a guarantee, however, that 10 per cent should be made good to the company, and that without their consent no further revision of their charges should be made for twenty-one years. And whatever may be the rate of divisible profits at the expiration of the twenty-one years, the Treasury may purchase any such railway, in the name and on behalf of her Majesty, upon giving three months' notice, and on payment of 25 years' purchase of the annual profits estimated on the average of the three preceding years; subject to arbitration however, in particular cases, and to certain exceptions. And in order to give effect to these provisions, full powers are given to examine all the books and accounts of the companies for three years preceding the time at which the tolls may be revised or the railway purchased. For reasons which are well explained in the second report of the Railway Committee of 1846, it is doubtful if these prospective securities will ever be available; but immediate advantages were also secured to travellers and to the government.

In order to provide for the poorer class of travellers the means of travelling by railway at moderate fares, and in carriages protected from the weather, it was enacted that every railway company incorporated in the session of 1844, or in any future session, or which should obtain from parliament any extension or amendment of its powers, shall provide one third-class passenger train, at the least, all along the line, on every day on which other passengers are carried, and under the following conditions:—

1. The hour of starting to be subject to the approval of the Board of Trade.
2. The speed to be, upon an average, not less than 12 miles an hour for the whole distance travelled, including stoppages.
3. The train shall, if required, take up and set down passengers at every passenger station.
4. The carriages shall be provided with seats, and protected from the weather in a manner satisfactory to the Board of Trade.
5. The fare of each passenger shall not exceed 1*d.* a mile.
6. Each passenger shall be allowed to take half a *cwt.* of luggage, not being merchandise or other articles carried for hire or profit, without extra charge; and any excess of luggage is to be charged by weight, at the lowest rate charged for passengers' luggage by other trains.
7. Children under three years of age, accompanying passengers, are to be taken without charge, and under twelve years of age, at half price.

With the exception of the fares, which are in no case to be exceeded, the Board of Trade were empowered to dispense with any of these conditions, in consideration of other arrangements made by railway companies, which may appear more beneficial and convenient for the passengers by the cheap trains. And as an encouragement to cheap trains, it was further provided that no tax shall be levied upon the receipts of any railway company, which arise from the conveyance of passengers at fares not exceeding a penny a mile.

If any passenger train shall run on Sundays on any railway, subject to the above provisions, it is required that a sufficient number of third-class carriages shall be attached to the train which stops at the greatest number of stations, and that the passengers shall be carried, as in the cheap trains, at fares not exceeding a penny a mile. By the act 5 & 6 Vict. c. 79, the duty upon passengers conveyed by railway is chargeable at the rate of 5 per cent. 'upon all sums received or charged for the hire, fare, or conveyance of all such passengers.' The amount paid by the several companies from the 1st September, 1845, to 5th July, 1846, was 154,885*l.*, and the amount not charged on account of this exception of third-class passengers, was 21,358*l.* (Parliamentary Paper, 1846, No. 656.)

By an act of the 1 & 2 Vict. c. 98 provision had been made for securing advantageous arrangements upon railways for the conveyance of the mails, and by this act additional facilities were given for that purpose.

In regard to new railways also, a further provision was introduced in respect to the conveyance of troops, requiring every commissioned officer proceeding on duty to be conveyed in a first-class carriage at fares not exceeding 2*d.* a mile, and every soldier or policeman, and their wives, widows, and children above twelve years of age, in a carriage provided with seats, and protected from the weather, at 1*d.* a mile:

children under three years being taken without charge, and under twelve at half price, as in the case of the chesp trains. And the companies are required to convey military stores, baggage and arms, at 2*d.* a ton per mile, the assistance of the military being given in loading and unloading them; and gunpowder and other combustible matters at such prices and under such conditions as may be contracted for with the secretary at war.

It was also enacted that every railway shall be bound to allow a line of electric telegraph to be laid down for her majesty's service upon lands adjoining the railway, and to give every facility for erecting and using the same, subject to such reasonable remuneration as may be agreed upon, or, in case of disagreement, as may be settled by arbitration. Such telegraphs, subject to the prior use of the government, may be used by the company for the purposes of the railway, upon terms to be agreed upon or settled by arbitration. And where an electric telegraph shall have been established by the railway company, or by any company or person, otherwise than exclusively for the public service, or exclusively for the purposes of the railway, or jointly for both, the use of it, for the purpose of receiving and sending messages, shall be open to all persons alike, without favour or precedence; but subject to priority of use by the government and the railway company, and to such equal charges and reasonable regulations as may, from time to time, be made by the company.

By the 3 & 4 Vict. c. 97, a power had been given the Board of Trade to appoint persons to inspect railways, and by this act the board were empowered to appoint permanent inspectors, not only to inspect railways, but also to enable the Board to carry into execution the provisions of the various railway acts. This enactment resulted in the nomination of the Railway Department of the Board of Trade, of whose functions and proceedings we shall presently have to speak.

Whenever it shall appear to the Board of Trade that the provisions of any acts for the regulation of railways have not been complied with, or that the companies have been acting in a manner unauthorised by such acts, or ought to be restrained from so acting, the Board of Trade shall certify the same to the Attorney-General for England or Ireland or to the Lord-Advocate of Scotland; who shall proceed against such companies at law or in equity, as the case may require.

A practice had arisen of issuing loan notes not authorised by the acts under which railway companies were empowered to borrow, and by this act the issue of such notes in future was prohibited, but validity was given to those which had been already issued, and companies were authorised to renew them for five years after the passing of the act. A register of such loan notes was, at the same time, required to be kept by the secretary of the company.

A remedy was also provided for the speedy recovery of tithe-rent charges payable upon lands which had been taken for railways.

The experience of railway companies who had applied to parliament, from time to time, for powers to make and maintain their lines had suggested various clauses which were usually adopted in all railway bills. These were very numerous, and conferred extensive powers upon each company which obtained an act to authorise its own separate undertaking. These powers, though generally very similar in all cases, were sometimes varied by the parties applying for acts, and such variations were sanctioned by parliament. In this manner not only was a want of uniformity occasioned in the powers given to parties engaged in precisely similar undertakings; but all these important provisions were contained in local acts, little known and very partially promulgated. Another inconvenience of less consequence, arising from this system of legislation, was the necessity of repeating in every railway act the same multitudinous enactments.

To remedy these inconveniences several acts were passed in the session of 1845, which are now commonly called the 'Consolidation Acts.' The first is the 'Companies' Clauses Consolidation Act' (c. 16), by which were consolidated all the provisions which had usually been inserted in acts with respect to the constitution of companies incorporated for carrying on undertakings of a public nature. This act is not peculiar to railways alone, but affects all companies which apply to parliament for incorporation, and which require the powers contained in it. It regulates the distribution of the capital into shares, the registry of shareholders, the transfer of shares, the payment of calls, the remedies against shareholders, the powers of the company to borrow money, their general meetings, the votes of the shareholders, the appointment and rotation of directors, their powers and proceedings, the appointment and duties of auditors, the accountability of the officers of the company, the form of books of accounts to be kept, the declaring of dividends, the making of by-laws, the settlement of disputes by arbitration, the service of notices upon the company and by the company upon shareholders, and the recovery of damages and penalties. By a similar act (c. 17) the provisions of a like nature are consolidated with respect to all companies incorporated for carrying on undertakings of a public nature in Scotland.

The next act is the 'Lands' Clauses Consolidation Act' (c. 18), by which are consolidated all the provisions usually inserted in acts authorising the taking of lands for undertakings of a public nature. It provides for the purchase of lands by agreement, for the compulsory purchase of lands and the assessment of their value, for the form of conveyances, the entry upon the lands of the promoters of the undertaking, and for dealing with the various interests in land, as copyholds, common lands, mortgages, rent-charges, leases, &c. A similar act for the same purposes was passed for Scotland (c. 19). These acts also are applicable not only to railways but to all other undertakings in which compulsory powers of taking land are necessary.

The last of the series is the 'Railways' Clauses Consolidation Act' (c. 20), which consolidates all the usual provisions of previous railway acts, which relate generally to the construction of the line and the works connected with it, to the drainage of lands affected by the railway, the temporary occupation of land during the progress of the works, the crossing of roads, the construction of bridges, and the works required for the protection and accommodation of adjoining lands. It regulates the traffic in goods and passengers on the line, and prescribes the use of suitable carriages and engines.

These acts did not affect the provisions of local acts which had been passed before the session of 1845; but the acts of that session and all subsequent acts have simply adopted the three consolidation acts without repeating them, and where any special powers not contained in these acts are sought for by the parties, they are contained in distinct clauses, which are obvious variations from the ordinary law.

In the same year it was observed that various railway acts of that session had given to companies general powers of granting or accepting leases, sales, or transfers, of their own or other lines of railway; and as the exercise of such powers without control was regarded with jealousy, as being liable to lead to an amalgamation of lines, for which separate acts have been passed, without the distinct authority of parliament being obtained, in each case; an Act (8 & 9 Vict., c. 96) was passed, declaring that no such sale, lease, or transfer, should be lawful, unless under the authority of a distinct provision in some act of parliament, to that effect, specifying by name the railway to be leased, sold, or transferred, and the company or party by whom such lease, &c., may be made, granted, or accepted.

Another act must here be referred to in connexion with railways. The Joint Stock Companies' Act of 1844 (7 & 8 Vict., c. 110), though applying generally to another class of companies, contains provisions which affect the laws relating to railways. Before the passing of this act, it was only necessary for railway companies to comply with the standing orders of both Houses of Parliament before they applied for a bill to authorise the undertaking: but other conditions must now be complied with. Before the promoters of a railway may publish any prospectus, handbill or advertisement, they must return to the Registrar of Joint Stock Companies, 1st, the proposed name of the company, 2nd, its business or purpose; and 3rd, the names, occupations, &c., of the promoters; and either before or after the prospectus is published, they must return their provisional place of business, the names of the committee, &c., with a written consent of each promoter to become such, and an agreement to take one or more shares; the names, residence, &c., of the officers of the company, and of the subscribers; and a copy of the prospectus itself before it is circulated or made public. When the three first particulars, at least, are complied with, the promoters are entitled to receive a certificate of provisional registration.

The promoters may then assume the name of the proposed company 'provisionally registered,' and may open subscription lists, and allot shares and receive deposits not exceeding 10*s.* for every 100*l.*, and such further deposit as may be required by the standing orders, and may perform all the acts necessary for obtaining an act of parliament.

In order to obtain a certificate of complete registration, the company must send to the registrar a copy of the 'Parliamentary Contract,' and the 'Subscribers' Agreement,' together with certificates of the deposit, at the proper offices, of the subscription contracts, plans, sections, and books of reference. When the certificate has been obtained, the promoters may use the name of the company 'registered,' may have a common seal, may sue and be sued in their registered name, and may enter into contracts, conditionally upon the passing of the act, for the execution of works, for the supply of stores, or for any other necessary purpose of the company.

Subject to these conditions the companies must comply with the standing orders of both Houses of Parliament, and apply for bills to incorporate them and authorise their undertakings.

In the session of 1846 several acts were passed affecting railways. The first (9 & 10 Vict., c. 20) introduced an improved method of effecting the deposits of moneys required by the standing orders of Parliament, to be deposited by the subscribers to undertakings; and granting the privilege of depositing Exchequer Bills and other public securities instead of money. This act was rendered necessary on account of the great inconvenience sustained by the promoters of railway bills and by the public, from large sums of money being suddenly withdrawn from the money market which were locked up unprofitably in the hands of the accountant-general of the Court of Chancery, and were not very readily invested in government securities.

The second (9 & 10 Vict. c. 28) facilitated the dissolution of railway companies which had not on the 3rd of July, 1846, obtained acts of parliament to authorise their undertakings, and prescribed the form and arrangements under which such dissolution should be effected.

The third is an act for constituting Commissioners of Railways, which transfers to the commissioners to be appointed all the powers and duties of the Railway Department of the Board of Trade. The commission is to consist of a president, with a salary of 2000*l.* a year, two paid commissioners, with salaries of 1500*l.*, and two unpaid commissioners. The president and the two unpaid commissioners will be qualified to sit in Parliament; but the two paid commissioners will be disqualified. In addition to the ordinary power of the Railway Department they are to examine and report upon any subject relating to any railway or proposed railway, which shall be specially referred to them for their opinion, by Her Majesty or by either House of Parliament. And authority is given them, for that purpose, to inspect and survey any proposed line of railway, with all the powers possessed by the officers engaged in the Ordnance Survey, and to charge the expenses to the promoters. (9 & 10 Vict. c. 105.)

Two other acts, though not directed peculiarly to railways, may here be cited. By one the ancient law of deodands was abolished (9 & 10 Vict. c. 62); and by the other a mode of recovering compensation where death is caused by accidents, is established. In such cases an action may be brought by the executor or administrator of the deceased, for the benefit of the wife, husband, parent, and child; and the damages which may be recovered from the parties by whom the accident was caused, are to be divided amongst the several parties in such shares as the jury shall direct. (9 & 10 Vict. c. 93.) This is assuredly a wise amendment of the law, as it substitutes a compensation to the relatives of the deceased for a deodand upon the engine or carriage, which is paid, as chance may determine, to the lord of the manor or to the crown.

These are the several statutes relating to railways; and a few remarks will be sufficient to explain their general operation and the proceedings which have been adopted for carrying into effect their provisions. It has already been stated that, by virtue of the act of 1844, the Railway Department of the Board of Trade was constituted. Its general object was to enforce the provisions of that and other acts, and to report to Parliament its own proceedings, the progress of railway communication, the accidents which occurred, and other matters which come within its cognizance. Its functions were originally confined therefore to the general supervision of railways already authorised by Parliament; and although railway bills were directed to be sent to the Board of Trade, the Railway Department took no active or ostensible part in reference to railway schemes about to be submitted to parliamentary investigation; but in consequence of the recommendations of a select committee of the House of Commons in 1844, the Board was instructed by the Lords of the Committee of Privy Council for Trade to undertake a preliminary examination of all railway schemes, to publish their decisions in the 'London Gazette,' and subsequently to submit detailed reports for the information of Parliament. This plan of investigating railway schemes out of Parliament was not altogether without precedent. It had been tried in the case of the four competing lines to Brighton in 1836; and in respect of the communication between London, Dublin, Edinburgh and Glasgow, and more extensively in regard to the railway communications of Ireland, in 1837; but this was the first experiment that had been made of a systematic investigation of all railway schemes by a government department, in anticipation of the judgment of parliament. The committee of 1844 had expressly declared that the reports of the railway department would in no sense be conclusive of the merits of the several schemes submitted to it, but that they would be regarded by parliament merely as aids towards the formation of its own conclusions (5th Report, p. xv.): but the publication of its decisions in the Gazette, and the authoritative character of its proceedings and reports produced a very general impression that it had been invested with much greater authority than it really possessed, and that its adjudications would be acknowledged by parliament as final. On the meeting of parliament, however, in 1845, this opinion was very soon discovered to be erroneous, and committees of the House of Commons proceeded with the investigation of the several bills very much in the same manner as if no reports had been referred to them for their guidance. In many cases their decisions may have been influenced by the reports of the Board, but the reports themselves, though ably written and often of the highest value, were not founded upon a public examination of witnesses and a full hearing of the parties, and on that account did not obtain such confidence as to be held conclusive, when interests of such magnitude were concerned. And it may be doubted whether, under any circumstances, any body whatever, less strong and irresponsible than parliament itself, could at that time have withstood the manifold influences of railway companies and speculatists. At all events this experiment of the railway department was admitted to be a failure, and by a minute of the committee of Privy Council for Trade, of the 10th of July, 1845, the Board has since directed its attention to questions affecting the public safety and to considerations of public utility, but has in no case pronounced an opinion on the actual or comparative merits of any railway schemes. During the whole of the session of 1846 there was an unprecedented pressure of railway business before parliament, but without any aid from the government it was disposed of, in the usual manner, by committees. It has been stated that all the powers of the Railway Department of the Board of Trade have been transferred, by a recent act, to the Commissioners of Railways; and it is most probable that the experiment of reporting upon the merits of railway schemes, which failed before, may now be revived; but under the act it will be confined to such cases as may be specially referred by the crown or either House of Parliament. The difficulty which existed before in regard to the degree of authority which preliminary inquiries and reports should possess will remain, it is feared, as great as ever. Unless the reports of the commissioners be regarded as conclusive of the matters referred to their consideration, the intolerable evil will exist of three distinct investigations before three tribunals, and at an enormous expense to the promoters of railways. The decisions of the commissioners may be reversed by the Commons, whose decisions again may not meet with the concurrence of the Lords; and thus after three inquiries a bill may be lost at last. The only mode of avoiding this evil, which was produced in 1845 by inconclusive preliminary inquiries, will be to refer questions of fact to the investigation of the commissioners and to hold their reports as final in reference to those facts. It will be necessary, also, that their inquiries shall be of a more public and judicial character, in order to secure public confidence.

Principles of Design and Construction.—Under that division of the article RAILWAY, pp. 249-251, which treats of the designing of a railway, it is shown that the tendency of experience was rather to lead to economy in the original cost of railway works by the admission of comparatively steep gradients, than to the sacrifice of every other consideration to the obtaining of a very level road. In the new railways for which acts have been obtained since 1840 the result of the modified opinions of engineers upon this point is apparent in the frequent adoption of gradients of 1 in 200, 1 in 150, 1 in 100, and, in several cases, of still steeper slopes, which, by allowing a nearer adherence to the natural surface, leads to considerable saving of expense in comparatively easy countries, while it allows the conducting of railways in many cases through districts which, a few years since, would have been deemed utterly impracticable. The Lancaster and Carlisle and Caledonian railways, passing through a mountainous country where, notwithstanding the introduction of gigantic engineering works to improve the gradients, several long and steep slopes occur, are cases in point. On the Caledonian line especially very formidable slopes were found inevitable, those between Beattock and the summit of the Clyde pass, a distance of nearly 14 miles, averaging 1 in 97, and comprising an ascent of 1 in 75 for 5½ miles. The Tunbridge Wells branch of the South-Eastern Railway is another example, upon a smaller scale, in which experience has proved that with engines of suitable construction, a line with an average rise of 1 in 100 for upwards of 4 miles, part of which has a slope of 1 in 80, and which, owing to the peculiarly difficult nature of the country, forms a continuous series of curves of smaller radius than is usual upon locomotive lines, may be worked in both directions with speed, safety, and regularity. In the Report of the Railway Department of the Board of Trade in 1845 upon projected railways in the Manchester and Leeds district many cases are cited in proof of the assertion 'that such gradients as were formerly thought objectionable are now adopted every day as a matter of course; and as the capabilities of the locomotive have been enlarged, gradients of a class which would have been considered a few years ago altogether impracticable, have come into general use.' Among the cases cited are the inclined planes on the London and Birmingham Railway, from the Euston Square station to Camden Town, rising in some parts at the rates of 1 in 66 and 1 in 75; that by which the Manchester and Leeds Railway is connected with the Victoria station at Manchester, rising 1 in 59 for 1000 yards and 1 in 49 for 640 yards; and that by which the Edinburgh and Glasgow Railway is conducted into Glasgow, with a slope of 1 in 42 for a distance of 1½ mile; in all of which the use of stationary engines and ropes had been either wholly or in a great measure discontinued, it being found that the trains might be worked efficiently and more conveniently by locomotive engines. The Lickey incline, on the Birmingham and Gloucester Railway, is likewise referred to as 'a conclusive proof that a gradient of 1 in 37½ for a length of 2 miles 3 chains may be worked by the aid of an engine constructed for the purpose, without serious inconvenience to an extensive traffic;' and as 'a proof that such an incline may be descended without danger by the force of gravity, regulated by the action of breaks.' In reference to curves it is observed in the same Report that practical experience has led to a similar modification of the views formerly entertained. 'The Newcastle and Carlisle Railway,' observes the Report, 'presents an instance of a line which is almost one continued succession of curves, of every degree of curvature, up to 8 chains radius, and with steep inclines, being worked with economy and safety; and, among other cases, there are upon the Manchester and Leeds Railway two curves of 10 chains (220 yards) radius, 'away from any station, and in a gradient of 1 in 82, over which their trains have been worked for upwards of four years, without the slightest accident or practical inconvenience.' Special precautions are, however, adopted to prevent danger; the engine-drivers being warned by inscribed boards at the side of the railway to shut off their steam on approaching the curves referred to.

As connected with the design of a line of railway we may further observe, that *surface-crossings* have been allowed much more extensively in recent railway acts than in those of 1836 and the years immediately following. For some years after the great period of railway speculation in 1836 and 1837 the degree of uncertainty which yet remained respecting the remunerative character of railways, combined with the enormous excess in the cost of most of the lines in progress above the parliamentary estimates, and with some other circumstances, almost put a stop to the commencement of any new schemes; and when at length, in the sessions of 1842 and 1843, symptoms of revival began to appear, the new schemes brought forward were mostly under a guarantee from some established company, and were, almost without exception, distinguished by features calculated to reduce the cost of construction; such as having only a single track, and the reduction of the earth-works by the adoption, as above explained, of comparatively steep gradients. This peculiarity, by keeping the level of the railway nearer to the natural surface of the ground, led necessarily to the more frequent use of surface-crossings; because the economy of construction aimed at would have been neutralised if, as must often have happened in a level country, the roads crossing the railway had to be raised or lowered, and passed by means of bridges. These principles of cheap construction were very closely canvassed in 1843, in a warm parliamentary contest upon the bill for the Northampton and Peterborough branch from the London and Birmingham railway; and having been sanctioned by parliament in that case, were soon applied to several other lines, for which acts were obtained in 1844 and 1845. Most of the lines thus projected for working with a single track either have been or are likely to be doubled, the increase of traffic having proved, in many cases, sufficient to render such a measure necessary; but their other peculiarities remain, and have been largely imitated in the new lines sanctioned in 1846, upon which surface-crossings are very numerous. Wherever this mode of crossing is allowed, the gates are kept shut across the road, excepting when opened by an attendant, so that the danger occasioned to trains upon the railway is exceedingly slight.

Permanent Way.—In the construction of the upper works of a railway, to which this name is given, more extended experience appears to be leading engineers to a greater uniformity of practice than prevailed when the P. C. article, which treats of this subject in pp. 254-256, was written. The plan of affording continuous support to the rails by means of longitudinal timber bearings, although still adhered to by Mr. Brunel, and employed upon lines in connexion with the Great Western railway, appears to have lost favour with some engineers; it being found that their use involves some loss of engine-power, probably from the greater yielding of the road, occasioned or favoured by the actual lightness of the rails as compared with those which are supported at intervals only, and by the comparative weakness of their form. This peculiarity has been ingeniously turned to advantage by Mr. Brunel in the descending track in the Box tunnel, upon the Great Western railway, which occurs upon a slope of 1 in 100. By substituting for the ordinary rail a comparatively thin plate of iron, the inner edge of which rests upon a considerable thickness of felt, he has produced a road in which the yielding character attributed to the longitudinal timber construction is increased to such a degree as to act as a constant, though slight, retardation to the trains running down the line. A road laid upon longitudinal timbers appears also to be more difficult to *pack* or keep to the true level than another; and the working of the trains, combined with the effect of expansion and contraction, causes the connexion between the rails and the timbers to work loose. Much evidence both for and against this construction of road was laid before the Gauge Commissioners, from which we gather that the comparative smoothness and quietness ensured by it do not, in the opinion of most engineers, afford sufficient advantages to counterbalance its defects. On the Hull and Selby (narrow gauge) line, which was partly laid upon longitudinal timbers and partly upon transverse wooden sleepers, a good opportunity was afforded for comparing the two plans; and the evidence of Mr. Gray, who was formerly locomotive superintendent upon that line, shows a decided preference for the cross-sleepers. He observes that there was a great difficulty in keeping the rail in perfect contact with the longitudinal timbers; that they require to be pressed upon the timber with a constant pressure nearly equal to that coming upon them during the passage of a train; and that in the absence of such a pressure, which is unattainable by any mode of fastening now in use, water gets in between the rail and the timber in wet weather, and is forced out with great violence during the passage of an engine; each wheel forcing it out against the opposite one. 'I have,' says Mr. Gray, 'seen the engine going out almost as clean as a new pin, and before half an hour had elapsed you could scarcely see a clean spot on it.' He further states that, having been told by an engine-driver that his wheels slipped more upon the longitudinal timbers than upon the cross-sleepers, he, though incredulous, tried it himself one frosty morning, and found that after the engine slipping so much upon a level part of the road which was laid upon longitudinal timbers as to lead him to fear that the train would be unable to ascend an incline of 16 feet per mile which it was approaching, he found, on reaching the incline, which was laid with cross-sleepers, that the slipping ceased, and the engine 'went up like an arrow.' The slipping re-commenced on reaching another portion of road laid on longitudinal timbers, and again stopped on reaching the cross-sleepers. Upon the Croydon railway, which was originally laid with longitudinal timbers, the construction has been found so unsatisfactory that, in the relaying, which is nearly completed at the time we write (November, 1846), heavy bridge rails, laid upon cross-sleepers, have been employed.

The kind of rail now most commonly employed resembles that marked *k* in the cut inserted at p. 255 of the article RAILWAY, P. C., which is variously called the I, the H, and the double-T-rail; and the weight is seldom less than 70 or 75 lbs. per yard. In some cases heavier rails have been used; the heaviest yet employed, we believe, being those laid on the Great Southern and Western (of Ireland) Railway, between Dublin and Carlow, by Sir John Macneill, which weigh 90 lbs. to the yard. These rails however are laid in a peculiar method of Macneill's invention, which was first tried on the Dublin and Drogheda Railway, and in which the use of cast-metal chairs, keys, and pins is avoided, the rails being connected with the sleepers in a more direct and simple manner, which is stated to be highly favourable to security and smoothness of motion.

While longitudinal bearings of timber have lost favour, transverse wooden sleepers, which were formerly regarded rather as temporary substitutes for stone blocks upon embankments and places where sinking might be expected, than as a permanent means of support for the rails, have been brought into very extensive use, and are considered by many to afford the best kind of foundation. The ease with which they are laid, the comparatively small depth of ballast which they require, and their efficiency in keeping the line in gauge, or preserving the parallelism of the rails, in the event of a derangement of level, favour their use; while the adoption of some one or other of the protective processes noticed under TIMBER, PRESERVATION OF, P. C. S., p. 632, removes the objections arising from the natural tendency of the material to decay. The permanent way of the South Eastern Railway, laid under the superintendence of Mr. William Cubitt, is an excellent example of the cross-sleeper construction, which has been imitated in relaying the Croydon line, and upon some other railways. A minute account of this permanent way, communicated by Mr. Pope to the Institution of Civil Engineers, was printed in the 'Civil Engineer's and Architect's Journal,' for June, 1842, pp. 200-202, which, as well as a shorter notice in the 'Railway Chronicle' for 1846, p. 899, is illustrated by engravings of the mechanical details. The most striking feature of this construction is the use of sleepers of a regular triangular section, 9 feet long, 11½ inches broad, and 7 inches deep, formed by sawing square baulks of Baltic fir diagonally into four pieces. These are laid with the broadest flat surface (the base of the triangle) uppermost, the double slope of the under side constituting a form admirably adapted for bedding itself well in the ballast. The chairs, which are of a pattern patented by Messrs. Ransome and May, of Ipswich, are of a shape well devised for ensuring sound casting, and obtaining the greatest strength from a given weight of iron, and have a single projecting rib or buttress in the centre of each cheek or jaw; and those used for the intermediate points of support are secured to the sleeper by two pins, one at each end, the holes to receive them being formed alternately on opposite sides of the medial line of the chair and sleeper, that the driving of the pins may have the least possible tendency to split the sleeper. The joint-chairs however, or those which are used at the junction of two lengths of rail, have three instead of two holes to receive the fastening pins, which are trenails of compressed oak, 6 inches long, and tapering from 1½ inch to 1¼ inch in diameter. The cavity in the chair is so contrived that the rail shall only touch it at two points, the base and the top of the cheek or jaw, in order that the true angle of obliquity of the rail, and its steadiness in the chair, may not be affected by any trifling irregularity of shape; and the rails are secured in their place by keys of compressed fir. Upon the South-Eastern line the rails weigh 70 lbs. per yard, the ordinary chairs 20 lbs. each, and the joint-chairs 28 lbs.; and the chairs and sleepers are placed at an *average* distance of 3 feet from each other, though the first chair from the joint, in each direction, is placed at a distance of 2 feet 6 inches to 2 feet 8 inches, while the intermediate space is divided into three equal parts. Upon the Croydon line rails of 75 lbs. to the yard are used, with intermediate chairs of 21 lbs., joint-chairs of 38 lbs., and six, instead of five, sleepers to the 15-feet rail.

In a communication made by Mr. W. H. Barlow to the Institution of Civil Engineers on the 14th of January, 1845, and reported in the 'Athenæum' for that year, p. 72, a kind of hollow or tubular key of wrought-iron, made to press equally against the jaw of the chair, the middle web of the rail, and its top and bottom flanches, is recommended as a substitute for the compressed wooden keys so generally used; which, from their position just above the surface of the ground, are much exposed to decay, and are also liable to shrinking, and to injury from driving up when they have shrunk. On the Midland Counties Railway the wooden keys have not been found to last more than about five years; and as they cost from 8*l.* to 10*l.* per 1000 (upwards of 7000 being used in a mile of railway with double track and sleepers 3 feet apart), the expense of renewal becomes an important item. The hollow iron keys had, Mr. Barlow states, been tried with success on the Midland Counties, South-Eastern, Warwick and Leamington, and some other railways.

In addition to the evidence before the Gauge Commissioners, already referred to, which is well worthy of diligent perusal for its information upon this and other branches of railway engineering, the reader may consult with advantage the reports given in the 'Civil Engineer's and Architect's Journal,' of Mr. Vignoles's lectures, delivered when professor of civil engineering at University College, London, two of which, reported in the number for September, 1842, pp. 312, 313, relate solely to the permanent way, or upper works of railways.

Gauge.—It has been stated under RAILWAY, p. 256, that the gauge, or width of track, upon the Liverpool and Manchester railway, which subsequently became the model for other lines, was copied from some of the colliery railways in the North of England, where a width of 4 feet 8½ inches had been found amply sufficient for mineral traffic, allowing as it does, by the projection of the body over the wheels, the use of carriages to the full as large as any employed upon common roads. That railway was in a great measure formed before it was determined by what power to work it, so that, although practical experience might have been cited in proof of the sufficiency of the width for the use of locomotive engines, the gauge appears to have been selected on other grounds, and without reference to the motive power. Soon, however, after the successful application of locomotive engines to the attainment of a high rate of speed, some inconvenience began to be felt from the want of sufficient space for cleaning and repairing the machinery as then arranged, and, as the case is pithily put by Mr. Sidney, in his 'History and Prospects of the Railway System, Illustrated by the Evidence given before the Gauge Commission,' 'it became a favourite idea with many engine-builders, that a few additional inches to the gauge would increase the power, and in every way much improve the locomotive;' while 'others, considering that all railways must eventually communicate, applied themselves to simplifying the engine and adapting it to the gauge;' and, he adds, 'even up to the present day, the question is, shall the engine be adapted to the gauge, or the gauge to the engine?'

The railways which were projected in immediate connexion with the Liverpool and Manchester adopted its gauge, and the same was at first contemplated for the Great Western railway, which, as originally projected in 1833, was to commence by a junction with the London and Birmingham line a few miles from London. As, however, it ran into an entirely new district of country, and one in which gradients of a very superior order were attainable, it was determined, upon the recommendation of Mr. Brunel, to seek for an independent entrance into London, and, by the adoption of a wider gauge, to aim at a higher degree of speed, safety, and accommodation than any other line could afford. It was then believed that each main-trunk railway would continue in a great measure independent of every other, and therefore that no serious difficulties would arise from the diversity of gauge, and Mr. Brunel conceived that by the adoption of a gauge of 7 feet instead of that of 4 feet 8½ inches, he should be able, by placing the bodies of the carriages between instead of over the wheels (a construction, we may observe, which he has not tried, and against which several important reasons might be urged), to save friction by the employment of larger wheels, without throwing the centre of gravity higher than in ordinary railway carriages; that he should thus also ensure greater stability and a more steady motion; that he should be able to convey stage-coaches and other common road carriages upon low trucks, by running them between the railway wheels; that he should obtain facilities for the adoption of larger and more powerful engines than had as yet been used upon any railway; and thus, by a combination of mechanical facilities, be able to take advantage of the superior levels of the line for the attainment of very high speed. During the progress of the works some of the shareholders became dissatisfied with the increased expenditure involved in the adoption of this greatly enlarged gauge, and at length, in 1838, Messrs. Wood and Hawkshaw, two experienced engineers, were called in to examine and report upon the works of the Great Western line, which was then completed as far as Maidenhead, especially in reference to the increased gauge. Their reports, although upon the whole unfavourable to the wide gauge, did not lead to any change in this particular, and consequently the construction of the Great Western line, with its extension to Exeter, and its first important branch, the Cheltenham and Great Western Union line, were completed upon the 7 feet gauge. In the mean time the Eastern Counties railway, another line which was then expected to continue in a great measure isolated, was, upon the recommendation of Mr. Braithwaite, who simply desired an extra width of a few inches, to accommodate the mechanism of the engines, laid with a gauge of 5 feet, which was necessarily followed in the laying of the Northern and Eastern line, after it had been determined to connect it with the Eastern Counties at Stratford. When, however, in 1844, the Eastern Counties company, with which the Northern and Eastern was then amalgamated, obtained powers for extensions which would eventually bring their lines into connexion with the existing lines towards the North of England, the evil of diversity was stopped before any practical inconvenience arose from it, by the alteration of the eighty-six miles of railway then completed to the national standard of 4 feet 8½ inches; an alteration which, though involving also the modification of all the engines and carriages, was effected without stopping the traffic for a single day, and without any accident. In the same year the Bristol and Gloucester railway, which was originally projected as a narrow-gauge line in extension of the Birmingham and Gloucester, but which, through the influence of the Great Western company, had been laid down on the broad gauge, was opened, and then, for the first time, the evils which had been predicted as likely to arise whenever a *break of gauge*, or point of meeting between two different gauges should occur, were actually felt. The necessity imposed upon travellers between Bristol and Birmingham of changing carriages at Gloucester was found to be sufficiently annoying; but the effect of the break upon goods and cattle trains, and the transhipment of horses conveyed by passenger trains, was found to be far more formidable.

In the parliamentary session of 1845 the gauge question assumed great prominence in consequence of the obstinate contest then carried on between the broad and narrow gauge interests for the privilege of constructing lines between Oxford, to which place the Great Western company had a broad-gauge branch formed under an act of 1843, and Rugby on the one hand and Worcester and Wolverhampton on the other. The Board of Trade reported against the broad-gauge lines mainly upon the ground that an extension of the broad gauge into a new district of such importance was objectionable, both from its comparative unfitness for mineral traffic, and from the belief that the break of gauge would be more injurious if carried into the interior of the commercial district than if limited to the port of Bristol (it being then proposed to reduce the Bristol and Gloucester line to the narrow gauge), and the junction at Oxford. Parliament, however, finally determined in favour of the lines promoted by the Great Western company, chiefly upon the ground of their engineering superiority, but without expressing any decided opinion upon the question of gauge, which had, by this memorable contest, assumed a national importance. Indirectly it led to a full investigation of the question in all its bearings, an address being, before the close of the session, voted in the House of Lords on the motion of Lord Dalhousie, and in the House of Commons on the motion of Mr. Cobden, for a royal commission to inquire and report 'whether in future private acts for the construction of railways provision ought to be made for securing a uniform gauge; and whether it would be expedient and practicable to take measures to bring railways already constructed, or in progress of construction, into uniformity of gauge.'

The commissioners appointed in consequence of this motion were Colonel Sir Frederick Smith, of the Royal Engineers, who had for some time held the office of Inspector-General of Railways under the Board of Trade; Professor Barlow, of the Woolwich Military Academy, who had some years before been upon the Irish Railway Commission; and Professor Airy, the Astronomer-Royal. After a careful investigation, in the course of which many experienced witnesses were examined, experiments were tried upon both gauges, and important statistical returns were obtained from the various railway companies, these gentlemen, in January, 1846, made a report in which the subject is treated under three distinct heads: the effects of break of gauge, the remedies proposed for the evils of breaking gauge, and considerations on the general policy of establishing a uniformity of gauge throughout the country. As the subject is likely to increase rather than diminish in general interest, it may be well to present a brief outline of the views of the commissioners under each head.

With reference to the evils of break of gauge, they express an opinion that they will be less felt by persons travelling in fast or express trains than by any others, such persons being seldom encumbered with much luggage, and no carriages or horses being, under ordinary circumstances, conveyed by such trains. With such therefore the evil may be limited to a comparatively trifling delay, confusion, and personal discomfort, with some risk of loss of luggage during the transfer. In the case of ordinary or mixed trains, which convey many more passengers, and a much larger quantity of luggage, the evils would be much more serious. Experience shows how greatly those trains are preferred in which, although the traveller may have to pass over the lines of different companies, passengers may be conveyed from end to end of the journey without change of carriage; and many companies meet this preference, and the desire to have luggage undisturbed, by running carriages through, even at the cost of bringing them back empty. The transfer of carriages and horses involves also much delay, and in the case of many horses, danger also. With reference to such trains the commissioners observe that 'the change of carriages, horse-boxes, and trucks, and the transference of luggage of an entire train of much extent, must even in the day-time be an inconvenience of a very serious nature; but at night it would be an intolerable evil: and we think legislative interference is called for to remove or mitigate such an evil.' With reference to goods trains also, the evidence of carriers was very decisive as to the evils attending any such disturbance and re-packing as must take place in removing goods from one set of trucks to another. Under present circumstances very little re-arrangement of goods takes place in the course of the journey, and even at the important station at Birmingham five-sixths of the goods waggons pass without re-arrangement. In the conveyance of minerals the inevitable expense of the transfer from one set of waggons to another would, without taking into account other considerations, seriously affect the cost of transmission; and 'the difficulty of shifting cattle would be so great as to present an insurmountable obstacle to such an arrangement, from the excited state of the animals after travelling by railway, and the resistance they in consequence offer when it is attempted to force them a second time into a railway waggon.' In reference also to the conveyance of troops the interruption would cause much confusion and delay, requiring, as indeed it does to meet the more ordinary contingencies of general traffic, a much larger carrying stock than is required when the carriages of one company can run over the lines of another.

With regard to the means suggested for remedying or mitigating the evils of breaking gauge, the commissioners express a very decided opinion against the safety of *telescopic axles*, or contrivances by which the wheels of one carriage, or of a whole train, might be shifted at pleasure to suit different gauges, on account of the inevitable danger, to say nothing of the increased expense attending any such mechanism. They also reject 'as entirely inapplicable to the traffic of railways,' the proposal to convey narrow-gauge carriages upon the broad-gauge lines by mounting them upon trucks; an arrangement which could only meet the difficulty as regards a certain portion of the traffic, and that by the conveyance of an enormous additional dead weight, attended by both delay and danger. The plan of using shifting bodies for passenger-carriages, capable of being removed from one carriage-frame to another, although practised to a limited extent in France in the conveyance of diligences which run partly upon a railway and partly upon a common road, is open to serious objections on the score of insecurity and inconvenience, and it is not expected that the system will be retained in France when the railways on which it has been tried shall be completed. The use of loose boxes, or shifting bodies, for goods and minerals, constructed so as to be transferred by machinery from one truck to another, was the subject of some rather contradictory evidence; but the commissioners express their belief of its inefficiency for the purpose proposed: and they sum up their conclusions upon this head by stating their belief that no method had been proposed to them 'which is calculated to remedy in any important degree the inconveniences attending a break of gauge.'

In reference to the policy of establishing uniformity of gauge throughout the country, the commissioners express their conviction that the time has arrived when, if steps cannot be taken to remove the existing evil of diversity, it appears at least imperative that the wider spread of the evil should be prevented. The question, as applied to the existing state of things in this country, involves, they observe, not only the consideration of the relative length of the lines laid on the two different systems which now remain in England, 'the comparative mechanical efficiency of each, the general superiority of one over the other, their adaptation to the wants of the country, and the possibility as well as the policy of a change, but also the pecuniary means of effecting it.' Another view of the subject relates to the expediency of laying additional rails to enable carriages suitable for both gauges to run upon the same line, a plan attended with several difficulties, but which is expected to be adopted in some places where, under present arrangements, the two gauges will intermingle. The difficulty of keeping such a double-gauge road in repair would be serious, and the complication introduced at points and crossings would be very likely to occasion accidents. If done in the cheapest way, by the addition of a third rail only, carriages of both gauges could not be safely used in one train, because the centre of traction would not be the same, while if two additional rails were used the expense would be great, and the complication would be still further increased. This point was illustrated in the evidence of Mr. Wyndham Harding, who showed by a diagram that while at a junction between two railways of ordinary construction, with two tracks each, there are only *six* crossings or intersections of the rails, the number is increased by the addition of two supplementary rails to each track, to *twenty-eight*. It was further pointed out in the evidence that great inconvenience would attend the use of carriages of different widths on the same line from the circumstance that the station-platforms made to suit the broad would be too far off from the narrow carriages.

With reference to the question, so important in connexion with the suggested enforcement of uniformity, as to what is the best gauge, the commissioners discuss first the question of comparative safety, to which we shall have occasion to advert hereafter; and respecting which they report 'that as regards the safety of the passengers no preference is due, with well-proportioned engines, to either gauge, except perhaps at very high velocities,' where they 'think a preference would be due to the broad guage.' As regards the relative accommodation and convenience for passengers and goods, they consider that the narrow-gauge carriages affording seats for three persons abreast in the first-class, and four in other carriages, are rather preferable to the broad-gauge vehicles, which contain four and six persons respectively in similar cases, because passengers usually like to sit where they can look out at the window. Privacy is provided for in some broad-gauge carriages by a partition in the middle, by which the large compartments for eight passengers each are subdivided into two for four each. 'Until lately the broad-gauge carriages were,' the report observes, 'altogether more commodious than those of the narrow-gauge; but recently carriages have been introduced on several of the narrow-gauge lines nearly as lofty as those on the broad-gauge, and equally commodious.' The evidence as to the comparative ease and smoothness of the motion, which is affected by many other circumstances than the width of gauge, was very contradictory; but upon the whole the commissioners believed, from personal observation, that at the higher velocities the motion is usually smoother on the broad gauge.' For merchandise and mineral traffic the chief bearing of the evidence is in favour of the narrow gauge, small waggons being generally preferred for meeting the contingencies of a fluctuating traffic, in which it is frequently necessary to send waggons partially laden; and also for the conveyance of goods which are liable to injury from pressure. In both kinds of traffic small vehicles (comparatively small, we should say, the ordinary narrow-gauge waggons being much larger than those used on common roads) appear to be found most convenient and economical. Witnesses from the mineral districts especially, 'state that the smaller waggon can be more easily handled and can be taken along sharper curves than would be suited to a broader waggon;' and are therefore more suitable where, as is often the case in such districts, the broken nature of the ground renders curves of large radius inconvenient and expensive. On the whole the commissioners 'consider the narrow gauge as the more convenient for the merchandise of the country.' The observations relating to comparative speed may be passed over with the remarks, that while upon the Great Western line the speed both of ordinary and express trains is somewhat greater than upon other lines, the excellence of the gradients, and some other circumstances independent of gauge, doubtless contribute to this result; and that while, looking to prospective improvements in locomotive engines, analogy would confirm the claim of the advocates of the broad gauge to the power of increasing their speed beyond its present limit, it may be questioned whether the present construction of railways would justify the attempting of a higher rate of speed than has been shown to be possible even upon the narrow gauge. In regard to the question of comparative economy the commissioners show that the cost for land, earth-works, masonry, permanent-way, turn-tables, &c., must be greater on the wide than the narrow gauge; that the cost of maintenance must also be somewhat greater; and that the first outlay for engines and carriages is affected in like way by the increase of width. How far this is compensated by the increased power of the engines and capacity of the carriages it is very difficult to ascertain; for in comparing statements of working expenses obtained from different companies, the circumstances are found to be so different as to render it impossible to deduce satisfactory information with strict reference to the economy of the gauges. By calculations based upon data furnished by the broad-gauge advocates themselves, the commissioners come to the conclusion that the traffic of the Great Western Railway might, if that line were altered to the narrow gauge, be worked at about the same expense for locomotive power as at present; and they argue that, 'if for the greater trunk-lines' of railway, such as are now in practical operation, 'a superiority were due to the broad-gauge system, that superiority would be less for lines yet to be constructed of a smaller amount of traffic;' so that 'if the preference were given to the narrow gauge for the existing lines, that system would be still more entitled to the preference for the railways of smaller traffic to which we look forward.'

After enumerating the several conclusions already quoted, the commissioners observe that, 'esteeming the importance of the highest speed of express trains for the accommodation of a comparatively small number of persons, however desirable that may be to them, as of far less moment than that of affording increased convenience to the general commercial traffic,' they consider the narrow gauge preferable for public convenience, and, were it imperative to produce uniformity, would recommend the alteration of the broad to the narrow gauge; especially taking into consideration 'that the extent of the former at present in work is only 274 miles, while that of the latter is not less than 1901 miles;* and that the alteration of the former to the latter, even if of equal length, would be the less costly, as well as the less difficult operation.' The question of an intermediate gauge is treated very briefly by the Commissioners, who felt that the evidence offered as to the efficiency of the 4 feet 8½ inches gauge, upon both English and Continental railways, was such as to counterbalance any theoretical advantage to be derived from a costly alteration to a gauge of 5 feet, 5 feet 3 inches (which, upon the recommendation of the Board of Trade, had been previously determined as the national or standard gauge for Irish railways), 5 feet 6 inches, or 6 feet, which latter is the largest dimension now advocated by any not directly interested in the 7-feet gauge. They computed that the total expense of altering the then existing broad-gauge lines to the narrow gauge, including the alteration or substitution of locomotives and carrying stock, would not much exceed 1,000,000*l.*; and though they neither recommend such an alteration at the public expense, nor conceive that the broad-gauge companies could be fairly required to make it at their own cost, they do recommend 'that the gauge of 4 feet 8½ inches be declared by the legislature to be the gauge to be used in all public railways now under construction, or hereafter to be constructed, in Great Britain;' that no subsequent alteration of such gauge be permitted without the consent of the legislature; that measures be taken to complete the general chain of narrow-gauge communication from the north of England to the southern coast; and that to avoid the evils of breaking gauge at the junctions to be formed by new lines if laid, as proposed,

* These figures are taken from a return made by the Board of Trade, and profess to be correct, to the 31st of July, 1845. If the openings which have taken place since that time were added, the case would appear much stronger.

on the narrow gauge, with the existing broad-gauge railways, some equitable means should be found of either producing entire uniformity by the reduction of the broad-gauge lines, or of adopting such measures as shall admit of the narrow-gauge carriages passing without interruption or damage along them.

The appearance of this report was speedily followed by the publication of various pamphlets upon the subject, and by the most strenuous efforts on the part of those interested in the broad gauge, to reverse or modify the recommendations of the commissioners, which, it was contended in 'Observations on the Report of the Gauge Commissioners,' issued by the broad-gauge party as a kind of counter report, would, if adopted, 'inevitably terminate all chance of future improvements in railway travelling,' by arresting the progress of that competition between the two systems to which we are undoubtedly indebted for recent achievements in speed, and from which it is pleaded much further advantage may be derived. The report was handed over to the Board of Trade for their consideration, and at a late period of the session of 1846 a bill was introduced, which subsequently became law, founded upon their suggestions. Admitting the general conclusions of the commissioners, the Board appears to have deemed the attainment of uniformity impracticable; and the act for the regulation of gauge therefore simply provides for uniformity upon such new lines as are not directly connected with the existing broad gauge, leaving it open to extend the broad gauge, under the acts of 1845, to Rugby and Wolverhampton, and into South Wales; and also in the country lying to the south and west of the Great Western and Bristol and Exeter lines, but restricting further extensions to branches of a few miles in length from the Great Western railway, and to such other cases as may be specially sanctioned by parliament. Under the operation of this act, the Birmingham and Oxford Junction line, although projected as an extension of the broad-gauge system, must be laid upon the narrow gauge, unless, as its promoters anticipate, powers for adopting the wide gauge can be obtained in a future session. It is felt by many who have deeply studied the subject, that this compromising arrangement must be regarded merely as a temporary adjustment of the difficulty, and that increased experience will convince even the proprietors of the broad-gauge lines of the necessity, for the promotion of their own interests as well as of the convenience of the public, of reducing their gauge to the national standard.

This important subject has already occupied so much of our space, that our remarks, founded upon the instructive evidence which has been brought before the public by the recent investigation, must be limited to two leading points, in both of which the public are deeply interested. The first of these is safety at high velocities. Happily the number of accidents which have already happened which can be regarded as even remotely bearing on the question of gauge, is too small to enable us to found any general conclusions upon them. Practically, the amount of safety attained on both gauges, where due care is exercised, is almost as great as can be expected. The comparative narrowness of base, which, as far as we remember, is the only definite element of danger charged upon the narrow gauge, does not appear by evidence to have proved injurious in any important degree. Probably no accident has ever occurred of which it can be regarded as the cause, and we are not aware of any in which it can be proved to have increased the damage. On the other hand, while it might be difficult to say that any particular accident which has happened upon a broad-gauge line might not have occurred had the gauge been narrower, the increased width may in many cases be seen to have an injurious effect. The greater weight of the engine and the larger amount of dead weight which, in practice, attends the use of broad-gauge carriages, increase the injurious effects of that almost irresistible momentum which so frequently leads to collisions, and which gives so fearful a character to many railway accidents. The greater length of the axles, although accompanied by increased thickness, increases the probability of fracture, or of such strains as might cause a carriage to run off the line, while, under ordinary circumstances, this evil is aggravated by the use of large wheels, which, when their flanges come in contact with the rails, act upon the axles with greater leverage than small ones would do. Adding to this the circumstance that a curve of given radius is less easily rounded by a broad than by a narrow-gauge carriage, and that the rails are more likely to be deranged by a heavy than by a light engine, we cannot avoid the conclusion that the risks of breaking down or running off the line by the failure of axles are considerably augmented by an increase of gauge. Another circumstance which materially affects this question is the effect of increased width upon the oscillatory or lateral motion of both engines and carriages. A short carriage is obviously more liable to this motion (which, at high speed, becomes dangerous from the flanges striking the rails on each side alternately, until at length the motion is sufficient to throw the carriage off) than a long one; and therefore a carriage suitable for the 7-feet gauge will, unless it be half as long again as would be used upon the 4 feet 8½ inches gauge, be less safe in this respect. Even upon some narrow-gauge lines the importance of a long proportion has led to the use of six-wheeled carriages, and such are exclusively used in the fast trains upon the Great Western line; but in order to attain an equal degree of safety in this respect, the broad-gauge carriages must be made so very large and heavy, as to be difficult to move at stations, where they must often be shifted by hand power, besides involving the conveyance of an enormous amount of dead weight when, as is often necessary in working branch lines, a carriage must be sent through for the accommodation of only two or three passengers. The ordinary second-class carriages of the Great Western line, mounted upon six wheels, accommodate *seventy-two* passengers, and are therefore only suitable for a very large and steady traffic; yet in these the length is no greater in proportion to the breadth than in the ordinary second-class carriages for *thirty-two* passengers each upon the narrow gauge. In goods waggons the same argument holds good with even greater force; while in the case of carriage-trucks and horse-boxes the length of the vehicle is absolutely regulated by the use to which they are applied. Some of the horse-boxes upon the Great Western line are, or were not long since, even shorter than they are wide, as regards the base upon the rails; the distance between the axles being only 6 feet 6 inches, while the distance between the wheels is 7 feet. Such a carriage, running as it were broadside foremost, must, at very high velocities, be productive of fearful danger to the train of which it forms a part. The same reasoning will of course apply to the engines as well as the carriages.

The second point to which we would direct attention is the bearing of the guage question upon the future prospects of the railway system, not as regards the importance of uniformity, or the comparative cost of construction and working, which points have been fully considered by the commissioners, but in reference to another feature involving the comparative merits of the gauges themselves. Admitting, for the sake of argument, that the broad gauge does offer greater facilities for conducting a very extensive traffic, which may be advantageously concentrated into heavy trains, it is well to bear in mind that the tendency of the numerous competing lines now in progress and contemplation, often promoted by the owners of the existing trunks, is to promote and render necessary the subdivision of traffic into small rather than its concentration into large trains, in order that the local traffic of such numerous lines may be developed to the utmost by very frequent dispatches, and by the lighter trains calling at numerous minor stations. All these considerations point towards the peculiar facilities of a narrow gauge as prospectively more desirable than the power of moving occasional large and heavy trains by such huge engines as are employed upon the broad gauge. Another important point is the facility offered by the use of small carriages for the extension of agricultural traffic, which has scarcely been touched by many railway companies. 'The traffic of the West of England,' observes Mr. Sidney, requires 'not huge unwieldy carrisges and trucks, but handy waggons, which may without inordinate trouble or expense be run into small road stations and sidings, to which a farmer may send his couple of fat oxen, or his score of sheep, or his load of corn, in conjunction with one or two more neighbours.' Of such local traffic, he states, there has been little upon the Great Western railway, although it runs through rich corn-growing and cattle-feeding countries, because 'the whole machinery is on too vast, costly, and magnificent a scale;' and he conceives that were it not for the inconvenience of break of gauge, a yet narrower gauge than 4 feet 8½ inches would be preferable for such districts. Mr. Robert Stephenson, in his evidence before the commissioners, referred to a line of about 60 miles laid down by M. Deroider between Ghent and Antwerp, upon a gauge of, he believed, 3 feet 9 inches, which was worked satisfactorily by locomotive engines, both for passengers and goods, and was constructed very economically, as a proof that even narrower gauges than our own may be used in some cases with advantage. In South Wales, where the broad gauge is about to be introduced through the influence of the Great Western company, its unfitness appears even more striking. The mines and iron-works in that district are usually situated in narrow valleys or gullies, in which sharp curves are unavoidable; and, to suit the peculiarities of the country, the local tramways are usually narrower than the common narrow gauge, and some of them as narrow as 2 feet 8½ inches.

Allusion was made in the course of the gauge evidence to the practice of sending passengers through from end to end of their journey without change of carriage, although they might have to pass over the lines of different companies. Those witnesses who endeavoured to mitigate the evils of variety of gauge pleaded, that as branches and connecting lines multiply, the practice of running carriages through must of necessity be in a great measure discontinued. The evidence of Messrs. Brunel and Saunders, the engineer and secretary of the Great Western railway company, was so calculated to convey an erroneous impression as to the practice of the other great companies in this matter, as to call forth an explanatory pamphlet on 'The Origin and Results of the Clearing System, which is in Operation on the Narrow-Gauge Railways; with Tables of the Through-Traffic in the year 1845,' in which it is observed that 'No sooner had the railways which extend from London to Liverpool been completed and connected in 1838, than it became evident that arrangements must be adopted to facilitate the passage of the through-traffic,' at the points where the three railways (then under different managements) joined, so that passengers might 'be permitted to perform any journey within the limits to which continuous communication by railway extended, without being required to change their carriage;' and that 'a similar principle must pervade the arrangements for working every description of through-traffic if the public were to be conciliated, and the resources of the railway-system developed to their full extent.' The importance and at the same time the difficulty of carrying out these principles became still more obvious when the lines extending from Rugby and Hampton to York were completed. For some time, however, dissensions arose between the different companies; it was difficult to obtain accurate returns of, and payment for, the use made by the several companies of one another's carriages and waggons respectively, and some of them 'came in the end to make an unacknowledged use of the carriages and waggons of others to an extent which amounted to a positive grievance.' Under these circumstances it occurred both to Mr. Robert Stephenson and to Mr. K. Morrison, the present manager of the Railway Clearing-house, that a remedy might be found in the establishment of a central office on the principle of the Clearing-house by which the business of the London bankers is so materially facilitated. [BANK, P.C., p. 385.] After some difficulties the proposed system was, on the 2nd of January, 1842, brought into operation on the railways extending from London to Darlington in one direction, and from Manchester to Hull in another, and it has been since adopted by the companies whose lines extend from Darlington to Carlisle, Sunderland, Hartlepool, and Scarborough; and from Birmingham to Gloucester, Birkenhead, Liverpool, Fleetwood, Lancaster, and Manchester. 'In a few months,' according to the pamphlet above quoted, which does not allude to the probable further extension to the north of Scotland, to which recent events leave no doubt that it will soon be extended, 'it will be in force on all the railways included in the area defined by a line passing from London through Gloucester, Liverpool, Fleetwood, and Glasgow, to Edinburgh, and returning by Berwick, Newcastle, Scarborough, Hull, Yarmouth, and Cambridge, to the metropolis; or, in other words, on all the narrow-gauge railways in Great Britain lying north of the Thames, with the exception of the few short lines which are beyond the limits of the area just described; an area which, it is hardly necessary to observe, is only prevented from extending to the southern parts of England by the intervention of a differential gauge.'

The fundamental principles of the Clearing-house system, the regulations founded upon which are very rarely departed from, are, that passengers shall be booked through at all principal stations, and conveyed to their destination without change of carriage; that horses and cattle be in like way carried through without change of conveyance, and goods without being shifted or re-assorted; that the companies respectively shall pay a fixed rate per mile for such carriages and waggons, not their own property, as they may use, and a further sum per day by way of fine or demurrage for detention, if kept beyond a prescribed length of time; and that all traffic accounts between the several companies shall pass through the Clearing-house. Without entering into the details of the method by which these objects are attained, or the advantages which either have been or are expected to be derived from the establishment of this system, the ultimate result of which will be to give to all the connected railways of Great Britain, as far as regards the working of the through-traffic, the character of one concern, conducted on a uniform system, we may state that the tables appended to the pamphlet show that in the year 1845, 517,888 passengers were conveyed an average distance of 146 miles each; while the average length of the railways upon which the system is in operation being only 41 miles, each travelled on an average over nearly four different railways, and passed three junctions or points of convergence; and that to accommodate these passengers, 59,765 railway carriages and 5813 trucks with private carriages were sent through. The tables further show that, in addition to the very large number of waggons used for the conveyance of coke, coal, and other minerals, of which no record is kept at the Clearing-house, 180,606 waggons loaded with merchandise were sent through in a similar manner.

Junctions, Station Conveniences, and Signals. Many ingenious contrivances of the switch kind are in use, which may appear to render accidents almost impossible, so far as the action of the moveable rails is concerned; but one of the most important precautions attending their use is that now generally adhered to, of making all sidings and crossings join the main line in such a way that trains must proceed backwards in order to enter them. By turning to the diagram, *Fig.* 18, p. 257, of the article RAILWAY, P. C., and reversing the position of the arrows in the crossing marked *e f*, the reasons for this precaution will be readily understood. As the diagram now stands, a train running upon either line *meets* the switches, and is therefore liable, if they should be accidentally misplaced, to be turned into the wrong track, with imminent danger; but if, by reversing the position of the arrows, the upper track in the diagram be appropriated to traffic running from *e* to *f*, and the lower to traffic running from *f* to *e*, it will be seen that (assuming the switches to be, as they usually are in such situations, of a self-acting kind, on the principle of that represented at *Fig.* 16, upon the same page), instead of being turned into the wrong line, the flanges of the train would open the switch, and it would continue its journey without danger. In order to enter a siding or crossing so laid, the train must run on past the switches, must then be brought to a stand, and be propelled backwards, by reversing the motion of the engine, when the switches are properly adjusted; but the trifling inconvenience and delay occasioned by this manœuvre is amply compensated by the greater security afforded by the arrangement to the transit of the ordinary trains, and all such as may have to pass the junction at considerable speed. The last few months have produced two or three alarming accidents, illustrative of the danger of laying sidings into the main line so as to meet the traffic, upon the Brighton, Lewes, and Hastings railway, where, as there was at first but a single track for the greater part of the distance, such an arrangement was of course inevitable; while the increasing use of fast or express trains renders it highly important to adopt every precaution which may lessen the risk of running at full speed through stations where the use of switches and sidings is necessary. Accidents have occurred through the rolling of carriages from a siding on to the main line by the action of wind, or from some other cause, and thereby exposing passing trains to danger; to guard against which *self-acting chocks* have been introduced in some situations. These consist of pieces of bent rail or other iron bar so mounted that, while they may be turned aside out of the way by the wheels of a carriage which is being pushed into the siding, they rise up as soon as the carriage has passed, and prevent it from rolling back towards the main line, excepting while they are held back or clear of the rails by an attendant, by means of a lever handle similar to those used for working switches.

Another contrivance, which is sometimes adopted with similar intention to the above, affords the power of laying such tracks as are often required at stations to cross the main line for the conveyance of carriages and waggons from one siding to another, without in any way interfering with the rails of the main line. It consists in laying the rails which constitute the cross track about an inch above the level of the main line, cutting them off, of course, a little short of the points of intersection. By this arrangement the flanges of a carriage being pushed along the cross track, mount upon and roll over the rails of the main line, supporting the weight of the carriage until the wheels again reach the elevated rails of the cross track. The necessity for breaking the continuity of the main rails by grooves or nntches for the passage of the flanges is thus avnided, and the smoothness of the transit upon the main line is undisturbed.

Some important improvements in *turn-tables*, tending to diminish the risk attending their use, and the concussion and noise occasioned by passing nver them, deserve a passing nntice. Some are laid with elevated cross tracks of the kind just described, so as to leavn the rails of nne track smooth and unbroken; and others are distinguished by contrivances to ensure firmness and stability during the passage of trains nver them. Dunn's patent turn-table, the details of which are illustrated in the 'Railway Chronicle' for 1846, p. 347, provides for the safe passage of trains even in case of the turntable being accidentally left in a wrong positinn. In this contrivance the central portion nf the tracks, both of the main and cross lines, is fixed or statinnary, the only portion that actually turns being an annular platform, the surface of which is so adjusted to the level of the rails, that a carriage coming upon it when turned into a wrong positinn would roll nver it upon its flanges, coming upon the fixed track in the centre soon enough to avoid any risk of being turned out of its proper course, and, crossing the second half of the annulus again upon its flanges, would reach the fixed track beynnd it without being thrown off the line. Some ingenious features of this turn-table, designed to ensure steadiness during the passage of a train, are the subject of dispute between Mr. Dunn and Mr. Ellis, the patentee nf another improved turn-table.

In the use of efficient *signals* great prngress has been made within the last few years; but of the numerous inventions of this character we shall nnly advert to the admirable system of signals on the semaphnre principle, introduced by Mr. C. H. Gregory upon the Londnn and Croydnn railway, and which, with varinus improvements suggested by experience, have been adopted nn the lines of the Snuth-Eastern, Brighton, and some other railway companies. The ordinary apparatus mnunted at every station, and at each approach to stations of the more important class, consists of an elevated post with two mnveable arms mounted upon a commnn pivot near its upper extremity, either nf which is capable of being mnved independently of the nther by means nf a handle near the bottom of the post; so as either to hang vertically, in which position it falls into a slit in the post so as to be invisible; to prnject from it in a horizontal directinn, or at an angle nf 90°; nr to assume a position intermediate between the vertical and the horizontal, projecting dnwnwards at an angle nf 45°. Each arm, whatever be its positinn, refers to its own particular track; that projecting tnwards the right referring to the right-hand track, and that prnjecting towards the left to the left-hand track; and when dropped within the post the arm indicates that the line to which it refers is clear, so that trains may pass on safely; when prnjected hnrizontally, that a train is a short distance ahead, that there is some obstructinn on the line, or that, for some other reasnn, any approaching train must stnp; or when projected at an angle of 45° that, owing to a train being ahead, though at a safe distance, or owing to snme other circumstance, any approaching train shnuld slacken its speed, and proceed cautiously until again reaching a signal of safety, or 'all right.' As these semaphore signals can only be seen in the day-time, signal lamps, with powerful parabolic reflectors, and capable, by the turning nf handles at the bottom nf the post, of being shifted so as to throw their light through either a white or colnurless, a red, nr a green glass, according tn whether the signal required be to indicate safety, danger, nr the necessity of cautinn, are also mounted near the tnp of each post; nne lamp directing its light up, and the nther down the railway, and each being visible nnly in its own proper direction, for the guidance nf approaching trains. At the junctinn nf twn lines nf railway similar signals are used, but twn posts are emplnyed, one for each line, each having twn arms, one for the down and the nther for the up track of its particular line. The arms and lamps in this case have but two positions each; the danger or stop signal, which is always displayed excepting while the switch-man is at his post and actually hnlding the switches in the required position; and the cautinn signal, which is shown when the track to which it refers is prnperly adjusted for the passage of a train; and the wnrking nf the switches and the signals for bnth lines is effected simultaneously by the hands and feet nf one attendant. The engine-driver of every train, on approaching the junction, indicates by whistling and holding out his hand nr a signal light in what directinn he wishes to proceed. In addition to these fixed signals, the mechanical details of which are fully illustrated in the 'Railway Chronicle' of 1846, pp. 423 and 615 (from which we learn that the nrdinary station signal apparatus, for night and day signals, costs about 30*l*), hand signals are made by the attendants and wnrkmen upon the line either with the arms alone, with white, red, and green flags, nr, at night, with hand-lamps; and at night, nr even in the day-time when tunnels are tn be passed through, white lamps attached to the front of the engine, and red lamps behind the last carriage nf the train, are used as signals with every train, their number and relative positions serving to distinguish the trains destined for nne line from those nf annther, wherever, as in the case of the Croydon, Brightnn, and South-Eastern lines, the junctinn nf different railways renders snch distinction necessary. An extra red lamp, nr an oval board painted red, hung at the tail of the last carriage nf a train, serves to indicate that it is tn be followed by a special nr express train; and a similar signal attached to the front of the engine nf an express train acts as a special warning to keep the line clear nn its approach.

In cases where the foggy state of the atmnsphere might prevent the signals from being seen, and in other cases of emergency at night, the *fog signals* invented by Mr. E. A. Cowper are very useful. These are flat circular boxes of about two inches in diameter, filled with an explosive mixture, and furnished with a narrow slip of sheet lead, by which they may be readily fixed upon the tnp of the rail, in such a positinn that, when run nver by the wheel nf the engine, they will produce a loud detonation which warns him to stop. Such signals, with printed directinns for their use, are deposited in every station, and carried with every train, upon the lines where they are adopted; and in case of an accident happening at night, several are fixed at intervals behind the point of obstruction, so as to give repeated warnings tn an approaching train. When the line is clear they may be taken up again and kept for future use. Such signals are used to stop all trains approaching a junctinn during a fog, until, by the snunding of the engine whistle and of a bell mnunted for the purpose at the junctinn, the switchman ascertains the destination of the train, and indicates that the line is clear for it.

Carriages. Snme remarks having been made nn the advantages of increased length in carriages in treating on the gauge question (see p. 667), we need only observe on that point that six-wheeled carriages are nnw used with advantage upon many narrow-gange lines, and that still lnnger vehicles, having eight wheels, and snme provision for adapting their axles to a curved track, have been tried, though on a limited scale. In the 'Railway Times' of 1843, pp. 992, 993, are some extracts frnm a report emanating from the carriage factory of the Leipzig and Dresden railway cnmpany, upon carriages of extraordinary dimensions, constructed there for the German railways, illustrated by an engraving of an eight-wheeled carriage, 47 feet long, and containing seats fnr 112 passengers. From this paper it appears that bow-springs, which, owing perhaps to the comparative shnrtness nf English railway carriages, had not been hrought intn use so extensively in this country as was anticipated, were greatly preferred in Germany. This kind of spring is described under SPRING-CARRIAGE, P. C., pp. 387, 388. The inconveniences attending the use of very capacious vehicles for a fluctuating traffic may be met in some measure by extending the plan, which is gaining ground in this country even with carriages of the ordinary dimensinns, of combining accommodation for different classes of passengers in different compartments of the same vehicle; a plan which is especially desirable where many branch and cnnnecting lines have to be provided for, to enable the railway companies to send passengers through withnut a change nf carriage, and withnut involving the conveyance of more dead weight than is absnlutely necessary. As a general remark we may say that while the most modern English railway carriages are mnrn elegant in appearance than those of older build, they are both mnre roomy and strnnger in the frame-work, which, in some of the most recently cnnstructed, is made of wrought-iron; experience having shnwn that light carriages would not bear the strains to which they are exposed.

Locomotive Engines. Amnng the results consequent upon the use of cnmparatively steep gradients, coupled with the great increase of railway traffic, and the growing demand for increased speed, is a general enlargement of the locomotive engine, usually combined with some deviations from the construction most commonly preferred when the remarks in P. C., pp. 259, 260, were written. Coupled wheels, which were formerly used almost exclusively for goods trains, are now largely and increasingly employed for passenger traffic, it being found practicable to work them at very high velocities. To this change we are inclined to attach considerable importance as a matter of safety, since, independently of the injury done to the road by throwing an enormous weight upon a single pair of driving-wheels, in order to increase their adhesion, the tendency of the engine to a dangerous rocking motion at high speeds is undoubtedly often increased by that circumstance; for if a disproportionate share of the weight of the machine be thrown upon the central axle, the two ends will have a degree of play upon their bearing springs which may allow the motion we refer to to increase until the engine is thrown off the line, as there is some reason to believe has been the case in one or two accidents in which no obvious cause could be discovered for the engine leaving the rails. There can be no doubt that, with an equal amount of adhesion, a firmer and steadier bearing upon the rails may be obtained when the principal weight is divided between two axles than when it is thrown upon one. The necessity for increased power, calling for the use of larger boilers and cylinders, is leading to the very general abandonment of that construction of engine in which the cylinders are placed at the bottom of the smoke-box, and the machinery is under the boiler; and a growing preference for those in which the cylinders are fixed outside the framing, and the power is conveyed to the wheels by external cranks and connecting-rods. Engines in which the machinery is thus arranged may be greatly enlarged in all their parts without raising the centre of gravity, the depth required for working the cranks and eccentrics under the boiler being saved; and they have the further advantages of far greater strength in the axle, and of the whole of the machinery being easy of access for the purpose of examination and repair. The most important parts of the mechanism, indeed, may be examined and attended to while the engine is running; iron foot-plates, with hand-rails, being constructed along the sides of the frame of the engine. In some narrow-gauge engines boilers are used of 3 feet 9 inches diameter, being the largest dimension that the gauge will allow, and the sectional form has in a few instances been made slightly elliptical, the longer axis of the ellipsis being placed vertically, in order to save room; but more generally increased power of generating steam is sought by lengthening rather than enlarging the diameter of the boiler. The occurrence, in December, 1845, of a fatal accident on the Norfolk railway, with an engine on the recent long-boiler construction of Mr. Robert Stephenson, led to much discussion on the merits of this kind of engine; General Pasley having given evidence against their safety, which called forth a reply from Mr. Stephenson, in which he denies the assertion that the additional length of boiler was inefficient on account of the distance of the farther end from the fire-box, and states that 'even with the longest tube yet introduced in locomotive engines, the temperature at the chimney end has been found sufficient to melt lead, which is upwards of 200 degrees above the temperature of the water in the boiler;' a fact which indicates that locomotive-engine builders have not even yet attained the length desirable so far as the economy of fuel is concerned, although, perhaps, looking to the difficulties occasioned by the expansion and contraction of the metal, they may have reached the utmost attainable length with the present construction of boiler. Mr. Stephenson does not state the precise length to which he has extended the boiler; but General Pasley observed that in his long engines it is four or five feet longer than in those formerly used. The distance between the hind and fore axles of the engine to which the accident happened (a six-wheeled one), is 10 feet 6 inches; and from that to 12 feet 9 inches (which, in his evidence before the Gauge Commissioners, Mr. Stephenson stated was, in his opinion, too long) is the length of bearing of most recently constructed engines for the narrow gauge; while 5 feet 6 inches was the length of bearing formerly employed on the London and Birmingham railway, with four-wheeled engines, though it has been extended of late to about 7 feet. Notwithstanding the great length of bearing, the fire-boxes of the long-boiler engines referred to project beyond and overhang the hinder axle, so that the whole length of the engine is about as much beyond the length of bearing upon the rails as in the original four-wheeled engines of the Birmingham line, with a bearing of only 5 feet 6 inches. Such large and powerful engines, by which it is anticipated that a speed rivalling that obtained on the broad-gauge lines may be safely attained, are necessarily much heavier than those of the older construction, though, perhaps, not so in proportion to their increased base. The Great Western company, however, are constructing engines of considerably greater magnitude. The first of these, called the 'Great Western,' accomplished an experimental trip from London to Bristol, in June, 1846, in 2 hours and 26 minutes, including two stoppages, being at the average rate of 50 miles per hour, with a train of ten carriages, weighing 100 tons. The run from Paddington to Didcot, a distance of 51 miles, with a rise of 118 feet, was accomplished at the rate of more than 56 miles per hour; and two miles on another part of the road, with a fall of 8 feet per mile, at the rate of 69 miles per hour. This engine has about 1750 square feet of heating surface in the boiler; has cylinders of 18 inches diameter and 24 inches stroke; driving-wheels of 8 feet diameter; and two pair of bearing-wheels of 4 feet 6 inches diameter. The total length is 24 feet; the distance between the supporting wheels 16 feet; the weight of the engine alone, without fuel or water, 28½ tons, and of the tender, 10 tons; and the total weight of engine and tender, when loaded, about 56 tons. Whether the railway will be able, without ruinous expense in repairs, to bear the rapid action of so enormous a weight, remains to be seen; but if unofficial reports may be trusted, both road and engine have proved already very costly to keep in order. It is worthy of remark, though we have no means of testing the absolute truth of the statement, that about the time when the above-mentioned feat of speed was accomplished, the newspapers announced the turning out from the establishment of Messrs. Sharp and Roberts, eminent engine-builders of Manchester, of a narrow-gauge engine called the 'Atlas,' which, after being tested on the Birmingham and Gloucester railway for two months, had been found capable of maintaining a speed of 58 miles an hour with a train of ten carriages, over undulating gradients, and which, with its tender, weighed only 25 tons. Allowing largely for exaggeration, this statement suggests the necessity of pausing before the astonishing speed of the 'Great Western' engine is set down to the credit of the broad gauge.

The revival, by Mr. Parsey, within the last few months, of the often attempted scheme of employing compressed air as a motive power in locomotive engines, perhaps only deserves notice here to call attention to the fact that, supposing the mechanical difficulties to be overcome, which, from the action of Mr. Parsey's beautiful models, may be supposed to be the case, it remains a question whether the power required for the condensation of air into the reservoirs from which the proposed locomotives were to be supplied, might not be as well or better employed in propelling the trains in some other way; and to remark, that many of the assertions made respecting the superiority of the proposed air-locomotives to steam-engines in locomotive and tractive power, are too absurd for serious refutation.

Atmospheric Railway System. To what has been already said on this subject under Railway, P. C., p. 260, and Atmospheric Railway, P. C. S., pp. 149-152, very little need be added. Of the proposed atmospheric line alongside of the London and Croydon railway, alluded to in the last-mentioned article, a portion of about 5 miles, between Croydon and the Forest Hill station, was so far completed in 1845 as to admit of the running of experimental trains, and has been employed for working the regular traffic, in conjunction with locomotive engines from London to Forest Hill, for several months. This railway is constructed upon the eastern side of the locomotive line, and therefore, to avoid interference with the Brighton line at the point where it diverges from the Croydon, it is conducted over that railway by a timber viaduct, to which it rises on each side by a slope of 1 in 50. The first experiments were highly satisfactory, a speed of from 60 to 75 miles per hour, with considerable loads, having been attained, and the formidable slopes of 1 in 50 ascended without difficulty, even when the train was deprived of momentum by being brought to a stand at its foot. It was also found, by stopping the action of the stationary engine near the middle of the 5-mile length, and leaving the whole 5 miles to be worked by one engine at its extremity, that trains might be propelled through the whole distance at the rate of 60 miles per hour. The working of the ordinary traffic, however, has not proved so satisfactory; although in several cases the defect appears to lie rather with the stationary engines, the construction of the air-pumps, or some other matter capable of easy remedy, than with the system of propulsion itself. In several cases the power has, from some cause or other, proved insufficient, especially at the inclined planes of 1 in 50 above referred to; and during the very hot summer of 1846 an unexpected difficulty arose by the iron tube becoming so heated as to melt the composition by which the valve is sealed;

by the failure of which the vacuum was destroyed, and it became necessary again to transfer the traffic to the locomotive line until a harder composition could be prepared, and a new, and, it is anticipated, a better valve fixed. In the mean time the continuation of the atmospheric line from Forest Hill to New Cross has been nearly completed, and arrangements have been made for its further extension to London Bridge. While however the Croydon and Epsom line has been constructed, and is expected to be ready for traffic about Christmas, 1846, the atmospheric apparatus has not been laid upon it, and it is intended to work it in the first instance with locomotive power; the engineer-in-chief, Mr. William Cubitt, having recommended that course on the ground that the atmospheric system, as now at work and in progress towards completion, is 'too important a matter either to be hastily extended or hastily thrown aside.' In the session of 1846 the act for the projected Direct London and Portsmouth railway (which was deferred from the session of 1845 for want of time to pass through the House of Lords) was passed; but the arrangements which have been entered into between its promoters and the London and Brighton and London and South-Western railway companies render it almost certain that it will be constructed as a locomotive line. Under these circumstances, which render the anticipated extension of the atmospheric system for the present doubtful, it is unnecessary to enter upon the consideration of the various topics suggested by a comparison between it and the locomotive system, or to notice the arguments which have been adduced in favour of atmospheric traction on the ground of its superior safety, economy, and power of adaptation to purposes for which locomotive engines are unsuitable. To what has been said under ATMOSPHERIC RAILWAY on the history of schemes for atmospheric propulsion we may add that since that article was written many new contrivances have been propounded, of which perhaps the most deserving of notice is that of the late M. Hallette, in which the connexion between the carriages and the piston is effected by a thin flat bar or coulter, passing vertically through a slit in the upper part of the atmospheric tube, which slit is closed excepting during the passage of the coulter by the contact of two continuous air-bags, or air-tight and highly elastic hose or pipes of caoutchouc covered with cotton and leather, which are inserted, in a collapsed state, in grooves or cavities formed on the top of the pipe to receive them, and are then inflated with air so as to press against one another with considerable force. The action of this, the most simple of all the proposed valves, is illustrated by the passing of a paper-knife between the closed lips; the valve itself consisting, as it were, of a pair of continuous lips, capable of being pressed together with any required force by inflation with compressed air. Many of the other proposed plans are more remarkable for their complication than anything else. We may refer to the 'Mechanic's Magazine' for January 24, 1846, for a brief notice of one which does not bear that character, although we need further information in order to judge of its practical value. The invention to which we allude is the magneto-atmospheric railway, patented by Messrs. Conder and Taylor, in which the necessity for a valve is avoided by the employment of electro-magnetic force to connect the carriage with the piston in the tube. From a letter in the following number of the magazine it would appear that the patentees are not alone in their claim to this ingenious idea.

Railway Labourers and Railway Accidents. The condition of the labourers employed on railways, the state of wretchedness and demoralization in which they are often compelled to live, and the loss of life, injuries of person, and deterioration of health, to which they are subjected by the careless management of contractors, have become matters of anxious investigation to all those who are interested in the welfare of the labouring classes. 'A Report of the Select Committee of the House of Commons, appointed to enquire into the Condition of the Labourers employed in the construction of Railways and other public works, and into the Remedies which may be calculated to lessen the peculiar evils, if any, of that condition,' has been published (1846). The Statistical Society of Manchester have also published (1846) the following Papers, which had been read before the Society:—'A Return of the Fatal Accidents, Wounds, and Injuries, sustained by Workmen engaged in the construction of the Summit Level Tunnel of the Sheffield and Manchester Railway; and a Description of the Demoralization which prevailed amongst them, with Observations; being a Letter of John Roberton, Esq., Surgeon. President of the Society. 'Statements on Railway Contracts and Railway Labourers, by Robert Rawlinson, Esq., Engineer of the Bridgwater Trust.' 'Observations as to some of the Effects produced in this Country by the past expenditure of Capital on Labour in the construction of Railways; together with Observations on the Principles of Legislation and Jurisprudence applicable to the Public Protection, by Prevention of Fatal Accidents, and the better Regulation of Labourers employed in dangerous works; by Edwin Chadwick, Esq., Barrister-at-Law,' &c.

It is abundantly proved, by the evidence adduced in these papers, that large bodies of workmen are hastily collected, and crowded into hovels, without any provision being made for comfort or decency; that they are not only hard worked, but exposed to great and frequently unnecessary risk of life and limb; that they are cheated of a considerable part of their hard-earned wages, by being compelled to deal at tally-shops by means of tickets, while payments are only made once a month or even two months, thus, by a system of credit, exposing the men to the temptation of spending carelessly, and of drunkenness, by receiving the balances due to them in an accumulated sum; that no provision is made for instruction, religious or merely educational, for the men or their children; and that there is, in consequence of all this want of care and want of principle on the part of the contractors, great wretchedness, discontent, disorder, drunkenness, and debauchery, on the part of the labourers. The Directors of the Liverpool and Bury Railway are stated to have voted 1000*l.* a year for the special purpose of the care of the workmen, to obtain good lodgings and rooms for living in, and other comforts and conveniences.

As many millions of pounds must be spent, and many thousands of men be employed in the construction of the railways which have already received the sanction of Parliament, it is deemed fit that the Legislature should interfere to protect the labourers, by suitable legislative measures, from the neglect and cupidity of those who employ them.

With respect to accidents which occasion loss of life or injury of limb, either to workmen in the construction of railways, or to passengers in transit, Mr. Chadwick was examined by the Committee of the House of Commons before mentioned as to the provisions of the French law in such cases. Mr. Chadwick adduced the following provisions of the 'Code Civil':—

'Art. 1382. Every act whatsoever of the man who occasions a damage to another, obliges him by whose fault it happens to repair it.

'Art. 1383. Every one is responsible for the damage he has caused, not only by his act, but by his negligence or by his imprudence.

'Art. 1384. A man is responsible not only for the damage occasioned by his own act, but also for that which is occasioned by the act of persons for whom he should answer, or of things which he has in his charge.'

These provisions of the French law, Mr. Chadwick states, were understood to extend to companies, as well as to individuals; yet, by a law of July 15, 1845, on the general management of railways, a chapter was introduced to provide for the greater safety of railway passengers. The 22nd clause makes all owners or lessees of railroads responsible to individuals and the state, for injury caused by managers, directors, or any people employed in any capacity whatever in the working of them. Other clauses, from 16 to 21, enact penalties against those through whom accidents may be brought about, and for the mere violation of the regulations established by the king or prefects for the management of railways, even when no accident resulted therefrom.

BRITISH RAILWAYS.

In the following tabular view of railway acts passed since 1840, supplementary to that given in P. C., p. 261, a large proportion of those described as for new lines are merely for constructing branches from or extensions of lines previously authorised; while among the amendment acts are several which authorise deviations or alterations of lines previously sanctioned. The figures which follow, indicative of the aggregate number of miles of railway sanctioned in each year, must be taken only as an approximation to the truth, as various circumstances combine to render perfect accuracy unattainable. The aggregate length also needs some reduction to account for the cases in which an act passed in one session authorises works to supersede wholly or in part those sanctioned by a previous act; and for those in which two different companies have received powers for making the same line.

Such cases however would not require any serious deduction from the figures given:—

Year.	New lines.	Amendments.	Total.	Length.
1801-1840	135	164	299	(See P. C., p. 261.)
1841	2	17	19	14½ miles
1842	5	17	22	67½ ,,
1843	10	14	24	91½ ,,
1844	33	15	48	797 ,,
1845	104	16	120	2883 ,,
1846	227	43	270	4790 ,,
	516	286	802	8643½ ,,

By adding the above computation of mileage to those given in P. C., it will be seen that, in round numbers, without any deduction for abandoned schemes, about 11,600 miles of railway have been sanctioned by 516 acts of parliament between 1801 and the close of the session of 1846, of which upwards of 10,000 miles have been designed for working by locomotive engines for passenger and general traffic. Of this latter class about 1100 miles were open down to the close of 1840, while the length opened since that time down to the close of 1846, as reported year by year in the 'Companion to the Almanac,' where accounts of the more important lines are given, is about 1550 miles, making a total of at least 2650 miles in operation, besides many hundred miles in progress and on the eve of completion. Of the vast addition of 4790 miles (without deductions for a few lines to be made for joint use, although the acts give powers for their construction to two distinct companies) sanctioned in 1846, it is probable that several lines may, owing to changes in the financial state of the country, be abandoned for a time; but numerous other schemes, several of them of considerable importance, are announced to be preparing for the session of 1847. Great however as is the number of railway acts passed in the session of 1846, the schemes sanctioned by them form but a small proportion of the projects which were in agitation about the close of 1845. In such a matter it is difficult to arrive at even a tolerably correct estimate; but it was stated in a great tabular statement compiled by Mr. Spackman, and published in the 'Times' newspaper of November 17, 1845, that the capital then invested in completed railways amounted to 70,680,877*l.*; that that already laid out, and yet remaining to be expended, upon lines then under construction, amounted to 67,359,355*l.*; and that the capital which would be required to carry out 620 schemes, of which the estimates were then before the public, would be about 563,203,000*l.*; in addition to which mention is made of 643 projected companies, of which, as they had not yet registered their prospectuses, the proposed capital could not be estimated. These figures sufficiently indicate the extent of the railway mania of 1845. In compiling the following tables of English, Scotch, and Irish railways, we have inserted none but those for which acts have been passed, excepting a very few which have been constructed without parliamentary powers, and, to economise space, we have made no reference to the amount of capital which each company is empowered to raise. Though compiled with the utmost care these tables cannot be presented as absolutely to be depended upon, especially as regards the acts of 1846, because the alterations and curtailments sometimes made in a railway bill after it has passed the Select Committee by whom its details are reported to the House of Commons, and a variety of other contingencies, render it more difficult than could be conceived by any who have not made the attempt, to obtain authentic and correct materials for such a compilation; but from the precautions which have been adopted the compiler believes his statements to present the fullest and most accurate record yet issued of the railways completed, in progress, or sanctioned by act of parliament, in each division of the United Kingdom. Where nothing is said to the contrary, it may be presumed that all lines sanctioned prior to 1846, if not marked as opened, are in progress; and even of those of 1846 several have been already (November, 1846) commenced. As the capital is not mentioned in each particular case, it may be well to state that the aggregate share-capital authorised to be raised under acts of 1844 for the construction of about 797 miles of railway was 11,121,000*l.*, indicating an average estimated cost of somewhat less than 14,000*l.* per mile; in addition to which each company had the usual power to borrow to the amount of one-third of the capital. A similar calculation in reference to the acts of 1845, including some new capital to be raised for completing former undertakings, and also the estimated cost of such new lines as were granted to existing companies without any fresh powers for raising money, shows an aggregate estimate of 43,844,907*l.* for the construction of about 2883 miles of railway, indicating an average of rather over 15,000*l.* per mile; while the like computation for the acts of 1846, including several large sums for the completion or improvement of existing works and the construction of costly stations, but exclusive of money to be raised for the purchase of existing railways, gives a total capital of 91,165,550*l.*, which, for about 4790 miles of railway, amounts to rather over 19,000*l.* per mile. These computations are, like that for 1844, exclusive of the usual power of borrowing one-third in addition to the capital. It will be observed, in reference especially to the new lines of 1846, how many of the recent projects are either promoted by, or are by agreement to be absorbed in or united with, established companies; although in this point we cannot pretend to perfect accuracy, as the connexion of new projects with existing undertakings is not always mentioned in the acts themselves; while in many cases, where it is of a permissive character, circumstances may lead to its being broken off. In some cases also parliament has refused to ratify agreements for amalgamation which had been formally concluded by the companies interested, and such may be the case with some of the agreements here indicated. It was stated in the 'Railway Chronicle' of June 6, 1846, that out of 210 bills of which a classified list is there given, only 61 were for new or independent companies, all the rest being for lines promoted by existing corporations as branches or extensions of, or auxiliaries to, their own lines; and several lines which were granted as independent undertakings have since that time been purchased by established companies.

Railways of England and Wales.

Aberdare.—From the Taff Vale Railway, near Ynys Meyrick, to Aberdare; length, with a branch, 8½ m.; act passed 1845; opened August, 1846.

Ambergate, Nottingham, and Boston and Eastern Junction.—From the Ambergate station of the Midland Railway, through Nottingham, to Spalding and Boston, with branches. Main line to Spalding, exclusive of portions of the Midland and Nottingham and Lincoln lines which are to be used, 59½ m.; Boston extension 19½ m.; Sleaford branch 9 m.; canal branch 1 m.; Boston harbour branch ½ m.; total length 89½ m.; act passed 1846. Sold to the *Great Northern* Railway Company. The act confers powers to purchase the Nottingham and Grantham canals.

Ashburton, Newton, and South Devon.—A broad gauge branch from the South Devon Railway, near Newton Abbott; length 10½ m.; act passed 1846. The *South Devon* Company has an interest in this line.

Ashford and Hastings.—See *Brighton, Lewes, and Hastings; Rye and Ashford Extension.*

Ashton Branches.—See *Manchester and Birmingham,* and *Sheffield, Ashton-under-Lyne, and Manchester.*

Ashton, Stalybridge, and Liverpool Junction.—Sold to the *Manchester and Leeds* Railway Company, from whose line it branches out. Length 6¼ m.; act passed 1844; opened to Ashton in April, and to Stalybridge in September, 1846. An act of 1845 authorises a branch of 1¾ m. to join the Manchester and Birmingham line in Ardwick, Manchester.

Avon and Gloucestershire. [P. C., p. 262.]

Aylesbury [P. C., p. 262].—Sold to the London and Birmingham, now *London and North-Western* Railway Company.

Basingstoke and Salisbury.—See *London and South-Western.*

Bedford and London and Birmingham.—Worked by the *London and North-Western* Railway Company, whose line it joins at Bletchley. Length 16 m.; act passed 1845; opened November, 1846.

Berks and Hants.—A broad gauge line from the Great Western Railway at Reading to Newbury and Hungerford, 25½ m., with a branch of 13½ m. to join the London and South-Western Railway at Basingstoke. Total length 39 m.; act passed 1845; sold to the *Great Western* Railway Company.

Birkenhead, Lancashire, and Cheshire Junction.—From the Chester and Birkenhead Railway at Hooton to the Manchester and Birmingham Railway at Stockport, 38½ m., with branches amounting to 7½ m.; total length 46 m; act passed 1846. The Company has agreed to amalgamate with the *Chester and Birkenhead.*

Birmingham, Bristol, and Thames Junction.—See *West London.*

Birmingham and Derby Junction [P. C., p. 262].—Final opening February, 1842. Merged in the *Midland* Railway.

Birmingham and Gloucester [P. C., p. 262].—Main line, from the London and Birmingham Railway, at Birmingham, to Gloucester, 53 m.; branch to Tewkesbury 2 m; branch to Berkeley Canal at Gloucester 1 m.; completed 1841. Amalgamated with the Bristol and Gloucester Railway, and the united lines leased in perpetuity to the *Midland* Railway Company. An act of 1845 authorised extensions at both ends of the line, and a branch at Stoke Prior, amounting together to 1¾ m.; and in 1846 the

Midland Company obtained an act for a branch from King's Norton to Hales Owen, length $5\frac{1}{2}$ m.

Birmingham, Lichfield, and Manchester.—From the Grand Junction Railway at Aston, near Birmingham, to the Trent Valley Railway at Lichfield; length $14\frac{1}{2}$ m.; act passed 1846. Sold to the *London and North-Western* Railway Company.

Birmingham and Oxford Junction.—Main line from Birmingham to join the Oxford and Rugby and Oxford, Worcester, and Wolverhampton Railways, $32\frac{1}{2}$ m.; Stratford branch, $10\frac{1}{2}$ m.; extension into Birmingham (under a separate act) nearly $1\frac{1}{2}$ m.; total length about 44 m.; acts passed 1846. This undertaking was projected in connexion with the Great Western Railway, to continue the broad gauge from Oxford to Birmingham and the surrounding districts, and thus to compete with the London and Birmingham Railway. Under the Gauge Regulation Act of 1846, however, both this line and the *Birmingham, Wolverhampton, and Dudley*, with which it is intended to amalgamate, must be laid upon the narrow gauge; but as the break of gauge thereby occasioned at Fenny Compton, where the Birmingham and Oxford Junction line joins the Oxford and Rugby, would impair the value of this competing route, it is intended in next session to seek again for power to adopt the broad gauge. The Stratford-on-Avon Canal is to be purchased by the Oxford, Worcester, and Wolverhampton Railway Company, and made over to this company. Both this and the *Birmingham, Wolverhampton, and Dudley* lines are to be sold to the *Great Western* Railway Company.

Birmingham, Wolverhampton, and Dudley.—Main line, from Birmingham to the Oxford, Worcester, and Wolverhampton (broad gauge) line at Wolverhampton, 11 m.; branch to Dudley, $3\frac{1}{2}$ m.; total length, $14\frac{1}{2}$ m.; act passed 1846. See *Birmingham and Oxford Junction.* Part of this line is to be used in common by this and the *South Staffordshire Junction* Railway Companies.

Birmingham, Wolverhampton, and Stour Valley.—From Birmingham to Wolverhampton, and to the Grand Junction Railway, in the parish of Bushbury, by a main line of $15\frac{1}{2}$ m., with a branch of $3\frac{1}{2}$ m. to Dudley; total length $18\frac{1}{2}$ m.; act passed 1846. Promoted by, and under the powers of the act may be sold to, the *London and North-Western* and *Shrewsbury and Birmingham* Railway Companies, and the Birmingham Canal Company.

Bishop's Auckland and Weardale [P. C., p. 262].—Length, $8\frac{1}{2}$ m.; opened November, 1843. See *Wear Valley.*

Bishopstoke and Salisbury.—See *London and South-Western.*

Blackburn, Burnley, Accrington, and Colne.—From the Manchester, Bury, and Rossendale (now East Lancashire) Railway, to Blackburn, Burnley, Accrington, and Colne; length 24 m.; act passed 1844. Amalgamated with the *East Lancashire.*

Blackburn, Clitheroe, and North-Western Junction.—Main line from Blackburn, by Clitheroe, to the North-Western Railway at Long Preston, near Settle, 23 m.; branch to join the Leeds and Bradford Extension Railway, nearly 9 m.; branch to old Banks Lime-works, $\frac{1}{2}$ m.; total $32\frac{1}{2}$ m.; act passed 1846, and gives power to lease the line to, or amalgamate it with, the *Blackburn, Darwen, and Bolton.*

Blackburn, Darwen, and Bolton.—From Blackburn to Bolton; length 14 m. Original act passed 1845, but a second act, obtained in 1846, provides for a shorter junction with other lines at Bolton. See also *Blackburn, Clitheroe, and North-Western Junction.*

Blackburn and Preston.—Original line, for which the act was obtained in 1844, from Blackburn to the North Union Railway at Farrington, about 3 m. south of Preston, $9\frac{1}{2}$ m. This line, after being somewhat modified by a deviation act of 1845, was opened in June, 1846; and a third act was obtained in 1846, for a branch of about $1\frac{3}{4}$ m. to the North Union line at Bamber Bridge, to shorten the approach to Preston, and for two short branches at Blackburn, making altogether about $2\frac{1}{2}$ m. Another act of the same session confirms the amalgamation of the whole undertaking with the *East Lancashire* Railway.

Blaydon, Gateshead, and Hebburn. [P. C., p. 262.]

Bodmin and Wadebridge [P. C., p. 262].—Main line, 12 m.; branch to Bodmin, $1\frac{3}{4}$ m.; branch to Ruthern Bridge, about 1 m. Total, with branches and sidings, about 17 m. The *Cornwall* Railway Company have taken powers to purchase or lease this line.

Bolton and Leigh [P. C., p. 262].—Purchased by the *Liverpool and Manchester* Railway Company.

Bolton and Preston [P. C., p. 262].—Completed 1843. Amalgamated with the *North Union.*

Boston, Stamford, and Birmingham.—From the Syston and Peterborough line of the Midland Railway, near Stamford, to the Wisbech Branch of the Lynn and Ely (or East Anglian) Railway, near Wisbech; length, 22 m.; act passed 1846. Sold to the *Great Northern* Railway Company.

Brandling Junction [P. C., p. 262].—Purchased by the *Newcastle and Darlington Junction* Railway Company.

Brandon and Peterborough Extension.—See *Eastern Counties.*

Bricklayer's Arms Branch and Station.—From the London and Croydon Railway to the Kent Road, London. Length, $1\frac{3}{4}$ m.; act passed 1843; opened May, 1844. This branch and station was made by the *South-Eastern* and *London and Croydon* Railway Companies jointly, as a goods' station, a terminus for West-end traffic, and a means of escaping the high tolls of the London and Greenwich line; but the Croydon Company's share was subsequently sold to the South-Eastern, who, in November, 1846, discontinued the running of passenger-trains to the Bricklayer's Arms terminus, retaining it only for goods and cattle traffic.

Bridgend. [P. C., p. 262.]

Bridgewater Navigation and Railway.—A short line of $\frac{3}{4}$ m. to connect the quays at Bridgewater with the Bristol and Exeter Railway; act passed 1845.

Bridgewater and Taunton Canal, Railway, and Harbour.—The act for this line, passed in 1846, is to enable the Bridgewater and Taunton Canal Company to make a railway from Bridgewater to the Bristol Channel at or near Stolford, about $9\frac{1}{2}$ m., with three short branches, increasing the total length to nearly 11 m.; and to make a harbour at Stolford. This and the *Chard Canal* Railway are intended to form portions of a projected line to connect the Bristol and English Channels.

Bridlington Branches.—See *Hull and Selby*, and *York and North Midland.*

Brighton and Chichester.—An extension of the Shoreham Branch of the London and Brighton Railway, by Worthing, and between Littlehampton and Arundel, to Chichester. Length, $22\frac{3}{4}$ m.; act passed 1844; opened June, 1846. Purchased by the London and Brighton, now *London, Brighton, and South Coast* Railway Company. Acts were obtained in 1846 for branches of $1\frac{1}{4}$ m. to Littlehampton, and $4\frac{1}{2}$ m. to Steyning.

Brighton and Chichester; Portsmouth Extension.—Main line, from Chichester to Portsmouth, 16 m.; branch to the Gosport line of the London and South-Western Company at Fareham, 6 m.; total length, 22 m.; act passed 1845. To be transferred when completed to the *London, Brighton, and South Coast* Company.

Brighton, Lewes, and Hastings.—The original act, passed in 1844, was for a line of $32\frac{1}{2}$ m. from Brighton, by Lewes (superseding the branch included in the original act of the London and Brighton Company) to near Hastings, with a branch of about $\frac{1}{2}$ m. to the river Ouse at Lewes. Under an act of 1845, a branch of 9 m. from Lewes to the London and Brighton Railway at Keymer, to shorten the distance to London, was added; and under that for the line next following in this table the original line was deviated from at the Hastings end. The main line was opened in June, 1846, from Brighton to Bulverhythe, $32\frac{1}{2}$ m. from Brighton and about 2 m. from Hastings, whence an extension to the permanent Hastings and St. Leonard's terminus at Bopeep was opened in November, 1846. An act of 1846 sanctions some deviations in the Keymer branch, and branches to Eastbourne, nearly $4\frac{1}{2}$ m.; to Hailsham, nearly 3 m.; and to Seaford and Newhaven (the Newhaven branch of the London and Brighton Company not having been made) $8\frac{1}{2}$ m.; total, 16 m. Sold in 1845 to the London and Brighton, now the *London, Brighton, and South Coast* Railway Company, by whom the above branches are to be made.

Brighton, Lewes, and Hastings; Rye and Ashford Extension.—Length 29 m.; act obtained in 1845, by the London and Brighton Railway Company, but its powers transferred to the *South-Eastern* Railway Company, who will make the line.

Bristol and Birmingham.—Formed by the amalgamation of the *Bristol and Gloucester* and *Birmingham and Gloucester* lines, which, immediately after the agreement, were leased by the *Midland* Railway Company. Their consolidation with one another and with the Midland is sanctioned by an act of 1846.

Bristol and Exeter [P. C., p. 262].—Completed May, 1844. An act of 1845 sanctions a new branch of $\frac{1}{2}$ m. at Bristol, one of $3\frac{3}{4}$ m. to Clevedon, one of 20 m. to Yeovil, and one of $4\frac{3}{4}$ m. to Tiverton, total 29 m.; and one of 1846 authorises a branch of $8\frac{1}{2}$ m. to Crewkerne. See also *Bridgewater Navigation and Railway; Cornwall* Railway; *Exeter and Crediton* Railway; *Portbury Pier and Railway;* and *South Devon* Railway. Leased to the *Great Western* Railway Company until May, 1849.

Bristol and Gloucester [P. C., p. 262].—An act of 1843 authorised a junction line of about 1000 yards at Bristol. The line was completed, on the 7 feet gauge, in July, 1844. Including the portion of the Cheltenham and Great Western Union line used, between Standish and Gloucester, the length is $37\frac{1}{2}$ m. Amalgamated with the Birmingham and Gloucester, as the *Bristol and Birmingham* Railway, and leased in perpetuity to the *Midland* Railway Company. See *South Devon.*

Bristol and Gloucestershire. [P. C., p. 262.]

Bristol and South Wales Junction and Ferry.—Length, from Bristol to the New Passage, $11\frac{1}{2}$ m.; branch from the tenth mile to the Old Passage or Aust. $2\frac{1}{2}$ m.; from the opposite side of the ferry to the South Wales Railway, including a branch towards Chepstow, nearly 1 m.; total, nearly 15 m. To be laid on the broad gauge. Act passed 1846.

Buckingham and Brackley.—See *Buckinghamshire.*

Buckinghamshire.—This undertaking consists of two distinct lines, sanctioned by separate acts of 1846; one, called the Oxford and Bletchley Junction, from Oxford to the London and Birmingham Railway at Bletchley, length, $29\frac{1}{2}$ m.; and the other, which is only part of a projected line from Tring to Banbury, from the first-mentioned line to Buckingham and Brackley, about $10\frac{1}{2}$ m.; total length, 40 m. The acts confer power to sell or lease the lines to the London and Birmingham, now *London and North-Western* Railway Company.

Bullo Pill.—See *Forest of Dean.*

Burnley Branch.—See *Manchester and Leeds.*

Caermarthenshire. [P. C., p. 262.]

Cambridge and Huntingdon.—See *Eastern Counties.*

Cambridge and Oxford.—See *Royston and Hitchin.*

Cameron's Coalbrook Steam Coal and Swansea and Loughor.—From Maln-y-Manach to Rhydydefydd, in the county of Glamorgan; length, 5 m; act passed 1846. Joins the Oystermouth tramway at Rhydydefydd.

Canterbury, Ramsgate, and Margate Branch.—See *South-Eastern.*

Canterbury and Whitstable [P. C., p. 262].—Purchased by the *South-Eastern* Railway Company, and now worked wholly by locomotives.

Chard Canal.—An act of 1846 authorises the Chard Canal Company to convert into a railroad the portion of their canal between Creech Saint Michael and Ilminster; length, 8¾ m. See *Bridgewater and Taunton Canal, Railway, and Harbour.*

Cheltenham and Great Western Union [P. C., p. 262].—Opened to Cirencester, May, 1841; to Gloucester, May, 1845. The remainder of the line to Cheltenham forms part of the Birmingham and Gloucester Railway. Purchased by the *Great Western* Railway Company.

Chester and Birkenhead [P. C., p. 262].—An act of 1845 authorises an extension of 7 furlongs at Birkenhead. See *Birkenhead, Lancashire, and Cheshire Junction.*

Chester and Crewe. [P. C., p. 262.]

Chester and Holyhead.—Length, about 84¾ m. The original act, passed in 1844, deferred the portion near the Menai Strait, which it was then proposed to cross by the existing suspension-bridge. A second act, obtained in 1845, supplies the deficiency, providing for a new bridge, which is to be made in the form of a wrought-iron tube or hollow beam, of about 460 feet span, so elevated that ships may sail under it. See *North Wales;* and *Shropshire Union.*

Chester and Wolverhampton.—See *Shropshire Union.*

Churnet Valley.—See *North Staffordshire.*

Clarence. [P. C., p. 262.]

Clay-Cross and Newark.—See *Midland.*

Cockermouth and Workington.—Length, 8¾ m.; act passed 1845.

Cockermouth and Workington Extension.—From Cockermonth to Keswick; length, nearly 14½ m.; act passed 1846.

Colchester, Stour Valley, Sudbury, and Halstead.—From the Eastern Counties Railway at Marks Tey, near Colchester, to Sudbury, nearly 12 m.; line to Halstead, 5¾ m.; branch from the Eastern Union Railway to the Hythe, at Colchester, and short junctions, 1½ m.; total, 19½ m.; act passed 1846. The company has bought most of the shares in the Stour Navigation; and the whole undertaking is to be leased to the *Eastern Union* and *Ipswich and Bury St. Edmund's* Railway Companies.

Coleorton. [P. C., p. 262.]

Commercial.—See *London and Blackwall.*

Cornwall.—Main line, from Falmouth to Eldad, near Plymouth, 63½ m.; branch to Padstow, 15¾ m.; branches to the Liskeard and Caradon Railway, and to the quays at Truro and Penryn, about 1¾ m.; total length, about 71 m. Promoted by the Great Western, Bristol and Exeter, and South Devon Railway Companies, and to be laid on the broad gauge. The act, passed in 1846, authorises the purchase or leasing, if desired, of the *Bodmin and Wadebridge* and *Liskeard and Caradon* Railways, and the Liskeard and Looe Canal.

Coventry, Nuneaton, Birmingham, and Leicester.—From the Trent Valley Railway near Nuneaton to the Midland Railway at Wigston Magna, Leicestershire; length, 15 m.; act passed 1846. The continuation from Nuneaton to Coventry, struck out of this bill, is provided for by a line granted in 1846 to the London and Birmingham, now *London and North-Western* Railway Company, who have purchased this undertaking.

Cromford and High Peak. [P. C., p. 262.]

Croydon and Epsom.—Length 8 m.; act passed 1844; sold to the *London and Croydon* Railway Company. Projected as an atmospheric railway, but is to be worked for the present by locomotives. See *Direct London and Portsmouth.*

Croydon, Merstham, and Godstone. [P. C., p. 262.]

Delabole and Rock.—From Mellorn, in the parish of Minster, to Black Rock, in the parish of St. Michael, St. Minver Lowlands, Cornwall; length, 16¾ m.; act passed 1844. To be worked by horses, though some passenger-traffic is expected.

Deptford Pier Junction [P. C., p. 262].—Abandoned.

Devonport, Bristol, and Dover Junction.—See *Reading, Guildford, and Reigate.*

Direct London and Portsmouth.—From the Croydon and Epsom Railway at Epsom to Portsmouth; length 60½ m.; act passed 1846. This line was projected by the London and Croydon Railway Company, as an atmospheric railway; but it now (November, 1846) appears probable that locomotive power may be adopted. The line is to be sold to the *London, Brighton, and South Coast* and *London and South-Western* Railway Companies jointly. See *Reading, Guildford, and Reigate.*

Duffryn-Llynvi and Porth Cawl [P. C., p. 262].—Amalgamated in 1846 with the *Llynvi Valley* Railway; and may probably be converted into a locomotive line.

Dunstable and London and Birmingham.—From the London and Birmingham line near Leighton Buzzard; length, 7 m.; act passed 1845. To be leased or sold to the *London and North Western* Railway Company.

Durham Junction [P. C., p. 263].—Length, from the Seaham Railway to the Stanhope and Tyne Railway (both of which were made without acts of parliament), nearly 5 m. Purchased by the *Newcastle and Darlington Junction* Railway Company.

Durham and Sunderland [P. C., p. 263].—Purchased by the *Newcastle and Darlington Junction* Railway Company, and to be adapted to locomotive engines.

East and West India Docks and Birmingham Junction.—From the East and West India Docks to the London and Birmingham railway at Camden Town; length, 8 m.; act passed 1846. Promoted by the *London and Birmingham* Railway Company.

East and West Yorkshire Junction.—From Knaresborough to the Great North of England Railway about 1½ m. from York; length, barely 15½ m.; act passed 1846.

East Anglian.—Under this title it is proposed to amalgamate the *Lynn and Ely, Lynn and Dereham,* and *Ely and Huntingdon* Railways, and to lease them to the *Eastern Counties* Railway Company.

East Lancashire (originally *Manchester, Bury, and Rossendale*).—From the Manchester and Bolton Railway at Clifton Hall, about 4 m. from Manchester, by Bury, to Rawstenstall; length 14 m.; original act passed 1844; amendment act, in which the name was altered, 1845; opened September, 1846. Amalgamations have been arranged with the *Blackburn, Burnley, Accrington, and Colne,* the *Blackburn and Preston,* and the *Liverpool, Ormskirk, and Preston* lines. An act of 1846 authorises the Bacup branch, of 4½ m., and the Crawshaw Booth branches, of 1½ m; and deviations to the extent of 8½ m. on the extension line.

East Lincolnshire.—From Great Grimsby, by Louth and Alford, to Boston; length 48 m.; act passed 1846. Sold to the *Great Northern* Railway Company.

Eastern Counties [P. C., p. 263].—Opened from London to Colchester, 51½ m, in March, 1843, and the remainder of the original parliamentary line abandoned; the *Eastern Union; Ipswich, Bury, and Norwich;* and *Yarmouth and Norwich* lines taking its place. In 1843 the Eastern Counties Company made terms of amalgamation with the *Northern and Eastern* Company, and became possessors of their finished line of about 29 miles from the Eastern Counties line at Stratford to Bishop's Stortford, with its Hertford and Ware branch, and of the unfinished extension of about 10 m. from Bishop's Stortford to Newport. In 1844 the Eastern Counties Company obtained an act for extending this northern line by Cambridge to Ely, and thence eastward to Brandon, and westward to Peterborough, making altogether 72 m. of new line, of which the portion from Bishop's Stortford to Cambridge, Ely, and Brandon, was completed in July, 1845. The course of the Ely and Peterborough line was altered for a length of 23¾ m. under an act of 1845, in order to pass through March. It is (November, 1846) nearly completed. Another act of the same session authorised a line of 17½ m. from Cambridge to Huntingdon. In 1846 the Eastern Counties Company obtained acts for enlarging their London and Stratford stations; making a line from Ilford to Epping, 10½ m. long; and two branches, amounting together to little more than ½ m., from the *Eastern Counties and Thames Junction* line, which, as well as the *North Woolwich,* they have purchased. See also *East Anglian; Enfield and Edmonton; London and Blackwall Extension; Maldon, Witham, and Braintree; Midland; Newmarket and Chesterford;* and *Wisbech, St. Ives, and Cambridge Junction.* The gauge of the Colchester and Northern and Eastern lines was altered in 1844 to 4 f. 8½ in.

Eastern Counties and Thames Junction.—From Stratford to the mouth of the river Lea; length, 2½ m.; act passed 1844; opened April, 1846. Sold to the *Eastern Counties,* which see. See also *North Woolwich.*

Eastern Union.—From Colchester to Ipswich; length, 17 m.; act passed 1844; opened June, 1846. For 2½ m. from Colchester the line was made by the Eastern Counties Company, the land being theirs; but this portion has been sold to the Eastern Union Company. See *Colchester, Stour Valley, Sudbury, and Halstead Eastern Union and Hadleigh Junction;* and *Ipswich and Bury St. Edmunds.*

Eastern Union and Hadleigh Junction.—Length, with two junctions with the Eastern Union line, 6½ m.; act passed 1846. Sold to the *Eastern Union* Railway Company.

Ely and Huntingdon.—Length, under the original act of 1845, 22 m.; but subsequently shortened by an arrangement for using the Eastern Counties line about 1 m. from Ely. See *East Anglian.*

Enfield and Edmonton.—From the Northern and Eastern Railway at Edmonton; length, 3 m.; act passed 1846. Power given to sell the line to the *Eastern Counties* Company.

Epping.—See *London and Blackwall Extension;* and *Eastern Counties.*

Erewash Valley.—From the Midland Railway at Sawley to the Mansfield and Pinxton Railway; length, 13¾ m.; act passed 1845; sold to the Midland Railway Company. For extension and branches see *Midland.*

Exeter and Crediton.—Length 5¾ m.; act passed 1845. Leased to the *Bristol and Exeter*. To open December, 1846. An act for a similar line was passed in 1832, but not carried into effect.

Exeter and Exmouth.—Length, with a very short branch at Topsham, 10½ m.; act passed 1846.

Festiniog. [P. C., p. 263.]

Fleetwood, Preston, and West Riding Junction.—From Preston to Clitheroe; length, nearly 16 m.; act passed 1846. See *Preston and Longridge.*

Forest of Dean (formerly *Bullo Pill*). [P. C., p. 263.]

Furness.—Original line, under an act of 1844, intended to connect iron-mines near Dalton Lindale, and slate-quarries at Kirkby-Ireleth, with the coast at Barrow and Rampside; length, 15½ m. Opened in June, 1846, and passenger-traffic worked in connexion with steamers from Piel harbour to Fleetwood. An act of 1846 authorises an extension of 3½ m. from Sandside to Broughton, one of 4 m. from Dalton to Ulverstone, and branches to the Whitriggs and Butts iron-mines, making a total of 9 m.

Gloucester and Cheltenham. [P. C., p. 263.]

Gloucester and Dean Forest.—From Gloucester to the Monmouth and Hereford Railway, and to the South Wales Railway at Awre; main line, 15¼ m.; branches, 2½ m.; act passed 1846. To be laid on the broad gauge, and leased or sold to the *Great Western* Railway Company.

Gosport Branch [P. C., p. 263].—Opened February, 1842.

Grand Junction [P. C., p. 263].—Besides the amalgamations mentioned in P. C. the Grand Junction Company has since, by various arrangements, become possessed of the *Liverpool and Manchester* and (jointly with the Manchester and Leeds Railway Company) the *North Union* lines, with their several branches and connexions; and by an act of 1846 the Grand Junction itself, with these additions, has been amalgamated with the *London and Birmingham* and *Manchester and Birmingham*, with their associated lines, under the new title of the *London and North-Western* Railway. Other acts of the same session authorise the Huyton and Warrington branch, of 12 m.; the Huyton and Aston branch, of 12 m., with a subsidiary branch of 1 m. to Runcorn; the Huyton, Preston, and St. Helen's branch, of 5½ m.; the Warrington and Kenyon branch, of nearly 5 m.; the Warrington and Parkside branch, of 4½ m.; and the Edgehill and Huyton branch, of 4½ m.; making a total of about 44½ m.

Gravesend and Rochester.—Made in anticipation of an act of parliament, by the Thames and Medway Canal Company, alongside of the canal, and opened in February, 1845. An act was obtained in 1845. Length, 6½ m. Sold to the *South-Eastern* Railway Company, who will close the canal and double the line.

Great Grimsby and Sheffield Junction.—From near Gainsborough to Great Grimsby, with branches to New Holland and Market Rasen; total length 59½ m. These lines were included in the original act of 1845; others, passed in 1846, sanction deviations to the extent of 4½ m.; the establishment of a steam-ferry across the Humber; an extension from Bole to Newark-upon-Trent, 20½ m.; an extension of 16 m. from the Market Rasen branch to Lincoln; a branch of nearly 4 m. to Barton-upon-Humber; and a branch of 2¾ m. to Caistor; making about 43½ m. of new lines. Under another act this, the Sheffield, Ashton-under-Lyne, and Manchester, and other companies, are united as the *Manchester, Sheffield, and Lincolnshire* Railway Company.

Great North of England [P. C., p. 263].—Opened from York to Darlington, 44¾ m. March, 1841; and the remainder of the parliamentary line abandoned, the *Newcastle and Darlington Junction* being substituted for it. The completed line has been sold to the Newcastle and Darlington Junction Company, the name of which, under an act of 1846, which sanctions the purchase, is changed to the *York and Newcastle* Railway Company. Under an act of 1845, a branch of 9¾ m. has been formed from a few miles south of Darlington to Richmond, which was opened in September, 1846; and under acts of 1846 the York and Newcastle Railway Company have power to make branches to Bedale, 7 m.; to Boroughbridge, 5¾ m.; and from Thirsk to Malton, 20½ m., with subsidiary branches of 5 m. to Helmsley, ¾ m. to New Malton, and 2¾ m. to Sessay.

Great North of England, Clarence, and Hartlepool Junction [P. C. p. 263].—Acts of 1843 and 1845 authorised new branches of ½ m. and ½ m. respectively. The whole undertaking has been sold to the *Hartlepool* Dock and Railway Company, and has merged with it in the *York and Newcastle*. Opened October, 1846, in connexion with a re-opening of the Hartlepool line as a branch of the York and Newcastle.

Great North of England and Richmond—See *Great North of England.*

Great Northern (originally *London and York*).—Main line from King's Cross, London, by Hitchin, Biggleswade, Huntingdon, Peterborough, Grantham, Newark, East Retford, Bawtry, Doncaster, and Selby, to the Great North of England Railway at or near the York station, nearly 186 m.; loop or diverging line from near Peterborough, by Spalding, Boston, Lincoln, and Gainsborough, rejoining the main line at Bawtry, 86 m.; branch to Bedford, nearly 8 m.; minor branches and junctions, about 5½ m.; total length, 285½ m. The *Stamford and Spalding* line, though the subject of a separate act, is a branch of the Great Northern, and several others are projected. The company also proposes to deviate in some places from the parliamentary line, including an extension at the London end to a point between the Gray's Inn and Bagnigge Wells roads, north of the Middlesex House of Correction. The proprietary is formed by amalgamating with the London and York the rival direct Northern Company. See *Ambergate, Nottingham, and Boston and Eastern Junction; Boston, Stamford and Birmingham; East Lincolnshire; Royston and Hitchin;* and *Sheffield and Lincolnshire Extension.*

Great Western [P. C., p. 263].—Completed June, 1841. The company have purchased the *Berks and Hunts*, the *Cheltenham and Great Western*, the *Monmouth and Hereford*, and the *Oxford and Rugby* lines; lease the *Bristol and Exeter;* and possess the *Oxford Branch*, which see. See also, for further connexions, *Birmingham and Oxford Junction; Birmingham, Wolverhampton, and Dudley; Bristol and South Wales Junction; Cornwall; Gloucester and Dean Forest; Great Western and Uxbridge; Great Western and Wycombe; Oxford, Worcester, and Wolverhampton; Portbury; South Devon; South Wales; West Cornwall; West London;* and *Wilts, Somerset, and Weymouth.*

Great Western and Uxbridge.—Joins the Great Western line at West Drayton; length rather over 2½ m.; act passed 1846. To be sold to the *Great Western* Railway Company

Great Western and Wycombe.—From the Great Western line at Maidenhead to High Wycombe; length over. 9½ m.; act passed 1846. To be sold to the *Great Western* Railway Company.

Greenwich and Gravesend—See *South-Eastern.*

Grosmont. [P. C., p. 263.]

Guildford Extension, Portsmouth, and Fareham.—Projected as the Guildford, Chichester, Portsmouth, and Fareham Railway; but the greater part of the line being superseded by the *Direct London and Portsmouth*, the act, passed in 1846, sanctions only a line of about 4 m. from Guildford to the Direct London and Portsmouth at Fareham, and one of about 8 m. to connect Fareham with Portsmouth. The power to make these has been sold to the *London and South-Western* Railway Company.

Guildford Junction.—From Woking, on the London and South-Western Railway; length 6 m.; act passed 1844; opened May, 1845. Sold to the *London and South-Western* Railway Company. See *Guildford Extension, Portsmouth, and Fareham.*

Harecastle and Sandbach.—See *North Staffordshire.*

Hartlepool [P. C, p. 263].—Sold, together with the Hartlepool Dock, and the *Great North of England, Clarence, and Hartlepool Junction* line (which see), to the Newcastle and Darlington Junction, now *York and Newcastle* Railway Company.

Hay. [P. C., p. 263.]

Hayle [P. C., p. 263].—Adapted to passenger-traffic in 1843. See *West Cornwall.*

Heckbridge and Wentbridge. [P. C., p. 263.]

Hereford. [P. C., p. 263.]

Hertford and Ware Branch.—See *Northern and Eastern.*

Huddersfield and Manchester Railway and Canal.—A railway from the Sheffield, Ashton-under-Lyne, and Manchester line at Stalybridge to the Manchester and Leeds line at Kirkheaton, 21½ m., with a branch of 1½ m. to Delph; act passed 1845. The Company to purchase the Huddersfield and Sir John Ramsden's canals. Acts of 1846 authorise a deviation at Huddersfield; a branch of 1½ m. from Cooper Bridge; and a branch of 4½ m. to Oldham. The undertaking is to be leased or sold to the *London and North-Western* Railway Company.

Huddersfield and Sheffield Junction.—From Huddersfield to the Sheffield, Ashton-under-Lyne, and Manchester Railway at Penistone, 13½ m., with branch to Holmfirth, 2 m.; act passed 1845. An act of 1846 sanctions the amalgamation of this company with the *Manchester and Leeds.*

Hull and Selby [P. C., p. 263].—An act of 1845 sanctioned a branch of 31 m. from Hull to Bridlington, the greater part of which was opened in October, 1846; another of 1846 authorises the lessing or sale of the whole undertaking to the *York and North Midland* and *Manchester and Leeds* Railway Companies.

Ipswich and Bury St. Edmunds.—An extension of the Eastern Union line; length, 26¾ m.; act passed 1845. A second act of 1846 allows an extension of 31 m. to Norwich, with a branch of 1 m., and changes the name to the *Ipswich, Bury, and Norwich.* The original line is (November, 1846) nearly completed; and the company proposes to amalgamate with the *Eastern Union.*

Ipswich, Bury, and Norwich.—See *Ipswich and Bury St. Edmunds.*

Kendal and Windermere.—Length 10½ m.; act passed 1845.

Kenyon and Leigh [P. C., p. 263].—Merged, with the adjacent lines, in the *London and North-Western.*

Kington. [P. C., p. 263.]

Lancashire and North Yorkshire.—See *Liverpool, Manchester and Newcastle-upon-Tyne Junction.*

Lancashire and Yorkshire North-Eastern.—See *Wharfedale.*

Lancaster and Carlisle.—Length 69¾ m.; act passed 1844. An act of 1845 authorises a deviation and branch, amounting to 4½ m.; and one of 1846, an extension of ½ m. to a joint station at Carlisle. A proposed amalgamation with the Lancaster and Preston Junction has been broken off. Opened November, 1846. See *Scottish Central.*

Lancaster and Preston Junction. [P. C., p. 263.]

Launceston and Victoria [P. C., p. 263].—Abandoned.

Leeds and Bradford.—Original line, under an act of 1844, from Leeds, along the valley of the Aire, and by Shipley, to Bradford, 13½ m., with a branch of 1¼ m. to the North Midland Railway at Leeds; opened July, 1846. An act of 1845 authorises an extension from Shipley to Colne, with a branch to Haworth, together 30½ m.; and acts of 1846 provide for an alteration of that extension, and a line of 1 m. to join the West Riding Union Railway, at Bradford. After agreeing to amalgamate with the *Manchester and Leeds*, an arrangement was made in 1846, to supersede it by a perpetual lease of the whole undertaking to the *Midland* Railway Company.

Leeds, Dewsbury, and Manchester Junction.—From the Leeds and Bradford line, near Leeds, to the Manchester and Leeds Railway at Kirkheaton, and thence to Huddersfield, being a main line of 16m. with branches amounting to 4 m. The line from Kirkheaton to Huddersfield, however, is only to be made if the *Huddersfield and Manchester* Company fail to complete theirs. Act passed 1845. A second act of 1846 provides for deviations at Dewsbury and Leeds; the Holden Clough branch of 2 m.; and the Birstall branch, nearly 3 m. To be leased to the *London and North-Western* Railway Company.

Leeds and Selby [P. C., p. 263].—Purchased by the *York and North Midland*.

Leeds and Thirsk.—Main line 39½ m.; branches to Knaresborough and Harrogate, and to the Leeds and Bradford and Great North of England Railways, amounting together to 6½ m. These are under the original act of 1845; others, passed in 1846, provide for the extension of the Knaresborough branch, for ½ m. across the river Nidd; for a line (the only part sanctioned of a proposed line from the Leeds and Thirsk Railway at Wath to Hartlepool) from the Great North of England Railway at Northallerton, to the Stockton and Hartlepool Railway at Billingham, near Stockton, nearly 20¼ m., with short branches, amounting to about 1½ m. to the Stockton and Darlington Railway, to the Yarm branch of the same, and to the Clarence Railway; and for a deviation or new branch of over 2 m. between the Leeds and Thirsk line, near Horseforth Woodhouse, and the Leeds and Bradford line near Calverley Bridge. This last-mentioned line is called the St. Helen's branch. See also *Wharfedale*.

Leicester and Swannington [P. C., p. 263].—Acts of 1846 confirm the purchase of this line by the *Midland* Railway Company, and confer on the purchasers power to alter 1½ m. of the line, and to make new branches to Leicester, 2¾ m.; to Burton-upon-Trent, 14 m.; and to Swadlincote colliery, nearly 2½ m.

Liskeard and Caradon.—Length, main line, 6½ m.; branch to the Cheesewring, 2½ m.; act passed 1843; partly opened 1844. For mineral traffic. Worked by gravity and horse-power. See *Cornwall*.

Liverpool and Bury.—Original line, under an act of 1845, from Liverpool to Wigan, Bolton, and Bury, 34 m. Acts of 1846 authorise an extension of ½ m. to Tythe Barn Street, Liverpool; a branch of nearly 1 m. from the New Springs branch to the North Union Railway at Whalley; a branch of over ½ m. to Westhoughton; and an amalgamation with the *Manchester and Leeds*.

Liverpool and Manchester [P. C., p. 263].—The junction line referred to in note (*c*) of the above page was completed in May, 1844. An act of 1845 authorises a new entrance into Liverpool, and a branch to join the Manchester, Bury, and Rossendale line at Clifton, making together 7¾ m. of new line. Another act of the same session ratified the amalgamation of the Liverpool and Manchester, with its connexions, the Bolton and Leigh and Kenyon and Leigh, with the *Grand Junction*, with which it is now merged in the *London and North-Western*.

Liverpool, Manchester, and Newcastle-upon-Tyne Junction.—Main line, from the Leeds and Bradford Railway at Elslack, to the Richmond branch of the Great North of England Railway at Scorton, 47½ m.; branch to Hawes, over 9 m.; act passed 1846. This undertaking comprises the main line of the *Lancashire and North Yorkshire* Railway, and, in the Hawes branch, a portion of that projected by the Liverpool, Manchester, and Newcastle-upon-Tyne Junction Company, the two schemes having been consolidated while before parliament. The Hawes branch, being identical with part of the *Yorkshire and Glasgow Union* projected line, is not to be made if that line be, as intended, constructed by the *Northern Counties Union* Railway Company, which see. The capital is partly subscribed by the *Manchester and Leeds* Railway Company.

Liverpool, Ormskirk, and Preston.—Main line, from the Liverpool and Bury Railway at Walton-on-the-Hill to the North Union Railway at Penwortham, 22½ m.; branch to the Blackburn and Preston Railway, nearly 2½ m.; branch to Blague-Gate Collieries, 3 m.; branch to near the junction of Walter Street and Regent Road, Liverpool, nearly 1 m.; total 29 m. Amalgamated with the *East Lancashire* Railway.

Llanelly [P. C., p. 264].—The total length of this line and its branches, according to evidence before the Gauge Commissioners (Q. 6044), is 45 m.

Llanvihangel [P. C., p. 264].—See *Newport, Abergavenny, and Hereford*.

Llynvi Valley.—From Llangynwyd to Margam; length 15 m.; act passed 1846. As it joins the South Wales Railway, this line is to be laid on the broad gauge. The company has amalgamated with the *Duffryn-Llynvi and Porth-Cawl* Rlaiway Company.

London and Birmingham [P. C., p. 264].—Under an act of 1843 this company has made a branch of 47½ m. from Blisworth, by Northampton, to Peterborough, which was opened in June, 1845. It has also purchased the *Aylesbury*, the (unfinished) *Trent Valley*, and the *Warwick and Leamington Union* Railways; and under an act of 1846, has amalgamated with the *Grand Junction* and *Manchester and Birmingham* Railway Companies, incorporating the numerous lines and connexions of the three companies under the comprehensive title of the *London and North-Western* Railway, which see. Other acts of 1846 confirm certain arrangements with the Birmingham Canal Company, and confer powers for making an extension of nearly 1 m. at Birmingham, to near Navigation Street; a branch of 10½ m. from the London and Birmingham line near Coventry, to the Trent Valley Railway at Nuneaton; an extension of ¾ m. at Leamington; and a line of nearly 6 m. from their main line at Weedon to the Northampton and Peterborough line at Northampton; and to enlarge their stations at London, Rugby, and Coventry. For other connexions and arrangements (enumerated here, rather than under the title of London and North-Western, because they have for the most part been made by the London and Birmingham Railway Company as such) see *Bedford and London and Birmingham*; *Birmingham, Lichfield, and Manchester*; *Birmingham, Wolverhampton, and Stour Valley*; *Buckinghamshire*; *Coventry, Nuneaton, Birmingham, and Leicester*; *Dunstable and London and Birmingham*; *East and West India Docks and Birmingham Junction*; *Rugby and Leamington*; *Rugby and Stamford*; *Shrewsbury and Birmingham*; *Shrewsbury and Hereford*; *Shropshire Union*; *South Staffordshire*; and *West London*.

London and Blackwall (formerly *Commercial*) [P. C., p. 264].—Extension line of ½ m. to near Fenchurch Street opened in August, 1841. An act of 1846 gives power to widen the line from Stepney to Fenchurch Street, to accommodate the traffic expected from the *Eastern Counties* Railway by the *London and Blackwall Extension* line (which see), which has been purchased by the London and Blackwall Company. The *East and West India Docks and Birmingham Junction* line will join the London and Blackwall near the West India Dock station.

London and Blackwall Extension.—Projected as the *Epping* Railway, but by agreement with the Eastern Counties Company, who have since obtained an act for a line to Epping, limited to a junction line of 1¾ m. between the London and Blackwall Railway at Stepney and the Eastern Counties Railway at Bow. Act passed 1845, since which the line has been sold to the *London and Blackwall* Railway Company, which see.

London and Brighton [P. C., p. 264].—The main line, of 41½ m., from near Croydon to Brighton, was completed in September, 1841; the Shoreham branch, of 5½ m., in May, 1840. The other branches mentioned in P. C. were abandoned, but are replaced by branches granted in 1846 in connexion with the Brighton, Lewes, and Hastings line. The 12 m. between the Croydon Railway and Reigate or Redhill, is worked over by the Brighton and South-Eastern Companies jointly, one-half of its cost having been repaid by the South-Eastern Company, who possess and maintain the southern half of that portion of the line. The London and Brighton Railway Company have purchased the *Brighton and Chichester* Railway, with its *Portsmouth Extension*, and the *Brighton, Lewes, and Hastings* Railway, which see for new branches authorised in connexion with them. In 1845 they obtained an act for a branch of 8½ m. from their main line to Horsham; and in 1846 they obtained others for a branch of 6¾ m. from the main line to East Grinstead, and a branch or extension of 6½ m., partly following the course of the abandoned *Surrey Iron Railway*, from Croydon to the London and South-Western Railway at Wandsworth, and for confirming an amalgamation with the *London and Croydon* under the name of the *London, Brighton, and South Coast* Railway Company, which see.

London, Brighton, and South Coast.—This is the new name of the *London and Brighton* Railway Company, with its branches to Hastings, Chichester, and Portsmouth, as above mentioned, conferred by the act which amalgamates it with the *London and Croydon*. See also *Direct London and Portsmouth*.

London and Croydon [P. C., p. 264].—The Company have purchased the *Croydon and Epsom* Railway (which see), and are (1846) laying down in connexion with it an atmospheric line alongside of their original works, under the authority of an act of 1845. Acts of 1846 authorise the construction of a branch of nearly 1 m. to Deptford, called the Thames Junction branch, and the amalgamation of the Company with the *London and Brighton*, under the name of the *London, Brighton, and South Coast*. See also *Direct London and Portsmouth*.

London Grand Junction [P. C., p. 264].—Abandoned.

London and Greenwich [P. C., p. 264].—The line was widened from London to the Croydon junction, by the London and Greenwich Company, the new portion being brought into use in May, 1842. Since that time a lease for 999 years has been granted to the *South-Eastern* Railway Company, who obtained powers in 1845 for a further widening, and in 1846 for a line from the

Greenwich Railway to Gravesend. The London Bridge station was formed at the expense of the London and Brighton, London and Croydon, and South-Eastern Railway Companies.

London and North-Western.—Under this new title, by an act of 1846, the *London and Birmingham, Grand Junction,* and *Manchester and Birmiugham* Railway Companies, with their respective connections, are amalgamated. The aggregate share-capital of the united company, according to the amalgamation act, is 17,242,310*l.*; and the amount of loans, 5,747,000*l.*; making a grand total of 22,989,310*l.*; which, however, will be greatly extended when the capital for the various new lines granted in 1846 to the amalgamating companies shall be raised, and when the numerous additional purchases and amalgamations proposed shall be carried into effect. Besides the lines referred to as connections of the several companies now nnited under this title, the London and North-Western Company possess shares, or bave some other interest in the *Chester and Holyhead, Lancaster and Carlisle,* and *Caledonian* Railways; and in October, 1846, an arrangement was concluded for leasing the *Scottish Central* Railway jointly to the London and North-Western, Lancaster and Carlisle, and Caledonian Companies. See also *Huddersfield and Manchester;* and *Leeds, Dewsbury, and Manchester.*

London and Portsmouth.—See *Direct London and Portsmouth.*

London and South-Western (formerly *London and Southampton*) [P. C., p. 264].—Acts of 1844 anthorise a branch of 21½ m. from Bishopstoke to Salisbnry, which is (November, 1846) nearly completed, and a short extension from the Nine Elms station, which has not been carried into effect. An act of 1845 anthorises an extension of about 2 m. from Nine Elms to a point near Waterloo and Hungerford bridges; and acts of 1846 sanction a further extension of nearly 1¾ m. to the Thames near London Bridge; a branch of nearly 32½ m. from Basingstoke, by Whitchnrch and Andover, to the Wilts, Somerset, and Weymouth Railway at Salisbnry, with a subsidiary branch of 1½ m. to join the Bishopstoke and Salisbnry branch; a branch of 6¼ m. from the Weybridge station to Chertsey and Egham; a branch of 19 m. from the Guildford Junction line, near Guildford, to Fareham and Alton; and a branch of 1¾ m. to Hampton Court bridge. The *Gosport Branch,* opened in February, 1842, is incorporated witb this undertaking. See also *Direct London and Portsmouth; Guildford Junction; Guildford Extension, Fareham, and Portsmouth; Richmond;* and *Southampton and Dorchester.*

London and York.—See *Great Northern.*

Lowestoft Railway and Harbour.—From Lowestoft to the Yarmonth and Norwicb Railway at Reedham; length 11¼ m.; act passed 1845. Under an act of 1846 this line is to be leased or sold to the *Norfolk* Railway Company.

Lydney and Lidbrook.—See *Severn and Wye.*

Lynn and Dercham.—Lengtb 26½ m.; act passed 1845; part opened October, 1846. Agreed to amalgamate with the *Lynn and Ely* and *Ely and Huntingdon* lines, under the name of the *East Anglian* Railway, wbicb see.

Lynn and Ely.—Main line, from the Lynn and Dereham Railway at Lynn, to the Eastern Counties Railway at Ely, 26½ m.; branch to Wisbecb 10 m.; branch to the harbour of King's Lynn, nearly 1 m.; act passed 1845; part opened October, 1846. Agreed to amalgamate with the *Lynn and Dereham* and *Ely and Huntingdon* lines, as the *East Anglian* Railway, wbich see.

Macclesfield Branch.—See *Manchester and Birmingham.*

Maidstone Branch.—See *South-Eastern.*

Maldon, Witham, and Braintree.—Length, 12 m.; act passed 1846; sold to the *Eastern Counties* Railway Company.

Malton and Driffield Junction.—From tbe Scarborongh branch of the York and North Midland Railway at Norton, near Malton, to the Bridlington brancb of the Hull and Selby Railway at Great Driffield, nearly 19 m.; brancb from Great Driffield to Frodingbam Bridge, 5 m.; total 24 m. Act passed 1846. Will probably be leased or sold to the *York and North Midland.*

Manchester and Birmingham [P. C. p. 264].—By the abandonment of the Parliamentary main line through the Potteries, the original undertaking was reduced to a line of 30½ m., from, Mancbester to the Grand Jnnction Railway at Crewe, which was completed in Angust, 1842, and the Macclesfield branch. The powers for making the latter were snffered to expire; but a new act was obtained in 1844, for an improved line of nearly 11 m. from near Cheadle-Hulme, abont 3 m. sonth of Stockport, to Macclesfield; and also for a short brancb from it to Poynton collieries. The Macclesfield branch was opened iu November, 1845. An act of 1845 authorises a line of 5 m., called the Ashton branch, to connect the main line with the Sheffield, Ashton-under-Lyne, and Mancbester Railway, near Guide Bridge; and an act of 1846 sanctions a branch of 2 m. from the Macclesfield branch to Bollington. The Mancbester and Birmingham Railway Company possessed some interest in the *Manchester, Buxton, Mutlock, and Midlands Junction,* and the *Manchester South Junction and Altrincham* Railways; and, by virtue of an arrangement with the Loudon and Birmingbam Company, it is, with its connexions, merged in the *London and North-Western* Railway Company.

Manchester and Bolton [P. C., p. 264].—The *Manchester, Bolton, and Bury Canal Navigation and Railway* Company, by whom this line was made, is amalgamated, under an act of 1846, with the *Manchester and Leeds* Railway Company. Part of the line is used by the *East Lancashire* Railway Company.

Manchester, Bury, and Rossendale.—See *East Lancashire.*

Manchester, Buxton, Matlock, and Midlands Junction.—Main line, from the Manchester and Birmingbam Railway, at Cheadle, to the North Midland line near Ambergate, 42½ m.; Norbury Collieries branch, 1¼ m.; Chapel-en-le-Frith branch, nearly 1¼ m.; total 45½ m. The Company intend to purchase the Cromford Canal, and to divert part of their line for a better route through Chatsworth Park. The *Manchester and Birmingham* and *Sheffield, Ashton-under-Lyne, and Manchester* Railway Companies have an interest in this undertaking.

Manchester and Leeds [P. C., p. 264].—Main line completed in March, 1841; Heywood branch of 1½ m. (made without parliamentary powers, bnt sanctioned by an act of 1844), opened April, 1841; Oldham branch, 3 m., opened March, 1842; Manchester Extension, to join, at the Victoria station, an extension from the Liverpool and Manchester line, about 1 m., opened January, 1844; Halifax branch 1½ m., opened July, 1844. An act of 1845 sanctions a branch of between 8 and 9 m. from Todmorden to Bnrnley; the extension of the Heywood branch for 4 m., to Bury; and the extension of the Oldham branch for 1 m., to Mumps. Acts of 1846 anthorise new branches to the extent of abont 14¾ m., these being the Bacup branch, 8¼ m.; Middleton branch, nearly 1½ m.; Thornhill branch, nearly 3 m., with a snbsidiary branch of ½ m. from it to Whitley; and the Crigglestone branch, 1¾ m.; and also the amalgamation with the Manchester and Leeds of the *Liverpool and Bury* Railway, the *Manchester, Bolton, and Bury Canal Navigation and Railway,* and the *Preston and Wyre Railway, Harbour, and Dock* Companies. The company has agreed to purchase the Rochdale Canal. For other railway connections see *Ashton, Stalybridge, and Liverpool Junction; Huddersfield and Sheffield Junction; Hull and Selby; Liverpool, Manchester, and Newcastle-upon-Tyne Junction; North Union; Sheffield, Rotherham, Barnsley, Wakefield, Huddersfield,* and *Goole; Wakefield, Pontefract, and Goole;* and *West Riding Union.*

Manchester and Lincoln Union Railway, and Chesterfield and Gainsborough Canal. The act, passed in 1846, authorises a railway of nearly 13½ m. from the Midland railway at Staveley to Worksop, and the consolidating into one undertaking the proposed railway and the canal from Chesterfield to the river Trent. This is part of a more extensive scheme, the remainder of which is superseded by the *Sheffield and Lincolnshire Junction* line, with which it is intended to amalgamate this undertaking.

Manchester, Sheffield, and Lincolnshire.—Under this title the *Sheffield, Ashton-under-Lyne, and Manchester,* the *Sheffield and Lincolnshire Junction,* the *Sheffield and Lincolnshire Extension,* and the *Great Grimsby and Sheffield Junction* Railway Companies, together with the Grimsby Dock Company, are amalgamated by an act of 1846.

Manchester South Junction and Altrincham.—Connects the Manchester and Birmingham, and Liverpool and Manchester lines south of the town of Manchester; total length 9¼ m.; act passed 1845. Projected in connection with the *Manchester and Birmingham* Railway Company, wbose interest in it is transferred to the *London and North-Western* Company.

Mansfield and Pinxton. [P. C. p. 264.]

Maryport and Carlisle [P. C., p. 264].—Completed February, 1845. An act of 1844 added some very short brancbes at Carlisle to the original line.

Middlesborough and Redcar.—Length 7½ m.; act passed 1845 opened Jnne, 1846. Joins the *Stockton and Darlington* Railway at Middlesborough.

Midland.—This company was formed in 1844 by the amalgamation of the *Midland Counties, North Midland,* and *Birmingham and Derby Junction* Railway Companies. Acts were obtained in 1845 for a line of 47¼ m. from the Midland Connties line at Syston to Peterborough, and of 33½ m. from Nottingham to Lincoln. The latter was opened throughout in August, 1846; and of the former about 11 m., from Syston to Melton, was brought into use in September, 1846, and abont 12 m., from Peterborougb to Stamford, in October, 1846; the last-mentioned portion being for the present leased to the *Eastern Counties* Railway Company. The intermediate portion will be altered under the powers of an act of 1846, which also anthorises a branch of 6½ m. from Barnack to Elton, and one of less than ½ m. at Syston. Other acts of 1846 empower the Midland Company to make an extension of 1¼ m. at Birmingham, forming a new junction with the London and Birmingham Railway, and avoiding the lift at the junction with the Birmingham and Gloucester line; to form a brancb to Hales Owen, noticed under *Birmingham and Gloucester;* to make a railway of 23½ m. from Barton-npon-Trent to Nuneaton, with the Swadlincote and Wooden Box branches of abont 2½ m. each, making a total of 28½ m., and to purchase the Ashby-de-la-Zouch canal; to make a railway of 26½ m., called the Clay Cross and Newark line, from the North Midland line at Clay Cross to the Nottingham and Lincoln line at Rolleston, with a branch of less than ½ m. to the Mansfield and Pinxton Railway, and one of nearly 1¾ m. to the proposed Nottingham and Mansfield line, making nearly 28½ m. in the whole; to make several short branches, amounting to about 9½ m. from the *Erewash Valley* Railway, which they have purchased; to make a line, called the Erewash Valley Extension Railway, of nearly 8½ m. from Pye Bridge to the North Midland line at Clay Cross, with a branch of 1¼ m. at Crich; to purchase the *Leicester and Swannington* Railway, and to construct the several branches elsewhere described in connection with it; to make a railway of 16¾ m. from Nottingham to Mansfield; and to purchase and close the Oakham Canal, the traffic of which will be diverted by the Syston and Peterborough line. In addition to the above lines the company have purchased or leased the *Bristol and Birmingham, Leeds and Bradford*, and *Sheffield and Rotherham* Railways, which see.

Midland Counties [P. C., p. 264].—Merged in the *Midland* Railway, which see.

Monmouth. [P. C., p. 264.]

Monmouth Branch.—See *South Wales.*

Monmouth and Hereford.—Main line 22 m.; branch to Westbury 10 m.; branch to the Forest of Dean 4½ m.: total 36½; act passed 1845. Projected as an extension, upon the broad gauge, from the Cheltenham and Great Western line at Standish, but (see *South Wales*) the works necessary for crossing the Severn have not been sanctioned by Parliament in 1845 or 1846. The line has been purchased by the *Great Western* Railway Company.

Monmouthshire.—The act, passed in 1846, is for making branch railways, to the extent of 6½ m., in connection with the *Newport and Pontypool* Railway, and for incorporating a new company to carry on the Monmouthshire Canal navigation. Portions of the original scheme having been abandoned when before parliament, the only lines authorised are one of nearly 5 m. to Blaenaven, and three very short ones to Pontnewynydd, Pontrhydyrun, and Hanson's brick-works.

Morecambe; Harbour and Railway.—The act, passed in 1846, is for making a harbour and docks at Heysham, on Morecambe Bay, with a railway of 4½ m. and branch of 2 m. to connect the harbour with Lancaster and the North-Western and Lancaster and Carlisle Railways. The line is to be transferred to the *North-Western* Railway Company.

Nantlle. [P. C., p. 264.]

Newark Extension.—See *Great Grimsby and Sheffield Junction.*

Newcastle and Berwick.—Total length, under the original act of 1845, 95½ m., including 8½ m. of branches for local traffic. An act of 1846 authorises an additional branch of nearly 5 m. to Warkworth harbour. The company has, jointly with the *Newcastle and Darlington Junction*, now *York and Newcastle* Railway Company, leased the *Newcastle-upon-Tyne and North Shields* Railway.

Newcastle upon-Tyne and Carlisle [P. C., p. 264].—The length of the main line is 61¾ m.; that of the branch from Blaydon to Redheugh (for which the company purchased part of the *Blaydon, Gateshead, and Hebburn* line), 3¾ m.; total 65½ m. An act of 1846 sanctions an extension of nearly ½ m. to Neville Street, Newcastle, and a branch of 17 m. from Haltwhistle to Alston.

Newcastle and Darlington Junction (originally *Northern Union*).—Acts passed 1842, 1843, and 1845. Main line of 23 m. from Great North of England Railway at Darlington to the Durham Junction Railway, with a branch of 2½ m. to Durham, opened in 1844. The further course of the trains is over the *Durham Junction* and *Brandling Junction* lines, both of which have been purchased by the company; and under the act of 1845 a new approach to Newcastle, with other branches, amounting to 6 m., are in progress. Other acts, passed in 1846, sanction the construction of a branch of nearly 7 m. to the Durham and Sunderland Railway, one of 12½ m. to the Bishop's Auckland and Weardale Railway, and two shorter branches amounting to nearly 2 m., making together about 21½ m.; and confer powers for making the branches described under the *Great North of England* Railway, in connection with that line, and for sanctioning the purchase of the *Pontop and South Shields* Railway, the *Durham and Sunderland* Railway, and the Wearmouth Dock; and for the leasing and purchase of the *Great North of England* Railway, by virtue of the possession of which the name of this company is changed to the *York and Newcastle* Railway Company. See also *Great North of England, Clarence, and Hartlepool Junction; Hartlepool;* and *Newcastle-upon-Tyne and North Shields.*

Newcastle-upon-Tyne and North Shields [P.C., p. 264].—Leased to the *Newcastle and Darlington Junction* and *Newcastle and Berwick* companies. An act of 1845 authorises an extension to Tynemouth, opened in October, 1846; and a branch to the quay adjoining the river Tyne at Newcastle, amounting to about 1 m. additional.

Newmarket and Chesterford.—Main, line from the Eastern Counties Cambridge Extension line at Chesterford to Newmarket, 16¾ m.; branch to Cambridge nearly 6½ m. Act passed 1846. Leased to the *Eastern Counties* Railway Company.

Newport, Abergavenny, and Hereford.—Main line 32 m.; Usk branch, 4¾ m.; Ragland branch, 6½ m. Four other short branches, two of which are to Pontypool and Portfield, swell the total length to rather over 45 m. The act, passed in 1846, confers power to purchase the *Llanvihangel* Railway.

Newport and Pontypool.—To be made by the Monmouthshire Canal Company; length, 13 m.; act passed 1845. See *Monmouthshire.*

Newtown and Crewe.—See *Shropshire Union.*

Norfolk.—Formed by the amalgamation of the *Norwich and Brandon* and *Yarmouth and Norwich*, which see. An act of 1846 authorises an extension of 22½ m. from the Dereham branch (see *Norwich and Brandon*) near Dereham to Wells, with a branch of nearly 6½ m. to Blakeney; total, 29½ m.; and another sanctions the purchase or lease of the *Lowestoft* Railway, Harbour, and Navigation.

North Midland [P. C., p. 264].—Merged in the *Midland* Railway.

North Staffordshire.—The company incorporated under this title in 1846, which is in friendly relation with the *London and North-Western*, and may probably be united with it, obtained three distinct acts, authorising, respectively, the Churnet Valley line, of nearly 45 m., from the Macclesfield branch of the Manchester and Birmingham line at Macclesfield to the Birmingham and Derby line at Willington, with the Burton-upon-Trent termination, nearly 4 m., and a branch of 16½ m. from Uttoxeter to the Potteries line near Stoke-upon-Trent, making together nearly 65½ m.; the Potteries line, of 38½ m., from the same point at Macclesfield to the Trent Valley Railway at Colwich, with the Crewe branch, 8½ m., the Newcastle-under-Lyme branch, under 4½ m., and the branch to join the Grand Junction line at Norton Bridge, rather more than 3½ m.; making together about 54¾ m.; and a line from the Potteries line at Harecastle to the Manchester and Birmingham Railway at Sandbach, about 8 m.: making an aggregate length of about 128½ m. The Company is empowered to purchase the Trent and Mersey Canal.

North Union.—Formed by the consolidation of the *Preston and Wigan* and *Wigan Branch* Railways. [P. C., pp. 264, 265.] An act of 1844 confirms the amalgamation of the *Blackburn and Preston* with this undertaking; and one of 1846 sanctions an arrangement for leasing the whole in perpetuity to the *Grand Junction* (now merged in the *London and North-Western*) and the *Manchester and Leeds* Railway Companies jointly.

North Union and Ribble Navigation.—From the North Union Railway to the Victoria Quay, Preston, ¾ m.; act passed 1845. To be made by the *North Union* Railway and Ribble Navigation Companies.

North Wales.—From Porth Dynllaen to Bangor, length 28½ m.; act passed 1845. An amendment act of 1846 authorises a deviation or loop line of 1½ m. at Carnarvon, and a branch of ½ m. to join the Chester and Holyhead line at Bangor; and gives power to lease or sell the line to the *Chester and Holyhead* Railway Company.

North Wales Mineral.—Under the original act of 1844 this was to consist of a line of 10½ m. from the Chester and Holyhead Railway, near Chester, to Wrexham, with a junction line or branch of ½ m. to the river Dee. An act of 1845 authorised an extension of rather more than 6 m. from Wrexham, past Ruabon, to join the Shrewsbury, Oswestry, and Chester Junction line at Cefn Mawr, and a branch of about 6 m. from Rhos Robin to Minera, to accommodate iron and coal mines; and one of 1846 sanctions a deviation of 2½ m., and two branches, the Ffrwd branch, of nearly 1½ m., and the Bryn Mally branch, of ½ m. Another act of 1846 consolidates this undertaking with the *Shrewsbury, Oswestry, and Chester Junction*, under the title of the *Shrewsbury and Chester* Railway. The main line, from the junction with the Chester and Holyhead Railway, at Saltney, near Chester, to Ruabon, was opened in November, 1846.

North Western.—From the Leeds and Bradford Extension Railway to the Lancaster and Carlisle Railway, 42¾ m., with a branch or diverging line of nearly 18½ m. to Lancaster; total length, 61 m.; act passed 1846. See *Morecambe.*

North Woolwich.—From the Eastern Counties and Thames Junction Railway near the mouth of the river Lea to the bank of the Thames opposite Woolwich; length 2¾ m.; act passed 1845; nearly completed November, 1846. Sold to the *Eastern Counties* Railway Company.

Northampton and Peterborough.—See *London and Birmingham.*

Northern and Eastern [P. C., p. 264].—The reduced line to Bishop's Stortford was opened in May, 1842. The Hertford and Ware branch, from Broxbourne, 5¾ m. long, formed under an act of 1841, was opened in October, 1843. In 1843 an act was obtained for extending the main line from Bishop's Stortford to Newport, about 10 m., and subsequently the company amalgamated with the *Eastern Counties*, which see. The gauge has been altered to 4 ft. 8½ in.

Northern Counties Union.—From the Great North of England Railway at Thirsk to the Lancaster and Carlisle Railway at Clifton, 69 m., and from Bishop's Auckland to the Lancaster and Carlisle Railway at Tebay, 50½ m., making, with the Wath branch of 7 m., and the Auckland branch of ¾ m., a total of 127 m. A portion of this, however, is coincident with the Hawes branch of the *Liverpool, Manchester, and Newcastle-upon-Tyne Junction* Railway, and is to be constructed by agreement for joint use. Act passed 1846. This undertaking is formed by the consolidation of the York and Carlisle and Yorkshire and Glasgow projected lines, adopting the course of the latter from Thirsk to Clifton and a portion of the former from Bishop's Auckland to Tebay.

Northern Union.—See *Newcastle and Darlington Junction.*

Norwich and Brandon.—By the original act of 1844 this was to be a main line of 35 m., with a branch of 3 m. to Thetford; but under an act of 1845 the main line was diverted to pass through Thetford, making the length about 36¾ m. Opened July, 1845. Amalgamated with the *Yarmouth and Norwich* as the *Norfolk* Railway, which see. The act of 1845 allows a branch of 11¾ m. from Wymondham to East Dereham.

Nottingham and Lincoln.—See *Midland.*

Nottingham and Mansfield.—See *Midland.*

Oldham Branches.—See *Huddersfield and Manchester*, and *Manchester and Leeds.*

Oxford and Bletchley Junction.—See *Buckinghamshire.*

Oxford Branch.—From the Great Western Railway at Didcot to Oxford, 9½ m.; act passed 1843; opened June, 1844. Made by the *Great Western* Railway Company. Gauge 7 feet.

Oxford and Rugby.—From the Oxford branch of the Great Western Railway at Oxford to the London and Birmingham and Midland Railways at Rugby; length 50½ m; act passed 1845. Sold to the *Great Western* Railway Company, who are constructing it as a broad-gauge line. See *Birmingham and Oxford Junction* Railway, and also the account of the gauge controversy, p. 665.

Oxford, Worcester, and Wolverhampton.—The original act, passed in 1845, was for a main line of 92½ m. in extension of the Oxford branch of the Great Western Railway, with the Worcester branch, 1½ m., the Stoke branch, 4 m., the Stourbridge branch, 1 m., and the Kingswinford branch, 2½ m., making a total of 101½ m. An act of 1846 provides for some alterations in the line, and a branch of 8¾ m. to Stratford-on-Avon, one of 4½ m to Witney, and a connecting line of ½ m. at Droitwich, making together 13½ m. of new line. The line is being constructed for the broad gauge, and under a guarantee from the *Great Western* Railway Company; but provision is made in the original act for laying additional rails where the connection with narrow-gauge lines may render it necessary in order to avoid a break of gauge. (See remarks on the gauge question, p. 665.) The company have leased the *Stratford and Moreton* Railway; and the act of 1846 gives power to purchase the Stratford-on-Avon and Stourbridge Extension Canals, the former of which they will transfer to the Birmingham and Oxford Junction Railway Company.

Oystermouth. [P. C., p. 264.]

Plymouth and Dartmoor. [P. C., 264.] See *South Devon.*

Pontop and South Shields.—A private company, formed about 1831 or 1832, constructed, without the authority of an act of parliament, an extensive line called the *Stanhope and Tyne* Railway, running for about 34 m. from South Shields, through the northern part of the county of Durham, to Stanhope, which was worked, at least partially, by locomotive engines, and used principally for coal traffic. It proved an unsuccessful speculation; and in 1842 a new company was incorporated by act of Parliament for working a portion of the line, the old company being dissolved. In 1844 the new company, which took the name of the Pontop and South Shields Railway Company, obtained an act for widening a part of their line, and making a new branch of ½ m. to the Brandling Junction Railway; and under an act of 1846 the whole undertaking has been consolidated with the *Newcastle and Darlington Junction*, now the *York and Newcastle* Railway.

Portland. [P. C. p. 264.]

Portbury Pier and Railway.—The act, passed in 1846, is for making a pier at Portbury, and a railway of nearly 8½ m., with a branch of nearly 1 m., to connect it with the Bristol and Exeter line near Bristol; to be laid on the broad gauge, and may be leased to the *Great Western* or *Bristol and Exeter* Railway Company.

Portsmouth.—See *Brighton and Chichester, Portsmouth Extension; Direct London and Portsmouth;* and *Guildford Extension, Portsmouth, and Fareham.*

Potteries Line.—See *North Staffordshire.*

Preston and Longridge [P. C. p. 264]. To be leased or sold to the *Fleetwood, Preston, and West Riding Junction* Railway Company.

Preston and Wigan.—See *North Union.*

Preston and Wyre [P. C., p. 265]. An act of 1845 authorises branches to Blackpool, 3½ m.; to Lytham, about 4¾ m.; and to Lytham Dock, under ½ m.; total 8½ m. These were opened in April, 1846. An act of 1846 sanctions the amalgamation of the Preston and Wyre Railway, Harbour, and Dock Company with the *Manchester and Leeds* Railway Company.

Reading, Guildford, and Reigate.—Length, main line 45¾ m., and two branches at Farnborough, where the line joins the London and South-Western, rather over ½ m. each; total nearly 46½ m. This line, which is part of the projected Devonport, Bristol, and Dover Junction Railway, is to be leased to the *South-Eastern* Railway Company, whose line it joins at Reigate, and who have the option of purchasing the portion between Reigate and Dorking. By a proposed arrangement with the *Direct London and Portsmouth* Railway Company for the use of part of their line, the construction of about 11 m. of this line may be avoided.

Redruth and Chasewater (or *Deveron*). [P. C., p. 265.]

Richmond (Yorkshire). See *Great North of England.*

Richmond (Surrey).—From the London and South-Western Railway at Battersea, through Waodsworth and Putney, to Richmond, length 6 m.; act passed 1845; opened July, 1846. Sold to the *London and South-Western* Railway Company.

Royston and Hitchin.—Length, about 12 m.; act passed 1846. This is the only part yet sanctioned by parliament of the *Cambridge and Oxford* Railway, a far more extensive project. It is proposed to extend the line from Royston to Cambridge, and to lease or sell it to the *Great Northern* Railway Company.

Rugby and Leamington.—Length 14½ m.; act passed 1846. This line, which was projected to extend to Warwick, has been sold to the *London and North-Western* Railway Company, from whose station at Rugby it commences.

Rugby and Stamford.—From the Rugby station of the London and Birmingham Railway to the Syston and Peterborough line of the Midland Railway near Stamford; length nearly 35 m. The act, which was passed in 1846, was obtained by the *London and Birmingham*, now *London and North-Western*, Railway Company.

Rumney. [P. C., p. 265.]

Rye and Ashford Extension.—See *Brighton, Lewes, and Hastings, Rye and Ashford Extension.* See also *South-Eastern.*

St. Helen's and Runcorn Gap [P. C., p. 265].—The company was amalgamated in 1845 with the Sankey Canal Company under the name of the *St. Helen's Canal and Railway* Company; and in 1846 they obtained an act for making an extension railway from the township of Eccleston to the township of Garston, amounting, with branches, to nearly 7½ m., and docks at its extremity at Garston.

Salisbury Branches.—See *London and South-Western.*

Saundersfoot [P. C., p. 265].—In 1842 the company obtained an act for an extension and two new branches, amounting together to 4½ m., for mineral traffic and horse-power. See *Tenby, Saundersfoot, and South Wales.*

Selby and Market Weighton.—See *York and North Midland.*

Severn and Wye (originally *Lydney and Lidbrook*). [P. C., p. 265.]

Sheffield, Ashton-under-Lyne, and Manchester [P. C., p. 265].—The main line, and a branch of 2½ m. to Ashton, made nuder an act of 1844, were completed in December, 1845. Acts of 1846 sanction branches of nearly 1 m. to Dukinfield; of 1 m. 132 yards to Glossop (this branch having been made without parliamentary powers, and opened in 1845); of 12½ m. to Whaley Bridge, and of 2¾ m. to Hayfield; the purchase of the Peak Forest and Macclesfield Canals; and the amalgamation, under the name of the *Manchester, Sheffield, and Lincolnshire* Railway Company, of this with the *Sheffield and Lincolnshire Junction*, the *Sheffield and Lincolnshire Extension*, and the *Great Grimsby and Sheffield Junction* Railway, and the Grimsby Dock companies. The company have also agreed to purchase the Manchester, Ashton-under-Lyne, Oldham, and Stockport Canal; and they possess an interest in the *Manchester, Buxton, Matlock, and Midlands Junction* Railway. See *Sheffield and Rotherham.*

Sheffield and Lincolnshire Extension.—From the Sheffield and Lincolnshire Junction Railway, near Retford, to Lincoln, 15¾ m.; act passed 1846. About 6 m. of this line, between Saxelby and Lincoln, being common to this and the *Great Northern* (late London and York) Railway, that portion is to be constructed for joint use by the Great Northern Railway Company. Merged in the *Manchester, Sheffield, and Lincolnshire* Railway.

Sheffield and Lincolnshire Junction.—Main line, from Sheffield to Gainsborough, 33½ m.; Woodhouse Mill branch, under 1½ m.; Beighton branch, nearly 1¾ m.; total about 36½ m. Act passed 1846. See also *Sheffield and Lincolnshire Extension;* and *Manchester and Lincoln Union Railway, and Chesterfield and Gainsborough Canal.* The undertaking is merged in the *Manchester, Sheffield, and Lincolnshire* Railway.

Sheffield and Rotherham.—[P. C., p. 265.]—An act of 1845 confirms the consolidation of this undertaking with the *Midland* Railway Company, and authorises a branch of about ½ m., which was completed in 1846, to connect the line with the Sheffield, Ashton-under-Lyne, and Manchester Railway.

Sheffield, Rotherham, Barnsley, Wakefield, Huddersfield, and Goole.—Main line, rather over 21 m.; Silkstone branch, nearly 2 m.; Dodworth branch, 3 m.; total 26 m.: act passed 1846. The portion north of Barnsley is to be leased to the *Manchester and Leeds* Railway Company, and the remainder to the *South Yorkshire Coal, Railway, and Canal* Company, who, having failed to obtain their act in 1846, are to apply for one to sanction this arrangement in 1847.

Shildon Tunnel.—See *Wear Valley.*

Shipley and Colne.—See *Leeds and Bradford.*

Shrewsbury and Birmingham.—The act obtained by the Shrewsbury and Birmingham Railway Company in 1846, was for a main line of 22½ m. from Shrewsbury to Wolverhampton, with a branch or fork of 7½ m. to the Abbey Foregate, Shrewsbury, and a branch of 4½ m. to Coalbrook Dale, making a total of 34 m. These lines form part of a much more extensive scheme, the objects of which are to be attained by means of complicated arrangements with the *Shrewsbury, Wolverhampton, and South Staffordshire Junction* Railway Company (with which this company is amalgamated or united for the purpose of making the line granted to this company betweeen Shrewsbury and Wolverhampton, and so much of the line granted to the other company, as lies between Tettenhall and Wolverhampton), the *Birmingham, Wolverhampton, and Stour Valley* Railway Company, and the *Shropshire Union Railways and Canal* Company. All of the lines granted to these companies may be regarded as parts of a system of communication connected with the *London and North-Western* Railway.

Shrewsbury and Chester.—This is the title given by an act of 1846 to the amalgamated *Shrewsbury, Oswestry, and Chester Junction* and the *North Wales Mineral* Railways, which see.

Shrewsbury and Hereford.—Length, 50½ m.; act passed 1846. Projected by parties interested in the *London and North-Western* in opposition to a similar line promoted by the Great Western Railway Company.

Shrewsbury, Oswestry, and Chester Junction.—From Shrewsbury to the North Wales Mineral Railway at Cefn Mawr, with branch to Oswestry; length 23½ m.; act passed 1845. Acts of 1846 sanction an extension of less than one furlong into Shrewsbury, and deviations at Shrewsbury and other places amounting to 8½ m.; branches of 6½ m. to Crickheath, and of nearly 7 m. to Wem; and the amalgamation of the whole undertaking with the *North Wales Mineral* Railway, under the name of the *Shrewsbury and Chester* Railway.

Shrewsbury and Stafford.—See *Shropshire Union.*

Shrewsbury, Wolverhampton, and South Staffordshire Junction. Length, main line from Shrewsbury to Wolverhampton, rather over 29½ m.; branch at Shrewsbury, nearly ¾ m.; act passed 1846. Under an arrangement referred to under *Shrewsbury and Birmingham*, a considerable portion of this line will be abandoned, the two companies uniting to execute certain portions of the works projected by each.

Shropshire Union Railways and Canal.—Three acts were obtained in 1846 by a company with the above title, authorising, respectively, the formation of a railway of nearly 46 m., from the Chester and Crewe branch of the Grand Junction Railway, at Calveley, to Wolverhampton, called the Chester and Wolverhampton line, including power to purchase the Ellesmere Canal, and to convert part of it into a railway; the formation of a main line of railway of nearly 60 m. from Newtown, in the county of Montgomery, to Crewe, with branches to Ellesmere, Wem, and Whitchurch, and one at Crewe, amounting to 9½ m.; and the formation of a main line of railway of rather over 29 m. from Shrewsbury to Stafford, with a branch of 11½ m. to Stone, including power to purchase the Shrewsbury Canal. The aggregate length of the above lines is rather over 155 m.; but the company are restricted from making that portion of the last-mentioned line which lies between Shrewsbury and Wellington, in case either the Shrewsbury and Birmingham or the Shrewsbury, Wolverhampton, and South Staffordshire Railway Company should obtain their act, which both did, although, as explained under *Shrewsbury and Birmingham*, only part of the scheme of each is to be carried into effect. Arrangements are (November, 1846) pending for the leasing of the whole of the above undertakings to, or the amalgamation of the company with, the *London and North-Western* Railway Company. The *Chester and Holyhead* Railway Company possess an interest in the Shropshire Union.

Sirhowey. [P. C., p. 265.]

South Devon.—From the Bristol and Exeter Railway at Exeter to Plymouth; length, about 51¾ m., exclusive of a branch of about ¾ m. to Mill Bay, and an alteration of about ½ m. of the *Plymouth and Dartmoor* Railway, which the company are empowered to lease or purchase; act passed 1844; gauge 7 feet. Intended for working by atmospheric power; but 15 m., from Exeter to Teignmouth, opened in May, 1846, with locomotive engines. An act of 1846 sanctions a branch of 5 m. from Aller, near Newton, to Torquay; a deviation of the main line near Newton; and several alterations in connection with the towns of Plymouth and Devonport. Part of the capital for this line was subscribed by the *Great Western, Bristol and Exeter,* and *Bristol and Gloucester* Railway Companies, which are empowered to lease it; and the South Devon Company possesses an interest in the *Ashburton, Newton, and South Devon* and the *Cornwall* lines.

South-Eastern [P. C., p. 265].—The main line, which was extended about ½ m. at the Dover end under an act of 1843, was opened throughout in February, 1844. A branch of 10 m. from Paddock Wood to Maidstone, made under an act of 1843, was opened in September, 1844. In 1844 the company obtained acts for a branch of ¾ m. to Folkestone Harbour (which they had purchased), which has since been completed; and for a branch of 32¾ m. from Ashford to Canterbury, Ramsgate, and Margate, which was completed in 1846. In September, 1845, they opened the greater part of the Tunbridge Wells branch, from near Tunbridge station, which was made in anticipation of an act of parliament and completed in 1846. In 1845 they obtained acts to sanction the last-mentioned branch; to enable them to alter and extend the Canterbury, Ramsgate, and Margate branch, and to make a branch of 9½ m. from it near Minster to Deal; to enable them to purchase the *Canterbury and Whitstable* Railway; and to widen the *London and Greenwich* Railway, which they had leased for 999 years. In 1846 they obtained acts for enlarging the station at Ashford, as a central locomotive depot; for making a railway of 22½ m. from the London and Greenwich Railway, about 2½ m. from London Bridge, by Blackheath, to Woolwich and Gravesend, being part only of a proposed line to Chilham, near Canterbury, which, but for the objections of the Admiralty, would have taken a more direct course under Greenwich Park; for a line of 25¾ m. from their Tunbridge Wells branch to join the Rye and Ashford extension of the Brighton, Lewes, and Hastings Railway near Hastings, with a diverging line of 5¾ m. towards Rye; for a branch of 1¾ m. from Rye to Rye Harbour; and for authorising the purchase of the *Gravesend and Rochester* Railway and Canal. See also *Bricklayer's Arms Branch; Brighton, Lewes, and Hastings, Rye and Ashford Extension;* and *Reading, Guildford, and Reigate.*

South Staffordshire.—Formed by the amalgamation of the *South Staffordshire Junction* and *Trent Valley, Midlands, and Grand Junction* Railways, which see. The united company is on terms of friendly alliance with the *London and North-Western* Railway Company.

South Staffordshire Junction.—Main line, from the Oxford, Worcester, and Wolverhampton Railway at Dudley, to the *Trent Valley, Midlands, and Grand Junction* Railway (with which it is amalgamated, as the *South Staffordshire* Railway), near Walsall, 8½ m.; Darlaston branch, 1½ m.; Birmingham branch, nearly 1 m.; Wyrley and Daw-End branches, under ¾ m. each; total, about 12¼ m.; act passed 1846. See *Birmingham, Wolverhampton, and Dudley.*

South Wales.—Projected as a broad-gauge line in connection with the Great Western Railway, to commence by a junction with the Cheltenham and Great Western Union Railway at Standish; but owing to objections to the proposed crossing of the Severn, the original act of 1845 was limited to a main line of 160¾ m. from Chepstow to Fishguard Bay and Pembroke Dock, with a branch of 22½ m. to Monmouth. An act of 1846 provides for an extension of 12 m. from Chepstow to join the Gloucester and Forest of Dean Railway at Haglow Farm; a branch of rather over 1½ m. to Swansea, and one of nearly 5½ m. to Haverfordwest, making in the whole 18¾ m. of new line; and also sanctions several deviations, amounting to 23¾ m., on the original main line and branch; but the company were again unsuccessful in their efforts to obtain a direct connection with the Great Western line by means of a bridge or tunnel at Hock Crib. The undertaking is leased to the *Great Western* Railway Company, with provision for a future amalgamation. See also *Bristol and South Wales Junction; Llynvi Valley; Tenby, Saundersfoot, and South Wales;* and *Vale of Neath.*

South-Western.—See *London and South-Western.*

South Yorkshire.—See *Sheffield, Rotherham, Barnsley, Wakefield, Huddersfield, and Goole.*

Southampton and Dorchester.—Length, 60 m.; branch to Poole, 2 m.; act passed 1845. Gauge, 4 ft. 8½ in.; and to be leased to the *London and South-Western* Railway Company; but provision made for interchange of traffic with the Wilts, Somerset, and Weymouth broad-gauge line, at Dorchester.

Stamford and Spalding.—From the main line of the Great Northern Railway in the parish of Ufford, Northamptonshire, to the loop-line of the same railway in the parish of Crowland, Lincolnshire; length, 6¾ m.; act passed 1846. Sold to the *Great Northern* (late London and York) Railway Company.

Stanhope and Tyne.—See *Pontop and South Shields.*

Stockton and Darlington. [P. C., p. 265.]

Stockton and Hartlepool.—This line, 8½ m. long, from the Clarence Railway about 4 m. north-east of Stockton to Hartlepool, was made without an act of parliament and opened in 1840; but in 1842 the company obtained an act of incorporation.

Stratford-on-Avon Branches.—See *Birmingham and Oxford Junction;* and *Oxford, Worcester, and Wolverhampton.*

Stratford and Moreton [P. C., p. 265].—Leased or sold to the *Oxford, Worcester, and Wolverhampton* Railway Company.

Stratford and Thames Junction.—See *Eastern Counties and Thames Junction.*

Surrey Iron [P. C., p. 265].—Company dissolved by an act of 1846. See *London and Brighton.*

Swansea and Loughor.—See *Cameron's Steam Coal, &c.*

Syston and Peterborough.—See *Midland.*

Taff Vale [P. C., p. 265].—Main line opened throughout, April, 1841. Some of the branches have been abandoned, but the total length made in 1845 appears, by the evidence before the Gauge Commissioners, to have been about 34 m.; in addition to which an act of 1846 provides for new branches amounting to rather more than 17 m., of which the principal are the Rhondda Fawr branch of upwards of 9 m., the Rhondda Fach branch of 5 m., the Acrw branch of rather over 1 m., and the Dinas branch of less than ½ m. The gauge of the line is 4 ft. 8½ in. See *Aberdare*.

Taw Vale [P. C., p. 265].—An amendment act passed in 1845; and in 1846 the company obtained powers for extending their line from Barnstaple to the Exeter and Crediton Railway at Crediton, a distance of nearly 31 m. An arrangement for leasing the line to the Bristol and Exeter Railway Company has been broken off.

Tenby, Saundersfoot, and South Wales.—The act, passed in 1846, is 'for making a Railway to connect the Saundersfoot Railway with the South Wales Railway, with the Harbour of Saundersfoot, and with the Town of Tenby.' Main line, from the South Wales Railway at Reynalton to Tenby, nearly 6½ m.; branch from St. Issell's to Saundersfoot, over 1 m.; total, 7½ m. The act gives power to purchase the *Saundersfoot* Railway and Harbour.

Thames Haven Dock and Railway [P. C., p. 265].—This project has not been carried into effect; but in 1846 the company obtained an act for continuing their powers for a further period of five years, a similar act having been obtained in 1842.

Trent Valley.—From the Grand Junction Railway near Stafford to the London and Birmingham Railway at Rugby; length, 49½ m.; act passed 1845. Sold to the *London and Birmingham* Railway Company, and merged in the *London and North-Western* Railway.

Trent Valley, Midlands, and Grand Junction.—Main line, from Walsall to the Midland Railway at Wichnor Forge, in Tatenhill, 16½ m.; branch to join the Trent Valley Railway at Lichfield, ¼ m.; act passed 1846. This line, which is part of a more extensive project, portions of which will be superseded by other lines, is amalgamated with the *South Staffordshire Junction*, under the name of the *South Staffordshire* Railway.

Tunbridge Wells, Hastings, and Rye.—See *South-Eastern*.

Vale of Neath.—Main line, from the South Wales Railway, near Neath, to Merthyr Tydvil, nearly 22¾ m.; four branches, one of which joins the Aberdare Railway, about 5½ m.; total 28¼ m. Act passed 1846. To be laid on the 7-feet gauge, as a branch of the *South Wales* Railway, to the proprietors of which it may be leased or sold.

Wakefield, Pontefract, and Goole.—The original act, passed in 1845, is for a line from the Manchester and Leeds Railway at Wakefield to Pontefract and Goole, with some short branches, amounting altogether to 28¾ m. Others, obtained in 1846, sanction the construction of a jetty and other works at the port of Goole, and the construction of branches amounting to about 19 m.; consisting of the Methley branch, of nearly 4¾ m.; the Askern branch, 10¼ m.; and the Oakenshaw branch, of rather over 4 m. The whole undertaking is to be amalgamated with the *Manchester and Leeds* Railway.

Warrington and Newton [P. C., p. 265].—See *Grand Junction*.

Warwick and Leamington Union.—From the London and Birmingham Railway at Coventry to a point about midway between Warwick and Leamington; length rather under 9 m.; act passed 1842; opened December, 1844. Sold to, and made by, the *London and Birmingham* Railway Company.

Wear and Derwent.—See *Wear Valley*.

Wear Valley.—From the Bishop's Auckland and Weardale Railway to Frosterley, with a branch to Bishopley Crag; total length 11¾ m.; act passed 1845. The company have agreed to lease or purchase the *Bishop's Auckland and Weardale* Railway, with its short connected lines for mineral traffic, the *Wear and Derwent* and *Weardale Extension* Railways. and the *Shildon Tunnel*, which was formed to establish a more direct connexion between the Bishop's Auckland and Weardale and the Stockton and Darlington railways than that afforded by the Black Boy branch. The three last-mentioned undertakings have been executed without parliamentary powers.

Weardale Extension.—See *Wear Valley*.

Weedon and Northampton.—See *London and Birmingham*.

West Cornwall.—Main line, from the parish of Kenwyn to Penzance, nearly 26 m.; branch from near Redruth to the Cornwall Railway near Ponsanooth, to complete the communication between Falmouth and Penzance, 5½ m.; total, about 31½ m. To be laid on the broad gauge. The act, passed in 1846, gives power to purchase the *Hayle* Railway.

West Durham [P. C., p. 265].—Opened June, 1841.

West London (formerly *Birmingham, Bristol, and Thames Junction*) [P. C., p. 265].—Opened May, 1844, with a single track, but three rails, forming a double gauge, and worked by locomotive engines. Leased for 999 years to the *London and Birmingham* and *Great Western* Railway Companies, who obtained an act jointly in 1846 for altering about 1 m. of the line, and extending it nearly 2 m. to the river Thames at Chelsea.

West Riding Union.—This undertaking consists of a series of lines to connect Leeds, Bradford, Halifax, Huddersfield, Brighouse, Dewsbury, Cleckheaton, Heckmondwike, Stanningley, Pudsey, Lowmoor, &c., with one another, and with the main line of the Manchester and Leeds Railway; aggregate length about 45¾ m., act passed 1846. Amalgamated with the *Manchester and Leeds* Railway.

Wharfdale.—From Skipton to the Leeds and Thirsk Railway at Arthington, 21 m.; and two short branches, one at Skipton and one to form a second junction with the Leeds and Thirsk line, about 1 m.; total 22 m.; act passed 1846. It was proposed to lease this line, which was originally called the *Lancashire and Yorkshire North-Eastern* Railway, and intended to extend to York, to the *Leeds and Thirsk* Railway Company; but (November, 1846) the terms proposed have been rejected.

Whitby and Pickering [P. C., p. 265].—Purchased by the *York and North Midland* Railway Company, who obtained an act in 1845 for adapting it to locomotive engines, and another in 1846 for an extension of about 10½ m. to near Castleton.

Whitehaven and Furness Junction.—Crosses the Duddon sands; length, with two junctions with the Furness Railway, 32½ m.; act passed 1845. An act of 1846 allows a deviation of nearly 2 m. at Kirksanton; an extension of ¾ m. at Whitehaven, to join the Whitehaven Junction line; and the leasing of the undertaking to the *Whitehaven Junction* Railway Company.

Whitehaven Junction.—From the Maryport and Carlisle Railway at Maryport, along the coast, to Whitehaven; length 12 m.; act passed 1844; part opened 1846. See *Whitehaven and Furness Junction*.

Wigan Branch [P. C., p. 265].—See *North Union*.

Wilts, Somerset, and Weymouth.—Under the original act of 1845 this railway is to extend from Corsham, on the Great Western Railway, to Salisbury and Weymouth by two main branches, amounting to about 96 m., with smaller branches to Devizes, 7 m.; Bradford, 1¾ m.; Radstock, 9 m.; Sherborne, 4 m.; and Bridport, 11¾ m.; total 129½ m.; but an act of 1846 authorises several new branches and deviations, amounting in the whole to nearly 36½ m., of which length about two-thirds is to replace parts of the original scheme which have been abandoned. These additions and alterations are, the Bath branch, 7½ m.; the Weymouth extension, nearly 1 m.; the Salisbury extension, 2½ m.; the Devizes branch (substituted for that of 1845), 8½ m.; the Laycock deviation and Corsham extension, 2¼ m.; the Westbury deviation, 3 m.; the Frome deviation, 6¾ m.; the Radstock branch deviation, ¾ m.; and the Herringstone deviation, 4 m. The undertaking was projected in connexion with the *Great Western* Railway Company, whose gauge is to be adopted.

Wisbeck, St. Ives, and Cambridge Junction.—Main line, from Wisbech to St. Ives, 27½ m.; branch from St. Ives to the Cambridge and Huntingdon line of the Eastern Counties Railway at Fenny-Drayton, 1¾ m.; total 29 m.; act passed 1846. Sold to the *Eastern Counties* Railway Company.

Yarmouth and Norwich.—Act passed 1842; opened May, 1844. Length 20½ m. Amalgamated with the *Norwich and Brandon*, under the name of the *Norfolk* Railway, which see. See also *Lowestoft*. The amalgamation act of 1845 sanctioned an extension of about ½ m. at Norwich. The connexion with the Brandon line near that city by a moveable bridge over the Wensum was completed in December, 1845.

Yeovil Branch.—See *Bristol and Exeter*.

York and Beverley.—See *York and North Midland*.

York and Carlisle.—See *Northern Counties Union*.

York and Leeds.—See *York and North Midland*.

York and Newcastle.—This is the new title given by an act of 1846 to the *Newcastle and Darlington Junction* Railway, with the *Great North of England*, and other lines now associated with it. According to a statement made at a meeting of the company in October, 1846, the aggregate length of the lines belonging to this company, or which they have power to construct, is about 225 m.

York and North Midland [P. C., p. 265].—By an act of 1844, this company was empowered to make a line of about 42 m. from York to Scarborough, with a branch of 6½ m. to Pickering. The Scarborough line, an alteration of which for 3 m. near York was sanctioned by an act of 1845, was opened in July of that year. Other acts of 1845 authorise a branch of 19¾ m. from the York and Scarborough line to Bridlington, which was opened as far as Filey, about 6 m., in October, 1846; and a branch of 18¼ m. from their main line to Harrogate. Acts of 1846 authorise the York and Beverley branch of rather over 31 m., with the East Dock branch of 4 m., making together 35 m.; the Selby and Market Weighton branch of 16 m., with the Hornsea branch of 10½ m.; together 26½ m.; a new line of 17 m. for more direct communication between York and Leeds; the widening and enlargement of about 13¾ m. of the original York and North Midland line; and the extension to Castleton noticed under *Whitby and Pickering*. The company have purchased the *Leeds and Selby* and *Whitby and Pickering* lines, and also the *Hull and Selby*, with its Bridlington branch, although the act for leasing and selling the last-mentioned undertaking provides for the Manchester and Leeds Railway Company taking a share in it, which it is probable they will do. From a statement made by the chairman at a meeting of the York and North Midland Railway Company in October, 1846, it appears that the total length of railway under their management, or authorised to be made by them, is about 306 m. See also *Malton and Driffield Junction*.

York and Scarborough.—See *York and North Midland*.

Yorkshire and Glasgow Union.—See *Northern Counties Union*

Railways of Scotland.*

Aberdeen.—From Aberdeen to the Arbroath and Forfar line at Friockheim, $49\frac{1}{4}$ m.; branch to form a second junction at Guthrie, 2 m.; Montrose branch 3 m.; Brechin branch, $3\frac{1}{2}$ m.; total 58 m.; act passed 1845. To lease the *Arbroath and Forfar* Railway. See also *Deeside.*

Airdrie and Bathgate Junction.—From Airdrie to Bathgate, nearly $14\frac{1}{2}$ m.: branch to Whitburn, $3\frac{1}{4}$ m.; Branch to Blackburn nearly $2\frac{1}{4}$ m.; total, 20 m. Act passed 1846, and gives power to lease or sell the line to the *Edinburgh and Glasgow* Railway Company.

Alford Valley.—From Kintore to Alford; length nearly 16 m.; act passed 1846.

Arbroath and Forfar. [P. C., p. 265.]—An act of 1846 sanctions the leasing of the line to the *Aberdeen* Railway Company, in consequence of which the gauge will bealtered to 4 f. $8\frac{1}{2}$ in.; and a second track will be laid.

Ardrossan (formerly *Johnstone and Ardrossan*). [P. C., p. 265.]—Gauge originally 4 f. 6 in., but altered to 4 f. $8\frac{1}{2}$ in. The railway, together with the harbour of Ardrossan, has been sold to the *Glasgow, Kilmarnock, and Ardrossan* Railway Company.

Ayrshire and Bridge of Weir.—From the Glasgow, Paisley, Kilmarnock, and Ayr Railway at Johnstone to the Bridge of Weir, 3 m.; eastern branch or fork at Johnstone, 1 m.; branch to Kilbarchan, 1 m.; total length, 5 m.; act passed 1846. Sold to the *Glasgow, Paisley, Kilmarnock, and Ayr* Railway Company.

Ballochney. [P. C., p. 266.]—Gauge originally 4 f. 6 in., but to be altered to 4 f. $8\frac{1}{2}$ in., under an act of 1845. See *Monkland Mineral.*

Caledonian.—Main line, from Carlisle to Carnwath, $72\frac{3}{4}$ m.; thence to Edinburgh by a branch of $27\frac{1}{2}$ m.; and by another branch of 12 m. to the Wishaw and Coltness Railway, by which and the Clydesdale Junction line it approaches Glasgow. The original act, passed in 1845, also sanctions branches to the Scottish Central Railway at Castlecary and to Dumfries, and some minor junctions, making in the whole $137\frac{1}{2}$ m. Under several acts of 1846 the amalgamation of the *Clydesdale Junction* and *Polloc and Govan* Railways with the Caledonian, and the purchase of the *Glasgow, Garnkirk, and Coatbridge* line, are sanctioned; and the Caledonian Company are empowered to deviate their line for $1\frac{1}{2}$ m. near Carlisle; to deviate about 3 m. of the Clydesdale Junction line; to form short branch and terminal railways at Glasgow, amounting to about 2 m.; and to make branches amounting to $1\frac{1}{2}$ m. from their Castlecary branch to the Glasgow, Garnkirk, and Coatbridge Railway. See also *Glasgow, Barrhead, and Neilston Direct; Glasgow, Kilmarnock, and Ardrossan; Glasgow Southern Terminal;* and *Scottish Central.* The company also propose to amalgamate with the *Glasgow, Paisley, and Greenock.*

Caledonian and Dumbartonshire Junction.—According to the title of the act, which was passed in 1846, this is a railway 'from Glasgow to Dumbarton and Lochlomond,' 'with branches to Helensburgh and other places.' The length of the main line is $20\frac{3}{4}$ m.; of the branches, $12\frac{3}{4}$ m.; total, $33\frac{1}{2}$.

Clydesdale Junction.—From the Polloc and Govan Railway at Rutherglen to Hamilton, with a branch to the Wishaw and Coltness Railway at Motherwell. Main line rather over 8 m., Motherwell branch $6\frac{1}{2}$ m., and another short branch, making $15\frac{1}{4}$ m. in the whole. Act passed 1845. Amalgamated with the *Caledonian* Railway, which see.

Cumnock Branch.—See *Glasgow, Paisley, Kilmarnock, and Ayr.*

Deeside.—From Ferryhill, near Aberdeen, to Aboyne; length, 29 m. The act, passed in 1846, confers powers for leasing the line to the *Aberdeen* Railway Company.

Dunblane, Doune, and Callander.—Length $10\frac{1}{2}$ m.; act passed 1846. Power given to lease to the *Scottish Central* Railway Company, whose line it joins at Dunblane.

Dundee and Arbroath. [P. C., p. 266.]—Gauge to be altered to 4 f. $8\frac{1}{2}$ in. An act of 1846 authorises a branch to Broughty Ferry Castle, and another to the Arbroath and Forfar line at Almericeloss. Length, under $1\frac{1}{4}$ m.

Dundee and Newtyle. [P. C., p. 266.]—Leased to the *Dundee and Perth.* Original gange, 4 f. $6\frac{1}{2}$ in.

Dundee and Perth.—Length, $20\frac{3}{4}$ m.; act passed 1845. A second act, of 1846, sanctions some deviations in the line, a short extension at Perth; and the leasing or purchase of the *Dundee and Newtyle* Railway.

Drumpeller.—To connect coal-fields with the Monkland canal. Length $1\frac{3}{4}$ m. Act passed 1843.

Dunfermline and Charlestown.—Length $3\frac{1}{4}$ m. Made without an act of parliament, prior to 1840. Passengers and goods conveyed by horse-power.

East of Fife.—From the Edinburgh and Northern Railway at Markinch to Anstruther Easter, nearly 18 m., with a branch of $\frac{1}{4}$ mile to the Kirkland iron-works. Act passed 1846.

Edinburgh and Bathgate.—Main line, from near the Ratho station of the Edinburgh and Glasgow Railway to Bathgate, nearly $11\frac{1}{4}$ m.; Mid Calder branch, nearly $2\frac{1}{4}$ m.; Binny quarries branch, $1\frac{1}{2}$ m.; Whitburn branch (from Barrack), nearly $5\frac{1}{4}$ m.; Whitburn branch (from Bathgate), nearly 3 m.; total, about $23\frac{1}{4}$ m. Act passed 1846. Leased to the *Edinburgh and Glasgow* Railway Company.

Edinburgh and Dalkeith. [P. C., p. 266.]—Original gauge, 4 f. 6 in. Purchased, and to be improved for locomotives, by the *North British* Railway Company.

Edinburgh and Glasgow. [P. C., p. 266.]—Opened February, 1842. An act of 1844 authorised an extension of $1\frac{1}{4}$ m. at Edinburgh, to join the North British and Edinburgh, Leith, and Granton Railways at the North Bridge, which extension was opened in 1846. An act of 1845 authorised several short connecting branches, amounting in the whole to 6 m., and also the *Glasgow Junction* line, described elsewhere; and an act of 1846 authorises a branch of nearly $6\frac{3}{4}$ m. from the Gogar station to South Queensferry. Arrangements had been made by the Directors for amalgamating with, purchasing, or leasing, the *Monkland Mineral* railways, consisting of the *Monkland and Kirkintilloch, Ballochney,* and *Slamannan* lines; the *Airdrie and Bathgate Junction;* the *Edinburgh and Bathgate;* the *Glasgow, Airdrie and Monklands Junction;* the *Stirling and Dunfermline;* the *Stirlingshire Midland Junction;* and the *Wishaw and Coltness* Railways; and also the Forth and Clyde Canal; but in September, 1846, the canal amalgamation was broken off, and a subsequent change of directors may probably be followed by the abandonment of other contemplated arrangements. It is reported (November, 1846), that the Wishaw and Coltness line has been relinquished by this and taken up by the Caledonian Railway Company.

Edinburgh and Hawick.—This line, branching out of the North British Railway, and forming a continuation of the Edinburgh and Dalkeith line, has been amalgamated with the *North British.* Length, $45\frac{1}{2}$ m.; act passed 1845. The bill for a proposed extension to Carlisle was lost in 1846. For branches see *North British.*

Edinburgh, Leith, and Granton (originally *Edinburgh, Leith, and Newhaven*). [P. C., p. 266.]—The name was changed in 1844, by an act which authorised a new branch of $1\frac{1}{4}$ m. to Leith, and one of 1 m. to Granton. The total length of the present lines is nearly $4\frac{1}{2}$ m. Part of the main line was opened in 1842, and the branches and tunnel to Princes Street in 1846. The company proposes to amalgamate with the *Edinburgh and Northern* Railway Company.

Edinburgh and Northern.—By the original act of 1845 this is a main line of $35\frac{1}{4}$ m. from Burntisland, on the Firth of Forth, to Perth, with a branch of $5\frac{1}{4}$ m, to Cupar or Coupar, and one of $\frac{1}{2}$ m. to Kirkcaldy harbour; total, $41\frac{1}{4}$ m. Acts of 1846 add a branch of nearly 15 m. from Thornton to Dunfermline, of nearly $15\frac{1}{4}$ m. from Cupar to Newport, and of 600 yards from Kinghorn to Pettycur harbour; and also a line of 9 m. from Newburgh to the Scottish Central Railway at Hilton (called in the bill the Strathearn Deviation), and a deviation of 3 m. near Dysart. Exclusive of the Dysart deviation the new lines amount to about 40 m. Another act allows the purchase of the ferry across the Tay between Ferry-Port-on-Craig and Broughty. See *Edinburgh, Leith, and Granton.*

Garnkirk and Glasgow. [P. C., p. 266.]—The original gange of this line was 4 ft. 6 in., and not, as there stated, 4 ft. $8\frac{1}{2}$ in.; but by an act of 1845 it is to be increased to that width. By an act of 1844, authorising extensions to the amount of $2\frac{1}{4}$ m., the name of the company was changed to the *Glasgow, Garnkirk, and Coatbridge,* which see.

General Terminus and Glasgow Harbour.—From the Polloc and Govan Railway to the river Clyde and the harbour of Glasgow, 1 m.; with branches to the joint line of the Glasgow, Paisley, and Greenock, and Glasgow, Paisley, Kilmarnock, and Ayr Railways, and to the Glasgow, Barrhead, and Neilston Direct line; total length, under $2\frac{1}{4}$ m.; act passed 1846.

Glasgow, Airdrie, and Monklands Junction.—Main line, from Glasgow to Airdrie, $10\frac{1}{2}$ m.; branches to the Clydesdale Junction and Garnkirk extension lines, and to Mile-End, 4 m.; total, $14\frac{1}{2}$ m.; act passed 1846. Leased to the *Monkland Mineral* Railways, which see.

Glasgow, Barrhead, and Neilston Direct.—From Glasgow to Croftbead, near Neilston, 9 m.; branches out of the Glasgow, Paisley, and Greenock Railway. Act passed 1845. Under an act of 1846 branches to Thornliebank and Househill, together under $1\frac{1}{2}$ m., are authorised. Together with the *Glasgow Southern Terminal* line, this undertaking is to be leased to the *Caledonian.* See also *Glasgow, Kilmarnock, and Ardrossan,* and *Glasgow, Strathaven, and Lesmahagow Direct.*

Glasgow and Belfast Union.—From the *Glasgow, Paisley, Kilmarnock, and Ayr* line (to the owners of which it is to be made over). to Girvan, $21\frac{1}{2}$ m., with a branch of nearly 1 m. to Maybole; act passed 1846. This is only part of a much more extensive project.

Glasgow, Dumfries, and Carlisle.—From the Glasgow, Paisley, Kilmarnock, and Ayr Railway, near Cumnock, to the Caledonian Railway near the crossing of the river Sark, nearly 65 m.; Canobie branch, $8\frac{1}{2}$ m.; Annan harbour branch, under $1\frac{1}{2}$ m.; Crawick branch, $16\frac{1}{4}$ m.; total, $90\frac{3}{4}$ m. Act passed 1846. To be

* In the case of several of the earlier Scotch railways the gauge is erroneously stated in P. C. to be 4 f. $8\frac{1}{2}$ in., whereas, as will be seen by the cases in the above table in which the matter is noticed, most of them were laid with a gauge of 4 f. 6 in. Some are already, and others will be ere long, altered to the ordinary mode of gauge of 4 f. $8\frac{1}{2}$ in.

amalgamated with the *Glasgow, Paisley, Kilmarnock, and Ayr*, and the portion from Annan to Gretna to be worked by the *Caledonian* Railway Company.

Glasgow, Garnkirk, and Coatbridge.—This railway is the line originally called the *Garnkirk and Glasgow* (which see), as extended under an act of 1844 by new lines, one of which joins the Wishaw and Coltness, to the extent of 2¼ m. Of these the Garnkirk and Coatbridge extension, of rather more than 1 m., was opened in 1845, in which year an act was obtained to widen the gauge to 4 ft. 8½ in. Under three new acts of 1846 the line is transferred, by sale, to the *Caledonian* Company, and an extension of 173 yards at Glasgow, and the connecting branches mentioned under *Caledonian* are sanctioned.

Glasgow Junction.—From the Edinburgh and Glasgow Railway near Pinkston Bog to the Cut of Junction Canal at or near Broomhill, and to the north quay of the harbour of Glasgow. To be made by the *Edinburgh and Glasgow* Railway Company. Length, under act of 1845, 2¼ m.; but by an act of 1846 a length of 425 yards is to be abandoned, and a new line of 372 yards substituted for it.

Glasgow, Kilmarnock, and Ardrossan.—From the Glasgow, Barrhead, and Neilston Direct Railway at Crofthead to Kilmarnock, 14¼ m.; Ardrossan branch, nearly 10¾ m.; Irvine branch, 3¼ m., and some smaller branches; total length, about 29¾ m. Act passed 1846. The company have purchased the *Ardrossan* Railway and Harbour; and the line has been projected in connexion with the *Caledonian.*

Glasgow, Paisley, and Greenock. [P. C., p. 266.]—Opened throughout in March, 1841. Acts of 1846 authorise a branch of 352 yards to the Clyde at Greenock, and one of 330 yards to the Polloc and Govan Railway. See also *Glasgow, Barrhead, and Neilston.* To be amalgamated with the *Caledonian.*

Glasgow, Paisley, Kilmarnock, and Ayr. [P. C., p. 266.]—Main line completed in August, 1840; Kilmarnock branch, 11 m., April, 1843. Acts passed in 1845 for a branch of 18¼ m. to Cumnock, and in 1846 for deviating the Cumnock branch for 1¼ m. near Kilmarnock, and making new branches to Linwood, over 1 m.; to Swinlees, 2¼ m.; to Troon, nearly 1 m.; from Bushy to Irvine, 5¼ m., with subsidiary branches of about ¾ m. each to Perceton and Irvine harbour; and from near Blair to Strathaven, 18 m.; making a total of nearly 30 m. See also *Ayrshire and Bridge of Weir; Glasgow and Belfast Union; Glasgow, Dumfries, and Carlisle;* and *Kilmarnock and Troon.* The company has leased or purchased the Glasgow, Paisley, and Johnstone Canal.

Glasgow Southern Terminal.—From the Glasgow, Barrhead, and Neilston Direct to the Caledonian Railway; length rather over 1 m.; act passed 1846. Part of a more extensive project; and is to be made over to the *Glasgow, Barrhead, and Neilston Direct* Railway Company.

Glasgow, Strathaven, and Lesmahagow Direct.—From the Glasgow, Barrhead, and Neilston Direct Railway near Pollokshaws, to Strathaven; length 15¼ m.; act passed 1846.

Great North of Scotland.—From Aberdeen to Inverness, with branches to Banff, Portsoy, Garmouth, and Burghead. Main line, 107¾ m.; branches, 33¼ m.; total length, 138¼ m.; act passed 1846. See *Great North of Scotland; Eastern Extension.*

Great North of Scotland; Eastern Extension.—From Dyce to Fraserburgh, with branches to Peterhead, &c. Main line, 36¾ m.; branches, 10¾ m., total length, 47¼ m.: act passed 1846. To be leased to the *Great North of Scotland* Railway Company.

Hawick Branch.—See *Edinburgh and Hawick.*

Johnstone and Ardrossan.—See *Ardrossan.*

Kilmarnock Branch.—See *Glasgow, Paisley, Kilmarnock, and Ayr.*

Kilmarnock and Troon. [P. C., p. 266.]—The act of 1837, mentioned in P. C., note (*h*), was never carried into effect; but an act of 1846 sanctions the leasing of the line to the *Glasgow, Paisley, Kilmarnock, and Ayr* Railway Company, the alteration of certain parts, the conversion of the whole into a locomotive line, and two new branches, amounting to 2¼ m.

Leith Branch.—See *Edinburgh and Dalkeith.*

Monkland and Kirkintilloch. [P. C., p. 266.]—An act of 1843 authorised new branches amounting to about 1 m., and one of 1846 sanctions a branch of 2 m. 1100 yards to Chapel Hall, and one of 231 yards to the Glasgow, Garnkirk, and Coatbridge Railway. The original gauge of the line was 4 ft. 6 in.; but an act of 1845 provides for an alteration to 4 ft. 8½ in. See *Monkland Mineral.*

Monkland Mineral.—This is the collective title of the *Monkland and Kirkintolloch, Slamannan,* and *Ballochney* Railways, which have amalgamated with one another, though without the authority of an act of Parliament, and have leased the *Glasgow, Airdrie, and Monklands* Junction line. It was agreed to amalgamate the whole with the *Edinburgh and Glasgow;* but as intimated under that line, the carrying out of the arrangement is (November, 1846) very uncertain.

Morayshire.—From Stotfield and Lossiemouth Harbour to Elgin, Rothes, and Craigellachie; length 11¼ m.; act passed 1846.

Newtyle and Coupar Angus. [P. C., p. 266.]—Purchased by the *Scottish Midland Junction* Railway Company, to form part of their line.

Newtyle and Glammis. [P. C., p. 266.]—Length, 7¼ m. Purchased by the *Scottish Midland Junction* Railway Company to form part of their line.

North British.—Main line, from Edinburgh to Berwick 57¾ m.; branch to Haddington, 4¼ m.; act passed 1844; opened June, 1846. The company has purchased the *Edinburgh and Dalkeith* line under the powers of an act of 1845, which authorises them to improve it and to make new branches amounting to 1¾ m. in connexion with it. In the same session an act was obtained for the *Edinburgh and Hawick* line, which is now incorporated with the North British; and in 1846 acts were passed for making alterations in the Musselburgh and Leith branches of the Edinburgh and Dalkeith line; for making new branches to the extent of about 15¼ m., consisting of the Tranent branch, of ¾ m., the Cockenzie branch, of nearly 1½ m., the North Berwick branch, of over 4¼ m., and the Dunse branch, of rather more than 9 m.; and also for making branches to the extent of about 25 m. in connexion with the Hawick line, consisting of the Selkirk branch, rather over 5 m.; the Kelso branch, nearly 12¼ m., and the Jedburgh branch, nearly 7¼ m.

Paisley and Renfrew. [P. C., p. 266.]—Gauge, 4 ft. 6 in. Both passengers and goods are conveyed by horse power.

Polloc and Govan. [P. C., p. 266.]—See *Clydesdale Junction.* Amalgamated, under an act of 1846, with the *Caledonian* Railway.

Scottish Central.—The original act, passed in 1845, was for a main line of nearly 46¼ m., from the Edinburgh and Glasgow Railway, by Stirling, to Perth, with a branch of 1¼ m. to Falkirk; others, passed in 1846, sanction branches of 4¼ m., by Alloa Ferry to Tillicoultry; of nearly 9¼ m. to Crieff; and of 3¼ m. to Denny; and also terminal branches amounting to 2¼ m. at Perth. It had been agreed to amalgamate with the Edinburgh and Glasgow Railway Company; but the bill for that purpose having been thrown out in 1846, arrangements have been since made for leasing the line to the *London and North-Western, Lancaster and Carlisle,* and *Caledonian* Railway Companies jointly. See also *Dunblane, Doune, and Callander.*

Scottish Grand Junction.—Main line, from Oban to Crianlarich, in the county of Perth, 39¾ m.; branch to Lochlomond, 6¼ m.; act passed 1846. Part of a more extensive projected railway, for connecting the West Highlands and islands of Scotland with Glasgow.

Scottish Midland Junction.—The original act, passed in 1845, was for a main line of 30¾ m. from Perth to Forfar, with short branches, increasing the length to 33¼ m., to connect it with the Scottish Central and Arbroath and Forfar Railways. An act of 1846 sanctions additional branches to the extent of nearly 16 m., consisting of the Dunkeld branch, 8¼ m., the Blairgowrie branch, 5 m., and the Kirriemuir branch, over 2¼ m. The company have purchased the *Newtyle and Coupar Angus* and *Newtyle and Glammis* Railways, which will be altered so as to form part of their main line. It had agreed to amalgamate with the Edinburgh and Glasgow and Scottish Central Railway Companies, before their contemplated union was broken off.

Shotts and Wilsontown.—See *Wilsontown, Morningside, and Coltness.*

Slamannan. [P. C., p. 266.]—The original projected branch to Bathgate not having been executed, the company obtained an act in 1846 for a new one of nearly 4¼ m., and also for a branch to Jawcraig, of 1¾ m. See likewise *Slamannan and Borrowstounness* and *Slamannan Junction.* Both of those lines were included in the arrangements by which, prior to the recent changes noticed under *Edinburgh and Glasgow,* it was intended to amalgamate the Slamannan Railway, with its associated lines, the *Ballochney,* and the *Monkland and Kirkintilloch,* under the general name of the *Monkland Mineral* Railways, with the Edinburgh and Glasgow. Like the other mineral lines in the district, the Slamannan Railway was originally laid on the 4 ft. 6 in. gauge.

Slamannan and Borrowstouness.—Main line, from near the northern terminus of the Slamannan Railway to the Frith of Forth, and thence to the town or harbour of Borrowstouness, 5¼ m.; and two branches to the Edinburgh and Glasgow Railway, about 1½ m., total length, 6¾ m. Act passed 1846. To be made by the *Slamannan* Railway Company, which see.

Slamannan Junction.—A line of about 1 m. to connect the Slamannan and Edinburgh and Glasgow Railways. Act passed 1844; containing power to lease or sell the line to the Edinburgh and Glasgow or Slamannan Railway Companies. See *Slamannan.*

Stirling and Dunfermline.—Main line, 20¾ m.; branches from near Alloa to Tillicoultry and the harbour of Alloa, 3¾ m.; total 24¼ m.; act passed 1846. Proposed to be leased to the *Edinburgh and Glasgow* Railway Company.

Stirlingshire Midland Junction.—Main line, from the Edinburgh and Glasgow Railway to the Scottish Central Railway, 5¼ m.; branch to Carron iron-works, 1¼ m.; branch to Falkirk iron-works, ¾ m.; total, 7¾ m.; act passed 1846. Sold to the *Edinburgh and Glasgow* Railway Company.

Strathtay and Breadalbane.—From the line of the projected

Perth and Inverness Railway, (a scheme abandoned for the present during the session of 1846,) to Aberfeldy; length, nearly 9¼ m.; act passed 1846.

Wilsontown, Morningside, and Coltness, (originally called *Shotts and Wilsontown*).—A mineral line of about 8½ m., in extension of the Wishaw and Coltness Railway; made under an act of 1841, and opened in June, 1845. Acts of 1846 authorise the improvement of the original line, and the construction of branches of nearly 1½ m. to Shotts, of nearly 4¾ m. to Climpy, of 5½ m. to Bathgate, and of 8¾ m. to join the Caledonian Railway.

Wishaw and Coltness. [P. C., p. 266.]—An act of 1846 authorises the construction of a line of nearly 2¼ m. from near the southern termination of the Cleland branch to Murdieston, with a branch from it of rather more than 2¼ m. to Goodockhill, in the parish of Shotts; making a total of 5 m. An agreement had been made for the sale of the whole undertaking to the *Edinburgh and Glasgow* Railway Company; but it is now (November, 1846) expected that a union with the *Caledonian* Railway Company will be substituted for the intended arrangeme

RAILWAYS OF IRELAND.*

Belfast and Ballymena.—Main line nearly 33 m.; Carrickfergus branch 3 m.; Randalstown branch 2 m.; total 38 m.; act passed 1845.

Belfast and Cavehill. [P. C., p. 266.]

Belfast and County Down.—From Belfast to Downpatrick. 24¼ m.; with branches to Holywood, Newtownards, Bangor, and Donaghadee, amounting to 20¾ m.; total length, 45½ m.; act passed 1846.

Clonmel and Thurles.—From the Waterford and Limerick Railway at Clonmel, to the Great Southern and Western Railway at Cashel, 15½ m.; branch to the Slievardagh Collieries, 10¼ m.; total, 25¾ m. Act passed 1846. Sold to the *Great Southern and Western* Railway Company.

Cork and Bandon.—Length, 20 m.; act passed 1845.

Cork, Blackrock, and Passage.—From Cork, through Blackrock, to Passage West; length, 6¾ m.; act passed 1846.

Cork and Passage. [P. C., p. 266.]—Abandoned; but see *Cork, Blackrock, and Passage*.

Cork and Waterford.—Main line, 78 m.; branch to Fermoy, 18 m.; branch to Tramore, 1½ m.; total length, 97½ m.; act passed 1846.

Dalkey.—See *Dublin and Kingstown*.

Dublin, Belfast, and Coleraine Junction.—Main line from Armagh to Portrush, 70 m.; branch to Randalstown, 13 m.; branch to Ballymoney, 4¾ m.; total length, 87¾ m.; act passed 1846.

Dublin and Belfast Junction.—Main line, from Drogheda to Portadown, 56 m.; branch to Navan, 17¼ m.; act passed 1845. An agreement was made in 1846, for selling the Navan branch to the *Dublin and Drogheda* Railway Company.

Dublin and Drogheda. [P. C., p. 266.]—Opened May, 1844; gauge 5 ft. 3 in. An act of 1845 authorises the *Howth Branch*, 3¾ m. long, the greater part of which was opened in July, 1846. The company has purchased the Navan branch of the *Dublin and Belfast Junction*, which see.

Dublin, Dundrum, and Rathfarnham.—Dublin to Dundrum, rather over 3 m.; branch to Rathfarnham, over 2¼ m.; total length, nearly 5¼ m.; act passed 1846.

Dublin and Kingstown. [P. C., p. 266.]—An extension of 1¾ m. to Dalkey, worked by atmospheric power, was made without an act of parliament, and opened in March, 1844. It follows the line of a tramroad made by the Commissioners of Kingstown harbour. An act of 1846 authorises a further extension of 7¼ m. to the bridge of Bray. See *Waterford, Wexford, Wicklow, and Dublin*.

Dundalk and Enniskillen.—From Dundalk to the Newry and Enniskillen line at Clones, 40¾ m.; the remaining distance, about 36 m. from Clones to Enniskillen, to be made by the Newry Company, with provisions for its joint use by both lines; act passed 1845.

Dundalk Western. [P. C., p. 266.]—Abandoned.

Galway and Kilkenny.—See *Kilkenny and Great Southern and Western*.

Great Leinster and Munster. [P. C., p. 266.]—Owing to financial difficulties the act of 1837, amended by one of 1841, was never carried into effect. The *Great Southern and Western* line has superseded the Great Leinster and Munster between Dublin and Carlow, but an act of 1846 confers renewed powers for the remainder of the line from Carlow to Kilkenny, about 25¼ m. with a branch of 1½ m. to Milford; and another act of the same session authorises an extension of 31¼ m. from Kilkenny to Clonmel. The *Wexford, Carlow, and Dublin Junction* line is to be amalgamated with this undertaking under the new name of the *Irish South-Eastern* Railway.

Great Southern and Western.—Main line from Dublin to Cashel, 98¼ m.; branch from Monasterevan to Carlow, 24 m. For these the act was obtained in 1844. A second act, passed in 1845, allows an extension of 77 m. to Cork, with a branch of 21½ m. to Limerick. The Limerick branch, however, being identical with part of the *Waterford and Limerick* Railway is not to be made if that line is carried into effect. Another act passed in 1846, authorizes an extension of nearly 1¼ m. to the river Lee at Cork. Of the original line, the portion between Dublin and Carlow, about 56¼ m. was opened in August, 1846. See also *Clonmel and Thurles*; *Limerick, Ennis, and Killaloe Junction*; *Mallow and Fermoy*; *Mountmellick Junction*; and *Templemore and Nenagh*.

Irish South-Eastern.—See *Great Leinster and Munster*; and *Wexford, Carlow, and Dublin Junction*.

Kilkenny and Great Southern and Western.—From Kilkenny to the Great Southern and Western Railway near Cuddagh; length 26 m.; act passed 1846. Part of a much more extensive scheme called the *Galway and Kilkenny* Railway. Power given to lease or sell the line to the *Waterford and Kilkenny* Railway Company.

Killarney Junction.—From Mallow to Killarney, length 39¾ m.; act passed 1846.

Limerick, Ennis, and Killaloe Junction.—Main line, from Limerick to Ennis, 23¼ m.; branch from Limerick to Killaloe, 12¼ m.; branch from Limerick to Clare, nearly 1 m.; junction with Great Southern and Western line, ½ m.; total length, about 37 m.; act passed 1846. Power given to lease or sell the line to the *Great Southern and Western* Railway Company.

Londonderry and Coleraine.—Main line, crossing Lough Foyle, 32¼ m.; branch to Newtown Limavady, 6¾. Act passed 1845. To reclaim 18,000 acres of land from the sea.

Londonderry and Enniskillen.—Length, by original act of 1845, 56 m. An act of 1846 sanctions a deviation of 22 m.; a branch of nearly 1 m. to Omagh; and an extension of 1½ m. Nearly completed (November, 1846) from Londonderry to Strabane.

Mallow and Fermoy.—Joins the *Great Southern and Western* Railway (with which the act gives power to amalgamate) at Mallow; length, 16¾ m.; act passed 1846.

Midland Great Western.—The original act, passed in 1845, authorises a line of 77½ m., from Dublin to Mullingar and Longford, chiefly running upon the banks of the Royal Canal, which has been purchased by the company. Acts of 1846 sanction an extension or branch of nearly 28 m., from Mullingar to Athlone; a branch of 2¾ m. to the river Liffy, at Dublin; and a deviation of 14¼ m. near Longford.

Mountmellick Junction.—From the Great Southern and Western Railway at Carne or Curraghane to Mountmellick; length, barely 3¾ m.; act passed 1846. Gives power to lease or sell the line to the *Great Southern and Western* Railway Company.

Mullingar and Athlone.—See *Midland Great Western*.

Navan Branch.—See *Dublin and Belfast Junction*.

Newry and Enniskillen.—Length, 71¼ m.; act passed 1845. See *Dundalk and Enniskillen*.

Newry, Warrenpoint, and Rostrevor.—Main line, from Newry to Rostrevor, 8¼ m.; branch to Warrenpoint, ½ m.; act passed 1846.

Slievardagh Collieries Branch.—See *Clonmel and Thurles*.

Sligo and Shannon.—From Lough Allen to Lough Gill, in the county of Leitrim; length, 13 m.; act passed 1846.

South-Eastern.—See *Irish South-Eastern*.

Templemore and Nenagh.—Length, 20¼ m; the act, passed in 1846, gives power to amalgamate with, or lease or sell the line to, the *Great Southern and Western* Railway Company.

Ulster. [P. C., p. 266.]—Completed in September, 1842, to Portadown, about 25 m. The remaining 11 m. to Armagh was abandoned, but a new act was obtained for it in 1845. Gauge 6 ft. 2 in., but to be altered to 5 ft. 3 in.

Waterford and Kilkenny.—Main line, 31 m.; branch to Kells, 6¼ m.; act passed 1845.

Waterford and Limerick.—Length, including a short branch at Waterford, 78 m.; act passed 1845. An act for a similar line was obtained in 1826, but the project was abandoned.

Waterford, Wexford, Wicklow, and Dublin.—Main line, from Waterford to Dublin, 111¼ m.; line from Wexford to join it near Scarawalsh Bridge (to connect it with a projected line from Enniscarthy to Carlow), 22 m.; branch to Wicklow, rather over 2 m.; total length, 135¼ m. The act, passed in 1846, confers power to lease the *Dublin and Kingstown* Railway.

Wexford, Carlow, and Dublin Junction.—From Wexford to Carlow; length, 29 m.; act passed 1846. Amalgamated with the *Great Leinster and Munster* under the title of the *Irish South-Eastern* Railway Company.

TRANSOM. [MULLION, P. C.]

TRANSPOSITION, in Music, is a change of the original key to one higher or lower. This is generally performed, at a moment's notice, by the accompanist,—sometimes to suit the reasonable convenience, but more often to gratify the whim, of the singer.

To the singer Transposition is unattended by any difficulty whatever: the change is little more than imaginary, except so far as relates to the compass of the voice. To the accompanist it is far otherwise. The latter, unless playing from memory, must assign to all the notes, as regards their pitch,

* The gauge of all Irish railways is required to be 5 feet 3 inches, in accordance with a recommendation made by the Board of Trade in 1843.

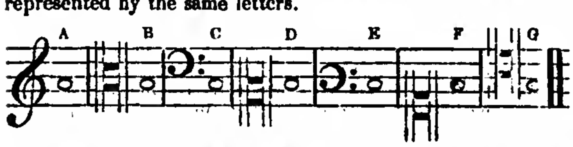
or their situations on his instrument, names wholly different from those in the copy placed before him. To accomplish this he has to *suppose* a change of clef, or clefs, and thus give new designations to all the lines and spaces. For instance—and without going into the extreme case of transposing from a score—a pianoforte player is required to transpose an air a whole tone lower,—from A to G. For this purpose he must assume a change in both clefs, the treble into the tenor, and each note to be played an octave higher than it is written; the base into the alto, and each note to be played an octave lower than it is written. Example in A.

The same as read by the performer, when transposed to G.

The difficulty attending this process is so great, that no amateur, and few discreet musicians, unless professed accompanists, or well acquainted with the composition to be transposed, will undertake the task; for to perform it in an artist-like manner, at first sight, requires a degree of practical skill only to be gained at the expense of much time that might be employed to far greater advantage in studying those higher branches of the art in which the most experienced will always find something to learn. Our remarks, it will be understood, relate to performers on the pianoforte and organ. To those who read from a single staff, and play single notes only, as violinists, flutists, &c., the task of transposing is comparatively easy.

To meet all the demands of Transposition, a familiar knowledge of no less than seven clefs is necessary, and two of these—the mezzo-soprano, and barytone, or bass clef on the 3rd line [CLEF, P. C.]—may be said to have become obsolete, for we venture to assert that not one musician in five hundred is practically acquainted with either.

The annexed table will exemplify the use of clefs in transposition. It shows how to transpose a given key-note—A for instance—into any other note of the scale, and, consequently, how to transpose the whole of any composition. It is hardly necessary to add, that the semitonic scale, as concerns line and space, is governed by the diatonic; that A ♯, A ♭, &c., have the same places in the staff as the natural notes represented by the same letters.



TRAVERS, JOHN. The author of compositions so popular, elegant, and charming as 'Haste, my Nanette,'—'I, my dear, was born to-day,'—'When Bibo thought fit,'—'Soft Cupid,'—is fairly entitled to a few lines in our biographical department, though his life was void of any remarkable incident. He was educated first in St. George's Chapel, Windsor, afterwards under the celebrated Dr. Greene [GREENE, P. C.]. About the year 1725 he followed Kelway as organist of St. Paul's, Covent Garden, and subsequently filled the same situation also at Fulham. In 1737 he was appointed organist to the Chapels Royal. He died in 1758, and was succeeded in the latter office by Dr. Boyce.

Travers composed much cathedral music, but except an anthem, 'Ascribe unto the Lord,' and a 'Te Deum,' his productions for the church have fallen into disuse. We will only add, that Dr. Burney's notice of him is neither discriminating nor just.

TRAVERSE. [PLEADING, P. C.]

TREASON. [LAW, CRIMINAL, P. C. S.]

TRENTO, ANTONIO DA, supposed to be the same person as Antonio Fantuzzi. He was born at Trent about the commencement of the sixteenth century; and was, according to Vasari, the pupil of Parmigiano at Parma. Parmigiano employed Antonio to engrave his works in wood, and he was one of the first and most eminent of the Italian wood-engravers: he appears to have imitated the cuts of Hugo da Carpi. Antonio Fantuzzi lived with Parmigiano, but apparently unwillingly, for about 1530 he decamped from his master, taking with him many of his drawings, plates, and wood-cuts, and went, it is supposed, to France, where he appeared again under the name of Antonio da Trento. He attached himself in France to Primaticcio, who employed him to engrave or etch some of his works in copper: he executed also etchings after some other masters while in France. Bartsch describes 37 etchings by him, but he is more celebrated for his wood-cuts which he engraved in chiaroscuro. The time of his death is not known, but it happened probably about 1550; the dates on his prints reach to 1545.

Some of the wood-cuts of Antonio are printed with three, others with two blocks; they are chiefly after Parmigiano, as —The Twelve Apostles; St. John in the Wilderness; the Martyrdom of St. Peter and St. Paul; St. Cecilia; the Tiburtine Sibyl; and others. Among his etchings is one of Regulus in the Cask, after Giulio Romano.

(Vasari, *Vite de' Pittori*, &c.; Bartsch, *Peintre-Graveur;* Nagler, *Allgemeines Künstler Lexicon.*)

TRETOSTE'RNON, fossil genus of Chelonidæ from Tilgate forest. (Owen.)

TREVI'GI, or TREVI'SI, GIRO'LAMO DA, born at Trevigi in 1508, was apparently the son of the painter Piermaria Pennacchi, who was doubtless his son's instructor in the art. Girolamo, however, not wholly satisfied with the accuracy of the Venetian painters, became an imitator of the style of Raphael, and combined to a considerable extent the qualities of both schools. He lived some time in Bologna, where he painted some excellent works, especially from the story of Sant' Antonio of Padua, in oil, in the cathedral. He left Bologna in consequence of the superior fame of Perino del Vaga, then at Bologna. After painting several works in fresco at Venice, Trent, and some other places, he came to England and entered the service of Henry VIII., who employed him as architect and engineer, with a fixed salary of nearly 100*l.* per annum. He was engaged in the capacity of engineer in the year 1544 before Boulogne, and was there killed by a cannon-shot, in his 36th year.

There are some excellent portraits by Girolamo; they are well coloured and in an elaborate but broad manner, much in the style of the portraits by Raphael: there is a fine specimen in the Colonna palace at Rome; it is a half length of a man in the picturesque costume of the period, holding a ring or signet in his hand. There are or were other pictures by Girolamo in this palace. A picture of the Madonna with various saints, which, according to Vasari, was Girolamo's masterpiece, is now in the collection of Mr. Solly, in London: it was formerly in the church of San Domenico at Bologna.

There was an earlier painter called Girolamo da Trevigi by whom there are still works bearing dates from 1470 to 1492: his surname according to Federici was Aviano.

(Vasari, *Vite de' Pittori*, &c.; Ridolfi, *Vite*, &c.; Lanzi, *Storia Pittorica*, &c.)

TRICARPEL'LITES, a genus of fossil fruits from Sheppey. (Bowerbank.)

TRICHO'MANES, a genus of ferns belonging to the sub-order Hymenophyllaceæ. The thecæ are on an elongated filiform receptacle within a cup-shaped involucre of the same texture with the frond.

T. speciosum is the only British species. It is extremely rare, and very beautiful, combining the characters of the true ferns, mosses, and sea-weeds. In texture as well as in scent it resembles some of the marine algæ, and it is found to assume the same life-like appearance when immersed in water after being kept perfectly dry for many years. It is found at Killarney, Wicklow, and Youghal in Ireland, in great beauty. The soil which seems to suit it best is a mixture of loam and sand, interspersed with pieces of turf.

(Newman, *British Ferns;* Babington, *Manual of British Botany.*)

TRICHONE'MA, a genus of plants belonging to the natural order Irideæ. It has a regular 6-cleft perianth, with spreading segments. The 3 stigmas are bifid, the lobes slender. *T. columnæ* is the only British species; it has a solitary 1-flowered nodding scape, filiform compressed leaves, the spath longer than the tube of the corolla, the style shorter than the stamens. The flower is pale purple or violet, with a yellow centre. It is found in sandy places in Jersey and Guernsey. (Babington, *Manual.*)

TRIE'NTALIS, a genus of plants belonging to the natural order Primulaceæ. It has a 7-parted calyx, a rotate 7-parted corolla, and 7 stamens inserted at the base of the corolla. The capsules are many-seeded, opening with 5 revolute fugacious valves. The seeds are invested with a reticulated tunic. *T. Europæa* has oblong obovate obtuse leaves, a stem from 4 to 6 inches high, with the leaves mostly at the top. The flowers are on short peduncles, white, with a yellow ring. The valves of the capsules soon fall off. It is native of England and the Highlands of Scotland. (Babington, *Manual.*)

TRIGLA, a genus of Acanthopterygious osseous fishes, popularly known as Gurnards, and belonging to the family *Loricati* in the arrangement of Cuvier.

The head of *Trigla* is mailed and angular: the opercle and shoulder-bones armed with spines; the body is scaly; there are two distinct dorsal fins; beneath the pectorals are three detached rays; the branchiostegous membrane has seven rays; both jaws and the front of the vomer are armed with fine velvety teeth. The gurnards are fishes always remarkable for singularity of form, and often for brilliancy of colouring. They derive their popular appellation from a grunting noise which they make when taken out of the water. In the British seas the commonest species are the grey gurnard (*Trigla Gurnhardus*), a silvery grey fish more or less clouded with brown and speckled with black; the red gurnard (*Trigla Pini*), of a bright rose-red colour; and the sapphirine gurnard (*Trigla Hirundo*), a large and handsome fish remarkable for the vivid green and blue hues of the inner surface of its large pectoral fins. The two last are most abundant in the western coasts. Several other rarer species are also inhabitants of the British seas. There are some beautiful small species in the Mediterranean, where also lives the flying-gurnard (*Dactylopterus volitans*), which differs generically from *Trigla* in having the fin-rays of the pectorals connected by membranes, by means of which the fish is enabled to support itself for some time in the air in the manner of the flying-fish. It is a handsome species, above a foot long. Another flying-gurnard (*Dactylopterus Orientalis*) lives in the Indian Ocean.

TRIGLYPH. [CIVIL ARCHITECTURE, P. C.]

TRIGONELLI'TES. This obscure genus of fossil mollusca, to which many names have been applied (as Aptychus, Ichthyosagonites, &c.), contains several forms which undoubtedly appertain to Cephalopoda, and offer analogies to a part of the Sepiosteum, and a part of the Belemnite.

TRIGONOCARPUM, a genus of Monocotyledonous fossil fruits in the coal formation of England. (Brongniart.)

TRILLIUM, a genus of plants belonging to the natural order Melanthaceæ. It has 3 herbaceous sepals, 3 coloured petals, and 3 sessile stigmas. The berry is superior and 3-celled, the cells many-seeded.

T. erectum has a large præmorse rhizoma with thick horizontal fibres. The stem is about a foot in height, and sheathed at the base. The leaves large, acuminate, and sessile. The peduncle about half as long as the leaves, inclining to one side. The flower is large and of a dark purple. (Lindley, *Flora Medica.*)

TRINU'CLEUS, a large and remarkable group of Trilobites chiefly or wholly found in the lower Silurian strata of Europe. (Murchison.)

TRIO'DIA, a genus of grasses belonging to the tribe Avenineæ. The glumes are from 2 to 3 flowered; the outer palea rather coriaceous, smooth, rounded on the back, bifid with an intermediate broad point sometimes becoming the base of a kneed awn. *T. decumbens* has a racemose panicle, few oval spikelets, the flowers scarcely extending beyond the glumes, without awns. The leaves flat, sheaths rather hairy. Ligule reduced to a tuft of nerves. The glumes smooth, coriaceous, and hiding the flower. It is found in mountain pastures in Great Britain. (Babington, *Manual.*)

TRI'ODON. [GYMNODONTES, P. C. S.]

TRIO'STEUM (from τρι, three, and ὀστέον, a bone; in reference to the three bony ends in each berry), a genus of plants belonging to the natural order Caprifoliaceæ. It has a calyx, with an ovate tube and a 5-parted permanent limb, with linear lanceolate permanent lobes. The corolla is tubular, almost equally 5-lobed, gibbous at the base, and longer than the calyx. The stamens are 5, and inclosed; the stigma oblong and thick; the berry coriaceous, obovately triquetrous, crowned by the calyx, 3-celled, and 3-seeded. The species are permanent herbs, rarely suffruticose.

T. perfoliatum, Fever-wort, has an erect hairy fistular round stem from one to four feet high. The leaves opposite, the pairs crossing each other, ovate, lanceolate, acuminate, entire, rather flat, abruptly narrowed into the petiole; the flowers sessile, apparently verticillate. It is native of North America, in the United States, on rich rocky grounds, particularly in limestone soil.

The species of *Triosteum* will grow in almost any kind of soil, although they prefer a vegetable or peat mould, and they are easily propagated by dividing at the root or by seeds, which generally ripen in abundance.

(Don, *Gardener's Dictionary;* Lindley, *Flora Medica.*)

TRISE'TUM, a genus of grasses belonging to the tribe Avenineæ. It has crowded spikelets. Glumes from 2 to 6 flowered. The outer palea with fenced lateral nerves, ending in 2 acute teeth, armed. The awn dorsal, kneed, and twisted. The ovary glabrous. The fruit neither crested nor furrowed. *T. flavescens* has a much-branched panicle, diffuse and equal; the glumes very unequal, about 3-flowered. The radical leaves and sheaths hairy. The ligule very short and obtuse. The spikelets yellowish. The upper glume oblong, lanceolate, acuminate. The floral axis hairy. It is found in fields in Great Britain. (Babington, *Manual.*)

TRISTI'CHIUS, a genus of fossil fishes from the coal measures near Glasgow and Fermansgh. (Agassiz.)

TRIXA'GO, a genus of plants belonging to the natural order Scrophularineæ. It has a tubular 4-cleft calyx, a tubular 2-lipped corolla, pointed capsules, and many-seeded cells. The seeds are slightly angular and very minutely crenate ribbed. *T. viscosa*, the only British species, has a round high simple stem, a fibrous root, and opposite leaves; the upper leaves are alternate, ovate, lanceolate, sessile, and acutely serrate. The flowers axillary, distant, and yellow; the anthers hairy. It is found in damp places in the west of Scotland and south of Ireland. (Babington, *Manual.*)

TROCHO'CRINUS, a group of fossil Crinoidea (Portlock), from the Silurian strata of Tyrone.

TROSSACHS are in Scotland, on the northern declivities of Ben Venu, on the southern banks of Loch Katrine. They constitute a landscape of a very peculiar kind: for about two miles in length the surface of the ground presents the greatest imaginable irregularity, consisting of a succession of ravines, depressions, slopes, level tracts, and descents, sometimes gentle and sometimes precipitous. The whole is overgrown with bushes or trees, and constitutes the most complete maze which can be conceived. The paths which traverse this tract turn at every few paces into a different direction, and thus the traveller finds himself almost at every minute in a country which has totally changed its aspect, and presents quite different objects from those which met his eyes a few moments before. The difficulty of exploring and searching the recesses of this tract, favoured, in the last century, the illicit distillery of whiskey; but it is stated that, at present, this trade has entirely ceased.

TROUGHTON, EDWARD, the first astronomical instrument maker of our day, was born October, 1753, and died at his house in Fleet Street, June 12, 1835. He came of a family of respectable yeomen, and was placed in the firm of his uncle and brother, who carried on business in London as mathematical instrument makers. In 1782 the Troughtons established themselves in Fleet Street; in 1826 Edward Troughton, then the sole survivor, took Mr. W. Simms into partnership. There is a full memoir of Troughton in the monthly notices of the 'Astronomical Society,' vol. iii. p. 149. A handsome subscription bust, by Chantrey, is in the Observatory at Greenwich. In the last years of his life Mr. Troughton was nearly deaf, only hearing by the help of a powerful trumpet; and he never could distinguish colours otherwise than by their brightness,—a ripe cherry and its leaf were to him of the same colour.

The larger astronomical instruments are not the facsimiles of one another, which the smaller and more usual ones are, any more than the great architectural displays of a large city are of the same resemblance to one another which exists in the houses of one and the same street. Each one has its own difficulties, its own objects, and its own way of overcoming the first to meet the second. The great works of Troughton are as well known in the astronomical world as those of Wren in the architectural; but he also applied himself to all the minor branches of his business, and 'of him it may be said with truth that he improved and extended every instrument he touched, and that every astronomical instrument was in its turn the subject of his attention.' 'The instruments which facilitate navigation were peculiarly objects of interest to Mr. Troughton; and long after his infirmities were an effectual bar to the application of his most esteemed friends, he exerted himself to supply the seamen with well-adjusted and accurate sextants.' The articles on astronomical instruments in this work contain frequent references to Troughton's improvements. He wrote one or two articles in the 'Philosophical Transactions,' and several in Brewster's 'Cyclopædia,' &c., references to which will be found in the memoir cited.

TROUS DE LOUP, in the military art, are pits dug in the ground in the form of inverted cones or pyramids, in order to serve as obstacles to the advance of an enemy: each is made about 6 feet in diameter, or in breadth, and as many in depth, and a pointed stake is planted upright in the bottom. The pits should be disposed chequer-wise in two or three rows, their centres being at distances of about 10 feet from one another; and their sides should have such a slope that the enemy's riflemen, should they attempt to occupy them, may not be concealed in them from the view of the troops whom the pits protect.

The earth obtained from the excavations should be formed into a sort of glacis within the line of pits in order that the enemy may not use it to fill them up. Trous de loup are generally formed before the salient points of field-works or in the intervals between them; and they are sometimes executed in rear of such works in order to protect the gorges when these are withou parapets.

TRYPHONI'NUS, CLAUDIUS, a Roman jurist who lived under Septimius Severus and his son Antoninus Caracalla. He wrote notes on the works of Cervidius Scaevola, and twenty-one books of Disputationes, from which there are excerpts in the Digest. There is a rescript of Antoninus to him (Cod. 1, tit. 9, s. 1), but whether in his capacity of governor of Syria or as the agent of the Fiscus is uncertain. He is cited once by Paulus.

TUNNY. [THYNNUS, P. C. S.]

TYLO'PHORA (from τύλος, a swelling, and the root φορ, to bear, in reference to the ventricose pollen masses), a genus of plants belonging to the natural order Asclepiadeæ. It has a rotate 5-parted corolla, the coronet 5-leaved, the leaflets simple and fleshy. The anthers terminated by a membrane; the pollen masses erect, fixed by the base, with simple margins, transverse or ascending, minute and ventricose. The follicles smooth, tapering to the point, compressed, and somewhat angular on one side. The species are twining herbs or subshrubs. The leaves opposite, membranous, and flat. The flowers usually small.

T. asthmatica has a root consisting of many long thick whitish fleshy fibres issuing from a small hard head. It has several twining slender stems, the young parts downy. The leaves are opposite, petioled, linear, cordate-ovate, and from two to three inches long. The flowers rather large, on long pedicels, purplish; the segments of the corolla acute. The roots are acrid, and are used on the coast of Coromandel for the same purpose as ipecacuanha. It is native of various parts of the East Indies. The species grow freely in loam, peat, and sand, and are easily managed. Cuttings readily take root in a moist heat under a glass.

(Don, *Gardener's Dictionary;* Lindley, *Flora Medica.*)

TYMPANO'PHORA, a genus of fossil plants from the Oolitic series of Yorkshire. (Lindley.)

TYPHA, a genus of plants belonging to the natural order Aroideæ and the suborder Lemneæ. The sterile and fertile spikes are cylindrical. The stamens surrounded with setæ. The three anthers on one filament; the ovary surrounded with setæ, at length stalked.

T. latifolia, great Reed-mace, has a stem from six to seven feet high; linear leaves, nearly flat; the sterile and fertile catkins contiguous and very long. The leaves very broad and overtopping the inflorescence. It is found in ponds and lakes in Great Britain. (Babington, *Manual.*)

TYPHUS, a form of fever, in which low nervous symptoms predominate. The following are its principal features:—It has a slow and insidious origin, lasting from fourteen to twenty-eight days. It is attended during the principal part of its course with symptoms of depressed or exhausted nervous power, with feeble pulse, great muscular weakness, and low delirium. There is a dry, rough, dark tongue, black sordes on the teeth and gums, and general fœtor of the body. It is capable of being propagated by the contagious emanations from the person affected. This is the low nervous or typhoid fever of this country. For an account of fever and its distinctions, see FEVER, P. C.; SYNOCHUS, P. C. S.

INDEX TO THE LETTER T.

VOLUME II.

U.

UDAL TENURE. [SHETLANDS, P. C., p. 385.]

UDOTEA. A spongoid fossil from Bridlington is referred to this genus by Mr. J. E. Lee.

ULODENDRON, one generic division of the great group of Lepidodendroid families of plants which occur in the coal formations.

UNDULATORY THEORY OF LIGHT. This subject has been already treated briefly, under the same designation; and for further notices concerning its principles, as well as for its applications explanatory of the remarkable phenomena of light, the reader is referred to DIFFRACTION, and to POLARIZATION OF LIGHT (P. C.), also to the following articles, which have been introduced in this Supplement: CIRCULAR POLARIZATION; COLOURS OF PLATES; ELLIPTICAL POLARIZATION; POLARIZATION, MOVEABLE; POLARIZED RINGS; SWIFTEST PROPAGATION, PRINCIPLE OF; and VIBRATIONS OF LIGHT.

UNION OF ESTATES. [MERGER, P. C.]

UNITED STATES OF NORTH AMERICA. Since the article OREGON QUESTION, P. C. S., was written the dispute concerning the Oregon territory has been settled. On the 29th of June, 1846, Sir Robert Peel, in the speech in which he announced his resignation of office, informed the House of Commons that the British government had offered a convention to the government of the United States, of which the President of the United States, on the 13th of June, 1846, announced the acceptance by the American government, without the addition or alteration of a single word. The first proposal of the British government was as follows:—

'That from the point in the 49th parallel of N. lat. in which the boundary laid down by existing treaties between Great Britain and the United States terminates, the line of boundary between the territories of the two countries shall be continued westward along the 49th parallel to the middle of the channel which separates the continent from Vancouver's Island, and thence southerly through the middle of the said channel and the Fuca Straits to the Pacific Ocean. Provided the navigation of the channel and straits, south of the 49th parallel, shall be free and open to both parties.'

This leaves to the British the whole of Vancouver's Island, with equal rights of navigation in the Straits. The second proposal was—

'That from the point at which the 49th parallel of N. lat. intersects the great northern branch of the Columbia river, the navigation of the said branch shall be free and open to the Hudson's Bay Company, and for all British subjects trading with the same, to the point where the said branch meets the main stream of the Columbia, and thence down the said main stream to the ocean, with free access into and through the said river or rivers; all the usual portages along the line thus described to be free and open to both parties. Provided that in navigating the said river British subjects shall be on the same footing as those of the United States: it being always understood however, that nothing herein shall be considered as preventing the government of the United States from making any regulations as to the navigation of the river not inconsistent with the present convention.'

The circumstances under which Texas has been annexed to the Union are stated under TEXAS, P. C. S.

Michigan, described as a territory in P. C., was admitted into the Union as a State at the end of 1835. The Governor is elected for two years, and his salary is fixed at present at 1500 dollars per annum. The Senate consists of 18 members, elected for two years; the House of Representatives of 53 members, elected annually. The pay of the members is three dollars a day during the session. The seat of government is at Detroit, or wherever the legislature shall direct, till 1847, when it is to be established permanently. The legal establishments are, a Court of Chancery, a Supreme Court, Circuit Courts, and a District Criminal Court. The Chancellor has a salary of 1500 dollars, and there are five Chancery Circuits. In the Supreme Court there is a Chief Justice, with a salary of 1600 dollars, and three associate Justices with salaries of 1500 dollars each. The four Judges of this court are appointed by the Governor, with the advice and consent of the Senate, for a period of seven years. There are four judicial circuits, in each of which one of the Judges of the Supreme Court presides. The University of Michigan, which was opened at the end of 1842, has since been gradually increasing. At the end of 1845 the main institution at Ann Arbor had about 70 students, and the five branches, or preparatory schools, at Tecumseh, Romeo, Kalamazoo, White Pigeon, and Ann Arbor, about 180 students. The professorships were—1, Greek and Roman Language,; 2, Mathematics; 3, Moral and Mental Philosophy; 4, Geology and Mineralogy; 5, Botany and Geology. In 1844 the number of scholars in the Common Schools was 66,818, and the amount apportioned from the state treasury among the several districts was 28,063 dollars. Michigan is thought, both as to the means of education and the success of the system pursued, to be little behind the most forward of the eastern States. The state prison at Jackson is constructed on the Auburn plan. The Central Railroad runs from Detroit to Marshall, 110 miles, and 36 miles more of the road were expected to be completed by the end of 1845. The Southern Railroad runs from Monroe to Hillsdale, 68 miles. The population of Michigan in 1830 was 31,639; in 1840 it was 212,267. There are no slaves.

Florida was admitted into the Union as a State in 1845, the first Governor having entered upon his office in October of that year. The Governor is elected for four years, the Senators for two years, the Representatives for one year. The number of Representatives is never to exceed 60. The Judges of the Supreme Court are to be elected by a concurrent vote of both Houses, at first for five years, and after that according to good behaviour. The right of voting is to belong to every free white male, aged 21 or upwards, who has resided in Florida two years, and six months in the county in which he votes, and who shall be enrolled in the militia or by law be exempt from serving therein. No laws are to be passed to emancipate slaves, or to prohibit the immigration of persons bringing slaves with them. The General Assembly may prevent free coloured persons from entering the State. The population in 1830 was 34,730; in 1840 it was 54,447, of whom 25,717 were slaves. (*American Almanacs*, 1837, 1845, 1846.)

URANOSCOPUS, a genus of Acanthopterygious osseous fishes of the perch family, and very nearly related to the weavers (*Trachinus*) of the British seas. One or two species inhabit the Mediterranean. The head is nearly cubical, and the eyes placed in the flat summit, so that they look upwards: hence the name. The mouth is turned up in a similar manner. This arrangement agrees with the habits of the fish, which buries itself in sand all but the summit of the head, and thus lies in wait for its prey. Its colour resembles the sand in which it lives.

INDEX TO THE LETTER U.

VOLUME II.

V.

VACHELLIA, a genus of plants belonging to the natural order Leguminosae. The flowers are polygamous; the calyx 5-toothed; the corolla tubular, gamopetalous, and 5-toothed. The stamens are numerous and distinct; the legume cylindrical and turgid, scarcely dehiscent, filled with pulp, and a double row of seeds.

V. Farnesiana is a native of the East and West Indies and Africa. It is a large shrub or small tree, with straight sharp thorns. The leaves are bipinnate, the leaflets linear and nearly glabrous; the peduncles and petioles more or less hairy; the flowers capitate, the heads globular, 2 or 3 together, each on an axillary peduncle. The bark exudes a considerable quantity of gum. The flowers when distilled yield a delicious perfume.

(Lindley, *Flora Medica.*)

VAILLANT, WALLERANT, a very distinguished portrait painter, was born at Lille in 1623, and was the pupil of Erasmus Quellinus, at Antwerp. He painted the portrait of the Emperor Leopold I. at Frankfort, and many of the people of his court. He subsequently went with Marshal Grammont to Paris, and was there equally distinguished by the French court. After having amassed considerable riches he died at Amsterdam, in 1677.

Vaillant was employed in 1656 at Brussels by Prince Rupert to assist him in executing some plates in the new method of mezzotinto engraving then communicated to the Prince by Siegen [SIEGEN, LUDWIG VON, P. C. S.]. As Vaillant is the first *artist* who engraved in this style, his prints have more than ordinary interest. Among these are two portraits of Prince Rupert, one of which is inscribed—Prins Robbert, vinder van de Swarte Prent Konst, which is one of the principal causes of Siegen's being so long deprived of the merit of his invention.

Vaillant had four younger brothers, who were all painters or engravers and his pupils.

(Descamps, *Vies des Peintres Flamands*, &c.; De Laborde, *Histoire de la Gravure en Manière Noire.*)

VALENS, ABURNUS, a Roman jurist, whose age is partly determined by the fact that he cites Javolenus and Julianus (Dig. 4, tit. 4, s. 33), from which we may conclude that he was younger than both. He is called Aburnius in the Florentine Pandect. He was a Sabinian, as appears by his being placed by Pomponius among the followers of Javolenus. It appears that he was living under Antoninus Pius (Capitol., *Pius*, 12), though, as the text of Capitolinus stands, he is called Salvius Valens. His complete name may have been Salvius Aburnus Valens; or Salvius in this passage may be separated from Valens and may mean Salvius Julianus. But there is a rescript of Pius (Dig. 48, tit. 2, s. 7, § 2) addressed to Salvius Valens.

Valens wrote seven books on Fideicommissa, from which there are excerpts in the Digest; and there is also in the Digest a passage from the seventh book of a work on Actiones. Valens is mentioned by Pomponius, and cited several times by Paulus (Dig. 4, tit. 4, s. 33).

VALVASOR. [VAVASOR, P. C.]

VAN, or WAN. [ARMENIA, P. C., p. 360.]

VAN HOECK, JAN, a distinguished Flemish painter, was born at Antwerp about 1600. He first studied for one of the learned professions, but became the pupil of Rubens, and studied afterwards some time in Rome. While in Italy he was invited by the Emperor Ferdinand II. to his court, and was much employed by him. He eventually returned to his own country, where he died, according to Houbraken, in 1650.

Van Hoeck was admirable in history and portrait, and excelled both in light and shade and colour; his figures also are better drawn than is the case with those of the pupils of Rubens and the Flemish school generally. The 'Christ on the Cross' in the church of Saint-Sauveur, or the cathedral, at Bruges, is one of the finest pictures in Belgium. The Christ, which is of the size of life, has extraordinary effect and reality, and is certainly superior to the celebrated Christ of the church of St. Michael, at Ghent, by Vandyck, and it is more real and impressive than any of those of Rubens: beneath the cross are the Virgin and other saints. There is a print of it by the younger Cornelius Galle; this engraver however is not very accurate in his drawing. Independent of the Christ, the composition of the picture is meagre and formal, and wants dramatic truth.

VARIATION OF PARAMETERS. A *parameter* was a name originally given to a particular line connected with a conic section: being the third proportional to a diameter and its conjugate. In time the word was applied to any line which serves by its value to distinguish, or to help to distinguish, one individual of a family of curves from another: thus the radius of a circle, the axes of an ellipse, the co-ordinates of the centre of either, were called parameters. When a word gets into the descriptive name of a method, it may happen, as part of a phrase, to outlive its own separate use: and such has been the case with the word *parameter*. As this word is now generally abandoned, and *element* is the most frequent substitute for it, it would be desirable to speak of *variation of elements*.

Whatever phrase we may use, the thing occurs both in physics and mathematics, in modes which are closely connected with each other. A planet moves in a curve which is not an ellipse, but which would change and become an ellipse if the disturbing attractions of the other planets were removed, and that of the sun only continued. The easiest way of calculating the planetary motions is to consider the planet as moving in this ellipse, while during the motion the elements which determine the ellipse are perpetually changing: so that the form and position of the ellipse both vary. This is done in such manner that the ellipse of each moment is that which the planet would go on to move in, if at that moment the disturbing attractions were all removed. The advantage is that in this case the elements will vary very slowly, or it will be long before the disturbing attractions produce much effect. In theory, any curve might be taken. A planet for instance might be supposed to move in a parabola, which varies its dimensions and position in a manner to be determined. In TROCHOIDAL CURVES, P. C., all the curves given are produced by a point moving in a circle with variable elements; that is, of variable centre, though given radius. If it were required to investigate trochoidal curves with loops and undulations of different magnitudes, the best way would be to consider them as made in the same manner, with a circle of variable radius also: or else to make both circles variable.

In the differential calculus the variation of elements is introduced thus:—If an algebraical expression containing some variables and some constant elements be proper to answer a certain purpose, it is not impossible that it may answer the same purpose when the constants are made variable, provided they are made to vary in a proper manner. Now, if the purpose which is to be answered involve differentiation, the infinity of the number of suppositions which may be made as to the variation of the (former) constants is equivalent to introducing an arbitrary function instead of each constant, to be determined by the conditions of the question. Two species of cases have frequently arisen.

1. When under certain circumstances a problem is solved by an expression containing certain constants, and the circumstances are then altered; it is often convenient to inquire whether the altered problem might not be solved by the same expression, on the supposition that the constants become variable. And the question then is, how the (former) constants are to be made to vary.

2. Without any alteration of the circumstances, having a solution which contains constants, it may be asked how to substitute variables in place of constants, so that the altered expression may still be a solution.

In both cases it is obvious that as soon as the constants are made variable the differential co-efficients of all expressions into which they enter will receive an accession of terms above what they had before. These new terms, which we may describe as functions of the variations of the elements, must, in the first case above noted, be so taken as to provide for the effect of the altered circumstances. But in the second case they must destroy one another's effects altogether. We shall take a few instances in which the variation of elements is successful or unsuccessful.

1. The equation $y'+Py=0$, P being a function of x, is solved by

$$y=C\varepsilon^{-\int Pdx}$$

C being a constant. Now alter the equation into $y'+Py=Q$, and to meet the alteration, let C become a function of x. On this supposition $y'+Py$ becomes

$$-CP\varepsilon^{-\int Pdx}+C'\varepsilon^{-\int Pdx}+CP\varepsilon^{\int Pdx}$$

But this ought to be Q: therefore we must have

$$C'\varepsilon^{-\int Pdx}=Q, \quad \text{or } C=\int(Q\varepsilon^{\int Pdx})+E$$

E being another constant. Here $y'+Py=Q$ is solved by $y'+Py=0$ and subsequent variation of an element.

Now try $y'+y^2=0$ and $y'+y^2=Q$ in the same manner. The first is solved by $y=(x+C)^{-1}$ and if C be made variable, and y thus altered be introduced into the second, it is found, making $z=x+C$, to require the solution of

$$z'+Qz^2-1=0$$

as difficult an equation as the original. In this case then we are unsuccessful.

2. Let $\frac{du}{dx}+\frac{du}{dy}=x$. One solution of this is $u=\frac{1}{2}x^2+a(x-y)+b$, a and b being constants. To find a more general solution of this same equation let b be a function of a, a being a function of x and y. We have then

$$\frac{du}{dx}=x+a+\left(x-y+\frac{db}{da}\right)\frac{da}{dx}$$
$$\frac{du}{dy}=\quad -a+\left(x-y+\frac{db}{da}\right)\frac{da}{dy}$$

and the equation will obviously still be satisfied if b and a be so related that

$$x-y+\frac{db}{da}=0$$

Now as b is what function of a we please, so also is $\frac{db}{da}$: hence it follows that if $b=\phi a$, and $x-y=-\phi' a$, we may make a what function of $x-y$ we please. Let $a=\psi(x-y)$ and let $\chi v=-\int v\psi' v dv$. We have then

$$u=\frac{1}{2}x^2+(x-y)\psi(x-y)+\chi(x-y)$$

of which the last two terms merely amount to an arbitrary function of $x-y$, so that the complete solution is

$$u=\frac{1}{2}x^2+\phi(x-y)$$

ϕ meaning any function whatever.

This subject has many developments. We have introduced it here under the idea that some students of the differential calculus may be led to consider it at an earlier period of their reading than books will give it to them.

It is to be remarked that this method does not merely search for *some* solutions of a question: if the number of constants be sufficient, it goes direct to the most general solution. In our first example, there is no function of x but what is capable of being represented by $C\varepsilon^{-\int Pdx}$; in our third there is no function of x and y but what is capable of being represented even by $\frac{1}{2}x^2+a(x-y)$ or $\frac{1}{2}x^2+b$, and also by $\frac{1}{2}x^2+a(x-y)+b$ with a relation between a and b. Whatever function of x, or of x and y, will solve these equations, is sure to be found, if the method be successful. This point would need a little more development than we have here space to give.

VEGETABLE MORPHOLOGY, or METAMORPHOSIS, is that department of science which contemplates the laws which regulate the forms of plants and of their particular parts. In the earlier period of the history of botany plants were studied as individuals or groups of individuals, without any reference to the general laws which governed either the external or the internal forms of plants, or those which influenced the production of various forms in the same individual at different periods of its existence, or of the same species under varying circumstances.

Linnæus, although he never made any practical application of his idea, seems to have been the first to have suspected that the varied forms of the flowering organs, and even other appendages of the axis of the plant, were modifications of the leaf. In his 'Philosophia Botanica' he has the following remarkable passage:—'The origin of the flowers and the leaves is the same; the origin of the buds and the leaves is the same: the bud consists of the rudiments of the leaves; the flower comes from the rudiments of the leaves united.' Although the doctrine of morphology, to a limited extent, was thus aphoristically proclaimed by the great Swede, and many facts pointed out by him to prove its truth, yet little or no notice was taken of this department of science by his followers. The next person who drew attention to this subject, and apparently quite independent of Linnæus, was not a botanist, but a poet. Goethe frequently occupied himself with natural history studies; and in one of his letters, dated 1786, mentions that he believed he had discovered 'the whole secret of the generation and organization of plants, and that it is the simplest thing that can be imagined.' It was some years after that he first published his poem on the metamorphoses of plants, in which he distinctly states the great law of morphology, that every part of the plant is but the repetition of a primitive type:

> Gleich darauf ein folgender
> Trieb sich erhebend erneuet,
> Knoten auf Knoten gethürmt,
> Immer das erste Gebild.

This was followed by a paper on the subject, in which he clearly points out the importance of this idea of the unfolding of a primitive type. At the time these papers were published they were regarded as the fancies of a poet rather than the sober realities of science. In Great Britain they found but little favour, but were quietly thought over by Robert Brown, who by a series of accurate observations demonstrated the practical value of the morphological idea in the arrangement of the various families of plants. The idea of Goethe was also adopted by De Candolle, in his doctrine of a primitive type among plants, from which all departed by the decrease, increase, and adhesion of their organs. In this way the doctrine of morphology has more or less influenced the greatest botanical observers of the present day, and it assumes a position of the first importance in botanical inquiries.

Morphology may be divided into great divisions. First, that which treats of the forms of plants and their organs in general, and which is only concerned with a few of those general forms which are found common to all plants; and secondly, that which treats of the forms of particular groups of plants and of individual organs. This latter department is by far the most extensive and is that which contributes so greatly to the just apprehension of the relations which exist between the various groups of plants and their organs. It may be divided into two parts, one of which regards the external form of the plant, as resulting from the combination of the various tissues into organs; the other treats of the internal form which the various tissues of the plant assume.

There are certain general principles in morphology which have been everywhere assumed in the description of the organs of plants in the Penny Cyclopædia, such as that every plant has an ascending and descending axis; the former of which is called the stem [EXOGENS, P. C.; ENDOGENS, P. C.], and the latter the root [ROOT, P. C.]. These may be traced downwards or upwards through the various series of plants: downwards till we arrive at a point where the cells exhibit no tendency to either an ascending or descending growth, as in the cells of Protococcus; or upwards till the increasing development of the stem exists in the most complicated variety of forms. It is in the latter or higher groups of plants that the laws of morphology have been studied with greatest attention, and have led to the belief that its only application existed in the series of changes which the leaf of the higher plants undergoes in its conversion into the parts of the flower and the fruit. It is from this department of botany that the most convincing illustrations of the truth of the laws of morphology may be drawn, and it is here that the most obvious practical applications of them may be made; but form does not more distinguish the higher than the lower plants, and in many of the phenomena of the latter morphological laws as general may be applied as to the highest plants.

The leaf however affords the best illustration of the nature of morphological laws. This organ may be regarded as a *theoretical* point of departure for all other organs which are found upon the stem. The word theoretical is used here to prevent the supposition ordinarily entertained, that organs which are said to be metamorphosed have ever really been leaves at all. The leaf is only the theoretical type on which the other organs are formed, and from which they are supposed to have departed. In support of this theory we have the fact, that all the organs of the axis may be traced by insensible gradation either to or from the leaf. Thus the bract is often undistinguishable from the leaf, the sepal from the bract, the petals from the sepals, the stamens from the petals, the carpels from leaves, and the ovules from leaf-buds. This is the series of gradations which prove the positions of morphology. When these gradations take place, as they mostly do in nature, from the leaf to the internal organs of the flower, it is called an ascending metamorphosis; when it takes place from the central organs of the flower to the leaf, it is called a descending metamorphosis. This latter phenomenon is frequently observed in cultivated plants, and such changes are called monsters. Most of the double flowers of our gardens are the result of a descending metamorphosis, in which petals are developed instead of stamens. As an instance of organs which have not assumed the development of leaves, but which yet are formed on the same type and obey the same laws, we may name the stipules and scales of leaf-buds.

The result of these facts is that we may regard the flower as a collection of leaves arranged in whorls, and in fact a branch with a short axis. This idea explains at once those apparently anomalous occurrences where branches grow out of the fruit of the pear or the apple. The apple does but represent the growing point of a branch, which, if the circumstances no longer exist which produced the peculiar leaves from which it is formed, will take on the ordinary growth of a branch. The admission of these principles has led to the expression of certain laws which regulate the growth of the flowers and fruits of plants, and which, being applied to their peculiarities, are the best means of securing a natural classification. These laws are—1. That each series of floral envelopes must normally alternate with that which preceded it. 2. That the number of parts in every series must be equal to or a multiple of the number of parts in the first or outer series. The actual departures from this theoretical structure are numerous, but they may be reduced to the simple conditions of the increase, decrease, or adhesion of the various organs, which also obey definite laws.

VEII. [Etruria, P. C., p. 56.]

VELLA (Latinised from *Velcor*, the Celtic name of the cress), a genus of plants belonging to the natural order Cruciferæ. It has an ovate pouch, with a dilated winged leafy flat style, longer than the convex valves. The flowers are yellow, and are, as well as the pod, erect.

V. annua was found in the time of Ray on Salisbury plain, but has not since been noticed. It has doubly pinnatifid leaves and deflexed pouches.

V. pseudocytisus, False Cytisus, or Cress-Rocket, is a native of Spain; it has yellow petals with long dark purple claws; the larger stamens are connate by pairs; the seeds two in each cell.

This shrub, though generally kept in a greenhouse, is sufficiently hardy to live during the winter in the border in a warm aspect. Young cuttings will strike root in sand under a handglass.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

VENTRE INSPICIENDO, WRIT DE. 'When a woman is suspected to feign herself with child in order to produce a supposititious heir to the estate, the heir presumptive may have a writ *de ventre inspiciendo*, to examine whether she be with child or not; and, if she be, to keep her under proper restraint till delivered; which is entirely conformable to the practice of the civil law: but if the widow be, upon due examination, found not to be pregnant, the presumptive heir shall be admitted to the inheritance, though he hath to lose it again, on the birth of a child within forty weeks from the death of a husband' (Blackstone, *Comm.* i. 456). The Roman practice is explained in the Title of the Digest (25 tit. 4): *De inspiciendo ventre custodiendoque partu.* This title contains a Rescript of Aurelius and Verus, in a case in which a wife denied her pregnancy and the husband maintained it. The wife had separated from the husband, and probably wished to keep the child that might be born, though by law it would belong to the husband. If a woman alleged that she was left pregnant by her deceased husband, it was her duty to announce the fact to those whom it concerned, and to inform them that they might, if they pleased, send women to inspect her (quæ ventrem inspiciant). All the proceedings of inspection and of watching the woman, if she should be reported to be with child, are minutely described in the Prætor's Edict. The penalty in case of the woman not complying with the Edict was, that the Prætor would refuse to the child the Bonorum Possessio.

The form of the English writ De Ventre Inspiciendo is given Co. Litt. 8 b. It is directed to the sheriff, and commands him to empanel a jury of twelve women to search whether she be enseint. If they find that she is with child, another writ issues, which commands that she shall be safely kept and duly inspected by the women, who must be present at the delivery. Bracton is the writer by whom this work is first mentioned.

The use of this writ is an instance in which what is called a proceeding at common law is taken from the Roman system. The writ is not obsolete, as some people suppose; it has issued within the last few years. (Co. Litt. 8 b., and N. 44 in Butler's edition; Comyns, *Digest*, Bastard, C.)

VENULEIUS. [Saturninus, P. C. S.]

VERMIGLI, PIETRO MA'RTIRE, born at Florence in 1500, studied for the church, and entered early the Order of the Regular Canons of St. Augustin; in which he became distinguished for his learning, and rose to offices of trust. Being at Naples he became acquainted with John Valdes, a Spaniard, who had become a convert to the doctrines of the Reformation. Vermigli adopted some of those tenets, but concealed them for a time. Being sent by his superiors to Lucca, as prior of San Frediano, he there publicly avowed his new doctrine, and was soon after compelled to fly to Switzerland, in 1542. He thence went to Strasburg, where he was appointed Professor of Divinity. In 1547, at the invitation of Bishop Cranmer, he repaired to England, where he was graciously received by King Edward VI. and was appointed Lecturer upon the Holy Scriptures at Oxford, where he met with much opposition from the heads of colleges and the higher graduates, and ran some personal risk. In 1553, after the accession of Queen Mary, being obliged to leave England, he returned to Strasburg, where he resumed his chair as Professor of Divinity, and likewise of Aristotelian philosophy. In 1556 he was invited by the senate of Zürich to fill the chair of theology in that University, which he accepted. In 1561 he repaired, with other Protestant divines, to the conference of Poissy, in France. In the following year Vermigli died at Zürich, much regretted. He wrote on dogmatic and ethical subjects, commentaries on parts of the Scripture, besides numerous epistles to 'His Brethren of the Protestant church of Lucca,' to the Protestant churches in Poland, to the English church, to Calvin, Bullinger, Beza, Melanchthon, and other reformers, to Queen Elizabeth, and to several English prelates and noblemen. Tiraboschi, a zealous Catholic, acknowledges Vermigli was free from the arrogance and virulence of Luther and other Reformers, that he was deeply acquainted with the Scriptures and the fathers, and was one of the most learned writers of the reformed communion. His works were translated from the Latin into English. 'The Common Places of the most famous and renowned Divine Doctor Peter Martyr, divided into four principal parts by Anthony Marten,' dedicated to Queen Elizabeth, in 1583, with a biography of Vermigli by Josias Simler, of Zürich: this collection contains a complete course of Christian ethics, and may be read with advantage even now.

VERNET, ANTOINE CHARLES HORACE, commonly called Carle Vernet, a French historical, genre, and battle painter, was born at Bordeaux, August 14, 1758, and was the pupil of his father, Claude Joseph Vernet, the celebrated marine and landscape painter. He studied also in the French Academy at Paris, where he gained the second prize for painting when in his eighteenth year, and in 1782, six years afterwards, he obtained the grand prize, and with it the privilege of studying for a certain period in the French academy at Rome.

In 1787 he was elected a member of the French Royal Academy of Painting for a large picture of the Triumph of Paulus Aemilius, and he was subsequently, after the remodelling of the academy, nominated a member of the Institute of France.

His principal works are—the large picture of the Battle of Marengo, and a battle against the Mamelukes, exhibited in 1804; the Morning of the Battle of Austerlitz, with the Emperor giving orders to his Marshals, and an equestrian portrait of Napoleon, in 1808; the Bombardment of Madrid, the Battle of Rivoli, and another picture of the Emperor, in 1810; John Sobieski forcing the Turks to raise the Siege of Vienna, in 1683, exhibited in 1819; the Taking of Pampeluna in 1824; the Entrance of Napoleon into Milan; and the Battle of Wagram.

Carle Vernet has painted also an immense number of pictures of small dimensions, chiefly of military subjects, but also many of the chase, of scenes of familiar life, and from the imagination. He was also a celebrated painter of horses, and by some considered the best of his time; among his pictures are many small equestrian portraits. In 1806 he was appointed painter to the Dépôt de la Guerre: and he was made subsequently Chevalier of the orders of St. Michel, and of the Légion d'Honneur. He died September 27, 1836. Horace Vernet, the most able painter and most prolific pencil of the present century, is the son of Carle Vernet, and was first instructed by him in his art.

(Gabet, *Dictionnaire des Artistes de l'Ecole Française au dix-neuvième Siècle.*)

VESTED REMAINDER. [REMAINDER, P. C.]

VIBRATIONS OF HEAT. [HEAT, P. C.]

VIBRATIONS OF LIGHT are the movements conceived to take place among the molecules of an ætherial medium which is supposed to exist in space and even to occupy the interiors of bodies; they are the cause of the waves by which are obtained perceptions of light and vision; and they are considered as analogous, in some cases, to the vibrations of the molecules of air by which sound is excited.

From experiments which are alluded to in the article [UNDULATORY THEORY OF LIGHT, P. C., p. 512] it has been determined that the length of a wave in air, for the light at the red extremity of the spectrum, is 0·0000266 inches, and for the light at the violet extremity is 0·0000167 inches; hence the velocity of the waves of light, of each colour, being estimated at 192,000 miles per second, if the inches in this number of miles be divided by each of the above numbers, it will be found that the number of ætherial undulations which are made in air, in one second of time is, for the first kind of light, about 458 millions-millions, and, for the last, about 727 millions-millions, it follows that, if unity be divided by each of these numbers, the quotient will express the very small fraction of a second in which a complete vibration is performed in air by a molecule of the lumeniferous æther.

The waves of sound move in air through less than 1200 feet per second; and it follows that the velocity of light is more than 800,000 times greater than that of sound; but the velocity of an undulation varies with the square root of the elasticity of the medium in which it is propagated; and hence it should follow that the elasticity of the luminiferous æther is to that of air in a ratio exceeding that of the square of 800,000 to unity.

Undulations of the lumeniferous æther are presumed to take place within the substances of all refracting media, as air, water, glass, &c.; but it is probable that the vibrations of the molecules of æther in such situations are modified by the vibrations of the molecules of the substances; the observed phenomena of refraction render it necessary to consider that the greater is the refracting power of a medium, the less is the elasticity of the æther within it, and the less is the velocity with which the waves of light are propagated through it.

The ætherial vibrations which, by affecting the retina of the eye, give rise to the sensation of light, take place, as above stated, with great rapidity, but the impression made by any single vibration is inconsiderable; therefore, in order that the combined actions of the vibrating molecules may be sufficiently powerful to produce effects which are sensible, it is necessary to suppose that the vibrations are performed in equal intervals of time, the intervals depending on the nature of the vibrations of which the retina is susceptible; as in order to give motion to a pendulum by a repetition of very small forces, these must be made to act at the end of equal intervals of time which depend on the length and form of the pendulum. The particular colour of light is made to depend on the velocity of the ætherial molecules, or on the extent to which those molecules vibrate on either side of their mean places; and whatever be the number of vibrations made by the particles of æther in a given time, that is, whatever be the colour of light, it is to be understood, agreeably to the laws of the propagation of motion in elastic media, that the velocities of the waves of light are uniform in every direction. The intensity of the impression of light in the eye depends on the square of the greatest extent to which a molecule of æther vibrates on each side of its point of rest. [UNDULATORY THEORY OF LIGHT, P. C, p. 510.]

In common or white light, the vibrations of the ætherial molecules may be conceived to take place in any manner, but M. Fresnel assumed that when light is polarized, the eye is affected by the transverse vibrations only, or those which take place in planes perpendicular to the direction of the motion of the wave or ray, the vibrations in this direction, if such exist, being of a nature to produce no sensible effect. The hypothesis is supported by experiments made on a pencil of light which, after diverging from a radiant point, is reflected from two mirrors inclined to one another at a very obtuse angle, or is made to pass through a prism of glass having a great refracting angle, so as to proceed as if it formed two pencils diverging from different points; the reflected or refracted waves are found to interfere with one another so as to produce dark fringes or bars alternating with such as are bright; but when two plates of tourmaline having their axes at right angles to one another, which consequently polarize the light in planes at right angles to one another, are placed in the directions of the waves reflected from the two mirrors or transmitted through two faces of the prism, the waves cease to interfere with one another and no dark fringes are seen. It follows that no vibrations could have then taken place in the directions of the motions of the waves; since if they had, interferences ought to have been observed in the light which was polarized as well as in that which was not so.

For the composition of the vibratory motions in two polarized pencils, by which circular and elliptical polarizations are produced, see CIRCULAR POLARIZATION, P. C. S.

VICTOR, CLAUDE PERRIN, Duke of Belluno and Marshal of France, was born at La Marche, in the Department of the Vosges, on the 7th of December, 1764. He was seventeen years of age when, on the 16th of December, 1781, he enlisted as a private soldier in the 4th regiment of artillery, at that time in garrison at Auxonne. He had obtained his discharge when the first events of the Revolution of 1789 occurred, but, animated with the warlike spirit which then pervaded the French nation, he again eagerly sought for military employment, and entered as a volunteer the third battalion of the Department of the Drôme. A few months sufficed for this young and intrepid soldier to raise himself from the lowest rank to that of adjutant-major and 'chef de bataillon.' With the battalion under his command he distinguished himself at Coarara, by foiling the attack of three thousand Piedmontese and a regiment of emigrants. At the head of the same battalion he obtained considerable success, in 1793, at the siege of Toulon; under the orders of General Lapoye, he gained the important heights of Pharon, and afterwards, with similar good fortune, attacked the Fort l'Aiguillette, the capture of which greatly contributed to the favourable issue of the siege. These brilliant actions, in which he was twice wounded, were rewarded by his promotion to the rank of adjutant-general. Transferred to the army of the Eastern Pyrenees, with the rank of general of brigade, he rendered himself conspicuous for his skill and bravery at the sieges of Collioura (June 5, 1794) and Rosas (January 2, 1795). After the termination of the war between France and Spain by the treaty of peace signed on the 22nd of July, 1795, Victor joined the army of Italy. The courage which he displayed in the several battles of that campaign, and particularly in the action at Borghetto (May 30, 1796), brought him under the favourable notice of Bonaparte, who gave him every opportunity for further distinction by entrusting him with the management of manœuvres as honourable as they were perilous. His conduct during the sanguinary engagements which took place at Cossaria and Mondovi (April 5 and 16, 1796) justified the high estimation in which he was held by his chief, and were recognised by the government at Paris in a flattering letter which they sent him. The following year, by a series of skilful manœuvres, he greatly contributed to the success obtained by Masséna [MASSÉNA, MARSHAL, P. C. S.] over the Austrian general Wurmser [WURMSER, P. C.] at Corona (August 11, 1797). It was on account of his successes during this campaign, of which we have enumerated a very small portion, that he was raised to the rank of general of division. In this capacity he powerfully seconded the operations directed by General Lannes against the Papal States [LANNES, P. C. S.], after defeating the Roman troops on the river Serio, he occupied with the troops under his command the towns of Faenza and Cesena; he afterwards marched against Ancona with a detachment of twelve hundred men, and captured it without a shot being fired, though it was defended by one hundred and twenty pieces of cannon, and a garrison of five thousand degenerate Romans. 'General Victor,' says Napoleon, 'crossed the Po at Borgo Forte, at the head of four thousand infantry and six hundred horse, and formed a junction, at Bologna, with the Italian division of four thousand men, under General Lahoz. These nine thousand men were quite sufficient to conquer the States of the Church.' (Montholon, *History of the Captivity of Napoleon at St. Helena*, vol. ii. p. 56.)

After the peace of Campo Formio, General Victor was appointed to the difficult command of the province of the Vendée. By his skilful dispositions, and by his conciliatory, but firm and decisive conduct, he maintained the tranquillity of that country. Being recalled, in 1798, to the army of Italy, he was placed at the head of a division. In the following year he acquired fresh renown at the engagement of Sta. Lucia (March 30, 1799). Shortly after this battle he received orders to cross the Apennines, and to facilitate the retreat of the French army of Naples through the valley of the Bormida; in effecting this movement, his division was attacked by a large body of Piedmontese insurgents, in the narrow and difficult passes of those mountains; his troops however bravely repelled this attack at the point of the bayonet, and, after surmounting great dangers, he was enabled to effect a junction with the army under the command of General Macdonald. [Macdonald, Marshal, P. C. S.] Victor bore a distinguished part in the engagement on the banks of the Trebbia, which proved disastrous to the French. He was afterwards sent to Paris by General Moreau, to solicit from the Directory reinforcements for the army in Italy. On the failure of his mission, he returned to Italy and resumed the command of his division, which acquired fresh laurels at the battle of Bassano, where it formed part of the centre under the command of General Championet.

At the memorable battle of Marengo, the division of Victor formed part of the advanced guard; to the bravery and perseverance which he displayed on this occasion may in a great measure be ascribed the favourable issue of this long-disputed engagement. His services were rewarded by the presentation of a sabre of honour, on which was inscribed a flattering testimonial to his merit. He was afterwards transferred to the Batavian army, with the rank of second in command; his conduct in that campaign, though unmarked by any brilliant exploit, was such as to maintain the high reputation he had acquired.

After the peace of Amiens, he was sent to the court of Denmark as ambassador from the First Consul. He held this office till 1806, when, on the breaking out of the war with Prussia, he was appointed to the command of the tenth corps of the grand army. A wound, which he received at the battle of Jena, did not prevent him from directing in person the operations of the corps under his command during this short but brilliant campaign; and he powerfully contributed to the victory obtained over the combined forces of the Prussians and Russians at Pulstuck (December 26, 1806). In this campaign he was taken prisoner by a body of partisans, but, by means of an exchange, he speedily recovered his liberty. The following year was marked by the great battle of Friedland (June 14), in which Victor, at the head of the first corps of the grand army, so greatly distinguished himself, that Napoleon, on the field of battle, raised him to the dignity of Marshal of the empire.

After the treaty of Tilsit (July 6-9, 1807), Marshal Victor was appointed Governor of Berlin, a government including the greater part of Prussia. This office, which he held for fifteen months, was one which afforded many temptations to an abuse of power, but he appears to have exercised his authority with dignity and moderation.

In 1808 he was intrusted by Napoleon with the command of the first corps of the French army in Spain. Shortly after his arrival in that country, he obtained important advantages over the Spaniards in the engagements of Epinosa (November 10 and 11, 1808), Sommo Sierra (November 30), and Madrid (December 4). On the 13th of January, 1809, he routed the remnants of the Spanish army which had been defeated at Tudela [Lannes, P. C. S.], but which, reinforced by fresh levies from the provinces of Murcia and Valencia, had taken up a menacing position at Ucles. In this engagement upwards of three hundred officers, including two generals and twelve thousand soldiers, were made prisoners; all the enemy's artillery and thirty standards were captured by the French. According to the Spanish accounts, this victory was stained by the exercise of wanton cruelty towards the prisoners, in retaliation for similar cruelty exercised on former occasions by the Spaniards towards the French. (Napier, 'History of the Peninsular War,' vol. ii. p. 16.) At Medelin (March 28, 1809) Marshal Victor obtained another important victory over the Spanish army under General Cuesta, in which six thousand Spaniards are said to have fallen, and three thousand to have been taken prisoners. He was afterwards sent with his division to the support of the army of Marshal Soult in Portugal; but he had scarcely entered that country, when he was obliged to effect a retreat. Having formed a junction with the troops of Joseph Bonaparte, Marshal Jourdan, and General Sebastiani, he was induced to attack the army of Sir Arthur Wellesley, which was advancing into Spain. The issue proved disastrous to the French arms; after a long contested and sanguinary engagement, Victor was defeated at Talavera de la Reyna (July 28, 1809). This battle however did not materially change the position of the hostile armies. [Talavera, P. C.] Victor having united his forces with those of Marshal Ney and Mortier, and the British army being obliged to retire before the superior numbers of the enemy, the French were again enabled to occupy the town of Talavera. To the credit of the French commander of Talavera, it may be stated that a large number of sick and wounded English soldiers were treated with the greatest kindness.

On February 4, 1810, the duty of investing Cadiz was assigned to Marshal Victor, whom Napoleon had created Duke of Belluno; he conducted the operations of this siege with skill and perseverance, but though protracted for a considerable length of time, they finally proved unavailing. In 1812 he was summoned from the blockade of this town to join the grand army destined for the expedition to Russia, and was appointed to the command of the ninth division. His name stands conspicuous in the annals of this disastrous campaign. [Bonaparte, P. C.] During the retreat, he rendered the most important services to the French army, and in particular at the perilous passage of the Beresina (November 28, 1812), where, with six thousand men, he successfully resisted the efforts of General Wittgenstein [Wittgenstein, P. C.] and thirty thousand Russians. His courage in this action was rendered more remarkable by his humanity. Being recalled, on the approach of evening, from the position which he occupied at Stoudziancka, he took upon himself to disobey his orders, and remained there during the whole night, for the purpose of giving every assistance to the remnants of the French army, which had not yet effected the passage of the river. At daybreak, he skilfully managed to evacuate this position, without loss of either baggage or artillery, taking with him the wounded and a large number of camp followers, who, without his humane aid, must have fallen into the hands of the pursuing enemy.

The following year, Marshal Victor commanded the second division of Napoleon's army: to the conduct of that division at the battle of Dresden (August 26, 1813) the victory the French there obtained has generally been attributed. With the same division he likewise greatly distinguished himself at the battles of Wachau (October 16, 1813), Leipzig (October 18, 19), and Hanau (October 30). After the passage of the Rhine had been effected by the French army, Marshal Victor was actively employed in putting in an efficient state of defence the strong places of Alsace and the Franche Comté; he also for a long time bravely opposed the entrance of the Russian army into France. Compelled at length to fall back upon the Meuse, he effected this movement with his usual skill. He afterwards dislodged the allies from the position they had taken up at St. Dizier (January 27, 1814), and drove them out at the point of the bayonet from the village of Brienne. During the whole campaign he zealously seconded the efforts of Napoleon and the French army in checking the advance of the allies. On the 9th of February he marched his troops towards the Seine, for the purpose of more effectually co-operating with the movements of his chief, and sustained his high character as a soldier in the defence of the bridge of Nogent (February 11, 1814) and in the actions of Nangis (February 17) and Villeneuve le Roi. His failure in dislodging the allies from Montereau, where he had the misfortune to lose his son-in-law, General Château, exposed him to the displeasure of the emperor, who deprived him of his command. The marshal, it is said, refused to leave the service, and observed with emotion to his chief, that 'he had once been a private soldier, that he had not forgotten the use of the musket, and would again take his place in the ranks.' The emperor, moved by this proof of his fidelity, put him at the head of two brigades of his guard, with which he distinguished himself, a few days after, at the battle of Craonne, where he was severely wounded, and was obliged to retire from the field

When the success of the allies and the abdication of Napoleon had replaced the Bourbon dynasty on the throne, he was among the first to offer them his allegiance, and was rewarded by an appointment to the command of the second military division. On the return of Napoleon from Elba, he issued a proclamation, in which he allowed himself to speak of the creator of bis fortunes in terms which reflect high discredit upon his character; he describes him as 'the man who has tyrannized, desolated, and betrayed France during twelve years;' and he urges every Frenchman to pursue to the utmost not only this tyrant, but 'his satellites who have accompanied him on his plundering excursion.' Independently of the ingratitude which this language betrays, it evinces a singular want of discernment, coming from one who had once been among the most conspicuous of these satellites. He afterwards followed the examples of Marshals Berthier [BERTHIER, P. C.] and Marmont in accompanying Louis XVIII. to Ghent. [LOUIS XVIII., P. C.] On the second restoration, he was created a peer of France, and appointed one of the four major-generals of the royal guard. He was also unfortunately conspicuous as the president of the commission charged to inquire into the conduct of his former brethren in arms during the hundred days [NEY, MARSHAL, P. C. S.]: in that capacity he is reported to have displayed an unnecessary and pertinacious severity. In 1816, Marshal Victor was appointed to the command of the sixteenth military division of France. In 1821, he was named by Louis XVIII. minister of the war department; in this capacity he altogether disappointed the expectations to which his military talents had given rise; he alienated the affections of the new army as effectually as he had done those of the old, and lost the little popularity he had hitherto enjoyed. He actively promoted the expedition to Spain of 1823 [SUCHET, P. C. S.], and, having retired from the ministry, accompanied the army as second in command to the Duke of Angoulême. After the revolution of 1830, [CHARLES X., P. C. S.] he ceased to take any active part in public affairs; though he gave in his adhesion to the government of Louis-Philippe, he attached himself to the legitimist party, and appears on one occasion to have been seriously compromised, with several of the leading men of that party, in espousing the cause of the Bourbon claimant to the throne of France. He died on the 3rd of March, 1841.

The position occupied by Marshal Victor among the generals of Napoleon is not a very high one. Though his services to the Imperial cause were numerous and many of his exploits were brilliant, he is rather distinguished as a brave soldier than as a skilful commander. At the head of a division he executed with boldness and precision the movements indicated to him by his chief, but he was devoid of the military genius requisite to originate a skilful plan of battle. Hence, in a separate command, as in many instances in the Peninsular War, he was generally unsuccessful. He does not however appear to have merited the very harsh remark made concerning him by Napoleon, which O'Meara records: 'Victor était une bête sans talens et sans tête.' ('Napoleon in Exile,' vol. i. p. 511.) Such a judgment probably escaped Napoleon under the influence of the feelings which Victor's conduct, on his return from Elba, had excited. It is indeed scarcely possible that it was the real estimate he had formed of this general's military character, since he had raised him from the position of a private soldier to the highest dignities of his empire, dignities which were in every case the reward of some species of merit, and not the mere fancy of favouritism.

VIEN, JOSEPH MARIE, one of the most celebrated French painters of the eighteenth century, was born at Montpellier, June 18, 1716, and was the pupil of various painters, among them A. Rivalz, of Toulouse, and finally C. Natoire, at Paris, whither he repaired in 1740. He was very sickly in his youth, and his parents thought that even the fatigue of the drawing board was more than his strength could bear, and endeavoured to lead him to other pursuits; his own enthusiastic devotion to art, however, got the better of all obstacles, and in the year 1743, he competed successfully at Paris, for the grand prize of the French Academy, and obtained accordingly also the government pension for Rome. The subject of the picture was the Plague of the Israelites, in the time of David. In 1744 he departed for Rome and remained there until 1750, when he returned to Paris. Besides numerous studies he painted many excellent pictures during his six years' residence in Rome, including several church or altar-pieces of great merit, as the Slaughter of the Innocents, St. John for the town of Montpellier, and the only two pictures by Vien now in the gallery of the Louvre, Saint Germain and Saint Vincent receiving the Crown of Glory from the hands of an Angel, and the Sleeping Hermit.

These were followed by a long series of works at Paris, many of them compositions of the highest pretensions, and indicating a decided revival in the French school of painting from the insipid puerile state to which it had been reduced by Vanloo and Boucher. The pictures of Vien approach the style and technical excellence of the scholars of the Caracci, though for some time his works were much maligned by the scholars of Boucher and Vanloo, and among them his own master Natoire. His St. Denis preaching to the Gauls, one of his best works, was pronounced by them inferior to the picture by F. Doyen of the Miracle des Ardons, illustrating the tradition of the miracle performed by St. Geneviève when by her prayers she arrested the conflagration of Paris, which was caused by lightning in the year 1129. Vien's picture was placed in the church of St. Roch, where Doyen's is also now placed: they are nearly the same size, being about 24 feet high by 13 wide. In a few years however, and before the French revolution, Vien was justified by his contemporaries, who gave him the title of regenerator of painting in France: Count Caylus had always been an admirer of his genius. It was his object to restore the study of the antique, and of nature as represented in the works of the best Italian masters, and he succeeded to a considerable extent in both respects; but his admiration for the antique was carried to the utmost extreme by his pupils Vincent and David and their scholars.

Vien was elected a member of the French Academy in 1754, when he gave as his presentation piece a picture of Dædalus attaching his wings. In 1775, after the painting of his picture of St. Denis, which was exhibited in the Louvre in the previous year, he was decorated with the order of St. Michel, and was appointed director of the French Academy at Rome, where he resided from that time until 1781, and was elected in the meanwhile member of the Academy of St. Luke. After his return to Paris he became one of the rectors and director of the Academy there (he had previously been professor); and he was finally appointed principal painter to the king in 1789. This post he of course lost at the revolution, but he was from its foundation a member of the Institute of France; he was also created by Napoleon a member of the senate, a count of the empire, and a commander of the Legion of Honour. He died at Paris, March 27, 1809, having nearly completed his ninety-third year, and he was buried in the Pantheon. He painted until within a year of his death. Vien's pictures are very numerous, amounting to little short of two hundred; this number would not be great, if many of them were not of very large proportions. Few of them have however been engraved; the St. Denis, already mentioned, which is by some considered his master-piece, has been engraved only in outline by C. Normand for the 'Annales du Musée,' published by Landon, and in the 'Musée de Peinture,' &c. of Réveil and Duchesne. His works are from various subjects, but chiefly from the Sacred Scriptures, from antient and modern history, and from Greek mythology. Among his more celebrated pictures are—Julius Cæsar contemplating the Statue of Alexander at Cadiz, and regretting that he was still unknown at an Age when Alexander was already crowned with Glory; the Consecration of the Equestrian Statue of Louis XV.; Marcus Aurelius causing Provisions to be distributed among the People; St. Louis vesting the Regency of the Kingdom in his Queen, Blanche of Navarre; St. Jerome; the Embarkation of St. Martha; Christ breaking Bread; the Resurrection of Lazarus; the Virgin attended by Angels; St. Gregory; Briseis in the Tent of Achilles; the Parting of Hector and Andromache; Hector exhorting Paris to go out to battle; Venus wounded by Diomede; Æneas pursuing Helen during the burning of Troy; Andromache showing the Arms of Hector to her Son; Mars forcing himself from the Arms of Venus; Cupid and Psyche; Sappho playing on her Lyre; Proserpine adorning the Statue of Ceres;

Cupid flying from Slavery; a Woman selling Cupids; and a young Greek Girl comparing her Bosom with a Rose-bud.

Vien has left also many drawings, some in series, as—the Sports of Nymphs and Cupids, in 20 pieces; the Vicissitudes of War, also in 20 pieces; and the Union of Cupid and Hymen, Love and Marriage, in 36 pieces. There are also some etchings by Vien: he executed a set from a series of designs of the Adventures of Lot and his Daughters; and a Fête or Masquerade given by Vien and other students of the French Academy at Rome to the Cardinal de Larochefoucauld in 1748: it is in 32 pieces, under the following title—'Caravane du Sultan à la Mecque, Mascarade Turque donnée à Rome par Messieurs les Pensionnaires de l'Académie de France et leurs Amis, au Carnaval de l'Année 1748; Jos. Vien, inv. et sc.'

Madame Vien, born Marie Reboul, was a distinguished painter of birds, flowers, and still life; and was a member of the old French Academy of Painting. She died in 1805, aged seventy-seven.

Joseph Marie Vien, the younger, the son of M. and Madame Vien, though a distinguished portrait-painter, practised only as an amateur. He was born at Paris, in 1761. He exhibited several pictures in the Louvre from 1800 until within the last few years: among them a portrait of his father, as M. Vien, sénateur, in 1804.

(Gabet, *Dictionnaire des Artistes de l'Ecole Française au dix-neuvième Siècle;* Fiorillo, *Geschichte der Mahlerei*; Landon, *Annales du Musée;* Réveil et Duchesne, *Musée de Peinture*, &c.; Brulliot, *Dictionnaire des Monogrammes*, &c.)

VIGAN LE, a town in the arrondissement of Le Vigan, in the department of Gard, in the south of France. It is out of the high road, and its distance from Paris can only be given, approximately, at from 385 to 390 miles S. by E., by the road through Fontainebleau, Montargis, Briare, Nevers, Moulins, Gannat, Clermont, St. Flour, Mende, and Florac. The town stands on the left bank of the Arre, a small feeder of the Hérault, in a very beautiful and romantic valley amid the lower south-eastern declivities of the Cévennes, amid green fields and orchards, watered by a number of clear streams. The town is old and ill built. The principal 'place' is decorated with a bronze statue of Le Chevalier d'Assas, a native of the town, who died, with circumstances of peculiar self-devotion, in the battle of Clostercamp, near Guelders, fought in October, 1760, between the French and the allies during the Seven Years' War. The population of the commune in 1826 was 4246; in 1831 it was 4909, of whom 4480 inhabited the town itself, the remainder the outparts of the commune; in 1836 it was 5049. The principal manufacture carried on is of hosiery, especially of silk stockings: cotton-yarn is also spun; and there are tanyards and currying-shops, a paper-mill, and a glasshouse. There are six fairs in the year. Coal is dug in the neighbourhood of the town.

The government establishments are, a subordinate court of justice, a stamp-office, and a board of indirect taxation; and there are a consulting chamber of manufactures, an agricultural and two Biblical societies.

The arrondissement of Le Vigan has an area of 543 square miles, with a population in 1831 of 65,247, and in 1836 of 65,755. It comprehends ten cantons or districts, each under a justice of the peace.

VILL. [Town, P. C.]

VILLEHARDOUIN, GEOFFROY DE, was born near Arcis-sur-Aube about the year 1167, and was descended from one of the most ancient and distinguished families of the Comté de Champagne. He was Maréchal of Champagne when, in 1199, his sovereign lord Thibault, Count of Champagne and of Brie, determined upon joining the cause of the crusades, and Villehardouin was among the first chosen to accompany him. Previous to the departure of his lord he was sent as ambassador to Venice, to solicit the aid and co-operation of that Republic in their enterprise. He arrived at that city with five other deputies in the beginning of Lent, 1201, and met with an honourable reception from Henry Dandolo, the Doge. Admitted before the council of state, Villehardouin eloquently explained the motives of his mission, and the reasons which had induced the Count of Champagne to apply to the Venetians for assistance, in preference to other powers. 'We have chosen you before all other nations in Europe,' he said, 'as being the most powerful, the most generous, and the most capable of seconding so glorious an enterprise. We have come to demand your assistance and the junction of your forces to ours, without which we can never expect to re-conquer Jerusalem; and, as we are resolved to undertake this conquest, we have been commanded not to leave your city till we have received a favourable answer to our request, leaving it to you to impose the conditions on which it is to be granted.' To this energetic appeal were joined the tears and entreaties of the other deputies, who, in the holiness of their mission, forgot the shame of kneeling as suppliants before the haughty representatives of commercial power. Moved by their appeal, and by the pecuniary advantages which were likely to result from the transaction, an unanimous acclamation arose from the assembly of 'Nous l'octroyons! Nous l'octroyons!' A treaty was concluded between the French deputies and the Republic, by which it was agreed, that the Venetians should furnish the vessels necessary for the transport of 4500 horsemen and 9000 squires and attendants, and also 20,000 foot soldiers, with nine months' provisions; that the vessels should be equipped and ready to sail in the month of June in the following year, and that their service should only count from the time that they left Venice. For these services the crusaders were to pay the Venetians the sum of 80,000 marks of silver, or, according to some accounts, 85,000. The payment of so exorbitant a sum, for that period, proves equally the generous zeal of the crusaders and the attentive regard of the Venetians to their interests. After the conclusion of this treaty, Villehardouin returned to France, where he found the Count Thibault dangerously ill. The death of Thibault, which occurred soon after, left the crusaders without a chief. The command of the expedition having been offered to the Duke of Burgundy, and afterwards to the Count of Bar, who both declined it, it was finally accepted by the Marquis of Montserrat, who appointed Venice as the place of general meeting.

The first exploit of the crusaders, after leaving Venice, was, at the solicitation of Alexis Comnenus, to re-establish on the throne of Constantinople the Emperor Isaac his father. The French having afterwards to complain of the conduct of Alexis, who had not ratified the stipulated conditions for the succour they had lent him, sent Villehardouin as their deputy to make the necessary remonstrances.

Villehardouin was present at the siege of Constantinople in 1204, when that city was taken by the Venetians and French [Constantinople, P. C.], and to him history is indebted for a minute and graphic description of this remarkable siege. He thus describes the impression which the first appearance of the imperial city made upon his rude companions in arms:—'That such a city could be in the world they had never conceived, and they were never weary of staring at the high walls and towers with which it was entirely encompassed, the rich palaces and lofty churches, of which there were so many that no one could have believed it, if he had not seen with his own eyes that city, the queen of all cities; and know that there was not so bold a heart there that it did not feel some terror at the strength of Constantinople.' Chap. 66. (See the notes at the end of vol. xxiv. of the 'Waverley Novels,' Edinburgh, 1843.) The services of Villehardouin were rewarded by the Emperor Baldwin, whom the victorious Franks had placed on the throne, by his appointment to the important office of 'Maréchal' of the province of Romania. His military skill and bravery also insured him the esteem of the Emperor Henry, the successor of Baldwin, to whom the Marquis of Montserrat had given his daughter in marriage; from him he received, as a free gift, the entire city of Messinopolis, together with its dependencies. This valuable donation induced him to reside in Thessaly, where he died about the year 1213. While however enjoying the honours which his merit had acquired, he appears not to have been unmindful of the country of his birth; in 1207, he richly endowed the abbeys of Froissy and Troyes, to which his sisters and his two daughters belonged. The lustre of his name gave power and influence to his descendants, who for nearly two centuries ruled over the most important principalities of Greece.

It is chiefly as an historian that the name of Geoffroy De Villehardouin has become celebrated. To him we are principally indebted for the history of one of the most important periods in the wars of the crusades [Crusades, P. C.], from 1198 to 1207. His work is entitled 'L'Histoire de la Prise de Constantinople par les Français et les Vénitiens.' The author relates the events in which he was an active participator with modest simplicity and tolerable candour. His narration is remarkable for brevity and clearness, and generally bears the impress of truth. His talents as a negotiator caused him frequently to be employed on missions of importance, and to be summoned to the councils of the army; he has thus been enabled to give a minute detail of several events, of which we might otherwise have remained ignorant. His history is rendered the more valuable from the fact, that it is probably the oldest historical record in prose which the French language possesses. The first edition of it was published at Venice in 1573, the second in Paris in 1585: the most valuable is that by the learned Du Cange, 'whose notes,' says Mills, 'are as valuable as his notes on the Alexiad.' [BYZANTINE HISTORIANS. P. C.] The title of this edition of Du Cange, which is now not easily to be met with, is as follows: 'Histoire de l'Empire de Constantinople, divisées en deux parties, &c., écrite par Geoffroy De Ville-Hardouin, avec la suite de cette Histoire jusqu'en 1240, tirée du Manuscrit de Philippe Mousker, &c., le tout avec Observations faites par Charles du Fresne, Sieur du Cange; Paris, de l'Imprimerie Royale, 1657, in fol.' In this edition the old text is accompanied with a modern French version. The history of Villehardouin is also to be found in vol. xxviii. of the 'Recueil des Historiens des Gaules et de la France;' Paris, 1822, in fol.: the text in this edition has been revised on three manuscripts, and to it is appended a glossary.

(*Biographie Universelle*, tome xlix., Paris, 1827; Laugier, *Histoire de Venise*, tome second, livre vi., Paris, 1758; Mills, *History of the Crusades*, vol. ii., London, 1820; Michelet, *Histoire de France*, livre iv., chap. vi.)

VINCENT DE PAUL, SAINT, was born on the 24th April, 1576, at Ranquines in the parish of Pouy, near the Pyrenees, in the present department of the Landes. He was the third son of Guillaume de Paul, who owned and cultivated a small farm in that parish. The narrow means of his family promised him a life of laborious toil, and till the age of twelve he assisted his parents in the care of their farm. He had however from early youth manifested so great an acuteness of intellect and sensibility of disposition, that they were induced to endeavour to give him a suitable education. He was placed as a student in a convent of the Cordeliers at Acqs, the residence of the bishop of his diocese. At the age f sixteen, he was considered qualified to become tutor to the children of M. de Commet, an advocate of Acqs, and the magistrate of his native village. This situation enabled him at the same time to relieve his parents from the expenses attendant on his education, and to prepare himself for the ministry of the church, to which he had now determined upon devoting himself. He assumed the tonsure on the 20th December, 1596, and the next year he went to Toulouse, in order to follow the course of theology of that university. But he was compelled, on account of the slender pittance which was allowed him, to combine the duties of a teacher with those of a student. In the year 1600, after having received the previous orders, he was made a priest by the Bishop of Perigueux; in the same year the offer was made him of the parish of Tilh, one of the most valuable in the diocese of Acqs, which he declined in order to devote himself more entirely to the study of theology. In this study, notwithstanding the difficulties under which he laboured, he soon became eminent, and on the 12th October, 1604, obtained the degree of bachelier des lettres, with a permission to lecture.

In 1605, a legacy of fifteen hundred livres, which had been left him by a friend who had died at Marseille, compelled him to make a journey to that city. After taking possession of his legacy, he was returning by sea, when he was taken prisoner by some Tunisian corsairs, and was wounded in the conflict. He has left us a minute relation of his capture and imprisonment, in a letter written to his early patron, M. de Commet, on his return to France in 1607, of which there is a copious extract in the 'Biographie Universelle.' During his captivity at Tunis and Algiers, he became the slave of three successive masters; the last of them, an Italian renegade, he converted to his former faith. After a delay of ten months, he was sufficiently fortunate to induce his master to forego the temporal advantages of a residence in a land where he was obliged to conceal his profession of Christianity, and to escape with him to France, in which country they landed on 28th June, 1607. At Avignon, the penitent renegade was publicly readmitted to the privileges and consolations of the religion he had denied. Shortly afterwards the vice-legate of the pope, Paul V., who had performed this ceremony, induced Vincent and his companion to accompany him to Rome. He there became acquainted with the ambassador of the French king, who selected him to be the bearer of an important and confidential message to Henry IV. He arrived in Paris at the commencement of the year 1609, and obtained several interviews with the king. His time however he chiefly devoted to the service of the sick of l'Hôpital de la Charité, near which he had taken up his residence.

The period of Vincent's residence in Paris was embittered by an accusation of robbery made against him by a fellow-lodger, a native of the same province as himself, and for six years he was unable to clear himself of the charge. During that time, though suffering severely from the cruel imputation, he contented himself, when questioned concerning it, with a simple denial, joined to the remark that 'God knew the truth.' The real author of the robbery was at length discovered, and the reputation of Vincent rose still higher in the estimation of those who had witnessed the patience and resignation which he had displayed under the false accusation. His adversity however was alleviated by the sympathy and support of several influential personages, whose friendship and esteem his merit had conciliated. Among them was Margaret of Valois, sister of Henry III., and the divorced queen of his successor, who appointed him her almoner, and Pierre de Berulle, afterwards cardinal, and founder of the congregation of the Oratoire. By the latter he was induced to accept the cure of the parish of Clichy in the neighbourhood of Paris, where he discharged his duties with exemplary diligence. His short residence in that village was blessed with the happiest results; not only were the sick attended to, the poor assisted, and the afflicted consoled, but family discords and dissent in religious matters were made by his pious influence to cease.

In 1613, he was obliged to abandon this peaceful scene of spiritual labour, to undertake the education of the three sons of Philippe Emmanuel de Gondi, Count of Joigny, and general of the galleys of France. These pupils of Vincent were destined to occupy an important position in the history of their country: one of them became the well known Duc de Retz; another, the famous cardinal, who acted so conspicuous a part in the civil wars of the Fronde. [RETZ, P. C.]

In 1616, he accompanied the Countess de Joigny to her country residence at Folleville, in the diocese of Amiens, where he commenced a series of missionary labours among the inhabitants, which were eminently successful. The memory of this mission he was in the habit every year, on the festival of the conversion of St. Paul, of celebrating with pious gratitude. The following year, he left the residence of the Count de Joigny to undertake the cure of the parish of Châtillon, in Bresse, where his labours were attended with similar success. It was there that he first established and organized a religious association for the relief of the temporal and spiritual wants of the sick and poor, to which he gave the name of the 'confrérie de charité,' which became the model of many similar institutions in France and other countries. Towards the end of the same year, he was induced to return to the Count's family, and, with the permission and co-operation of the Countess, a lady of pious disposition and intelligent mind, who had placed herself under his spiritual direction, he undertook several successful missions in the dioceses of Beauvais, Soissons, and Sens. An opportunity was now afforded him to labour in a cause still more important, and which presented the prospect of much danger, disappointment, and difficulty. He was in the habit of accompanying to Marseille the Count de Joigny, whose situation as commander of the royal galleys rendered it necessary for him frequently to visit that city. He was there moved with compassion on witnessing the sufferings and severities to which were subjected the unhappy criminals condemned to the galleys. To ameliorate their condition and to alleviate their sufferings was the pious task which Vincent took upon himself He found them in narrow and unhealthy dungeons, almost entirely deprived of air and light, with bread and water for their only food: disfigured by filth, and covered with vermin, these wretched victims of their own misdeeds, and of the misguided policy of the state, sank shortly after their admission into a brutal state of ignorance and ferocity. Vincent began his work of reformation by introducing himself among them as their friend and benefactor, and, undeterred by the rude scoffs and jests to which he was at first exposed, and undismayed by the havocks of a pestilential disease, which was the habitual sojourner of these prisons, he unremittingly pursued his charitable mission: his kindly manner, his patient attention to their wants, his reproofs, tempered by mildness and Christian charity, and, above all, his own example of humility and self-devotion, soon overcame all obstacles; he gained their confidence, and thus secured a ready acquiescence in his efforts for their welfare. In a short time, the most unexpected success attended the improvements which he introduced and the reformation which he effected. The ameliorated condition of these criminals was sensibly felt and gratefully acknowledged by his patron, who called the attention of the king, Louis XIII., to the change which had taken place among the criminals under his care and to the devoted man by whom it had been produced, and the king, with appropriate consideration for the services he had rendered, appointed Vincent almoner-general of the galleys of France; the date of his appointment to this important office was 8th February, 1619. In the beginning of the following year, Francis de Sales, the celebrated bishop of Geneva, whose intimacy he had for some time previously enjoyed, confided to him the direction of the first convent of the Order of the Visitation, which he had lately established. [SALES, DE, FRANCIS, SAINT, P. C. S.]

In 1623, Vincent established two 'confréries de charité' in the town of Mâcon, one for men and the other for women. He next visited the city of Bordeaux, for the purpose of inquiring into the condition of the criminals there condemned to the galleys. On leaving that city, he visited his friends and relations in his native village; having assembled together those who remained of his family, he informed them of his determination to die as he had lived, destitute of all worldly wealth; told them that money left by a priest to his family seldom prospered, and thus weaned them from any expectation they might have formed of obtaining property at his death. This resolution however did not prevent him, on a subsequent occasion, from distributing among them about a hundred pounds of our money, which had been bequeathed to him.

The next scene of Vincent's labour was the town of Chartres, where he founded an association under the name of the 'Congregation of the Missions,' which was intended to supply the provinces of France with efficient teachers of religion, who were to act as assistants to the regular clergy, and were to be subordinate to the authorities of the church. On 6th March, 1624, the 'Collége des Bons Enfans' was given to him as the first residence of the new company he had formed. For the better watching of his infant institution, he left the family of the Count de Joigny, and retired to this college. In 1627, he had the satisfaction to see the Congregation of the Missions authorized by letters patent from the king, and in 1631, formally approved by a bull of the Pope Urban VIII. During this period he was actively employed in establishing retreats for the members of the society, and for persons destined to enter the orders of the church; a measure which greatly tended to the reformation of many existing abuses. In 1632, he yielded to the repeated requests of the Prior of St. Lazarus, Adrien Lebon, to accept his house and property for the purpose of furthering his projects for the instruction and relief of the poorer classes of the peasantry. Small as were the beginnings of this institution, he lived to see the order of the Lazarists spread its charitable influence over the greater part of Europe. The institution however which has probably been productive of the most beneficial consequences was that which he established in 1634; it was composed of a company of pious females, called Sisters of Charity, who especially devoted themselves to the attendance of the sick; a branch of this society, called 'les Dames de la Croix,' was intended for the sole service of l'Hôtel Dieu at Paris. To Vincent de Paul this city indeed has been peculiarly indebted for many valuable institutions, whose utility is recognised to this day. Among them may be mentioned the hospitals of 'La Pitié,' 'Bicêtre,' 'La Salpêtrière,' and 'Les Enfans Trouvés,' or Foundling Hospital. [PARIS, P. C.; FOUNDLING HOSPITAL, P. C.] The origin of this last-mentioned institution exhibits a striking proof of the disinterested zeal of Vincent. Previous to the establishment of the Foundling Hospital in Paris, an immense number of children, the fruits of licentious intercourse or the victims of their parents' poverty, were daily exposed in the streets and public places of that city, and often left there to perish. The pitiable condition of these innocent sufferers excited the commisseration and stimulated the charitable zeal of this devoted minister of the church. For the purpose of affording them food and succour he enlisted in his cause several ladies of the capital, over whom his simple piety had already exercised a beneficial influence. He called them together at the commencement of the year 1640, and so energetically set before them the motives for their charitable intervention in the cause of these unhappy foundlings, that they determined upon making the trial of taking under their protection all who should hereafter be discovered. The generous gift of an annual rent of 12,000 livres from the Queen Anne of Austria was the first assistance they received in their humane design. Soon however the wants of these foundlings exceeded the funds which charity could raise; discouraged in their efforts, and fearful that the task which they had undertaken was beyond their means and abilities, the adopted parents of these children were about to abandon their charitable enterprise. To avert so unhappy an issue to his charitable project, in 1648, Vincent called together another and more numerous assembly. He there summoned to his aid every argument which could be urged in support of his cause, and pleaded the interests of these innocent outcasts of society in a language of fervid and impassioned eloquence; an eloquence unaided indeed by the arts of a polished education, but which was the utterance of deep-seated sincerity and ardent zeal. The termination of his address on that occasion has been recorded by a high authority as one of the finest pieces of eloquence in any language. (Maury, 'Essai sur l'Eloquence de la Chaire.') [MAURY, P. C. S.] Rich and plentiful were the fruits of his energetic pleading; alms were collected in abundance, two large buildings were converted into hospitals for foundlings, and the capital of France was no longer disgraced by the daily exhibition in its streets of helpless children dying from the want of food and succour. Besides the hospital already mentioned, Vincent founded two others, which have been productive of considerable benefit: one at Paris, which went under the designation of the name of Jesus, for the maintenance of forty poor men, whom age had incapacitated for labour; the other, that of Sainte Reine, in the diocese of Autun, in Burgundy, for the relief of the poor and sick among the numerous pilgrims who are accustomed to visit the shrine of that martyr.

While occupied in the formation of societies and in the establishment of institutions destined for the permanent relief of his fellow-creatures, he was no less zealous and persevering in attending to the immediate wants of those who came within the reach of his assistance. The province of Lorraine was, during the latter period of the reign of Louis XIII., suffering under the threefold calamity of war, pestilence, and famine. To that province, by his charitable exertions, for several successive years, Vincent caused considerable sums of money, which he collected in Paris, to be sent for the succour of its inhabitants. His biographers differ with respect to the amount, the highest stated being two million livres, and the lowest from five to six hundred thousand.

During the wars of the Fronde, the Queen-regent, Anne of Austria, instituted a council for the settlement of disputes on questions of theology, and appointed Vincent de Paul its president. In this capacity, he took an active part in the religious controversies of that period, and warmly espoused the cause of the Jesuits against the followers of Jansenius. [JANSENISTS, P. C.; PORT ROYAL, P. C.] Through his influence, a letter signed by eighty-eight bishops was sent to the reigning pontiff, praying him authoritatively to condemn the witness of Jansenius, and in particular the work entitled 'Augustinus.' In carrying on this controversy however, he does not appear to have exceeded the bounds of moderation, and to have employed against his adversaries only the legitimate weapons of argument and expostulation. The four last years of his life were spent under the burden of infirmities, which compelled him to keep within the precincts of the convent of St. Lazarus, where nevertheless he continued efficiently to preside over the interests of the community he had established. His death, which occurred on the 27th September, 1660, was preceded by severe and protracted sufferings, which were borne with his accustomed patience and resignation. His remains were deposited in the church of St. Lazarus, in presence of the assembled clergy and the highest dignitaries of the capital, who mourned his loss as that of their spiritual father; but perhaps the tears of most genuine affection were shed on his tomb by the multitude of the poor and needy, who gratefully remembered that they had often been consoled by his counsels and relieved by his charity.

The panegyric of this eminent minister of the church has been written by two of its most distinguished prelates, Boulogne, Bishop of Troyes, and the Cardinal Maury; the last of these has been greatly admired for the beauty of its style and the energy of its expressions; it may be seen in the last edition of his 'Essai sur l'Eloquence de la Chaire.' [MAURY, P. C. S.] The memory of Vincent de Paul was consecrated by a ceremony, known in the church of Rome by the name of Beatification, by Benedict XIII., on 14th August, 1729, and he was canonized as a saint on 16th June, 1737, by Clement XII., who appointed 19th July as the day of his festival in the Roman calendar.

The name of St. Vincent de Paul stands deservedly high in the list of benefactors of mankind. His entire life was devoted to the advancement of the best interests of humanity; he was a constant actor on the ever recurring scene of sickness and suffering, poverty and crime, and his presence was always attended by consolation and relief to their victims. Men of all creeds and persuasions have rendered homage to his worth, and the members of his own church have ascribed to his relics the power of working miracles. The greatest miracle however was himself, and the mighty works of which he was the instrument; the many hospitals which he founded, the religious communities which he established, the missionaries whom he sent abroad, the vast sums of money which he caused to be distributed to the poor and sick, his untiring activity in ministering to their wants, his disinterestedness and self-devotion, his evangelical patience and religious resignation; above all, his genuine humility, which, while it shed lustre on those of his charitable deeds which are known, has caused a large proportion of them to be unknown and unwritten, save in the records of the book of life;—these, it must be allowed by all, are the real miracles on which stands the fame of this apostolical man.

The following is a list of the writings he has left:—1, 'Regulæ seu Constitutiones communes Congregationis Missionis,' Paris, 1658; 2, 'Lettre au Pape Alexandre VII., pour solliciter la Canonization de François de Sales, prince-évêque de Genève;' 3, 'Conférences spirituelles pour l'Explication des Règles des Sœurs de la Charité,' Paris, 1826, in 8vo.

The two most important biographies of St. Vincent de Paul are those of Abelly, who was intimately acquainted with him, and Collet, who was a member of his community; there is also a third, by M. de Capefigue, Paris, 1827, in 8vo.

(*Biographie Universelle*, tome xlix., Paris, 1827: the article in this biography is written by Labouderie, and is valuable from the research and impartiality which it displays; *Life of St. Vincent of Paul, Founder of the Congregation of the Missions and of the Sisters of Charity*, by Mons. Collet, Priest of the Mission: translated from the French by a Catholic clergyman, Dublin, 1846; *Vies des Pères, Martyrs*, &c., from Alban Butler, traduction de Godescard, Versailles, 1819, tome vi.; *Penny Magazine* for 1838, p. 4; Abelly, Evêque do Rhodez, *Vie de St. Vincent de Paul*, Paris, 1839, 2 vols. 8vo., the most complete and valuable biography of St. Vincent.)

VINCULA'RIA. A species of fossil Zoophyte is referred to this genus of Defrance by Portlock, from the carboniferous limestone of Ireland.

VINER, CHARLES, died June 5, 1756, at his house, Aldershott, Hampshire. When or where he was born has not been recorded. He is known as the compiler of 'A General and Complete Abridgment of Law and Equity,' 24 vols. folio, 1741-1751, and as the founder of the Vinerian Professorship of Common Law in the University of Oxford. The 'Abridgment' was printed at his own house, at Aldershott. The 24th volume is an Index, by a Gentleman of Lincoln's Inn. It appears to have occupied only ten years in printing, but Viner was probably occupied many years previously in preparation. Blackstone says he was half a century about it. This stupendous work was reprinted in 24 vols. roy. 8vo., 1792-1794, and was followed by 6 supplemental volumes, roy. 8vo., 1799-1806, the compilers of which were James Edward Watson, Samuel Comyn, James Sedgwick, Henry Alcock, John Wyatt, James Humphreys, Alexander Anstruther, and Michael Nolan.

Viner having resolved to dedicate the bulk of his property, as he himself states, 'to the benefit of posterity and the perpetual service of his country,' bequeathed by his will, dated December 29, 1755, about 12,000*l.* to the Chancellor, Master, and Scholars of the University of Oxford, to establish a Professorship, and to endow such Fellowships and Scholarships of Common Law in the university as the produce of his legacy might be thought capable of supporting. The Professor is to read a lecture in the English language within a year after his admission, and a course of lectures on the laws of England every year in full term. The course is to consist of at least twenty-four lectures, to be read in one and the same term, with such intervals that not more than four are to be read in a week. As relates to the reading of the lectures, Easter and Trinity Terms are reckoned as one Term. There are at present (1846) two Fellowships with 50*l.* a year each, and five Scholarships with 30*l.* a year each. Both Fellowships and Scholarships expire at the end of ten years after each election.

Blackstone was elected the first Vinerian Professor. He had commenced his lectures on English law in the year 1753, two years before Viner made his will, and it is therefore probable that Blackstone's lectures gave Viner the hint for founding the Professorship. The succession of professors is as follows:—1758, William Blackstone, D.C.L.; 1760, Richard Chambers, Knt., B.C.L.; 1777, Richard Wooddeson, D.C.L., author of 'Lectures on the Law of England,' 3 vols. 12mo.; 1793, James Blackstone, D.C.L.; 1824, Philip Williams, B.C.L.; 1843, John Robert Kenyon, D.C.L.

(Chambers's *Biographical Dictionary*; *Oxford University Calendar*, 1846.)

VIOLIN STRINGS. [CATGUT, P. C. S.]

VISMIA (in honour of M. de Visme, a Lisbon merchant), a genus of plants belonging to the natural order Hypericaceae. The calyx is five-parted, the petals 5, usually villous on the inside. The berry membranous, the styles 5, stigmas peltate. The stamens are numerous, disposed into 5 bundles opposite the petals, alternating with 5 glands or scales. The anthers are small, roundish, 2-celled, bursting lengthwise, the seeds with a double covering. The leaves usually protected with a rusty down, rarely with pellucid dots.

V. guianensis is a small tree with a stem about eight feet high, the leaves ovate, lanceolate acuminate, dilated at the base, rufous beneath, smooth above, filled with transparent dots. The petiole is short, the calyxes ovate, obtuse, tomentose with ciliated margins. The flower yellow and corymbose. The berry yellowish, ovate, soft, and somewhat 5-cornered. The bark when wounded yields a gum resin, which when dry becomes hard, and resembles gamboge. The leaves and fruit likewise yield a similar secretion. It is used in medicine as a purgative, in doses of from 7 to 8 grains. A decoction of the leaves is recommended in intermittent fever. This species is native of Guiana and Bengal. There are about twenty other species growing in the East Indies, Bengal, and Guiana: those from Guiana yield a resinous gum, which finds its way into Europe under the name of American Gamboge.

(Lindley, *Flora Medica*.)

VITRU'VIUS BRITA'NNICUS. [GANDON, JAMES, P. C. S.]

VITTORI'NO DA FELTRE, born in 1379, at Feltre in North Italy, studied at Padua under the celebrated Guarino of Verona, and afterwards became professor of rhetoric and philosophy in the same university. Being some time after invited by G. F. Gonzaga, lord of Mantua, to superintend the education of his children, Vittorino repaired to Mantua, where a separate and commodious residence was prepared for himself and his pupil, which was named 'La Giocosa.' Other youths of distinction repaired thither in succession to avail themselves of Vittorino's instruction, and among them Federico di Montefeltro, afterwards duke of Urbino, Giberto, prince of Correggio, Taddeo Manfredi, of the princely house of Faenza, Gio. Battista Pallavicino, afterwards bishop of Reggio, Lodovico Torriano and Bernardo Brenzoni, who became afterwards celebrated as jurists, Theodore Gaza and George of Trebisond. Ambrogio Traversari, or Camaldulensis, who visited the school of Vittorino at Mantua, gives in his Epistles (lib. vii. & viii.) an interesting account of his system of education; and Carlo Rosmini, who died lately, has written a work on the same subject, entitled 'Idea dell' ottimo precettore nella vita, e disciplina di Vittorino da Feltre a de' suoi discepoli.' It appears from the example of Vittorino, of Guarino Veronese, and others, that education, in the larger sense of the term, was better understood in Italy in the fourteenth century than it has been since, but it was confined to the upper classes. Gymnastics formed a part of Vittorino's system. He lived with his pupils and took his meals with them. Their fare was wholesome, but plain. He had tablets of various colours to teach his younger pupils the rudiments of reading. His older pupils were instructed in rhetoric, mathematics, and ethics. He was very strict with regard to their morals. He watched the disposition and abilities of each pupil, in order to direct him to that particular professional course for which he was best adapted. Temperate in his corrections, he allowed time to pass between the offence and its punishment, and he never showed himself out of temper. He was beloved by his disciples, and he loved them like a father. Such was the character of this distinguished preceptor.

(Corniani, *I Secoli della Letteratura Italiana;* Tiraboschi, *Storia della Letteratura Italiana;* Rosmini, as above mentioned.)

VOLPI, GIAN ANTONIO, born at Padua in 1686, studied in his native town, and became a good Latin and Greek scholar. In 1717 he and his brother Gaetano Volpi established a printing-press in their house for the purpose of bringing out correct editions of classic authors, and they engaged for their assistant the printer Giuseppe Comino. This press—known by the name of Volpi-Cominiana, produced among others a valuable edition of Catullus with copious notes. The edition was much commended by scholars, and the city of Verona struck a gold medal, which was presented to Volpi: the title is, 'Calus Catullus Veronensis et in eum Jo. Antonii Vulpii novus Commentarius,' 4to., Padua, 1737. Volpi afterwards edited Tibullus and Propertius. He translated from the Greek into Italian the dialogue of Zacharias Scholasticus; he wrote a disquisition on the satire of the Romans: 'Liber de satyræ Latinæ natura et ratione, item paraphrasis perpetua et commentarius uberrimus in X satyram Juvenalis,' Padua, 1744; he edited the poems of Sannazaro, with a biography of the author; he published a new edition of Dante; and he wrote three books of Latin poems, to which he added those of his ancestor and namesake Gian Antonio Volpi, the elder, who was bishop of Como and was one of the Fathers of the Council of Trent. Volpi was for many years professor of philosophy and of rhetoric in the University of Padua. In his old age he became blind, and he died in 1766. His brother Gaetano Volpi edited Sallust in 1722, and he was an active assistant to his brother at the press. He wrote an account of their joint labours: 'La Libreria dei Volpi e la Stamperia Cominiana.' Giuseppe Comino having died in 1752, his son Angelo Comino continued to carry on the business. Another brother of Volpi, named Giuseppe, undertook the continuation of Cardinal Corradini's great work, 'Vetus Latium profanum,' which he completed.

(Tiraboschi, *Storia della Letteratura Italiana*, with the continuation by Lombardi.)

VO'LTZIA, a genus of fossil (coniferous?) plants which occurs in the Magnesian limestone of England, and in the new red sandstone of Germany. (Brongniart.)

VOYAGE. [SHIPS, P. C.; BOTTOMRY, P. C.]

INDEX TO THE LETTER V.

VOLUME II.

W.

WACE, ROBERT, MASTER. The name of this early Anglo-Norman poet is variously written in different manuscripts of his poems, and in the ancient writings which make mention of him. Tho most usual forms are Wace, Gasse, Gace, Guaze, Huace, and Huistace, names which appear to be abbreviations of Eustache or Eustace. His Christian name is likewise doubtful, as he never styles himself otherwise than 'Master Wace.' Du Cange supposed it to have been Matthew, and Huet is tho first writer who calls him Robert. He was born in the island of Jersey about the year 1112, and received his early education at Caen; he completed his studies, which appear to have been chiefly connected with the clerical profession, during a residence of some time in the territories of the King of France, and he afterwards returned to Caen, where Henry I. usually held his court. In this town ho spent the greatest portion of his life; his chief occupation was the composition of metrical romances, so called from their being written in the Roman or vulgar dialect. The 'Roman du Rou,' which he completed in 1160, was dedicated to Henry II., and was presented to him by Wace in person, who was rewarded with a canonry in the cathedral church of Bayeux; this preferment, according to the antient capitularies of that church, he held from 1161 to 1171. As he frequently styles himself 'clerc lisant,' reading clerk, it has been supposed that he was attached to the private chapel of Henry II. He complains, however, and that somewhat bitterly, that the reward ho received from the Dukes of Normandy neither answered his anticipations nor came up to the promlses they bad made him. He is said to have died in England, about the year 1184.

The principal details in this brief notice of the life of Wace, are given to us by himself in his 'Roman du Rou.'

"Lunge* est la geste des Normanz,

Nevou Henri, père Henri."

The rhymed chronicle from which this extract is taken is entitled 'Le Roman du Rou (Rollo) et des Ducs de Normandie,' and is the best known of the writings of Wace; it is held in high esteem as a monument of the language and as an historical document, which, though incorrect in some of its details and sometimes inexact in its dates, presents a faithful picture of society during that period. It contains the history of the Dukes of Normandy from the first invasion by Rollo down to the eighth year of King Henry I., and not simply, as Hallam states, the narrativo of the battle of Hastings and conquest of England by the Normans. The first, or introductory part, is written in lines of eight syllables, and presents us with the history of the first irruption of the Normans into England and France. The second part or section is written in Alexandrine verse, and relates the principal events which took place in the reign of Rollo; the third, in the same metre, the history of William Longsword and his son Richard, tho first Duke of Normandy of that name; in the fourth part, which is alone longer than the three preceding, he resumes the eight-syllable measure, and presents us with a sequel of the history of Richard, and that of his successors to the year 1106. [NORMANDY, P. C.] The whole poem contains oxactly 16,547 lines. He generally follows Dudon and William of Jumièges as his guides in the relation of historical facts, but he adds many interesting and curious details which he reports to have received from hearsay.

His description of the battle of Hastings [WILLIAM I., P. C.] is given with considerablo minuteness of detail, and has been largely drawn upon by succeeding historians. Among the disadvantages under which the English laboured, Wace says that they could not fight on horseback, nor shelter themselves under a buckler with one hand, while with the other they directed their blows against tho enemy.

The other recognised poems of Waeo are—1, 'Lo Brut d'Angleterre,' a work which preceded his 'Roman du Rou.' The date of it is ascertained by the following lines near the end of the poem:—

'Pois ke Dex* Incarnation
Prist por nostre rèdemption
M.C.L. et cinq ans. (1155)
Fist mestre Wace cest romanz.

The prinoipal incidents in it are derived from a Latin translation, by Geoffrey of Monmouth, of a poem composed in tho dialect of Lower Brittany. The subject of it is a certain Brutus, who is imagined to have been the great grandson of Æneas, and who ruled over Great Britain. It contains nearly eighteen hundred lines, in the same metre as those above quoted, and is by some supposed to have been the first work containing the origin of Arthur's round table, his knights, and tournaments. [ARTHUR, P. C.]

The next authentic work of Wace is styled 'La Chronique ascendante des Ducs de Normandie:' it commences with Henry II. and goes back to Rollo. It is a short poem of only three hundred and fourteen Alexandrine verses, and is published in the first volume of the 'Mémoires de la Société des Antiquaires de la Normandie,' p. 144. It must have been written later than 1173, as it makes mention of the troubles excited in Normandy during that year by the revolt of the sons of Henry II. against their father.

The other two remaining poems of Wace possess less interest, and are not so generally known. The first of them is entitled 'L'Establissement de la Feste de la Conception, dicte la Feste as Normands;' the second, 'La Vie do S. Nicolas,' of which Hickes has published several extracts in his 'Thesaurus Litteraturæ Septentrionalis.'

The above-mentioned works are the only ones which have been preserved, and on their authenticity no doubt exists. Two other poems have been ascribed to him, 'Le Roman du Chevalier au Lion,' and 'Le Roman d'Alexandrie;' but, though they are undoubtedly productions of the twelfth century, they are now generally supposed by the best critics not to belong to Wace.

The manuscripts of his poems are very numerous; there are complete manuscripts of the 'Roman du Rou' both at the Royal Library of Paris, No. 7567, and at the library of the Arsenal; that in the Royal Library is supposed to have been written in the fourteenth century. The most antient is in the British Museum, and was probably written in the first years of the thirteenth century; it contains however only the fourth part of the 'Roman du Rou.'

There is a valuable essay on the manuscripts of the 'Roman du Rou' by M. de Brequigny, in the fifth volume of his 'Notices des MSS. de la Bibliothèque Royale.'

In 1827, there was published at Rouen a remarkably fine edition of the 'Roman du Rou,' in two octavo volumes, with very valuablo notes, by M. Frederic Pluquet, who had devoted several years to the laborious task of carefully collating the texts of tho various manuscripts in existence.

The following works may be consulted for a more ample account of the life and writings of Wace:—1. Capefigue, 'Essai sur les Invasions Maritimes des Normands dans les Gaules,' 1823; 2. Depping, 'Histoire des Expeditions Maritimes des Normands,' 1826; 3. Wheaton, 'History of the Northmen,' London, 1831. In these two works there are copious and interesting extracts from the 'Roman du Rou;' Depping particularly has very justly appreciated the value of Wace as a poet and an historian. 4. Pluquet, 'Notice sur la Vie et les Ecrits de Robert Wace, suivie de Citations extraites de ses Ouvrages,' Rouen, 1824. In this work will be

* Longue. † Qui dit cela. ‡ Histoire. § Je. ‖ Fief. ¶ Appartient. ** La. †† Je revins. ‡‡ Demeurai. §§ Beaucoup. ‖‖ Aide. ¶¶ Autre excepté lui. *** Prébende.

* Puis que Dieu.

found the most complete account of the writings of Wace. In the 'Guernsey and Jersey Magazine,' London, 1836, vol. ii., p. 89, is to be found a notice of Wace, which is however chiefly a translation of Pluquet's work. In the same magazine, vols. ii., iii., iv., is a very interesting analysis of the 'Roman du Rou.' Roquefort, 'Glossaire de la Langue Romane,' Paris, 1808, 2 vols., will be found useful to the readers of Wace.

WAIGATZ is a large island in the Russian government of Archangel, situated in the Frozen Ocean at the entrance of the Gulf of Kara. It is separated by the Straits of Waigatz from the continent, and by the Straits of Woronowskai from the island of Nova Zembla. It lies between 57° 30′ and 59° 25′ E. long. and 67° 20′ and 68° 5′ N. lat. It is desolate, rocky, without wood, and almost without vegetation: it abounds in fur-bearing animals, snipes, plovers, fish, and is inhabited by a few families of Samoieds, and frequented by the Russians for the sports of hunting and fishing. Some old accounts speak of mountains connected with the Ural, and a map indicates a mountainous chain, which corresponds with that on the continent. There are some other islands, Maldigef, Dolgoi, and Bilinof in the Straits of Waigatz, which are small, desolate, rocky, low, without wood, and only frequented by the Samoieds and Russian fur-hunters. The strait was discovered by the Dutch in 1594, who were endeavouring to find a new way to China.

(Hassel, *Handbuch*; Stein, *Lexicon*.)

WAKHAN is a very remarkable alpine valley in Asia, situated in the Tartash-l-lIng, or Bolor Tagh, between 36° 40′ and 37° 30′ N. lat., and between 71° 30′ and 73° 40′ E. long. It is more than 130 miles long, and traversed in its whole length by the river Oxus, which issues from the western extremity of Lake Sir-i-col, and in these parts is called Panja. The lake occupies the eastern extremity of the valley, and is 15,600 feet above the sea-level. The river runs for about 60 miles in a glen, and here the valley is not cultivated, but the declivities of the mountain supply excellent pasture-ground during the summer; in winter they are covered by a layer of deep snow. When the river leaves the glen it enters a valley, which in general is one mile wide, though in some places it is narrowed by rocky masses projecting from the snow-capped mountains which enclose it on the north and south. This larger portion of the valley extends for about 70 miles, when it terminates at a high ridge which advances close to the bed of the river. This ridge is traversed by a mountain-pass whose summit is 10,900 feet above the sea-level. The higher portion of the wider valley is 10,000 feet, and the lower probably not less than 9000 feet above the sea. A small part of this valley is cultivated, and produces peas and barley, and also some wheat. [TARTASH, P. C. S.]

The land requires to be irrigated, and to yield even a moderate crop it must be richly manured. The strong wind that blows with little intermission throughout the winter and spring down the valley of the Oxus, is unfavourable to vegetation. Their flocks of sheep and goats constitute the wealth of the Wakhani; the goats yield that kind of wool of which the shawls of Cashmere are made. The horses are small, but strong. Of quadrupeds, wolves, foxes, and hares are mentioned. There is also a kind of wild sheep called *Kutch-kar*, which is of the size of a two-year-old colt, and has splendid curled horns; in autumn, when this animal is in prime condition, no venison is better flavoured. It lives in herds of several hundreds. The skin rather resembles the hide of a cow than the fleece of a sheep. There is still another animal found in the adjacent mountains called *Rass*, which is described as being larger than a cow and smaller than a horse, and has immense horns; it appears to be rare. The population of the valley does not exceed 1000 individuals, according to the statement of Lieut. Wood. The Wakhani boast of being descended from Hazrat Zekunder, or Alexander the Great, but Lieut. Wood did not discover any difference between them and the Tadjiks who inhabit the plains of Turan, whose language they also speak. The chief of Wakhan is dependent on the sovereign of Kunduz; but this dependence appears only to be nominal, except that he sends an annual present to the Uzbeck prince. Through this valley runs a caravan-road which leads eastward to the town of Yarkand, in Chinese Turkistan, and westward to Kunduz and Balkh, and thence to Bokhara, Kabul, and Candahar.

(Burnes, *Travels into Bokhara;* Wood, *Journey to the Source of the River Oxus.*)

WALCHIA, a genus of Lycopodioid fossil plants from the coal and oolite formations. (Sternberg.)

WALKING WHEEL is a cylinder which is put in motion about an axle by the weight of men or animals; it is used for the purposes of raising water, grinding corn, and various other operations for which a moving power is required.

It is probable that a wheel so put in motion was employed in the East, in a very early age, to raise water; for Moses reminds the posterity of Israel (*Deuteronomy* xi. 10), that in Egypt they sowed their seed and '*watered it with the foot*' as a garden of herbs; and in China walking wheels are used for raising water to the higher grounds on which rice is grown. In a treatise on machines, which was published at Nürnberg in 1661, there is a description of a walking wheel which was used for grinding corn; it consisted of an inclined plane of a circular form, and turned upon an axle placed obliquely to the horizon, the axle resting at its lower extremity in a gudgeon firmly fixed to the ground, and at its upper extremity, in one which was attached to a part of the building in which the machinery was contained. The wheel or plane was made to revolve on its axis by men, who, while stepping on its upper surface, pressed with their hands against a horizontal rail and with their feet against slips of wood which were nailed to the surface in the direction of the radii; and, below the wheel was a pinion whose *leaves*, acting against the cogs of a trundle on a horizontal shaft, gave a revolving motion to the machinery.

A similar kind of walking wheel was at one time proposed in this country, but it does not appear to have been much used: it was provided with a brake by which it might be rendered immovable at the will of the person employed to give it motion; and consequently the danger of accidents from a failure of the machinery might be considered as obviated. Such a wheel permits a man, by merely changing his place on it, to put his power in equilibrio with different degrees of resistance; thus, when the resistance is great, he may walk near the circumference of the wheel, and when small, he may find a place near the centre at which he may act with most convenience to himself; but a serious objection to it is, that the force arising from the weight of a man being oblique to the surface of the plane, its effect in giving motion, compared with that of an equal weight applied at the circumference of a vertical wheel of equal diameter, is only as the sine of the inclination of the plane to the horizon (about 30 degrees) is to unity; therefore the former effect is only about half of the latter. The weight of the man or men employed to walk on a large wheel of this kind causes its plane to bend; and when, in order to prevent this effect, the wheel is supported by vertical props, the friction is greatly increased, notwithstanding the application of friction rollers at the points of support.

Wheels for drawing water from deep wells, as well as for other purposes, were at one time constructed in the form of hollow cylinders, and turned on horizontal axles by the weight of men or animals moving on their concave surfaces; they were of considerable dimensions, sometimes about 15 feet in diameter; and they had an advantage over the inclined wheel in being subject to less resistance from friction. The weight of the moving agent, a horse or a man, could not, however, be made to act on the circumference at a point more than 20 or 30 degrees from a vertical line passing through the axle, or where a tangent to the circumference makes an angle of 25 or 30 degrees with the horizon, and consequently the effect of the moving power compared with that of an equal weight applied at the extremity of a horizontal diameter, is only as the sine of that inclination is to unity. Two ranks of men were sometimes made to walk in the wheel behind one another; when, since the rear-rank men were necessarily at a less distance than those in the front rank from a vertical plane passing through the axle, their weight must have been still more disadvantageously applied. The lives of the men employed to give motion to such wheels were evidently in great danger on any accident happening to the machinery.

In the year 1803 the late Mr. David Hardie, then in the service of the East India Company, obtained a patent for a wheel which turned on a horizontal axle by men on its convex surface; the wheel was six feet in diameter, and projecting from its surface like the floats of a water-wheel were 24 boards or steps whose planes, if produced, would pass through the axle. On these boards the men trode as in the act of ascending steps, keeping themselves in vertical positions and very nearly at the extremity of a horizontal diameter of the wheel; consequently in the most advantageous circumstances for the application of their weight. Above the wheel were fixed a number of vertical bars, by holding which the men might keep themselves steady; a number of bars were also made to project horizontally from a fixed beam above the wheel, at about three feet from the board on which the foot of the man was placed in stepping; and taking hold of two of these, pulling upwards as if he were lifting two bodies from the ground, a man might add his muscular energy to his dead weight, so as on an emergency to press vertically with a force amounting to double that weight.

The circumference of the wheel is about 19 feet; and in raising up weights, by means of a rope passing over its axle, two revolutions are generally made in one minute; therefore, if a working day be estimated at eight hours, and a man rest during a quarter of an hour after being on the wheel half-an-hour, so as to be actually at work during 320 minutes daily, the space which the man causes a point on the circumference of the wheel to describe during one day will be 12,064 feet; hence, assuming the weight of the man to be 160 pounds, his daily action is equivalent to 1,930,240 pounds raised one foot vertically, or about 365 pounds raised one mile. According to the experiments of Coulomb, the daily action of a man ascending stairs unburthened is equivalent to 291 pounds raised one mile vertically. [ANIMAL STRENGTH, P. C. S.]

The TREAD-WHEEL which has been introduced by Mr. Cubitt into prisons as a means of employing the culprits in useful labour is of the same nature as that which has just been described [TRANSPORTATION, P. C., p. 150]. These wheels, which are about 5 feet in diameter, vary in length from 8 to above 20 feet, and they are connected with machinery for grinding corn, beating hemp, or pumping.

WALLACE, WILLIAM, a mathematician of considerable eminence, was born September 23rd, 1768, at Dysart, in Fifeshire, N.B., in which town his father, a manufacturer of leather, had settled. He received the rudiments of education at a dame's school in his native town, and, at seven years of age, he was sent to a school in which, under a master, he acquired the power of writing, but to his father he was indebted for instruction in arithmetic. In 1784 his father, after the failure of his business at Dysart, having gone with his family to reside at Edinburgh, he was placed with a bookbinder in that city, to whom soon afterwards he was bound as an apprentice; he lodged, however, with his parents, and thus he continued to have the benefit of his father's moral superintendence, as well as advice and assistance in the prosecution of his studies. Without any encouragement from his master the youth derived some advantage from the opportunities which occasionally presented themselves of perusing the books which he was employed to bind; and having, besides, found means to purchase some mathematical works, he succeeded in making himself master of their contents. It is said that before he was twenty years of age he had acquired a knowledge of elementary geometry and trigonometry, algebra with fluxions, conic sections, and astronomy.

About the same time he became acquainted with a man who was employed by Dr. Robison as an assistant in making the experiments by which the subjects of his lectures were exemplified; and, when the term of his apprenticeship expired, he accepted the offer of this person to introduce him to that distinguished professor. Dr. Robison finding, after an examination, that the young man had attained to considerable proficiency in mathematical science, and being made acquainted with his humble condition in life, kindly permitted him to attend the course of lectures on Natural Philosophy which was then about to commence. Of this permission he thankfully availed himself, and he regularly attended the class, though, in order to be enabled to do so, he was obliged to labour in his vocation during a portion of the time which should have been given to repose. Dr. Robison soon afterwards proposed to him to give lessons in geometry to one of his own pupils; he also introduced him to Professor Playfair, who, taking an interest in his welfare, contributed both by advice and by loans of books to facilitate his progress in acquiring a knowledge of the higher branches of mathematics.

In the hope of obtaining more time for the prosecution of his studies, Wallace quitted the calling for exercising which he had qualified himself by serving an apprenticeship, and became a warehouseman in a printing-office: while engaged in this employment he acquired, with the assistance of a student in the university, a knowledge of Latin; and soon afterwards he began the study of the French language. He subsequently became a shopman to one of the principal booksellers of Edinburgh, and while holding this situation he gave lessons occasionally in the evenings in mathematics.

In 1793 his increasing love for science, and a desire to have greater opportunities of cultivating it, led him to resign his employment, and become a private teacher of mathematics; he, however, followed this occupation about a year only (during which time he attended the lectures of Professor Playfair, and a course of lectures on chemistry), for in 1794 he was appointed assistant teacher of mathematics in the Academy at Perth. He married soon afterwards, and during the vacations he regularly visited Edinburgh, where his talents procured him an introduction to the distinguished scientific men of that city.

Mr. Wallace continued to fulfil the duties of his appointment at Perth during nine years; but in 1803 he was invited to offer himself as a candidate for the post of a mathematical master in the Royal Military College, which had then recently been formed at Great Marlow, in Buckinghamshire, and by the advice of Professor Playfair he accepted the invitation. On presenting himself at the College, his qualifications were found to be such as entitled him to a preference over his competitors, and he was immediately appointed. The institution was afterwards removed to Sandhurst, in Berkshire; and at both places he performed the duties of his post greatly to the satisfaction of the persons in authority. In the year 1818 it was determined that a half-yearly course of lectures on Practical Astronomy should be given for the benefit of the students, and that these should be combined with instruction on the manner of making celestial observations; for these purposes the plan of a small observatory was furnished by Dr. Robinson, of Oxford; and Mr. Wallace, who was appointed to deliver the lectures, superintended the details of its construction. Such instruments were provided as suffice for the object proposed; and it may be said that the establishment of a course of astronomy at the college has contributed materially to the efficiency of military officers holding staff appointments abroad.

In the following year the death of Professor Playfair and the appointment of Mr. (Sir John) Leslie to succeed him in the chair of Natural Philosophy at Edinburgh, left a vacancy in the chair of Mathematics; and Mr. Wallace, whose highest ambition had always been to obtain a professorship in a Scottish university, immediately became a candidate for the post. He was elected, after a severe contest, by a majority of votes, and he held the appointment till the year 1838, when, on account of ill health, he resigned it. On this occasion the university conferred on him the honorary title of Doctor of Laws, and he received from government a pension in consideration of his attainments in science, as well as of his services in the Military College and at the University of Edinburgh.

Mr. Wallace died at Edinburgh, respected and regretted, on the 28th of April, 1843, and consequently in the 75th year of his age, after an illness which for several years had prevented him from entering into society. He had been a Fellow of the Royal Astronomical Society from the time of its formation; he was also a Fellow of the Royal Society of Edinburgh; a corresponding member of the Institution of Civil Engineers; an honorary member of the Cambridge Philosophical Society; and, a few weeks before his death, he was elected an honorary member of the Royal Irish Academy.

In 1796 he presented to the Royal Society of Edinburgh his first paper, which was entitled 'Geometrical Porisms, with Examples of their Applications to the Solution of Problems;' it contains some new porismatic propositions, investigated according to the method of the ancient geometers, and affords proof of considerable inventive power. About the same time he contributed the article 'Porism' to the third edition of the 'Encyclopædia Britannica.'

In 1802 he presented to the Royal Society of Edinburgh a paper containing a new method of expressing the co-efficients in the development of the formula which represents the mutual perturbation of two planets; and, in an appendix, he gave a quickly converging series for the rectification of an ellipse. In one point the subject of the paper had been previously investigated by Le Gendre, but the works of that great mathematician were then little known in this country, and apparently Mr. Wallace had not seen them. Six years afterwards he presented to the same society a third paper, entitled 'New Series for the Quadrature of the Conic Sections, and the Computation of Logarithms,' which contains some remarkable formulæ for the rectification of circular arcs and the sectors of equilateral hyberbolas, and for computing logarithms. In 1823 he presented a paper on the 'Investigation of Formulæ for finding the Logarithms of Trigonometrical Quantities from one another;' and in 1831 one entitled 'Account of the Invention of the Pantograph, and a Description of the

Eidograph,' the latter being an instrument which he had invented in 1821. [EIDOGRAPH, P. C. S.] In 1839 he gave a paper on the 'Analogous Properties of Elliptic and Hyperbolic Sectors;' and his last contribution to the society was one entitled 'Solution of a Functional Equation, with its Application to the Parallelogram of Forces, and the Curve of Equilibration:' this paper, which was published in vol. xiv. of the 'Transactions,' contains a table to ten decimal places of the values of the ordinates and arcs of a catenary.

Mr. Wallace contributed to the 'Transactions of the Royal Astronomical Society' a paper entitled 'Two Elementary Solutions of Kepler's Problem by the Angular Calculus,' which is published in the volume for 1836; and in the sixth volume of the 'Transactions of the Cambridge Philosophical Society' there is a paper by him under the title of 'Geometrical Theorems and Formulæ, particularly applicable to some Geodetical Problems.' In 1838, while suffering from sickness, he composed a work on the same subject, which he dedicated to his friend Colonel Colby.

In his early life Mr. Wallace was a contributor to Leybourne's 'Mathematical Repository,' and 'The Gentleman's Mathematical Companion;' he also wrote the principal mathematical articles for the 'Edinburgh Encyclopædia,' and for the fourth edition of the 'Encyclopædia Britannica.'

(*Monthly Notices of the Royal Astronomical Society*, vol. vi.)

WARNER, WILLIAM, a native of Oxfordshire, is supposed to have been born about 1558. He was a student at Oxford, but left the University without a degree, and, going to London, became an attorney in the Common Pleas. He died suddenly in 1609, and was buried in the parish church of Amwell. He was the author of 'Albion's England,' an historical poem, or rather a collection of ballads, in thirteen books, in the Alexandrine stanza. This work, in his own time, was exceedingly popular, and was frequently reprinted in the course of the thirty years after 1586, when it was first published. Some of his contemporaries compared, or even preferred him, to Spenser. The general simplicity of the feeling and language, and the frequent indelicacy of the images, are alike instanced in the beautiful pastoral episode of 'Argentile and Curan,' which is given by Percy and Campbell, as well as in several other collections. The whole poem, reprinted, is in Chalmers' 'British Poets:' a distinction which it well deserved, although it was far from meriting the extravagant commendations of older times. Warner was also the author of 'Syrinx, a Seavenfold Historie,' a collection of prose stories, published in 1597; and he is supposed also by Warton and others to have been the writer of a translation of the 'Menæchmi' of Plautus, which first appeared in 1595, and was reprinted by Steevens in 1779, in his 'Six Old Plays, on which Shakspeare founded.'

WATER, COMPRESSIBILITY OF. [COMPRESSIBILITY OF WATER, P. C. S.]

WATER-PLANTAIN. [ALISMACEÆ, P. C.]

WATSON, CHARLES, VICE-ADMIRAL, was born in the year 1714, and was the son of the Rev. Dr. Watson, Prebendary of Westminster. The loss of his father when he was but nine years of age enabled him to follow the inclination he had already manifested of entering the naval profession. His skill and bravery soon procured him promotion; in February, 1738, he was appointed captain of the Garland frigate, and, in 1744, he was transferred to the Dragon of 60 guns, under Admiral Matthews, on the Mediterranean station. In that command his services were required on several important occasions, and were generally attended with success. He was afterwards sent by his admiral to Cadiz, with orders to cruize off that harbour for a certain time, afterwards to proceed to Lisbon, and from thence to England. Though these orders opened to him the prospect of making many rich prizes, he ventured to disobey them on receiving intelligence that the enemy's fleet was preparing for sea at Toulon; and, regardless of his interests, he directed his course to the Hieres, in order to join the English fleet. During the course of the war, Captain Watson obtained distinction in the several ships which he commanded; his conduct in the action of the 3rd of May, 1747, elicited the admiration even of his enemies, and honourable mention was made of it by the French admiral. In another action, during the same year, in which Sir Edward Hawke commanded in chief, he displayed great intrepidity. On the 12th of May, 1748, his services were rewarded by his promotion to the rank of rear-admiral of the blue, and in this capacity he received orders to sail with a small fleet to Cape Breton.

In 1754, he was appointed to the command of the squadron destined to co-operate with the expedition of Colonel Clive [CLIVE, ROBERT, LORD, P. C.] in the East Indies; and soon after his arrival in that country he received his Majesty's commission appointing him rear-admiral of the red. His first exploit was the reduction of Fort Geriah, which was held by a piratical prince, who had for many years annoyed the English trade in the East Indies. This service was performed by Admiral Watson on the 13th of February, 1756. His conduct towards the wives and children of this prince, who had become his prisoner, was marked by the most courteous humanity. In the attack made by Colonel Clive on Chandernagore, a place of great strength, and the chief settlement of the French in Bengal, in conjunction with Admiral Pocock, he commanded the small fleet of only three ships of the line destined to co-operate with the land-forces. The French had prepared to resist him by sinking several large vessels in the river below the fort; but the admiral having found a safe passage by carefully sounding as he approached, directed so severe a fire upon the enemy's defences, that, seconded by Colonel Clive's batteries on the shore, the place capitulated in less than three hours (24th of March, 1757). By the capture of this fort, a large number of prisoners, one hundred and eighty-three pieces of cannon, and a considerable booty fell into the hands of the English. With this exploit may be said to end this admiral's short but successful career; on the 16th of August 1757, he fell a victim to that unwholesome climate. His death was severely felt by his companions in arms, by whom he was admired for his skill and bravery, and beloved for his moral qualities and amiable disposition. On the 18th of June, 1763, the memory of his services was consecrated by the erection of a monument in Westminster Abbey, with the following inscription: 'To the memory of Charles Watson, Vice-admiral of the White, Commander-in-chief of his Majesty's naval force in the East-Indies, who died at Calcutta the 16th of August, 1757, in the 44th year of his age. The East India Company, as a grateful testimony of the signal advantages which they obtained by his valour and prudent conduct, caused this monument to be erected.'

(*Annual Register*, Dodsley, for the years 1758 and 1763; *Lives of Illustrious Seamen*, &c., London, 1803; Smollett, Continuation of Hume's *History of England*.)

WAVRE is a town in the Province of South Brabant, in the kingdom of Belgium, situated on the river Dyle, in 4° 30′ E. long. and 50° 2′ N. lat. Wavre has about 4500 inhabitants, who cultivate tobacco, have a considerable trade in corn and cattle, and several breweries.

Wavre has become celebrated by the battles of the 18th and 19th of June, 1815, between the Prussians and the French under General Grouchy. After the loss of the battle of Ligny, Blücher had taken (on the 17th) an advantageous position with the 1st, 2nd, and 3rd corps of the army, partly to wait for the 10th corps coming from Liège, partly to effect more easily his junction with Wellington, who had engaged to maintain as long as possible the position at Mont St. Jean, while Blücher hastened to support him with the whole Prussian army. The whole army, except the 3rd corps, was already on the march, when Marshal Grouchy with a far superior force suddenly appeared and attacked the town of Wavre. General Thielmann immediately turned to meet him, but the other corps continued their march. A severe action between Thielmann and Grouchy was interrupted by the night, and renewed the following morning; when both parties, having learnt the result of the battle of Waterloo, retreated.

(Hassel, *Handbuch*; Stein, *Geographical Lexicon*.)

WAX-MODELLING. Wax has been in all ages an important agent in the art of statuary; and in the formative art generally, whether as a fine art, or for the purposes of science. In statuary it is used in making the models for the metal cast, but more formerly than at present, for now clay is frequently substituted in its place: it is however still used by silversmiths in casting cups and other cylindrical or spherical objects, especially such as are required to be kept free from the markings of joints, to avoid injury to the design or embossed work. In fine art it is used in forming images, and iconic portraits, small busts, and bassi-rilievi; and it is also very usefully and largely applied in the preparation of anatomical models, especially in pathology, and in the preparation of fruit, flowers, and many objects of natural history. Wax-modelling, when applied as above described, as a fine art, is frequently termed the ceroplastic art (κηροπλαστική; from κηρός, wax, and πλαστική, the art of fashioning into forms).

Wax was formerly indispensable in metal-casting, though when and how it was first used is wholly unknown. It may have been used for the models of solid casts even in the earliest periods, but was almost certainly used in hollow casting, which was a later invention, and which will presently be described; though of an art so entirely practical, no description can convey more than a general idea.

Different writers of different ages give various directions for the preparation of the wax to be used. Vasari, who doubtless mentions that used in his own time, recommends the admixture of a little tallow, turpentine, and pitch, with the common yellow wax, but he does not specify any particular quantities. The tallow renders it more soluble and fluid, the turpentine more adhesive, and the pitch colours it, and assists it in hardening after the operation is complete: it may also be coloured with a little red ochre in powder, which must be mixed with the wax in its liquid state. It may be made any other colour in the same way. A French mixture is—to one hundred pounds of yellow wax, ten pounds of turpentine, ten of pitch, and ten of hogs'-lard, which probably would be similar in its properties to the mixture described by Vasari. When the wax is melted, great care must be taken that it does not boil, or it cannot be repaired when cold. M. Fiquet, in his 'Art du Mouleur en Plâtre,' of which there is an abstract in Panckoucke's 'Encyclopédie Méthodique,' gives the following compound for founder's wax—to four of wax, mix one of tallow and two of Burgundy pitch (poix de Bourgogne), which when melted together are fluid and manageable. This was probably the composition used by J. B. Keller and Girardon in preparing the mould for Girardon's equestrian statue of Louis XIV., which was cast entire, or in *whole getto*. Several other mixtures were and are probably employed by different sculptors; the above however were those employed in France and Italy in the great ages of founding, when the wax method was generally in use. We may now proceed to describe the methods of its application.

Andrea Verrocchio, a celebrated sculptor of the fifteenth century [VERROCCHIO, P. C.], is said by Vasari to have been one of the first among the moderns to introduce casting from moulds taken from life, or, in Vasari's words, to bring the practice into general use—'che fu de' primi che cominciasse a metterlo in uso' (ed. 1568). These casts he made in wax and in plaster; and some writers have spoken of him as the inventor of moulding from the human figure, and others even as the inventor of casting in plaster; neither of which is said nor could have been intended to be conveyed by Vasari. Many arts have been known, and occasionally practised, before they have been applied to the ordinary uses to which they were well adapted. There is in Florence still preserved in the cathedral a cast thus formed from the head of Brunelleschi, which, as Bottari has remarked, must have been taken when Verrocchio was only fourteen years of age. And with regard to casting in plaster, if metal casts were made long before the time of Verrocchio, it is more than probable that plaster casts were also made. The first distinguished Italian founder of modern times was Andrea Pisano [PISANO, P. C. S., p. 426], who modelled the gates of the Baptistery of St. John at Florence, which were cast by some Venetian founders in 1330. The same sculptor had previously sent by Giotto a present of a bronze crucifix to Pope Clement V. (1305-1314) at Avignon, which must have been about 120 years before Verrocchio was born. This crucifix is represented as having been of excellent workmanship; it must have been fashioned consequently by an artist or artists well acquainted both with mould-making and with casting, and the idea therefore that either art can have been ever first *practised* at so late a period as Verrocchio is quite untenable. The fact of bringing artists from Venice to cast the gates of the Baptistery of St. John does not so much show that Florence was without good metal-founders, as that Venice had obtained celebrity for its artists of this class. William Austen, a celebrated English founder, was anterior to Verrocchio. [AUSTEN, WILLIAM, P. C. S.] Bell-casting, which was practised throughout the middle ages, is comparatively so simple an art that the modelling requisite in its process is of quite a different character from the modelling of works of imitative art. However, at whatever period and by whatever process the early Italians first prepared their moulds for metal-casting, they most probably in all works of consequence used wax in the preparation of the model for the casting. The antient Greeks and Romans also most probably used wax for the same purposes. There are few antient bronzes of a large size now extant; the principal of them is the equestrian statue of Marcus Aurelius before the Capitol at Rome. This monument is hollow, and was cast in two parts; and probably the antient method was not very different from that described by Vasari; some antient works were cast solid. The antients were also in the habit of making plaster moulds of objects, in fact the Greeks and Romans were more or less familiar with almost every method and contrivance known to the modern statuary. (Müller, 'Handbuch der Archäologie der Kunst,' Mechanische Technik.)

It is generally allowed that the triumph of casting in modern times was Girardon's colossal statue of Louis XIV., cast by J. B. Keller; it stood on the Place Vendôme at Paris until 1792, when it was destroyed by the French populace. The weight of the monument is said to have been 60,000 lbs., and its height, including the bronze pedestal, 21 feet. This enormous mass of metal was cast at once, or in a single *getto*. The preparation of the model and mould was on the following plan:—When the model of the statue was finished, a safe mould of plaster and brickdust was made from it, in many parts. [MODELLING, P. C. S.] Each of these parts, being marked and numbered, and removed from the model, was then oiled, and carefully filled on the inner side to a certain thickness, an inch or two, with the modelling-wax already described; the thickness depending upon the height or position of the part, the lowest parts being the thickest, for the metal is destined to fill exactly the space occupied by the wax. When all the parts of the mould were thus prepared, the whole was again put together in a pit, around a simple framework of iron bars, so as to support it firmly in each direction; the lowest parts of the mould being first placed, and the joints of the wax of the various contiguous parts being filled in, and the pieces carefully united together with melted wax with a brush, as the work proceeded. When the whole was put together, it was bound on the exterior with strong bars of iron attached to the extremities of the bars of the interior framework. The mould is now a hollow shell, with a thick coating of wax all over the interior, the whole being kept together by iron supports, inside and outside. The next step is to fill this hollow shell, through an aperture left at the top, with a composition of plaster and brickdust, which is fire-proof. This fire-proof body is termed in English a *core* (in some books written corps), by the French *noyau*, by the Germans *kern*, and by Vasari the *anima*. Air-vents must be made in the shell before the casting of the core.

When the core is fixed, the original mould or shell is taken off, and a wax model of the statue appears to the eye. The sculptor now examines his wax model, and improves it where there is occasion and repairs or makes good all imperfections. When it is perfectly finished, the preparation for the founding commences. Over this wax statue a new fire-proof mould is made of plaster, brickdust or sand, cow-hair, and horse-dung, and sometimes very fine ashes. This composition, used at first as a fine liquid plaster, is put on in many coats with a brush, and care must be taken that every particle of wax is covered with the finer plaster: each coat is allowed to dry before the successive coat is put on, and the composition may be gradually made of a coarser mixture. When this new shell or mould is of a sufficient thickness and is properly strengthened by iron bars, a coal fire must be kindled round it and be allowed to burn until the whole of the wax is burnt out, proper vents being made for its escape. This burning out of the wax is a most tedious and difficult process, lasting sometimes as much as four or even six weeks. (Söltl, *Bildende Kunst in München*, Stiglmayor, p 484.) Vasari, in his 'Introduzione,' c. xii., says the only way of knowing whether the wax is all out is to carefully weigh the quantity of wax that you put in the first place upon the mould, and then to weigh what you get out of the mould afterwards and to see that they nearly tally. If any wax is left in, there is danger of the mould bursting, independent of the hard untractable surface it gives to the metal. The quantity of wax used in proportion to the metal is as one pound weight to ten: in Girardon's statue therefore, if the weight has been correctly given, six thousand pounds of wax had to be melted out of the mould. By the quantity of wax used also in modelling, the quantity of metal required to be melted was accurately ascertained. The great difficulty and long process of melting out the wax was the cause of what is called the wax method going comparatively out of use; but it is only recently that the clay and sand modelling as its substitute has been generally established. Until 1824 Stiglmayer used the wax method; from that time the clay method. The largest single cast by Stiglmayer does not amount to one-half of the given weight of this enormous cast by Keller: it is however now no longer considered desirable to cast a monument in a single *getto*. [BRONZE, P. C.]

When the wax is at length melted out, the mould must be strengthened by brickwork, and the whole pit must be closely filled with sand. A channel is now made from the furnace, and is divided in its course into three smaller channels or ducts which lead to three openings in the now hollow mould, which is buried in the earth a little below the furnace. The vacuum in the mould caused by melting out the wax is to be filled with metal; the original iron framework, which was constructed before the casting of the core, keeps both the core and the mould in their proper places; and air-vents in various parts of the mould preclude any great probability of accident. When all is ready, the furnace is opened at a given signal, the liquid fire runs in the channels simultaneously into the mould, and that part of the work which was previously soft wax becomes perennial bronze. The cast is accomplished when the metal pours out from the vents. When cool, the mould is broken away piecemeal, and the metal is exposed. The core is then removed from the inside through an aperture made on purpose; the whole is then repaired and finished by the bronze-workers. [BRONZE, P. C.] Johann Balthasar Keller, who cast in this method the statute of Louis XIV., was a Swiss, and originally a goldsmith. He was born at Zürich, in 1638, and died at Paris, superintendent of the royal foundry, in 1720. There is a print of the statue by C. Simoneau: it was cast in 1699.

It is remarkable, says Fiquet (*L'Art du Mouleur*, &c.), that only half a century after the execution of this monument no one could be found who was capable of casting a similar monument of Louis XV. for Bordeaux; and the process of Keller and Girardon would have been lost had it not been for the Mémoire of G. Boffrand, in which it is described 'Description de ce qui a été pratiqué pour fondre d'un seul jet la Statue Equestre de Louis XIV. en 1699.' The practice of the Italian sculptors in and before Vasari's time was by far not so ingenious as the method just described. The core was not cast, but built up and gauged on an iron frame, and layer by layer as in bell-modelling, until it was within the intended thickness of the metal, the size of the model: each layer was burnt dry before the successive layer was put on. The composition of this core or *anima* was the same as that of the mould—a mixture of cow-hair, horse-dung, brickdust, and plaster. The parts of the mould taken from the original model were now well oiled and each separately filled with wax; these pieces of wax, when hard, were taken out of the pieces of mould and built up against the core, and fitted by judgment and measurement. When the whole wax model was thus built and cemented together with wax, and pins when necessary, the mould for the metal cast, as in the other process, was gradually covered over it, and, when of a proper thickness, bound and made firm with iron. The wax was then burnt out, and the cast accomplished as in the other case described. In some casts the metal is made to enter at the bottom of the mould, for being in a liquid state it will find its own level, and gradually rise to the top of the mould, which however must be below the level of the furnace.

Vasari (*Introduzione*, l. c.) describes a very simple method for casting small figures in bronze. When the mould is made, it must be reversed in water; melted wax is then poured into it, that coming in contact with the cold wet surface of the mould cools immediately, while the interior portion remains liquid; the mould must be again turned over, when the still liquid wax in the centre will immediately run out, leaving in the mould a hollow wax shell. The shell must now be filled with the proper plaster, and this constitutes the core of the object. The wax is then burnt out, and the cast is made as usual. The words used by Vasari in speaking of this art are worthy of note. The mould he calls *cappa* and the core *anima*; these words may have been in common use with sculptors, but in many cases Vasari has evidently had to invent his own language. There was no written terminology in art in his time, and doubtless the vulgar technical language of artists would have been unintelligible to the great majority of his readers, and artists themselves probably of one part of Italy would have a difficulty in understanding the technicalities of those of another part: it is more than probable that Vasari had the difficult task of inventing a great portion of his terminology: he has been followed by all subsequent writers.

It remains to treat of that department of wax-modelling termed ceroplastic. Under this term is comprehended modelling and casting in wax, though not in the manner already described. The art of casting in wax from nature was, according to Pliny (*Hist. Nat.* xxxv. 44), invented by Lysistratus, of Sicyon, the brother of Lysippus, about 300 B.C., who, he says, first of all men took plaster moulds from the face and made wax casts from them. These wax portraits became eventually very common, and especially among the Romans. It is however very unlikely that the many treasured wax portraits we read of in antient writers were made from moulds taken from the face itself. Such would be the mere resemblance of death, for they would be without eyes and otherwise void of expression. They were probably cast from moulds taken from models, though such masks may have been used in the formation of the models.

Pliny (xxxv. 2), speaking of the corrupt taste which prevailed among the Romans in his own time, regrets the good old customs of their ancestors. He says, 'Now all men think more of the material in which their likenesses are made, than of the art or the resemblance. The effigies they leave behind them are rather images of their wealth than of their persons. Thus it is that noble arts decay and perish. With our ancestors it was very different; their halls were not filled with either strange images of brass or of stone, but with the lively portraits of themselves and of their forefathers, in wax, exact similitudes.' From this it appears therefore that the Romans were in the habit of having wax images of themselves made, to be handed down to their posterity. Many writers notice and praise the custom. Valerius Maximus (v. 8. 3), alludes to the advantages of the practice by virtue of example. It was indeed a privilege to which only some were entitled. None could make them but those who had themselves or whose ancestors had borne some curule magistracy. Cicero speaks of the right of handing down your image to posterity. The number of ancestral images therefore became an object of pride and an evidence of ancient nobility, and the antiquity of a family was sometimes expressed by applying the epithet smoky to its images, 'fumosæ imagines.' (Cicero *in Verr.* vi. 14.; *in Pisonem*, 1.; and *de Leg. Agrar.* ii. 1.)

The most striking passage concerning these images is in Polybius (vi. 52), who as a Greek and a stranger would be more impressed by so peculiar a custom as he describes. He says, 'Upon solemn festivals, these images are uncovered, and adorned with the greatest care. And when any other person of the same family dies, they are carried also in the funeral procession, with a body added to the bust, that the representation may be just, even with regard to size. They are dressed likewise in the habits that belong to the ranks which they severally filled when they were alive. If they were consuls or prætors, in a gown bordered with purple; if censors, in a purple robe; and if they triumphed or obtained any similar honour, in a vest embroidered with gold. Thus apparelled they are drawn along in chariots preceded by the rods and axes, and other ensigns of their former dignity. And when they arrive at the forum, they are all seated upon chairs of ivory; and then exhibit the noblest object that can be offered to a youthful mind warmed with the love of virtue and of glory. For who can behold without emotion the forms of so many illustrious men thus living, as it were, and breathing together in his presence? Or what spectacle can be conceived more great and striking? The person also that is appointed to harangue, when he has exhausted all the praises of the deceased, turns his discourse to the rest, whose images are before him; and, beginning with the most antient of them, recounts the fortunes and the exploits of every one in turn. By this method, which renews continually the remembrance of men celebrated for their virtue, the fame of every great and noble action becomes immortal; and the glory of those by whose services their country has been benefited is rendered familiar to the people, and delivered down to future times.' (Hampton's translation.)

This wax-modelling has continued apparently from the time of the Romans until the present day. In the middle ages it was used for the images of saints and votive images. The first modeller however of this class noticed in the history of art is Orsino, the contemporary of Andrea del Verrocchio, in the middle of the fifteenth century. Vasari represents Orsino as a wax-modeller (ceraiuolo) of good repute in Florence, and that he attained, through the advice of Verrocchio, the highest excellence in his art. Verrocchio and Orsino made some interesting figures together, of which three of Lorenzo de' Medici are worthy of especial notice: they are described by Vasari as something remarkable. The conspiracy of the Pazzi in 1478 was the cause of the production of these figures: they were voted by his friends in commemoration of his escape. Orsino made, under the direction of Verrocchio, three wax images of Lorenzo of the size of life. The frameworks or skeletons of these figures were made of wood and cane, and the heads, hands, and feet were cast in wax, of considerable thickness, but hollow; they were then furnished with hair and glass eyes, and painted in oil-colours to the exact imitation of life; and were draped in clothes which had been worn by Lorenzo; to give the draperies a fixed character they were waxed. These figures were altogether so successful, says Vasari, that they appeared to be living. One of them was placed in the church of the Monacho di Chiarito, in the Via di San Gallo; another in the Servitant church of the Annunciation; and the third in the church of Santa Maria degli Angeli at Assisi. In this Servitant church were many other wax figures by Orsino, all of which were marked with an O, in which was an R, and above it a cross; but they have all long since perished. Vasari adds that few works of later wax-modellers were to be compared with those of Orsino, and complains that the art had declined. A few years however after the death of Vasari, Jacopo Vivio distinguished himself by a model on slate, in coloured wax, of Michelangelo's Last Judgment in the Sistine Chapel. It was engraved by Ambrosio Brambilla, and a particular description of it was published in Rome in 1590 — 'Discorso sopra la mirabil opera di Basso-Rilievo di cera stuccata con colori, scolpita in pietra nera, da Jacopo Vivio.'

Two centuries after Verrocchio, and one after Vasari, this art was very usefully and with the utmost skill applied by Gaetano Giulio Zummo, born at Syracuse in 1656, to the preparation of anatomical models and pathological examples. Zummo obtained a European celebrity for his two groups of figures representing the various stages of corruption of the human body and the effects of the plague. He modelled also an anatomical head at Paris, which is described in the Mémoires of the French Academy of Sciences, of 1701, the year of his death. [ZUMMO, P. C.]

The first collection of anatomical preparations which was made for the purposes of science is that of the Institute of Bologna, established by Benedict XIV. It was commenced under the direction of Ercole Lelli, but the greater part of the preparations were made by Giovanni Manzolini of Bologna and his wife Anna Morandi Manzolini. Manzolini died at Bologna in 1755, aged 55. There are some of his models in London and in many other cities of Europe. Anna Manzolini obtained still greater celebrity than her husband: she executed all or the greater part of the obstetric models in the Stanza Ostetricia of the Institute which were prepared under the direction of Dr. Antonio Galli. She also gave public lectures on anatomy in Bologna, illustrating her discourse by appropriate models. She died in 1774, aged 57. (Crespi, *Felsina Pittrice*, where there are portraits of both the Manzolini.)

There is a still more extensive and remarkable collection of wax anatomical models in the Museum of Natural History at Florence: it was established by the Grand-Duke Leopoldo, and occupies fifteen chambers. It contains the works of various artists, but the principal contributors to its treasures were Felice Fontana and Clemente Susini. The works of the earlier modellers in wax are set apart in a chamber by themselves: here are some of the models of Zummo, among which is one showing the whole anatomy of the human head, similar probably to the one made at Paris.

The Musée Dupuytren at Paris is celebrated for its morbid specimens; it is perhaps the richest pathological collection in the world. It was purchased by the University of Paris, of tho heirs of M. Dupuytren, the celebrated anatomist. Most of the principal cities of Europe have now their collections, and good wax-modellers are numerous. The Museum of University College, London, contains many excellent specimens by the late Mr. William Tuson.

In this department of modelling none but the purest wax is used, which is tho case also in all works where the wax is the final substance of the work. Different modellers use different compositions; and some allowance must be made for hot and cold weather, as what would be well adapted for summer weather might be too brittle for winter use. Some modellers use simply wax and a small proportion of Venetian turpentine; others wax, resin, common turpentine, and a littlo olive-oil; the wax being at least two-thirds of the whole composition. It is seldom if ever used pure, as in all objects to be modelled white or some colour must predominate: for instance in modelling the brain, white in powder must be mixed in the composition, and the same respect must be had with regard to the predominant colour of every object to be modelled.

No strict rules can be given for the process of modelling, as each modeller will soon acquire methods of his own, and generally speaking artists of this class object to disclose their peculiar processes, imagining it to be detrimental to their interests. However, we may speak of general principles. Nearly all wax models are cast from moulds, and the casts only in some cases require the assistance of modelling: these moulds are generally taken from the objects themselves, either in plaster of Paris or in a composition of bees'-wax, Burgundy pitch, and Venice turpentine, with a very small quantity of olive-oil. The advantage of this latter composition is, that even when cold, if properly mixed, which must be learnt by experience, the mould is elastic or flexible; and if made thin, when cut on the edges can be peeled off the cast in pieces without any danger to the cast: in taking moulds in plaster of Paris, the object moulded must sometimes be destroyed to render the mould available. Round objects must be moulded in two or more parts. Sometimes when the object is cast in the mould, the mould must be destroyed before the cast can be removed, and in destroying the mould there is danger of destroying the cast also; the *elastic* mould therefore has great advantages in such cases over the plaster mould. When only one view of an object is presented, and it is only slightly convex, the plaster mould is quite sufficient, except the object itself, as the brain, presents a very uneven and delicate surface. When the cast is to be taken from the plaster mould, the mould must be moist with water, but not absolutely wet, or the water would injure the very delicate surface, which occurs in some pathological cases: the mould may be moistened by allowing it to stand with the interior or face uppermost in a dish of water, when it will soon absorb sufficient moisture for the purpose. The mould must not be oiled when any delicate work is to be done, as the oil will dissolve the surface of the wax, and thus perhaps counteract the principal aim of the cast. The wax-composition mould must be slightly touched with a soft hair-tool with oil, to enable it to peel away afterwards without the slightest danger to the cast: being of a perfectly smooth surface, the small quantity of oil it retains is immaterial.

When the cast is made, and what they call *backed up* (that is, strengthened with a coarser composition within), the process of painting commences; but all effects cannot be given by mere colour, some morbid deposits and effects require to be expressed by adding wax of the proper colour with a hair-pencil or other tool. The colouring is done from the natural object represented, with fine hair-pencils and powder colours moistened with turpentine and tempered with a little wax; simple water is also sometimes used as the colouring vehicle. When the colouring is finished, the whole is covered with mastic varnish. In cases where the morbid effects or evidences of disease are of a distinct substance from the healthy texture, different coloured wax should be used in casting the healthy and diseased portions, and the parts may be corrected by modelling. Tho same process must be employed in modelling fruit and other objects of natural history, as in preparing anatomical models: but fruit, which is generally in full or high relief, will require piece-moulds, that is, to be moulded in several pieces, which is done half or part at a time. Flowers are not all cast; they are prepared from leaves of coloured wax made expressly for the purpose. These leaves are cut the required shape; they then, with the necessary colour and a hair-pencil, receive their local tints; and are finally joined and fashioned into the required flower. Insects are modelled by combining the two processes. In moulding objects with hair or delicate raised parts, a little oil must be carefully put over the parts, unless they are wet. Dry firm objects may be moulded without oil; the plaster must be removed as soon as it is set.

It remains yet to speak of the mode of making images. These likewise are made in various ways; but the essential process is casting. A head may be simply cast, and when the hair and eyes have been added to it, the local tints be given with turpentine and colour. This method however uses a considerable quantity of wax, and various devices have been had recourse to to save wax. One mode is to cast the pure wax thin, and to back up or fill in to a considerable thickness with a course composition of bees'-wax, resin, and cow-hair or tow; in casting images the mould may be oiled. Ordinary heads however may be made in this manner:—Let a thin block head be fashioned in a mould or otherwise, of coarse paper pulp and size; when dry it must be coloured all over with flesh-tint, the local colours being put on, a higher degree than is natural, as the colours of the cheeks, lips, and eyebrows; the whole then may be covered with wax, which must be poured over it two or three times, until the surface is well covered; its regularity may be secured by retarding the cooling of the wax and assisting it to run, by means of a hot iron or burner (called cauterium by the antients) which must be held near it until the whole has a uniform surface. The colour originally painted on the paper block will show through the wax, and the head will require but tho hair, the eyes, and a few local touches to finish it. Masks may be also dipped in wax, or the wax may be put on with a hair-tool, if the mask be kept warm; or a wax cast may be backed up or strengthened with strong paper pulp. There are however other methods of modelling wax figures, but no method can be properly explained by a verbal description; such mechanical processes must be witnessed to be understood. A detailed description of the several processes would scarcely convey a sufficient notion to one wholly ignorant, and those well acquainted with the art have no need of such descriptions: for this reason this article has been limited to mere general principles, which is as much as the general reader can require or understand.

Many wax preparations of all kinds are of course made from mere models made by the artist; and many preparations in museums, which appear to be wax, are painted plaster of Paris.

Sculptors also are in the habit of making wax models of small objects in the round, or for bassi-rilievi to be cast in metal, in the same manner and with the same tools that common clay models are made of: the same wax is used as is required for casts. [MODELLING, P. C. S.] Medals and small bronzes are generally modelled in wax. Impressions from seals, engraved gems, and cameos are taken with wax. The wax, which is prepared with a little powdered sugar-candy, turpentine, and lamp-blank, after being melted, is preserved in small cakes. These cakes when wanted aro softened by repeated pressure of the fingers, and are then compressed into or upon the seals or cameos, previously wetted, from which the impressions may be required.

WEBSTER, NOAH, LL.D., was born at West Hartford, in Connecticut, U. S., on the 16th of October, 1758, and was descended from John Webster, who, having been one of the original emigrants from Massachusetts by whom the colony of Connecticut was founded, was afterwards governor of the state in the year 1656. Noah Webster entered Yale College in 1774; in 1777 he was withdrawn for a time from his studies by joining the military service under the command of his father, who was a captain in the Alarm List, during Burgoyne's expedition from Canada; but notwithstanding this interruption he took his degree with great distinction the following year. He was called to the bar in 1781; but, instead of following the profession of the law, he engaged in that of a teacher of youth. His 'First part of a grammatical institute of the English Grammar,' published at Hartford in 1783, was the first of a number of elementary works produced by him, all of which were well received and were generally admitted to be much superior to any that his native country had previously possessed. He also however took a leading part in the discussion of the political questions of the time, both by his 'Sketches of American Policy,' published in 1784, and his other writings in support of the principles of federalism, and by the establishment in 1793 of a daily paper in New York, which still subsists under the name of the 'Commercial Advertiser and New York Spectator.' In 1798 ho removed to Newhaven, where he spent the remainder of his life. His great work, and that which has chiefly made his name known in this country, his 'New and complete Dictionary of the English language,' was begun in 1807, and the first edition was published in 1828. This work, which has been since several times reprinted, the last edition, we believe, being that of Newhaven, 1841, in 2 vols. 4to., is a performance of great labour and care, and is perhaps more precise in its explanations than any of our other English dictionaries. Its etymological portion however is more ingenious and showy than really learned or profound. Dr. Webster, whose degree of LL.D. was we believe bestowed upon him after the publication of his dictionary, died at Newhaven on the 27th of May, 1843.

(Memoir in *Gentleman's Magazine* for August 1843.)

WERNER, JOANNES, a German mathematician and astronomer, was born at Nürnberg on the 14th of February, 1468. Nothing apparently is known of his life, except that, when he was twenty-five years of age, he went to Italy, where he made some astronomical observations; and he is said to have made a series of observations on the comet which appeared in the month of April in the year 1500; from observations which he made on the positions of Regulus, *a* Virginis, and *a* Libræ, compared with those which had been assigned to the same stars by Ptolemy and Alphonso, he determined the precession of the equinoxes to be 70 minutes of a degree in 100 years, a quantity much too small: and he found the obliquity of the ecliptic to be 23° 28′.

In the year 1514 he published 'Annotations on the First Book of Ptolemy's Geography,' in which he endeavoured to explain an obscure passage concerning the projection of the celestial sphere on a plane surface; and it deserves to be remarked that in this work we find the first notice of the method of determining geographical longitudes by the angular distance of the moon from some star: he recommends, for making the observation, the *cross-staff* or *fore-staff*, a rude instrument which has long since been disused by mariners. In 1522 he published at Nürnberg, in 4to., his 'Opera Mathematica,' in which is contained a tract on conics: he also published a work on Trigonometry, in five books, containing a great number of astronomical and geographical problems.

Werner wrote explanations of the construction and uses of meteorological instruments; and it is said that he collected a number of observations with a view of discovering from them rules for determining the changes which take place in the atmosphere. He executed a machine in which the movements of the sun, moon, and planets were represented conformably to the Ptolemaic system; and he wrote a work on *The Movement of the Eighth Sphere.* He died in the year 1528.

(*Historia Astronomiæ*, by Weidler; *Histoire de l'Astronomie Moderne*, by Delambre.)

WESTERN PORT. [WALES, NEW SOUTH, P. C.]

WETHERE'LLIA, a genus of fossil fruits from Sheppey. (Bowerbank.)

WHETSTONE, GEORGE, a voluminous writer of prose and verse, lived in the latter half of the sixteenth century. Both the place and time of his birth are unknown; but he claimed kindred with Serjeant Fleetwood, the recorder of London. His history was that of a succession of misadventures. He began by wasting his patrimony in seeking a place at court: he then served abroad as a soldier, and was an eye-witness to the fall of Sir Philip Sidney at Zutphen: he was next an unsuccessful farmer; afterwards he sailed with the abortive expedition of Gilbert to Newfoundland; and, finally, returning to England, he appears to have been chiefly occupied during the remainder of his life in literary labour, which he had previously practised occasionally, and now attempted with indifferent success as a means of subsistence. He is now chiefly known as having been the author of the rude play (or rather two plays) called 'Promos and Cassandra,' which, having been printed in 1578, ranks as one of our earliest extant comedies; while it has the further interest of having the same plot with Shakspere's 'Measure for Measure.' It is reprinted in Steevens's 'Six Old Plays,' 1779. In Chalmers's English Poets is Whetstone's Life of George Gascoigne: of his other works, a curious account, with specimens, will be found in Mr. Collier's 'Poetical Decameron.'

WHITE, REV. JOSEPH BLANCO, was descended paternally from an Irish Roman Catholic family. In the early part of the last century, William White came over to Seville, in Spain, where he succeeded to the then flourishing business of an exporting merchant carried on by his mother's brother. He was raised by the king of Spain to the rank of the *noblesse*, which his posterity retained. But when after his death the business fell into the hands of his son, the house failed, and the family were left for a time with very limited resources. This son had married a Spanish lady of the name of Crespo y Neve, connected with the old Andalusian nobility; and Joseph Blanco White, commonly designated in Spain Don Jose Maria Blanco y Crespo, who was born at Seville, 11th July, 1775, was their son.

The commercial business of the family had been re-established after the bankruptcy, and Joseph was placed in the first instance in his father's counting-house. When he was about twelve years old, however, his parents complied with his own desire of allowing him to be educated for the church. In the end of the year 1799 he was ordained a priest. But a dislike to the profession be had thus chosen soon took possession of him. He came to England in March, 1810, and spent the remainder of his life in this country. The same year he set up in London a monthly periodical work in Spanish, entitled

'El Español,' which he carried on for nearly five years; and in 1814 upon its discontinuance the English government bestowed upon the editor a pension of 250*l*., which he enjoyed so long as he lived. About the same time he joined the Church of England, originally with the view of pursuing the clerical profession; but this intention he soon dropped. His religious creed after this gradually passed from evangelicalism to common orthodoxy, from that to unitarianism, then to rationalism, till at last it seems to have very nearly evaporated into scepticism. He first made himself generally known to English readers by a series of papers which he contributed in 1820 to the 'New Monthly Magazine,' under the title of 'Letters from Spain, by Don Leucadio Doblado,' and which were afterwards extended and published separately in 1822. In the last-mentioned year he set up a second Spanish Journal, 'Las Variedades,' which was published quarterly, and continued for about three years. Other separate works followed, both in Spanish and English; those among the latter that attracted most attention being his 'Practical and Internal Evidence against Catholicism,' 1825, and again 1826; 'The Poor Man's Preservative against Popery,' 1825, several times reprinted; 'Second Travels of an Irish Gentleman in search of a Religion,' (in answer to Moore's well known work) 2 vols. 12mo., Dublin, 1833. He was also an occasional contributor to the 'Quarterly Review,' to the 'London Review,' established in 1829 (of which he was the editor for the six months that it lasted), to the 'London and Westminster Review,' to the 'Journal of Education' (in an early number of which he wrote one article on the State of Education in Spain), to the 'Dublin University Review,' and to the 'Christian Teacher.' He resided occasionally at Oxford and Dublin as well as in London; and in 1839 he settled in Liverpool, where he continued till his death, which took place on the 20th of May, 1841. He left a son, who in 1845 was a major in the English army. Of White's writings probably those that will last the longest are the papers which have been published since his death under the title of 'The Life of the Reverend Joseph Blanco White, written by himself; with portions of his correspondence; edited by John Hamilton Thom,' 3 vols. 8vo., London, 1845.

WHITE LIGHT is the name generally given to the light which comes directly from the sun, and which has not been decomposed by refraction in passing through a transparent prism; it is not, however, considered as a colour of light, being rather a union of all the differently coloured rays of which common light is composed.

A white light produced by mixing together 24 parts of saltpetre, 7 parts of flour of sulphur, and 2 of red arsenic, was used for the signals employed to render visible by night the stations by which the trigonometrical survey of France was connected with that of England. This light was very brilliant, and could be seen by the naked eye in cloudy weather at distances exceeding 40 miles; but it has, since, been superseded for such purposes by other kinds of light. [DRUMMOND'S LIGHT, P. C. S.]

WILLIAM FREDERICK I., King of the Netherlands, Grand-Duke of Luxemburg, Prince of Orange Nassau, was born at the Hague on the 24th of August, 1772. His father, William V., Prince of Orange Nassau, Hereditary Stadtholder, was descended from John the youngest brother of the great William I. of Orange, and died at Brunswick, April, 1806. His grandfather William IV., the first Hereditary Stadtholder of the United Netherlands (from 1748 who died in 1751), had re-united the possessions of the four branches of the line of Nassau—Otho, Hadamar, Siegen, Dillenberg, and Dietz with his own branch, that of Dietz. His mother was Frederica Sophia Wilhelmina, daughter of Prince Augustus William of Prussia. In 1788 he made a journey to Germany, and passed some time at the court of his uncle Frederick William I. He afterwards studied for a time at Leyden.

After his marriage on the 1st of October, 1791, to Frederica Louisa Wilhelmina, daughter of Frederick William of Prussia, he, in conjunction with his brother Frederick, subsequently distinguished as a general, effected considerable improvements in the Dutch army; but many impediments were occasioned by internal dissensions, the patriots, who had been put down in 1787 by a Prussian force, secretly intriguing against the house of Orange. Some of them had taken refuge in France, and on the 1st of February, 1793, the National Convention declared war against the Stadtholder. Hoping with the assistance of the patriots, to obtain possession of the rich provinces of Holland, Dumouriez conquered Dutch Brabant, which was however recovered by the hereditary prince, who was commander-in-chief of the Dutch army, which was joined by a body of the allies, after the victory of Neerwinden on the 18th of March, which had been gained over Dumouriez by the Austrian field-marshal the Prince of Coburg. The hereditary prince then hindered the French army of the North from penetrating into West Flanders; but on the 13th of September he was attacked in his position between Menin and Werwick with such overwhelming force, that, after a most gallant resistance, in which his brother Prince Frederick, who commanded the right wing, was wounded, he was obliged to retreat behind the Schelde. Soon after this the hereditary prince took Landrecies, and then, at the head of a Dutch and Austrian army, drove the enemy beyond the Sambre: but in the great battle of the 16th of June, 1794, the French having taken Charleroi by storm and defeated the prince's left wing at Fleurus, he was again obliged, by the directions of the Prince of Coburg, to retreat. The Austrians retreated, before Pichegru and Jourdan, behind the Meuse; and the hereditary prince, with his weakened army, had no alternative but to cover the republic in connection with the army of the Duke of York. But the fortresses fell, and the frost enabled the enemy to pass the Waal on the ice, so that Pichegru entered Utrecht on the 17th of January, 1795. The party of the patriots favoured the enemy, and the stadtholder was unable to save the republic, forsaken by its allies. His sons had resigned their commands on the 16th of January, and William V., with his family and a few faithful friends, embarked at Scheveningen on the 18th and 19th for England, where the palace of Hampton Court was assigned him as his residence. His two sons returned to the Continent to arm a body of Dutch emigrants, at the expense of England, which however was dispersed again after the peace of Basle. Prince Frederick then entered the Austrian service, and died at Padua on the 6th of January, 1799.

The hereditary prince then went with his family to Berlin, where he expected a favourable change in his position, from the diplomatic influence of the Prussian court, then in alliance with France. He acquired some estates in the vicinity of Posen and in Silesia, and when his father made over to him, on the 29th of August, 1802, the indemnity in Germany allotted to him by the Recess of the Empire (Fulda, Corvei, Dortmund, Weingarten, and other places), he took up his residence in Fulda, where, in the place of the inefficient university, he established a lyceum, and appropriated the revenues of two suppressed convents to the foundation of a national hospital. After the death of his father he assumed the government of his Nassau hereditary dominions; but as he declined joining the German Confederation of the Rhine, he lost the sovereignty of the possessions of the house of Orange, which were obtained by his relations of Nassau-Usingen and Weilburg, and Murat, Grand-Duke of Berg; while Weingarten fell to Würtemberg. In August, 1806, he went to Berlin, where, as commander of a Prussian regiment, he obtained in September the command in chief of a division of the Prussian army between Magdeburg and Erfurt. After the fatal battle of Jena he followed field-marshal Möllendorf to Erfurt, and became a prisoner of war in consequence of the capitulation concluded by Möllendorf; he was allowed however to reside with his consort in Prussia. Napoleon declared that he, as well as the Elector of Hesse and the Duke of Brunswick, had forfeited his dominions; and Fulda was forced already, on the 27th of October, to do homage to the French Emperor. Corvei, Dortmund, and the county of Spiegelberg were incorporated in 1807 with the kingdom of Westphalia and the grand-duchy of Berg. Even the domains reserved to him, in the act of the Confederation, were taken possession of by Berg and Würtemberg; Bavaria did not do so, and the other princes of the Confederation promised at least to pay to him the net surplus of the revenue. William had come in the mean time with his consort and family to Danzig. When the war approached the Vistula, he desired to return to Berlin, but only his consort, who was ill, was allowed to reside there; he himself was obliged to pass the Oder, and went to Pillau. No mention was made of him in the treaty of Tilsit. He retained the possession of his estates in the grand-duchy of Warsaw, and again lived at Berlin with his family, and devoted himself to literary pursuits. In the war between France and Austria in 1809, William, with the friend of his youth and constant companion, Fagel, joined the army of the Archduke Charles as volunteers, and fought in the battle of Wagram. He then returned to Berlin, and in 1814 obtained the rank of Austrian field-marshal. Meantime, especially after the battle of Leipzig in 1813, influential men such as Hogendorp, v. d. Duyn, Limburg-Stirum, Hoop, Driel, Jonge, and others, were exerting themselves at Amsterdam, the Hague, Rotterdam, Zwolle, and other places, to effect the restoration of the house of Orange. William was at that time in England to concert measures with the British government for the support of the Netherlands. When the victors at Leipzig approached the frontiers of Holland, the inhabitants of Amsterdam rose on the 15th and 16th of November, and on the 17th the Hague declared for the prince.

This prompt resolution of the Dutch patriots to seize the opportunity of recovering their independence was attended with the most important consequences. The *prestige* of the name of Napoleon, and of the invincible power of France, was dispelled; but France still had great resources; the formidable barrier of the Rhine was not yet passed, and when that decisive step should have been taken it might be followed by an internecine war in the interior of France. The insurrection of Holland created a sensation of alarm in Paris, while the allies hailed it with joy, as an earnest of further success, and were encouraged to prosecute their military operations with increased vigour. When Captain Wautier was sent from the Hague to the head-quarters of the allies at Frankfort, he met at Münich, on the 22nd of November, the Prussian general Bulow, who being informed of what had passed in Holland, observed that this insurrection would be as advantageous to the allies as a successful campaign; and the same general, a few days afterwards, assured Baron Van Zuylen, Van Nyeveldt, and Count Bylandt, sent from Holland on a diplomatic mission, that but for this great event the allies would never venture to think of crossing the Rhine *before the return of spring*. What might have been the consequence if the allies had waited till the spring, instead of carrying the war into tho bosom of France in the midst of winter, thus leaving so much time to Napoleon, may be inferred from what actually happened in the wonderful campaign on tho banks of the Seine and the Marne in 1814, in which Bonaparte displayed all the extraordinary resources of his fertile genius.

As soon as William learnt what had passed, he embarked on the 28th of November, and landed at Scheveningen on the 29th. He was received with acclamations by the people of the Haguo on tho 30th, and on the 2nd of December at Amsterdam, where Kemper and Scholten, the commissioners of the provisional government, had issued on the 1st of December a proclamation, announcing 'Holland is free,' and 'William I. the sovereign Prince of this free country.' The prince gratefully assented, and declared that a constitutiun must guarantee the rights and liberties of the people, and secure them against all encroachments. Twenty-three fortresses were still in the hands of the French, who were encamped near Utrecht, but the army of the allies, and the volunteers, who were called to arms, occupied the country. William hastened the arming of the people, and appointed a commission to draw up a constitution, which was accepted on the 29th of March, 1814, by the deputies of the people, and then sworn to by the prince. He had already taken possession of his hereditary dominions in Germany, before tho end of 1813; hereupon the congress at Vienna decided that Belgium and Liege, together with the Seven United Provinces, should be formed into one kingdom, and on the 16th of March, 1815, the prince was proclaimed at the Hague as King of tho Netherlands and Duke of Luxemburg. But he was obliged to cede to Prussia his hereditary possessions in Germany for Luxemburg, which after the 22nd of May, 1815, belonged to the German Confederation, and which he now raised in May to the rank of a grand-duchy.

The union of so many provinces, the inhabitants of which, though of the same origin, differed very much in manners, customs, and religious doctrines, made a change in the constitution necessary. A commission, consisting of an equal number of Dutch and Belgians, was appointed to make such changes as were requisite. After the king had approved of this draft of a constitution, it was laid before the States-general and deputies from tho southern provinces, and finally proclaimed on the 26th of August. In 1814 the king founded the military order of William, and in 1815, after the battle of Waterloo, the civil order of the Belgian Lion, and on the 21st of June, 1816, joined the Holy Alliance. He resided alternately at Brussels and the Hague. On the 17th of May, 1816, a Dutch fleet, under Admiral Van der Capellen, joined the British fleet, under Lord Exmouth, in the Bay of Algiers, and compelled the dey to conclude a treaty, by one article of which all Christian slaves were to be restored to liberty.

In the interior of the kingdom, a want of harmony between the inhabitants manifested itself on several occasions, which, but for the moderation and firmness of the king, might even then have led to serious dissensions: the unbounded influence of the Roman Catholic clergy, even over the higher classes in Belgium; the mutual aversion of the Belgians and the Dutch, and the dissatisfaction of the latter with the long residence of the court at Brussels; divisions in the northern provinces between the friends of the old republican system and those of the new or monarchical system—all tended to produce discontent, which was kept within bounds only by confidence in the character of tho king, and the mild conciliatory principles of his government. In the foreign relations the government, in the main, followed the British system. The marriage of the Prince of Orange to the Grand-Duchess Anne of Russia improved the connexion with that empire, but subsequently weakened the interest taken by England in the affairs of tho Netherlands. Some differences had arisen with Prussia, with which kingdom a closer union was however caused by the marriage of Prince Frederick to the Princess Louisa, daughter of the King of Prussia, on the 21st of May, 1825.

The union with Holland and various commercial treaties with foreign powers had given an extraordinary impulse to the manufactures and commerce of Belgium, especially of the cities of Antwerp and Ghent, but the government could not succeed in blending the Dutch and the Belgians into one nation. Their mutual aversion was manifested with great acrimony in the church, in the army, and even in the assemblies of the States general. The intolerance of the Roman Catholic clergy, encouraged by the pope, who even excommunicated the Jansenist bishops of Utrecht, Haarlem, and Deventer, who had taken the oath of allegiance to the king, and the prohibition of the French language in all judicial proceedings, created great irritation in the southern provinces (so that it was found necessary to modify it in several points); and besides these important differences respecting religion and language, there were several financial points in which the interests of the northern and southern provinces clashed; and which, notwithstanding several very beneficial measures, could not hinder the final separation of the two parts of the kingdom.

The union of Belgium and Holland had subsisted for fifteen years. The cities, the manufactures, the commerce of Belgium, had attained the highest degree of prosperity, but nothing could conciliate the refractory spirit of the Belgians with the phlegmatic character of the Dutch, nothing could conquer the aversion of the people of Brabant and Liege, founded on differences in manners, religion, and language, from Protestant Holland. The July Revolution of 1830 in France revived the old mutinous pride of the Belgian cities, and a rising of the mob in Brussels, on the 25th of August, 1830, commenced the revolution which separated the northern and the southern provinces. In consequence of a second insurrection in Brussels, on the 20th and 26th of September, conflicts arose between the 6000 troops, commanded by Prince Frederick, and the armed insurgents, commanded by foreign officers, which ended in the retreat of the Dutch. Meantime the king, yielding to the desire of a Belgian deputation of the 30th of August, had assembled the States-General at the Hague on the 13th of September to discuss with them the question of a separate administration, and an alteration of the fundamental law. The two chambers were in favour of it, but the insurgents, supported from Paris hy the Propagandi, contended for a total separation, which already existed in fact, when the five powers, Great Britain, France, Austria, Russia, and Prussia, imposed a cessation of arms on both nations, and, by the protocol of the 4th of November, 1830, recognised the independence of Belgium. This is not the place to inquire into the motives which induced four of the great powers, instead of exerting themselves to maintain and defend the bulwark which they had themselves erected as a security against the future encroachments of France, to unite with France in demolishing their own work. But justice requires us to acknowledge that the conduct of William I. on this great and trying occasion was such as was dictated by honour, good faith, and regard for the interest of all, and far from prejudicing the rights or legitimate interests of any government, it entitled him to the esteem and gratitude of all the cabinets of Europe.

King William protested, on the 12th of July, 1831, against the eighteen articles presented by the great powers, particularly against that which proclaims the freedom of the Scheld. Holland, with extraordinary enthusiasm, resolved to have recourse to arms; not to obtain a re-union with Belgium, which it did not wish, but for the assertion of its rights. On the 2nd of August the Prince of Orange, at the head of 70,000 men, crossed the Belgian frontier; Turnhout and other places were taken; one Belgian army was defeated near Hasselt on the 8th of August, and again near Louvain on the 10th; but a French army advanced by forced marches, and the English and French ambassadors at the court of Brussels negotiated an armistice, according to which the Prince of Orange evacuated Louvain on the 14th, and his army retired to its position before the war. A treaty in twenty-four articles was then proposed by the London Conference, which was acceded to by Belgium, but rejected by King William. Russia, Prussia, and Austria likewise wished some articles unfavourable to Holland to be modified, but France and England had recourse to measures of coercion. England blockaded the coast of Holland, an embargo was laid on the Dutch ships, and the citadel of Antwerp taken on the 24th of December, 1832, after a memorable siege by a French army of 70,000 men. This did not immediately lead to peace between Holland and Belgium, but a suspension of arms was effected on the 21st of May, 1833.

The London Conference resumed its difficult task; many important questions remained to be settled: an interminable series of protocols ensued; William did his utmost to delay the conclusion of these negotiations, in hopes of some turn in his favour, and hostilities between Holland and Belgium were on the eve of recommencing at the end of 1838, and were prevented only by the remonstrances of the Conference. At length, induced chiefly by his financial embarrassments, William gave way, and, on the 4th of February, 1839, signed the twenty-seven articles, modified to his disadvantage; and the definitive treaty was concluded on the 19th of April, 1839, by the plenipotentiaries of the Netherlands and Belgium, and of the five great powers.

But though Holland was now wholly separated from Belgium, there was great excitement in the Dutch Chambers in 1839. They hoped for favourable financial laws and judicious reforms; instead of which proposals were laid before them for a loan of fifty-six millions of florins. The loan was rejected on the 20th of December, and the budget on the 23rd; a loan of only six millions was granted, and the budget voted for six months only. At the next meeting of the States-General, in March, 1840, the king caused several modified projects of law to be laid before them; in consequence of which the civil list was fixed at one million and a half of florins; and it was resolved to vote the budget for two years only instead of ten as hitherto. But notwithstanding this endeavour of the government to satisfy the people, the discontent with the king and the ministers increased. The king's passion for the Countess Henrietta d'Oultremont, a Roman Catholic lady, excited the general indignation of the people, so that he declared on the 25th of March, 1840, that he renounced his projected union with her. This affair, and the discovery of an extensive conspiracy in Belgium, in which the Dutch appeared to be concerned, and finally the financial difficulties of the state, induced the king solemnly to resign the government on the 7th of October, 1840, into the hands of his son William II. Under the name of Count of Nassau, with an immense private fortune, he fixed his residence at Berlin, where, on the 17th of February, 1841, he married the Countess d'Oultremont, and died on the 7th of November, 1843. He left his large property to his family, besides a gift of ten millions of florins to the Dutch treasury.

(Baron de Keverberg, *Du Royaume des Pays Bas*, vol. iii. 8vo., La Hague, 1834; Brockhaus, *Conversations Lexicon*, 1846; *Mémoires tirés des papiers d'un homme d'état;* Mr. Chad, *Narrative of the Revolution in Holland*, London, 1814.)

WILLIAMS, DANIEL, D.D., a Protestant Dissenting minister of the Presbyterian denomination, was born at Wrexham, in Denbighshire, in the year 1644. The disadvantages of his early education were compensated by the natural energy of his mind, and by his diligence. He was one of the first of the new generation who entered the Christian ministry after the ejection of the Nonconformists in 1662; and at the age of nineteen he was regularly admitted as a preacher. His first years in the ministry were passed in preaching in several parts of England, though the times were so unsettled that there was little prospect of his continuing his labours without hazard. This circumstance, however, did not deter him from remaining among the Nonconformists, though his talents and his prudence would have enabled him to enter the church-establishment with a fair chance of advancement. As, in these days, more religious liberty was granted by the government in Ireland than in England, Mr. Williams repaired to the sister-country, and unexpectedly received an invitation to become chaplain to the Countess of Meath, which he accepted. Some time afterwards he was settled over a respectable congregation in Wood Street, Dublin. Here he remained nearly twenty years, and filled his station with great credit, being at the same time much respected by the Irish Protestants in general. During his residence in Dublin, he married a lady of an honourable family, with a considerable fortune. Towards the close of the reign of James II., his warm opposition to Romanism exposed him to some danger; and he consequently came to England in 1687, and settled in London. On occasion of the proposal of an address upon the king's dispensing with the penal laws, Mr. Williams firmly took his stand with the opposition. He 'never would,' he said, 'concur in laying down his liberty at his majesty's feet;' and his views of the question prevailed in the conference of dissenting ministers. He now became the patron of those Irish Protestants who fled to England from the violence of Tyrconnel; assisting them himself, and procuring for them the sympathy and aid of the public. He rejoiced greatly in the Revolution of 1688; and was often consulted on Irish affairs by King William. In 1700 he went to Ireland on his own private business, and to visit his friends, by whom he was warmly received, and his services in the cause of Protestantism were even acknowledged by some who had been prejudiced against him. About the period of this visit he had settled as a pastor in Hand Alley, Bishopsgate Street. Here he continued twenty-seven years. He was most esteemed by Mr. Richard Baxter, on whose death, in 1691, Mr. Williams was chosen to succeed him at the Merchants' Lecture at Pinners' Hall. The Antinomian controversy created parties among the Dissenters connected with this lecture, and Mr. Williams rendered himself obnoxious to those who advocated the tenets of Dr. Crisp, the avowed champion of the Antinomian doctrines. A secession took place, and another Tuesday lecture was established at Salters' Hall. On this occasion, Dr. Bates, Mr. Howe, and Mr. Alsop, who had been among the lecturers at Pinners' Hall, retired with Mr. Williams. When Dr. Crisp's works were reprinted, Mr. Williams, by request, wrote his 'Gospel Truth Stated and Vindicated;' a work of which Mr. Alsop, in his 'Faithful Rebuke,' says, 'It is fairly written, rationally argued, exactly methodized, and piously designed.' Mr. Stephen Lob having charged this work with Socinianism, an appeal was made on both sides to Dr. Stillingfleet, then Bishop of Worcester, and to Dr. Edwards of Oxford, both these learned persons being regarded as masters in that controversy; and they both acquitted Mr. Williams of the charge. In his 'End of Discord; wherein is demonstrated that no doctrinal controversy remains between the Presbyterian and Congregational Ministers fit to justify longer divisions,' he distinctly states the opinion of the 'Orthodox, the Socinian, and the Antinomian' on the doctrine of the 'satisfaction of Christ,' and he adheres to the views of the first. So great was the heat occasioned by the Antinomian controversy, that we are informed that Mr. Williams's enemies, being foiled in impugning his opinions, endeavoured to misrepresent his character by arraigning his morals. So completely however did he triumph over the charges brought against him, that, after spending eight weeks over the affair, the committee of dissenting ministers in and about the city, reported to sixty of their body, who met April 8th, 1695, 'That it is the unanimous opinion of the united ministers that Mr. Williams is entirely clear and innocent of all that was laid to his charge.' His whole conduct throughout this painful trial appears much to have increased the attachment of his congregation, as well as his general estimation by the public. Having been now for some time a widower, Mr. Williams married Mrs. Backstead, a widow lady of great excellence, and with a considerable estate.

Diligent as was Mr. Williams in his attention to the pastoral office, he was a man of great public spirit. So long as opposition availed, he strenuously opposed the 'Occasional Conformity Bill,' and the Irish Sacramental Test Act, in the reign of Anne. He was a great promoter of the union between England and Scotland, which took place in 1707. In 1709 he received a diploma of D.D. from the universities of Edinburgh and Glasgow, at the same time with Dr. Oldfield and Dr. Calamy. Anxious for the honour and usefulness of his order, he was very desirous that all the candidates for the dissenting ministry should have at least a part of their education at one or other of the Scottish universities, as they were excluded by the subscription from the English; but his scheme for this purpose did not meet with encouragement, which proves that he was in advance of the age among his contemporaries. Towards the close of the reign of Queen Anne, Dr. Williams became apprehensive respecting the safety of the Protestant succession, from tne measures of the prime minister, the Earl of Oxford; and he remonstrated on the subject with that statesman, with whom he had formed a previous acquaintance. It happened, not long after, that a copy of a letter which Dr. Williams had written to his friends in Ireland on Lord Oxford's measures fell by accident into the hands of a lawyer who was under obligations to Dr. Williams, but who immediately took the letter to his lordship, who, already displeased with the doctor for the counsel which he had volunteered, now never forgave him. On the accession of George I. in 1714, Dr. Williams had the honour of presenting the address to his majesty, at the head of the London dissenting clergy of the three denominations; and from this time it has been usual for this body to go to court on similar occasions, it being one of the bodies who are received on the throne, and by their committees in the royal closet. Dr. Williams's health had by this time visibly declined for a year or two, though he still continued the exercise of his ministry. At length, after a short attack of asthma, he died on the 26th of January, 1716, in the seventy-third year of his age, and was buried in Bunhill Fields. In his funeral sermon, Dr. Evans, who had been his co-pastor for eleven years, ascribes to him 'a copious invention, a penetrating judgment, a faithful memory, and vigorous affections, which were cultivated by much application to study.' His moderation was shown by his desire for a comprehension at the Revolution, on condition of a free toleration to such dissenters as would not be included. His great conscientiousness and his unusual readiness to forgive injuries are also mentioned to his praise. He was accustomed to deliver a lecture to young people on Christmas-day, which was attended by vast audiences from all parts of the town. His discourses and treatises extend to six volumes 8vo., and have been collected and published at different periods: the last volume consists of Latin versions of several of his treatises, translated for the benefit of foreigners, agreeably to the instructions of his will. He also directed that his treatise entitled 'The Vanity of Childhood and Youth' should be rendered into Welsh for the use of schools, and printed often for the benefit of the poor.

Dr. Williams bequeathed the bulk of his estate to benevolent and useful objects. Having provided for his widow, he left donations to the Society for the Reformation of Manners; for the education of youth in Dublin; for an itinerant preacher to the native Irish; to the poor of the Wood Street congregation in Dublin, and of that in Hand Alley in London; to the French refugees; to the poor of Shoreditch parish; to assist poor ministers and students; to several ministers' widows; to St. Thomas's Hospital; to the London workhouse; to the Society for promoting Christian Knowledge in Scotland; for the support of two preachers to the Indians; and for the maintenance of charity-schools in Wales. He also left estates to the university of Glasgow, which at present furnish six handsome exhibitions to students for the ministry among Protestant dissenters in England, who are to be nominated by his trustees. The last grand bequest in his will was four the establishment of a public library in London. For this purpose he had bought Dr. Bates's collection of books for between 500*l.* and 600*l.* to add to his own. He directed his trustees to erect a suitable building, the site for which was purchased by them in 1727, in Red-cross Street; and the library was opened in 1729. All persons may obtain admission on application to one of the trustees. Since the library was established, very considerable additions have been made to it by legacies, as well as by contributions in money and books. It contains upwards of 16,000 volumes; and in 1841 a new catalogue was made, in two volumes; the second volume contains tracts and sermons which had never been catalogued before.

Dr. Williams's library will be memorable in future time as the scene of preparation for many of those noble struggles for civil and religious liberty which have issued in the improved social position which dissenters from the established church now enjoy. The large room in which the deliberations of the united ministers of the three denominations were carried on for many years, while striving for an equality of civil and religious rights, is adorned with a magnificent collection of the portraits of the nonconformist fathers, and of their more immediate successors. It is well known however that the lapse of time brought with it great changes in the doctrinal opinions of at least one of the three bodies, though still retaining its original name. So long as there was common ground of sympathy on which all could meet to redress common grievances, all things went on with harmony. The differences were felt on both sides to be great and momentous, but they were not brought into question: other objects intervened, and the three denominations continued to be a political body aiming at a great social object, rather than a religious union. But scarcely had their united efforts brought about the repeal of the Corporation and Test Acts when differences arose, and the want of religious sympathy in the sections of the body began to show itself. The controversy respecting Lady Hewley's charity at length severed the alliance which had lasted for a century. The Unitarian members, who formed the great majority of the Presbyterian body, seceded from the three denominations on the 4th of March, 1836, and the orthodox Presbyterians, few in number, alone remained in the connexion. The government considerately yielded to the seceding party the right of addressing the throne separately under the name of the Presbyterian denomination; and the Congregationalists, the Baptists, and the remaining orthodox Presbyterians are still known and recognised by the government as the 'Three Denominations,' whose meetings are now held in the Congregational Library, Blomfield Street.

(Dr. Williams's *Works;* Calamy's *Continuation;* Bogue and Bennett's *History of Dissenters; Congregational Magazine* for 1836.)

WILSON, DR. THOMAS, a noted statesman and scholar of Queen Elizabeth's time, was the son of Thomas Wilson of Stroby, in Lincolnshire. He was educated at Eton and at King's College, Cambridge, and afterwards became tutor to the two sons of the Duke of Suffolk. In 1551 he published 'The Rule of Reason, containing the Art of Logic;' and in 1553, 'The Art of Rhetoric.' Both works were frequently reprinted in the course of the century, and both have received much commendation from modern critics; the latter in particular being held to give the author a title to be considered as the earliest critical writer in the English language. Full specimens of it are given by Warton. On the accession of Queen Mary, Wilson found it convenient to retire to the Continent. He took the degree of doctor of laws at Ferrara; but, on proceeding to Rome, was apprehended by the Inquisition, and is said to have been put to the torture; the grounds of charge being said to have been found in the works he had published. On the death of pope Paul IV. (1555), the discontented populace of Rome broke open the prison of the Inquisition; and Wilson was one of those prisoners who then escaped. On Elizabeth's accession he returned to England, was immediately taken into the public service, and rose rapidly from place to place. He was at first master of requests, and master of St. Katherine's Hospital, and private secretary to the queen: in 1576 he was sent as an envoy to the Low Countries; and in 1577 he was appointed one of the secretaries of state, and afterwards became a dean of Durham. He died in 1581.

WILSON, ALEXANDER, was born at Paisley, in Scotland, July 6, 1766. His mother died when he was ten years of age, and his father, embarrassed with the charge of a young family, soon married again. In 1779 Alexander was bound apprentice to a weaver for three years, on the expiration of which he worked about four years as a journeyman weaver, and then abandoned the loom, and spent nearly three years as a pedlar. From an early age he had been cultivating a talent for poetry which he imagined himself to possess, and in his excursions for the sale of his wares endeavoured to procure subscriptions for a volume of his poems, but without success. The volume was never published, but verses and single poems were published in newspapers and separately. 'The Laurel disputed,' a poem on the respective merits of Ferguson and Ramsay, be recited before a literary society in Edinburgh, and published there in 1791. In 1792 he published anonymously his 'Watty and Meg,' which some at first ascribed to Burns, to the no small gratification of Wilson. His poetry however made no impression on his countrymen in general, and he resolved to emigrate to the United States of North America.

On the 14th of July, 1794, Alexander Wilson landed at Newcastle, in the State of Delaware, with only a few shillings in his pocket, and immediately proceeded to Philadelphia. He was employed for a few weeks by a copper-plate printer; he then resumed successively his former occupations of weaver and pedlar, but afterwards became a land-measurer, and ultimately turned schoolmaster, and pursued his new avocation at different places in Pennsylvania and New Jersey. At length, in 1802, he made a contract with the trustees of a school at Gray's Ferry, on the river Schuylkill, in the township of Kingsess, about four miles from Philadelphia, and here he became acquainted with Mr. Bartram, the botanist and naturalist, whose gardens were always open to him, and whose conversation stimulated and improved the taste for natural history which his turn for observation and his rambling life had developed. Here too he became acquainted with Mr. Lawson, the engraver, who gave him instruction in drawing, providing him with landscapes and sketches of the human figure, but with little promise of his becoming a draftsman, till Mr. Bartram proposed a trial of birds, in which he succeeded beyond the expectation of his friends; and from that time the ruling passion of his after-life was brought into play. Writing to a friend in Paisley, in June, 1823, he says, 'Close application to the duties of my profession, which I have followed since Nov., 1795, has deeply injured my constitution; the more so, that my rambling disposition was the worst calculated of any one's in this world for the austere regularity of a teacher's life. I have had many pursuits since I left Scotland—mathematics, the German language, music, drawing, &c.,—and I am now about to make a collection of our finest birds.' In October, 1804, Wilson, accompanied by two friends, set out on a pedestrian journey to the Falls of Niagara. They reached the Falls, and satisfied their curiosity, but were overtaken by the snows of winter on their return. One of his companions remained with his friends near the Cayuga lake, the other availed himself of a conveyance; but Wilson walked on with his gun and bundle, through trackless snows and uninhabited forests, over mountains and along dangerous rivers, and reached home at the beginning of December, after a journey of 1257 miles, of which he walked 47 the last day. All the time he could spare was now devoted to the examination of birds, and making drawings of them in colours. In 1806 Mr. Bradford, bookseller, of Philadelphia, being about to publish a new edition of Rees's 'Cyclopædia,' engaged Wilson as assistant editor. Soon afterwards he explained to Bradford his views of a large work on American ornithology, and the bookseller undertook the publication.

Wilson was assiduous in attention to his duties as assistant-editor, while at the same time he prosecuted the great undertaking which had become the favourite object of his ambition with an enthusiasm which was characteristic of him. At length, in Sept., 1808, the first volume of the 'American Ornithology' was published. From the date of the first arrangement a prospectus had been put in circulation, in which the nature and intended execution of the work were specified, but no adequate idea had been formed of the book which was in preparation, and when the superb volume made its appearance the American public were alike astonished and delighted. It was in folio, with plates carefully engraved from Wilson's own drawings, coloured after nature, and with admirable letterpress descriptions; the price was 120 dollars. In the course of September, 1808, Wilson journeyed eastward and northward, and during the winter went through the southern States, exhibiting his book and endeavouring to obtain subscribers. He visited in fact every town within 150 miles of the Atlantic coast, from the river St. Lawrence to St. Augustine in Florida. He received much praise, but got few subscribers. Wilson however was not depressed.

The second volume was published in 1810, and soon afterwards he set out for Pittsburg on a journey to New Orleans. From Pittsburg he descended the Ohio by himself in a skiff. He started on the 24th of February, and on the 17th of March moored his boat safely in Bear Grass Creek, at the rapids of the Ohio, after a voyage of 720 miles. His hands had suffered a good deal in rowing. He had made excursions from the banks of the river, as he proceeded, with his gun and drawing materials, in search of new species of birds, of which he made drawings and wrote descriptions on the spot where he shot them. He afterwards walked from Louisville to Lexington, 73 miles, and on the 4th of May set out from Nashville for St. Louis through the wilderness on horseback, with a loaded pistol in each pocket, a loaded fowling-piece belted across his shoulders, a pound of powder in his flask, five pounds of shot in his belt, and some biscuits and dried beef. On the fourteenth day he arrived at Natchez, in Mississippi, after a journey through swamps and across rivers, which had nearly killed both his horse and himself. The other volumes of his work were brought out in succession, with astonishing rapidity and regularity; the number of his subscribers increased, and before his death included perhaps every royal personage in Europe. In 1812 he was elected a member of the American Philosophical Society. In 1813 he published the 7th volume. He had completed the pictorial materials for the 8th and 9th when he was carried off by an attack of dysentery in his forty-eighth year. He died August 23, 1813, at Philadelphia. The 8th and 9th volumes were completed and published in 1814 by Mr. George Ord, who had been his companion in many of his exploring expeditions. Mr. Ord supplied the letter-press descriptions for these two volumes, as well as a biography of Wilson in the 9th. Three supplemental volumes were afterwards supplied by Charles Lucian Bonaparte, folio, 1825-1828.

Wilson's pictorial representations of the birds are considered to be of great excellence. His descriptions are not only technically accurate, but exceedingly clear and graphic in whatever relates to their motions and characteristic habits. It is a delightful book. The mind is so much absorbed with the images and scenes as to be hardly conscious of the act of reading.

Wilson was about five feet ten or eleven inches in height, handsome and vigorous, but rather slender. He was always distinguished by the neatness of his dress and appearance. He was a man of the strictest honesty and the most scrupulous regard for truth; social, affectionate, and benevolent, but somewhat irritable under contradiction and critical objection. He was never married.

(*Memoir of Wilson*, annexed to the *American Ornithology*, by Alexander Wilson and Charles Lucian Bonaparte, in *Constable's Miscellany*.)

WOLF-FISH. [Anarrhicas, P. C. S.]

WOLFSBANE. [Aconitum, P. C. S.]

WOOD, DECOMPOSITION OF. [Timber, Preservation of, P. C.]

WOO'DSIA, a genus of ferns, having circular sori, with an inferior involucre, divided at the edges into numerous capillary segments.

W. ilvensis is one of the rarest of our British ferns; it is found in only two localities in Europe, one in Wales, and one in Scotland. It takes root in the fissures of rocks and in the bleakest part of mountainous places. The fronds are elongated, the pinnae triangular, with deep lobes, the rhizoma tufted. There are varieties of this species, which are by some writers considered as distinct species, but Mr. Babington thinks this division unnecessary.

X.

XANTHIAN MARBLES. These interesting marbles, which will shortly be opened to the public in the apartments built expressly for them on the western side of the British Museum, are likely to form one of the most attractive portions of the British collection of antiquities. They consist of a large collection of sepulchral marbles of various ages, which were first made known to the European public by Mr. (now Sir Charles) Fellows, who discovered them in 1838, when performing a tour through Asia Minor. They were all found in or near Xanthus, the antient capital of Lycia, a small country on the southern coast of Asia Minor. [ANATOLIA, P. C. S.] Xanthus is an antient town, and was built on the river of the same name (now Etchen-Cháï), at the distance of seventy stadia, or nine or ten miles, from its mouth. The first mention of the Xanthians in history is in the first book of Herodotus, c. 176, where he describes the capture and destruction of their city, in the middle of the sixth century B.C., by Harpagus, the general of Cyrus. Herodotus says that the Xanthians, after burning their wives and children, were all destroyed by the soldiers of Harpagus. He continues, that those who inhabited the city in his time were all foreigners except eighty families, who were absent on a foreign expedition. He says nothing of their monuments. Five centuries later nearly a similar fate happened to them when they were besieged by Brutus: the city was destroyed, and only one hundred and fifty Xanthians were left, says Plutarch, and this against their will. Many of the monumental buildings of Xanthus must have perished in this second destruction: it was however again restored, as is evident from the Greek inscriptions and the state of its ruins when discovered by Sir C. Fellows. These different conquests will in some way account for the various characters of its monuments and inscriptions.

The origin of the Xanthian collection of marbles may be briefly described. In 1839 the attention of men of letters and artists, both in England and in other countries, was called to the subject by the following publication and its illustrations:—'A Journal written during an Excursion in Asia Minor,' by Charles Fellows, 1838. In this account the remains of Xanthus were represented as of a very early age, and portions of its walls as Cyclopian. The ruins were in many places covered with inscriptions, many in a perfect state, but in an unknown language, which Mr. Fellows represented as resembling in appearance the Phœnician or Etruscan. Many of the ruins, the rock tombs, were described as resembling those of Persepolis. The ruins consist of walls, temples, tombs, triumphal arches, and a theatre, and are situated in a site 'extremely romantic, upon beautiful hills, some crowned with rocks, others rising perpendicularly from the river, which is seen winding its way down from the woody uplands, while beyond, in the extreme distance, are the snowy mountains in which it rises.' These picturesque ruins are covered with sculptures, and their elegant designs, says Mr. Fellows, evince the talent of the Greeks; and the highly poetical subjects of the bas-reliefs, some of them blending in one figure the forms of many, probably to describe its attributes, are also of Greek character.

The account of these ruins attracted more attention than their discoverer expected, and soon after the publication of his first journal, he made, in 1840, a second journey to Lycia, to give a more satisfactory account of his discoveries. The results of this journey appeared in 'An Account of Discoveries in Lycia, being a Journal kept during a second Excursion in Asia Minor,' by Charles Fellows.

In consequence of the more accurate and satisfactory account in this work, and the representations of various persons to the Government, of the advisability and practicability of transporting some of these Xanthian remains to England and preserving them from further destruction, an expedition was fitted out in the autumn of 1841 for the purpose, and permission being obtained from the Sultan for their removal, a portion of the Marbles was deposited in the British Museum in 1842. In 1843 a second expedition was sent out, and the remainder of the Marbles arrived towards the end of the following year. The Marbles comprise four tombs and many fragments of other monuments, and the whole will be shortly opened to the public, partly arranged in the Museum as they were originally found by Sir C. Fellows. The tombs have been named, from their sculptures, the Winged-chariot Tomb, the Harpy Tomb, the Chimæra Tomb, and the Lion Tomb: the first two were found entire, the others in fragments. These two entire tombs, which it is contemplated to reconstruct, are the principal marbles of the Xanthian collection. One, the Winged-chariot Tomb, is a sarcophagus, entirely of white marble, and stood on the side of a hill. The marble being finely worked, the polish has greatly assisted in its preservation from the effect of the atmosphere. The roof is somewhat grey, and the fractures of the lower parts are tinged with the red tint which white marble assumes after long exposure to the weather, and in places with yellow blended with brown. On the top or *hog's mane* is a hunting scene; some figures are running, others are on horseback galloping, with spears in their hand, and mantles blown by the wind, chasing a stag and a wild boar, which has turned to attack the pursuer. All the figures, though small, are, in the opinion of Sir C. Fellows, well formed and finished. On each of the sloping sides of the roof are two stones projecting about a foot, as found on all these tombs, but which upon this are carved into lions' heads crouching on their paws. Upon one side of the roof is a group, in which a warrior carrying a shield is in the act of stepping into his chariot, which is of the early simple form, with wheels of four spokes only; the driver is leaning forward, with his arms stretched out, holding the reins and a whip or goad; four beautifully formed horses, prancing in various attitudes, are attached to the car. A nearly similar chariot and horses are carved on the other side of the roof, varying only in the attitudes of the figures. In the upper panels at the ends or gables are traces of small carved figures. On one side of the tomb (of which a sketch is given in the 'Journal' of 1838), under two lines of Lycian characters, is a group of figures, which, beginning from the left, is thus described by Sir C. Fellows:—'A finely formed figure in a simple robe, his hands folded before him, and with a head of bushy hair, stands as if in attendance behind the chair or clawed seat of the principal figure, who, clothed in rich folded drapery, with short hair, sits in the attitude of a judge, with one arm somewhat raised; before him stand four figures: the first is mutilated, but appears similar to the second, who has long bushy hair, confined round the head, and looking like a wig; his attitude is that of a councillor pleading for the others; the loose robe falls gracefully from one shoulder, and is thrown over, so as almost to conceal one arm; two other figures, differing only in having the hair shorter and the arms hanging down, stand apparently waiting the decision of the judge, and complete the well-formed group.' The word or name Paiafa is inscribed over the judge.

At the end, on a larger scale, are two figures of warriors, clothed with short mantles, and girdles of armour round their loins, above petticoats reaching nearly down to their knees. The back-ground of this bas-relief contains a long but, from mutilation, illegible inscription: it is copied in the Second Journal. On the opposite end of the tomb are two other figures of the same size; one, clothed in a loose robe, stands in a commanding attitude fronting the spectator, with an arm raised over the head of a naked figure, also standing. (Second Journal, p. 166, where both ends are engraved.)

On the second side of the tomb, under a single line of inscription, is an animated battle-scene: 'men on horses are fighting with others on foot; all have helmets, and those on foot have shields; some fight naked, others with a loose shirt or blouse descending below the thighs, and confined by a belt round the waist. The horse of the principal figure is ornamented with, and the rider has, a kind of armour to protect his legs.'

The groups upon the two sides of the tomb are three feet six inches high by nine feet in length. The height of the whole tomb, including the base, is about twenty feet, or twice its width at the sides. The interior was quite exposed; it had been broken open in all its parts. In style of architecture it is the imitation of a wooden structure.

Upon the other or Harpy tomb, a high square pedestal which was near the theatre at Xanthus, are some very curious bas-reliefs. (First Journal, p. 232, and Second Journal, p. 170, where they are engraved.) On the four extremities of the north and south sides are four figures of similar design; the head is that of a female, the breast is exposed, and the body, which terminates with the trunk, has wings and a tail like a pigeon's; from under the wings comes a bird's claw, clasping the legs of a child, which is carried in the bosom of the figure. The tomb has acquired its name from these figures, which resemble the Harpy of the antients. They are all flying upwards and outwards from the middle of each group. In the middle of the south side, seated on an elegant chair, is a small figure wearing a loose robe, with a long stick resting on his shoulder, and two round objects in his hands. A female figure draped, but much mutilated, is presenting a pigeon held by its wings. In the middle of the north side is an old man with a peculiarly pointed beard, seated on a stool, in front of which, by his side, is what appears to be a pig; he also has loose drapery, and a stick resting against his shoulder and held in his hand; before him is the figure of a warrior delivering up his armour: in one hand he holds the helmet, in the other a shield. On the middle of the east side an old man is also seated in a chair, likewise with a long stick resting against his shoulder; in one hand, which is raised, he holds what appears to be a small bird towards his face, and before him a child or youth is presenting a cock; behind the child are a figure with one hand raised, and a dog looking back up into the face of the figure: behind the chair of the old man are two female figures, one holding down by her side some small object in her hand, the other holding likewise some small object up before her face. On each extremity of the west side is seated a female in a chair, looking towards each other; next to one of these females, who has a patera in her hand, towards the middle, is, more than half way up, and on a very small scale, a cow suckling its calf; beneath the cow and calf is an opening in the tomb, which may have been intended as the doorway into the tomb; next to the opening, and looking towards the other female seated in the chair, are three females standing, similarly attired in loose drapery and in similar attitudes, each holding some small object down by their sides, and with the other hand raising a cup or other object to the mouth; the seated figure on this side is similarly occupied. They have all low head-dresses; some the tiara, others wreaths or plaited hair with tresses hanging down behind. The figures are about three feet high, and he four compartments, about nine feet in length, form the top of the tomb, and are elevated about twenty feet above the ground upon a square pedestal of grey stone, and roofed with two flat stones of a similar material; the bas-reliefs are in white marble. There is no inscription on this tomb, which, from the flying figures carrying off the children, is supposed to allude to the story of Pandarus, King of Lycia; these figures are the harpies carrying away the daughters of Pandarus: Homer, *Odyssey*, b. xx. (Second Journal, p. 170.)

Close to this tomb was another similar tomb of the same dimensions, entirely covered with Lycian characters. These Xanthian tombs extend over several miles of country.

The walls of the city are extensive and massive; Cyclopian is blended with Greek architecture; and several gateways with their paved roads still exist. In the walls of the acropolis many beautifully wrought marbles are built in as materials, without any regard to their sculpture. Lions, warriors, chariots, and horses are to be traced in many fragments, and birds like our game-cocks fighting. On the site of a small temple Sir C. Fellows found a frieze about ten or twelve feet long and one in width, representing a series of fifteen small dancing figures with flying drapery. There were the ruins of many small temples in the neighbourhood: Sir C. Fellows considered the sculptures to be Greek. He says however of the ruins generally—'Xanthus possesses some of the earliest archaic sculpture in Asia Minor, and this connected with the most beautiful of its monuments, and illustrated by the language of Lycia. These sculptures to which I refer must be the work of the sixth or seventh century before the Christian era, but I have not seen an instance of these remains having been despoiled for the rebuilding of walls; and yet the decidedly more modern works of a later people are used as materials in repairing the walls around the back of the city and upon the acropolis; many of these have Greek inscriptions, with names common among the Romans. The whole of the sculpture is Greek, fine, bold, and simple, bespeaking an early age of that people. No sign whatever is seen of the works of the Byzantines or Christians.'

Many Greek inscriptions upon pedestals are built into the walls, which, says Sir C. Fellows, are mostly funereal, and belong to an age and people quite distinct from those of the many Lycian remains. Among the many inscriptions copied by Sir C. Fellows, at Xanthus, is a Lycian inscription of 250 lines taken from an obelisk. (Second Journal, p. 168.)

Many of these fragments of sculpture built into the walls of the acropolis are now in the Museum; they are also engraved in the Second Journal of Sir. C. Fellows. The construction of the chariots and the costume of the figures of some pieces are of an early age. The forelocks of the horses are tied in a peculiar way, similar to those of some horses in a bas-relief at Persepolis: the whip of the driver of a chariot, as well as his costume, are in the Persepolitan sculptures the same as in the Xanthian specimens. The horses have also their interest; some resemble the subjects seen upon antique gems: the lion and the bull also are represented as prominent objects in these Lycian sculptures. Many of the Greek inscriptions, already mentioned, appear to be subsequent to the Roman conquest of Asia, and some are of the time of the emperors.

None of them are of any service in pointing out the date of the various sculptures. They are translated in an 'Appendix to the Journal of the Second Excursion of Sir C. Fellows,' by Mr. Hermann Wiener. Few of them are however quite perfect. The same work contains an Essay on the Lycian Alphabet and Inscriptions, by Mr. Daniel Sharpe. The sculptures and ruins of Cadyanda, Myra, Limyra, Tloss, and other places in Lycia, appear to be equally interesting as those of Xanthus.

There are in the British Museum fragments of and casts from some of these marbles, as those of Tloss, Telmessus, Pinara, Myra, and Cadyanda. With the collection are also drawings and paintings of the original sites of the various ruins and marbles, and of some of them entire models as they were first found by Sir C. Fellows in 1838. There is likewise a panoramic view of Xanthus with all its ruins, taken from the acropolis by Mr. George Scharf, who accompanied Sir C. Fellows on his expedition: there are also drawings of the operations of the excavators. In this panoramic view is a group of fragments of peculiar interest. These fragments are now in the Museum, and as they appear all to belong to the same monument, and few pieces are wanting to complete it, a restoration of the whole has been attempted, and it will form one of the most striking features of the collection. It consists of a small amphiprostyle temple of the Ionic order, on a lofty stylobate pedestal without a base, but above a plain lower basement. It measured in height nearly 30 feet above the basement, and as much in length. The stylobate, being rather more than half the height of the whole, is ornamented with the bas-reliefs, and has a cornice with a deep egg-and-tongue moulding. The height of the columns, of which there are four at each end, is ten feet; and between and on the outer sides of these columns are altogether ten figures, five at each end, upwards of five feet in height, but much mutilated. The pediments were ornamented with sculpture, and three smaller statues stood on the acroteria at each end. All the fragments were found except some of the pediment sculptures. The sculptures of the stylobate, or upper ornamented basement, are complete in both their series, though all the figures are mutilated, and there is but one head entire: this is on the socle, or in the lower series, and has on a Phrygian cap. The bas-reliefs of the socle represent a battle between Greeks and Asiatics, and are about three feet high; those of the frieze above, or upper series immediately under the cornice, are smaller, and represent the storming of a city.

This interesting monument, which appears to have been wholly without inscriptions, is considered by Sir C. Fellows and some others to be a monument raised in commemoration of the capture of the city by Harpagus. There is however nothing whatever in the monument itself to support the supposition. From the style of the sculptures it is a work of a much later age; the statues are evidently, from the peculiar and masterly character of their draperies, of an age subsequent to the marbles of the Parthenon. There is also no parallel in the description of Herodotus with that part of the frieze which represents a Persian or Phrygian satrap or general receiving a deputation or giving audience to some aged men. The soldiers also who are ascending the ladder to enter the town are without shoes, and appear to be Greek. In alluding to the victory of Harpagus, Herodotus speaks rather of the self-destruction of the Xanthians than of the capture of the town. The Xanthians, having destroyed their wives and children, sallied out, and were all put to the sword. The monument is more likely to commemorate the recovery of the city from the Persians: it is a Greek and not a Persian work. The fallen Persian of one of the pediments also shows that the Persian is the defeated, not the victorious party. That the monument is a commemoration of some victory is evident from all its parts.

If this monument can be explained into a monument to Harpagus, it must have been executed about 150 years after the event commemorated; for though it may be hazardous to fix the time of any monument from the style of its workmanship, there is not much rashness in pronouncing when it was not executed; and there is evidence in the design and workmanship in this monument to show that it was not executed until after the time of Phidias and the completion of the Parthenon, or certainly not earlier than about 400 B.C., and probably considerably later. After a certain time, when mastery has superseded hesitation in design and unskilfulness of execution, the former hardness and littleness of detail and cramped stiffness of attitude are replaced by freedom and facility, with everywhere the evidence of a skilful expression of what was required. The journeymen also by whom such marbles are executed, long accustomed to the easy mastery of the models of a finished age, themselves acquire peculiar characteristics of execution; touches given with little trouble, but by which much is accomplished; grown old in mastery, they become careless and free to extravagance in their execution. All these evidences are in this Xanthian monument: the draperies of the mutilated female statues combine the highest mastery in design with the utmost facility of execution.

Besides the works above quoted on these marbles, Sir C. Fellows has published a pamphlet entitled 'The Xanthian Marbles, their acquisition and transmission to England,' 1842. Their inscriptions are already incorporated in the 'Corpus Inscriptionum Graecarum,' by Aug. Boeckh and J. Franz, in the first part of the third volume of the Transactions of the Academy of Sciences of Berlin for 1844. Some corrections are ventured upon by the editors of this edition, especially in an inscription on a stele or column described as erected to a son of Harpagus, who was a celebrated boxer. (*Kunstblatt*, 1845, p. 326.)

XANTHIDIUM. Some of the minute organic bodies in the chalk and flint of England are referred to this genus of Infusoria, but perhaps without sufficient reason. (Mantell.)

XAVIER, FRANCIS, SAINT, was born at the castle of Xavier, in Navarre, on 7th April, 1506. His father, Don John do Jasso, was counsellor of state to the King of Navarre, and his mother, Maria Azpilcueta, was heiress of the two illustrious houses of Azpilcueta and Xavier. Francis was the youngest of a large family of children, the eldest of whom bore the surname of Azpilcueta, and the others that of Xavier. Under the paternal roof he received all the advantages of a careful education. His devotion to study, and the talents which he manifested, induced his parents to send him at tho age of eighteen to the Collège de Sainte Barbe, at Paris. It was there that he first became acquainted with Ignatius Loyola, and thenceforward to the time when he set out on his missionary labours, the history of Xavier is intimately blended with that of Loyola and his disciples. [JESUITS, P. C.; LOYOLA, P. C. S.]

In 1538, he joined Ignatius Loyola at Rome, where he actively assisted him in the furtherance of his great design of associating a body of devoted men for the special service of the Church of Rome. While in that city, he exercised the functions of the ministry in the church of St. Lawrence in Damaso, and attracted to it large multitudes by his zeal and talents. Among them was a Portuguese of the name of Govea, who had been sent to Rome on a mission of importance by King John III. In his communications with the king he had expressed himself in terms of high commendation of the new society which had lately sprung up under Loyola; and had suggested the propriety of selecting missionaries from among them to plant the standard of the faith in the Portuguese colonies of Asia. Influenced by these representations, the king dispatched an order to his ambassador at Rome to obtain six members of that society, who might be willing to devote themselves to missionary labours. Two only however could be spared, and Simon Rodriguez, a Portuguese, and Nicholas Bobadilla, a Spaniard, were selected by Loyola. As he was about to set out on his journey to Lisbon, Bobadilla fell sick, and Francis Xavier joyfully received the command of his chief to become his substitute. Having previously obtained the benediction of the Pope, Paul III., on himself and his holy enterprise, he left Rome in company with the Portuguese ambassador, on 15th March, 1540. Their journey by land to Lisbon was long and tedious. As they passed through the town of Pampeluna, which was only eight leagues from the castle of Xavier, he was pressed by the ambassador to take leave of his mother, who was still living, and his other friends and relations, whom it was probable he might never again see. In the excess however of his zeal for the prosecution of the purpose to which he had devoted himself, he declined availing himself of the opportunity, fearing, as he said, that the transient pleasure of a last farewell might leave too lasting an impression of melancholy on his sacred enterprise.

Xavier and his companions arrived at Lisbon towards the end of June. After a stay of eight months in Lisbon, on 7th April, 1541, Xavier embarked on board a vessel, which carried Don Martin Alphonso de Souza, governor of the Indies, but unaccompanied by Rodriguez, who had been persuaded by the king to remain in Portugal. After a voyage of five months, they arrived at the coast of Mozambique in Africa, where they wintered, and at Goa, the Portuguese seat of government in the East Indies, on 6th May, 1542.

On landing, the first visit of Xavier was to the hospital; his next to his spiritual superior, the bishop of Goa, to whom he presented the briefs of Paul III., and implored his sanction and blessing on his missionary enterprise. He had scarcely commenced it, when he made the painful discovery that the doctrines in which he was anxious to instruct the infidels, were openly contradicted by the life and example of the greater part of the Christian residents in Goa. To their spiritual reformation therefore he directed his first endeavours; going from street to street, with a bell in his hand, he summoned every inhabitant to send him his children and slaves, in order that they might receive Christian instruction. Having secured his influence over the young, he exerted himself in his ministrations to expose the prevailing vices, and to present the remedies which religion affords. From the Christians, his zeal extended itself to the infidels, whose temples he caused to be destroyed, and churches to be erected on their site. His labours were speedily rewarded in Goa by a marked reformation among the inhabitants. After a residence of six months in that town, he left it to visit the coast of the pearl fishery, which extends from Cape Comorin to the isle of Manar. He there found that, although a large proportion of fishers had been baptized in the Christian faith, they had, for want of instruction, retained the vices and superstitions of heathenism. In order to give them that instruction, he laboured for some time most assiduously in acquiring the Malabar language. His first preaching among them was attended with extraordinary success. After a stay of fifteen months on this station, he returned to Goa for the purpose of procuring assistants to his work; with them he returned, in 1544, to the fishers of the pearl coast, and left several of them in different parts, to prosecute the labours which he had begun. He then proceeded to the kingdom of Travancore, where, in one month, as he states in his letters, he baptized ten thousand Indians. Xavier then visited Malacca, a place at that time of considerable trade, and to which merchants from every part of Asia were in the habit of resorting. He arrived there on 25th September, 1545, and, according to his custom, took up his residence at the hospital, where he devoted himself to the service of the sick, without neglecting the principal object of his mission, which was to instruct the people. A large number of converts from among Mohammedans, Jews, and others, was the result of his labours. While at Malacca he was joined by three other Jesuit missionaries, whom Ignatius Loyola had sent to co-operate with him. In company with them, on the 1st January, 1546, he set sail for the islands of Banda, and, it is said, became the happy instrument of the conversion of the entire crew of the vessel which carried him. From thence he proceeded to the island of Amboina, where he baptized a large number of the inhabitants; he then preached the Gospel in other islands, and, having made a considerable stay in the Moluccas, he brought over great numbers to Christianity. Xavier then returned towards Goa, visiting on his voyage the islands where he had planted tho faith: he arrived at Malacca in 1547. After leaving Malacca he made some stay at Manassar, near Cape Comorin, and afterwards passed over to the island of Ceylon, where he converted the King of Candy and several of his subjects; on the 20th May, 1548, he returned to Goa. At Malacca, he had met with a Japanese exile, named Auger, of noble birth and high station in his country, whom he had instructed in the faith, and induced to accompany him to Goa. The description given by this Japanese of the state of his native islands determined Xavier on making them the next object of his missionary labours. Having baptized Auger, with two of his domestics, and given him the more Christian name of Paul of the Holy Faith, he set out with him from Goa on this difficult enterprise. After making a short stay at Malacca, he embarked on board a Chinese vessel, and arrived on the 15th August, 1549, at Cangoxima, in the kingdom of Saxuma, in Japan. [JAPAN, P. C.]

The chief difficulty he had to overcome in this new ission was his ignorance of the Japanese language. Xavier, uring his voyage, had, by means of his convert, acquired me little knowledge of it, which was increased by his stay of forty days at Cangoxima, and which was sufficient to enable him to translate into it the Apostles' creed with a short exposition. The little progress, however, which he made in it proved a serious hindrance to his success, as appears from the letters he sent home. Through his companion, he was introduced to the King of Saxuma, who gave him a favourable reception, but declined hearing him on the subject of religion. In the hope of finding a more suitable field for his missionary exertions, he left Saxuma, and proceeded to Firando, the capital of another small kingdom. He was there allowed freely to exercise his ministry, and numerous conversions were the fruits of it: in that city he baptized more infidels, in twenty days, than he had done at Cangoxima in a whole year. Encouraged by this success, he left these converts under the care of one of the Jesuits who had accompanied him, and set out for Meaco, the capital of the whole empire and the residence of its ecclesiastical chief. [JAPAN, P. C.] On his way thither he visited Amanguchi, the principal town of the kingdom of Naugato, where he was allowed to preach in public and before the king and his court, but with little success. After a month's stay in that city, he continued his journey towards Meaco. Though it was the depth of winter, and the rugged roads, difficult at all times, were now rendered almost impassable by drifts of snow and mountain torrents, yet, thinly clad and barefoot, he journeyed onwards, resigned and cheerful. He arrived at Meaco in February, 1551, having been about two months on his journey. There his mean appearance and wayworn garments proved a subject of offence to the inhabitants; accustomed to the gorgeous rites and pompous ceremonial of their own religion, the priests, whose influence was paramount in that city, could not see in this humble person the ambassador of the Most High. Though rejected with contumely, Xavier did not abandon his holy purpose, but returned to Amanguchi, where he provided himself with a rich suit and a retinue of attendants, and thus attired presented himself before the court. This harmless device produced the desired effect; he obtained the protection of the king, and preached with so much success, that he baptized three thousand persons in that city. These converts he left to the care of some Jesuits who had been the companions of his journey; and, accompanied by two Japanese Christians, who, rather than renounce the consolations of the religion he had taught them, had cheerfully suffered the confiscation of their property, he departed from Amanguchi, in September, 1551, and, on the 20th of November following, embarked to return to India, having remained in Japan two years and four months. This mission was, for upwards of a hundred years after the death of Xavier, successfully continued by the Jesuits. [MISSIONS, P. C., vol. xv., p. 267.] On his voyage he made some stay at Malacca, chiefly for the purpose of concerting measures with the governor of that place for the prosecution of a mission to China. A serious obstacle to it was the law which forbids strangers, on the severest penalties, to enter that country. To remove it, it was agreed between Xavier and the governor of Malacca that an embassy should be sent in the name of the King of Portugal to establish a commercial treaty, and that Xavier should join it. On his return, however, to Malacca, he found the new governor, who had arrived there during his absence, opposed to the projected embassy, and, after many unavailing entreaties to procure his compliance, he was obliged to embark alone for his intended mission on board a Portuguese vessel bound for the island of Sancian, near Macao, in China, a place where the Chinese were permitted to traffic with the Portuguese merchants. On arriving there, the merchants of Sancian endeavoured to dissuade him from his design of prosecuting his journey farther, and strongly represented to him the danger. Xavier however was not to be deterred; he provided himself with an interpreter, and entered into an agreement with a Chinese merchant to land him by night on some part of the coast. This plan also was frustrated by the Portuguese residents of Sancian, who feared that this attempt to infringe the laws might be visited upon them by the vengeance of the Chinese authorities. While thus disappointed in his fondest hopes, he fell seriously sick. His sufferings, which were most acute, were aggravated by the inattention and want of skill of those around him; in the midst of them however he displayed a cheerful countenance and a holy resignation. He died December 2, 1552. His remains were brought over to Malacca on the 22nd of March, 1553, where they were received with the greatest honour; they were afterwards transferred to Goa, and deposited in the principal chapel of the church of Paul, on the 15th of March, 1554. The memory of Francis Xavier was consecrated by a ceremony known in the church of Rome by the name of Beatification, by the Pope Paul V., in 1619, and he was canonized as a Saint by Gregory XV. in 1622. In 1747, John V. King of Portugal, obtained a brief of Benedict XIV., which conferred on him the title of patron and protector of the East Indies. His festival is observed by the Church of Rome on 3rd of December.

The following works are all that Francis Xavier has left:—1, a Collection of Epistles, in five books, Paris, 1631, in 8vo.; 2, a Catechism; and, 3, 'Opuscula.'

(Alban Butler, *Lives of the Fathers, Martyrs, and the other principal Saints*, vol. xii. p. 29-40, Derby, 1846: in this biography there is an error in the date both of his beatification and canonization; *Biographie Universelle*, tome li.; the article 'Xavier' in this work is by Léguy; Fabre, *Continuation de l'Histoire Ecclésiastique de Fleury*, livres cxxxv., cxxxix.-cxli., cxliv.-cxlviii.; *Lettres édifiantes et curieuses, écrites par des Missionnaires de la Compagnie de Jesus*, 40 vols., Paris, 1832, vol. xxvii., a work of great curiosity and interest, and not sufficiently known in England; *Pen. Cyclo.* art. 'Missions;' the statement made in it that Xavier was canonized by Urban VIII. is erroneous, but it is true that this pope first gave him the title of the Apostle of the Indies. The Life of St. Francis Xavier has also been written in Latin, by Turselinus, Rome, 1594; in Italian, by Orlandino, Bartoli, and Maffei; and in French, by Bouhours, a work which was translated into English by Dryden in 1688.)

XULIONOSPRIONI'TES, one of the fossil fruits of Sheppey. (Bowerbank.)

XYLO'PIA, a genus of plants belonging to the natural order Anonaceae. It has 6 petals and numerous stamens; the calyx from 3- to 5-lobed, the segments ovate, conaceous, and acute; the ovaries distinct and numerous; the ovules ascending in one row attached to the central angle; the carpels indefinite, ovate, compressed, indehiscent, stalked, and from 1- to 4-seeded.

X. longifolia is a tree 70 feet high, the leaves oblong, acuminated, silky, and shining beneath, revolute at the margin, especially near the base. The peduncles are from 2 to 4, axillary and smooth; the three outer petals oblong, linear, acuminate, silky, brownish, externally white, and excavated in the inside; the three interior ones linear, white, red at the base, 3-cornered at the point.

X. glabra is a tree native of Jamaica and Barbadoes. The branches are smooth and scarcely dotted; the leaves oblong, ovate, and smooth, on very short stalks. The peduncles are 1-flowered, solitary or in pairs. The calyx is smooth, trifid, with very obtuse lobes; the carpels smooth. The flower-buds are oblong, pubescent on the outside. The wood, bark, and berries of this tree have an agreeable bitter taste, similar to that of an orange-seed.

All the species of this genus require a stove-heat. They grow best in sandy loam and peat, and ripened cuttings will root in sand under a hand-glass in moderate heat.

ZAMI'TES, a genus of fossil Cycadeous plants from the oolitic, wealden, and cretaceous formations (Presl.) synonymous with Mantellia and Brongniart.

ZEILA is a town and harbour in Africa, at the western extremity of the Gulf of Aden, not far from the Straits of Bab-el-mandeb. It is situated in 17° 45′ N. lat. and 43° E. long. The harbour is small and shallow, so that even small vessels must anchor at a distance of nearly half a mile from the beach. The town is enclosed by walls now in ruins. The houses, with the exception of eight or ten, which are built of stone, are either of wood or reeds, or of both these materials. Some guns planted on the wall from the land side are a sufficient protection against the Somaulis, who inhabit the surrounding country. The population is stated not to exceed five hundred souls. All families are engaged in trade, Zeila being one of the harbours by which the inhabitants of Hurrar carry on a commercial intercourse with Arabia. Three cafilas arrive annually from the interior, especially from Hurrar. They bring to Zeila slaves, both male and female, large quantities of gum and myrrh, coffee, jowari, ghee, and ostrich feathers, also some grain, especially millet, wheat, and beans. Most of these articles are sent to Mocha, and at present probably also to Aden. In return they take back blue and white coarse cloths, Indian piece-goods, European prints, silks, silk thread, shawls, red cotton yarn called shumlah, beads, zinc, copper-wire, frankincense, and Austrian dollars. Zeila is subject to the Pasha of Egypt, by whose authority the Dolâh of Mokha nominates the Emir Zeïla, who pays an annual tribute of 300 dollars, and keeps a garrison of seventy soldiers, armed in part with matchlocks.

(Isenberg and Krapf, *Journals detailing their proceedings in the Kingdom of Shoa*; Barker, *Report on the probable Geographical Position of Harrar*, in *London Geogr. Journal*, vol. xii.)

ZEMAUN, SHAH. [SHAH ZEMAUN, P. C.]

ZINC, *Medical Properties of.*—In the purely metallic state, zinc produces no effect on the human system, but its combination with oxygen is sufficient to invest it with considerable power over the organs, both those with which it comes into direct contact and some remote ones, especially the nervous centres. Its local action is that of an irritant, astringent, and desiccative, while its remote action is that of a tonic and antispasmodic. Its emetic properties are less than those of the sulphate or acetate, unless it meets with acids in the stomach. In this way it is rarely employed. It is for its remote effects, when taken in small long-continued doses, that it is valued. While it has the properties common to all tho metallic antispasmodics, it is distinguished by its power of restraining inordinate action of the nervous system; being calming and soothing. The brain and the function of sensation appear to feel less of its influence than the spinal chord. Hence the nerves of motion, and the functions of the circulation and respiration, are chiefly acted upon; it produces its effects speedily, but they quickly disappear when given in such doses as can be safely administered. The long-continued use of it seems to produce a dryness and induration of the frame, which if carried to excess is dangerous, but the lesser degree of which is in all probability the source of the utility of this medicine, by diminishing the mobility of the system, irregularities in the circulation, and sudden congestions of blood, being the immediate causes of attacks of epilepsy and hysteria, the diseases which are most benefited by oxide of zinc.

In spasmodic affections of the chest, such as asthma, angina pectoris, and palpitation of the chest, when these do not proceed from organic derangements, oxide of zinc is often serviceable, especially when combined with conium. In the cramps of the stomach to which habitual drunkards are subject, it is very useful.

Impure oxide of zinc is called tutty. It is sometimes used externally as a dusting powder, as a mild absorbent, on excoriations, and to heal chaps and cracks in the skin. It is also used as an ointment. Pure oxide of zinc forms an ointment of much value where a mild astringent is needed, especially in the chronic inflammation of the cyelids.

Carbonate of zinc when impure is termed calamine; this after being subjected to divers processes, is called *prepared* calamine. The only use made of it is to form an ointment, which is most useful as an application to burns, excoriations, and superficial ulcers.

Sulphate of zinc is in small doses a very valuable astringent, tonic, and antispasmodic; in larger doses it is a very certain and speedily acting emetic; and in very large doses it is poisonous. It is the most useful emetic in cases of narcotic poisoning, as it is not so apt to inflame the stomach as tartarized antimony: but the stomach-pump is preferable to either.

The tonic effects are best seen in affections of the mucous membranes. In the suffocative catarrh of aged persons, and the extreme defluxions on the chest after influenza, sulphate of zinc affords a valuable remedy: it must be given in small doses, as the sudden suppression of the secretion may cause inflammation. The use of the solution as an injection requires the same caution.

Acetate of zinc is possessed of nearly similar properties, but in a weaker degree; and as an injection, seems in some cases entitled to a preference.

Chloride of zinc, called also butter of zinc, is a powerful escharotic or caustic; this action results from its strong affinity for albumen and gelatine, which principles it abstracts from the living tissues, and so forms an eschar. Its powers in this way have been taken advantage of to destroy parts affected with malignant diseases, such as cancer and lupus, and to remove naevi materni, or mother-marks. In none of these is it to be resorted to unless they are very superficial. Deep-seated cancer of glands can scarcely be removed by it, but other forms are often successfully treated by it. (Walshe *On Cancer*, p. 219.)

Cyanide or cyanuret of zinc is a powerful antispasmodic and tonic. No medicine is so potent in allaying irritability of the stomach attended with great debility. The dose must be small and often repeated. Valerianate of zinc has lately been much recommended as a remedy against tic-douloureux and other nervous affections. Where the patients can tolerate the repulsive odour and persevere in its use, it often proves very serviceable.

Zinc pans have been much recommended for use in dairies, as the milk speedily coagulates in them, and the quantity of cream is great: but if the milk become sour while in them, the acid acts upon the zinc, and forms unpleasant, though perhaps not poisonous compounds. Upon the whole, white porcelain vessels, kept thoroughly clean, are the best material for milk-vessels.

ZI'NGIBER OFFICINA'LE:—(GINGER), *Medical Properties of.* The native country of this plant seems unknown, though Goebel asserts that it is Guinea. It is however extensively cultivated in China, Java, and the East and West Indies. From the cultivated plant alone is the ginger of commerce procured. Of this there are two varieties, the black and white; but some writers affirm that these are the produce of two distinct species, while others ascribe the difference of appearance to diversity of treatment after the rhizome is dug up. The rhizome or root-stock is perennial, but it is only that of a young plant, or the annual shoots from an old one, which are met with in commerce. When first dug up, the colour internally is red. Those procured the first year are used fresh, or preserved in sugar, and constitute the sweetmeat known as *preserved ginger*. This, when sent from the West Indies, is in small, round, tender pieces; when from the East, larger, flat, and stringy portions: the former is preferred.

Black ginger is stated to be the rhizome dug up, scalded in hot water, and dried in the sun. White ginger is also scalded, and then scraped to free it from the rind before it is dried, which last operation is said to be effected by artificial heat, but probably mostly by the sun. Both kinds are very liable to the attacks of an insect: to prevent these attacks the rhizomes are dipped in a solution of lime; the white particles of which often adhere to the surface. To cause black ginger to resemble the white it is bleached, after its arrival in this country, in a solution of chloride of lime, or exposed to the fumes of burning sulphur. This impairs the activity of the article.

Ginger occurs in commerce in pieces termed *races*, of various shapes, but generally flattish, branched, lobed, or palmated, rarely more than four inches long. The unscraped has a wrinkled epidermis; the scraped is devoid of this covering. Jamaica ginger, which is most esteemed in this country, occurs in races larger, rounder, and thinner than the other kinds; externally of a yellowish white, internally of a yellower hue. The taste is agreeably aromatic and pungent, but this is lost with age, so that old pieces are worthless, as are also portions which have been digested in alcohol to form *essence of ginger*. Ginger when chewed excites a flow of saliva; the powder applied to the nostrils causes sneezing. The quantitative analysis of 100 parts of ginger has been given by Bucholz:—

Pale yellow volatile oil	1·56
Aromatic, acrid, soft resin	3·60
Extractive soluble in alcohol	0·65
Acidulous and acrid extractive, insoluble in alcohol	10 50
Gum	12·05
Starch (analogous to bassorin)	19·95
Apotheme, extracted by potash	26·00
Bassorin	8·30
Woody fibre	8·00
Water	11·90
	102·31

Morin's analysis yields also acetic acid, acetate of potash, and sulphur; while the ashes give numerous metallic salts and alkaline salts.

The volatile oil is of a pale yellow, lighter than water; taste at first mild, then hot. The soft resin, obtained by digesting the alcoholic extract of ginger first in water, then in æther, and evaporating the etherial tincture, is not quite analogous to the principle *zingiberin*, procured by Beral, and by him termed *peperoid*. This last is got by submitting ginger directly to the action of sulphuric æther. Beral recommends many preparations of this principle, but, except from their smaller bulk, it is difficult to perceive what advantage they possesses over common ginger and its preparations. Ginger is an aromatic stimulant of considerable power. The effects are greater on organs with which it comes into direct contact than on remoter ones. Thus, when chewed, it is a powerful sialogue, and relieves tooth-ache, rheumatism of the jaw, and also relaxed uvula. When received into the stomach, it promotes digestion in languid habits, and relieves flatulent colic. Gouty subjects are much benefited by it, and for such persons no form is more beneficial than that of preserved ginger taken at dessert after a mixture of viands. But it has the disadvantage of impairing the flavour of the wine taken at the same time.

The action of ginger on remote organs is greatest on the mucous membranes. Hence the lungs are markedly excited in the relaxed and suffocative catarrh of old people. The mucous membranes of the urino-genital organs are also excited by it in languid habits; many feeble females receive much advantage from the domestic preparation termed ginger-tea. Some headaches of a sympathetic kind, originating in irritation of the intestinal canal, are often relieved by it. A poultice of scraped ginger, to which warm water has been added, forms a substitute for a mustard poultice, and often relieves headache when applied to the forehead. Ginger-beer is often a grateful beverage in summer heat, but with some persons it disagrees; this is owing to the sugar, for if made without it, it agrees with such persons well. Lemon-juice, when taken with sugar, often disagrees, as for example with pancakes. The lemon-juice alone is most wholesome.
