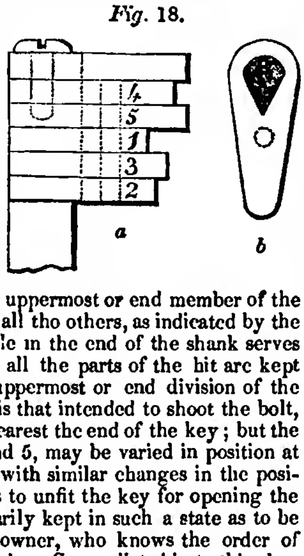
As a means of security somewhat differing from any of the above, and affording certain advantages peculiar to itself, we may here notice the *permutation* or *combination* principle, of which the simplest application is in a kind of padlock often termed a puzzle-lock, which opens without a key, but is regarded rather as an ingenious toy than as an available substitute for locks of the more usual construction. In the commonest form of these locks a bar, with square or other projections from one or more of its sides, is slipped through a series of circular plates or discs, each of which is capable of being turned round upon it as an axis. The holes or apertures through the centres of these circular plates, discs, or rings, are so formed that unless the whole of them are turned round to the exact position which they occupied when the bar was slipped in, it cannot be withdrawn. To provide for bringing the rings to this position after they have been disturbed from it, the periphery of each is marked with a series of letters or numbers, a certain predetermined combination of which, which should be known only to the possessor of the lock, must be brought into a straight line by turning the several rings round with the thumb and finger. As the number of combinations which may be effected, like the number of changes in the relative positions of the tumblers or sliders of a Barron's or Bramah's lock, is almost infinite, while only one combination will enable a person to open the lock, a high degree of security may thus be attained. The essential defect of this arrangement is, that the secret of the lock must be known to the person who made it, and is liable to become known to persons from whom it is desirable to secure the lock. The Marquis of Worcester, in whose 'Century of Inventions' several different kinds of lock, which lay claim to the most marvellous properties, are enumerated, would appear, from the seventy-second article in the 'Century,' to have devised an improvement upon this apparatus, as he refers to 'an escutcheon to be placed before any of these locks,' one of the properties of which he describes as being that 'the owner, though a woman, may, with her delicate hand, vary the ways of coming to open the lock ten millions of times beyond the knowledge of the smith that made it, or of me who invented it.' The details of this invention are not given, but in the third volume of the 'Transactions' of the Society of Arts, pp. 160-165, is a description of an escutcheon of similar character, invented by Mr. Marshall, and rewarded by the Society in 1784, in which the escutcheon or door by which the key-hole is closed is held by a pin passing through a similar series of rings to those used in the common letter or puzzle padlock, but with this important difference, that instead of the rings or plates being formed each of a solid piece of metal, each consists of an inner and outer ring; the inner one, which contains the notches for allowing the bar to pass through, being so mounted within the outer one, which has the letters or numbers on its periphery, that it may be turned round within it, or held fast in any required position, at pleasure. The result is, that the relative positions of the internal notches, and the external letters which serve as an index of their situation, may be varied almost infinitely; and thus, whenever the owner suspects that the secret is known to any improper person, he can vary the combination of letters by which the opening is determined. The details of this ingenious contrivance are fully given in the volume above referred to. In the thirty-eighth volume of the 'Transactions' of the Society of Arts, pp. 111-115, is a minute account of a lock invented by Mr. Ainger, in which, in addition to other ingenious features, is an application of the principle of permutation to a key, which provides, without any great complication, the means of not only rendering the imitation of the key all but impossible, but also of so throwing the key itself out of order, that there would be 512 chances to one against a stranger being able to make use of it should it fall into his hands. This paper also describes a means of rendering a draw-back lock or latch as difficult to pick when on the first shoot as when double-locked. Another, and a beautifully simple permutation lock, invented by Mr. Mackinnon, of Sheffield, is described in the fiftieth volume of the same work, part ii. pp. 86-88. It is a tumbler lock, in which each tumbler is numbered, and a corresponding number is stamped upon each of a series of small plates, which, when put together upon an axis at the end of the shank of the key, as represented in *Fig.* 18, which gives a side and end view of the key, constitute, collectively, a bit resembling that of the key of an ordinary tumbler lock. The end view at *b* shows the general form of the several members of the bit, each of which is pierced with two holes, one of such a shape as to fit upon the pear-shaped end of the shank, represented by a tint in *b*, while the other is round, a little in front of that which fits on the shank, to receive a pin which is attached to the uppermost or end member of the bit, and which passes through all the others, as indicated by the dotted lines in *a*. A small hole in the end of the shank serves to receive a screw by which all the parts of the bit are kept firmly in their place. The uppermost or end division of the bit, which is not numbered, is that intended to shoot the bolt, and must always be placed nearest the end of the key; but the others, marked 1, 2, 3, 4, and 5, may be varied in position at pleasure, so as to correspond with similar changes in the positions of the tumblers, or so as to unfit the key for opening the lock. It may thus be ordinarily kept in such a state as to be quite useless to any but the owner, who knows the order of numbers necessary to set it right. Somewhat akin to this class of contrivances is the curious secret lock invented by Mr. Friend, and described in the forty-third volume of the Society's 'Transactions,' pp. 114-118, in which it is impossible to open the lock even with the proper key, without the application, at the same time, of an apparatus which is called the guide, and which is so portable that it may be put into a pocket-book. As the action of the guide depends on the permutation principle, even it will not enable a person unacquainted with the number or cipher to which it is set, and which may be varied as often as necessary, to open the lock.

Fig. 18.



In some locks increased complexity, though it may be doubted whether any practical advantage in increased security, is obtained by the use of two distinct sets of tumblers, capable of impeding each other's motion except when rightly acted upon. Hebert refers to locks of this character, which possess some other features worthy of notice, but which are too much matters of detail to be given here; and Holland gives an engraving of a lock invented by one of the ingenious Strutt family, in which the shooting of the bolt is effected by a knob or handle which raises an ordinary tumbler, which, however, can only be lifted by previously bringing a series of other tumblers into such a position that a notch cut in all their edges shall be brought over a projection from the ordinary or bolt tumbler. The most noticeable feature of this contrivance is, that while the motion of the bit of the key, and consequently of that part of the series of tumblers upon which it acts, is not greater than usual, those edges of the tumblers in which the notch is cut are capable of moving through a large arc, thus affording the opportunity for cutting a great number of serrations, or false notches, upon their edges, to baffle any attempt at picking by the tentative process.

Of some other curious inventions for additional security we can only give a passing notice. Some locks have been made in which the action depends on the key being a powerful magnet. In others the difficulty of opening is increased by requiring a peculiar method of applying the key; but in addition to the circumstance that the secret must be known to several persons, these contrivances have the disadvantage of being very inconvenient in use. As a mere mechanical curiosity we may refer to one, contrived by Mr. Thomas Arkwright, and described in the eighteenth volume of the 'Transactions' of the Society of Arts, pp. 239-242, in which a key with two bits, and requiring eight or nine distinct movements in the act of unlocking, is used with a double lock capable of shooting two distinct bolts. In Mr. Lawson's lock, referred to by Holland, there is a sliding curtain, by which, it is stated, 'the key-hole is so perfectly closed during the act of unlocking, that it would be impossible to move the bolt while a pick remains in the aperture.' In Gottlieb's lock, patented in 1829, a piece of paper is so placed that no key can be put in without perforating it, and that it cannot be removed excepting by an application of the proper key; and to prevent the possibility of substituting a fresh paper, its inventor proposed to use pieces bearing some device, and torn from a cheque-book which would serve as a tally. In 1831 a patent was obtained by Mr. Rutherford, of Jedburgh, for the application of a stop-plate to the bolt of a lock in such a manner that it should be impossible to open the lock with its own key until, by the action of clockwork within or connected with the lock, the stop-plate should be brought into a certain position. By this contrivance a person locking up a bank-safe, cash-box, or a package intended to be sent to a distance, may so arrange the lock that it cannot be opened until the expiration of a certain number of hours. Many contrivances have been effected for attaching an alarum to locks, by which the introduction of a false key should ring a bell or fire a pistol. A good alarum-lock, acting upon a bell enclosed within the case or box of the lock itself, invented by Mr. Meighan, is described in the 'Transactions' of the Society of Arts, vol. li. part i. pp. 128-130.

The compound locks used for the doors of iron safes, and for similar purposes, though ponderous and complicated in their appearance, are, in reality, of simple construction. Although they often throw out two or three bolts in every direction, that is to say, on each side, and towards the top and bottom of the door, these are usually but so many branches of four massive pieces of iron, capable of being simultaneously projected or retracted by a fixed or removeable handle in the centre of the door; the actual lock being but small, and merely intended to move an apparatus by which the great bolts are themselves locked or held fast; so that the key need not bear any proportion to the magnitude of the bolts by which the door is secured. In such cases a single lock may be made to serve for securing all the bolts; but in an excellent quadruple lock invented by Mr. D..ce, of Wolverhampton, rewarded by the Society of Arts in 1823, and published in the forty-second volume of their 'Transactions,' p. 125, four bolts, each secured by a distinct set of tumblers resembling those used in Chubb's locks, are shot in succession by a single key, in one complete revolution. To pick this lock, therefore, would require as much time and trouble as to pick four distinct locks of the same kind.

In conclusion, without attempting even to enumerate the various kinds of lock in common use, we may notice two useful inventions relating to street-door locks. Of the contrivances for moving draw-back and other bolts by means of fixed handles we have said nothing, as these are matters readily understood by an inspection of any common door-lock, and are not essentially connected with the principles of security. It is a defect of ordinary draw-back locks that occasionally, from want of oil, from the bevelled end of the bolt becoming rusty, or from some other cause, they will not close without slamming the door violently, and are liable not to act at all, so that the door may be, to all appearance, shut properly, without the bolt shooting into its socket. To remedy these inconveniences, Mr. Bullock devised, and submitted to the Society of Arts in 1801, a very simple addition to the ordinary door-lock, consisting of an internal catch which detains the bolt when it is drawn back, but is released the instant the door is thoroughly closed, by the pressure of a small projecting piece against the check or jamb of the doorway. The details are fully given in the Society's 'Transactions,' vol. xix. pp. 290-293. The second invention referred to is Chubb's combination latch, which combines the simple lifting action of the ordinary French latch, or that which opens with a handle inside the door, and with a key from without, with much of the security of a tumbler lock. In it two, three, four, or more distinct latches are mounted, like a series of tumblers, upon one axis, and made to shut into or behind a double catch, in such a way that they can only be disengaged from it by being all of them raised at once to one exact height, by an arrangement similar to that by which a series of tumblers are raised.

LOCUST (the *Gryllus migratorius* of Linnæus, *Locusta migratoria* of modern entomologists), a well-known insect, belonging to the order *Orthoptera* and family *Locustidæ*. Locusts are endowed with great strength for leaping and flying, and, being gregarious, are thus enabled to commit great devastation, so that when a swarm has destroyed the vegetation of one district, they are enabled to take flight to and traverse another even though at a considerable distance. The migratory locust has occasionally visited England, and about the middle of the last century did some damage in many parts of our own country. In Southern Europe, the East and Northern Africa, this species and its allies are exceedingly destructive, the swarms being so vast as to destroy all vegetation, whilst the putrifying carcasses of their dead infect the air. The Arabs and people of Nigritia use these insects as food. For full details of the habits, &c. of the Locusts, see Kirby and Spence, *Introduction to Entomology*.

LODGE, THOMAS, is supposed to have been born about the year 1556. He was entered at Trinity College, Oxford, in 1573, took a degree, and then, going to London, became an actor and play-writer. About 1580, in an answer to Gosson's 'School of Abuse,' he wrote a 'Defence of Stage-plays,' which was suppressed by authority, and is now one of the rarest of English books, only two copies being known. Another work of Lodge, his 'Alarum against Usurers,' which takes up incidentally the defence of the stage, was printed in 1584. In the same year he was a student of Lincoln's Inn. Afterwards, it has been conjectured, he became a soldier; and it is known that, in some capacity or other, he accompanied the expeditions of Clarke and Cavendish. According to the opinion most commonly received by the historians of our early literature, this flighty person went through yet another change; for he is usually identified with a Doctor Lodge, who took his degree in medicine at Avignon, printed in 1603 'A Treatise on the Plague,' and in 1616 obtained a passport from the Privy Council to 'travel into the Archduke's country,' and recover debts owing to him. Lodge is believed to have died of the plague in 1625.

He was a voluminous and versatile writer. He translated Josephus and Seneca ('The Works of Josephus,' Lond. 1602, fol.; 'Seneca's Works, both Moral and Natural,' Lond. 1614, fol.); he wrote several novels, volumes of verses, and miscellaneous pamphlets; and he was a distinguished contributor to the drama in the years immediately preceding the appearance of Shakspere. His extant dramatic works are two: 1, 'The Wounds of Civil War, lively set forth in the True Tragedies of Marius and Sylla,' 1594, 4to., reprinted in the last edition of Dodsley's Old Plays, vol. viii.; a stately historical play, with some eloquence, much action, and little interest either of character or incident. 2, 'A Looking Glass for London and Englande; made by Thomas Lodge, Gent., and Robert Greene, in Artibus Magister,' 1594, 1598, 1602, 1617, 4to.; a whimsical but animated dramatic picture, alluded to already in our notice of Greene. But Lodge's own exertions as a dramatist, although they entitle his name to a place beside those of Greene and Peele, are less interesting to us than the assistance which one of his works furnished to a greater than himself. One of his novels is entitled 'Rosalynde: Euphues Golden Legacie; found after his death in his cell at Silexedra. Bequeathed to Philantus Sonnes, noursed up with their Father in England. Fetcht from the Canaries;' 1590, 1592, 1620, 1623, 1642, &c., 4to.; reprinted in Mr. Collier's 'Shakespeare's Library,' 1840. From this novel Shakspere borrowed closely the leading incidents (indeed many also of the minor ones), the grouping of the characters, and many of the strokes of portraiture, for his 'As You Like It.' While a perusal of the novel cannot diminish our admiration of the play, it is yet an agreeable duty. In the midst of much that is unskilful, somewhat that is dull, and a good deal in the bad taste of Lyly's Euphues, the novel is yet interesting, lively on the whole, and in many places finely poetical, both in its prose descriptions and narratives, and in the interspersed verses.

LODGINGS, THE LAW OF, differs according to the custom which regulates each particular case from the general rules of law between landlord and tenant. [TENANT AND LANDLORD, P. C.]

As the length of the term for which lodgings are let seldom exceeds or even extends to a year, it is rarely the case that a six months' notice to quit is necessary to be given by the party wishing to determine the tenancy. This can only happen when it is clearly understood that the tenancy is from year to year. But if the taking be for less than a year, as for a quarter, a month, or a week, which may be presumed from the rent being paid at the lapse of those terms, or other circumstances, the length of notice will be regulated accordingly, as a month for a month, and a week for a week, the expiration of the notice being that of the term. Unless the lodger gives up possession paying the rent for a whole term in advance, notice must always be given, and he will not be released from such a necessity merely from an apprehension, however just, of his goods being distrained for his landlord's rent.

A contract to let lodgings being a contract for land under the interpretation of the Statute of Frauds, unless such contract be in writing an action for use and occupation cannot be maintained against the party refusing to enter.

Lodgers are entitled without special contract to the use of such things as, though situated in another part of the house, are necessary to their convenience, as the knocker, door-bell, skylight, &c.

It has been held that a covenant by the lessee not to underlet, is not broken by taking in a lodger, and on this ground may be rested the right of the original landlord to enter and distrain the goods and chattels of the lodger for arrears of rent due from the lessee, it being considered that the occupation of the lodger is that of the lessee. The lodger however can resort to his right to recover against the lessee for the loss so incurred.

The 7 & 8 Geo. IV. c. 29, § 45, protects the property of those who let lodgings from the dishonesty of their tenants by making it felony for the person in occupation to steal or appropriate any chattel or fixture allowed to be used in any house or lodging.

(For the law relating to this subject see Woodfall, *Landlord and Tenant*; and Coote, *Landlord and Tenant*.)

LOGAN, JOHN, was born at Fala, in the county of Edinburgh, in 1748. He was the son of a small farmer, and, being destined to the clerical profession, was educated in the University of Edinburgh; after which he became tutor to the late Sir John Sinclair. In 1773, almost immediately on being licensed as a preacher in the Established Church of Scotland, he was appointed to be one of the ministers of the town of Leith. In 1770 he had edited the posthumous poems of his friend Michael Bruce, incorporating with them some pieces which he claimed (and probably justly) as his own, and among which was the well-known Ode to the Cuckoo. His poetical talents were further shown by several pieces of sacred poetry, some of which are inserted in the collection of hymns and paraphrases of Scripture annexed to the psalmody of the Scottish church. In 1779, patronized by Blair, Robertson, and other literary men, he delivered in Edinburgh a course of Lectures on the Philosophy of History; the reputation of which justified him next year in aspiring, though unsuccessfully, to the Professorship of Universal History in the University. Outlines of a part of his lectures were published under the title of 'Elements of the Philosophy of History, Part I.,' 1781. In the same year appeared his 'Dissertation on the Government, Manners, and Spirit of Asia;' and a volume of Poems, which reached a second edition before the year was closed. Logan, if not a learned divine, or a very profound thinker, was a man of much eloquence, and a highly popular preacher. But his poetical endowments, strongly lyrical in their tendency, were the highest he possessed; and unfortunately he was tempted to apply these in a path where he was ill calculated to shine, and the adoption of which proved fatal not only to his professional usefulness, but to his happiness. In 1783 he printed and caused to be acted in Edinburgh a tragedy called 'Runnamede,' which had been rehearsed at Covent Garden, but refused a licence by the Lord Chamberlain. This publication brought on him the anger of his Presbyterian associates; and these and other annoyances, aggravated by an hereditary tendency to hypochondria, drove him to intoxication for relief. In 1785 he quitted his parochial charge and repaired to London. There, retaining by agreement a part of his clerical income, he eked out his livelihood by literary labour, writing papers for the 'English Review,' and publishing, in 1788, two works. The one was 'A Review of the principal Charges against Mr. Hastings,' which brought on Mr. Stockdale, the publisher, a prosecution for breach of privilege; the other was a useful summary, entitled 'A View of Ancient History, including The Progress of Literature and the Fine Arts, by William Rutherford, D.D., Master of the Academy at Uxbridge,' 2 vols., 8vo. He died in London on the 28th of December, 1788. His friends Drs. Blair, Robertson, and Hardy, published a volume of his Sermons in 1790, and a second in 1791. These sermons long enjoyed very great popularity, and have been several times reprinted. They are among the most eloquent that the Scottish church has produced. A third edition of his poems, with an account of his life, appeared in 1805; and the poems are included in Dr. Anderson's collection.

LOGARITHMS, GAUSS'S. These are tables suggested by the celebrated Gauss for supplying an inconvenience connected with the use of logarithms described in § 21 of the following article. Though they have been suggested more than thirty years, they are only beginning to receive the attention which they merit.

If log a and log b be given, and log $(a+b)$ or log $(a-b)$ be wanted, the ordinary tables can only be applied by finding a and b from their logarithms, adding or subtracting them as found, and then finding the logarithm of the sum or difference. This requires three uses of the tables, and one process of addition or subtraction. Gauss's table substitutes one use of a table, and two processes of addition or subtraction. When the above necessity occurs only now and then, it may be hardly worth while to have recourse to such a table; but in any series of calculations in which the determination of log $(a \pm b)$ from log a and log b is a frequent constituent part, the table is a very great relief.

The construction of the table is as follows: There are three columns, styled A, B, C; the first, A, containing the *arguments*. [TABLE, P. C.] Also B and C are furnished with differences and tables of proportional parts, in the same manner as the seven-figure logarithms. In column A are entered successive decimal fractions, in a manner depending upon the extent of the table. In the one we shall mention, A contains ·0000, ·0001, ·0002, &c., up to 2·0000; then 2·001, 2·002, &c., up to 3·000; then 3·01, 3·02, &c., up to 4·00; then 4·1, 4·2, &c., up to 5·0, followed by 6 and 7. And whatever an A may be the logarithm of, say N, then its B is the logarithm of $1+\frac{1}{N}$, and its C is the logarithm of 1 + N. Thus, opposite to 2·00 in A, which is the logarithm of 100, the B is log 1·01, the C is log 101; accordingly in one part of the table we see

A	B	C
2·00	·0043214	2·0043214

Again, in another part of the table we see

A	B	C
·4845	·1031058	·6076058

And it will be found that ·4845 being the logarithm of N (not mentioned; it is 3·041406), ·1031058 is the logarithm of $1+1 \div N$, and ·6076058 of 1 + N.

The manner of using this table is as follows: Let x and y be two numbers, of which x is the greater, and let log x and log y be given. Then

1. To find $\log (x+y)$. Let $A = \log x - \log y$
   $\log (x+y) = \log x + B = \log y + C$
2. To find $\log (x-y)$. Let $B = \log x - \log y$
   $\log (x-y) = \log y - A = \log x - C$

Or thus: Let $\log x - \log y = C$
   $\log (x-y) = \log y + A = \log x - B$

It seems as if this were two tables, each of which might serve all purposes. And it is true that $\log (x+y)$ can always be found from either table. But the B table begins from ·3010300 or log 2, and *descends*, while the C table begins from the same, and *ascends*. Consequently ·23, for instance, cannot be found about the C's, nor ·32 among the B's. So that in finding $\log (x-y)$, $\log x - \log y$ must not be made B if it be greater than log 2, nor C if it be less.

For a list of tables published in aid of the above method, see TABLES, P. C. S.

LOGARITHMS, HYPERBOLIC. As tables of hyperbolic logarithms are not very frequently met with, the following table is given to facilitate the finding of the hyperbolic logarithm by means of the common one. It is in fact a table of the hyperbolic logarithms of the powers of 10: thus opposite to 12 we see 27·63102112, which is the hyperbolic logarithm of 10^{12}, or a million of millions.

To find the hyperbolic logarithm of a number, multiply the common logarithm of that number by 2·30258509, by means of the table. Set down the number opposite to the integer of the logarithm, then that opposite to the first pair of decimal figures, leaving out the two last figures, then that opposite to the second pair, leaving out the four last figures, and so on. Add the results together. But if the characteristic of the common logarithm be negative, subtract the united results of the pairs of decimal places from the result of the characteristic, and make the answer negative. For example, required the hyperbolic logarithms of 327 and of ·00142. The common logarithm of 327 is 2·5145478.

2·	4·60517019
51	1·17431839
45	1036163
47	10822
80	184
Hyp. log. 327	5·78996027

The answer can be depended on to about a unit in the seventh decimal place, and 5·7899602 is the answer to seven places.

Again, the common logarithm of ·00142 is $\bar{3}$·1522883

−3·	−6·90775528	
15	34538776	Subtract
22	506568	
88	20262	
30	69	
	−6·55709853	

Hence the hyperbolic logarithm of ·00142 is −6·5570985.

1	2·30258509	34	78·28789316	67	154·27320123
2	4·60517019	35	80·59047826	68	156·57578632
3	6·90775528	36	82·89306335	69	158·87837142
4	9·21034037	37	85·19564844	70	161·18095651
5	11·51292547	38	87·49823353	71	163·48354160
6	13·81551056	39	89·80081863	72	165·78612670
7	16·11809565	40	92·10340372	73	168·08871179
8	18·42068074	41	94·40598881	74	170·39129688
9	20·72326584	42	96·70857391	75	172·69388198
10	23·02585093	43	99·01115900	76	174·99646707
11	25·32843602	44	101·31374409	77	177·29905216
12	27·63102112	45	103·61632919	78	179·60163725
13	29·93360621	46	105·91891428	79	181·90422235
14	32·23619130	47	108·22149937	80	184·20680744

LOGARITHMS, USE OF. We have thought it advisable to add to this work directions on the method of using logarithms, independent of all considerations connected with the meaning and theory of these numbers. Thus a person who has a table of logarithms, and finds its preliminary explanations not sufficiently clear or complete, may possibly receive help from this article, which is not written to accompany any system of tables in particu... There are many reasons against our inserting the table of logarithms itself in a large work of reference, as was frequently done a century ago: we are pretty certain that it would not be used. ..

1. The object of logarithms is the performance of the second and third operations in the following ascending scales by means of the more easy one which precedes it:—

Addition,	Multiplication,	Raising of Powers.
Subtraction,	Division,	Extraction of Roots.

Thus multiplication is reduced to addition, raising of powers to multiplication, division to subtraction, extraction of roots to division.

2. The sum of the logarithms of two numbers gives the logarithm of their product, the difference of two logarithms gives the logarithm of the quotient, and so on. These rules are best expressed in symbols, thus:

$$\log A + \log B = \log (A \times B)$$

$$\log A - \log B = \log \left(A \div B \text{ or } \frac{A}{B}\right)$$

$$\log (A^m) \quad = m \times \log A$$

$$\log (\sqrt[m]{A}) \quad = \log A \div m$$

3. The logarithms wanted are taken partly from a table, partly from an easily remembered rule. The integer part of the logarithm is found by the rule; the fractional part by the table.

4. The integer portion of the logarithm is called the *characteristic* of the number: thus 2167·3 has 3·33592 for its logarithm, and 3 is the characteristic of 2167·3. It is very common to call this 3 the characteristic of the logarithm itself; but it is better to fix this appellation upon it in connection with the number from which it arises.

5. The characteristic of a number depends entirely upon the place which the decimal point occupies. But the rest, or fractional part, of the logarithm of that number depends upon the significant figures only of the number, and has no connection with the meaning which those figures gain by their position relatively to the decimal point. Thus ·21673, 21·673, ·00021673, 21673, 21673000, &c. are numbers with different characteristics, or different integer portions in their logarithms. But the fractional portions are the same in the logarithms of all, namely, ·33592.

6. The characteristic of a number may be either *positive* or *negative*. For our present purpose, it will be sufficient to lay down the rules for using these quantities, directing the reader who is not used to the distinction to try to explain them by considering positive quantities as gains, negative quantities as losses, addition as junction, subtraction as removal. Thus the addition of a positive quantity (annexation of a gain) is the same thing as the subtraction of a negative quantity (removal of a loss); and so on. The following examples will illustrate this; the negative quantity being distinguished from the positive one by a bar drawn above it:—

8 and $\overline{5}$ make 3.	$\overline{2}$ from $\overline{3}$ gives $\overline{1}$.
8 and $\overline{11}$ make $\overline{3}$.	$\overline{2}$ from 3 .... 5.
$\overline{2}$ and $\overline{7}$ make $\overline{9}$.	3 from $\overline{2}$ .... $\overline{5}$.
4 times $\overline{6}$ is $\overline{24}$;	$\overline{3}$ from $\overline{2}$ .... 1.
carry 3, which gives $\overline{21}$.	$\overline{8}$ from $\overline{3}$ .... 5.

7. The rule for finding the characteristic is as follows. When there are significant figures before the decimal point, the characteristic is one less than the number of them. But when the significant figures begin after the decimal point, the characteristic must be marked negative, and must point out *the place in which significance begins.* Thus the characteristic of 2791·68 is 3; that of 17462 is 4; that of 29·137 is 1; that of 9·999 is 0; that of ·763 is $\overline{1}$; that of ·0198 is $\overline{2}$, that of ·000072 is $\overline{5}$.

8. It is worth while to remark that this broken rule, as it seems to be, requires subdivision only on account of the notions generally attached to the *decimal point*, which is treated as if it were one of the places of the number. But if the decimal point were, as it ought to be, considered as part and parcel of the *unit's place*, so that 12·34, for instance, is not | 1 | 2 | · | 3 | 4 |, but | 1 | 2· | 3 | 4 |, then the two rules might be given under one, as follows. The characteristic of a number is the number of places by which the first significant figure is distant from the unit's place; and is positive when that first figure falls to the left, negative when to the right. Thus in 1234·567 or 123 (4·) 567 it is 3; in ·00029 or (0·) 00029 it is $\overline{4}$.

9. A mixed number, such as $\overline{3}$· 92741, is thus multiplied and divided:

$$\begin{array}{r} \overline{3}\cdot\ 92741 \\ 6 \\ \hline \overline{13}\cdot\ 56446 \end{array} \qquad\qquad \begin{array}{l} 6)\overline{8}\cdot\ 92741 \\ \hline \quad\overline{1}\cdot\ 65457 \end{array}$$

In multiplication, the multiplication of the negative figure produces a negative result, and the carriage from the positive part goes in diminution of this number. The last step is:— 6 times $\overline{3}$ is $\overline{18}$, and 5 is $\overline{13}$. In division, a divisible figure must be sought above the negative characteristic, not below it; and the units necessary to make up that divisible figure must be afterwards carried to the right in the usual way. Thus when $\overline{21}$·116 is divided by 5, the first step is:—5 is contained in $\overline{25}$, $\overline{5}$ times, carry 4; then 5 is contained in 41, 8 times, &c.

$$\begin{array}{l} 5)\overline{21}\cdot 116 \\ \hline \quad\overline{5}\cdot 823 \end{array} \qquad \begin{array}{l} 11)\overline{8}\cdot 212 \\ \hline \quad\ \overline{1}\cdot 292 \end{array} \qquad \begin{array}{l} 10)\overline{31}\cdot 606 \\ \hline \quad\ \overline{4}\cdot 961 \end{array}$$

10. The decimal part of the logarithm is taken out of the tables. These are not complete logarithms, which could not be given, since the real logarithms are generally interminable decimals. The only numbers which have logarithms capable of finite expression (in the system commonly used) are those in the series .... ·0001, ·001, ·01, ·1, 1, 10, 100, 1000, ... of which the complete logarithms are the characteristics themselves, or .... $\overline{4}$, $\overline{3}$, $\overline{2}$, $\overline{1}$, 0, 1, 2, 3, ... The tables give only a certain number of the first decimal places, and may be named after the number of decimals in the logarithms they give. Thus a table which gives four decimals in each logarithm may be called a four-figure table; and so on. A calculator chooses his table according to the degree of accuracy he wants: the general rule being that, so many decimals as there are in the logarithms, so many significant figures of the answer may be found correct, with perhaps an error of a unit or two in the last figure. Thus if the real answer to a question were ·00123769728, we might expect from four-figure tables to get ·001236, ·001237, ·001238, or ·001239. But seven-figure tables would probably give from ·001237695 to ·001237699. Perhaps the liability of the last figure to error is, for the general run of questions, rather over than under stated in the above. Four figures is very often enough; five figures almost always. When five figures are not sufficient, we should recommend having recourse to seven at once, for a reason presently mentioned.

11. We insert specimens of a four-figure, five-figure, and a seven-figure table.

Four-figure Table.

12. To find the logarithms of numbers and the numbers to logarithms, from the four-figure table, proceed as follows:— From inspection of the number, take the proper characteristic, and then note the first four *significant* figures. In the row which begins with the *first two*, find the figures which are in the column headed by the *third;* and add to them tho figures out of the side table which are in the column headed by the *fourth*. For instance, required, as well as it can be given from a four-figure table, the logarithm of 4275898·116. The characteristic is 6: and the first four significants are 4276 (reading 58 rather as 60 than as 50). In the row 42, and under 7, we see 6304, and in the side tablo opposite to 6 is 6, and 6304 + 6 is 6310. Hence 6·6310 is the logarithm of 4275898·116, as far as the four-figure table will give it. Similarly the logarithm of ·4 (which must be read ·400) is $\bar{1}$·6021, that of 430 is 2·6335, that of ·04179 is $\bar{2}$·6210.

To find the number to a logarithm, *in the four-figure table*, use the *decimals* of the logarithm with the antilogarithmic table in the same manner as the four significants of the number were used in the other table to find the logarithm; and then settle the place of the decimal point by means of the *integer* of the logarithm. The four-figure table goes into so small a space that it is worth while to print an inverse table of *antilogarithms*, or of numbers to logarithms; of which table we have also given a specimen above. Thus the number to the logarithm 5·6234 being required, we neglect 5, and, going into the anti-table with ·6234, opposite to ·62 and under 3 we find 4198, and under 4 in the side table wo find 4. Hence 4198 + 4 or 4202 are the first four significants of the number required; and its characteristic is 5: whence 420200 is the number to the logarithm, as near as the four-figure table will give it. Similarly the number to ·6111 is 4·084, that to $\bar{3}$·6208 is ·004177, that to 9·6000 is 3981000000.

13. We give an instance of the application of each of the rules in § 2. Let it be required to find, as nearly as four-figure tables will do it, the product of 17798 and 63426; the quotient of 17·293 divided by ·942942; the eighth power of 1·9273, and the eleventh root of ·00005569181. The processes are as follows:—

Log. of 17798 (say 17800) 4·2504 } Add
Log. of 63426 (say 63430) 4·8023 }

Log. of product 9·0527

Answer 1129000000 from the table.
True Answer 1128855948

Error 144052, about ·0001 of the whole.

Again, log. 17·293 (say 17·29) 1·2377 } Subtract
log. ·942942 (·9429) $\bar{1}$·9745 }

log. of quotient 1·2632
Answer 18·33.

log. 1·9273 (say 1·927) 0·2849
multiply by 8

log. of $(1\cdot927)^8$ 2·2792
Answer 190·2.

In raising powers, the errors are generally larger than in other processes, seeing that the necessary error of the logarithm is multiplied as many times as the logarithm itself.

log ·00005569181 (say ·00005569) $\bar{5}$·7458
Divide by 11 $\bar{1}$·6133 log $\sqrt[11]{\cdot00005569}$
Answer ·4105.

14. Before beginning to use five-figure tables, it is advisable to practise the formation of the tenths of numbers not exceeding 50, in the head. For instance, which is the nearest integer to 7-tenths of 37. The process at length would of course be

$$\begin{array}{r} 37 \\ 7 \\ \hline 10)259 \\ \hline 25\cdot9 \end{array}$$

Nearest integer 26

It should be done thus: Having multiplied 7 by 7, and got 49, reject the units, and carry 5 as the *nearest* number of tens. Then add 5 to 21 obtained from the three. When 5 units are thrown away, consider the ten next above as the nearest. Thus 9-tenths of 45 should be considered as 41, not 40, and 5-tenths of 17 as 9, not 8. Similarly, 8-tenths of 21 is 17; 3-tenths of 19 is 6. But 2-tenths of 32 is 6; 7-tenths of 42 is 29; 9-tenths of 28 is 25.

15. In the specimen of the five-figure table will be seen four figures of number, followed by five figures of logarithms, and an additional column marked D, which contains nothing but the differences between the successive sets of five figures in the logarithm. This column D is referred to under tho name of the column of *tabular differences*. To take the logarithm of a number, tako the characteristic as before, and five significants of the number. Find out the first four significants in the table, and to their five figures of logarithm *add* as many tenths of the tabular difference as there are units in the fifth significant. Thus to find the logarithm of ·011217, we find 1121 in the specimen, opposite to which is 04961, with 38 for a tabular difference. Now 7-tenths of 38 is 27, and 61 and 27 is 88; so ·04988 is the decimal part of the logarithm. Similarly if the significants of the number be 11223, the decimals of tho logarithm are ·05011; also 11201 gives ·04926; 11209 gives ·04957; 58332 gives ·76591; 58333 also gives ·76591; 58334 gives ·76592; and so on.

16. There is no antilogarithmic table to a five-figure table; and the way of finding the number to a logarithm is as follows: Seek out among the logarithms tho decimals *next under* the decimals of the given logarithm, and take the four figures of number belonging to them for the first four significants of the number. Find by how much the decimals just used fall short of the given decimals, and call this difference the *unattained part*. Annex a cipher to the unattained part, and divide by the tabular difference; the digit which most nearly expresses the quotient is the fifth significant of the number. For instance, what is the number to the logarithm $\bar{3}$·05016. Looking into the table, we find that the next under ·05016 is 04999, opposite to 1122. Tho unattained part is 17; the tabular difference 39: and 170 contains 39 4 times moro nearly than 5 times; so that 4 is the fifth figure. The fivo significants of tho number required are then 11224; and, looking at tho integer part of the logarithm, the characteristic is seen to be $\bar{3}$; whence ·0011224 is the number to the logarithm, as correctly as five-figure tables will give it.

17. The four questions worked above with four-figure logarithms are thus worked with five-figure logarithms:—

17798	4·25037
63426	4·80227
1128900000	9·05264
	05231
	38)330
1·9273	0·28495
	8
190·37	2·27960
	27944
	23)160

17·293	1·23787
·94294	$\bar{1}$·97449
18·339	1·26338
	26316
	24)220
·000055692,	11)$\bar{5}$·74580
·41044	$\bar{1}$·61325
	61321
	10)40

18. The seven-figure tables have five figures of number, with seven decimals of logarithm; and the sixth and seventh significants of the number are to be provided for by means of the tabular differences. But as these tabular differences run to three and four places of figures, their tenths are written down in small separate tables. [PROPORTIONAL PARTS, P. C.] To take out a logarithm, take out the seven decimals belonging to the first five significants of the number, and add from the table of proportional parts the number opposite to the sixth significant, and one-tenth of that opposite to the seventh significant. Thus to find the logarithm of 455173689, of which the first seven significants are 4551737, look in the table for 45517, and we have

	45517 ..	gives	6581736
Tab. Pro. P.	3	..	29
Do. do.	7		7
			6581772

So the logarithm required, as far as seven-figure tables will give it, is 8·6581772.

A little practice will enable the calculator to add together, without writing them down, the two contingents derived from the table of proportional parts. The computer must be careful not to miss the change of the third figure of a logarithm, which usually takes place in the middle of a line, though it can only be marked at the beginning. Thus, in the specimen the logarithm of 45603 has the decimals 6589934, but that of 45604 has 6590029, not 6580029. Some mark is usually made to give warning that the change has taken place; but those whose attention is so little alive to the circumstance as to stand much in need of this mark will often make the mistake in spite of it.

19. To take the number to a given logarithm out of seven-figure tables proceed as follows: Find the nearest decimals under the given decimals, and by subtraction find the *unattained part*. Take out the five number-figures belonging to the attained part, for the first five significants of the number. Look in the table of proportional parts for the nearest under the unattained part, and take the digit opposite to it for the sixth significant. Annex a cipher to the remainder of the unattained part, and take the digit opposite to the result (or its nearest) in the table of proportional parts for the seventh significant. For instance, required the number to the logarithm 1·6590176:

	6590176
45605 ..	6590125
	51
5	48
3	30

Number required 45·60553

20. The following is the working of the four questions already worked with four-figure and five-figure tables:

17798	4·2503712
63426	4·8022673
	9·0526385
11288	0526170
	215
5	193
6	220
Answer	1128856000
17·293	1·2378703
·942942	$\bar{1}$·9744850
18·33941	1·2633853
1·9273	0·2849493
	8
190·3682	2·2795944
00005569181	11)$\bar{5}$·7457913
·4104439	$\bar{1}$·6132538

21. More complicated questions may be *directly* solved by logarithms, that is, without requiring to seek the number to a logarithm until the end of the process, as long as the multiplications, divisions, involutions, and evolutions are not broken by additions or subtractions. Thus to calculate $\sqrt[10]{\{a^2 b \sqrt[3]{c} \div d\}}$ we form for the logarithm of the answer

$$\frac{1}{10}\left\{ 2\log a + \log b + \tfrac{1}{3}\log c - \log d \right\}$$

But if additions or subtractions intervene, the process must be broken to produce the result; that is, the logarithmic process must be suspended, and the results exhibited in numbers for the performance of the additions and subtractions (unless indeed the logarithms described in the next article be employed). Thus to find $\sqrt{(a^2 b + cd)}$, it would be necessary, not merely to form the logarithms of $a^2 b$ and cd, or $2\log a + \log b$ and $\log c + \log d$, but to find the numbers to them: these numbers being then added, and the logarithm of the sum being taken, half the last logarithm is the logarithm of the answer.

22. There is nothing in the trigonometrical logarithms more than is described in TRIGONOMETRICAL TABLES, P. C. Many young students, from seldom or never using the actual sines, cosines, &c. of angles, but only their logarithms, are apt to confound the former with the latter.

23. Some little additional correctness may be obtained by annexing to the use of the tables, as given above, an attempt to add something for one more figure of the number. Thus, suppose it required to find the logarithm of 11·374928. In the four-figure table 113 has 0531 and ...7 adds 26. The next figure is 4, which, had it been the fourth significant, would have added 15; being the fifth, let it add the tenth of 15, or its nearest integer, 2. Hence we add 28 instead of 26 to 0531, and get 0559 instead of 0557, as a nearer approach to the logarithm. Again, in the five-figure table, 1137 gives 05576, and the tabular difference is 38. The 4 gives 15, or 4-tenths of 38, and the 9 ought to give 9-hundredths of 38, or 3. Consequently 15 + 3, or 18, is added, giving 05594. Had 49 been read as 50, in the usual way, 19 would have been added. In the seven-figure tables 11374 gives 0559132; 9 adds 345, the 2 should add the tenth of 77, and the 8 should add the hundredth of 306: hence 3 more should be added than arises from the figures 92. This plan may be followed when the greatest accuracy is desirable, especially in the four-figure table. It is most useful when the tabular differences are large, that is, at the beginning of the table.

24. It may sometimes save a mistake if the computer remember that the significants of the number generally read less than those of the decimals in the logarithm. Thus 200.... has 301.... for the decimal figures of the logarithm. It is not so however at the beginning of the table, and the figures of the logarithm overtake those of the number between 13712 and 13713.

25. The rule of the characteristics, when well learnt, furnishes one of the easiest modes of assigning the place of a decimal point in a common division. For example, in dividing ·0017643 by ·018416, the characteristics being $\bar{3}$ and $\bar{2}$, we shall have to carry 1 to $\bar{2}$, because the significants of the divisor, 18, are greater than those of the dividend, 17. Take $\bar{1}$ then from $\bar{3}$, which leaves $\bar{2}$, the characteristic of the quotient, which has therefore ·0 before its significants. The rule is, to find the characteristic of the quotient, from that of the dividend subtract that of the divisor, carrying 1 if the significants of the divisor be greater than those of the dividend.

26. In using the trigonometrical tables, or any other, careful attention must be paid to the right choice of the method of interpolation. If the argument and tabular result [TABLE, P. C.], or the numbers with which we enter the table and those which we take from it, increase together or diminish together, then the alterations introduced by the table of proportional parts consist in adding to either for every addition to the other, and subtracting for every subtraction. But if

the tabular result diminish as the argument increases, then every addition to the one is accompanied by a subtraction from the other, and *vice versa*. In the tables of logarithmic cosines and cotangents, the young computer frequently falls into error from neglect of the last-mentioned direction. Thus the logarithm of the cosine of 84° 9′ in a five-figure table is 9·00828, and the tabular difference is 124, diminishing. Hence the log cosine of 84° 9′·5 is not 9·00828 + ·00062, but 9·00828 − ·00062. And if we ask for the angle whose log-cosine is 9·00840, we find the next underneath this in the table to be 9·00828, and 22 for the unattained part. Divide 220 by 124, and 2 is the nearest integer. But the angle required is not 84° 9′ + 0′·2, but 84° 9′ − 0′·2, or 84° 8′·8.

27. The equation $a^x = b$, in which x is unknown, is solved by taking the logarithm of both sides, which gives $x \log a = \log b$, or $x = \log b \div \log a$. The process may perplex a beginner when the logarithms have negative integers. We therefore subjoin an example. Let it be required to solve the equations

$$\left(\frac{4}{7}\right)^x = \cdot00163 \text{ and } 182^y = \cdot6$$

(The reader is supposed to know the complete interpretation of algebraical exponents.) We have then

$$x = \log(\cdot00163) \div \log\left(\frac{4}{7}\right) = \bar{3}\cdot21219 \div \bar{1}\cdot75696$$

$$y = \log\ \cdot6 \div \log 182 = \bar{1}\cdot77815 \div 2\cdot26007$$

Now throw the three logarithms which have negative integers into the more usual algebraical forms.

$$\begin{array}{lccc} & \cdot21219 - 3, & \cdot75696 - 1, & \cdot77815 - 1 \\ \text{Or} & -\ 2\cdot78781, & -\ \cdot24304, & -\ \cdot22185 \end{array}$$

And make the divisions, which give for the quotients 11·471, and − ·098161; or

$$\left(\frac{4}{7}\right)^{11\cdot471} = \cdot00163, \quad (182)^{-\cdot098161} = \cdot6$$

LOGGAN, DAVID, a line-engraver and designer, of considerable eminence in England in the time of Charles II., was born at Danzig in 1635. He appears to have first learnt his art from Simon de Pas in Denmark, and to have worked subsequently with Hondius in Holland. He came to England during the Commonwealth, and spent some time in engraving heads in London. But his first work of consequence in this country was a set of plates of the colleges of Oxford—'Oxonia Illustrata,' for the sale of which he had fifteen years' privilege; he executed afterwards a similar series of the colleges of Cambridge. He also engraved on eleven folio plates 'Habitus Academicorum Oxoniæ à Doctore ad Servientem.' Loggan is himself entered on the books of the University; in the matriculation registry there is the following entry—'David Loggan Gedanensis, Universitate Oxon. Chalcographus, July 9, 1672.'

He married Mrs. Jordan, of a good family, near Witney, Oxfordshire, by whom he had a son, who became a fellow of Magdalen College, Oxford. He died at his house in Leicester-fields in 1693.

Loggan engraved many portraits of illustrious persons in the time of Charles II., many of the drawings of which were executed in lead by himself from the life—as George, prince of Denmark; the Duke of Albemarle; the Earl of Clarendon; the Earl of Argyle; the Duke of Ormond: the Lord Keeper Guildford; Archbishop Sancroft; the Bishops Mew, Seth Ward, and Pearson; and many others. There are prints also by Loggan of Archbishops Usher and Boyle, and of Bishops Sprat of Rochester, Lake of Chichester, Crew of Durham, Compton of London, Gunning of Ely, Reynolds of Norwich, and Lloyd of St. Asaph. He engraved also three portraits of Charles II., in one of which the king is leaning his hand on Archbishop Sheldon; James, duke of York; the Duke of Monmouth; the Queens Catherine and Henrietta Maria; Pope Innocent XI.; the Earl of Derby, Sir Edward Coke, Sir John Chardin, Thomas Barlow, Titus Oates, and many others, which are enumerated by Vertue.

Loggan had the following assistants—A. Blooteling, G. Valck, Vanderbanck, and Peter Williamson; the first two came from Holland with Loggan.

(Vertue, *Catalogue of Engravers*, &c.)

LOGIC. [ORGANON, P. C. and P. C. S.]

LOIR, NICOLAS, a distinguished French painter and etcher, was born at Paris in 1624. His father was an eminent jeweller, and he placed Nicolas with Sebastien Bourdon, and sent him afterwards, in 1647, to complete his studies in Rome. Here Loir studied chiefly the works of N. Poussin, and so carefully that in some instances it is said to be scarcely possible to distinguish Loir's copies from the originals. He had great facility of execution, and excelled in various styles, as history, landscape, and architecture. He also composed with elegance, and his colouring is very agreeable; but his design is somewhat affected, and is not always vigorous or correct in its outline.

He painted at Rome an excellent picture of Darius opening the Tomb of Semiramis, which obtained him a great reputation. He returned to Paris in 1649, and was shortly afterwards employed by Louis XIV., at the Tuileries and at Versailles. He painted two apartments in the Tuileries—the Antichambre du Roy and the Salle des Gardes, where, by the mythical representation of the sun and other figures, he illustrated the distinctive character of the life and reign of Louis XIV.; and so far to the monarch's satisfaction, that he obtained by these works a life-pension of 4000 francs.

In 1663 he was elected a member of the French Academy of Painting, and he presented on the occasion, as his reception-piece, a picture representing the Progress of Painting and Sculpture during the reign of Louis XIV.; but his masterpiece is considered Cleobis and Biton drawing their Mother in a chariot to the temple of Juno, from the story of Herodotus (i. 31); Loir himself has made an etching of it. Another of his best works is Paul before Sergius depriving the Magician of sight, in the Cathedral of Notre Dame at Paris. He excelled in painting women and children, and particularly the Virgin Mary. He is said to have designed twelve Holy Families in a single day, which did not contain two figures alike. He died at Paris, rector of the Academy, in 1679. Loir's own etchings amount to 159 pieces, which, together with 80 engravings after his works by other artists, make a total of 239 prints. Several of the latter were engraved by his brother Alexis Loir.

Felibien describes several of the works of Loir at considerable length; his account of this painter contains also some curious digressions relating to the superstitions of the modern Romans, and other matter. Felibien and Loir were at Rome together, and Felibien's dates have been for this reason adopted in this article, where they differ from those of D'Argenville and Gault de Saint-Germain.

(Felibien, *Entretiens sur les Vies et sur les Ouvrages des Peintres*, &c.; D'Argenville, *Abrégé de la Vie des plus fameux Peintres*, &c.)

LOMBARDUS, LAMBERT, the designation of a painter whose actual name is not known. He is sometimes called Lamprecht Susterman or Suterman, and, according to some, Lambert Suavius, and also Lamprecht Schwab. The place of his birth is equally unknown: it is said to be Liege or Amsterdam, more probably Liege, as he settled there after his return from Italy in 1538, and he died there, in 1560, aged fifty-four. Vasari mentions Lamberto Lombardo as the most distinguished of all the Flemish painters, and styles him a great *letterato*, a judicious painter, and an excellent architect; but his account of him is contradictory: he had it from D. Lampsonius, who wrote Lambert's Life in Latin: it was published at Bruges in 1565, five years after his death. Lombardus studied under Jan de Mahuse before he visited Italy. Frans Floris, Hubert Golzius, and Willem Key were his scholars. His works consist chiefly of drawings with the pen in chiaroscuro: his coloured paintings are scarce; there are two of small dimensions in the Gallery of Berlin; there is a Pietà in the Pinacothek at Munich, which used to be attributed to Daniele da Volterra. Lambert's style is strictly Italian: he is said to have studied under Titian at Venice, and he lived some time in Rome. The surname of Lombardus was probably given to him by his Flemish countrymen on account of his style, which, different from their own, they distinguished as the Lombard style, Lombardy being formerly the general name for the northern part of Italy.

There are many prints supposed to be after Lambert's designs, some of which are marked Lam. Lombardus, and others Lam. Suavius; and it is not yet decided whether these names indicate one or two artists; Heineken considers them as two, and Van Mander notices Suavius as an engraver, without making any allusion to Lombardus. In a note to De Yongh's edition of Van Mander, Suavius is styled the pupil of Lombardus.

(Vasari, *Vite de' Pittori*, &c.; Van Mander, *Het Leven der Schilders*, &c.; Sandrart, *Teutsche Academie*, &c.; Heineken, *Nachrichten von Künstlern*, &c.; Fiorillo, *Geschichte der Zeichnenden Künste*, &c.)

LONDONDERRY, ROBERT STEWART, MARQUESS OF, was born at the family seat of Mount Stewart, in the county of Down, Ireland, on the 18th of June, 1769 (the same year which gave birth to the Duke of Wellington and to Napoleon Bonaparte). His father, of the same names, after representing the county of Down for many years in the Irish parliament, was made Baron Stewart of Londonderry in 1789, Viscount Castlereagh in 1795, Earl of Londonderry in 1796, and Marquess of Londonderry in 1816—all in the peerage of Ireland. Robert was his only child that survived by his first wife, Sarah Frances, daughter of Francis Seymour, First Marquess of Hertford, whom he married in 1766, and who died in 1770.

The estate of Mount Stewart was purchased by Mr. Alexander Stewart, father of the first marquess, who sat in the Irish parliament for the city of Londonderry. Beforo this the family were known as Stewarts of Ballylawn in the county of Donegal, of which property John Stewart, the great-great-grandfather of Alexander, the first of them who settled in Ireland, obtained a grant from King Charles I. There seems to be ground for believing that he was nearly related to some ennobled branch of the Stewarts: but the connexion appears not to be distinctly traceable, and is variously given in the several accounts. The descent of tho family is commonly deduced, or rather assumed to be, from Sir Thomas Stewart of Minto, who lived in the latter part of the fifteenth century, the ancestor of Lord Blantyre, and a younger brother of Sir Alexander Stewsrt of Dalswinton and Garlies, the ancestor of the Earl of Galloway. John Stewart is stated to have emigrated from Scotland to Ireland in the reign of James I.

The subject of the present notice received the first part of his education at the free grammar-school of Armagh; whence he was removed in 1786 to St. John's College, Cambridge. He was not yet of age when, on his father being raised to the peerage in 1789, he offered himself for the vacant seat in the representation of the county of Down, and was returned, though not without a severe contest, which lasted for three months, and is said to have cost the family 25,000*l*. or 30,000*l*. Nor did he come in without pledging himself, in contradiction to what had hitherto been the family politics, to the cause of parliamentary reform, which had for some time been a popular watchword in Ireland. For three or four years, accordingly, he was considered as belonging to the party of the opposition, though to the aristocratic and more moderate section of it. He very early began to take part in the debates.

His conversion from liberalism seems to have taken place about 1793 or 1794; and it may be fairly considered to have been the natural result of his family position cooperating with the more alarming aspect which popular politics in Ireland were every day assuming. Up to this time he appears to have been universally regarded as an unusually amiable as well as honourable young man: after his change of principles he was commonly represented as a prodigy both of perfidy and of heartlessness.

In the summer of 1794 he was returned to the British parliament for the borough of Tregony; and after remaining silent for a session he made his maiden speech in the House of Commons in seconding the Address on the 29th of October, 1795. It is said to have greatly disappointed the expectations excited by the reputation he had brought over with him. He was to the last a remarkably unequal speaker; at one time rising above, at another time—sometimes on the same night—falling below his ordinary or average style of execution in a degree scarcely credible, and the more wonderful in a person of so much nerve and self-possession.

Ho does not appear to have ever spoken again during this parliament, which was dissolved after the close of that its sixth session, in May, 1796. That year he became Viscount Castlereagh; and he was again returned to the next British parliament, which met in September, for the borough of Orford. But he vacated his seat in July, 1797; upon which he was re-elected to the Irish parliament for the county of Down, and was made Keeper of the Privy Seal for Ireland. In the beginning of 1798 he was appointed Secretary to tho Lord Lieutenant and an Irish privy counsellor: and from this date he may be regarded as having been distinctly the ministerial leader in the Commons. The credit or discredit of the measures adopted for the suppression of the Rebellion, which broke out and was put down in this year has also been commonly assigned to him, although it does not appear that he really did more than carry out the system which he found already in action when he came into office. He was no doubt one of the principal managers of the project of the Union, which followed two years after.

He was returned for tho county of Down to the first Imperial Parliament, which met in February, 1801; and also to the second, which met in November, 1802; though upon the latter occasion not till after a severe struggle with the interest of the Downshire family, whose hostility had been provoked hy the dismissal of the late marquess from the command of his militia regiment and tho lord-lieutenancy of the county for his opposition to the Union.

In the beginning of 1802 he had been made a privy counsellor of Great Britain, and President of the Board of Comtrol; and he retained that office after Mr. Pitt retired and throughout the Addington administration. After Mr. Pitt returned to power, Viscount Castloreagh was, in July, 1805, promoted to be one of his majesty's principal secretaries of state (taking the department of War and the Colonies). He was now, however, thrown out of the representation of Down, and was obliged to take refuge in the borough of Boroughbridge, for which he was returned in January, 1806, on a vacancy made by the death of the Hon. John Scott, son of Lord Eldon. He resigned with the rest of the cabinet on the death of Mr. Pitt shortly after this; and to the next parliament, which met in December, with a new ministry, he was returned for the borough of Plympton Earle.

Upon the formation of the Portland administration, in April, 1807, Lord Castlereagh was reappointed to his former office of Secretary of State; and he was again returned for Plympton to the parliament which met in May of this year. He was now considered the individual principally answerahle for the conduct of the war; and the failure of the disastrous expedition to Walcheren in the summer of 1809 not only drew upon him much general unpopularity, but involved him in a personal quarrel with his colleague Mr. Canning, the Secretary for Foreign Affairs, which led first to the resignation of both, and then to a duel between them, in which Canning, on tho second fire, was severely wounded. In the esrlier part of this same year, also, some sensation had been made by two reports of select committees of the Commons which charged Lord Castlereagh, along with other persons, the one with corrupt practices in obtaining the returns of members for Irish boroughs, tho other with irregularities in the disposal of Indian patronage.

Lord Castlereagh remained out of office till February, 1812; when, on the resignation of the Marquess Wellesley, he was appointed Secretary of State for the Foreign Department. After the death of Mr. Perceval, which followed in May, he was regarded as ministerial leader in the Commons. To the new parliament which met in November, 1812, he was once more returned as representative for the county of Down; and he also retained that seat in the next two parliaments, which met in August, 1818, and in April, 1820. The return to office of Mr. Canning, however, in 1816, had relieved him from a considerable part of his lahours in the conduct of puhlic business in the House, till that gentleman again retired in 1820.

Meanwhile in the end of the year 1813 Lord Castlereagh had gone as British plenipotentiary to the negotiations opened with the French government at Châtillon, which however broke off after a few weeks without any result; and he had also appeared as representative of the King of England at the Peace of Paris, in May, 1814; at the Congress of Vienna, in October of the same year; at that of Paris after tho battle of Waterloo in the following year; and at that of Aix-la-Chapelle in 1818. On such occasions as these, his fine figure and grace of manner showed to great advantage. He likewise attended George IV. to Ireland in 1820, where he had for the moment the gratification of being extremely popular among his countrymen. He had been made a Knight of the Garter in 1818, and he became Marquess of Londonderry hy the death of his father on tho 8th of April, 1821.

Lord Londonderry died by his own hand at his seat of North-Cray-Place, in the county of Kent, on the 12th of August, 1822. Something unusual in his manner had been occasionally observed for some months, and for a few days before the melancholy catastrophe his extreme irritability and other symptoms of mental disease had strongly excited the notice of his domestics and friends. On the 9th, the Duke of Wellington wrote to Dr. Bankhead:—'I sincerely hope that you will contrive, by some pretence, to go down to his lordship. I have no doubt he is very unwell; he appears to me to have been exceedingly harassed, much fatigued and over-worked during the late session of parliament; and I have no doubt he labours under mental delirium; at least this is my impression.' The coroner's jury which sat upon the body brought in a verdict of lunacy. He had married in 1794 Lady Emily-Anne Hobart, youngest daughter of John, second Earl of Buckinghamshire, but he died without issue, and the title went to his half-brother, the present Marquess.

There was no brilliancy of intellect in Lord Londonderry, scarcely even the ordinary amount of literary cultivation and taste. His speaking, though fluent and sometimes spirited, was always inelegant and slovenly, and occasionally so to a ludicrous degree. To any acquaintance with the philosophy of politics he made no pretension; nor did even his practical views commonly evince any superior sagacity. But he had great business talents; and that qualification, with his charm of manner, fitted him admirably for managing men, and was the main secret of his success in life. Something too, however, is to be attributed to certain moral qualities which he possessed. Whatever difference of opinion might be entertained about some of his political proceedings, or acts done in his political capacity, his personal character was admitted by all who knew him to be that of an honourable and high-minded man, upon both whose firmness and fearlessness every reliance could in all circumstances be placed. His integrity in this sense had even something of a roughness or sternness that might almost be said to contrast with the amenity of his manner.

(Memoir in *Annual Register* for 1822, which, however, abounds with omissions and inaccuracies; *Parliamentary History*, and other records of the time.)

LONGHI, GIUSEPPE, an Italian painter, and one of the most distinguished engravers of the nineteenth century, was born at Monza in 1766. His father was a silk-mercer, and intended his son for the church, but, through his own determination, Giuseppe was finally placed with the Florentine Vincenzo Vangelisti, professor in the Brera at Milan, under whom he learnt engraving. He studied afterwards some time in Rome, where he became acquainted with Raphael Morghen, a very celebrated engraver; and Longhi soon obtained a reputation himself by his print from the Genius of Music, a picture by Guido in the Chigi Palace.

After his return to Milan he was chiefly employed in miniature painting, until he was ordered by Napoleon to make an engraving of Gros's portrait of him; and he was appointed about the same time (1798) to succeed Vangelisti, deceased, as professor of engraving in the Academy of the Brera, to which, during Longhi's professorship, many distinguished engravers of the present time in Italy owe their education. It was one of Longhi's first principles to make the means subservient to the end, and not the end to the means: he always deprecated cleverness of line as a principal object, and in his own works manual dexterity is invariably subordinate to conformity of style. His first object was to give, as nearly as possible, the general character, colour, and texture of the original, and the etching-needle was accordingly his chief instrument. He excelled in light and shade. Among his principal works are—tho Vision of Ezekiel, after Raphael; the Sposalizio, or the Marriage of the Virgin, and a Holy Family, after the same; the Entombment, after D. Crespi; the Magdalen, after Correggio; the Madonna del Lago, after Da Vinci; Galatea, after Albani; and many heads, after Rembrandt. The Sposalizio was engraved as a companion-piece, or *pendant*, to Morghen's large print of the Transfiguration, by Raphael. He commenced in 1827 to engrave the Last Judgment, by Michelangelo, from a drawing by the Roman painter Minardi, but he died without finishing it: it was however considerably advanced, and, if not already finished, will probably be completed by some one of his distinguished scholars. The Madonna del Velo, after Raphael, Longhi also left unfinished, but it was completed in 1834 by his pupil the Cav. Toschi. Longhi died of apoplexy in 1831. He was a Knight of the Iron Crown, and member of many academies.

Besides a few poems and other essays, there is a treatise on engraving, by Longhi ('La Calcographia'), which has been translated into German by C. Barth; and contains a Life of the author, by F. Longhena. A Life of him, also, with a list of his works, was published at Milan in 1831; and there are notices of him in the *Kunstblatt*, and in Nagler's *Neues Allgemeines Künstler-Lexicon*.

LONGICORNES, the fourth family of tetramerous Coleoptera in Latreille's arrangement of insects. It includes a vast number of large and beautiful beetles, all remarkable for the length of their antennæ, which in many species are several times longer than their bodies. They inhabit woods, where the females deposit their eggs beneath the bark of trees, effecting the operation by means of a long, strong, horny ovipositor with which they are provided. The females are usually larger than the males. The larvæ live beneath the bark of trees or in the wood, in which they bore deeply and do much damage. The greatest assemblage of species and the largest forms are found in South America; but longicorn beetles are very generally dispersed. This family is divided into three great groups, of which the genera *Prionus*, *Cerambyx*, and *Leptura* are the respective types.

LONICE'RA, a genus of plants named after Adam Lonicer, a German botanist, who was born in 1528 and died in 1586. He practised as a physician at Frankfort-on-the-Main, and wrote a Herbal, which was merely a compilation of what had been done by others. There is also a John Lonicer mentioned who wrote a commentary on Dioscorides.

This genus is the type of the natural order Caprifoliaceæ, and has the tube of the calyx 5-toothed, the corolla tubular, campanulate or funnel-shaped, with a 5-cleft usually irregular limb; 5 stamens; a filiform style, a capitate stigma; 3-celled berries, and crustaceous seeds. The species are erect or climbing shrubs, with opposite exstipulate leaves and axillary flowers. There are about 60 species of Lonicera, most of which have handsome flowers and emit a delicious perfume.

L. caprifolium, Goatsleaf, or pale perfoliate Honeysuckle, has ringent whorled terminal and sessile flowers, deciduous obtuse leaves glabrous on both sides, the upper leaves connate perfoliate, the style glabrous. It has a twining stem, with white or purplish flowers and orange-coloured berries. It is a native of the middle and south of Europe, and is found in woods and thickets in many parts of England and the south of Scotland.

L. Periclymenum, the Woodbine, or Honeysuckle, has climbing branches, the leaves all separate, deciduous, sometimes downy, glaucous beneath, ovate, obtuse, attenuated at the base, upper ones the smallest; the heads of flowers all terminal ovate, imbricated; the flowers ringent. The flowers are pale yellow, the berries red, and accompanied with permanent bracts. This plant in early times was supposed to possess powerful medical properties, but it is not now used. It is however extensively cultivated in the gardens and shrubberies of Europe on account of the delicious perfume of its flowers. This plant is the true 'woodbine' of the poets, and Milton has applied to it the name 'twisted eglantine.' This plant has obtained the name of woodbine, a corruption of wood-bind, from its habit of twisting round the stems of trees. Thus Shakspere says—

> So doth the woodbine, the sweet honeysuckle,
> Gently entwist the maple.

The name honeysuckle is derived from the habit of children, who draw the corolla out of tho calyx, and suck the collected honey from its nectary. Several varieties of this plant are recognised by botanists. All these are beautiful climbers and very fragrant; and trained against a wall, twining round a pole, or climbing and rambling amongst bushes, are very ornamental in gardens. It is a native of middle Europe, and very abundant in some parts of Great Britain.

L. Xylosteum, Fly Honeysuckle, has 2-flowered woolly peduncles as long as the flowers, the calyx-limb deciduous, the berries slightly connected at the base, the leaves oval, downy, the stem erect. The flowers are of a pale yellow, and the berries are scarlet. It is a native of nearly the whole of Europe, in thickets, hedges, and rocky places, and by the side of woods. It is found in the same situations, but is a rare plant, in Great Britain.

L. Tartarica, the Tartarian Honeysuckle, has a glabrous erect stem; cordato-ovate sub-acute leaves; the peduncles shorter than the leaves; the berries distinct when young and nearly globose, but at length connate at the base; flowers rose-coloured, short, somewhat gibbous at the base; the fruit black with one of the berries usually abortive: the peduncles 2-flowered. It is a native of Tartary, and is one of the most hardy of European shrubs, growing in the open air in the gardens of Petersburg and Stockholm. It is very common in British gardens and is valued much on account of its early leafing and flowering.

L. Iberica, the Georgian Honeysuckle, is an erect plant with petiolate, cordate, roundish, tomentose or pubescent leaves; the peduncles 2-flowered, shorter than the leaves, the bracteas oblong, ciliated; the berries globose, blood-coloured, joined together to the middle globose; the ovarium tomenlose. This plant is a native of Georgia, about Teflis, and is a neat little bush with which to form garden-fences.

All the species of Lonicera may be cultivated, and are well adapted for gardens, shrubberies, &c. The climbing species may be trained on trellis-work, or in arbours or against walls. The upright hardy species are best adapted for shrubberies. They will grow in any common garden-soil, and may be propagated by cuttings planted in autumn, either in a sheltered situation or under a hand-glass, according as they are more or less tender.

(Don, *Gardener's Dictionary*; Loudon, *Arboretum et Fruticetum*; Babington, *Manual of British Botany*.)

LOOM. [WEAVING, P. C.]

LOPHIADÆ, a family of Acanthopterygious fishes, named *Pectorales pediculati* by Cuvier. Their pectoral fins are so constructed and placed as to perform the office of feet. The *Lophius piscatorius*, or fishing-frog, is a British example.

LOPHOBRANCHII, a family of fishes in which the gills, instead of being pectinated, are separated into small rounded tufts, which are arranged in pairs along the branchial arches, and covered by a large operculum, so fixed as to leave only a single small orifice for the passage of the water outwards. The pipe-fishes, *Syngnathus*, *Hippocampus*, *Solenostomus*, and *Pegasus*, are the genera included in this family.

LOPHOTES. [TÆNIOIDES, P. C. S.]

LORANTHUS (from *lorum*, 'a strip of leather,' and ἄνθος, 'a flower,' in allusion to the long linear shape and leathery substance of the petals), a genus of plants the type of the natural order Loranthaceæ. It has diœcious or hermaphrodite flowers, the calyx cup-shaped, adnate, with an entire border; the petals 5 or 6, linear, reflexed; the stamens inserted into the middle of the petals; the filaments short, anthers globose; the style thickish; stigma simple; the berry globose, 1-celled, 1-seeded. The species are evergreen shrubs parasitical on trees.

L. Europæus, the European Loranthus, is a glabrous much branched plant; the branches terete; the leaves opposite, petiolate, oval-oblong; the racemes terminal, simple; the flowers diœcious, of six petals. This plant is an evergreen parasitical plant, and has the habit of the common mistletoe (Viscum album). It is a native of the southern parts of Europe, and is found on the oak, but inhabits no other tree. 'This circumstance,' says Burnett, 'has led some naturalists to suppose the Loranthus to have been the Mistletoe of the Druids, and to believe, as it is not now indigenous to Britain, that when Druidism was suppressed, every vestige of that stupendous superstition was so completely swept away that even the sacred plant was extirpated here.' The fact however of the scarcity of the mistletoe upon the oak renders it probable that it was on this account more sought after, and thus contributed to render it an object of superstition. Several other species of Loranthus have been described, but none of them are easily cultivated, on account of their parasitical habits. The seeds of the Loranthi, like those of the mistletoe, contain tannin, and are astringent.

LORDS' ACT. [INSOLVENT, P. C.]

LORENZO, or LORENZETTO, AMBROGIO and PIETRO DI, two celebrated Italian painters of the fourteenth century, were born at Siena about the year 1300. They were brothers, as we learn from the following inscription formerly in the hospital of Siena: 'Hoc opus fecit Petrus Laurentii et Ambrosius ejus frater, 1330:' it was attached to pictures of the Presentation and of the Marriage of the Virgin, which were destroyed in 1720; and was preserved by the Cav. Pecci. This inscription explains the name given by Vasari to Pietro, whom he calls Petrus Laurati or Laureati, which is evidently an erroneous reading of Petrus Laurentii—Pietro di Lorenzo.

Some of the works of these painters still remain, though the principal of their works, by Ambrogio, which is described by Ghiberti (in 'Cod. Magliabecchiana,' f. 8 & 9), is destroyed. It was painted in the Minorite convent at Siena, and represented the fatal adventures of some missionary monks. In the first compartment a youth was represented putting on the monastic costume; in another, the same youth was represented with several of his brother monks about to set out for Asia, to convert the Mohammedans; in a third, these missionaries are already at their place of destination, and are being chastised in the Sultan's presence, and are surrounded and mocked by a crowd of scoffing infidels; the Sultan judges them to be hanged; in a fourth, the young monk is already hanged to a tree, yet notwithstanding he continues to preach the gospel to the astonished multitude, upon which the Sultan orders their heads to be cut off; the next compartment is their ceremonious execution by the sword, and the scaffold is surrounded by a great crowd on foot and on horseback; after the execution follows a great storm, which is represented in all the detail of wind, hail, lightning, and earthquake, from all of which the crowd are protecting themselves as they best can, and this miracle, as it was considered, is the cause of many conversions to Christianity. Such is the description of this picture by Lorenzo Ghiberti, the first sculptor of his time, and he finishes it by declaring it to be, as a painted story, a wonderful thing—'per una storia picta mi pare una maravigliosa cosa;' many of the actors, he says also, appeared to be living beings.

There is still in the Sala delle Balestre, in the public palace of Siena, a *tempera* painting of Peace, represented by a view within and without the city of Siena, with numerous inhabitants variously occupied in business and in pleasure. War was likewise represented in this hall, but is now defaced; there are however other allegorical works still remaining, and Rumohr observes that what remain justify Ghiberti's praises of what have disappeared, speaking with relation to the time of their production—1337, 1338.

Of the several pictures by Ambrogio Lorenzetti mentioned by Ghiberti, only one remains—the Presentation of the Virgin in the Temple, in the Scuole Regie, and in this some of tho women are excellent.

Ghiberti does not mention any works by Pietro Lorenzetti, and there is only one authenticated work by him; it is in the Stanza del Pilone, a room against the sacristy of the cathedral of Siena, and is marked 'Petrus Laurentii de Senis me pinxit, A. M.CCC.XLII.' It represents, according to Rumohr, some passages from the life of John tho Baptist, his birth, &c.

Vasari mentions many works by Pietro in various cities of Tuscany, where he says his reputation was greater than either Cimabue's or Giotto's. He attributes to him a picture of the early fathers and hermits in the Campo Santo at Pisa; it is engraved in Lasinio's 'Pitture del Campo Santo di Pisa.'

In 1355 Pietro was invited to Arezzo to paint the cathedral, in which he painted in fresco twelve stories from the life of the Virgin, with figures as large as life and larger, but they have long since perished; they were however in good preservation in the time of Vasari, who completely restored them. He speaks of parts of them as superior in style and vigour to anything that had been done up to that time.

The works of these painters, though relatively good, are not exempt from any of the errors and defects of the prevailing style in Italy previous to Donatello, Masaccio, and Ghiberti; and they display even some of the barbarities of the Byzantine school. Several pictures are attributed to them in various collections, but wholly without evidence as to their authorship.

(Vasari, *Vite de' Pittori*, &c.; Della Valle, *Lettere Sanesi*; Lanzi, *Storia Pittorica*, &c.; and especially Rumohr, *Italienische Forschungen*, in which the two Lorenzetti are treated of at considerable length.)

LOSS ISLANDS. [SIERRA LEONE, P. C.]

LOTTO, LORENZO, a celebrated Venetian painter of the sixteenth century. He is supposed to have been one of the scholars of the Bellini, and also an imitator of Lionardo da Vinci. He lived long at Bergamo and was generally considered a native of that place, 'but,' says Lanzi, 'we are indebted to Sig. G. Beltramelli for showing, in a work published in 1800, that Lotto was a native of Venice:' he found him thus noticed in a public contract, 'M. Laurentius Lottus de Venetiis nunc habitator Bergomi'—Master Lorenzo Lotto, of Venice, now a resident of Bergamo. Lotto lived also some time at Trevigi, at Recanati, and at Loretto, where he died. His works range from 1513 to 1554. Lanzi ventures an opinion that Lotto's best works could scarcely be surpassed by Raphael or by Correggio, if treating the same subject. His masterpieces are the Madonnas of S. Bartolomeo, and Santo Spirito, at Bergamo.

(Vasari, *Vite de' Pittori*, &c.; Tassi, *Vite de' Pittori, &c. Bergamaschi*; Lanzi, *Storia Pittorica*, &c.)

LOVAT, LORD. Simon Fraser, afterwards Lord Lovat, was born in 1668, at Beaufort near Inverness, in Scotland. He belonged to the family of the Frasers, who were powerful as early as the reign of Malcolm IV. about 1153, and who had large possessions in Tweedale and elsewhere in the south of Scotland. Simon Fraser's father died when his son was very young. After receiving the usual instruction at a grammar-school, he was sent to the University of Aberdeen, where he distinguished himself by his acquirements in classical learning.

In 1692 Fraser, through tho interest of the Marquis of Athol, received a commission as captain of a company in Lord Tullibardine's regiment, but soon afterwards resigned in consequence of a dispute with the Marquis, who was grandfather to the eldest daughter of the last Lord Lovat, and claimed the estates for her. Simon Fraser, on the coutrary, asserted his own right, as nearest male heir, not only to the estates, but to be chief of the Frasers. In 1694 he succeeded in winning clandestinely the affections of the heiress, then fifteen years of age and living with her mother, the dowager Lady Lovat, near Inverness, and she consented to elope with him. She did elope, but the man whom Fraser had engaged to conduct her changed his mind, took her back, and disclosed the plot to Lady Lovat. The heiress was immediately sent under an escort to Dunkeld, the seat of the Marquis of Athol. Fraser made some daring efforts to obtain possession of her, but without success.

About 1700 Fraser went to France, and to ingratiate himself with James II., then living at the court of St. Germain, formally renounced the Protestant faith, and embraced that of the Roman Catholics. James II. having died in 1701, his son, James Francis Edward, resolved to make an attempt to regain his father's kingdom, and Fraser was appointed by the courts of Versailles and St. Germain to stir up an insurrection in the highlands of Scotland. He was made a colonel (some say a major-general), was furnished with credentials to treat with noblemen, gentlemen, and chiefs of clans, and was supplied with arms, ammunition, and money. He embarked at Dunkirk, and landed in Scotland about the end of 1702. He pretended to perform his engagement, but after his return to France in 1703 it was discovered that he had abused his trust, and had disclosed the plot to the Duke of Queensbury. He was confined in the Bastile, where he remained till 1708, when, in order to obtain his release, he offered to enter into holy orders. By the influence of the pope's nuncio and other Roman Catholic clergymen he was set at liberty, took orders, retired to St. Omer, entered the College of Jesuits, and discharged for some years the duties of a priest with apparent sincerity and much diligence.

When the Rebellion broko out in 1715 Fraser repaired to London, and with some difficulty and risk got to the highlands of Scotland under the assumed name of Captain Brown. His great object was to obtain his hereditary estates; a large part of the clan of the Frasers received him as their chief, and were willing to act according to his decision; and as Fraserdale, who had married the heiress and held the estates, had joined the Pretender, Fraser adhered to the king. He took Inverness from the rebels, and after the Rebellion was suppressed his services was rewarded with the title of Lord Lovat and the grant of the forfeited estates.

In 1717 Lord Lovat married a daughter of the Laird of Grant, and by her had two sons and two daughters, who survived him. His wife having died, he married a young lady nearly related to the Argyle family, and had a son by her, but treated her with so much cruelty that a separation was the consequence. He was appointed governor of Inverness and lord-lieutenant of Inverness-shire, and lived in tolerable quietness till the second Rebellion broke out in 1745, when he joined the side of Charles Edward, the young Pretender, but kept himself at home, and sent his son with the Frasers, pretending, in his reply to the Lord President, who, on the 28th of October, 1745, wrote to reproach him, that his son had acted without his authority; there was however abundant evidence of his participation, and he fled aud concealed himself in the wildest parts of the Highlands; after many escapes ho was caught, and conveyed to London. He was confined in the Tower, and was not brought to trial till March 9, 1747. The trial lasted sevon days, and he was then found guilty, and sentenced to be beheaded. Both before and after his trial he amused every one near him with his jests. On the 9th of April, 1747, he was led to the scaffold on Tower-hill. He was then eighty years of age, and after sitting awhile in a chair, and talking deliberately to those about him, he laid his head quietly down on the block, and gave the sign quickly; and though he was very fat and his neck unusually short, his head was cut off at a single blow. Horace Walpolo, who was present, says, 'He died extremely well, without passion, affectation, buffoonery, or timidity, his behaviour being natural and intrepid.'

(*Memoirs of Simon Fraser, Lord Lovat*, 8vo. London, 1746; *Pictorial History of England*, vol. iv. p. 551, &c.)

LOUDON, JOHN CLAUDIUS, was born at Cambuslang, in Lanarkshire, on the 8th of April, 1783, where his mother's only sister, who was the mother of Dr. Claudius Buchanan, author of 'Christian Researches in Asia,' then resided. His father was a farmer, and lived at Kerse Hall, near Gogar, about five miles from Edinburgh. As a child, Loudon exhibited a taste for gardening, 'as his principal pleasure was in making walks and beds in a little garden his father had given him.' He was early sent to reside with an uncle at Edinburgh in order that he might be educated, and here he attended a public school, and also the classes on botany and chemistry. In addition to the Latin he learned at school, he obtained a knowledge of French and Italian, and paid his masters himself out of the proceeds of translations from these languages, which he sold. At the age of fourteen he was placed with a nurseryman and landscape gardener, and continued his attendance on the classes of botany and chemistry, and to these added agriculture, in the university of Edinburgh. During this period he acquired the habit of sitting up two nights every week for the purpose of study, a habit which he continued for many years.

In the year 1803 Loudon first camo to London, and as he brought good recommendations from Edinburgh, he found no difficulty in getting employment in his profession of a landscape gardener. One of his earliest literary efforts was made this year in the form of a paper contributed to the 'Literary Journal,' entitled 'Observations on laying out the Public Squares of London.' It was the practice when this article was published, to adorn the squares of London with a very sombre vegetation, consisting of yews, pines, and other heavy plants. This practice the author strongly condemned, and recommended the lighter trees, as the oriental plane, the sycamore, the almond, and others, which are now generally cultivated, and add greatly to the beauty of London squares. In 1804 he returned to Scotland, and in the same year he published his first work, entitled 'Observations on the Formation and Management of useful and ornamental Plantations,' 8vo., London. He returned to England in 1805, and published a small work, entitled 'A short Treatise on some Improvements lately made in Hothouses,' 8vo., Edinburgh. In 1806 he published a 'Treatise on forming, improving, and managing Country Residences, and on the choico of situations appropriate to every class of Purchasers,' 8vo., London. This work was illustrated with thirty-two copper-plate engravings of landscape scenery drawn by the author.

In 1806 an accident turned his attention to farming. Travelling one night on the outside of a coach, exposed to the rain, and neglecting to change his clothes, he became attacked with rheumatic fever, which left him so debilitated that for the sake of his health he took lodgings at Pinner near Harrow. Here he had an opportunity of observing the inferior farming then practised in England, and persuaded his father to take a farm near London. The result was that, conjointly with his father, they rented Wood Hall, and such was their success that the following year Loudon wrote a pamphlet entitled 'An immediate and effectual Mode of raising the Rental of the Landed Property of England, &c., by a Scotch Farmer, now farming in Middlesex.' This led to his introduction to General Stratton, the owner of Tew Park in Oxfordshire, and his undertaking the management of this estate as a tenant. Here he established a kind of agricultural college, in which he engaged to teach young men the principles of farming; and in 1809 he wrote a pamphlet on the subject entitled 'The Utility of Agricultural Knowledge to the Sons of the Landed Proprietors of Great Britain, &c., by a Scotch Farmer and Land-Agent.' Ho carried on bis farming so successfully that in 1812 he found himself worth 15,000*l*., and being more anxious for the cultivation of his mind than the improvement of his circumstances, he determined to give up his farm and travel on the Continent. He left England in March, 1813, and after visiting the principal cities of Germany and Russia, experiencing a variety of adventures, and recording with his pen and pencil all that he found worthy of notice in his own profession, he returned to his own country in 1814. On his return to London, finding that the chief part of his property was lost through unfortunate investments, he devoted himself with renewed energy to his old profession of landscape-gardening. He now determined to publish a large work on the subject of gardening; and in order to complete his knowledge of continental gardens, for the purpose of rendering his work more valuable, he visited France and Italy in the year 1819. In the year 1822 appeared his great work, 'The Encyclopædia of Gardening,' which contained not only a vast amount of original and valuable matter on every department of horticulture, but was copiously illustrated with woodcuts in the text. This work had a very extraordinary sale, and fully established tho reputation of the author as one of the most learned and able horticulturists of his day. A second edition was published in 1824. The success of this work led bim to engage in another equally laborious and extensive, and on the same plan, devoted to farming. This was published in 1825, with the title 'Encyclopædia of Agriculture.' Another work, though not exactly on the same plan, but similar in design and comprehensiveness, was edited by him, and published in 1829, with the title 'Encyclopædia of Plants.' This work however contained less of the author's own work than the preceding, the plan and general design being all that he claimed as his own. This was followed by another, the 'Encyclopædia of Cottage, Farm, and Villa Architecture,' which was all his own labour. 'The labour,' says Mrs. Loudon, 'that attended this work was immense; and for several months he and I used to sit up the greater part of every night, never having more than four hours' sleep, and drinking strong coffee to keep ourselves awake.' This book was published in 1832, and was very successful. He then planned a work of still greater extent, which demanded more time than any of the preceding: this was his 'Arboretum et Fruticetum Britannicum;' comprehending an account, with engravings, of all the trees and shrubs growing wild or cultivated in Great Britain. This work was brought out in 1838, and, with the preceding, was published at his own expense. After paying artists and other persons engaged in the work, 'he found at its conclusion that he owed ten thousand pounds to the printer, the stationer, and the wood-engraver who had been employed.' The sale of this work was slow, and seemed to have involved him in pecuniary difficulties, which, although they did not abate his energy, still preyed upon his mind, and hastened his death.

During the time that these works were going on he edited several periodicals. In 1826 he established the 'Gardener's Magazine,' which he carried on till his death. In 1828 he commenced the 'Magazine of Natural History,' which he edited till 1836, when it passed into other hands. In 1834 he started the 'Architectural Magazine,' which he gave up in 1838. In 1836 he commenced the 'Suburban Gardener,' a monthly publication; so that he had four monthly works, in addition to the 'Arboretum,' going on at the same time.

These labours would appear very extraordinary for a man in perfect health and with the use of his limbs, but they become more extraordinary when the circumstances are known under which be wrote them. His first attack of rheumatic fever, in 1806, was so severe as to produce permanent anchylosis of his left knee. Subsequently his right arm became affected, and this was so severe that after trying the usual remedies be was induced to submit to shampooing, during which process his arm was broken so close to the shoulder as to render it impossible to have it set in the usual manner; and on a subsequent occasion it was again broken, when it was found necessary, in 1826, to have recourse to amputation. In the meantime his left hand became affected so that he could only use the third and little finger. After this period he was obliged to employ for all his works both an amanuensis and a draftsman. With this infirm and maimed body, his mind retained its vigour to the last. Early in 1843 he was attacked with chronic inflammation in his lungs, which terminated bis existence on the 14th of December of that year. He continued working till the day of his death, and 'died standing on his feet.'

Few literary men have attempted or executed so much as Loudon, and that under circumstances of the most depressing and afflictive nature. The tendency of his mind was essentially practical, and in this will be found the cause of the success and the influence of his writings. In his works on gardening he displays great anxiety for the mental improvement and welfare of the class of men who make this their occupation; and the book on which he was employed at the time of his death is devoted to them, and is entitled 'Self-Instruction for Young Gardeners.' In all his works he never lost tho opportunity of pointing out the bearing of his subject on the moral and social improvement of his fellow-creatures.

He was married in 1831, and has left behind his wife and one daughter. Mrs. Loudon is the authoress of 'The Mummy;' 'Ladies' Flower Garden;' 'Ladies' Botany,' &c. The materials for this notice have been chiefly collected from a Memoir by Mrs. Loudon in 'Self-Instruction for Young Gardeners.' A complete list of Loudon's works is given in the 'Proceedings of the Linnean Society' for 1844.

LOVELACE, RICHARD, born in 1618, was the son of a Kentish knight. Educated at the Charterhouse and at Oxford, he was placed at court, and entered the army under the patronage of Goring. On the close of the civil war, he retired to his paternal seat, Lovelace Place, near Canterbury. The county deputed him to present their petition in favour of the king to the Long Parliament; and for doing this he was imprisoned in the Gatehouse, and released only on giving bail in forty thousand pounds. In 1646 he raised a regiment in the French service, commanded it, and was wounded at Dunkirk: and it is said that the lady he celebrated in his poems married another person, on a false report that Lovelace had died of his wound. Returning to England in 1648, he was again imprisoned, and remained in confinement till after the king's death. In 1649 be published a volume of poems, entitled 'Lucasta's Odes, Sonnets, Songs,' &c. He had spent his fortune freely in serving the Royal cause. He now fell into embarrassment and sickness, and lived for some years wretchedly. He died of consumption, in a mean lodging in London, in 1658. Lovelace was the anthor of two plays, which have never been printed. His lyrical poems, with much inequality and many other faults, are full of spirit and vigour. Specimens of them are in all the common collections; and one or two of them, such as the fine verses 'To Althea from Prison,' furnish some of the most backneyed of quotations.

LOWELL, a large manufacturing city in the United States of North America, is situated in the State of Massachusetts, on the south bank of the River Merrimack, where the Concord River flows into it, in 42° 39′ N. lat., 71° 19′ W. long., 439 miles from Washington, and 26 miles north from Boston by the railway. The site was formerly the head-quarters of the Pawtucket Indians, whose territory extended to the north of Massachusetts Bay, and included the present State of New Hampshire. The Pawtuckets amounted to about 12,000, and Wamesit, their chief town, was at the junction of the Concord River with the Merrimack, where the city of Lowell now stands. When first visited by the Europeans about 1650, the population of Wamesit was about 3000; but the Pawtuckets rapidly gave way before the white settlers; in 1674 the population of Wamesit was reduced to 250 men, besides women and children. The lands belonging to the Pawtuckets on the west of the Concord River were given up in 1686, and those on the east in 1726.

The banks of the Merrimack were covered with a forest, and it soon became an object of importance to float the timber, lumber, and fuel which it furnished down the river to Newburyport. In doing this the chief difficulty was in passing the Pawtucket Falls, where the river has a descent of thirty-two feet over a series of rapids. On the 27th of June, 1792, an act was passed which constituted certain persons into a body politic and corporate, by the name of the Proprietors of Locks and Canals on Merrimack River. A canal was forthwith commenced, and was completed in 1797; it extends from the Merrimack just above the Pawtucket Falls, in a sweep of a mile and a half, to the Concord River, near the point of junction of the Concord with the Merrimack. The descent of thirty-two feet was accomplished by four locks Into this canal the whole stream of the Merrimack could be turned, and might thus afford an immense water-power, perfectly under control, to be applied to manufacturing purposes. For upwards of twenty years this vast water-power seems to have been little noticed. In 1813 a cotton manufactory was erected on the Concord River, a little above the canal, which in 1818 was converted into a woollen manufactory; and there were two or three other manufactories on the Concord River and the Merrimack, below the Falls, but none on the Pawtucket Canal. In 1814 three large cotton manufactories were erected by a company at Waltham on the Charles River, comprising 231 looms, and were very successful. The Waltham Company, having discovered the use which might be made of the water-power of the Pawtucket Canal, purchased the shares of the Canal Company, as well as lands adjoining the canal. On the 6th of February, 1822, they were incorporated as tho Merrimack Manufacturing Company. They enlarged the Pawtucket Canal, making it sixty feet wide and eight feet deep, and at the same time dug the Merrimack Canal from the Pawtucket Canal to the Merrimack River, and on this latter canal the first manufactories were erected in 1823.

The town was at first called East Chelmsford, and in 1820 contained 200 inhabitants. In 1826 the number of inhabitants had increased to 2500, and on the 1st of March in that year East Chelmsford was incorporated into a town called Lowell. Francis Cabot Lowell, after whom it was so named, was the son of the Hon. John Lowell, LL.D., and was born in 1774, at Newburyport, Massachusetts. In 1810 he visited England, and on his return he invented, in conjunction with Patrick Tracy Jackson and Paul Moody, and erected at Waltham in 1812-13, the first power-looms which were brought into extensive operation in America, though upwards of twenty others had been patented at Washington previously. Lowell's looms, which gave rise to the Waltham Company before mentioned, were afterwards transferred to Lowell. Mr. Lowell died in 1817, at the age of forty-three.

Such was the origin of Lowell, the population of which, in 1830, had increased to 6477. On the 30th of March, 1836, it was incorporated as the City of Lowell, and the population was then 17,633; in 1840 it was 20,921; in 1844 it was 25,163; and is now (March, 1846) probably about 30,000.

Of this population about one-third, or 10,000, are persons employed in the cotton and woollen manufactories, or 'mills,' as they are called, and of these about 7000 are females and 3000 males. One interesting peculiarity connected with the Lowell mills is the superior character of these female operatives, as they are called in America, or factory-girls, as they are called in England; and of this superiority a singular proof was afforded by the periodical work called 'The Lowell Offering, a Repository of Original Articles, written exclusively by Females actively employed in the Mills;' the first number of which appeared in October, 1840, and the first volume was completed in December, 1841. A second volume was completed in 1842, and the work was still continued in 1845. A selection from the two first volumes, under the title of 'Mind amongst tho Spindles,' formed the second volume of the series of 'Knight's Weekly Volume,' in the editor's preface to which, and in a letter from Miss Martineau annexed to it, an interesting account of these female operatives is given.

There are about twelve large manufacturing companies, or corporations, besides several smaller companies. A brief description of the arrangements of a Lowell corporation will partly explain the means by which the moral if not the intellectual superiority of these girls is produced. On the bank of the river, or of one of the canals, stands a row of two, three, four, or five mills. A short distance from the mills are long blocks of brick boarding-houses, which are connected with the mills by a line of one-story brick building, containing the counting-room, superintendant's room, clerk's room, and store-rooms. The mill-yard is inclosed in such a manner that access can only be had to the mills through the counting-room. On one side are the boarding-houses, which are let only to persons of approved character, and are entirely under the superintendant's care; on the other side are the mills, in each room of which is placed an overseer, who is responsible for the work, good order, and management of the room. Thus the superintendant has the entire corporation under his inspection in the most complete manner, the whole forming a perfect system of subdivided and well-defined responsibility. Each of the long blocks of boarding-houses is divided into six or eight tenements, which are generally three stories high. No male operatives board with the female operatives, but distinct tenements are appropriated to each sex. The hour for taking meals is uniform throughout all the corporations. The number of hours which the mills run, and consequently during which the operatives are employed, taken on an average, is twelve hours ten minutes. The rate of wages varies. A young woman from the country, employed at first as a spare hand and in learning the business, receives fifty-five cents per week besides her board. In a few months she will earn a dollar or a dollar and a half per week, according to her dexterity and diligence. While however the average pay of the female operatives is somewhat less than two dollars per week, besides board, instances are not uncommon of their earning three and four dollars per week, besides board. The payments are entirely by notes, convertible at any hour into gold and silver.

As connected however with the superiority of the Lowell female operatives, it is to be observed that they are quite a different class of females from the factory girls of England. They come mostly from the country, where they have been respectably brought up in farm-houses or elsewhere, and seldom remain more than three, four, or five years, when they return to their homes, and are succeeded by others in continuous succession.

There are in Lowell twenty-three regularly constituted religious societies, and they have erected about twenty churches. Connected with these societies are 6123 Sunday-school pupils and teachers, or more than one-fifth of the entire population. There is 1 High School, 8 Grammar-schools, and 30 Primary Schools; a City-Library, of which a catalogue of 5000 volumes has been printed; a Savings-Bank, incorporated in 1829, which has about two thousand depositors, half of whom are factory girls, the amount of whose funds at interest is estimated at 100,000 dollars. Two per cent. interest is paid for every six months. The Lowell Dispensary was incorporated in 1836; the Lowell Hospital was established in 1839. There is a large Almshouse, a Poor-Farm, and a Gaol. The Lowell Cemetery is on the east bank of the Concord River, a mile above its junction with the Merrimack; it comprises about forty-four acres, and was consecrated June 20, 1841. The Lowell Institute is an association of gentlemen for the management of a course of lectures which are delivered every winter in the City-Hall, at which many of the female operatives attend. The City-Hall, for town purposes, with committee-rooms and stores underneath, was completed in 1830; another public hall with reading-rooms and library-rooms was built in 1835 for the use of the Middlesex Mechanics' Institution. In 1837 a large market-house was completed. There are two bridges over the Merrimack: one just below the Falls, called the Puwtucket Bridge; the other near the mouth of the Concord River, called the Central Bridge, which is connected with a new portion of town on the north bank of the Merrimack.

There are two railroads connected with Lowell. The Boston and Lowell railway, 26 miles in length, was opened July 4, 1835; in 1844 the dividend was 8 per cent. The Nashua and Lowell railway is 14 miles in length; it paid a dividend in 1844 of 10 per cent.

The following table is given in the 'American Almanac' for 1846:—

Lowell Statistics, January 1, 1845.

Capital stock . . . dollars	10,850,000
Number of mills, exclusive of print-works, &c.	33
Spindles	204,076
Looms	6,304
Females employed	6,320
Males employed	2,415
Yards made per week . . .	1,459,100
Bales of cotton used in ditto .	1,175
Pounds of cotton wrought in ditto .	464,000
Yards dyed and printed ditto .	287,000
Tons of anthracite coal per annum .	12,500
Cords of wood per annum . .	3,270
Gallons of oil per annum . .	64,842
Flour for starch, barrels, per annum	4,000
Charcoal, bushels, per annum .	600,000
Yards of cloth per annum . .	75,873,200
Pounds of cotton consumed . .	24,128,000

A pound of cotton averages 31·5 yards; 100 lbs. of cotton will produce 89 yards of cloth. Average wages of females, clear of board, per week, 1·75 dollar. Average wages of males, clear of board, per day, 70 cents. Average amount of wages paid per month, 138,500 dollars.

(*Lowell, as it was and as it is*, by the Rev. Henry A. Miles, 18mo., Lowell, 1845; *American Almanac*, 1846; *Knight's Weekly Volume*, vol. ii.)

LOXONE'MA. A group of spiral Gasteropoda is thus named by Phillips. The species occur in Silurian, Devonian, and carboniferous strata. (*Palæozoic Fossils of Devonshire.*)

LOYOLA, IGNATIUS. Don Iñigo Lopez de Recalde, more generally known under the name of Loyola, was the youngest child of Don Bertram, lord of Ognez and Loyola, a nobleman of high birth and distinction in his province, and of Marina Saëz de Baldi. He was born in the year 1491, at the castle of Loyola, in that part of Spanish Biscay afterwards called the province of Guipuzcoa. In early youth he was attached to the court of Ferdinand and Isabella, in the quality of a page; but the vivacity of his disposition little suited him for a situation so devoid of excitement, while the recital of the noble deeds of the Spanish knights, who had lately freed their country from the yoke of the infidel, rendered him desirous of emulating their fame. His father, when he sent him to the court of Spain, had placed him under the care of his relation Don Antonio Manriquez, duke of Najara. This nobleman, perceiving the military bias of his young ward, got him instructed in the art of war, and afterwards received him in his suite. The ardent imagination of Ignatius was in the meanwhile kept in constant excitement by the eager perusal of the various romances in which were idealized the religious spirit of Spanish chivalry; to this was added the example of his brothers, who were following with distinction the profession of arms. After joining the army he soon rendered himself conspicuous by his gallant bravery on every occasion; his conduct, in other respects, is described as having partaken in all the dissipations generally incident to a military life; one vice, however, that of gambling, he appears constantly to have avoided. He was in his thirtieth year when he assisted in the defence of Pampeluna, against the French; in the assault he was severely wounded, his right leg having been fractured by a cannon ball, and his left, at the same time, injured by a splinter. The French, into whose hands he had fallen prisoner, respecting his misfortune and admiring his bravery, had him conveyed to the castle of Loyola, which was situated at a small distance from Pampeluna. A long and painful confinement was the result of his wounds, and a cruel operation was resorted to, which, though endured with characteristic courage, reduced him to the last extremity. His recovery from the effects of the operation, though he saw in it a miracle, appears to have produced no change of conduct. A second operation, however, became necessary, owing to a deformity which had resulted from the first, and its consequences entailed a longer and more tedious confinement. To relieve its weariness he requested to be provided with those records of antient chivalry which had been the delight of his former years, but instead of them he was furnished with works of mystical devotion and the lives of saints. Of a disposition naturally visionary and romantic, deprived of the means of pursuing a career in which he hoped to attain the highest honours, the attentive perusal of these records of the zeal and suffering of holy men infused in his mind an ardent desire to imitate them. As he eagerly pondered over the recital of the actions of a St. Dominick, or a St. Francis, he was wont to ask himself what prevented him from imitating their deeds? But often were these heavenly aspirations clouded by the intervention of worldly thoughts and of temporal affairs. At other times, when in this spiritual combat the spirit was obtaining a mastery over the flesh, his vivid imagination would portray to him visions of celestial glory which, in that hour of struggle, encouraged and inspired him. He has graphically described the various scenes through which he passed in his introduction to a religious life, in his 'Spiritual Exercises,' the origin of which may be referred to the same time as his first awakening from worldly slumber. This remarkable work is not a book of doctrine, it is the description, to use his own words, of 'the longings of a soul seeking to be appeased, not by much knowledge, but by the sense and relish of inward things.' He first minutely details a variety of rules for the guidance of spiritual life; he then exhorts to the study of sacred history, to whose events he too frequently gives a fanciful interprotation; he afterwards gives an allegorical representation of the convert's progress from the prison of this world to the realms of celestial bliss. Loyola but detailed his own feelings in this extraordinary production. From this time all his desires were directed to one great object, an entire devotion to the service of God. For this purpose, renouncing all worldly pursuits, he tore himself from the paternal home, from his kindred, and from his friends. Regardless of the kindly opposition of his eldest brother, become by the death of his father the head of the house of Loyola, he resolved upon retiring to a Benedictine monastery at Mount Serrat, in order to prepare himself for a pilgrimage to the Holy Land. He became acquainted in that monastery with one of the brothers named John Chanones, of high reputation for austere and self-denying piety, and he was anxious to unfold to him the confession of his former sins and the confidence of his religious aspirations. While journeying towards Mount Serrat, he arrived at a village at the base of the hill on which it is situated, and he was then struck with the reflection that, though a destined pilgrim for Jerusalem, he was still clad in the garments of Babylon, and he exchanged his usual dress for the coarse raiment of a beggar. The night of the 24th March, 1522, the vigil of the Annunciation, was a memorable period in the life of Loyola; he passed it in the exercise of the most austere devotions in the church of the Holy Virgin at Mount Serrat; on its altar he hung up his arms, the trophies of his worldly triumphs, and, in the spirit of chivalry, vowed constant obedience to the demands of God and of his church. The better to put into execution his holy resolutions he determined to perform barefoot his intended pilgrimage, in order that this severe penance might excite in his mind a deeper remorse for sin. On leaving Mount Serrat, he directed his steps towards Manresa, a small town within three leagues of this monastery. There he repaired to the hospital of the Dominican convent, and, while attending upon the poor and sick, imposed upon himself a series of new and severe penances. His deeds of charity soon acquired for him celebrity in that town, and, though clad in the rags of destitution, he was unable to walk the streets without attracting the importunate admiration of the multitude. To avoid the temptation of vain glory, he retired to a cavern hollowed in a rock at a short distance from Manresa, where he redoubled the severity of his penances, and was one day found in a state of inanimate exhaustion at the door of his cell, and was borne back to the Dominican hospital. On his recovery, his mind, weakened by mortifications and fastings, fell into a state of spiritual despondency. His doubts and despair, his fears and temptations, are described with edifying minuteness in his own writings and by his early historians. It does not appear that any particular doctrine had made an impression on the mind of Loyola, as that of justification by faith alone had made on that of Luther. He lived, as it were, within himself, and his emotions were actuated by the alternate inspirations of good and evil; he has taught us in his 'Spiritual Exercises' the manner in which he distinguished their influences; the soul being gladdened by the one and depressed by the other. One day, at length, he awakened as from a dream, his imagination had portrayed to his mind the visible representation of heavenly mysteries. With tears of joy, he gratefully acknowledged the blessings vouchsafed to him, and, refreshed in spirit, he arose a new and a mightier man.

After residing ten months at Manresa, he left that town for Barcelona, from whence he embarked for Rome. In that city he remained a few days, in order to obtain the blessing of the Pope Adrian VI. upon his enterprise; he then resumed his journey, passing through Padua and Venice, travelling alone and on foot, fasting daily, and begging alms as he went. His voyage from Venice to Cyprus presented a fresh trial for his patience and constancy, his pious efforts for the conversion of the crew of the vessel in which he sailed being met by coarse insults and contumelies. From Cyprus he embarked with some pilgrims for the Holy Land, and reached Jerusalem on 4th September, 1523. He there visited with holy veneration the hallowed spots which religious tradition has consecrated. To accomplish the objects of his journey, he was desirous not only of contributing to the edification of the believers, but also to the conversion of the infidels. His projects, however, were defeated by the refusal of a permission of residence from the primate of the Church of Rome at Jerusalem. He then re-embarked for Europe, and arrived at Venice in January, 1524, and from thence he returned to Barcelona. In this town he determined upon making some stay, in order to acquire by study a greater influence in the conversion of souls. He addressed himself for that purpose to Jerome Ardebala, while a pious lady, Isabella Rosel, undertook to provide him with the necessary means. His early education had been greatly neglected, and the dissipations of a camp had obliterated from his mind the little he had learnt. At the age of thirty-three, he began with zealous industry to apply himself to the rudiments of grammar. But his active mind found extreme difficulty in applying itself to its tedious minutiæ; and absorbed in religious contemplation, each word he met with excited a train of pious thoughts. Still by constant application he appears to have made some progress in learning. He continued at Barcelona till the zealous attempts on his part to reform some irregularities which existed in a convent of nuns exposed him to the vengeance of those who had partaken in their disorders. He then retired to the University of Alcala, which had lately been founded by Cardinal Ximenes, in order to prosecute his studies. A religious address which he delivered to the students was the occasion of his dismissal from that University, and the obligation to study theology during four years, before he could again be permitted to teach in public, was imposed upon him. In 1527 he retired to Salamanca, where, having imprudently resumed his public teaching, he fell under the displeasure of the Inquisition, who punished him by a severe confinement, and dismissed him from their city with a similar injunction.

Discouraged by the rude reception which his pious labours had met with in his native country, he repaired to Paris, at that time the most renowned seat of learning in Europe. He arrived in February, 1528. The slender means which had been provided for him by the charitable generosity of his friends were purloined by the dishonesty of a fellow-student, and he was again compelled to have recourse to begging for his subsistence. He, however, zealously applied himself to the studies of the University: obliged to recommence his rules of grammar and tho principles of philosophy before he could be admitted as a theological student, he humbly placed himself in the class of the youngest and least advanced scholars, and besought their teacher to treat him as one of them. His time in Paris appears to have been spent partly in the laborious acquisition of knowledge, and partly in the endeavour to obtain a salutary influence over his companions. In the latter pursuit he was eminently successful. Two students shared his rooms, Peter Faber (called Le Fevre in Art. JESUITS), a native of Savoy, of humble origin and simple manners, and Francis Xavier of Navarre, of noble ancestry and aristocratic demeanour. These young men, of such different dispositions and habits, were the first-fruits of Loyola's labours. From that time the three companions formed the closest intimacy, dividing their gains, and sharing each other's toils. Shortly after three more students acknowledged the influence of Loyola, and joined his small society: their names are recorded in the article JESUITS, P. C. On 15th August, 1534, they assembled together at the Church of Montmartre, in one of whose subterraneous chapels Faber, who was a priest, administered to them the Sacrament of the Eucharist. They then took the solemn vows of chastity, absolute poverty, devotion to the care of Christians, and to the conversion of infidels. They further resolved on proceeding to Jerusalem, but, in case impediments to the accomplishment of this object should be put in their way, they decided upon placing themselves under the guidance of the Pope, and implicitly submitting to his directions. Such was the humble origin of the famous Order of the Jesuits, so called because they placed themselves under the banners of Jesus, as soldiers under their chief. The history of the founder now becomes mingled with that of the Order itself. Its early progress, the oppositions it met with, the history of its success, and the rules and constitutions by which it is governed, are fully and clearly detailed in another part of this Cyclopædia. [JESUITS, P. C.] We will only, therefore, briefly state the principal events in Loyola's life which are not alluded to in that article.

After revisiting his native country, where he religiously repaired the effects of some early faults, he proceeded to Venice, in which city he was joined by his companions, and from thence proceeded to Rome. Their intended departure for Palestine was interrupted by the war which broke out, in 1537, between the Venetians and the Turks; they therefore presented the offer of their services to the See of Rome. They were gratefully accepted by the reigning pontiff, who gladly availed himself of the support of a society of men full of zeal and enthusiasm, and bound together by the common tie of implicit obedience to his orders. 'Deeply shaken by open schism and lurking disaffection, the Church of Rome found an unexpected source of strength in her own bosom, a green shoot from the yet living trunk of the aged tree.' (Hallam.) On the 27th September, 1540, Paul III. published a bull sanctioning, under some limitations, the establishment of the Order; another was finally issued in 1543, which removed these limitations, and made the sanction unconditional. Meanwhile six of the oldest members met together to elect a president subject to no control but that of the See of Romo; their choice fell on Loyola. He remained at Rome as the centre from which he was to control and direct the movements of the Society. His time was spent there in revising its rules and constitutions, and in works of charity. He founded an asylum for the protection of Jews who had become proselytes to Christianity, and a penitentiary whero the victims of sensual seductions might, without binding themselves by any religious vow, lament their sins and reform their lives. In the year 1546 Francis Borgia, whom the Church of Rome honours as a saint, caused their first college to be founded at Gandia in Spain; the statutes were drawn up by Loyola, and the same privileges were accorded to it which belonged to the universities of Alcala and Salamanca. Not twenty years had elapsed since from these very universities Loyola, then a poor and despised student, had been contumeliously expelled as a factious and illiterate pretender.

On the 31st July, 1556, this extraordinary man, worn down by infirmities and self-inflicted mortifications, left a world which for so many years he had looked upon only as the scene of charitable labours. It were a useless task to attempt a delineation of Loyola's character; it is best known by his works. Whatever difference of opinion may be entertained respecting the order of the Jesuits, there can be but little respecting their founder.

The memory of Ignatius was consecrated by a ceremony known in the Church of Rome by the name of Beatification in 1609, and he was canonized as a saint by Pope Gregory XV. in 1622. His festival is celebrated on the 31st July.

His Life has been written by Gonzales and Ribadeneira, two of his early companions, the latter his confessor; also by Maffeus in Latin, Bartoli, and Bouhours in French. His 'Spiritual Exercises' were published at Rome in 1548, and have been translated into French by Drouet de Maupertuis and Clément. His 'Maxims' translated were published at Paris in 1683.

An elegantly written sketch of the life of Ignatius Loyloa is contained in 'The Portrait Gallery' published by Knight, vol. vii. By a misprint in this sketch of Knight's, his death is made to take place in 1566. Further information respecting him may be obtained in Ranke's 'History of the Popes,' vol. i. p. 181-200 of Miss Austin's translation; Alban Butler's 'Lives of the Saints;' Fabre's Continuation of Fleury, vol. xxvii.; De Thou, 'Hist. Universello,' vol. iii.; and Bayle, 'Dict. Historique.' Bayle is chiefly useful in correcting some errors of preceding writers; but the whole is written in a cold and sarcastic spirit.

LUCA'NIDÆ, the family of Stag-beetles, a name popularly applied to these insects on account of the very large and powerful mandibles with which the males are furnished. These in the genera *Chiasognathus* and *Pholidotus* equal the entire length of the body, and in the Lucanus cervus of our own country are very formidable instruments of offence. They live during the day in the trunks of trees and old wood, and take flight at dusk. The females are sluggish and not so numerous as the males, which fight with great ferocity among themselves for possession of their mates. The larva, which is supposed to have been the animal called Cossus by the Romans, and esteemed by them as a delicacy, lives in the willow and tho oak, and remains untransformed for several years. When full-grown it forms a cocoon of the dust of wood which it has ground down by its powerful jaws, and after remaining some time as a pupa it undergoes its final transformation to pass a very brief portion of its life as a perfect insect. Some of the foreign genera of Stag-beetles are remarkable for their brilliant colouring. In Britain we have four species which belong to as many genera. (See Westwood's *Introduction to the Modern Classification of Insects*, vol. i., and the writings of Macleay, Kirby, Roesel, and Hope.)

LUCERNAL MICROSCOPE. This is a hollow pyramidal box, of wood, at the smaller extremity of which is a tube carrying the usual system of lenses for magnifying objects. At the larger end, which is towards the observer, there are two lenses in frames; their axes, as well as those of the small lenses at the opposite extremity, being coincident with the axis of the box; and between the exterior of the two lenses and the eye of the observer thero is usually placed a plate of glass, rough-ground on one side, which serves as a screen to receive the rays of light proceeding from the object whose representation is to be viewed: the object is fixed in a small frame, as usual, and is placed in a groove made for the purpose immediately beyond the tube containing the system of lenses, at the small end of the pyramidal box.

This box, the axis of which is in a horizontal position, is mounted on a brass stand, which may be placed on the floor or on a table, and the parts of the apparatus are capable of being correctly adjusted by means of screws. The instrument was invented by Mr. George Adams, a distinguished optician in London, and it received its name from the images of the objects being projected on the ground-glass screen by the rays of light transmitted from a lamp through the lenses, the observations being made by night or in a darkened room.

The correct definition of the image depends upon tho achromatism of the lenses at the object end of the instrument, a subject which has been treated in the article MICROSCOPE, P. C.; and therefore it will be sufficient to notice here only the means employed to enlighten the field of view.

For this purpose, in general, an Argand lamp is placed beyond the object, with respect to the microscope; or, if thought necessary, two or more such lamps may be so situated: the light, after passing through a hemisphere of glass, is, when an opaque object is to be viewed, made to fall in a convergent state upon a small concave mirror, which is so inclined as to reflect the light back upon the object; and from the different points on the surface of the latter the pencils of rays proceed through the object-lenses and the box to tho glass screen.

By the refraction of the light in passing through the lenses a highly magnified image of the object is formed; and several persons may then place themselves so as to see the image on the screen at the same time; or, by placing the eye at a small aperture in the produced axis of the instrument, one person may, with a pencil, draw on the glass, or on tracing-paper laid over it, the figure of the object; it being understood that, by means of the proper adjusting-screws, the rays in each pencil are made to unite accurately in one point on the screen.

When the object to be viewed is transparent, the light is made to fall in a condensed state upon it, after having been transmitted through a convex lens, or two such; and, from the object, the rays proceed as before to tho screen through the system of lenses which constitute the compound object-glass of the microscope, and through those at the opposite extremity of the box.

Instead of having a plate of ground-glass to receive the image, the pencils of light from the object, after passing through the lenses, may be allowed to fall on a board painted white or covered with white paper; the distance of the board from the instrument (about 6 or 8 feet) being such that the rays in each pencil may converge to a point upon it: thus there will be obtained a greatly magnified image of the object, which may be observed by many spectators at one time. Such a screen should have the form of a segment of a hollow sphere, the light being received on its concave surface; for by that construction the image will be nearly equally distinct at the centre and about the margin.

The solar microscope, which was invented by Dr. Lieberkhun in 1738, produces a greatly magnified image of a small object in a similar manner by means of the sun's light. It consists of a conical tube fixed by its base to a frame of wood; the latter being screwed to a closed window-shutter at an aperture purposely made in the latter: the tube projects into the room, which, when the observations are to be made, is rendered quite dark, and is sometimes lined with black cloth. The magnifying power is produced by a system of lenses contained in the tube, as in other microscopes. On the exterior of the window is a frame carrying a rectangular piece of looking-glass; this frame is attached by a joint at one of its sides to a ring of wood or brass which is made to surround the aperture in the shutter. The mirror, by turning on the hinge, is capable of being fixed at any angle with the wall of the building; while the ring to which it is attached can, by means of a rack and pinion, be made to turn on the horizontal axis of the instrument, so as to permit the rays of the sun, whatever be the position of the latter, to be reflected into the tube. By means of lenses disposed for the purpose, these rays are made to converge on the object; and from thence, after refraction through the system of object-glasses, they proceed to a screen on which they depict the magnified image.

When the object is transparent, the rays of solar light are allowed to pass from the mirror directly through the lenses to the screen; but when it is opaque, a convex lens placed at the aperture in the window-shutter causes the solar rays to condense on a small mirror placed in a box at that end of the instrument which is within the room, and from this mirror the rays are reflected to the object. The condensed light thus thrown on the object diverges from thence and passes through the system of lenses, by refraction in which the magnifying power is produced; these lenses being placed in a tube which, as well as the object, is within the box containing the mirror last mentioned, but a little above the latter, so that the rays of light proceeding from the object to the magnifying lenses may not be intercepted.

The mirror by which the sun's light is reflected into the instrument is sometimes connected with a clockwork apparatus, by which its position is continually varied correspondently to the apparent change of the sun's place; and thus the reflected light is made constantly to pass through the tube. [Heliostat, P. C.]

Sir David Brewster has given, in his 'Treatise on New Philosophical Instruments,' p. 405, &c., a method of preparing objects of natural history for observation by the microscope, that their parts may preserve their proper shape and colour, and thus be seen to the greatest advantage.

The solar microscope will, probably, never be generally employed, on account of the necessity which it involves of having an apartment particularly situated, and of being used only when the sun shines. The lucernal microscope can, of course, be employed at any time; and if, for an Argand lamp, the oxy-hydrogen light be substituted, the lenses also being achromatic, the image will be distinct and correctly defined. [Microscope, P. C., p. 188.]

LUCHETTO DA GENOVA. [Cambiaso, Luca, P. C. S.]

LU'CUMA (a native name for one of the species), a genus of plants belonging to the natural order Sapotaceæ. It has a 5-parted calyx; a 5-cleft corolla; 10 stamens, 5 of which are sterile, and 5 fertile, alternating with each other; an ovarium 5-10-celled; the fruit 1-10-seeded; nuts or seeds bony, marked by a large umbilical areola without albumen. The species are trees, yielding a milky juice, with scattered entire coriaceous leaves, and 1-flowered axillary or lateral peduncles.

L. Mammosa, the Common or Mammee Sapota, has obovate lanceolate, oblong cuspidate, glabrous leaves, with solitary flowers. This plant grows from fifty to one hundred feet in height. It is a native of the tropical parts of South America, and of many of the West India Islands, where it is also cultivated. The fruit of this tree is eaten in the West Indies. It is of a large size, oval-shaped, and covered with a brownish rough skin, under which is a soft pulp of a russet colour, very luscious, and which, on account of its flavour, is called Natural Marmalade. P. Browne calls a variety of this tree Bully-tree, because it grows the tallest of all the trees in the woods of Jamaica.

Several other species of this genus have been described. They are all natives of various districts of South America, and yield edible fruits similar to the preceding species. They were at one time referred to the genus Achras, the species of which also yield edible fruits. [Achras, P. C.]

(Don, *Gardener's Dictionary*.)

LUIGI, ANDRE'A DI, commonly called *L'Ingegno*, and sometimes *Andrea di Assisi*, was born at Assisi about the middle of the fifteenth century.

The common story of this painter, originating with Vasari, has been completely overthrown by Rumohr in his 'Italienische Forschungen.' The account of Vasari, which has been invariably followed by all subsequent writers on the subject, down to the time of Rumohr, is that L'Ingegno was the rival of Raphael in the school of Pietro Perugino, that he became suddenly blind while assisting his master Perugino in the Sistine Chapel; and that the then pope, Sixtus IV., granted the unfortunate painter a pension for life, which he enjoyed until his eighty-sixth year. Rumohr has shown this account to be, with one exception, wholly incorrect; the only possible part of it is that L'Ingegno assisted Perugino in the Vatican; this he may have done, as he was his assistant in some works in the Cambio, or Exchange, of Perugia.

L'Ingegno cannot have been Raphael's fellow-pupil with Perugino, for he painted only one year after the birth of Raphael, in 1484, a coat of arms for the town-ball of Assisi, where he was then an established master. He also, long after the death of Sixtus IV., held official situations at Assisi, which can leave no doubt of his retaining his sight. In 1505 he was procurator; in 1507, arbitrator; in 1510, syndic—syndicator potestatis; and in 1511 he was appointed by Julius II. papal treasurer at Assisi—Camerarius Apostolicus in Civitate Assisii. L'Ingegno, therefore, instead of receiving a pension from Sixtus IV., received a salary from Julius II., 27 years after the death of Sixtus, who died in 1484. From these several appointments he had probably given up painting, which may have been either owing to weakness of sight or from greater advantages to be had elsewhere: his brother was one of the canons of the cathedral of Assisi.

The only certainly known work by L'Ingegno is the coat of arms already mentioned. The prophets and sibyls in the Cambio at Perugia are assigned to him, but it is quite uncertain what portion of those works was executed by him: the prophets and sibyls also in tho Basilica of Assisi were attributed to him, but it has been shown that they were executed in the sixteenth century by Adone Doni. There are further attributed to L'Ingegno two pictures in the galleries at Berlin and Vienna; and a Holy Family in the Louvre, a beautiful small work in the style of Perugino. Rumohr conjectures, from the style of L'Ingegno in these works attributed to him, that he was the pupil or imitator of Niccolo Alunno. He was probably called L'Ingegno more for a general aptness for business, than for any particular skill in painting.

(Vasari, *Vite de' Pittori*, &c.; Lanzi, *Storia Pittorica*, &c.;

Rumohr, *Italienische Forschungen;* Waagen, *Kunstwerke und Künstler in Paris.*)

LUI'NI or LOVI'NI, BERNARDINO, the most celebrated of the scholars and imitators of Lionardo da Vinci, was born at Luino on the Lago Maggiore, about the middle of the fifteenth century. There can be no doubt that this is the approximate time of his birth, as he painted himself as an old man in the picture of Christ disputing with the Doctors, at Saronno near Milan, which was executed, according to its inscription, in 1525. Lanzi has successfully shown that there is every probability that Luini was the actual scholar of L. da Vinci, and that Resta must be in error when he states that Luini did not go to Milan until the early part of the sixteenth century, when Da Vinci had already left it.

Luini's reputation is comparatively recent, which is owing to Vasari's silence regarding him, though he evidently alludes to Luini where he speaks of the paintings of Bernardino da Lupino in the church of the Madonna at Saronno. Luini painted much in the style of Lionardo da Vinci, and his works are in many instances, in the opinion of several judges, attributed to Da Vinci; this is the case with the Christ disputing with the Doctors, in the National Gallery, which Dr. Waagen and others have no hesitation in pronouncing to be by Luini. Fortunately many of Luini's best and greatest works, in oil and in fresco, are still in a good state of preservation, namely, the Magdalen, and St. John with the Lamb, in the Ambrosian library at Milan; the enthroned Madonna, painted in 1521, the Drunkenness of Noah, and other works in the gallery of the Brera at Milan; the frescoes of the Monastero Maggiore, or S. Maurizio, in the same city, from which, however, the ultramarine and gold have been scraped off; those already noticed at Saronno; and other extensive and equally good works in the Franciscan convent Degli Angeli at Lugano, on the lake of that name, which were painted subsequently to those at Saronno, and are among the last of Luini's works, but their colours have somewhat suffered. There are also many easel-pictures in oil by Luini, both in and out of Italy, in public and private collections.

Luini's style is something between that of Mantegna and Raphael, his earlier works approaching nearer to the style of Mantegna, and his later to that of Raphael; they are elaborately finished, beautifully coloured, and forcibly shaded, yet they want the exquisite tone, the fullness of style, and the greatness of character of the works of Da Vinci; in expression, however, they approximate very nearly to the works of that great master. Luini excelled chiefly in painting women and the more delicate qualities of human character. Several of his best works have been lately engraved in a superior style, by various masters. The Adoration of the Magi has been engraved by C. della Rocca; the Presentation in the Temple, by A. Ghiberti; and the Marriage of the Virgin, and Christ disputing in the Temple, by C. Rampoldi; all these works are at Saronno: the Madonna with the Infant Christ, and St. John, at Lugano, have been engraved by C. Artaria; St. John with the Lamb has been engraved by G. Gerriani and P. Anderloni; and Herodias with the Head of John the Baptist, in the Brera, by G. Caravaglia. The paintings at Lugano are described in the 'Kunstblatt' for 1822.

Luini was still living in 1530, but the date of his death is not known. He had two sons, Evangelista and Aurelio, who are both praised by Lomazzo, their contemporary. Aurelio assisted his father in the frescoes at Lugano. After Da Vinci, the founder or *Caposcuola* of the Milanese school of painting, Gaudenzio Ferrari and Luini are the principal masters of the school, the distinguishing characteristics of which, as a school, are simplicity of subject and composition, expression, force of colour and tone, and minute perspective.

In the gallery of the Brera at Milan there are several frescoes by Luini, and one by his son Aurelio, which have been removed from the walls, and transferred to panel or canvas. Luini was one of the most masterly of the old Italian fresco painters, and there is a marked difference between the execution of his works of this class and his oil pictures; they are painted with much more freedom. He must have painted in fresco with remarkable rapidity. According to the observation of Mr. Wilson, who was sent by the English Government to Italy to examine the state of the early Italian fresco paintings, Luini must have executed more than an entire figure of the size of life in a single day: his colouring is warm and transparent, the lights of his draperies being merely thinly glazed with the colour of the drapery mixed with a little white; the shadows are the pure colour, laid on thickly; the outlines are often strongly indicated in some dark warm colour. He does not appear to have worked from cartoons; in his faces the features are merely indicated by straight lines, yet many of his female heads, painted upon such slight preparation, are among the most beautiful of the Italian frescoes.

(Lomazzo, *Trattato della Pittura;* Lanzi, *Storia Pittorica,* &c.; Waagen, *Kunstwerke und Künstler in England.* &c.; *Report of the Commissioners on the Fine Arts,* 1843, Appendix.)

LUMBRICARIA, a genus of fossil Annelida, from the Silurian strata of Tyrone. (Portlock.)

LUNACY. [INSANITY, P. C.; LUNACY, P. C.] Some recent acts have made alterations in the proceedings under commissions of lunacy.

An act of the 3 & 4 Wm. IV. c. 36, is entitled 'An Act to diminish the Inconveniences and Expenses of Commissions in the Nature of Writs De Lunatico Inquirendo; and to provide for the better Care and Treatment of Idiots, Lunatics, and Persons of Unsound Mind, found such by Inquisition.'

An act of the 5 & 6 Vict. c. 84, is entitled 'An Act to alter and amend the Practice and Course of Proceeding under Commissions in the Nature of Writs De Lunatico Inquirendo.' The first section empowers the Lord Chancellor to appoint two serjeants or barristers-at-law, to be called 'The Commissioners in Lunacy;' and enacts that in future all Commissions in the nature of Writs De Lunatico Inquirendo shall be directed to such commissioners, and that such Commissioners shall jointly and severally have and execute all the powers, duties, and authorities now had and executed by commissioners named in commissions in the nature of Writs De Lunatico Inquirendo. The commissioners (§ 2) are to conduct all inquiries with respect to Lunatics and their estates in such manner as the Lord Chancellor shall from time to time direct; and it is provided that nothing in this act shall prevent the Chancellor from issuing any commission in the nature of a writ De Lunatico Inquirendo, addressed to any fit or proper person or persons, in addition to the Commissioners in Lunacy.

§ 3 empowers the Chancellor to refer to the Commissioners in Lunacy, or either of them, any of the inquiries and matters connected with the persons and estates of Lunatics which are usually referred to the Masters in Ordinary in Chancery; and § 4 makes the Commissioners in Lunacy visitors, under the direction of the Chancellor, of all persons found idiot, lunatic, or of unsound mind, by inquisition, jointly with the three visitors appointed by the 3 & 4 Wm. IV. c. 36.

§ 7 empowers the Chancellor from time to time to regulate the form and mode of proceeding before and by the said commissioners, and the practice in matters in Lunacy; and to regulate the number of jurymen to be sworn to try inquests on Commissions in the nature of Writs De Lunatico Inquirendo; but it is provided that every inquisition on such commission shall be found by the oaths of twelve men.

By the 8 & 9 Vict. c. 100, § 2, the two commissioners of lunacy are henceforth to be called Masters in Lunacy, and take the same rank and precedence as the masters in ordinary of the High Court of Chancery. Some other regulations as to the duties of the masters in lunacy are contained in 8 & 9 Vict. c. 100, § 95-98.

The other sections of the act 5 & 6 Vict. c. 84, make regulations as to fees and other matters, for which the act must be consulted. The salary of the commissioners is 2000*l.* a-year, free from all taxes or abatement.

The term Lunatic is only properly applied to a person who is found to be a lunatic by the verdict of a jury under an inquisition, as explained in LUNACY, P. C. But the term lunatic is also applied to those who, being considered lunatics, are confined in lunatic asylums or hospitals, under such regulations as the 8 & 9 Vict. c. 100, § 44-49 prescribe, without having been found lunatics under an inquisition; and also to any single patient who is boarded or lodged for pay as a lunatic in a house not licensed under the act, § 90; and also to any person who is under the care of any person who receives or takes the charge of such one lunatic only, and derives no profit from the charge (§ 112). As to the persons and property of such so-called lunatics, who have not been found lunatic by a jury, the 8 & 9 Vict. c. 100, § 94, enacts, That whenever the commissioners in lunacy shall have reason to suppose that the property of any person detained or taken charge of as a lunatic is not duly protected, or that the income thereof is not duly applied for his maintenance, such commissioners shall make such inquiries relative thereto as they shall think proper, and report them to the lord chancellor. § 98 enacts, That when any person shall have been received or taken charge of as a lunatic upon an order and certificate, or an order and certificate under the provisions of that act, and shall either have been detained as a lunatic for the twelve months then last past, or shall have been the subject of a report by the commissioners in lunacy in pursuance of § 94, the lord chancellor shall direct one of the masters in lunacy to inquire and report to him as to the lunacy of such person so confined, and the chancellor is authorised to make orders for the appointment of a guardian or otherwise for the protection, care, and management of such lunatic, and such guardian is to share the same powers and authorities as a committee of the person of a lunatic found such by inquisition now has, and to appoint a receiver or otherwise for the care and management of the estate of such lunatic, and such receiver is to have the same powers as a receiver of the estate of a lunatic found such by inquisition now has; and the chancellor is also empowered to make orders for the application of the income of the lunatic towards his maintenance, and the cost of the care and management of his person and estate, and also as to the investment or other application for the purpose of accumulation of the overplus; but such protection, care, and management are only to continue so long as such lunatic shall continue to be detained as a lunatic upon such order or certificate as aforesaid, and such further time, not exceeding six months, as the chancellor may fix; but the chancellor may in any such case, either before or after directing such inquiry, and whether the master shall have made such inquiry or not, direct a commission in the nature of a Writ De Lunatico Inquirendo to issue, to inquire of the lunacy of such person.

In the Roman system, persons of unsound mind (furiosi) might be deprived of the man gement of their property on application to the praetor by his next of kin. This legislation was either introduced or established by the Twelve Tables. The person who had the care of the lunatic and of his property was called a curator. [CURATOR, P. C.] The Twelve Tables gave the care of the lunatic to his agnati. In those cases where the law had not provided for the appointment of a curator, the praetor named one. (*Dig.* 27, tit. 10; *Instit.* 1, tit. 23.)

LUNATIC ASYLUMS. COMMISSIONERS IN LUNACY. STATISTICS, CONSTRUCTION, and MANAGEMENT OF ASYLUMS. HISTORY OF THE NON-RESTRAINT SYSTEM. The subject of insanity and asylums for the insane has of late years occupied a very large share of public attention; particularly as an opinion has prevailed that insanity is on the increase in this kingdom beyond the ratio of population. The want of accurate information renders this point doubtful; but it is certain that more than 20,000 insane persons are in confinement in the public asylums and licensed houses in England and Wales, of whom 16,000 are paupers. But as a great number of patients are confined separately, or in the care of their relatives, of whom no public returns are made, this number is probably far below that of the persons insane in the country.

Two acts passed in 1845 (8 & 9 Vict. caps. 100 and 126) have placed the powers vested in the Commissioners in Lunacy on an entirely new footing, and have in many respects modified the constitution of asylums. The first act repeals 2 & 3 Wm. IV. c. 107; 3 & 4 Wm. IV. c. 64; 5 & 6 Wm. IV. c. 22; 1 & 2 Vict. c. 73; 5 Vict. c. 4; and 5 & 6 Vict. c. 87. This first act appoints six commissioners, three of whom are physicians and three barristers, with salaries; and five other commissioners who act gratuitously. The rule that none of these shall be connected with any asylum is continued. No person can act as a commissioner who within one year has been directly or indirectly connected with any asylum. Licences are granted by these commissioners at each of their quarterly meetings. Any person who wishes to open a house for the reception of patients is required to send a plan upon a scale of one-eighth of an inch to a foot of every part of the premises at least fourteen days previous to his application. No additions to or alterations in a licensed house can be made without the consent of the commissioners. No licence is to remain in force more than thirteen months, and the notice of a wish to renew must give the number of patients then confined. The jurisdiction of the commissioners extends to the whole of London and Middlesex, and Southwark; and to all places within seven miles of London, Westminster, and Southwark: in the country the licences are to be granted by the justices of the peace in quarter-sessions, who are bound to appoint three of their number, together with one physician, surgeon, or apothecary, as visitors of the asylums licensed by them. Strict regulations are enforced for the reception of patients; it is required that every person, not being a pauper, received as insane, shall be certified to be so by two physicians or surgeons, who shall visit such patient separately, and shall have no interest in the asylum in which such patient is to be confined; and certain entries of these particulars are to be kept at each asylum. For a pauper, the certificate of one medical man and the order of two justices is required.

Penalties are fixed for neglecting these rules, or those which direct notice to be given of every admission, death, discharge, or escape. Houses having one hundred or more patients are to have a resident medical attendant, and those of smaller size are to be visited by a medical attendant at defined periods, according to their size. Every house within the immediate jurisdiction of the commissioners shall be visited by them at least four times in the year, and every other house at least twice in every year; these visits may be made at any hour, even by night, and it is penal to conceal any part of a house from them. Similar powers are given to the visitors in the country.

The commissioners are to present an annual report to the lord chancellor of the state of the different asylums visited by them, which Report shall be laid before parliament.

An important alteration is made in the law concerning the care of single patients. Orders and medical certificates must in future be procured for the care of one patient, similar to those used for the admission of patients into licensed houses; and copies of these documents are to be privately sent to and registered by the secretary to the commissioners. This act only extends to England and Wales, and it does not affect Bethlem Hospital, London. The persons appointed to hold commissions De Lunatico Inquirendo, heretofore styled commissioners, are in future to be termed 'Masters in Lunacy.'

The second act, which repeals 9 Geo. IV. c. 40, relates to the regulation of lunatic asylums for counties and boroughs, and the maintenance and care of pauper lunatics; and gives to the commissioners a great power over these institutions, which had previously been entirely under the control of justices of the peace. The justices of every county and borough are now to be compelled to erect or to join in the erection of an asylum, where none such already exists; and all proposals, agreements, and plans, and the rules and regulations of each asylum, are to be submitted to the commissioners, and all contracts and estimates approved by the secretary of state. Contracts for the care of insane persons in licensed houses do not exempt any county or borough from the obligation of providing an asylum. Power is given to committees to grant retiring allowances to the officers of asylums; and a medical officer must be resident in every asylum which contains more than 100 patients. Lists of all the patients are to be sent twice in every year to the commissioners by the medical officer. This act extends only to England and Wales, and does not apply to Bethlem Hospital.

Great advantages may fairly be anticipated from the restrictions imposed by these acts; and they may probably only be considered as steps towards the highly desirable result of making all insane persons immediately the care of the State. The duties of the commissioners have, until the last few years, been very imperfectly performed, and the utmost secrecy as to their names and movements was preserved. The management of private asylums must vary considerably, as such houses are rarely built for the purpose, and are frequently under the direction of persons unfitted by their want of education for such an important charge; but these circumstances can by no means be admitted as excuses for the scandalous instances of cruelty and mismanagement which have gone on under the eyes of the commissioners, and in houses which have received their praise; especially in those large private asylums, where an immense number of paupers are taken at low rates; the temptation held out in such cases to economy at the expense of the care and comfort of the patients ought to call forth an especial watchfulness on the part of the commissioners.

The patients who are confined in prisons, hospitals, workhouses, or in the houses of their relatives, are exposed perhaps more than any others to great neglect and mismanagement; and not unfrequently are treated with great cruelty, even when the intentions of the parties who have charge of them are good, through their entire ignorance of the nature and proper treatment of the disorder.

Management of Public Asylums.—There is considerable diversity in the internal regulations of different public asylums as to the power and position of the medical and non-medical officers. In some there is a resident physician who holds the supreme authority, and is also steward and general manager; in others the physician only presides in his own department; and in others the chief officer is not medical, and the physician is non-resident. The Norfolk asylum was before the passing of this act the only large one in England without a resident medical officer; and this fact is severely commented on by the commissioners in their report. Under the new act a resident medical officer has been appointed; but we understand that the chief authority still remains with the non-medical superintendent. In the 70th Report of the visiting justices of Hanwell (April, 1844) it is stated that they have appointed an officer in the army to superintend the institution, with a view to the preservation of greater order and discipline than had been maintained under medical rule; in the 72nd Report (October, 1844) the resignation of the governor is mentioned, and we cannot learn from the reports that any steps have been taken to appoint a successor, nor whether the advantages derived from his appointment equalled the expectation of the justices.

In all asylums the position of the matron is one which requires to be settled in some uniform manner; owing to the matron having been in many cases the wife of the superintendent, an undue importance has been given to her position; the appointment of the female attendants, and even the classification of the female patients, has sometimes been left in her hands. When we consider that the matron cannot possibly have had a medical education, and that in very few cases those who hold the situation possess any previous knowledge of insanity, or are even persons of good general information, it is manifestly improper to allow her too high an authority. In the French asylums, and we believe also in some of those in the United States, there is no matron; a few of the most experienced female attendants act as heads of departments, and receive the orders of the medical officers; and this arrangement, which is found to work exceedingly well at the Salpêtrière, where there are 1500 female patients, seems on the whole to be the best. The effect of placing the matron in a higher position is almost certainly to bring about interference on her part with the duties of the medical officers, which cannot fail to be injurious to the welfare of the patients. At Hanwell the salary of the matron is higher than that of the resident medical officers, or than that of any officer excepting the physician.

In the appointment of a chaplain, steward, secretary, accountant, and any other officers, the most important point is to confine their duties within certain proper limits, and to prevent their interference with the patients without the concurrence of the medical officers.

If the government should at any time take the entire supervision of asylums for the insane into its own hands, we trust that the mode of proceeding will be to appoint to each asylum one resident medical officer, who shall be responsible for the entire conduct of the asylum; and to whom, therefore, the power of appointing and dismissing all the subordinate officers shall be given. Uniformity of system, the want of which has been a great evil in many asylums, would thus be secured; and the careful selection of a competent principal officer responsible for every instance of negligence or cruelty in the asylum under his care, could not fail to improve the general management of these institutions. At Glasgow the whole authority has for some years been in the hands of the resident physician, with the most satisfactory results; and an approximation is made to this plan in the Irish district asylums, where the non-resident physician is the principal officer.

By the acts lately passed, the power which the justices who had the control of different asylums possessed of passing rules at any meeting which entirely changed the system of management, or of summarily dismissing any officer, is done away with. The caprices of the governors of some asylums have changed their entire constitution in a few years.

A great improvement has been made of late years in the class of persons appointed as attendants, or, according to the old phraseology, *keepers*. That all such persons should possess benevolence and intelligence is essential to the effective working of a humane and enlightened system; and they should be liberally paid. The proportion of attendants to patients in the different English public asylums varies from one to ten, to one to twenty; the former does not seem too much, and is far less than that in all well-managed private asylums. No ward, however small, should have less than two attendants, in order that it should never be left without one; this is enforced by the rules of several asylums. A large number of attendants renders a vigilant superintendence by night practicable, which is no less important than by day, although it is entirely omitted in some institutions.

Whilst many excellent asylums exist for the rich, and the law is providing an increase of accommodation for the poor, benevolent individuals are making efforts to secure the benefits of proper treatment for the middle classes. It is proposed to build an asylum in the neighbourhood of London for 300 patients, at a cost of 30,000*l.*, which sum is to be raised by donations and subscriptions. When once established, it will be self-supporting, and it is expected that payments of from 1*l.* to 1*l.* 10*s.* per week for each patient will cover all the expenses. No existing asylum offers to persons able only to pay such a sum the comforts to which their position in society has accustomed them.

Construction.—The site and construction of an asylum for the insane are matters of great importance. A healthy and cheerful situation should be the first consideration in an institution intended for the cure of diseased minds. In this respect some existing asylums are very well placed; Hanwell, Lincoln, and Surrey may be instanced. Others have been originally on the outskirts of towns, and have been surrounded and built in by the increase of building. The commissioners mention several so placed in proper terms of censure.

It is generally admitted that the building ought not to be larger than to accommodate 300 or 400 patients, but an additional asylum for Middlesex is projected to hold 1200. As to plan, no two of the existing asylums are alike, and the most recently erected are by no means the best. In the Surrey asylum a complete copy has been made of the worst and newest part of Hanwell, in which the bed-rooms face one another, and the galleries are lighted from the top, which renders proper ventilation impossible. To make wide galleries with rooms only on one side, would certainly increase the cost of the building; but by introducing a bow or expansion into each gallery, the necessity for a day-room will be done away with. An open fire should be in each of these expansions; it will be a great source of comfort to the patients, and an improvement in the ventilation as well as the general appearance of the gallery; and, with a light wire guard, is perfectly safe. This plan is to be adopted in the Derby asylum now building; and as a ward must occasionally be left with one attendant, there is an advantage in bringing the whole of it within sight from a central position. No ward should contain more than thirty patients; and of these from twenty to twenty-five ought to have single rooms. It is matter of regret to find that dormitories are approved by the commissioners, and supported by the officers of some asylums; they certainly lessen the cost of building, but the quiet and comfort of the institution must be much diminished. Their ventilation is also very difficult; single rooms may be warmed with a hot-water pipe passing along the floor (not over-head), and opening the window will be a sure means of making a complete change in the air; but in dormitories it will be difficult to preserve freshness of air with warmth, more especially as the great argument in favour of them is their economy, and an economy partly made by allowing to each patient a smaller number of cubic feet than would be given in a single room. For the sick, the violent, the dirty, and the noisy, single rooms are obviously necessary; and it will, we believe, generally be found that the remaining patients, those whose tranquillity and usefulness entitle them to indulgences, will consider a single room, which they can call their own, one of the greatest that can be given them.

An asylum containing 400 patients may probably be built in a straight line, which is desirable, without the necessity of carrying it higher than the first floor. The chapel and chief officers' rooms, and the rooms used for the work or amusement of the patients, should form the centre; behind which the kitchen may be conveniently placed, with the laundry on the side next the wards of the women, and the workshops on that of the men. In the wards branching off from the centre, those patients who are quiet and convalescent and the sick should be placed, and the most refractory at the extreme ends of the building, to prevent them from disturbing the others. Six classes of patients may usually be found, for each of which some modification of management will be required:—

1. Tranquil: convalescent and melancholic.
2. Moderately tranquil.
3. Refractory.
4. Sick and infirm.
5. Idiots and other dirty patients.
6. Epileptics of the better class. These are frequently in

the intervals of their fits the most intelligent of the patients, but during the fits they require great attention.

All the sick, idiots, and epileptics should be on the ground floor, which will be easily arranged, as the tranquil and moderately tranquil, who form the great bulk of the patients, may occupy the upper floor.

To describe the numerous minute particulars to be attended to in constructing and furnishing an asylum is unnecessary here; the great rule should be, that every possible amount of safety should be combined with every possible amount of cheerfulness. There should be the strength of a prison without its gloomy character. No part of the building, within or without, should be neglected; and scarcely a day passes without improvements being made in one asylum or other—improvements that are worthy of adoption in any to be hereafter built.

An abundant supply of warm and cold water should be secured; or in some cases it will be found that the cost of supplying this necessary article will neutralize the advantages of an otherwise favourable site.

Baths, water-closets, a store-room, and rooms for washing, are essential in every ward. Warm baths are considered by many authorities to be valuable remedial agents, as well as advantageous to the general bodily health.

The commissioners have expressed an opinion that incurable paupers may be accommodated in asylums apart from the curable at a much less expense, and an arrangement for a separate provision for incurables is required by the new act (s. 27); but they cannot be aware that while the incurables comprise all the most tranquil and intelligent of the patients, whose society is of great value to the curables, they also comprehend patients who display every different form of insanity, and require every variety of treatment. It is certainly much to be wished that provision could be immediately made for all insane paupers; but we cannot consider that the removal of all hope from a large number of them, by immuring them in an 'asylum for incurables,' would be the best mode of attaining this object.

The following is a statement of the cost of building and furnishing twenty-two asylums, including that of the land, which in some cases amounts to a large sum. The mean cost for each patient accommodated is 154*l.* 2*s.* 3*d.*, which is probably more than will be found necessary in most future asylums. The expense of maintaining patients varies from seven to fourteen shillings per week; this must of course depend in some degree upon the prices of provisions in different parts of the kingdom, and be modified by cheap and dear seasons.

Statistics.—There are in England and Wales 12 county asylums, 5 county and subscription, 11 partly subscription and partly charitable, 1 military, 1 naval, and 142 licensed houses; 14 of which last receive paupers. The hospital of Bethlem, which is exempt from the rules that affect other asylums, is to be added to this number.

Scotland has eight public asylums; in all of which, we believe, private patients as well as paupers are received; and some are assisted by charitable endowments.

Ireland has twelve public asylums; ten of these are district asylums for the poor; Cork is locally governed, and Swift's Hospital is founded by charter.

Several new asylums are in progress both in England and Ireland.

With a view to present in a few plain statistical tables the results of treatment in each of the existing public asylums, the writer of this article sent blank forms to each superintendent in the kingdom; in almost every case they have been filled up and returned, and their contents are embodied in the following tables. When information could not be obtained in this manner or from reports, the statistical tables published by the Commissioners in Lunacy have been resorted to; but these only extend to the end of the year 1843, and required much correction, as they are not upon one uniform plan. We may instance the tables furnished by Bethlem and St. Luke's as omitting many of the particulars desired by the Commissioners. In several asylums no average number of patients is given, and the per-centages of deaths and cures are calculated upon other numbers; in other asylums which have been opened many years, the early records are so incomplete as to be useless. In several asylums, even in some recently opened, the published returns do not contain any distinction of the sexes.

The First Table shows the whole number of patients admitted into the 49 public asylums of the United Kingdom to the latest date to which we can obtain information; being 38,537 males, 38,328 females, and 8394 of whom the sex is not specified. Thus the admissions of males exceed those of females by 209, or in the proportion of 1 to ·9945; a scarcely appreciable difference. Of the whole number of insane persons in England and Wales on the 1st January, 1844, according to the report of the Commissioners, 9862 were males and 11,031 females; thus the females exceed the males in the proportion of 1 to ·894. The greater mortality among men is the cause of this apparent discrepancy.

The following Table (II.) shows the result in the same asylums as to cures and deaths during the same period. This comparative table is recommended by the Commissioners, in addition to the tables showing the per-centage of cures and deaths on the average number.

The cures are taken as 1.

The term 'Removed' includes all discharged improved or uncured, or escaped.

This table likewise shows the number remaining in the different public asylums at the latest dates to which we have been able to make up the returns, and which appears to be 5163 males, 5044 females, and 236 of whom the sex is not specified.

The greater number of cures and smaller number of deaths among females must be in a great measure ascribed to

* Only for 24 years. † Only for 16 years. ‡ Only for 6 years. § Sexes not distinguished. ‖ Only for 1 year. ¶ Only for 6 years.

their comparative immunity from epilepsy and paralysis, which, when combined with insanity, render recovery very nearly if not quite hopeless. It is said also that women more frequently recover from the acute stage of mania, while men die of exhaustion.

The reverse of this apparent rule is found only in the results of some of the smaller asylums, where the deaths of either sex are few. In those returns where the sexes are not distinguished we have reckoned the proportion as equal.

The tables of per-centage of cures and deaths published by the Commissioners have unfortunately not been compiled upon any fixed plan. All computations, excepting upon the average number of patients in the asylum during the specified year, must be fallacious. The following Tables (III., IV.) have been made upon that principle; the blanks indicate the cases in which correct returns are wanting. Some asylums do not publish their average number of patients; others calculate the per-centage of cures and deaths upon the whole number admitted; but this is an entirely delusive method, as these numbers must be continually increasing, while the proportion of patients remaining decreases.

We have, as far as possible, made an average of all the public asylums for ten years past.

The mean number of cures thus appears to be 21·26 per cent., and of deaths 9·62 per cent.; but many asylums depart very widely from this standard. Bethlem, St. Luke's, and Liverpool receive only recent cases; and in the Liverpool institution their probation is very short. The large asylums at Hanwell, Surrey, and Lancaster are consequently compelled to receive almost entirely incurables, which accounts for their small number of cures. The large number cured in the Irish asylums may be in some measure accounted for by the peculiar character of their patients. The Irish patients in English asylums usually recover rapidly, the form of disorder being frequently pure excitement, which is soon allayed by quiet, by temperance, and the orderly regulations of an asylum.

Many attempts have been made to obtain a uniform system of keeping statistical tables; at present a different plan is adopted in almost every asylum. A great improvement would be effected if every report, in addition to its information for the current year, contained a condensed statement from the opening of the institution as to admissions, cures, and deaths; and there would be little difficulty in adding the ages, forms of disease, the causes of death, and other tables. Much important information as to the most favourable and unfavourable ages, and the results of immediate and delayed admission, would be easily gained, if a reference to the last report of any asylum were sufficient to show the experience of that institution from its opening in a condensed form. No asylum has yet published any such tables; but in the numerous new asylums which will be built in the course of a few years,

* Those discharged improved and uncured are included with the cures. † Sexes not distinguished.
‡ Great doubts exist as to the accuracy of the older books at the York Asylum.
§ There is some mistake here; the admissions are made to amount to 1389, and the cures, deaths, and remaining patients to 1623.

nothing could be more easy than to adopt them. The legislature may possibly enforce certain tables; and such a law would be exceedingly desirable, if we could hope that the practical experience of the superintendents of lunatic asylums would be allowed to be of any weight: but if the returns are to be made out according to the fancy of men ignorant of the subject upon which they legislate, the present system, by which every superintendent follows his own discretion, is far preferable.

The following points seem to deserve attention in any plan for uniform registration:—

I. Admissions for the current year:—
 1. Form of disease.
 2. Causes of disease.
 3. Duration of disease.
 4. Age.
 5. Age when first attacked.
 6. Social state.
 7. Station or occupation.

II. Similar returns for the whole number admitted from the opening of the asylum.

III. Cures for the current year:—
 1. Form of disease.
 2. Causes of disease.
 3. Duration of disease.
 4. Age.
 5. Age when first attacked.
 6. Duration of residence.
 7. Per-centage upon average number of patients.

IV. Similar returns for the whole number cured.

V. Deaths for the current year:—
 1. Form of mental disease.
 2. Causes of mental disease.
 3. Duration of mental disease.
 4. Age.
 5. Age when first attacked.
 6. Duration of residence.
 7. Per-centage upon average number of patients.
 8. Causes of deaths.

VI. Similar returns for the whole number who have died.

VII. Number discharged uncured, improved, by request of friends, removed by parishes, or escaped, during the current year, distinguishing the reasons for removal, and the duration of residence.

VIII. Similar returns for the whole number removed or escaped.

IX. Patients remaining in the asylum:—
 1. Form of disease.

The registers, to contain all this information, might be of very simple form, far less complicated than those at present in use in several asylums. The sexes should be distinguished in every statement.

Registers should likewise be kept of every instance of restraint, its nature and duration, and of the duration of every seclusion; also of employment and of the value of the work done. Many others might be suggested as useful in various ways, though not strictly necessary for statistical purposes.

Abolition of Personal Coercion.—No part of the treatment on insanity has of late years excited so much attention as the system adopted in several asylums of totally abolishing the use of all instruments of coercion, which has gained the name of the *non-restraint system.* We desire to preserve this name, as many asylums, which still continue to use all the antient instruments of restraint, endeavour, by professing to practise the 'humane system,' to lead the readers of their reports to suppose that there is no essential alteration made by the discontinuance of the use of those instruments.

In giving a slight sketch of the progress of this improvement in the mode of treating the insane, we shall consider it as a natural consequence of the progressive amelioration in the management of asylums.

Until the establishment of Bethlem in 1547, we have little or no records of the provision made for the insane; we can only gather that all who were harmless, and many who were dangerous, supported a miserable existence by wandering and begging; those who could not be permitted to be at large were probably chained in prisons, or in the hands of their friends. Some mention is made of an asylum for insane monks established at Jerusalem in the sixth century, where all the rigours of monastic discipline were embodied in the treatment.

Even in Bethlem little attention seems to have been paid to the comfort or cure of the patient; the only consideration was the safety of the sane part of the population. The patients were chiefly naked, and chained to the walls; and were exhibited for money, like wild beasts; and it is even said that the keepers were accustomed to allude to every subject most aggravating to the violent patient, that his rage might increase the amusement of the exhibition; while the propensities of the filthy were encouraged, and the voracious idiot was kept without food, that they might appear as more strikiug objects of wonder to the idle crowd. This shameful practice, by which it appears that an income of 400*l.* per annum was derived by the hospital, was abolished in 1770; but no improvement was made in any other respect in the treatment of the patients.

The benevolent and courageous Pinel was the first to attempt the restoration of the insane to a position among human beings. The scene of his exertions, which were the first great step of the non-restraint system, was the Bicêtre—hospital for insane men, near Paris. In this frightful prison the universal practice was to load patients with heavy chains,

which remained on for the remainder of their lives, and to immure them in dark, unwarmed, and unventilated cells. Pinel determined on at once releasing a large number of patients. The following account of the experiment is extracted from the 'British and Foreign Medical Review:'—

'Towards the end of 1792, Pinel, after having many times urged the government to allow him to unchain the maniacs of the Bicêtre, but in vain, went himself to the authorities, and with much earnestness and warmth advocated the removal of this monstrous abuse. Couthon, a member of the commune, gave way to M. Pinel's arguments, and agreed to meet him at the Bicêtre. Couthon then interrogated those who were chained, but the abuse he received, and the confused sounds of cries, vociferations, and clanking of chains in the filthy and damp cells, made him recoil from Pinel's proposition. "You may do what you will with them," said he, "but I fear you will become their victim." Pinel instantly commenced his undertaking. There were about fifty whom he considered might without danger to the others be unchained, and he began by releasing twelve, with the sole precaution of having previously prepared the same number of strong waistcoats with long sleeves, which could be tied behind the back if necessary. The first man on whom the experiment was to be tried was an English captain, whose history no one knew, as he had been in chains forty years. He was thought to be one of the most furious among them; his keepers approached him with caution, as he had in a fit of fury killed one of them on the spot with a blow from his manacles. He was chained more rigorously than any of the others. Pinel entered his cell unattended, and calmly said to him, "Captain, I will order your chains to be taken off, and give you liberty to walk in the court, if you will promise me to behave well and injure no one." "Yes, I promise you," said the maniac; "but you are laughing at me; you are all too much afraid of me." "I have six men," answered Pinel, "ready to enforce my commands, if necessary. Believe me then on my word, I will give you your liberty if you will put on this waistcoat." He submitted to this willingly, without a word: his chains were removed, and the keepers retired, leaving the door of the cell open. He raised himself many times from the seat, but fell again on it, for he had been in a sitting posture so long that he had lost the use of his legs; in a quarter of an hour he succeeded in maintaining his balance, and with tottering steps came to the door of his dark cell. His first look was at the sky, and he cried out enthusiastically, "How beautiful!" During the rest of the day he was constantly in motion, walking up and down the staircases, and uttering exclamations of delight. In the evening he returned of his own accord into his cell, where a better bed than he had been accustomed to had been prepared for him, and he slept tranquilly. During the two succeeding years which he spent in the Bicêtre, he had no return of his previous paroxysms, but even rendered himself useful by exercising a kind of authority over the insane patients, whom he ruled in his own fashion.

'The next unfortunate being whom Pinel visited was a soldier of the French Guards, whose only fault was drunkenness: when once he lost self-command by drink he became quarrelsome and violent, and the more dangerous from his great bodily strength. From his frequent excesses, he had been discharged from the corps, and be had speedily dissipated his scanty means. Disgrace and misery so depressed him that he became insane: in his paroxysms he believed himself a general, and fought those who would not acknowledge his rank. After a furious struggle of this sort, he was brought to the Bicêtre in a state of the greatest excitement. He had now been chained for ten years, and with greater care than the others, from his having frequently broken his chains with his hands only. Once when he broke loose, he defied all his keepers to enter his cell until they had each passed under his legs: and he compelled eight men to obey this strange command. Pinel, in his previous visits to him, regarded him as a man of original good-nature, but under excitement incessantly kept up by cruel treatment; and he had promised speedily to ameliorate his condition, which promise alone had made him more calm. Now he announced to him that he should be chained no longer, and to prove that he had confidence in him, and believed him to be a man capable of better things, he called upon him to assist in releasing those others who had not reason like himself; and promised, if he conducted himself well, to take him into his own service. The change was sudden and complete. No sooner was he liberated than he became obliging and attentive, following with his eye every motion of Pinel, and executing his orders with as much address as promptness: he spoke kindly and reasonably to the other patients, and during the rest of his life was entirely devoted to his deliverer. "And I can never hear without emotion (says Pinel's son) the name of this man, who some years after this occurrence shared with me the games of my childhood, and to whom I shall feel always attached."

'In the next cell were three Prussian soldiers, who had been in chains for many years, but on what account no one knew. They were in general calm and inoffensive, becoming animated only when conversing together in their own language, which was unintelligible to others. They were allowed the only consolation of which they appeared sensible, —to live together. The preparations taken to release them alarmed them, as they imagined the keepers were come to inflict new severities; and they opposed them violently when removing their irons. When released they were not willing to leave their prison, and remained in their habitual posture. Either grief or loss of intellect had rendered them indifferent to liberty.

'Near to them was seen an old priest, who was possessed with the idea that he was Christ: his appearance indicated the vanity of his belief; he was grave and solemn; his smile soft, and at the same time severe, repelling all familiarity; his hair was long, and hung on each side of his face, which was pale, intelligent, and resigned. On his being once taunted with a question that "if he was Christ he could break his chains," he solemnly replied, "Frustra tentaris Dominum tuum." His whole life was a romance of religious excitement. He undertook on foot pilgrimages to Cologne and Rome; and made a voyage to America for the purpose of converting the Indians: his dominant idea became changed into actual mania, and on his return to France he announced himself as the Saviour. He was taken by the police before the Archbishop of Paris, by whose orders he was confined in the Bicêtre as either impious or insane. His hands and feet were loaded with heavy chains, and during twelve years he bore with exemplary patience this martyrdom and constant sarcasms. Pinel did not attempt to reason with him, but ordered him to be unchained in silence, directing at the same time that every one should imitate the old man's reserve, and never speak to him. This order was rigorously observed, and produced on the patient a more decided effect than either chains or a dungeon; he became humiliated by this unusual isolation, and after hesitating for a long time, gradually introduced himself to the society of the other patients. From this time his notions became more just and sensible, and in less than a year he acknowledged the absurdity of his previous prepossession, and was dismissed from the Bicêtre.

'In the course of a few days, Pinel released fifty-three maniacs from their chains: among them were men of all conpitions and countries: workmen, merchants, soldiers, lawyers, &c. The result was beyond his hopes. Tranquillity and harmony succeeded to tumult and disorder, and the whole discipline was marked with a regularity and kindness which had the most favourable effect on the insane themselves; rendering even the most furious more tractable.'

If experience did not always prove that improvements of any kind are slow, and invariably met by opposition, we should be at a loss to account for the fact that in England, twenty-three years after the liberation of the lunatics at Bicêtre, a state of things equally bad, if not worse, generally existed. From the evidence given before the parliamentary committees in 1815, we gather facts, supported by the evidence of the attendants themselves, almost too horrible to be credible. Every artifice of cruelty seems to have been employed upon those who were already the most unhappy of mankind. The idea seemed to prevail that all the feelings of humanity were extinguished by tho visitation of insanity. The keepers were, in all the English madhouses, of the lowest and most brutal character, merely distinguished by their success in controlling the violence of their patients by still greater violence, and by possessing the power of punishment. The account of the inquiry into the management of the York Asylum in 1813, written by the late respected Mr. Gray, gives probably a true picture of the state of the condition of the insane in general. This asylum was opened in 1777, and bore a fair character for organization and management. Upon the establishment of the Retreat, at York, in 1796, a more humane system than had hitherto been known in England was introduced into its management; and in the description of it by the founder, Mr. Tuke, published in 1813, a recommendation of the milder mode of treatment was given. This was considered, and with some reason, to be an attack upon the management of the York Asylum; and it was followed up by a series of charges brought by Mr. Godfrey Higgins against this latter institution. The horrors ultimately made known would be beyond belief, were they not amply attested, and were it not certain that in some private asylums things are little mended even now. Though the committee of the York Asylum long refused to listen to the charges brought by Mr. Higgins, they could not entirely conceal the facts; and the extent to which frauds of all kinds were carried by the steward assisted much in developing the general state of the house. A committee of inquiry was appointed; and on the day after their deliberations ceased (28th December, 1813), one wing of the asylum was destroyed by fire. There could be no doubt of this being intentionally done; and that it was done to destroy the part of the house most obnoxious to inquiry. How many patients perished is unknown; but at least four were missing. *The steward barred the gates to prevent the entrance of those who were willing to assist;* and nearly all the officers and attendants were away. The steward entered four patients who were missing as 'died;' but it is far more probable that a larger number were sacrificed. The real number in the house was probably unknown; for either by negligence or design the books had been so irregularly kept that the number of deaths to July, 1813, actually 365, was entered as 221, and 101 of those dead had been calculated among the cures. The committee refused to adopt the only method of ascertaining the number missing by requiring from each keeper an account of the patients under his care, from a pretended delicate objection to the divulging of the names of the inmates.

Mr. Higgins thus sums up the state of the management of the house:—'In the asylum investigations, concealment appears at every step of our progress; 365 have died; the number advertised is 221. A patient disappears, and is never more heard of, and is said to be "removed." A patient is *killed*—his body is hurried away to prevent an inquest. He is *cured*, but it is by some medicine the composition of which is known only to the doctor. The public cry out that a patient has been neglected; there is a levy *en masse* of respectable governors to quell the disturbance, and to certify that the patient has been treated with *all possible care, attention, and humanity*. A committee of investigation desires to be shown the house: certain cells "in an extreme state of filth and neglect" are omitted to be pointed out to them. The governors examine the accounts: there are considerable sums of which neither the receipt nor the application appears. They inspect the physician's report: it only aids the concealment. The steward's books are inquired for: in a moment of irritation he selects for the flames such of them as he thought it not advisable to produce. And yet every circumstance of concealment is imputed by some to mere accident; and every attempt to tear off the mask, and exhibit the asylum in its true character, is stigmatised as a libel or an indelicate disclosure!'

The details which were brought before the committee to exhibit the brutality and profligacy of the keepers need not be repeated; but it is gratifying to find that Mr. Higgins persevered, notwithstanding all the obloquy heaped upon him, until a complete change of the officers and of the system was brought about.

The next asylum of which we shall have occasion to notice the mismanagement is Bethlem, concerning which we find many particulars in the evidence given before the parliamentary committee in 1815.

The severest restraint and the most cruel neglect seem to have been the almost uniform practice; and it must not be forgotten that this royal hospital, favoured with exemption from all visitation and from the effects of acts of parliament, has been, until a very recent period, the most determined in resisting the abolition of restraint, in preserving antient abuses, and in closing its doors against inspection. With such large funds at command, Bethlem ought to be a model where the student of medicine may see every late improvement in the treatment of mental disorder carried into effect, without regard to the economy which has been detrimental to the improvement of many other asylums.

In 1815 Bethlem appeared to have been going back, rather than improving, for half a century. From the time that the indiscriminate visits of the public had been prohibited, the secrets of the institution were known only to a few. The case of Norris, a patient in Bethlem, which was made public by the parliamentary committee, has often been related; but it will not be out of place here. William Norris had been an officer in the navy, and was first confined at Bethlem in 1801. In 1803 he is said to have struck Mr. Haslam, the apothecary; and whether from any real fear of him or as a punishment, a new and most ingenious instrument of torture was invented for his confinement. 'A stout iron ring was riveted round his neck, from which a short chain passed to a ring made to slide upwards or downwards on an upright massive iron bar, more than six feet high, inserted into the wall. Round his body a strong iron bar, about two inches wide, was riveted; on each side the bar was a circular projection, which being fashioned to and inclosing each of his arms, pinioned them close to his sides. The waist bar was secured by two similar bars, which, passing over his shoulders, were riveted to the waist bar both before and behind. The iron ring round his neck was connected to his shoulders by a double link. From each of these bars another chain passed to the ring on the upright iron bar. His right leg was chained to the trough, in which he had remained thus encaged and enchained twelve years. He read books of all kinds, and reasoned quite coherently on the events of the war.' During the whole of this period it was impossible for him, from the nature of the restraint in which he was placed, either to stand quite upright or to lie down at ease. It will be no matter of surprise that he died on the 26th of February, 1815.

From this time a gradual but very slow improvement in the condition of the insane may be observed. Chains were removed, and leathern restraints of much milder kinds substituted; and more care was given to the warming and clothing of the patients. Some of the largest asylums in England were opened between 1815 and 1825. The introduction of employment by Sir William Ellis at Wakefield, and afterwards at Hanwell, was a great advance in the amount of confidence reposed in patients; employment has since been introduced in almost every asylum, and no serious accident, so far as we are aware, has ever occurred from allowing the use of tools. The credit of declaring the total abolition of mechanical instruments of restraint to be desirable and practicable, belongs to Dr. Charlesworth and Mr. Hill, of the Lincoln lunatic asylum. The progress of the alteration was given by Mr. Hill in a lecture delivered by him at the Lincoln Mechanics' Institution, 21st June, 1838, and since published with the addition of extracts from the 'Proceedings' of the asylum, and tables showing the gradual disuse of restraint. A reference to a few of these will illustrate this part of the history of the non-restraint system. The Lincoln asylum was opened on the 26th April, 1820, and was conducted from the first on humane principles, but with all the usual instruments of restraint.

On the 29th February, 1829, it is reported that a patient has died in the night in consequence of being strapped to the bed in a strait-waistcoat; and an order is consequently given that the use of the strait-waistcoat shall be discontinued, except under the special written order of the physician; and also that every case of restraint shall be entered in a journal, with its nature and duration.

On the 4th May, in the same year, the 'heaviest pair of iron hobbles,' which were jointed, and weighed 3 lbs. 8 oz., and the 'heaviest pair of iron handcuffs,' which weighed 1 lb. 6 oz., are ordered to be destroyed; five strait-waistcoats are likewise condemned.

Numerous entries in 1829, 1830, 1831, and 1832 prove the diminished use of coercion. On the 16th July, 1832, is the first order for strong dresses for such patients as tear their clothes. These patients were in all asylums the most subject to continual restraint.

21st July, 1834. All the instruments which would confine the fingers were ordered to be destroyed: but manacles for the wrists and leg-locks were retained. March, 1837, the system of restraint was entirely abolished.

Year.	Total Number of Patients in the House.	Total Number of Patients Restrained.	Total Number of Instances of Restraint.	Total Number of Hours passed under Restraint.
1829*	72	39	1727	20,424
1830	92	54	2364	27,113
1831	70	40	1004	10,830
1832	81	55	1401	15 671
1833	87	44	1109	12,003
1834	109	45	647	6 597
1835	108	28	323	2,874
1836	115	12	39	334
1837	130	2	3	28

Mr. Hill's lecture, which contains much that is exceedingly interesting upon this subject, has the following sentence, which has been the text on which all the controversy on the abolition of restraint has been founded:—'In a properly constructed building, with a sufficient number of suitable attendants, restraint is never necessary, never justifiable, and always injurious, in all cases of lunacy whatever.' This sentence, when published in 1838, was declared even by those most inclined to the new system to be too decided, and likely to produce a bad effect; but fortunately the lapse of eight years has proved its perfect truth, by its adoption as a principle in all the most important asylums in the kingdom. But the upholders of the old system received the announcement of a doctrine so startling as if there were something atrocious in proposing to liberate those who were unfortunate enough to be insane; and for years after restraint had been actually abolished, the non-restraint system was declared 'utopian' and impracticable; then declared to be practicable, but not desirable; and at length, when every other argument has failed, those who have so strenuously opposed it come forward and claim it as their own system, which they have been practising for years, excepting that it is carried a little further.

Too much stress was laid by Mr. Hill on the necessity for tall and powerful attendants; and the management of Lincoln laid the early supporters of the non-restraint system open to the charge of using the coercion of fear and of the hands for that of straps and chains. A form of coercion called 'manual detention,' wherein the attendants held violent patients quiet, was actually at one time used at Lincoln; but it appears to be unknown in the other asylums where restraint is abolished.

The experience of the Lincoln Asylum has proved every advantage arising from the non-restraint system, notwithstanding divisions among the managers, and direct opposition from some of the medical officers, by whom every kind of unfair evidence was brought forward against the system, and the cruelties practised by unfit attendants were considered as part of it.

The next asylum in which restraint was abolished was that of the county of Middlesex at Hanwell. At the time of the appointment of Dr. Conolly to the superintendence of the Hanwell Asylum (June, 1839) it contained eight hundred patients; of these about forty were almost constantly in restraint-chairs, and a number of others wore strait-waistcoats, muffs, leg-locks, &c. In addition to these restraints, which were supposed necessary for the safety of the rest and of the officers and attendants, more than a hundred epileptic patients were fastened by one wrist in bed every night. This was considered a necessary precaution to prevent the patients from falling out of bed or from turning on their faces in a fit, and so becoming smothered, which, it is asserted, has sometimes happened. No such case has however occurred since the disuse of the hand-strap, which took place in July, 1839.

We extract from Dr. Conolly's first report (October, 1839) the following account of the discontinuance of restraint at Hanwell:—

'The article of treatment in which the resident physician

* From March 26th

has thought it expedient to depart the most widely from the previous practice of the asylum has been that which relates to the personal *coercion* or forcible *restraint* of the refractory patients. Without any intention of derogating from the high character acquired by the asylum, it appeared to him that the advantage resulting from the degree of restraint permitted and customary in it at the period of his appointment was in no respect proportionable to the frequency of its application; that the objections to the restraint actually employed were very serious; and that it was in fact creative of many outrages and disorders, to repress which its application was commonly deemed indispensable, and consequently directly opposed to the chief design of all treatment, the cure of the disease.'

* * * *

'By a list of restraints appended to this report, it will be seen that the daily number in restraint was in July so reduced that there were sometimes only four, and never more than fourteen, in restraint at one time; but that since the middle of August there has not been one patient in restraint on the female side of the house, and since the 21st of September not one on either side.' The 51st report of the visiting justices, which accompanies this report, speaks of the new system as requiring an additional number of attendants, and of a superior class to those previously employed.

In their 52nd report (January, 1840) the visiting justices report the satisfactory results of the new system. In the 53rd (April, 1840) they report that 'there has not been a single occurrence to weaken their confidence in the practicable nature of the system;' and also 'that no increased destruction of clothing or other property is occasioned by the personal freedom which the patients enjoy. Indeed, so far as clothing is concerned, the amount of destruction is somewhat lessened, because of the general tranquillity of the patients from the adoption of the new system.'

In the 54th (July, 1840) and 55th (October, 1840) the justices state their increased confidence in the non-restraint system. This last report is accompanied by the second report of Dr. Conolly. During the past year a suicide (by hanging) had taken place, being the only one at Hanwell since the non-restraint system has been introduced. That restraint would not have been very available is proved by the occurrence of the suicide of a female patient in Bethlem, who hung herself in 1840 by the strings of the strait-waistcoat in which she had been confined; and a man has since destroyed himself, also at Bethlem, by working the strait-waistcoat in which he was strapped down in bed so as to produce apoplexy by the pressure of a knot on the neck. The last report of the Lincoln Asylum states that not only have suicides ceased since the system of non-restraint was introduced, but that the tendency to suicide has disappeared. The latest report of Bethlem also contains an admission that restraints increase the tendency to suicide.

The second division of Dr. Conolly's report treats entirely of the management of the patients without restraint, and the substitutes for it. The marked improvement in the condition of the epileptic patients is noticed. Seclusion, the most important of the substitutes for restraint, is minutely described. This very useful remedial agent is styled by the supporters of the old system 'solitary confinement,' which term is also improperly applied by the commissioners in their report. That solitary confinement for days and weeks together *was* the practice in the days of restraint is certain; for then it was a common practice to strap a patient in bed or in a restraint-chair placed in his bed-room. Any abuse of seclusion so great as this can scarcely now take place. Dr. Conolly says, 'All the substitutes for restraint are, like restraint itself, liable to be abused; but none can be made such instruments of cruelty by abuse. All are also liable to great misrepresentation; and none more so than that which is of all the most useful, the most simple, and the most approved of by the highest medical authorities, namely, Seclusion. By seclusion is meant, temporary protection of the maniac from the ordinary stimuli acting upon the senses in the refractory wards of a lunatic asylum.'

In the sixth report (October, 1844) likewise, Dr. Conolly writes: 'It is to be ascribed to want of opportunities of observation that such a simple exclusion of irritations from an irritable mind, an exclusion not found to be necessary in more than four or five instances in any one day in the year among one thousand patients, and seldom prolonged beyond four or five hours in any of those instances, during which time the patient's state is frequently ascertained by means of the inspection-plate in the door of his room, and all his reasonable wants and wishes are attended to, – should ever have been confounded with the idea of Solitary Confinement; the latter in reality comprehending a privation of almost all the stimuli upon which the integrity of intellectual and physical life depends.'

The room should not be dark; the shutter which guards the window should therefore be perforated. Care should always be taken that the perforations of the shutters should not be available, as iron bars always are, as ready means of suicide. In the treatment of the insane nothing is trifling; for upon careful attention to the most minute matters must depend the perfection of the management of any asylum.

The report for 1841 contains many cases which illustrate the benefit of non-restraint. Dr. Conolly also states the result of two years' experience, under sixteen heads, which express that difficulties must be expected in abolishing restraint, from the indolence of attendants accustomed to rely on it, and from the violences at first committed by patients long deprived of freedom of action; but that if steadily persevered in it will be found to produce greater tranquillity, fewer outrages and accidents, more general cheerfulness, and less obstinacy and malice; that good effects will be especially observable in patients newly admitted and treated entirely without restraint; but that complete uniformity of feeling among all the officers, and a sufficient number of humane and vigilant attendants, are indispensable to carry the system to full perfection.

In this year (1841) a man aged 82 died in consequence of a kick given by another patient. The injury was not severe, but the weakness and great age of the patient produced a fatal result. The patient who inflicted the injury was subject to epileptic paroxysms: but was so quiet in the intervals as to be a helper in the wards, and he was actually so engaged at the time of the unfortunate occurrence; this very patient has become tranquil and manageable; and the ward in which the fatal occurrence took place has become, since the abolition of restraints, one of the quietest in the Hanwell Asylum; a ward of which the doors are always open, the windows full of flowers, and the airing-court a beautiful garden.

Dr. Conolly's fourth and fifth Reports (1842 and 1843) contain his confirmed opinion that, 'by the abolition of restraint, the general management of the insane has been freed from many difficulties, and their recovery in various degrees greatly promoted.' The sixth Report (1844) is in a great measure devoted to pointing out the erroneous notions which have been conceived as to the substitutes for restraint, and thus concludes:—

'After five years' experience, I have no hesitation in recording my opinion, that with a well-constituted governing body, animated by philanthropy, directed by intelligence, and acting by means of proper officers, intrusted with a due degree of authority over attendants properly selected and capable of exercising an efficient superintendence over the patients, there is no asylum in the world in which all Mechanical Restraints may not be abolished, not only with safety, but with incalculable advantage.'

Here we may consider the subject of non-restraint concluded so far as its practicability is concerned. If no case requiring restraint has occurred in an asylum containing nearly a thousand patients during six years, in which time eighteen hundred cases have been treated, it is unlikely that any more difficult cases can occur elsewhere. It is nowhere insisted that restraint can never be necessary in ill-constructed asylums, and until houses for private patients are constructed for the purpose for which they are used, some restraint will probably be used in many of them. The system introduced at Lincoln, and followed at Hanwell, was very shortly afterwards adopted at Northampton, Lancaster, Gloucester, Stafford, and Glasgow. The new asylum at Glasgow bears on its foundation-stone, laid on the 1st June, 1842, an inscription stating that one of the principles to be adopted in it is that 'of employing no mechanical personal restraint in the treatment of the patients, which had already been abandoned for a considerable time.' The non-restraint system was also introduced at Haslar Hospital, Portsmouth, in 1842, and we gather from the Irish Reports that it has been adopted at Armagh, Londonderry, and Maryborough, and that very little restraint is used at Clonmel and Waterford; and there appears every reason to hope that it will be one of the standing rules in the Irish District asylums that no coercion shall be employed. Dr. Jacob of Maryborough expresses his full confidence in the system after an experience of eighteen months. In by far the greater number of asylums which have not yet given in their adherence to non-restraint as a principle, the use of restraint forms an exception to the rule. At Dundee, no restraint has been used for two years; this asylum was one which declared most strongly against the principle of the new system, when first introduced. The reports of Nottingham, Dorset, Montrose, Edinburgb, and Dumfries speak of the advantages of restraint, although the writers abstain from availing themselves of it. On the contrary, the authorities of Bethlem, St. Luke's, Kent, Oxford, and the Retreat at York, profess the non-restraint system, while they practise tbe reverse.

The possibility and advantage of the abolition of restraint would seem sufficiently proved by the results reported in all these asylums; but a large number of persons still remain opposed to the new system, from various motives. First we must mention tbe unfair manner in wbich the subject has been noticed by the Commissioners in Lunacy; a body which had been so long paid to attend to the condition of the insane, and yet who had been proved to allow every evil to remain in the houses under their care, when all others were improving, should have been the last to despise the efforts of others. Their examples of the disadvantages of non-restraint are chiefly adduced from Hanwell, and are most ably answered in a pamphlet by Mr. Serjeant Adams. Many of the cases brought forward by them as proving the necessity for restraints, are in fact strong arguments on the other side of the question. The care with wbich the Commissioners have been selected, until lately, exclusively from persons ignorant of insanity, must be their excuse. The absurdities which they have allowed themselves to believe and to record, would almost induce us to think tbat they have been wilfully mystified by some of the medical officera of asylums.

In the Bedford, Chester, Cornwall, Exeter, Leicester, Liverpool, St. Luke's, York, and Pembroke asylums, coercion still appears to remain in force. The private asylums employ it almost without exception; tbese, being most immediately under the auperintendence of the Commissioners, are in every respect the last to improve.

Tbe pbysicians of the Surrey, Wakefield, and Belfast asylums bave been the most consistent opponents, both in principle and practice of the non-restraint system; one assertion in the last Report of the Belfast Asylum (31st March, 1845) deserves to be quoted.

After saying that 'the same system with reference to restraint continues to be pursued in this institution,' it goes on to observe, 'until insanity be blotted out from the "ills which flesh is heir to," or altogether cbanged in its more *striking* effects, physical restraint in some form or other—but still restraint--cannot be dispensed with. Truly the so-called "total abolition" of restraint appears to be only one of the many vulgar delusions and speciously popular *ad captandums* of the present day.' It may be that there is more difficulty in the management of Irish patients without restraint than Englisb ones; althougb many of the other asylums in Ireland are leaving off the use of it; but tbis passage, so utterly inconsistent with well-known facts, proves the writer to be ignorant of the proceedings of other asylums for nearly seven years past. Taking tbis into consideration, we may look with some doubt upon the very curious cases subjoined, wbere patients request the strait-waistcoat and the muffs as favours, and promise to bebave well if they are allowed the indulgence; more especially as such cases do not appear ever to be met with in asylums where restraint is entirely abolisbed. The absurdity of such an idea as that of a patient wishing to be put in restraint, is so monstrous as scarcely to deserve notice. As readily would we believe that negro slaves are in the habit of requesting the luxury of a flogging, or that thieves entreat their gaolers to allow them the agreeable exercise of the tread-mill.

With the results before us of the treatment of many tbousand patients without restraint, and taking into consideration the facts that in no asylum wbere the new system has been introduced it has been found necessary to abandon it, that the reports of all tbese asylums declare their general condition to be improved, that the cures are not decreased, and, whicb we consider of equal importance, that tbe comfort of the incurables is greatly increased, we consider ourselves justified in considering that the strait-waistcoat, the coercion-chair, and every kind of strap and instrument of restraint, will shortly disappear like the 'dark house and a whip,' the chains and straw, the starvation, the wbirling-chair, and every otber means of torture formerly considered a necessary part of the treatment of those who were afflicted with insanity.

('Report of the Metropolitan Commissioners in Lunacy to the Lord Chancellor,' 1844; 'Statistical Tables prepared by tbe Metropolitan Commissioners in Lunacy,' 1844: 'An Act for the Regulation of the Care and Treatment of Lunatics' (8 & 9 Vict. c. 100); 'An Act to amend the laws for the Provision and Regulation of Lunatic Asyluma for Counties and Boroughs, and for the maintenance and care of Pauper Lunatics, in England' (8 & 9 Vict. c. 126); 'Report of the Inspectors-General of District, Local, and Private Lunatic Asylums in Ireland,' 1845; 'Returns from each District Lunatic Asylum in Ireland,' 1845; 'Reports' of all the principal Asylums in England, Scotland, and Ireland, and information privately supplied by many of the superintendents; Farr 'On the Statistics of English Lunatic Asylums;' 'Benevolent Asylum for the Insane of the Middle Classes, Prospectus;' 'History of the York Asylum;' Tuke's 'Description of the Retreat near York;' Hill 'On the Management of Lunatic Asylums;' Browne's 'Lectures delivered before the Managers of the Montrose Lunatic Asylum;' 'Remarks by Mr. Serjeant Adams on the Report of the Metropolitan Commissioners in Lunacy;' Personal knowledge of the Middlesex Lunatic Asylum, Hanwell.)

The custody of the insane in Scotland is, like every other matter wbicb demands both magisterial and executive intervention, connected with tbe system of local courts. The law on the subject is contained in tbree statutes: 55 Geo. III. c. 69; 9 Geo. IV. c. 34; and 4 & 5 Vict. c. 60. By these acts no person can be confined as a lunatic, either in a public or private asylum, witbout a warrant from the sheriff. Any person accessory to a breach of this regulation is liable to a penalty of 200*l.*; and if he be the keeper of the asylum he is liable, instead of the pecuniary penalty, to imprisonment not exceeding three months' duration. The sheriff is not empowered to grant a warrant unless on the report of a qualified physician or surgeon; and the person granting such a certificate is liable to a penalty of 50*l.* if he have omitted carefully to examine the patient. The keeper of every house where two or more insane patients are kept requires a licence for an asylum. Any person acting as keeper to an insane individual, not his immediate relative, must make an annual report to the sheriff, certified by two medical men, of the state of the patient, and must notify the death or removal of the patient. In every licensed asylum a 'mad-house register' must be kept. By the act of 4 & 5 Vict. this record is appointed to be annually transmitted to the sheriff, sealed up, and the seals being broken by him, he reseals the book, and retransmits it. When a patient dies in a licensed asylum, a report must be made to the sheriff within twenty-four hours, accompanied by a certificate from the medical attendant, stating the nature of the disease, the length of time during which it has continued, the time wben his attendance was first required, and the number of visits he has paid. Asylums must be at all times open to the inspection of the sheriff. In the general case, either the sheriff or his substitute may perform the duties of the office regarding lunatics; but it is specially provided that the sheriff principal must make an annual visit to every asylum within his jurisdiction, and either he or his substitute must make a second; in these visits they are accompanied by medical inspectors. Tbe medical bodies in Edinburgh and Glasgow elect inspectors for their respective districts; in other parts of Scotland tbey are chosen by the sheriffs from the qualified medical practitioners.

It is believed that the system of the management of the insane in Scotland has, both in a purely medical and in an administrative point of view, been lately vastly improved. Until a comparatively late period the statute law was nearly inoperative, from a strong natural prejudice against the enforcement of general rules relating to the treatment of the insane, and the consequent toleration for breaches of the statutory regulations. Tbe general rule adopted in practice was, that insane persons were allowed to go at large until they had proved themselves dangerous to the lives of their neighbours, and that when confinement was in any case resorted to, the proceedings were not very rigidly investigated. It is believed that the law is now generally obeyed, and that the utility of treating insane patieuts according to the best scientific advice, is felt by all who are connected with them or concerned in the administration of the law. The Commissioners who in 1844 reported on the state of the poor in Scotland, did much for the removal of tbe remains of the old slovenly system, by exposing the state of some private asylums in the isle of Arran where insane patients were confined in violation of the rules of the statutes.

LURGAN, a market and post town in the parish of Shankill, in the barony of Oneilland East, in the north-east corner of the county of Armagh, in the province of Ulster in Ireland, 17 statute miles north-east of Armagh on the road to Belfast, and 86 miles north of Dublin, by Drogheda, Dundalk, Newry, Banbridge, and Waringstown.

The town consists of one wide street, extending from north-west to south-east along the Armagh and Belfast road. It contained, in 1841, 670 inhabited houses, 52 uninhabited, and 6 building. The population in 1841 comprehended 892 families, being an average of four families to three houses, or 4677 persons. The church is situated near the north-west end of the street. It is a handsome building, erected in 1725, and enlarged in 1832, capable of accommodating 1000 persons: it has a tower and an octagonal spire. There are Presbyterian and Quakers' meeting-houses in the town, and two Roman Catholic chapels in the outskirts. There are meeting-houses for Wesleyan and Primitive Methodists in the parish. There is a court-house, in which the quarter-sessions for the county are held, a Linen Hall, erected by subscription in 1825, and a small area planted with trees, called the Mall. The market-house and weigh-house are in the middle of the street. Of the families 250 were engaged in agriculture, 524 in manufactures or trade, and 118 in other pursuits. The principal manufacture is of linen, especially damasks and diapers (for both which the Lurgan manufacturers are eminent), and cambrics. A weekly market, well supplied with provisions, is held on Friday, and linens to the value of 2500*l.* or 3000*l* are sold on the market-day. There are two yearly fairs. There is a considerable brewery in the town, and a little way from the town is a large distillery. Besides the quarter-sessions, there are petty sessions for the district, held weekly, and a manorial court every three weeks: there is a small gaol or bridewell; and a body of the constabulary are stationed in the town.

Adjacent to the town on the north-east is the richly wooded demesne of Lurgan Castle, the seat of Mr. Brownlow. The house is of modern erection, in the Elizabethan style.

The whole population of the parish, which extends into the barony of Iveagh Lower in the county of Down, was, in 1841, 9350. The town and neighbourhood were, in 1841, rather above the average of the county of Armagh in respect of the diffusion of education, 60 per cent. of the population being able to read, while the average of the county was 56 per cent.; but they were far below the average of the adjacent counties of Antrim and Down. There were in the parish, in 1834, twelve day-schools, with 710 children (411 boys and 299 girls) on the books; and two Sunday-schools. The town is the centre of a poor-law union, and has a workhouse capable of accommodating 800 paupers.

The living of Shankill is a rectory, in the diocese of Dromore and the ecclesiastical province of Armagh: the gross yearly revenue was returned in 1831 (on the average of three years) at £681 16*s.*; the net revenue at £517 14*s.* 4*d.*

Lurgan was built in the reign of James I., on the settlement of Ulster, by William Brownlow, Esq., one of the English settlers; it was burned by the insurgents in 1641, and again destroyed by the army of James II., in the war of the Revolution. A patent for a market and fairs was granted in 1696, and the linen manufacture was established soon afterwards.

(Lewis, *Topographical Dictionary of Ireland; Ordnance Survey of Ireland; Parliamentary Papers.*)

LUTI, BENEDETTO, Cavaliere, a celebrated Italian painter, was born at Florence in 1666. He was the scholar of A. D. Gabbiani, and he went about 1690 to Rome, where he appears to have settled for the remainder of his life: he died in 1724.

Luti has been called by some the last of the Florentine masters. His style is very attractive, but it is more distinguished for agreeable than for great qualities. He painted in fresco and in oil, and executed also many pastel-drawings, a style much practised by the Florentine masters of the seventeenth century. Luti's masterpiece is the large picture of the Vest of San Ranieri, in the cathedral of Pisa, and it is reckoned the best picture in the church. Luti had always a great respect for his master Gabbiani, and after he had finished this picture in 1712, he sent it to Florence to Gabbiani for his correction before it was placed in its final destination. The letter from the scholar soliciting the master's revision is inserted in the second volume of the 'Lettere Pittoriche,' in which there are also ten other letters from Luti to Gabbiani. There are several good engravings from Luti's works.

(Pascoli, *Vite de' Pittori*, &c.; Lanzi, *Storia Pittorica*, &c.)

LÜTZELBURGER, or LEUTZELBURGER, HANS, called also Hans Frank, an early Swiss wood-engraver of Basel, about whom very much has been written, but as yet very little is known. He lived in the early part of the sixteenth century, and is supposed by some to have cut the blocks of the celebrated 'Dance of Death,' attributed to Holbein. This supposition, however, is founded solely on the facts of his being contemporary with Holbein and the circumstance of one of the cuts being marked H. L. This is maintained by some writers and combated by others, and especially by Rumohr in 1836, in a work entitled 'Hans Holbein der Jüngere in seinem Verhältniss zum Deutschen Formschnittwesen' (Hans Holbein the younger, in his relation to German wood-engraving).

There are many other celebrated old cuts, singly and in sets, some from drawings by Holbein, which are attributed to Leutzelburger, and which are described at length in the 'Kunstblatt,' and in the works of Bartsch, Heller, Massmann, and other writers on wood-engraving. The views of all parties are stated with considerable detail in Dr. Nagler's *Neues Allgemeines Künstler-Lexicon.*

LU'ZULA, a genus of plants belonging to the natural order Juncaceæ. It has a 1-celled 3-valved capsule, without dissepiments, with three seeds at the base of the cell. Several species of this genus have been described. *L. sylvatica*, the great Woodrush, is found in shady places in Great Britain. *L. campestris* is common in the pastures of this country, and seven species are natives of the British Islands.

LYCHNIS (from λύχνος, a lamp), a genus of plants belonging to the natural order Caryophylleæ, and to the sub-order Sileneæ. It has a 5-toothed naked calyx; 5 petals, clawed; 10 stamens; 5 styles; the capsules 1-celled, or half 5-celled, opening at the top with five or ten teeth. The species are smooth, hairy, or woolly herbs, with terminal corymbs of flowers, rarely solitary.

L. Chalcedonica, the Scarlet Lychnis, is a smoothish clammy plant, with corymbose flowers in bundles; the calyx cylindrical, clavate, ribbed; the calyx 2-lobed, the carpophore long; the leaves lanceolate, slightly cordate at the base, and clasping the stem. This plant, which produces scarlet, rose-coloured, or white flowers, and is a great favourite in our gardens, is a native of Siberia and Japan. Several varieties of this plant have been named.

L. grandiflora is a glabrous plant, the flowers solitary or ternate, terminal and axillary; the calyx terete, clavate, ribbed; the petals lacerated; carpophore elongated; the leaves ovate, almost sessile. It has large beautiful scarlet flowers, and is a native of China and Japan.

L. Flos Cuculi, Ragged Robin, has deeply 4-cleft petals, with a very short carpophore. It has rose-coloured petals, and is an abundant plant in the moist meadows and pastures of Great Britain, as well as the whole of Europe.

L. vespertina, White Campion, has the petals half-bifid, and the calyx teeth of the fertile flowers linear lanceolate, elongated; the capsule conical; the teeth erect. It is a common plant in the hedge-banks of Europe. This and the following species are frequently regarded as varieties, and then named *L. dioica.*

L. diurna, Red Campion, has the petals half-bifid, the calyx teeth of the fertile flower triangular, the capsule nearly globular, the teeth reflexed.

The other British species of the genus Lychnis are: *L. Githago*, the Corn-cockle, a pretty plant blossoming in corn-fields from June to September; *L. alpina*, found on the mountains of Forfarshire; and *L. Viscaria*, a rare plant.

Many of the foreign species are cultivated in our gardens. They thrive well in a light rich loamy soil, and may be propagated by cuttings or seeds.

(Don, *Gardener's Dictionary;* Babington, *Manual of British Botany.*)

LYCIA. In addition to the general description of the country in the P. C., and the geographical details in the article ANATOLIA in the Supplement to the P. C. (vol. i. p. 112), we give a few particulars respecting the inhabitants and natural productions of this most interesting portion of Asia Minor.

The country is, as it seems, well inhabited, chiefly by Turks, many of whom lead a life half settled and half nomadic; they are distinguished above all other inhabitants of Asia Minor by their excellent character. Most of them are farmers or herdsmen; trade is chiefly carried on by Armenians and Greeks who live in the sea towns, and form the greater portion of the population of the inland town of

Almali, which is the largest in Lycia, the population being about 25,000. Those among the Turks who wander with their herds on the high plateaus, like the Turcomans, show an independence of manners and character not very pleasant to the traveller, but on nearer acquaintance they appear to be a good sort of people. The Turkish population is exceedingly careless about money, and when they have enough to eat and to drink,—and they are moderate in their habits,—they are satisfied and care for nothing more. They are somewhat shy in receiving a stranger, through fear of being treated as they are by Turkish officers and the Sultan's couriers, who take away every thing they please without ever paying for it. Along the coast of Lycia as well as the adjoining provinces of Caria and Pamphylia, there lives a number of Arabs, (*Syrians?*) who are generally seamen, and seem to have settled there many centuries ago. Among the wild animals, the 'káplán' (which term is here applied to the leopard), and the 'arslán' or lion (perhaps the panther), commit great depredations among the herds; great numbers of them are annually killed, and a reward of from 100 to 200 piasters is given by the government for each 'arslán.' They are very frequent in the district of Sidyma, on the coast. The ox is precisely the same as represented on the antient coins and monuments of Lycia; but there is also a species of dwarf ox, of the size of a large dog, though more stoutly built. There are great numbers of buffaloes and camels. The breeding of horses is carried on to a great extent, and herds of many hundreds are often seen grazing together in the valleys. The only kind is that of which such spirited representations are seen in the antient marbles; the head is of Arabic cast, the chest is very large, the feet are remarkably fine and thin, and the ears are small, as in the antique. They are not shod. The rivers and lakes abound with large tortoises, and on their banks the trees swarm with the green climbing frog. No part of Asia Minor contain such splendid valleys as those of the Xanthus and the Dolomon Chái. Myrtle, oleander, and pomegranates cover the banks of the rivers; the plains along the rivers are well cultivated, and in many places the fields are enclosed by fences of myrtle and the small prickly oak, mixed with the orange, the wild olive, the pomegranate, the oleander, the elegant green storax, which are most beautifully matted together by vine, clematis, and many other climbers. Fruit trees are planted in enclosures. The hills are covered with large oaks and planes, which supply excellent timber, of which, however, only small quantities are shipped from the coast towns. The oak, 'quercus ægilops,' is a source of wealth from its acorns, the 'velanea' of the Smyrna merchants, which is used in tanning leather and gives it that agreeable smell which places the Turkish leather even above the Russian 'Jucht.' A sort of horse-radish is used as food, and as a substitute for soap. In proportion as the traveller approaches the high upland plains, the tender fruit-trees, as well as the olive, the aloes, and other Southern plants disappear, and are replaced by the walnut, apple, and pear trees. The high plain round Almali, which is 4000 feet above the sea, is one of the largest and best cultivated corn tracts in Asia Minor; its chief produce is barley, which is the common food for horses. Maize is chiefly raised in the valleys and on the coast.

(Fellows, *An Account of Discoveries in Lycia; a Journal written during an Excursion in Asia Minor.*)

LYCOPERSICON. [SOLANUM, P. C.]

LYCORTAS. [PHILOPŒMEN, P. C.; POLYBIUS, P. C.]

LYGODYSODEA'CEÆ, a natural order of plants closely allied to Cinchonaceæ. It differs from this order in possessing an ovary composed of two confluent carpels, 1-celled, with two ovules, and a single style; the pericarp brittle burst in four directions from the base, not adhering to the seeds, 1-celled; two free placentæ rising up between the pericarp and the back of the seeds; two seeds pendulous from the apex of the placentæ, with the embryo straight, foliaceous, compressed; the radicle short, inferior. The species are twining shrubs, and have single stipules between the petioles.

This little order was constituted by Bartling, but was afterwards examined by De Candolle, who thought there was no reason for separating it from Cinchonaceæ. 'According to De Candolle, what Bartling calls pericarp is calyx, and his seeds are carpels, and consequently all the most remarkable features of the order disappear, with the exception of the absence of the albumen.' (Lindley.) This is a subject that merits further investigation. The only genus of this order is *Lygodysodea*, of which two species, *L. fœtida* and *L. ciliata*, have been described. They are both natives of Peru and Mexico.

LYLY, LILY, or LILLY, JOHN, was a native of the Weald of Kent. His birth has been referred to the year 1554, on the faith of the entry of his matriculation as a student at Oxford in 1571, which asserts him to have then been seventeen years old. He became bachelor of arts in 1573. It appears from one of his prefaces that he was rusticated from Oxford; and, after having (it is said) studied likewise at Cambridge, he went to London, and spent his life in literary labour, as a dramatic and miscellaneous writer. Although his writings must for a considerable time have been fashionable at court, he appears to have shared to the full in the poverty and distresses of authorship. He is supposed to have served Lord Oxford, but to have been deprived of his place; and he was long and unsuccessfully an applicant for the office of master of the revels. In one of his petitions to the queen, which has been preserved, he, with melancholy quaintness, describes the history of his life as 'Lyly *De Tristibus*, wherein shall be seen patience, labours, and misfortunes.' The time of his death is unknown; but he must have survived the beginning of the seventeenth century.

The two most famous of his works bore the following titles: 'Euphues: the Anatomy of Wit, verie pleasant for all gentlemen to read, and most necessary to remember: wherein are contained tho delyghts that Wit followeth in his youth by the pleasantnesse of Love, and the happinesse he reapeth in age by the perfectnesse of Wisedome,' 4to., 1579 or 1580: 'Euphues and his England; containing his voyage and adventures, mixed with sundrie pretie discourses of honest Love, the description of the Countrie, the Court, and the manners of that Isle; delightful to be read, and nothing hurtfull to be regarded; wherein there is small offence by lightnesse given to the wise, and lesse occasion of loosenesse proffered to the wanton,' 4to., 1582. He wrote also a lively satirical tract against Martin Marprelate: 'Pap with a Hatchet; alias, a Fig for my Godson; or Crack me this Nut; or a Country Cuff; that is, a sound Box on the Ear for the Idiot Martin to hold his peace: written by one that dares call a Dog a Dog:' 1593. He was also the author of nine plays still extant: 1. 'Alexander and Campaspe,' 1584, 1591; reprinted in Dodsley's Collection, vol. ii. 2. 'Sapho and Phao,' 1584, 1591. 3. 'Endimion,' 1591; reprinted in Dilke's Old Plays, vol. ii. 4. 'Galathea,' 1592. 5. 'Midas,' 1592; and 6. 'Mother Bombie,' 1594, 1597; both reprinted in Dilke's Collection, vol. i. 7. 'The Woman in the Moon,' 1597. 8. 'The Maid's Metamorphosis,' anonymous, but generally attributed to Lyly, 1600. 9. 'Love's Metamorphosis,' 1601; the authorship of which has been doubted.

The first mentioned works of Lyly gave the name of 'Euphuism' to a fashionable style of language, of which, although he certainly did not invent it, he was the most eminent literary cultivator. The Euphuism of Lyly himself was just an exaggerated form of that strained, pedantic, over-elaborated imagery which was prevalent in refined society as well as in literature about the middle of Elizabeth's reign. In his hands it added to the classical pedantry of the day a pedantry of something like science, consisting in incessant images derived from a half-fabulous system of natural history. Drayton, in ascribing to Sir Philip Sidney (himself no very simple writer) the merit of having brought back the tone of language to nature, speaks of Lyly as

> Talking of stones, stars, plants, of fishes, flies,
> Playing with words and idle similies.

Shakspere's Don Armado has sometimes been considered as 'parleying Euphuism;' but, as Mr. Knight has observed, there is a nearer approach to this jargon in much of the language used by the higher personages in the same play. The absurdities of it are burlesqued by Jonson in his 'Cynthia's Revels.' Sir Piercie Shafton, in 'The Monastery,' is an unsuccessful attempt at representing the characteristics of Euphuism.

Lyly's dramas are almost everywhere deformed by the same false taste; yet they exhibit occasional touches of fine fancy, which however is shown to greater advantage in some of the short lyrical pieces interspersed through them. The wit of the dialogue is in some places lively. To success in portraiture of character these plays can make no claim; and as little can their mythological, pastoral, or classical stories be said to possess dramatic interest, or to be treated with dramatic skill. The author's claim to remembrance as a dramatist rests almost wholly on his position as one of Shakspere's immediate predecessors; and on the fact that his plays present, in strong relief, some of the distinctive characteristics of the literary tastes which prevailed in that interesting age.

LYON KING AT ARMS. [HERALD, P. C.]

LYSIMACHI'A, a genus of plants belonging to the natural order Primulaceæ. It has a 5-parted calyx, a rotate corolla with scarcely any tube, and a 5-parted limb. The stamens are inserted at the base of the corolla, and are 5 in number. The capsules open with 5 valves.

L. thyrsiflora is distinguished by its axillary stalked dense racemes; its leaves are opposite and lanceolate. The corolla is divided almost to the base into narrow petals often separated by a minute tooth, which as well as the calyx is yellow spotted with orange. It is found in marshes in the north of England.

L. vulgaris has an erect stem, with compound terminal and axillary panicles, ovate or ovate-lanceolate leaves nearly sessile or 3 or 4 in a whorl. The petals are entire with glabrous edges; the stamens 5, and combined for half their length. This species is the *L. punctata* of some botanists, and probably the λυσιμάχιον ἄνθος χρυσοειδὲς of Dioscorides, lib. iv. cap. 3.

L. Nummularia, Moneywort, has a prostrate creeping stem, solitary axillary flowers, ovate acute sepals, and glandular filaments connected at the base. The leaves are opposite, roundish, and shortly stalked. The peduncles shorter than the leaves. It is found in damp places in Great Britain.

L. nemorum has linear lanceolate sepals, smooth distinct filaments, and opposite ovate acute leaves. It is found in woods and damp shady places in Great Britain. *L. atropurpurea* is the λυσιμάχιον ἄνθος πυῤῥὸν of Dioscorides, lib. iv. cap. 3.

(Fraas, *Synopsis Plantarum Floræ Classicæ;* Babington, *Manual of British Botany.*)

LYTHRUM (from λύθρον, 'black blood,' from the purple colour of the flowers), a genus of plants belonging to the natural order Lythrariaceæ. It has a tubular cylindrical calyx, with from 8 to 12 teeth; from 4 to 6 of the teeth are broader than the rest and erect, the alternate ones being subulate and opposite to the petals. It has from 4 to 6 petals and a very short style. The capsules are 2-celled and many-seeded.

L. Salicaria, Purple Loosestrife, has lanceolate leaves from a cordate base and whorled. The flowers are in whorled leafy spikes, almost sessile. It is a native of Europe, in ditches and watery places, especially about the margins of ponds and rivers, and is found in Britain very plentifully. The colour of the flowers varies from crimson to purple. The herbage is generally almost smooth, and of a dark green, but in dry situations it becomes hoary and downy, or in some degree hairy, as well as more dwarfy in stature. This species is the *Lysimachia* of Pliny, lib. xxv. cap. 7; lib. xxvi. cap. 12, 14.

L. hyssopifolia has alternate linear-lanceolate blunt leaves. The flowers are axillary and solitary, with two minute subulate bracts. The calyx teeth are all short, and the stamens are usually six in number. The flowers are small and of a light purple colour. The whole plant is glabrous, and is found in damp places in Great Britain.

L. Hunteri, Hunter's Purple Loosestrife, is a native of the East Indies. The leaves are opposite, the calyx tubular and 6-lobed, the stamens 12, and the style subulate. The petals, 6 in number, are of a very beautiful red colour, and are used for dyeing in India. The hardy perennial species of Lythrum are handsome garden-flowers; they grow in any common soil, and are easily propagated by dividing at the root. The seeds of the annual kinds require to be sown in moist situations in the spring.

(Don, *Gardener's Dictionary;* Babington, *Manual of British Botany.*)

INDEX TO THE LETTER L.

VOLUME II.

M.

M'CRIE, THOMAS, a writer on ecclesiastical history and polemics, was born at Dunse in Berwickshire, in November, 1772. His father was a petty manufacturer and trader, who had by his industry and economy been enabled to purchase a small estate, and spend his old age in quiet independence. 'Dr. M'Crie's parents,' says his biographer, 'being connected with that branch of the secession usually termed Anti-Burghers, he was brought up under the ministry of the Rev. Mr. Whyte, at a period when the primitive strictness of that communion was retained in a measure which is now wholly unknown. In these circumstances he received that thoroughly religious education, of the importance of which he was ever afterwards so strenuous an advocate, and of the success of which he was himself a striking example.' Having received the rudiments of education at the parish school of his native place, he afterwards studied at the university of Edinburgh, which he entered in 1788. Contemporaneously with his academical studies, he occupied himself in teaching younger lads, an employment for which he seems to have been well qualified. In 1791 he commenced his peculiarly theological studies. In 1795 he was licensed as a clergyman by the associate presbytery of Kelso, and he was immediately afterwards chosen pastor of a congregation of the same body in Edinburgh. In the earlier period of his ministry he entered warmly into those discussions naturally prevalent among bodies who have so many points of repulsion from each other as the small Presbyterian sects which had sprung from the church of Scotland. He soon commenced however the important task of studying, for the purpose of some undefined literary projects, the early history of the Presbyterian church in its connection with its most remarkable champions. The body to which he belonged followed a rule of Presbyterian discipline, from the strict tenor of which they maintained that the established church had diverged; and, recurring perpetually to the conduct of the fathers of Presbyterianism, it was likely that any member of this body with sufficient talent would be the most zealous biographer of these primitive worthies. In 1812 he published 'The Life of John Knox.' Scholarship or literary ability were qualities which the clergy of his sect, consisting almost entirely of the humbler members of society, were never expected to display; and this first attempt, which showed both qualities in an eminent degree, accompanied by much patient research, was looked on as a literary phenomenon. In 1813 he received the degree of D.D. from the university of Edinburgh, previous to the appearance of the second edition of his work. It has since passed through several editions, and, while it is very popular with the uneducated classes in Scotland, is highly esteemed by historical students. In 1819 he published a work of still more extensive and curious research, 'The Life of Andrew Melville,' a celebrated champion of Presbyterianism in the reign of James VI. of Scotland. The indefatigable minuteness of the researches connected with this volume is scarcely matched in the English language, and it had the effect of resuscitating from the most obscure materials—records of births, marriages, and deaths, ecclesiastical and proprietary registers, and like sources—the circumstances connected with the lives of some interesting men who in the stir and bustle of their own active age had failed to find commemorators. The partisan zeal with which these works were undertaken is not their least remarkable feature. and obtained from Mr. Hallam the apt designation of 'Presbyterian Hildebrandism.' There is no doubt of the accuracy with which Dr. M'Crie stated facts and cited authorities, and that he was thoroughly honest; but from the beginning to the end each work is a piece of industrious and acute special pleading, and the reader whose position enables him to take an impartial view of the characters discussed in them sees plainly that he knows what portions may be favourably dwelt on, and what should be hastily passed over, if not omitted. His palliations and vindications are singularly ingenious; and amid all the rude morality and savage acts of the turbulent periods of which he gives the history, he vindicates his own heroes from all follies as well as from all vices; even the destruction of the Scottish ecclesiastical buildings has its meed of praise. Written in such a spirit, and being works of genuine learning and research, they are very popular with the ultra-Presbyterian party in Scotland. Their author led a blameless simple life, on a small salary, which, with the free use of the valuable public libraries in Edinburgh, contented his unmercenary disposition. He died on the 5th August, 1835, deeply lamented by the members of his congregation and a wide circle of private friends.

(*Life of Thomas M'Crie, D.D.*, by his son, the Rev. Thomas M'Crie, 1840.)

MAC CULLOCH, DR. JOHN, was born in Guernsey, on the 6th of October, 1773. He was descended from an antient Scottish family, the MacCullochs of Nether Ardwall, in Kirkcudbrightshire, a younger branch of the MacCullochs of Myretown, a family which at one time possessed considerable property in Galloway. He was the third son of James MacCulloch, Esq., and Elizabeth, daughter of Thomas De Lisle, Esq., one of the jurats of the royal court of Guernsey.

In his childhood Dr. MacCulloch was very thoughtful, and fond of being alone. He taught himself to write, and wrote Latin exercises at an age when many children have barely acquired a knowledge of the alphabet. He seldom played with other children, but when the hours of study were over was in the habit of going into a room which his father, who was a man of scientific and literary attainments and a good mechanic, allowed him to call his own, and the door of which he contrived to fasten with a large bent needle in such a manner as to prevent his brothers entering. Here he amused himself with drawing, carving various articles in wood and cocoa-nut shell, and, at a very early period, in attempts to make gunpowder, and, after he had effected that, in manufacturing fireworks. His family was at this time residing in Cornwall, and the first school he was sent to was the grammar-school at Plympton. He was afterwards removed to one at Penzance; and thence, in 1787, to the grammar-school at Lostwithiel, where he remained three years, and where his talents seem to have been appreciated by the master, Mr. M'Gilvray, of whom Dr. MacCulloch always spoke with the greatest respect and love.

In 1790 he went to prosecute his medical studies at Edinburgh, where he obtained his diploma of physician, at the age of eighteen. He subsequently entered the artillery as assistant-surgeon, and on the 5th of April, 1803, accepted the situation of chemist to the Board of Ordnance. In 1807 he resided at Blackheath, where he practised as a physician. His application while pursuing his studies at Edinburgh was intense, and probably received an additional stimulus from the circumstance that his father, who was settled as a merchant in Bretagne, was arrested at the beginning of the French revolution, and with his family imprisoned during the whole of the Reign of Terror, a state of things which naturally put a stop to the lucrative business in which he was at that time embarked. During Dr. MacCulloch's occasional visits to Penzance, whither his father, on the fall of Robespierre, retired, he became acquainted with Sir Humphry Davy, who was indebted to him for some of his earliest instruction in chemistry.

About the year 1811 he was engaged by government to make various surveys in Scotland. He in consequence gave up his practice, which he never regularly resumed, although he was frequently consulted. The first business on which he was employed in Scotland, was in a search for stones adapted to the use of the government powder-mills. The second was an examination of the principal mountains, with a view to the repetition of the experiments which had been made at Schehallian on the density of the earth. The third had for its object the correction of the deviations of the plumb-line on the meridian of the trigonometrical survey. Whilst he was making these surveys, he also employed himself in geological observations, and in collecting materials for a mineralogical map, as well for his own amusement and instruction as with the hope that they would be useful to the country. In 1826 he was desired by government to complete the work which he had begun; and this was the commencement of the last great public work in which he was employed - the mineralogical and geological survey of Scotland, which was continued every summer from 1826 to 1832, when he completed it. The winters of these years were spent in the laborious task of putting in order the observations made in the summer, in drawing sections, and preparing the map. This great work, precise and exact as it is, the labour of one individual, begun, carried on, and completed by himself alone, extending over a country richer in its variety of rocks than any country of equal extent in the world, abounding in geological difficulties, has never been surpassed, or even equalled, by any undertaking of a similar nature. In making this survey Dr. MacCulloch had to contend with many hardships, for great part of the time was spent upon a boisterous sea or a miserably poor comfortless land. It was his lot to do all the different works provided for in all other surveys by half a dozen men and as many salaries. As a proof of the aptitude which he possessed for doing anything that he willed, we may mention that he steered his own boat through the dangerous channels of the Scottish islands.

Some of the fruits of these separate surveys are published. The first publication was 'A Description of the Western Islands of Scotland, including the Isle of Man, &c.,' 2 vols. 8vo., with 1 vol. 4to. of plates, London and Edinburgh, 1819. Next, 'A Geological Classification of Rocks, with Descriptive Synopses, comprising the Elements of Practical Geology,' London, 1821, 1 vol. 8vo. Thirdly, 'The Highlands and Western Isles of Scotland, in a series of Letters to Sir Walter Scott,' London, 1824, 4 vols. 8vo. This work, in addition to a most graphic description of the country, contains many learned dissertations on the history, antiquities, language, music, and economy of the Highlands. Fourthly, A System of Geology, with a Theory of the Earth, and an Explanation of its Connection with the Sacred Records,' London, 1831, 2 vols. 8vo. In 1821 he published a Treatise on the Art of making Wines, which reached a fourth edition in 1829; and in 1823 he published anonymously an account of Blair and Dunkeld, forming a guide-book to those localities. He contributed many papers both to the Encyclopædia Britannica and to Brande's Journal, on various subjects connected with Scotland generally, or its rocks and minerals; besides others on different topics. One of these is a description of twenty-two species of Medusa found about Shetland and Orkney; so attentive was he to everything that surrounded him. He published many articles in the 'Transactions' of the Geological Society, and wrote frequently in the Edinburgh, Westminster, and Quarterly Reviews, and in the London and New Monthly Magazines.

Although unable to follow up the practice of his profession, Dr. MacCulloch never lost sight of it, the proofs of which we have in two elaborate works which appeared in 1827 and 1828. The first is entitled 'Malaria, an Essay on the Production and Propagation of this Poison, and on the Nature and Localities of the Places by which it is produced,' &c., 1 vol. 8vo., London. The second is 'An Essay on the Remittent and Intermittent Diseases, including generally Marsh Fever and Neuralgia,' &c., in 2 vols. 8vo., London. He appears to be the first who referred a large list of disorders, hitherto deemed anomalous, and which appear to have nothing in common with one another, to their true source—the poison of the malaria.

Dr. MacCulloch's writings contain internal evidence that they must have resulted from deep thought, based on an intimate knowledge of the subjects he treated of. The acquisition of this knowledge was gained by intense study, aided by a wonderfully retentive memory. The variety of his acquirements was not less remarkable than their extent. Allusion has been already made to his knowledge of medicine, geology, mineralogy, chemistry, and mathematics. He was also well acquainted with theology, astronomy, zoology, botany, physics, and the mechanical arts. He was skilled in architecture. He drew well, and has left an immense number of drawings. He was a good musician, and his musical compositions show that he was conversant with the theory as well as the practice of the science. His accomplishments, as they are called, were cultivated at times which many persons pass without employment. His drawings were done while others were employed in walking or riding. His flowers and herbs were examined, dried, and painted before breakfast in the long summer mornings. When he used to practise music, he did so during the twilight hours. In short, no portion of his time was unoccupied. And the magnitude of his labours appears still more remarkable from the fact, that for many years he was afflicted most severely by the effects of malaria.

He completed in 1830 a work entitled 'Proofs and Illustrations of the Attributes of God, from the Facts and Laws of the Physical Universe; being the Foundation of Natural and Revealed Religion.' It was intended for publication in the following year; but its appearance was delayed by the announcement of the Bridgewater Treatises. In obedience to his last will, it was published in 1837, in 3 vols. 8vo. Many papers on various subjects remain unpublished, and among them a corrected copy, with numerous additions, of his work on the Highlands.

Dr. MacCulloch was fellow of the Royal, Linnean, and Geological Societies, and at one time vice-president of the last. In 1820 he was appointed physician in ordinary to Prince Leopold of Saxe-Coburg. For some years, and till his death, he filled the situation of lecturer on chemistry and geology at the East India Company's Military Establishment at Addiscombe.

He married, in the summer of 1835, Miss White. He was with her in Cornwall, on a visit to an old friend, when the accident occurred which led to his death on the 21st of August, 1835. He was thrown out of a pony phaeton, by which, in addition to other injuries, his right leg was so shattered that amputation became necessary. He only survived the operation a few hours. He was buried in the churchyard of Gulval, a village near Penzance, in which his family had at one time resided.

Dr. MacCulloch was steady in his attachments, zealous to promote the interests of his friends, and ever ready to aid those who needed his assistance. He possessed very strong affections and acute sensibility, which the sufferings of many years seemed rather to have increased than diminished. His manners were courteous; his conversation was rich, varied, apparently exhaustless, though never urged so far as to exclude others, and remarkable for its unaffected simplicity. He was as willing to impart information as he was eager to acquire it.

(Principally from the *Annual Biography and Obituary* for 1836.)

MACDONALD, ANDREW, an unfortunate man of letters, furnishes the theme for one of the most affecting passages in D'Israeli's 'Calamities of Authors.' He was born about 1755, and was the son of a gardener in Leith. After having been educated in the University of Edinburgh, he took orders in the Scottish episcopal church, and in 1777 became pastor of a congregation in Glasgow. In 1782 he published 'Velina, a Poetical Fragment,' in Spenser's stanza. This volume was succeeded by a novel called 'The Independent;' and afterwards a tragedy of his, called 'Vimonda,' was played with success in the theatre of Edinburgh, with a prologue written by Henry Mackenzie. Becoming tired of a charge very ill remunerated, and being encouraged by the reception of his play, he resigned his place, and came to Edinburgh; first however marrying the servant-maid of the house he had lodged in, and then living for a short time very extravagantly. He next removed to London, where, in 1787, his tragedy was brought on the stage by Colman with much pomp and very considerable approbation. But the author was starving; and in 1788 he died in London, leaving his wife and child in beggary. A volume of his sermons was published in 1790; and a volume of poems, including 'Vimonda' and three other plays, appeared in 1791. His dramatic genius cannot be rated high; but he possessed no inconsiderable power both of poetic fancy and of expression. There is a good deal of vigour in some of his light poems, written in London, in the manner of Peter Pindar.

MACDONALD, ETIENNE JACQUES JOSEPH ALEXANDRE, Duke of Tarentum and Marshal of France, was born on the 17th Sept., 1765, at Sancerre in the department of Cher, though some authorities make Sedan the place of his birth. He was descended from a Scotch family, which, on account of its participation in the rebellion of 1745, was compelled to take refuge in France. In 1784 he entered the army as a lieutenant in the legion of Maillebois, and afterwards joined the regiment of Dillon, chiefly composed of Scotch and Irish, in the French service. He was induced, it is said, to remain in France at the breaking out of the Revolution, on account of his attachment to the daughter of Mons. Jacob, who warmly espoused the republican cause. His military talents procured him a place at the commencement of hostilities on the staff of General Dumouriez, and he rose to the rank of Captain after the battle of Jemappe; some biographers however state that his valour on that occasion was rewarded with the rank of Colonel. He served in the campaign of the Low Countries under General Pichegru, and distinguished himself by the passage of the Waal on the ice, under a severe fire from the batteries of Nimeguen, by which exploit the Dutch fleet was captured. Having risen to the rank of General of Division, he commanded in 1796 at Düsseldorf and Cologne. He then joined the army of the Rhine, and afterwards that of Italy; and when in 1798 the French became masters of Rome, Macdonald was appointed governor of that city. His behaviour in this new capacity appears to have been marked by some severities, but his position was one of extreme difficulty. On the approach of General Mack he was obliged to abandon Rome, and his army was attacked by the enemy at Otricoli; the Austrians however were defeated, and he was enabled to regain possession of Rome. He was afterwards sent by the French government in their enterprise against the kingdom of Naples, and when compelled to retire before the superior force of Suwarrow, he saved his army, and reconducted it to France by a retreat in which he displayed considerable skill. [SUVAROV, P. C.]

Macdonald had command at Versailles during the period of the revolution of the 18th Brumaire. [BONAPARTE, P. C.] In 1800 he was appointed commander-in-chief of the army of reserve in Switzerland. His celebrated passage of the Splugen, the dangers and difficulties which he surmounted, the persevering ability which he displayed, have rendered his name greatly celebrated in the annals of warfare. There are indeed but two events recorded in history to which this memorable exploit can be compared—the passage of Hannibal over the Alps, and that of Napoleon over the Great St. Bernard. Alison, in an elaborate comparison which he makes between the latter and that of Macdonald, considers that this general had greater difficulties than Napoleon to surmount, while he had less means at his command to surmount them. (Alison, *Hist. of Europe*, c. xxxii.)

In March, 1802, he was appointed French ambassador at the court of Copenhagen; and on his return to Paris he was created Grand Officer of the Legion of Honour. He afterwards remained some years without employment, on account of the free expression of his sentiments with respect to the conduct of the First Consul towards General Moreau. [BONAPARTE, P.C.; MOREAU, P. C.] It was not until the year 1809 that he was recalled to military service, when the command of a division of the army of Italy under Eugene Beauharnois was given to him by the Emperor. Macdonald on this occasion made a noble use of the opportunity of renewing his military reputation. The troops under his orders entered Styria; he compelled the Austrian general Meerfeldt to capitulate at Laybach (May 22, 1809); and he shared the glories of the victory of Raab. He was present on the 6th July at the famous battle of Wagram; the important duty of forcing the enemy's centre, which was defended by two hundred pieces of cannon, was committed to him, and he executed this critical movement with the most consummate skill and bravery, but with immense loss. On the morning after this great and sanguinary engagement, Napoleon, as he passed by Macdonald, stopped, and, holding out his hand as a pledge of their reconciliation, paid him a just tribute of praise for his share in the victory, and as an earnest of his admiration presented him with the marshal's staff. On this field of battle two other marshals were created for their distinguished services, Marmont and Oudinot, who afterwards obtained the respective titles of dukes of Ragusa and Reggio. It is also added that Macdonald with affectionate gratitude for the honour conferred, and especially for the manner in which it was conferred, pledged himself to abide by the destinies of Napoleon for life or death.

He was afterwards appointed governor of Gratz, where by the strict discipline he maintained among his troops he so conciliated the esteem of the inhabitants, that on his leaving the town they begged his acceptance of a most valuable gift of jewels, intended as a present to one of his daughters who was about to be married. This gift however he nobly refused, and added that the best proof of their gratitude towards him would be shown by their care of three hundred sick soldiers whom he was obliged to leave behind him.

In April, 1810, Macdonald returned to Paris, and was created Duke of Tarentum, and appointed to the command in Catalonia of the corps of Marshal Augereau, who was recalled. [AUGEREAU, P. C.] His conduct in Spain did not add to his military reputation. On one occasion indeed he was engaged in an enterprise which has tarnished the glory of his previous exploits. After the fall of Tortosa (March 29, 1811) this marshal was proceeding from Lerida to Barcelona by the circuitous route of Manresa. He was attacked on his march by the Spanish general Sarsfeld, and his troops met with a determined opposition on the bridge of Manresa; this obstacle overcome, the French, or rather the Italians in the French service, forced their way through the town, whose inhabitants offered them no resistance, and they wreaked their vengeance upon it by setting fire to its buildings. Seven hundred houses and two large hospitals were thus destroyed, and it is to be regretted that Macdonald, who witnessed the conflagration, made no efforts to put a stop to it, and offered no assistance to the sufferers. This unnecessary cruelty was condignly visited by universal indignation, and rekindled in all its vigour that guerilla warfare which proved so harassing in its effects and so important in its ultimate results.

In 1812 Macdonald accompanied Napoleon in the expedition to Russia, with the tenth corps of the army under his command. In the Saxon campaign of 1813 he distinguished himself at the battles of Bautzen and Lützen. In that of Katzbach (August 29, 1813) he met with a severe reverse. In direct violation of Napoleon's orders, he imprudently advanced against Marshal Blücher, who was at the head of an army very superior in numbers to his own, which was imprudently scattered over a space of thirty miles from Liegnitz to Schoenen; so that when attacked on his centre and his left by the concentrated masses of the Prussians, he had no adequate force at hand to arrest the onset of the enemy. The result of this engagement was the loss of one of his divisions, that commanded by Puthod, one hundred officers, including Puthod himself and all his staff. Three thousand soldiers became prisoners; twelve pieces of artillery also fell into the hands of the enemy. At the great and disastrous battle of Leipzig, more fortunate than the illustrious Poniatowsky, he was enabled in the retreat to swim safely across the Elster. [PONIATOWSKY, P. C.]

In 1814 Marshal Macdonald faithfully redeemed the pledge he had given to Napoleon on the field of Wagram, and constantly adhered to his declining fortune; he also warmly exerted himself with the allies to obtain favourable terms for the emperor and his family. He was with him at Fontainebleau [BONAPARTE, P. C.], where Napoleon expressed to him his regret at not having before appreciated his value, and presented him with a splendid Turkish sabre, the gift of Ibrahim Bey.

On the first restoration of the Bourbons, he was called to the chamber of peers, where he proposed several measures of justice towards the returned emigrants and the veterans of Napoleon's army. These just and expedient proposals were however rejected.

When his former chief returned from Elba, this marshal was solicited to accept a command which his loyalty refused. He proceeded to Lyon to join the Count d'Artois, afterwards Charles X., and endeavoured, though fruitlessly, to induce the troops to remain faithful to the Bourbon cause. On his failure he returned to Paris, and when Napoleon approached that city he accompanied to the frontier the fugitive king (March 20, 1815). It is however stated by some that he came back to Paris, and there performed duty as a simple soldier in the national guard.

On the second restoration of the Bourbons he was named chancellor of the Legion of Honour [LEGION OF HONOUR, P. C. S.], which office he retained till 1831. He likewise received the appointment of governor of the twenty-first military division, and that of major-general of the Royal Guard. The rest of Macdonald's life appears to have been chiefly passed in tranquil occupations on his estates. He visited Scotland, where he showed much kindness to some relatives whom he found in the Highlands in humble circumstances. He died at Paris on 24th September, 1840.

Marshal Macdonald, though not the most distinguished of Napoleon's generals for his military service, has not been surpassed by any of them in pure integrity of character, in disinterestedness, and in the maintenance of honourable principles. His highest praise is perhaps to be found in the brief but expressive remark made concerning him by Napoleon at St. Helena—'Macdonald was a man of great loyalty.'

(Alison, *Hist. of Europe*, vols. ii. iv. and ix.; *Court and Camp of Napoleon*; Las Cases, *Mémorial de St. Hélène*; *Dict. Hist. des Batailles*; *Biographie Moderne*, Paris, 1815; Napier, *Hist of the Peninsular War*.)

MACER, AEMI'LIUS, a Roman jurist, who lived under the Emperor Alexander Severus, or shortly after his time. He was either a contemporary of Ulpianus, or wrote after Ulpianus, for he cites him several times. There are 275 excerpts from Macer in the Digest. His works mentioned in the Florentine Index are two books on Military matters, two on Publica or Publica Judicia, two on the Officium Praesidis, two on the εἰκοστή or Vicesimae haereditatum, and two on Appellationes. According to Priscian be also wrote Annales.

MACHINERY. It is proposed to consider in this article the influence which is exercised by machinery upon the general interests of mankind, and especially upon the well-being of different classes of society. There is no subject in the present age which is more deserving of attention; and none perhaps in which all classes are so much concerned. Whatever theoretical opinions may be entertained by speculative men, the use of machinery in aid of human labour, or, as some contend, instead of it, is rapidly increasing and cannot be restrained; it is right therefore for all men to endeavour to judge for themselves in what manner it is valuable to society, and whether the injuries attributed to it be real or imaginary. By some, every new machine is viewed as an addition to the wealth and resources of a country; by others it is regarded as a hateful rival of human industry—as iron contending with straining sinews—as steam struggling against the life and blood of man. The one view is full of hope and promise; the other is fraught with gloom and sadness. One would present society advancing in wealth and comfort: the other would show it descending faster and faster into wretchedness. But even those who believe that the inventive faculties of men have been engaged in devising for themselves a curse, would gladly be convinced that cheerful anticipations of good are consistent with sound philosophy.

The influence of machinery is of two kinds: 1st, as it affects the production and consumption of commodities; and 2ndly, as it affects the employment of labour.

As regards production, the effects of machinery have been well described to be the same 'as if every man among us had become suddenly much stronger and more industrious.' (*Results of Machinery*, 7th edit. p. 36.) If, by the aid of machinery, ten men can perform the work of twenty, and perform it better and more quickly, the products of their labour are as much increased as if they had really 'become suddenly much stronger and more industrious,' and, it may be added, more skilful. Thus production, which is the object of all labour, is more abundant, and society enjoys the results of industry at a less cost. Who can doubt that this is a great benefit, unless it be attended with evils which are not at first perceptible? No man labours more than is necessary to effect his object, and his constant desire is to contrive modes of saving his own physical exertions. A rich soil and a fine climate are universally esteemed as blessings because the people enjoy abundance with comparatively little labour. A poor soil and bad climate are evils, because the husbandman must labour much though the produce of his industry be small.

Labour without adequate results is always regarded as a curse, and almost every human invention, from the earliest times, has had for its objects the saving of labour and the increase of production. Horses and other beasts of burden were made to work for man; to bear loads which otherwise they must have borne themselves; to draw the plough which otherwise their own strength must have forced through the soil. To the same object all nature has been made subservient. The stream turns the mill, and does the work of man; the wind performs the same office. A boat is built to save men the labour of carrying their goods to a distance, and it is less labour to row the boat than to carry its cargo: but rowing is laborious, and sails were invented that the wind should do the work of man. In all other matters it has been the same. Man is weak in body, and ill endowed by nature with the means of self-preservation and subsistence. Many animals are stronger and most animals are more active than himself: they can pursue their prey with more certainty, they are armed with weapons of offence and defence, and they need no shelter from the weather but that which nature has provided; their own powers and their own instinct suffice for their preservation. But man was created naked and defenceless. To live he must invent, and reason was given to him that he might force all nature into his service. His teeth and nails were powerless against the fangs and claws of the wild beast; but his hands were formed with wondrous aptitude for executing the tasks which reason set them. He invented tools and implements and weapons, and all nature became his slave. He was now able to make his own strength effect as much as if he had become stronger and more industrious. He produced more for his own comfort and subsistence, with little labour, than the greatest exertions could otherwise have obtained for him. Every successive invention has made him more powerful, has increased his strength, and multiplied the productions of his industry; and at length the giant power of steam has peopled the world with inanimate slaves who do his work faster and better than he did it himself with the greatest labour and the most ingenious tools.

The flint and fish-bone of the savage, the tool of the workman, and the steam-engine of the manufacturer, have but one common object—to save the labour of man and to render it more productive: but that is the most perfect invention which attains this object the most effectually. Can any one doubt the advantage of abundant production? It needs but a few words to point out its benefit. Whether it be for evil or for good, we are not satisfied with the enjoyment of the common necessaries of life; we all desire comforts, luxuries, and ornament: and in proportion as we desire them do we become civilized. There are many who sneer at civilization, and unhappily it has its vices, its follies, and its absurdities; but it seems the law of our nature to advance to that state, and with the increase of artificial wants our intellects become more active and enlightened, refinement of manners succeeds to barbarism, and all those moral qualities for which man is distinguished, become developed. We may conceive some Utopia in which all the noble parts of man's nature are cultivated, while his wants remain simple and easily satisfied, but the world we live in presents another picture. We might wish it were otherwise; but it is in vain to deny that refinement is the accompaniment and, in some degree, the consequence of riches, and brutality the condition of those people who have not been elevated by the increase of wealth. It follows therefore that to multiply the objects of comfort and enjoyment which human industry can produce, is to improve the condition of mankind, to raise them in the scale of moral and intellectual being, and to minister to their enjoyment of life. It is quite consistent to deprecate the vices and follies which are ever associated with our craving for new possessions, while we observe the benefits resulting from it. Throughout the world good and evil are found side by side; but the good, as we would fain believe, preponderates.

When once it is admitted that men are to be decently housed and clothed, and are to surround themselves with such comforts as they can obtain, it is clear that the more easily they can obtain them, and the more generally such possessions are enjoyed, the more completely are the objects of civilized life secured. If all men could obtain them easily, there would be no poverty, and infinitely less vice. Machinery, by diminishing the amount of labour required for the production of commodities, lowers their price and renders them more universally accessible to all classes of society. Working-men no longer toil for the rich alone, but they participate in the results of their own industry. If they desire such luxuries, 'purple and fine linen' are not beyond their reach; and their dwellings are more commodious and often more elegant than were the houses of the rich three centuries ago. If this increased facility of acquiring the comforts of life had been accompanied by greater prudence and frugality, we believe that the beneficial results of machinery would have been conspicuously shown by the improved condition of all the working classes of this country; but more money has been squandered by them in poisonous spirits, within the last fifty years, than would have sufficed to place themselves and their children beyond the reach of want.* Cheap production is more beneficial to the poor than to the rich. The rich man is certain of gratifying most of his wants, but the poor man is constantly obliged to forego one enjoyment in order to obtain another. If his shoes or his coat be worn out, his dinners must be stinted perhaps until he can pay for a fresh supply; and thus, unless his wages be reduced in consequence of the cheapness of such articles, it is beyond all question that cheapness is an extraordinary benefit to him, the money which he saves in the purchase of one cheap article is laid out upon another, and without privation or suffering he satisfies the wants which custom has made imperative. In short, he is no longer poor.

These facts are undeniable; but it is alleged that machinery not only makes articles abundant and cheap, but multiplies them beyond the wants of the world, and by causing gluts brings ruin and misery upon the working classes. For reasons explained elsewhere [DEMAND AND SUPPLY, P. C. S.] a universal glut of all commodities is impossible: the more men produce, the more they have to offer in exchange, and their

* The amount spent annually upon spirits is equal to the interest of the national debt; and the amount spent within the last fifty years may be estimated at considerably more than the entire capital of the funded debt. Six millions a year are now sufficient to support all the poor of the country; and thus some idea may be formed of the prosperity of the labouring classes of the present day, if they had accumulated a fund producing an income of thirty millions beyond the wages of their labour.

wants are only limited by their means of purchasing. But particular commodities are frequently produced in excess, and a glut of the market ensues. In causing such gluts machinery is a powerful agent, but only in the same manner as all labour would be, if applied in excess. The results would be precisely the same if too many men were employed in any department of industry; they would produce more than there was a demand for, and their goods would fall in value or be unsaleable. Commodities produced by machinery are subject to the same laws as govern all other commodities. If the supply of them exceed the demand, they are depreciated in value; but the power of producing with facility does not necessarily occasion an excess of production: it must be applied with caution, and its use be properly learned by experience. Suppose that the soil of any isolated country were extraordinarily fertile and the population very small; but that without considering these circumstances the people were to cultivate the whole of their land and bestow upon it all their skill and labour. An excess of food would be the result—more than could be eaten within the year; much would be wasted or sold without profit, and much laid up in store for another season. The husbandmen would be disappointed at the unfortunate results of their industry, but would they complain of the fertility of the soil? It would not be the soil that had caused the glut, but their own misapplied exertions; and so it is with machinery, which like a fertile soil gives forth abundance: its capabilities are known and its advantages ought to be appreciated; but if its productiveness be brought into excessive activity, it causes the evils of a glut.

The influence of machinery upon the production and consumption of commodities need not be followed any further. It increases the common stock of wealth in the world and is capable of multiplying indefinitely the sources of human enjoyment. But these benefits will be neutralized if, while it cheapens production, it has a tendency to diminish the means of employment for the people and the wages of labour;—and this leads us to the second part of our inquiry.

The invention of a machine which should immediately do the work of many men employed in a particular trade would certainly, in the first instance, diminish employment in that trade. Several men would be turned off to seek employment in other trades, and much individual suffering would be occasioned. There have been frequent instances of such a result, and so far as the immediate interests of the particular sufferers are concerned, it is an evil which cannot be too much lamented. In their case machinery is like a rival bidding against their labour, and is as injurious to them as if a fresh set of workmen had supplanted them in the service of their employer. But great as this evil is (and we would not underrate it) it is of comparatively rare occurrence and of short duration. If the invention of the machine caused no more production than the labour of the workmen had previously accomplished, the labour of a certain number of men would be permanently displaced: but as an equal quantity of goods is produced at a less cost of labour, their price is reduced and their consumption consequently encouraged. An increased supply is thus called for and more workmen are again required in the trade. In this manner the demand for increased production corrects the tendency which machinery would otherwise have to displace labour permanently. Even the temporary displacement which frequently occurs is less extensive than might be supposed. Machines are rarely invented which at once dispense with many workmen. They are at first imperfect, and of limited power: they make the labour of the workmen more efficient; but do not become substitutes for labour. Thus, even if the demand for commodities were not increased, the displacement of labour would be very limited and deferred to a distant period: but as an increased demand almost invariably follows every successive improvement in machinery, it will be found, practically, that more operatives are employed in every branch of manufacture, after the introduction of improved machinery than before.

Of this fact we shall offer some examples presently; but here it may be necessary to allude to the case of the hand-loom weavers, which is constantly adduced in proof of the supposed evils of machinery. Their unhappy condition can scarcely be overstated, nor can it be denied that it has been caused by machinery: but it must be recollected that while they have vainly contended against machinery—like pigmies against a giant—hundreds of thousands of other classes, unaccustomed to the labour of operatives, have gained a profitable employment by working *with* it, in the same trade as themselves. No one can suppose that the labour of the hands could compete with the power of steam, and the real cause of their distress is, that instead of adapting the form of their industry to the altered circumstances of their trade, they have continued to work, like an Indian caste, with the same rude implements which their fathers used before them. Their case is the same as that of a miller who should persist in grinding corn by hand, while his neighbours were building mills upon a rapid stream which ran beside his garden. His own ignorance or obstinacy, and not the stream, would be the cause of the failure of his trade.

If the case of the hand-loom weavers be adduced as an example of the permanent displacement of labour by machinery, and if it be contended that it is the natural result of machinery to diminish employment in other trades in the same manner, we must necessarily infer that wherever machinery has been largely introduced into any trade, the number of persons supported by it must have been diminished. We should infer that the agricultural population of this country must have been rapidly increasing, while the population engaged in those branches of manufacture in which steam-power is used must have been falling off or increasing less rapidly. The correctness of such an inference may be estimated from the following facts:—

In no trades has machinery been so extensively introduced as in the manufacture of cotton, wool, and silk, and nowhere has the population increased so rapidly as in the principal seats of these manufactures. Between 1801 and 1841, Manchester increased in population from 90,399 to 296,183, or 227·5 per cent.: Liverpool (whose prosperity has been caused by the cotton trade) increased, in the same period, from 79,722 to 264,298, or 231·5 per cent.; Leeds, from 53,162 to 151,874, or 185·6 per cent.; Bradford (York), from 6393 to 34,560, or 440·5 per cent.; Bolton, from 17,416 to 49,763, or 185·7 per cent.; Huddersfield, from 7268 to 25,068, or 244·3 per cent.; Macclesfield, from 8743 to 24,137, or 176 per cent.; and Dukinfield from 1737 to 22,394, or 1189 per cent. In Scotland the same results have followed from the use of machinery. Between 1801 and 1841 Glasgow increased from 77,385 to 274,533, or 254 per cent.; Paisley, from 31,179 to 60,487, or 94 per cent.; and Greenock, from 17,458 to 36,936, or 111·5 per cent.

Thus far of the manufactures of cotton, wool, and silk. The seats of the iron and hardware trades exhibit similar results. In the same period of forty years Birmingham increased from 73,670 to 190,542, or 158 per cent.; Sheffield, from 31,314 to 68,186, or 117·6 per cent.; Wolverhampton, from 12,565 to 36,382, or 189 per cent.; Merthyr Tydvil, from 7705 to 34,947, or 353 per cent.; and West Bromwich from 5687 to 26,121, or 359 per cent.

In this extraordinary ratio has the population increased in the seats of our staple manufactures, which by the aid of machinery have supplied the whole world with articles wrought by the industry of our people. Let us now compare these places with those agricultural counties in which machinery has exercised the least influence, and let us see if the absence of machinery has been equally favourable to the support of a growing population. In the same period, from 1801 to 1841, Devon increased 55·3 per cent.; Somerset, 59 per cent.; Norfolk, 50·9; Lincoln, 73·5; Essex, 52, and Suffolk, 49·5 per cent. The average increase of these six agricultural counties did not exceed 50 per cent. in forty years; while, setting aside the extraordinary increase exhibited in the particular towns already enumerated, the population of six manufacturing counties, viz. Lancaster, Middlesex, York, W. R., Stafford, Chester, and Durham, including all the agriculturists, increased 112·5.

These facts prove conclusively that machinery, so far from diminishing the aggregate employment of labour in those trades in which it is used, increases it in an extraordinary degree. And not only does it give employment to larger numbers of persons, but their wages are considerably higher. We will not stop to compare the income of an agricultural labourer with that of operatives engaged in the infinite variety of trades carried on in manufacturing towns, in connexion with machinery: but it is sufficient to ask, whence has come the manufacturing population? Its natural growth would have been comparatively insignificant if thousands had not been attracted to the towns from other places. And what could have induced them to leave their homes and engage in new trades but the encouragement offered by more certain employment and higher wages?

It has been shown that machinery has had a beneficial influence upon the employment of labour in the particular trades in which it has been used, and it now remains to consider its effects upon the employment of labour in other trades. In the first place, a few of its obvious results may be noticed. For example, the manufacture and repair of machinery alone gives employment, directly and indirectly, to vast numbers of persons who are unconnected with the particular trades in which the machinery itself is used. Again, the production of all commodities is increased by machinery; and thus the producers of the raw materials of manufactures, the carriers of goods by land and sea, the merchants, the retail-dealers, their clerks, porters, and others, must find more employment. It is clear also, that while the manufacturing and commercial population are thus increased by the use of machinery, the cultivators of the soil must receive more employment in supplying them with food.

In this and other ways the general employment of labour is directly extended by machinery. At the same time the application of machinery to existing branches of industry creates new trades and distributes capital into other enterprises which afford employment for new descriptions of labour. A hundred examples of this fact might be cited; of which railways and steam navigation are amongst the most remarkable; but such examples will be superfluous if it can be shown that it is the necessary result of the use of machinery to apply capital to new enterprises. It has been said that machinery cheapens production by reducing the amount of labour expended upon it: it follows that a less amount of capital with the aid of machinery will produce as much as a larger capital without such aid. A portion of capital is thus disengaged, either for increased production in the same trade, or for application to new speculations. In some way it must be employed, or it will yield no profit, and in some form or other it must be ultimately expended in labour. As long as a person can extend the accustomed operations of his own trade with a profit, he is disposed to do so; but as soon as he finds them less profitable than other investments, he changes the direction of his capital, and seeks new modes of increasing his profits.

There is no truth more certain than that the employment of labour is small or great according to the proportion which capital bears to the number of labourers. Capital is the fund which supports labour, and which must employ it or be unproductive; and thus, if in any country capital be increasing more rapidly than the population, employment will be abundant and wages high; if less rapidly, employment will be scarce and wages low. In the one case, capitalists will be bidding high for labour; in the other, labourers will be bidding against each other for employment. Accumulation of capital is therefore highly conducive to the interests of the labouring population generally, and the use of machinery is especially favourable to accumulation, as may be shown by a simple example. Suppose a man to have a capital of 10,000*l.*, which he is expending annually upon labour in a particular trade, and that his profits are ten per cent., or 1000*l.* a-year. Each year his whole capital is expended, and his means of accumulation are thus restricted to a portion of his annual profits only. But let him invent a machine to facilitate his business, and his position is immediately changed. If this machine should cost 5000*l.*, and the other 5000*l.* be still expended in labour, he may be said to have saved one half of his entire capital in a single year; for instead of spending the whole of it as before, in labour, he is possessed of a durable property which, at a small annual cost, will last for ten or probably twenty years. Nor can it be said that this saving is effected at the expense of labour; for the owner of the machine is placed in a new position in respect to his profits, which prevents him from securing to himself the difference between the amount paid now and that previously paid for labour. To gain a profit of ten per cent. it had been necessary for him, before the invention of the machine, to realize 11,000*l.* annually, being his whole capital and the profits upon it: but now, in order to obtain the same profit, it is sufficient if he realize 6500*l.* only: viz., 500*l.* profit upon his fixed capital of 5000*l.*; 500*l.* for repairs, and wear and tear, calculated at ten per cent.; and 5500*l.* to replace the sum spent upon labour with a profit of ten per cent. He would realize the whole 11,000*l.* as before, if he were able; but he is restrained by competition, which levels the profits of trade. For some time he will most probably obtain more than ten per cent. profit, and so long as he is able to do this, his means of accumulating fresh capital in addition to his machine will be increased, which capital will be expended upon additional labour. But when his profits had been reduced to their former level by competition, society has gained in the price of his goods 4500*l.* a-year, being the difference between 11,000*l.* formerly realized by him, and 6500*l.* his present return. But is this amount thus gained by society lost to the labourer? Unquestionably not. As a consumer, he participates in the advantage of low prices, while the amount saved by the community in the purchase of one commodity must be expended upon others which can only be produced by labour. It cannot be too often repeated, that all capital is ultimately expended upon labour; and whether it be accumulated by individuals in large sums, or distributed in small portions throughout the community, directly or indirectly it passes through the hands of those who labour. If a manufacturer accumulates by means of higher profits, he employs more labour; if the community save by low prices, they employ more labour in other forms. So long as the capital is in existence, it is certain to have an influence upon the general market for labour.

We are now speaking not of the interests of particular workmen to whose temporary sufferings caused by the use of machinery we have already adverted, but of the general and permanent interests of the working population of a country. As regards these, the statistics of British industry amply confirm all reasoning from principles, and prove beyond a doubt that machinery has had a beneficial influence upon the employment and wages of labour. Any one who will reflect upon the facts which have been noticed above, as disclosed by the Census [Census, P. C. S.], can scarcely fail to arrive at the conclusion that without machinery England could not have supported her present population, or could only have supported them in poverty and wretchedness. Nor must the degradation of a part of the manufacturing population be thoughtlessly attributed to machinery, instead of to moral and social causes, which are independent of it. Into these causes it would be out of place, at present, to inquire; but enough has been said to show, 1st, that machinery by increasing production multiplies the sources of enjoyment, and places them within the reach of a greater number of persons; and 2ndly, that by giving increased employment to labour it enables more persons to enjoy those comforts which it has itself created. These are the elements of social prosperity, and if evils have sprung up with it, like tares with wheat, it is not machinery which has caused them. Wherever the influence of machinery has been felt, wealth has advanced with rapid strides; and though in too many cases religion, virtue, and enlightenment may have lagged behind, the tardiness of their progress is to be ascribed, not to machinery, but to the faulty institutions of men.

MACKENZIE, HENRY, was born at Edinburgh in August, 1745. He was the son of Dr. Joshua Mackenzie, a physician in extensive practice and of literary habits. His mother belonged to an ancient family in the county of Nairn. He was educated at the high school and university of his native city; and afterwards he became one of the attorneys in the Scottish Court of Exchequer, a department of law-business which is now all but extinct, and which even then was extremely limited, and conducted by a very few practitioners specially appointed for the purpose. His professional duties, while he held this place, must have left him abundant leisure for indulging his literary tastes. While in London in 1765, studying the English practice in Exchequer, he had begun to write his earliest and best novel, 'The Man of Feeling,' which was published anonymously in 1771, and for some years was not acknowledged by the author. In 1783 he published his second novel, 'The Man of the World;' and next came 'Julia de Roubigné,' his last considerable work of this class. Meantime he had edited two well-known periodicals in the manner of the Spectator: 'The Mirror,' which continued to appear for seventeen months from January, 1779; and 'The Lounger,' which, begun in February, 1785, came to a close about two years afterwards. To the former Mr. Mackenzie contributed forty-two papers; to the latter fifty-seven. Among these are his small novels, such as 'The Story of La Roche,' and a kindly criticism on the poems, then new, of Robert Burns. The Transactions of the Royal Society of Edinburgh received from him several papers; and one of these, a memoir on German tragedy, was followed in 1791 by a volume of dramatic translations, which was one of the earliest causes that drew the attention of Walter Scott to German literature. The Highland Society likewise published in their Transactions papers of Mr. Mackenzie, one of which was his account of the Ossianic Controversy. In 1793 he wrote, for an edition of the works of the blind poet Blacklock, a memoir of the author; and a Life of John Home, the author of 'Douglas,' which he read to the Royal Society of Edinburgh in 1812, was afterwards prefixed to an edition of Home's works, and also published separately. Mr. Mackenzie himself wrote several plays, which are more remarkable for refinement of feeling, imagery, and language, than for dramatic force or effectiveness. The collected edition of his works contains three of these: 'The White Hypocrite,' a comedy, which was once performed at Covent Garden: 'The Spanish Father,' a tragedy, which Garrick had declined to bring on the stage on account of the harrowing nature of the catastrophe; and 'The Prince of Tunis,' which had been acted at Edinburgh with much applause in 1773, and printed separately the same year.

He was likewise a political writer in the Tory interest. His most elaborate work of this sort was 'An Account of the Proceedings of the Parliament of 1784,' which was revised and corrected by Mr. Pitt's own hand; and he published some anti-jacobin tracts at the time of the French Revolution. The merit of these services to the government, set forth by his friends Lord Melville and Mr. George Rose, procured for him in 1804 the place of comptroller of taxes for Scotland, an office of large emolument, but considerable labour and responsibility, which he held thenceforth till his death.

In 1808 he edited a complete collection of his literary works, in eight octavo volumes; and this was almost his last contribution to literature. 'The old stump,' as he himself was once heard to say, 'would still sometimes send forth a few green shoots;' but his official duties occupied much of his time; and the romantic fervour of sentiment, which had prompted his early literary efforts, had given way to practical habits of thinking and feeling, such as a man of business may unite with literary tastes and with a fondness for literary amusement. Indeed that tendency to sickly refinement, which characterised his exquisite novels, indicated a want of the vigour of mind essential to success in the highest walks of literary invention; and his is not the only case in which genius of this cast has put forth all its strength in youth, and been overborne in mature years by the realities of life.

Accordingly, for many years, Mr. Mackenzie's leisure was spent either in the society of literary and other friends, or in shooting and fishing, sports to which he was particularly attached, and which he pursued as long as his strength permitted. His old age was healthy, cheerful, and happy: a slight deafness alone indicated the decay of nature. He, who had in youth breakfasted with Dr. Johnson, and who had enjoyed the friendship of Blair and Robertson and Adam Smith, lived to see one generation after another, and revolution after revolution in the phenomena of literature.

He had married the daughter of Sir Lodovick Grant of Grant: and by this lady he had eleven children, one of whom has long been a judge in the Supreme Court of Scotland. Henry Mackenzie died in Edinburgh on the 14th of January, 1831, being in the eighty-sixth year of his age.

MACROCHE'ILUS, a genus of fossil Gasteropoda, proposed by Professor Phillips (*Palæozoic Fossils of Devon*) to include several species which occur in the Devonian and carboniferous strata

MACRO'POMA, a genus of fossil fishes, proposed by Agassiz: the species belong to the cretaceous strata.

MACROSE'MIUS, a genus of fossil fishes proposed by Agassiz. From the oolite.

MADNESS. [INSANITY, P. C.; LUNACY and LUNATIC ASYLUMS, P. C. S.]

MAECIA'NUS, LUCIUS VOLUSIUS, a Roman jurist, who lived in the time of Antoninus Pius and Marcus Aurelius. He was one of the legal advisers of Antoninus (Capitolinus, *Anton. Pius*, 12), and one of the instructors of Aurelius in law (Capitolinus, *Ant. Philosoph.* 3). He was held in high estimation by Aurelius, as appears from a Rescript of the Divi Fratres, in which he is styled their friend and a most careful student of the Civil Law (*Dig.* 37, tit. 14, s. 17). He was also a friend of the jurist Julianus (*Dig.* 35, tit. 2, s. 30, § 7). It is conjectured that he was made governor of Alexandria by Aurelius, for Vulcatius Gallicanus, in his Life of Avidius Cassius (c. 7), mentions a Maecianus who was put to death there by the army for joining in the rebellion of Avidius Cassius. The writings of Maecianus which are mentioned in the Florentine Index are sixteen books on Fideicommissa, and fourteen on Judicia Publica. There are 44 excerpts from Maecianus in the Digest. His Libri Quaestionum are also mentioned in the Digest (29, tit. 2, s. 86); and a commentary, or something of the kind, on the Lex Rhodia de Jactu (*Dig.* 14, tit. 2, s. 9). Maecianus is cited by Papinianus, Ulpianus, and Paulus.

An extant treatise, De Asse et Ponderibus, is supposed by some writers to belong to another author of the same name.

MAGIC LANTERN is a species of lucernal microscope, its object being to obtain an enlarged representation of figures, on a screen in a darkened room, by means of the pencils of light issuing from a lamp or candle and passing through a convex lens.

The instrument consists of a lantern, generally of tin, and of a cubical form, in the interior of which is the light; and at a perforation in one of the sides is applied a tube projecting horizontally from it. Immediately before the aperture, and within the tube, is a glass lens, often nearly a hemisphere and three or four inches in diameter, serving to condense the light which proceeds from the lamp both directly and by reflexion from a concave mirror attached to the side of the lantern which is directly opposite the aperture: this tube carries within it another, which is also provided with a convex lens, and is capable of a small movement for the purpose of adjustment.

A groove in front of the lantern and parallel to that front receives a rectangular frame containing the glass plates on which are painted, with transparent colours, the objects of which an enlarged view is to be obtained; and, as the amusement of young persons is chiefly intended by the exhibition, grotesque figures are usually those which are represented. Instead of a single convex lens, the sliding tube is sometimes provided with two such lenses; these are placed at a little distance from one another, and have between them a perforated plate of tin, crossing the interior of the tube: the lens, or pair of lenses, is of such a focal length that the rays in each of the pencils which proceed from the object may unite on the screen and thus produce the enlarged representation of the figure.

Several figures are usually drawn on the same plate of glass, and the plate is capable of being moved by hand in the groove so that the different figures may be brought successively before the spectator: there may thus be exhibited various scenes relating to one subject, which is generally some absurd fiction.

Persons who make it their occupation to exhibit the magic lantern frequently give, with the representations, descriptions of the objects on the screen; and these being expressed in a peculiar jargon, add in a certain degree to the amusement of the company: they frequently also, for the purpose of heightening the effect, give, by a simple wheel-work, motions to the figures which are painted on the plates of glass.

This ingenious toy, as it may be considered, is said to have been invented by Kircher, in the seventeenth century, and it is described by him in his 'Ars Magna Lucis et Umbræ.' The celebrated Euler proposed to substitute for the lens in the side of the lantern a concave mirror, perforated in the middle like that of a Gregorian telescope: this was to be placed in the interior of the lantern with its polished surface towards the light and its convexity towards the object. The light was to be so disposed that none of it should pass directly through the aperture in front of the lantern so as to fall on the screen; and that which was reflected from the concave mirror, after falling upon one with a plane surface, was from thence to be reflected in a contrary direction upon the object. The rays in the pencils proceeding from the object were to pass through a lens in the tube, as in the former construction; and, by converging with greater accuracy to points on the screen, they would have produced a more correct image than that which results from refracted light alone.

A remarkable improvement in the manner of employing the magic lantern was first exhibited in London in the year 1802. The lantern itself is similar to but larger than that which serves for more general purposes; and the sliding tube which carries the farthest lens has a greater range of motion. The objects to be exhibited are painted upon a glass plate, which is inserted in a groove as before stated; and the machine is placed upon a stage which is capable of being moved on wheels in a direction perpendicular to the screen on which the objects are represented.

The screen is a curtain made of fine muslin or gauze, and covered with varnish so as to be quite transparent: it is stretched in a vertical position across the theatre or apartment; and this being made quite dark, the spectators occupy the space in front of the screen, while the apparatus is disposed on the opposite side.

In any magic lantern when the tube carrying the lens which is farthest from the lamp is drawn out as much as possible, the magnitude of the image represented on a screen is the smallest; that image increases in magnitude in proportion as the tubes are diminished in length, or as the lens is brought nearer to the body of the lantern. It increases also in proportion as the whole machine is made to recede from the screen; and the variations of the length of the tubes must, by the exhibitor, be combined with the different distances of the lantern from the screen, in order that by the just convergence of the rays in each pencil, on the screen, the proper degree of distinctness of vision may be obtained under all the variations in the magnitude of the image.

Care is taken that during the exhibition all light shall be excluded both before and behind the screen, except that which, in proceeding from the lantern, produces the image to be observed; and the screen being itself invisible, the spectators can scarcely divest themselves of the idea that they are looking into a dark cavern, in which the objects, at first dimly visible as specks in its deepest recesses, appear to be gradually advancing towards them, increasing in magnitude as they seem to approach: after the objects have been some time apparently in the immediate presence of the company, perhaps surrounded by a blaze of light, they seem as gradually to retire, and at length they vanish, leaving the place in profound darkness. The effect of the exhibition is, moreover, heightened by the accompaniment of mournful or inspiring sounds, according to the character of the object, from musical instruments disposed for the purpose.

Spectres are frequently exhibited in this manner; but occasionally the heads, or the entire figures, of celebrated personages are shown; and the illusions produced have caused the name of *Phantasmagoria* to be applied to the apparatus.

MAGISTRATE, a word derived from the Latin *magistratus*, which contains the same element as *magnus* and *magister*, and signifies both a person and an office. A Roman magistratus is defined to be one who presides in a court and declares the law, that is, a judge. The kings of Rome were probably the sole Magistratus originally, and on their expulsion the two consuls were the Magistratus. In course of time other offices, as those of Praetor and Aedile, were created; and those who filled these offices were elected in the forms prescribed by the constitution, and they had jurisdictio. [JURISDICTION.] The original notion of a magistratus, then, is one who is elected to an office, and has jurisdiction

In England the term magistrate is usually applied to justices of the peace in the country, and to those called police magistrates, such as there are in London. It has also been applied in other ways; for instance, people have sometimes said that the king is the chief magistrate in the state. But these applications of the term do not agree with its proper sense. A Roman magistratus was elected, and so far he differed from a justice of the peace; he also exercised delegated power in his jurisdiction, in which respect, as well as being elected, he differed from the king of England, who is not elected, and does not exercise delegated jurisdiction, but delegates jurisdiction to others.

MAGNETISM, ANIMAL. [ANIMAL MAGNETISM, P. C. and P. C. S.]

MAGNETO'METER is the name given to a magnetized bar of steel, of considerable dimensions compared with the needle of an ordinary compass, which is employed to determine either the absolute amount of magnetic declination (commonly called the *variation* of the needle) or the resolved intensities of terrestrial magnetism in horizontal or vertical directions. It has the names of *declination magnetometer*, and *vertical* or *horizontal force magnetometer*, according to the purpose to which it is applied.

The declination magnetometer is of various sizes; for general purposes it is from 12 to 15 inches long, 1 inch broad, and ¼ inch thick; but that which is mounted in the Greenwich Observatory is 2 feet long, 1½ inch broad, and ¼ inch thick: the bar is placed so as to rest at the middle of its length, within a sort of stirrup made of gun-metal, and this, at its upper part, has a triangular aperture through which passes a metal cylinder. A skein or a number of fibres of untwisted silk, from 3 feet to 8 or 9 feet long, attached to the middle part of the cylinder, passes over a pulley at the top of the stand or near the ceiling of the apartment, and, afterwards descending, is connected with a small windlass, in order that the bar may be raised or lowered: thus the bar is suspended in a horizontal position, with freedom to turn on a vertical axis till it rests in the plane of the magnetic meridian. The whole apparatus is contained in a box of wood, in order to protect it from the agitations of the air, glazed apertures being provided for the purpose of allowing the observations to be made.

In some constructions, near each extremity of the magnetized bar is a sliding frame of gun-metal: one of these frames carries a small glass plate on which is a graduated scale, and the other carries an achromatic lens, the focus of which coincides with the scale. By means of a telescope placed at a certain distance in the direction of the magnetometer the graduations on the scale may be observed through the lens, so that the instrument becomes a sort of collimator; and by the number of the graduation which coincides with the wire in the eye-piece of the telescope, the absolute position of the axis of the bar and any variations in its position may be observed.

The stand which carries the suspending fibres of silk generally consists of two pillars of copper, firmly supported on a stone base; and at the upper extremity the apparatus to which the silk fibres are attached is connected with a horizontal circle, graduated, for the purpose of determining the value of any torsion which may exist in the fibres.

Previously to placing the magnetometer in the stirrup, a bar of gun-metal, called a *detorsion bar*, equal in weight to the magnetometer, and, like it, furnished with a graduated scale and lens, is suspended by the silk fibres: this is allowed to vibrate till it comes to a state of rest; the angle which its axis makes with the plane of the magnetic meridian is then observed, and the torsion circle, carrying the fibres depending from it, is turned round on its vertical axis till the detorsion bar is brought to that plane. Thus the torsion of the fibres is nearly obviated.

In order to find the point on the graduated scale which corresponds to the magnetic axis of the magnetometer, the latter is placed in the stirrup; and, looking through the telescope, the observer remarks the graduation of the scale which coincides with the vertical wire in the field of view: the like observation is made with the magnetometer in a reversed position; and then half the sum of the numbers on the scale is that which coincides with the axis; half the difference of the readings converted into angular space (the distance of the telescope from the scale being the radius) is the deviation of the optical axis of the telescope from the magnetic meridian. The telescope having a movement in azimuth, it must then be turned through an angle equal to the deviation, and thus brought into the plane of that meridian. The apparatus would then be ready for use if it were not that some remains of torsion may exist in the fibres; and this must be corrected by means of the detorsion apparatus as before.

When it is required to determine the absolute declination, the point which indicates on the scale the direction of the magnetic axis of the bar being in coincidence with the wire in the telescope, and a correction made for any existing error of collimation, the telescope is turned horizontally to some terrestrial object whose azimuth from the astronomical meridian is known. Then the difference between this azimuth and the angle through which the telescope was turned will evidently be the required declination, or the angle between the planes of the astronomical and magnetic meridians.

After the actual position of the magnetic meridian has been determined as above, any deviations of the axis of the magnetometer from it, indicated by a different division of the scale coinciding with the vertical wire of the telescope, will denote a variation of the declination; but it is evident that such deviation will be affected by the torsion induced in the silk fibres in consequence of the angular movement of the magnet. The correction due to this cause of error is to be found from an experimental determination of the relation between the force of terrestrial magnetism and the force of torsion: thus, a magnetized bar being already in the plane of the magnetic meridian, let the torsion circle be turned on its axis till a radius of it has described any angle (called the angle of torsion), and let the position of the magnetometer be observed when it rests between the force of torsion thus created, by which it is made to deviate from the meridian, and the horizontal force of magnetism, by which it is drawn towards the meridian. Then, by mechanics, the force (M) of magnetism is to the force (T) of torsion as the difference between the angle of torsion and the angular distance of the bar from the meridian is to the latter distance; or, by proportion, T+M is to M as the given angle of torsion is to the difference between that angle and the distance of the needle from the meridian. The last ratio being obtained from an experiment, holds good for any corresponding observation; consequently the observed changes of declination must be increased in the ratio of M to T+M, or be multiplied by $\frac{T+M}{M}$, in order to have the correct changes.

When it is required to determine the absolute horizontal intensity of terrestrial magnetism with an apparatus like that which has been described, a magnetic bar of the same dimensions as that which is suspended is used with the latter: this is called a deflecting bar. It is placed in the direction of a horizontal line passing through the centre of the suspended magnet, perpendicular to the magnetic meridian, at two different distances, R and R′, from that centre; and the angular deflexions produced by its actions on the suspended bar are observed; first, when the north end of the deflecting bar, at each distance, is towards the east, and again when it is towards the west. Half the difference between the observed deflexions at the two distances is taken as a mean deflexion. A second mean deflexion is obtained from observations made in like manner with the deflecting bar on the opposite side of the suspended bar: let these mean angular deflexions be represented by θ and θ'; then the formula

$$\frac{R'^5 \tan.\ \theta' - R^5 \tan.\ \theta}{2\,(R'^2 - R^2)} \cdot \frac{T+M}{M},$$

investigated by M. Gauss, will give the ratio of the force m of magnetism in the bar to the horizontal force F of the earth's magnetism, or the value of $\frac{m}{F}$. The second factor is the correction on account of the force of torsion in the suspending lines of silk.

The value of mF, or the momentum of the horizontal force of the earth's magnetism on the suspended bar, may be computed. For, representing the momentum of the bar's inertia with respect to a vertical axis passing through its centre of gravity by N ($N = \frac{1}{12}\mu(a^2+b^2)$ in which a is the length, b the breadth, and μ the mass of the bar, whose form is rectangular), $\frac{mF}{N}$ denotes the angular velocity of the bar. But, by mechanics, the angular velocity of a suspended body is expressed by $\frac{g}{l}$ (g being the force of gravity, and l the distance from the centre of suspension to that of oscillation in the magnetometer), or by its equivalent $\frac{\pi^2}{T^2}$ ($\pi = 3{\cdot}1416$, and T the observed time in which the magnet makes one vibration); therefore, applying also the correction for torsion,

$$mF.\ \frac{T+M}{M} = \frac{\pi^2 N}{T^2}.$$

From the values of $\frac{m}{F}$ and mF, the value of F, the required intensity of magnetism in the horizontal direction, may be found.

The bifilar magnetometer, invented by M. Gauss for determining both the absolute amount of the horizontal intensity of magnetism and its variations, has been noticed under Terrestrial Magnetism, P. C. The horizontal force magnetometer at the Greenwich Observatory is bifilar, and of the same dimensions as the declination magnetometer. Below it, and under the centre of motion, is fixed a mirror in a vertical plane, but oblique to one passing through the magnetic axis of the bar: this reflects to the eye of the observer a scale which is applied to the opposite side of the apartment; and, the telescope being directed to the mirror, in proportion as the magnet declines more or less from the meridian, the numbers which on the scale appear in coincidence with a wire in the telescope increase or diminish. Thus the variations of the horizontal intensity are obtained.

The instrument is held nearly perpendicularly to the magnetic meridian by the force of torsion in the two halves of the skein of silk by which it is suspended: these parts are each about 8 feet long. An oblong ring of copper, which entirely surrounds the magnet in a vertical plane, serves to diminish the extent to which the bar would vibrate; and both ring and bar are contained in a double rectangular box, one side of which is of plate glass: the box is covered with gilt paper, in order to obviate the effects of electricity in the apparatus.

The suspended bar being in equilibrio between the force of torsion and the horizontal force of magnetism, it is evident that if the former force be computed, the latter will be obtained. In order to determine the variations of the horizontal force by the observed deviations of the bar from its mean place the following formula is employed:

$$\frac{dF}{F} = -\text{cotan.}\ v\ du,$$

in which F is the absolute horizontal force, dF its variation, v the angle between a vertical plane passing through a line connecting the upper extremities, and one passing through a line connecting the lower extremities of the two parts of the suspending line; du is the observed deviation of the axis of the needle from its mean place, and is expressed by the length of an arc in terms of the radius. $\frac{dF}{F}$ evidently gives the variation of the horizontal intensity in parts of its absolute value.

The vertical force magnetometer is a magnetized bar which is crossed in the middle by a short axle perpendicular to its length, and has its lower part, on each side, reduced to an edge. This *knife-edge*, as it is called, passes nearly through the centre of gravity of the bar, and rests, on each side of the bar, on an agate plane; the whole is supported on a short copper pedestal, which rests on the base of the instrument. For the purposes of adjustment the bar is furnished on each arm with a screw, which acts as a weight: that which is attached to one arm is parallel to the magnetic axis of the bar, and by moving it backwards or forwards the bar is made to assume a horizontal position: the other is in a vertical position, or at right angles to the magnetic axis; and by moving it upwards or downwards the centre of gravity is made to coincide with the knife-edge. The whole apparatus is capable of being turned on a vertical axis, so that the bar may be placed in any azimuth with respect to the magnetic meridian.

In some constructions of the instrument there is attached to each extremity of the bar a ring of copper carrying two wires at right angles to one another; a line joining the intersections of the pairs of wires should be parallel to the magnetic axis of the bar, and the deviation, if any there be, is determined by observing the intersections on a scale in a microscope, which is fixed on a support near each extremity of the bar; the latter, while at right angles to the magnetic meridian, being for this purpose placed successively in a direct and a reversed position. Half the difference between the readings on the scale is the value of the error.

In order to put the magnetized bar in any required position, a brass bar of the same dimensions as the other, and like it provided with knife-edges, is made to rest on the agate planes, and is brought to the magnetic meridian by means of a magnetized needle which turns on a pivot at the top of the bar. A theodolite is placed on the base of the instrument, and its telescope is turned till the crossing of wires in the field of view bisects a distant object; the telescope is then turned horizontally through an angle equal to the required azimuth in which the magnetized bar is to be placed, but in a contrary direction, and lastly the stand carrying the whole apparatus is turned round horizontally till the telescope wires again bisect the object. The bar will then be situated in the required azimuth.

When the variations of the vertical intensity of terrestrial magnetism are to be observed, the interval between a fixed wire in the microscope and the apparent place of the intersection of wires on the bar is measured by means of the moveable wire in the former; the deviation is read on a scale provided for the purpose, and is expressed by a circular arc in terms of the radius. The formula for determining the ratio between the absolute vertical force of magnetism and its variation is

$$\frac{dF'}{F'} = \frac{t'^2}{t^2}\ \text{cotan.}\ \theta\ d\eta,$$

in which F′ represents the vertical intensity, dF′ its variation, t and t' are the times in which the needle would perform a vibration in a vertical and in a horizontal plane respectively, θ is the inclination (commonly called the dip), and $d\eta$ is the observed deviation of the bar from a horizontal position.

At the Greenwich Observatory the vertical force magnetometer is provided with a mirror, which stands over its centre of motion with its plane oblique to the magnetic axis of the bar. A scale is affixed to the opposite wall of the apartment, and the mirror reflects it to the eye of the observer, who, looking through a telescope, reads the division of the scale which appears in coincidence with the wire in the field.

The building containing the magnetic instruments at Greenwich is in the form of a cross on the plan; two of the walls are parallel, and the two others perpendicular to the magnetic meridian. The declination magnetometer is in the south arm, the horizontal force magnetometer in the east, and the vertical force magnetometer in the west arm of the building: both of these bars are perpendicular to the magnetic meridian. Three telescopes are placed in such situations that the observer, seated near all of them, can readily turn from one to another, and thus make his observations on the three magnetometers nearly at the same time.

MAGNO'LIA, a genus of plants named in honour of Pierre Magnol, who was professor of medicine and prefect of the botanic garden of Montpellier. He was born in 1638, and died 1715. He gave an account of the plants growing wild about Montpellier, in a work entitled 'Botanicum Monspeliense; seu Plantarum circa Monspelium nascentium Index,' 8vo., 1686. This work was illustrated with plates, as well as one published in 1689 with the title 'Prodromus Historiæ generalis Plantarum in quo Plantæ per Familias disponuntur,' was arranged according to a natural system of his own. In another work embracing the plants growing in the Montpellier garden, entitled 'Hortus Regius Monspeliensis,' he has arranged the plants according to the system of Tournefourt.

The genus Magnolia is the type of the natural order Magnoliaceæ. It has a calyx of 3 deciduous sepals that resemble petals; the corolla is composed of 6 to 9 petals; the stamens and pistils numerous; the carpels are disposed compactly in spikes, opening by the external angle, 1-2-seeded, permanent; the seeds baccate, somewhat cordate, pendulous, hanging out beyond the carpels by a very long umbilical white thread. The species of Magnolia are trees or shrubs, with alternate, stipulate, deciduous, or evergreen simple leaves, and large terminal solitary odoriferous flowers. They are all natives of North America and Asia.

M. grandiflora, Great-flowered Magnolia, or Laurel Bay, is an evergreen tree, reaching sometimes a height of 70 feet. It has oval-oblong coriaceous leaves with the upper surface shining and the under surface rusty; the flowers erect, with from 9 to 12 petals expanding. This plant is one of the tallest and handsomest trees of North America. It has large pale-green shining leaves nearly 10 inches long, with large white flowers. It has been cultivated in England for the last century, and in this country attains a height of from 20 to 30 feet. Several varieties of this species have been named and described. Amongst the most constant and best known varieties are, 1, *M. g. obovata*; 2, *M. g. Exoniensis*; 3, *M. g. angustifolia*; and 4, *M. g. præcox*. The first is known in the Carolinas by the name of the Big Laurel; the second is the Exmouth Magnolia; the third and fourth are varieties which have been produced in France.

In the cultivation of this species a deep sandy loam, dry at bottom, and supplied with vegetable mould, suits all the varieties. In planting it against a wall, almost any aspect may be chosen except a north-east. This plant may be propagated by stools, which should be laid down in autumn, and require two years before they are fitted for separation. They are then potted, and kept in pits or under glass during the winter. It may be also propagated by seeds from America.

M. glauca, deciduous Swamp Magnolia, is an almost deciduous plant, with obtuse elliptical leaves, glaucous on the under surface; the flowers from 9-12 petalled, contracted; the petals ovate, concave. This species is a tree rising from 15 to 20 feet in height. It is a native of North America, in low moist swampy ground at a little distance from the sea, from Massachusetts to Florida and Louisiana. This plant is also cultivated, and a number of varieties have been described. The bark has a bitter and aromatic odour resembling sassafras. On this account it has been used in America as a substitute for other aromatic bitter barks as Cascarilla, Canella, &c., and, it is said, with great success. Although not much used in Europe, very favourable reports of its efficacy in chronic rheumatism, ague, and remittent fever have been given. All the species of Magnolia possess more or less the properties which are most evident in *M. glauca*. When used, a tincture made from the bark, seeds, or cones, is equally efficacious. It is said that when the tincture is made from the leaves and cones whilst green, it is more efficacious. In America this tree is known by the names White Laurel, Swamp Laurel, Swamp Sassafras, Sweet Bay, and Beaver-tree. The last name is given to it on account of the fondness of the beaver for it. The flowers are of a cream colour and have a sweet scent, which Kalm says may be smelt at a distance of three miles. The flowers are followed by red berries, which give the tree a handsome appearance. The berries are steeped in brandy and used as a domestic medicine for various complaints.

M. umbrella is a deciduous tree with lanceolate spreading leaves, the adult ones smooth, the younger ones pubescent underneath; the petals 9-12, exterior ones pendant. It is a native of North America, in the Carolinas, Georgia, Virginia, and New York. The leaves are 1 to 2 feet long, placed at the ends of the branches in a circular manner, somewhat in the form of an umbrella, from which circumstance it has been called the Umbrella-tree. The wood is soft and spongy, and on the mountains of Virginia is called Elmwood.

M. acuminata, a deciduous tree with oval acuminate leaves, the under surface pubescent, the flowers with from 6 to 9 petals. It is a native of North America, from Pennsylvania to the Carolinas. The flowers are large, 3 or 4 inches in diameter, of a yellowish colour, mixed with faint blue or pea-green, but not remarkable for their beauty. The fruit is about three inches long, and resembles a small cucumber, whence in America it is called Cucumber-tree. A tincture is made of the fruit, and is used in cases of rheumatism. Several varieties of this plant have been described. It is often used in the London nurseries as a stock on which to engraft the other species.

There are several other species of this magnificent genus found in the forests of North America, all of which are valued in Great Britain for ornamental culture. The best known of these are *M. cordata*, the heart-leaved Cucumber-tree, with yellow flowers streaked with red, and having a disagreeable odour; and *M. auriculata*, Indian Physic, or long-leaved Cucumber-tree, having white flowers and a bitter bark, which is used as a medicine by the Indians.

M. Yulan, or *conspicua*, a deciduous tree with obovate abruptly acuminated leaves, the younger ones pubescent, expanding after the flowers, the flowers erect, 6-9 petalled; the styles erect. This plant attains a height of 30 or 40 feet in its native country, but reaches only 8 or 10 feet in our gardens. It grows in China, where it has been cultivated since the year 627. Its native name is Yulan. It is a very showy tree, having white flowers sometimes suffused with purple, which give out a most delicious perfume. It blossoms in this country from February to April, and is distinguished from the other species by the flowers appearing before the leaves. It is not quite so hardy as the American species; still, unless the weather is unpropitious, it will put forth an abundance of blossoms during the dreary months of February and March.

M. purpurea, the purple-flowered Magnolia, is a deciduous shrub, with obovate acute reticulately-veined leaves, almost smooth; the flowers erect, of 3 sepals and 6 obovate petals; the styles very short. This plant is a native of Japan, and seldom attains a greater height than 10 feet. The bark when bruised has an aromatic odour. The flowers are more or less purple without, and always white within. It is a very ornamental species and worthy of cultivation. The best situation for it is against a wall, when its branches will reach from 15 to 20 feet.

In their cultivation the hardy kinds may be treated in the same way as M. grandiflora. The Chinese kinds are often inarched or budded on *M. obovata*. When the plants are replanted after layering or propagation by seed, neither the roots nor leaves ought to be cut off, otherwise they will not succeed so well.

(Don, *Gardener's Dictionary*; Loudon, *Encyclopædia of Trees and Shrubs*.)

MAHADE'VA. [SIVA, P. C.]

MAHMUD II., Sultan of Turkey, the younger son of Sultan Abdu-l-Hamid, or Ahmed IV., was born on the 14th of Ramazán, A.H. 1199 (the 20th of July, A.D. 1785), and succeeded his elder brother, Sultan Mustafa IV., on the 28th of July, 1808. It has been shown [TURKEY, P. C.] how Sultan Selím, the uncle of Mahmud, was deposed and imprisoned in 1807 on account of his civil and military reforms, and that Mustafa had no sooner succeeded him than he abolished the new institutions of Selím, especially the Nizam Jedíd, or the body of troops who were disciplined on European principles. Mustafa Bairaktar, pasha of Rusjuk, an old friend of the deposed Selím, strongly objected to the policy of Sultan Mustafa, and no notice being taken of his remonstrances, put himself at the head of his troops, marched upon Constantinople, occupied the town, and proclaimed Selím sultan. But while Selím's name was shouted by the victors in the streets of Constantinople, he had ceased to live; he was assassinated by order of Mustafa, who thought that by removing the object of the revolution, he could also crush it. He was mistaken. Mustafa Baïraktar occupied the seraglio, after a bloody struggle, and after having confined Sultan Mustafa in the same prison in which Selím was murdered, he proclaimed Mahmud, who was found in a room hid under carpets and books, and more ready to believe that he was going to be murdered than to be placed on the throne of Osman. Hitherto Mahmud had spent his days in the quiet confinement of the seraglio, chiefly occupied with Turkish and Persian literature, and enjoying, during the last twelve months previous to his accession, the instruction of the captive Selím, who, it is said, foretold his nephew's future elevation, and initiated him in those principles of reform through which he had endeavoured, though in vain, to reorganise Turkey. Mahmud was also imbued with that deep hatred of the Janissaries which was one of the leading principles of his future actions.

Mahmud ascended the throne when Turkey was in a violent political and social crisis. In consequence of the enlightened but weak government of Selím the prejudices of the people were roused without meeting with a power sufficient to keep them in check; the sultan's authority was disregarded by the pashas of Europe, Asia, and Africa; and the Janissaries, who were exasperated through Selím's attempts upon their privileges, were ready instruments in the hands of those agitators who, under the pretext of either avenging the murder of Selím, or the deposition of Mustafa, were, at first secretly, then openly, sowing the seeds of discord. In spite of this threatening state of the empire, Sultan Mahmud boldly proclaimed that he would carry out the reforms of Selím, and by choosing Mustafa Baïraktar his grand vizír, he proved that he was not using idle words. Several pashas who were severely punished for disobedience were the first to perceive that Turkey was now governed by a reformer more energetic than Selím. When the turn of the Janissaries came, they broke out in open rebellion, and besieged Mustafa Baïraktar, whom they believed to the originator of the reforms, in his fortified palace. Unable to hold out longer, and receiving no relief from the sultan, who was himself assailed by the rebels, the gallant vizír blew himself up. Mustafa was proclaimed sultan, and the rebels cried out for the head of Mahmud. In this critical position Mahmud did a deed at which humanity shudders, but which was one of the boldest political strokes ever attempted by a Turkish sultan: he ordered his captive brother to be strangled together with his infant son; and those of Mustafa's women and concubines who were pregnant, four in number, were sewn up in leathern sacks, and drowned in the Bosporus. By these murders Mahmud became the only male descendant of Osman.

His life was in the utmost danger. Yet he had no higher thought than the glory of Turkey, and he made its existence depend upon his own, for with the death of the last of the house of Osman, the empire of Osman would have become a prey to anarchy. The very fact, however, of his being the only descendant of Osman, was a sort of guarantee for his life, for although the people had massacred more than one sultan, and the sultans themselves had shed the blood of more than a hundred royal princes, these crimes were committed against individuals and not against the reigning family, the popular belief being that Turkey would last no longer than the family by whose great ancestor the empire was founded. Mahmud was fully aware of this when he sacrificed his brother and his brother's children, and we may fairly presume that his object was to make himself the only representative of the founder's family.

Mahmud succeeded in crushing this bloody rebellion after a struggle of two days, and having conciliated the Janissaries by abolishing the Nizam Jedíd and establishing his authority at home, he turned his attention to his relations with the European powers. The war with Russia had just broken out. The Turks were defeated; Constantinople was in danger; the principal pashas in Asia, Africa, and Europe threatened a revolt or had revolted; and Czerni George raised the standard of independence in Servia. Mahmud, although pressed to make peace, persisted in continuing war, and he was encouraged to do so by French diplomacy, for a war between France and Russia was imminent. That war broke out in 1812, and Constantinople became the centre of European intrigue, Russia and Great Britain being active in making peace acceptable to the sultan, while Napoleon made the greatest efforts to rouse him to further resistance. Although the Russians had conquered Northern Turkey as far as the Danube, Mahmud could fairly hope that the Russian army would soon be compelled to evacuate the Turkish territory, and he would perhaps have continued the struggle, but for the strong remonstrances of England, which were backed by a large fleet in the Mediterranean. Under these circumstances he made peace with Russia at Bukarest, on the 28th of May, 1812, on conditions more favourable to him than the unfortunate turn of the war allowed him to expect. He lost only that part of Moldavia which lies east of the Pruth, which now became the frontier of the two empires, and a few districts in the Caucasus; while the Servians, abandoned by Russia, were obliged to submit once more to the Turkish yoke. Mahmud would perhaps never have waged war with Russia, but for the certainty that Napoleon had abandoned him, by a secret article of the treaty of Tilsit, to the Emperor Alexander, and the exorbitant demands which Russia made upon him in consequence of the Czar's friendship with Napoleon. The Russian army thus disengaged immediately set out to cut off the retreat of Napoleon from Moscow, who was outrageous at the news of the peace of Bukarest, for he had been outwitted by a prince whom he used to call an ignorant barbarian.

Mahmud availed himself of the peace to continue the work of reform, in which he was ably assisted by his personal friends Berber Bashi and Khalet Efendi. He succeeded in keeping down the rebellious spirit of the pashas of Baghdad, Damascus, Widdin, and Silistria; and he received good news from Mehemed 'Ali, the pasha of Egypt, who had retaken Mecca from the Wahábis who had seized it. His attention was chiefly directed to 'Ali Pasha of Janina, whom he watched with great suspicion, being convinced that sooner or later that great feudatory would kindle a rebellion all over Greece. His conduct towards 'Ali Pasha was signalized by that mixture of craft and frankness which is so striking in the character of eastern nations; and while he deprived the sons and grandsons of 'Ali of their offices, or drew them over to his side by bribes, he still professed to be a friend of 'Ali himself, till the moment came for ensnaring and crushing him. The downfall and death of 'Ali Pasha, in 1822, seemed to promise a harvest of future success to the sultan. But Turkey's enemies were like the hydra; the more heads fell the more foes rose; and no sooner was 'Ali's head exposed on the gate of the seraglio, than Mahmud had to prepare for a contest with Russia, a deadly struggle with Mehmed 'Ali of Egypt, and an open rebellion of the Greeks.

The Greek rebellion came first. The attempts of Alexander Ypsilanti in Wallachia, and of the Greeks of Constantinople, who had formed a plan to get possession of the Turkish fleet, were easily frustrated; but the insurrection in Greece compelled the sultan to make the greatest efforts. Unable to quell the revolution with the forces under his immediate command, Mahmud persuaded Mehmed 'Ali to join him, on the promise that he should be invested with Candia as soon as the object of the campaign was attained. An Egyptian fleet, with an army of 12,000 men, commanded by Mehmed Ali's son, Ibráhim, the conqueror of the Wahábis, sailed for the Peloponnesus, and the combined Turkish and Egyptian forces committed those atrocities which roused a cry of indignation throughout Europe, and induced Great Britain, France, and Russia to interfere on behalf of the unfortunate Greeks. Mahmud, bent upon crushing all rebellion within his dominions, and making himself equally respected by both his Turkish and Christian subjects, declined any interference, and the three powers entered into an alliance by the convention of the 7th of July, 1827. They proposed that Greece should be a vassal state of Turkey, and should acknowledge the sultan's suzerainty by paying an annual tribute. . The Greeks promised to submit on that condition, but the sultan rejected the proposition with disdain. Upon this the combined British, French, and Russian fleets attacked the Turko-Egyptian fleet in the bay of Navarino (20th of October, 1827), and the pride of the sultan, his splendid ships of war, which had cost him so dear, were destroyed after a gallant resistance. A French army now landed in the Peloponnesus, Ibráhim Pasha evacuated the country, and Greece, without being independent, was freed from her invaders. None of these defeats dispirited the sultan, and proud of having humbled the most dangerous of Turkey's internal foes, he boldly proclaimed 'a holy war' against Russia, well-knowing that the insurrection in Greece was in a great measure the work of the Czar. Before, however, we proceed to the Russian war, it is necessary to speak of the destruction of the Janissaries.

Mahmud accomplished this the greatest of his measures at a time when the whole of his attention seemed to be absorbed by the interference of the three powers in the Greek insurrection. At this time he proceeded so openly with his reforms as to leave no doubt of his firm intention to overthrow the antient institutions of Turkey, and to form an entirely new state of things. He had musical and theatrical entertainments performed in the seraglio; he dressed after the fashion of Europe, and abandoned the sacred turban for the fez; and, to the deep indignation of the Janissaries, gave orders to form another Nizam Jedíd, or Azásiri Mahammediyeh, as he now chose to call these troops. When he signed that order he had likewise resolved to destroy the Janissaries, who did not allow him to wait for an occasion to begin the contest. On the 15th of June, 1826, the sultan and the grand vizír being then in the country, a strong body of Janissaries, reinforced by a crowd of the worst characters, met at their great barrack, the Et-Meídán, and thence marched in battle array to the palace of the grand vizír, which they took and burnt after a feeble resistance on the part of the domestics, who were cut to pieces. The vizír's women escaped by hiding themselves in some subterraneous vaults in the garden. The grand vizír hastened to Constantinople as soon as he had heard of the riots, informed the absent sultan of the event, assembled the diván, and concentrated round the seraglio all the troops that he could dispose of. The shouts of 'Down with the Nizám Jedíd! we will have the heads of all those who advised the sultan to introduce new institutions!' soon reached the ears of the ministers, who were then assembled in the 'Arslán Khánéh,' or the menagerie of the seraglio. Thither crowded the 'ulemás and the students, the marines, the sappers, and the officers of the artillery with their guns, all ready to shed their blood for the sultan and his reforms. Encouraged by the presence of so many adherents, the grand vizír sent an answer to the rioters, that he would not satisfy their demands, but would repel force by force. The Janissaries were preparing for an attack upon the seraglio, when Mahmud arrived in a small boat from his country-seat at Beshik Tásh, on the Asiatic side of the Bosporus. Fully aware of the danger of his position, he harangued his troops, and declared that he would put himself at their head and attack the rebels, but having been dissuaded from this resolution he sent the grand vizír with a body of troops to the mosque of Sultan Ahmed, which was to be the chief meeting-place of the sultan's party, and contented himself with encouraging his men from a kiosk on one of the outer walls of the seraglio. On his order the mufti unfolded the 'sánják sherif,' or the standard of the prophet, and hundreds of 'cháush,' or criers, dispersed themselves through the capital, summoning all faithful Mohammedans to rally round the holy standard, and to defend the throne and their religion against a mob of impious rebels. An immense crowd soon gathered round the seraglio, and marched off to the mosque of Sultan Ahmed, cutting to pieces the detachments which the Janissaries had placed in all the streets leading to that mosque, for the purpose of isolating the grand vizír. At the sight of the holy standard the Janissaries concentrated their forces in the square, round the Et-Meídán, and threw up entrenchments. Huseín Pasha, Ibráhim Pasha, and Mohammed Pasha, who summoned them by order of the sultan, to lay down their arms, were received with a terrible yell and narrowly escaped assassination. 'They were strong enough, they said, to defend themselves till the evening, and the coming night would bring destruction over the reformers. Two thousand houses in flames would throw light upon their path!' The mufti now read with a loud voice the first chapter of the Korán, the 'Al-Fátihat,' the shortest chapter of the Korán, which is held in as much veneration by the Mohammedans as the Lord's Prayer by the Christians, and is considered to contain the quintessence of the whole Korán. The words run thus:—'Praise be to God, the Lord of all creatures; the most merciful, the king of the day of judgment. Thee do we worship, and of thee do we beg assistance. Direct us in the right way, in the way of those to whom thou hast been gracious; not of those against whom thou art incensed, nor of those who go astray.'—While the mufti was reading this prayer every man was prostrate on the ground, and at the close of the prayer the signal of attack was given. The entrenchments were soon levelled by the ordnance, and the Janissaries retired within their fortified barrack, whence they kept up a murderous fire upon the assailants. But their resistance only delayed their fate for a few hours; the massive walls crumbled under the fire of a heavy and well-directed artillery; fusees were thrown upon the roof; and the whole building was soon in a blaze. Thousands of the rebels were burnt under the falling ruins; others who tried to escape were received with grapeshot; and only two hundred succeeded in reaching the streets, where they were massacred and their bodies thrown round that majestic plane-tree which is said to have cast its shadow over the centre of the hippodrome for more than two thousand years. Six thousand Janissaries perished in the course of one day; several hundreds who had not taken part in the action, but were known as rebels, were massacred in the streets or in their houses, and 15,000, who had kept quiet, were exiled to different places in Asia Minor. On the following day, the 16th of June, a hatti sherif pronounced the abolition of the military corporation of the Janissaries, after it had been the bulwark of Turkey during five centuries from the time of its foundation by 'Alá-ed-dín, the vizír of Sultan Urkhan. Thus Mahmud crushed his most dreaded enemy at home, only four years after he had been compelled to sacrifice to the fury of the Janissaries his favourites Berber Bashi, the mufti, and his favourite wife.

Although Mahmud was sufficiently provoked by the Emperor Nicholas to take up arms against him, his declaration of war, in 1828, was a rash act. Mahmud thought that his army, being now organised after the European system, would behave as well as European armies, but he was greatly mistaken, and paid dearly for learning that it is easier to create a name than a thing. We shall not dwell upon the particulars of the Russian campaign. After an indifferent struggle in 1828, the Russians, commanded by Diebitsch and Paskiewicz, made astonishing progress in 1829, in Europe as well as in Asia; and after the victory obtained by Diebitsch over the grand vizír Jusuf Pasha at Shumla, in the eastern Balkan, and the capture of Erz-Rúm by Paskiewicz, Constantinople would have been lost, and the Turkish empire would have fallen a prey to the Russians, but for the interference of the great European powers, headed by England, through whose mediation the war was concluded by the peace of Adrianople, on the 14th of September, 1829. This was the most disastrous war that was ever undertaken by the Turks, although their loss of territory was comparatively trifling, and far less than the loss of Hungary and Servia after the peaces of Karlowicz and Passarowicz with Austria. Mahmud's direct loss was only a small tract on the Caucasian frontier. But Greece was now definitively separated from Turkey; the suzerainty of the Sultan over Moldavia and Wallachia was reduced to a shadow, and the Russian emperor acquired that sovereignty over the two principalities which was formerly possessed by the Sultans; Servia was acknowledged as an independent state, though tributary to Turkey; Russia obtained a free navigation from the Black Sea to the Mediterranean, and an effective protectorship over the Greek church throughout all Turkey; and the sultan at last was required to pay the expenses of the war, a sum so heavy that a few years afterwards he was compelled to solicit the remittance of about one-third of it. The circumstance most humbling for the pride of the sultan was that he obtained that peace through the mediation of the European powers.

During the years subsequent to the peace of Adrianople Mahmud, with unabated perseverance, was active in creating a new army and navy, and in improving his ruined finances. He wanted both men and money to check the increasing power of Mehmed 'Ali, whom he watched with hate and suspicion. A conspiracy detected at Constantinople to depose the sultan, was attributed to the intrigues of the Pasha of Egypt, and increased Mahmud's hatred: to reward those who had proved most loyal under such trying circumstances he founded a new order, the Nisheán Istíkhar. In 1831 hostilities commenced with Mehmed 'Ali, Ibráhim Pasha having made war against the Pasha of Damascus and conquered Syria; but there was not open war till 1832, on Mehmed 'Ali's refusal to withdraw his troops from Syria. The declaration of war took place on the 15th of April, 1832; on the 7th of July Ibráhim defeated the Turks at Hems; and on the 21st of December he obtained the splendid victory of Koniah, in consequence of which the Turkish army was disbanded, and the Egyptians advanced upon Constantinople. The mediation of the European powers effected a truce; but in spite of it Ibráhim pushed on and occupied Brúsa. The ruin of the sultan seemed to be inevitable. He was saved by his greatest enemy: a Russian fleet appeared off the Bosporus, and opposite Constantinople landed a strong body of Russians, commanded by General Lazaref, whose arrival stopped the progress of Ibráhim. On the 4th of May peace was concluded at Koniah, and Mehmed 'Ali obtained the object of his armament, the investiture of Syria and Adána, but he remained a tributary vassal of the Porte. So much was Turkey weakened through this war, that Mahmud, despairing of further independence, threw himself into the arms of Russia, and on the 8th of July signed the treaty of Unkiar Skelesi, by which Russia bound herself to assist Turkey with an army whenever she should want it, in acknowledgment of which Mahmnd promised that no armed ship of foreign nations should be allowed to pass the Dardanelles without the permission of Russia. Mahmud was more fortunate in an expedition against Tripoli, which was brought back under the sultan's immediate authority, and at Tunis also he succeeded in obtaining obedience to his orders.

Mahmnd's hatred of Mehmed 'Ali became now the principal motive of his actions. As early as 1834 things were so bad, that Mahmud not only resolved upon a fresh war, but put himself at the head of his troops in order to conduct it in person. But in crossing the Bosporus he dropped the sacred sword of Soliman II., which fell into the sea and was lost for ever, and this bad omen induced him to give up his plan and to return to Constantinople. War was prevented by the mediation of England, France, and Russia, but the sultan nevertheless continued preparing for a contest which he wished, and which could be postponed, but not prevented. The care which he bestowed upon his military preparations was surprising. Yet the result did not answer his expectations. He thought that because he had a system of order on paper, the administration would go as well as in Europe; and he forgot that the execution of his orders was to be intrusted to persons who themselves had first to learn obedience and impartiality. In his first war with Mehmed 'Ali he was the victim of the knavery and rapacity of some of his ministers, especially the old Khosrew Pasha, without ever suspecting how unfairly he had been dealt with. Sufficient money was intrusted to Khosrew to defray the expenses of the war, and the strictest orders were given to provide military stores in abundance; but Husein Pasha, who commanded part of the army, received only a scanty supply of ammunition, most of the ammunition waggons which were sent to his camp being found empty at their arrival. Mahmud also gave 4000 purses to Khosrew, directing him to send them to Husein, who had received orders to pay for the provisions and horses, which he should be obliged to take from the peasants; the money, however, remained in the hands of Khosrew, and when, after the end of the campaign, Husein returned to Constantinople, he did not dare to complain of the peculation of the powerful minister. Reshid Pasha, another commander, received the most solemn protestations that there was provision for three years for the army, in the different towns of that part of Asia Minor where he was to command, but when he came to Ak-Shehr, his men found that the best chance of getting a dinner was in the camp of Ibráhim Pasha.

The second war with Mehmed 'Ali would perhaps not have broken out so soon (1840), but for the pasha's manifest design to subject all Arabia to his authority; and it is said that the sultan was urged by Russia, and especially by Great Britain, to open the campaign in that year, although he knew that his army was not yet able to take the field with any chance of success.

On the 25th of June, the Turkish army under Hafiz Pasha was entirely defeated by Ibráhim Pasha, near Nisibis; and there being no other army to oppose his victorious career, it was evident that Turkey was lost if the European powers did not interfere. Mahmud was fortunately not destined to hear of the disgrace of his arms. He died on the 1st of July, 1840, a few days before the news of the battle of Nisibis threw the seraglio and the capital into consternation. It was after the passage of the Balkan by Diebitsch, in 1829, that for the first time in his life Mahmud evinced symptoms of despair. From that time care and disappointment produced a visible effect upon him; after his defeats in the first Egyptian war he looked careworn and dispirited, and his violent hatred of Mehmed 'Ali impaired both his body and mind. At the beginning of 1840, his health was so bad as to indicate a speedy dissolution, and he increased his weakness by excess in wine. Two German physicians, under whose care he was, declared his ailment to be tubercular phthisis; shortly before his death they were dismissed, and, as the younger Michaud in the 'Biographie Universelle' says, were superseded by an English quack, through whose efforts the sultan died two months before his death could have been expected to take place according to the nature of his disease. Mahmud was succeeded by his eldest son 'Abdu-l-Mejid, the present sultan.

Sultan Mahmud II. was a handsome man of majestic appearance. He was always active, and at no period of his life did he abandon himself to those sensual pleasures of which so many of his predecessors made themselves the slaves. He rose before daybreak to be ready to say his prayers the moment the sun was above the horizon; after prayer he used to work six hours or more, according to the state of business; he would then ride out, review the troops, and visit the arsenals, the docks, or the barracks. He always tasted the soldiers' dinner, rewarded the cooks when it was good, and punished them when it was bad. The soldiers he called his children, and many of them loved him as a father. For a Turk Mahmud possessed considerable knowledge: his handwriting was beautiful, an accomplishment which contributed much to his popularity among the learned, for the sultan is expected to surpass his subjects in penmanship. He was an excellent father, and loved his wives tenderly: on his death-bed he ordered his son 'Abdu-l-Mejid to come to his side, and he entreated him never to abandon the path of reform. Yet he was only half civilized, and, as Pouqueville observes, he combined the barbarity of a Turk with all the artfulness of modern diplomacy. His knavish tricks against 'Ali Pasha of Janina and Prince Milosh of Servia are well known. He could be cruel in cold blood: he assisted at the execution of the Greek Prince Constantine Morali, at the murder of the patriarch Gregory, and the violent death of many others who had incurred his hatred. For the details of his reforms we refer the reader to TURKEY, P. C., pp. 393, & 404, 405. Mahmud II. was decidedly one of the most remarkable men of his age, and one of the greatest sultans of Turkey. He may be compared with Peter the Great, and like him he was idolized by one portion of his subjects and hated by another. The adherents of the old school called him a heretic (ghiaur), and accused him of attempting to destroy the religion of Mohammed and to introduce the Christian faith, a calumny which grieved him very much, for he was a sincere Mohammedan, except as regards the prohibition of wine. If Mahmud was less successful than Peter the Great, it must partly be attributed to the circumstance that the Russian Czar ruled over one nation professing one religion, his Mohammedan subjects being proportionally too few in number to offer any serious resistance; Mahmud ruled over seven nations, Turks, Wallachians, Albanians, Greeks, Slavonians, Armenians, and Arabs, some of them Mohammedans, others Christians of various creeds, and all of them detesting each other. Among these the ruling nation, the Turks, form the great minority in European Turkey, and in Asia Minor are less numerous than the Greeks and Armenians together, while in Syria, Arabia, and Egypt the population is almost exclusively Arab. We conclude this sketch by an extract from the Turkish historiographer Asá Efendi, quoted by Michaud in the source mentioned above, who gives the following portrait of Sultan Mahmud:—

'Mahmud is terrible like Alexander. The slightest menacing cast of his countenance would check 100,000 rebels; and his awful frowning crushes the impious followers of Shedda who dare to take up arms against him. Such is his power, and such the soundness of his genius, that he silences the most subtle metaphysicians and rhetoricians, strikes them with astonishment, and compels them to lower their heads before his superiority. There is not his equal among the wisest of the kings, for, as the poet says, "He pleases equally the warriors, the learned, and the charitable, by his exploits, his speech, and his liberality." To quote only one of his merits, his handwriting is of extraordinary beauty; the points (diacritical) are like so many fixed stars; and it is worthy to be hung up under the vault of heaven near the girdle of the Gemini. The style of Mir-Feredún, so much praised, is flat in comparison with his. His generosity is so great that the waters of the ocean would be only a spoonful of his liberalities, and the mines of the earth a handful of his gifts.—To comment in a fit manner on the folio volume of his merits would be a task too high, not only for my poor pen and me who am only a parasite at the banquet of literature, but even for the most accomplished writer. I am not so presumptuous to undertake it. I shall only express my good wishes for His Highness. May Allah preserve this great monarch, the love of his people, the ornament of the throne; may he extend the shadow of his bounty over the East and the West; and may he grant no other limits to our sultan's success and years than those of numbers, namely infinity.'

MAIA'NO, BENEDETTO DA, a celebrated Italian sculptor and architect, was born at Florence, in 1444. He first distinguished himself as a carver and inlayer of wood, and in both of these arts he was the first artist of his time. He executed some very extraordinary inlaid-work for cabinets for the kings of Naples and Hungary, and an accident which happened to two which he made for the latter king caused Maiano to give up the art of inlaying in disgust. These two chests or cabinets suffered so much in the transport from Florence to Hungary by undue care or the change of climate, that when they were uncovered by Benedetto before the king, a great part of the inlaid-work, owing to the effect of the moisture on the glue, fell to pieces, to the great dismay of the king and the horror of the artist, and had to be remade. Benedetto felt that an art in which the works were subject to destruction by so slight a cause, was unworthy the attention of superior abilities, and he thenceforth applied himself exclusively to sculpture in marble and to architecture.

Benedetto's marble works however were also of an ornamental or decorative class, consisting of fonts, pulpits, and tombs. His fonts and pulpits were of a most elaborate character, being loaded with beautifully executed small figures, besides other decorations. One of his master-pieces is the marble pulpit of Santa Croce, which is still in good preservation: the sculptures represent the life of San Francesco, and the establishment of his order, in five compartments; with the figures also of Faith, Hope, Charity, Fortitude, and Justice. The whole has been beautifully engraved by Gio. Paolo Lasinio, and was published with letter-press description in 1823—'Il Pergamo scolpito in marmo da Bened. da Majano nella Chiesa di Santa Croce in Firenze.' Benedetto made also the crucifix over the altar of the cathedral of Florence; and he finished the Magdalen in Santa Trinità, which was left imperfect by Desiderio da Satignano. In architecture he did very little: he built the portico of the church of the Madonna delle Grazie near Arezzo; a chapel for himself on his own estate near Prato; and he is said to have designed the Palazzo Strozzi. He died rich in 1498, aged only fifty-four, and was buried in San Lorenzo at Florence. He left the reversion of his property to the brotherhood of the Bigallo.

GIULIANO DI NARDO DA MAIANO, the uncle of Benedetto, was likewise a distinguished artist, and in similar works as Benedetto. He was intrusted with several important charges in Florence, in Pisa, in Loreto, in Naples, and in Rome. He succeeded Brunelleschi as the architect of the cathedral of Florence in 1446. At Naples he built the palace of Poggio Reale, and executed the sculptures of the Porta Capuana, also the triumphal arch, and the reliefs of the Castello Nuovo (now the Arsenal). At Rome he built of Travertine stone the loggie of one of the courts of the Vatican; and the church and palace of San Marco for Pope Paul II. in the same material; and a report was long in circulation that part of the Colosseum was pulled down for the stones, but more charitable persons have presumed that the pope used only such stones as had already fallen. Giuliano commenced also, in 1464, a new nave to the church of the Madonna at Loreto, which was completed by his nephew Benedetto. Giuliano was still living in Florence in 1471, a fact clearly ascertained by Rumohr; Vasari's account therefore that he died at Naples, in the reign of Alfonso I. (1435-1458), is erroneous; this statement is also evidently incorrect from the fact of Giuliano being employed by Paul II., who was pope from 1464 to 1471.

MAINTENANCE, SEPARATE. [SETTLEMENT, P. C.]

MALATESTA, MALATESTI, Lords of Rimini, an historical family of Italy during the middle ages. Like many other great feudatories of Italy, the Malatesti are said to have originally come from Germany. One of the name is mentioned in some chronicles as 'Vicarius,' or Imperial Lieutenant of Rimini, under Otho III., A.D. 1002. It is not, however, until the second half of the thirteenth century that we find authentic records of this family as being at the head of the Guelph party in Rimini. Giovanni Malatesta, called 'il Zoppo,' or 'the lame,' married Francesca, daughter of Guido di Polenta, Lord of Ravenna. Paolo, brother of Giovanni, seduced his wife, and being caught in adultery with her, they were both killed by the outraged husband. This tragical event forms the subject of one of the most beautiful episodes of Dante's 'Inferno.' After many vicissitudes, owing to the factions of those times, we find Galeotto Malatesta, in the early part of the fourteenth century, acknowledged by the Pope as Lord of Rimini, Pesaro, Fano, and other places in fief of the Papal See. His descendants continued in possession of Rimini, with various interruptions, till the time of Clement VIII., in 1528, when Sigismondo Malatesta was deprived of his dominion by the Pope, and retired to Venice, after which several of the same family figured in the service of that republic. One Carlo Malatesta had already distinguished himself in the wars of the fifteenth century, between the Duke of Milan and the Venetians.

(Sansovino, *Famiglie Illustri d'Italia.*)

MA'LAXIS, a genus of plants belonging to the natural order Orchidaceæ, and to the tribe Malaxideæ. It has a patent perianth, the lip posterior, erect, entire, similar to the petals and smaller than the sepals; the spur absent; the stigma rhomboidal; the rostellum short, entire, acute; the anthers terminal, continuous with the short column, out of the apex of which it appears as if it were excavated with two imperfect cells; the pollen-masses connected at their apex; the germen upon a twisted stalk.

Of this genus there is one British representative, *M. paludosa*. It is a small plant, with a stem from one to four inches in height. The leaves are remarkable for being fringed at the end with bulbous gemmæ or leaf-buds. It is a native of spongy bogs, where it grows upon the moss, in the character of an epiphyte, and not amongst it as other bog-plants.

MALINGERING. [FEIGNED DISEASES, P. C. S.]

MALLOW. [MALVACEÆ, P. C.; MALVA, P. C. S.]

MALMESBURY, JAMES HARRIS, FIRST EARL OF, was the only son of James Harris, the learned author of 'Hermes,' and other well known works. His mother was Elizabeth, daughter of John Clarke, of Sandford, in the county of Somerset, Esq.; and he was born at Salisbury on the 21st of April, 1746, the day of the battle of Culloden.

The Harrises had been seated on their estate of Orcheston St. George, in Wiltshire, since about the middle of the sixteenth century. The father of the subject of the present notice was the first of them who was ever in parliament or employed in any political capacity; but they may be considered as having belonged to the first class of the gentry in their county. The father of the author of 'Hermes' married a daughter of the second Earl of Shaftesbury.

After having been put in the first instance to the grammar-school of his native town, the subject of this notice was sent to Winchester, where he remained till September, 1762. His father, who was by this time in office, now kept him with him in London for above six months, and then sent him to Merton College, Oxford. In a letter written in his advanced years he expresses himself as unable to decide whether his father did right or wrong in introducing him to society before he was sent to the university. 'I believe,' he says, 'the seeing many of the leading men in administration, hearing them converse on public business, contributed to form my mind to think on public affairs, and to give me an interest in them which, probably, otherwise I might never have acquired; but the mixing at that age (seventeen), and raw from school, in all the gaiety and dissipation of London, filled my mind at the same time with false objects of admiration, false notions of excellence, and gave me, in my own conceit, a knowledge of the world so much greater than I supposed my fellow-collegians could possibly possess, that I apprehend I carried to the university a considerable share of self-sufficiency, and no great propensity to attend lectures and conform to college rules.' But although he professes to look back upon the years he passed at Merton as the most unprofitably spent of his life, he appears to have by no means altogether neglected study amid the then prevailing idleness and dissipation of the place. Even in his own disparaging account he admits that, although he never saw his tutor at any other time, he did receive his instruction for one fortnight, when he took it into his head to be taught trigonometry.

On leaving Oxford in 1765 he was sent for a year to study at Leyden; and here at least he seems to have made excellent use of his time, spending many hours daily among his books, while he also mixed much in society. He then, after being eight months at home, set out in 1767 on a short continental tour, in the course of which he visited Holland, Prussia, Poland, and Paris; and in the autumn of the same year he was, through the patronage of Lord Shelburne, his father's colleague and friend, appointed secretary of embassy at Madrid, and thus entered public life at the age of one-and-twenty.

Three years after the affair of the Falkland Islands occurred, when he chanced to have been left at Madrid as chargé d'affaires, and, acting upon his own responsibility, he had the good fortune very quickly to bring the Spanish government to concede the object in dispute. The Falkland Islands, the acknowledgment of our right to which was thus obtained from Spain, were given up by England four years after; but the temper and firmness, as well as talent, with which Harris had managed his successful negotiation, gave so much satisfaction to his government, that he was the following year appointed to the post of minister at the court of Berlin. He retained this mission for four years, and then returning to England in 1776, married Harriet Mary, second daughter of Sir George Amyand Cornewall. In 1777 he was sent as ambassador to St. Petersburg, and, having in the mean time received the Order of the Bath in 1780, he remained in Russia till his health compelled him to return home in 1784. He had ever since 1770, notwithstanding his being abroad, held a seat in the House of Commons as member for Christchurch, and had, like most of Lord Shelburne's friends and connexions, attached himself to the party of Mr. Fox. When Fox, however, was now superseded in the direction of affairs by Pitt, the latter at once offered Sir James Harris the post of minister at the Hague, to which it had been intended that he should have been appointed if the Fox and North administration had remained in power; and he accepted it with the full approbation of Mr. Fox. While at the Hague he succeeded in negotiating, in April, 1788, the treaties of alliance with Holland and with Prussia, by which the power of the Stadtholder was at that time preserved from being overthrown by the democratic party, and Holland in all probability rescued from the grasp of France. For this great service, as it was considered, Sir James was, in September of the same year, raised to the peerage as Baron Malmesbury.

He now, after a short visit to Switzerland, returned to England. He continued to act with the Whig party in parliament till 1793, when he formed one of the large body of the friends of Mr. Fox who went over to ministers with Burke and the Duke of Portland. Lord Malmesbury was now sent over by Mr. Pitt on a mission to Berlin, where he prevailed upon the new King of Prussia to enter into a second alliance with England and Holland, which however did not last for quite two years. In 1794 he was employed to negotiate the marriage between the Prince of Wales and Caroline, the daughter of the Duke of Brunswick; and, after having gone through the ceremony of marrying her Royal Highness by proxy, he accompanied her to England. His published Diary relates many curious particulars respecting this affair, the issue of which was hardly more unhappy than he had anticipated that in all probability it would be; but his directions left him no discretionary power whatever. It is stated, however, that he was never forgiven for the part he acted by the Prince, 'with whom until then he had been on terms of great intimacy and confidence.'

His last missions were those on which he was sent in 1796 and 1797 to Paris and Lisle, to negotiate a peace with the French Republic, and which were attended with no result. He was then attacked by a deafness which, in his own opinion, unfitted him for being again employed on any foreign service of importance. In 1800 he was created Earl of Malmesbury and Viscount Fitzharris. He died at his house in Hill Street, London, Nov. 20, 1820, leaving a son, who succeeded him in the title, and three daughters.

Lord Malmesbury was without doubt one of the very ablest diplomatists of his time, and a man of great general talent. Talleyrand said of him, in a phrase the point of which cannot be preserved in a translation, 'Si on lui laissait le dernier mot, il avait toujours raison.' And he was equally noted for readiness and spirit in his ordinary conversation as when acting in his diplomatic capacity.

A very favourable impression, also, of his good sense and general right-mindedness is made by his 'Diaries and Correspondence,' which have been edited by his grandson, the present earl, in 4 vols. 8vo., Lond. 1844; and which, besides throw much valuable illustration upon many of the events and transactions o the important period in which it was his fortune to livo and act. The materials of the present article have been mostly abstracted from the Memoir prefixed to that publication.

MALTHUS, REV. THOMAS ROBERT, was born in 1766, at the Rookery, a small but beautiful estate in the county of Surrey, in the neighbourhood of Guildford and Dorking. His father, Daniel Malthus, was a gentleman of good family and independent fortune, attached to a country life, of retired habits, and devoted to literary and philosophic pursuits. He was the author of several works, published anonymously, which met with considerable success. Thomas Robert Malthus, who was his second son, was never sent to any public school except to the academy at Warrington, and that for a very short time. Besides the instruction which he received from his father, he was for some time under the private tuition of Robert Graves, author of the 'Spiritual Quixote,' whose house, however, he left when young, and was afterwards instructed by Gilbert Wakefield, with whom he remained till 1784, when he was admitted of Jesus College, Cambridge. He took the degree of B.A. in 1788, and that of M.A. in 1797, when he was made a Fellow of his college. Having taken orders about the same time, he undertook the care of a small parish in Surrey, near his father's house, but he occasionally resided at Cambridge, in order to pursue his favourite course of study with more advantage.

Mr. Malthus, about the year 1797, wrote a pamphlet called 'The Crisis,' which however, at the request of his father, he did not publish. It was directed against the government of Mr. Pitt in general as well as against certain specific measures connected with the poor laws. In 1798 he published 'An Essay on the Principle of Population, as it affects the future Improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and other Writers.' The book excited considerable attention; but finding that his facts and illustrations were imperfect, in 1799 he went abroad in search of materials to establish his theory more completely. He sailed for Hamburg in company with three other members of his college, Dr. Edward Clarke, Mr. Cripps, and Mr. Otter. In Sweden the party separated, when Dr. Clarke and Mr. Cripps preceded to the north, and Mr. Malthus and Mr. Otter journeyed leisurely through Sweden, Norway, Finland, and part of Russia, and then returned to England. During the short peace of 1802 Mr. Malthus travelled through France and Switzerland with some of his relations, observing whatever was curious in nature or art, but especially examining into the state of the people, and collecting materials for the improvement of his work. In 1803, he published a new edition of his 'Essay on the Principle of Population,' with the omission of the controversial parts, but much enlarged in what related to the general subject.

In 1805 Mr. Malthus married Harriet, eldest daughter of Mr. Eckersall, and was soon afterwards appointed Professor of Modern History and Political Economy at the East India College at Haileybury, in Hertfordshire, which situation he held till his death. He attended to his professional duties, preached regularly in his turn in the college chapel, and enjoyed the society of his family and friends. He was taken ill suddenly, when apparently in strong health, while on a visit to his father-in-law Mr. Eckersall, at Bath, where he died December 29, 1834. He left a widow and a son and daughter.

The attention of Mr. Malthus had from an early age been directed to political economy, in which he was much stimulated by his conversations with his father. The two most important of his works are, the 'Essay on the Principle of Population,' of which an analysis is given in the article POPULATION, P. C., and the 'Inquiry into the Nature and Progress of Rent,' the leading principles of which are stated in the article RENT, P. C.

When a boy, and while at Cambridge, Malthus displayed a great love of fighting for fighting's sake, a keen perception of the ludicrous, much relish for wit and humour, and considerable comic power of imitation; but his character gradually changed: he retained indeed his cheerfulness and playfulness, but he became placid, temperate, patient, and forbearing under the obloquy which was heaped upon him. His manners were kind and gentle, his conversation mild but earnest and impressive, his deportment gentlemanly. In politics he was a Whig and a decided advocate of all salutary reforms, but strongly attached to the institutions of his country, and fearful of all imperfectly considered changes and innovations.

The following is a list of his works in the order in which they were published:—

1. 'An Essay on the Principle of Population, as it affects the future Improvement of Society; with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and other Writers.' Anonymous, London, 8vo. 1798.

2. 'An Investigation of the Cause of the present high Price of Provisions, containing an Illustration of the Nature and Limits of Fair Price in Time of Scarcity, and its Application to the particular State of this Country.' 8vo. 1800.

3. 'An Essay on the Principle of Population; or a View of its past and present Effects on human Happiness; with an Inquiry into our Prospects respecting the future Removal or Mitigation of the Evils which it occasions.' New edition, London, 4to. 1803.

4. 'A Letter to Samuel Whitbread, on his proposed Bill for the Amendment of the Poor Laws.' London, 8vo. 1807.

5. 'A Letter to Lord Grenville, occasioned by some Observations of his Lordship on the East India Company's Establishment for the Education of their Civil Servants.' London, 8vo. 1813.

6. 'Observations on the Effects of the Corn Laws, and of a Rise or Fall in the Price of Corn on the Agriculture and general Wealth of the Country.' London, 8vo. 1814.

7. 'The Grounds of an Opinion on the Policy of restricting the Importation of Foreign Corn;' intended as an appendix to the 'Observations on the Corn Laws.' London, 8vo. 1815.

8. 'An Inquiry into the Nature and Progress of Rent, and the Principles by which it is regulated.' London, 8vo. 1815.

9. 'Statements respecting the East India College, with an Appeal to Facts in Refutation of the Charges lately brought against it in the Court of Proprietors.' London, 8vo. 1817.

10. 'Principles of Political Economy, considered with a View to their Practical Application.' London, 8vo. 1820.

11. 'The Measure of Value stated and illustrated; with an Application of it to the Alteration of the Value of the English Currency since 1790.' London, 8vo. 1823.

12. 'Definitions in Political Economy, preceded by an Inquiry into the Rules which ought to guide Political Economists in the Definition and Use of their Terms.' London, 8vo. 1827.

13. 'A Summary View of the Principle of Population.' 1830. (From the 'Supplement to the Encyclopædia Britannica.')

(*Memoir of Malthus*, prefixed to the 'Principles of Political Economy.' 2nd edition, Pickering, London.)

MALUS, ÉTIENNE LOUIS, a distinguished philosopher and military engineer, was born at Paris, June 23rd, 1775. He received his first lessons under the eyes of his father, Anne Louis Malus of Mitry; and, in early youth, his time appears to have been nearly equally divided between classical and mathematical studies. This judicious combination of the two great branches of education had the happiest effect in expanding the mind of the pupil, and laying the foundation of those developments of genius by which his name will descend to the remotest posterity. His memory was very retentive, and it is said that, even near the close of his life, he could repeat several passages of the 'Iliad' of considerable length. His taste for classical literature is shown by the fact that, when seventeen years of age, he had written a tragedy entitled 'The Death of Cato;' but subsequently his studies were almost exclusively of a scientific character.

At the time that the tragedy is said to have been written, young Malus was, after a strict examination, in which he acquitted himself to the satisfaction of the persons in authority, admitted as a pupil in the Ecole du Génie Militaire, it being the intention of his father that he should enter into that branch of the public service; and he is said to have immediately distinguished himself by his diligence and his scientific talents. From some cause, however, which is not explained, but probably because his father, who held the post of Treasurer of France, had become suspected by the government (the great revolution having commenced), he was dismissed from the Institution; and, either from choice or compulsion, he entered the army as a private soldier. He was for a short time employed in that capacity, with the battalion to which he was attached, in repairing the fortifications of Dunkirk. But on the termination of the reign of terror, the government having decided upon the formation of the Ecole Polytechnique, inquiry was made for a certain number of young men who, having completed the usual course of education, might be the first to receive instruction in the higher branches of science; and it is recorded to the honour of M. Le Père, the commandant of the engineers at Dunkirk, that, knowing the great talents of the young soldier, he withdrew him immediately from the ranks and sent him to Paris with a recommendation to the celebrated Monge. Malus was immediately admitted, and was joined, in a class, with about twenty other persons, to attend a course of instruction in mathematics, physics, and engineering.

During three years he prosecuted his studies with extraordinary ardour, and distinguished himself by his applications of analysis to the solutions of some intricate propositions; he is said also to have occasionally delivered lectures on mathematical subjects. It is added that he then commenced those researches concerning the properties of light, which prepared the way for his subsequent discoveries in optics; and his first step in this brilliant career consisted in investigating the path of a ray of light after being reflected from or refracted into a medium having a surface of any form.

On quitting the Ecole Polytechnique, Malus was for a time employed as a professor of mathematics in the military school at Metz; but the small fortune which he possessed, his family having suffered great losses during the Revolution, and perhaps an inclination in favour of a more active life, induced him to abandon the project which he at one time entertained of devoting himself entirely to the sciences. He therefore entered the corps of engineera with the rank of captain; and, in 1797, he was sent to join the Army of the Sambre and Meuse. He accompanied that army across the Rhine, and was present at the actions of Ukratz and Altenkirk.

At the termination of the campaign Malus went to Paris, and, in the following year, he embarked with the expedition to Egypt under Bonaparte. He was engaged in the battle of the Pyramids and in the affair of Chebrces: he was also employed as an engineer at the sieges of El Arish and Jaffa; and, after the taking of the latter place, he was appointed to superintend the repair of its fortifications. While performing this duty he fell ill of the plague, and lay for some time in the military hospital which he had assisted to form: he recovered, however, with little aid from medicine, and he was almost immediately sent to fortify Damietta. He was afterwards engaged in the action with the Turkish forces which landed at Aboukir; he was also at the battle of Heliopolis, at the affair of Coraim, and at the surrender of Cairo.

When the Institute was founded in that city, he was appointed one of its members; and in the first volume of the 'Décade Egypticnne' there is an account of an excursion which he made far into the country, with his discovery of a branch of the Nile which had not before been noticed. Malus continued in Egypt till the remains of the French army capitulated, when, in 1801, he returned to his native country in an English vessel. Exhausted by the arduous services in which he had been engaged, and with his health nearly ruined, he yet performed the duties of an officer of engineers, having, in 1804, been appointed by the government to superintend the construction of the works which were being added to the fortifications of Antwerp. He had then the title of sub-director of fortifications, and he was made a member of the Legion of Honour. Five years afterwards he was appointed superintendent of barracks in the department of the Seine; and in the following year, 1810, he was made a member of the Committee of Fortifications and Lieutenant-Colonel of Engineers.

Almost immediately on his return to France, Malus married a daughter of Koch, the Chancellor of the University of Giessen, to whom he became attached before his departure for Egypt; and, during the rest of his life, all the time he could spare from his professional avocations was spent in the cultivation of the sciences, particularly in the continuation of those optical investigations which he had commenced at the Ecole Polytechnique. His first published work was entitled 'Traité d' Optique,' in which he treated the phenomena of the reflexion and refraction of light as they were then known; and he particularly distinguished himself by his experiments and researches concerning the reflexion of light in transparent media. It was known that when a pencil of light has entered into glass at a considerable angle of incidence, the internal reflexion takes place either before it arrives at the posterior surface, or at a certain distance from that surface on the exterior; but it had been found impossible to determine, though an inequality in the angles of reflexion in the two cases was manifest, to which of the cases either of the observed reflexions should be referred. Malus overcame this difficulty by applying successively to the surface an opaque medium, which, by preventing the reflexion of the emergent rays, proved that the observed reflexion had taken place within the glass, and a transparent medium which, by permitting the rays to pass quite through the glass, afforded a reflexion from the exterior of the latter.

The subject of double refraction in crystals was very imperfectly known, when, in 1808, the Institute of France offered a premium for the best Mémoire on the subject; and Malus immediately entered with ardour into this field of research. It was while prosecuting his experiments that there occurred to him one of those fortunate accidents which only men of genius have the power of rendering available as steps to great discoveries. He then resided at Paris, and, happening one day to direct a prism of crystal which he held in his hand to one of the windows of the Luxembourg palace, on which there was a brilliant light produced by the reflected rays of the setting sun, he was surprised to find that, while turning the crystal round, one of the images produced by the double refraction in it varied in intensity, and alternately appeared and disappeared. As such phenomena had not been observed when the prism was directed to any other bright object, as the flame of a candle, Malus was for a time at a loss to divine the cause; but after making several observations on the light from the same windows, he ascertained that the effect was produced only when it fell on them at a particular angle of incidence, which he determined from the known position of the sun with respect to the surface of the building.

In the prosecution of the researches to which this interesting discovery gave rise, Malus found that when a pencil of light is reflected from unquicksilvered glass, at an angle of incidence equal to 54° 35′, or from the surface of water at an angle of incidence equal to 52° 45′, the reflected light possessed the same properties as were exhibited by one of the pencils produced by double refraction in a crystal. He observed also that when the pencil reflected from a transparent medium, at a certain angle of incidence, is made to fall on another such medium at an equal incidence; if the plane of the second reflexion is coincident with the plane of the first, the light is reflected as usual; but if the planes are at right angles to one another, no reflexion takes place at the second surface, the pencils of light being wholly refracted.

To the effect produced on light so reflected, Malus gave the name of polarization; conceiving that the particles of light have poles or axes, and that, on entering the doubly refracting crystal, those which form one of the pencils may arrange themselves so as to be capable of being transmitted through it, while those which should have formed the other ray may have such dispositions as prevent the passage, in certain directions, from being effected.

These phenomena may be said to have laid the foundation of a new branch of physical optics; and an account of them is given in the 'Mémoires de la Société d'Arcueil,' as well as in the 'Mémoires' of the French Institute. Of this learned body Malus was immediately elected a member; and in 1811, though, on account of the war, there was scarcely any intercourse between Great Britain and France, the Royal Society of London awarded him the Rumford medal; thus performing a noble act of homage to scientific merit in the person of a foreigner, and one who carried arms among the enemies of the country.

In 1810 Malus published at Paris his 'Théorie de la Double Refraction de la Lumière dans les Substances cristallisées;' and in the following year he presented two papers to the Institute on some remarkable phænomena of polarized light. In the first of these it is shown that when a pencil, after being polarized by reflexion, falls on glass, part of it is reflected and part transmitted; the reflected part is wholly polarized in one direction, while the transmitted part consists of two portions, in one of which the particles preserve the character of direct light, and in the other the light is polarized in a direction contrary to that of the reflected pencil: it is added that the portion which has the character of direct light diminishes gradually by transmission through several plates of glass successively; and at length the whole of the transmitted ray becomes polarized in a direction contrary to that of the reflected pencil. In the second paper it is shown that all polished bodies, opaque and transparent, polarize light by reflexion; and that, in different bodies, the polarization takes place with different angles of incidence. Polished metals, however, resisted for a time the efforts of Malus to produce the phænomena of polarized light; but, at length, by a particular disposition of the reflecting surface, he succeeded in exhibiting them: he discovered that the pencils reflected from polished metals are polarized in opposite directions, while those which are reflected from transparent bodies are polarized in one direction only. He observed the modifications which parts of organized bodies, whether animal or vegetable, produce on light when they are thin enough to transmit the polarized pencil through them; and he noticed the coloured and multiplied images which are sometimes seen in Iceland spar. He ascribed these images to the effects of fissures parallel to the longer diagonal of the crystal rhomboid; but Sir David Brewster has since ascertained that they arise from veins which act upon the transmitted light at both of their surfaces.

During the short remainder of his life, Malus continued his scientific researches amidst all the duties which his post as a member of the Committee of Fortifications required. He was chosen Examiner in Physics and Descriptive Geometry at the Ecole Polytechnique; and though his health was fast declining, he neglected no occasion of performing the functions of that office. He was on the point of being made Director of the Studies in that Institution when he was removed by death from the scene of his useful labours.

He died in Paris, February 23rd, 1812, in the thirty-seventh year of his age; and his wife who, ever since their union, had alleviated his labours by her attentions, and watched him in his last days with affectionate solicitude, survived him but two years.

Malus enjoyed the esteem of the public for the qualities of his mind, and was beloved by all who knew him for the benevolence of his character.

(*Eloge de Malus*, by Delambre; *Biographie Universelle.*)

MALVA (the Latin Malva), a genus of plants belonging to the natural order Malvaceæ. It has numerous styles, a double calyx, the outer one three-leaved, the inner one five-leaved. The capsules are orbicular and many-celled; the cells one-seeded and circularly arranged.

M. Moschata, the Musk Mallow, has an erect stem, kidney-shaped leaves, with five or seven deep pinnatifid lobes, the lower leaves inciso-crenate, the stipules lanceolate-acute, the fruit-stalks erect, and the fruit hairy. The flowers are large and rose-coloured, on axillary single-flowered peduncles, crowded at the extremity of the stem and branches. It is native in many parts of Europe, and is found in Britain in grassy borders of fields and by waysides.

M. sylvestris, Common Mallow, has an erect stem, and is distinguished by its kidney-shaped leaves with seven deep crenate lobes; the fruit is glabrous, reticulate-rugose. The flowers are large and of a purple colour, much longer than the calyx, which is hairy. It grows on waste places and road sides in Britain, and is native in most parts of Europe. The whole plant, but especially the root, yields when boiled a plentiful tasteless mucilage, which is used in some cases of internal irritation. Decoctions of the leaves are employed in dysentery and in general for removing supposed acrimonious humours, but their chief utility is in clysters, fomentations, and poultices. This species is the Malva of Pliny, lib. 20, cap. 21; also, in Columella, lib. 10, cap. 247: it is the *μαλάχη* of Theophrastus, lib. 9, cap. 17, and the *κηπευτὴ μαλάχη* of Dioscorides, lib. 2, cap. 144.

M. rotundifolia, Dwarf Mallow, has a decumbent stem, roundish heart-shaped leaves with five shallow acutely crenate lobes, the outer sepals linear lanceolate shorter than the ovate acuminate stellately hairy inner ones. The flowers are small and purple, and two or three times longer than the calyx. It is common in waste places in most parts of Europe, and is native of Britain. It is the *M. vulgaris* of Fries, the *ἀγρία μαλάχη* of Dioscorides, loc. cit., and the Malache sylvestris of Pliny, loc. cit.

M. borealis has its outer sepals linear, as long as the ovate acute glabrous but strongly ciliated inner ones, the petals as long as the calyx, the fruit pubescent, margined, reticulate-rugose. It is the *M. pusilla* of Smith, the M. rotundifolia of Fries. It is found in Britain, near Hythe in Kent. There are many other species of Mallow.

Those mentioned are the only natives of Britain, and the others are of little importance excepting as ornamental plants. Those best worth cultivation for this purpose are *M. Moschata*, *Morenii*, *alcea*, *Muroana*, and *purpurata*. The stove species will succeed in any kind of rich soil, and cuttings of them will strike root freely if planted in light soil underneath a handglass. The greenhouse species may be propagated in the same manner. The hardy perennial kinds should be planted in the open border, and may be propagated either by seed or by dividing the roots.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

MANDATE, as one of the contracts of the Roman law, was constituted where one by special agreement, or by tacit assent, had undertaken to perform some act gratuitously for another. The obligations incumbent on the mandatary, and enforced against him by law, arose, not from his receiving a consideration for what he had undertaken to do, but from his leading the mandant to believe that he would perform it, and thus causing damage if he should neglect it. It is distinguished from Negotiorum Gestio, where the person performing the service undertakes it without authority from the person for whose behoof it is undertaken; and from Locatio-Conductio, where the service is remunerated. The characteristics of Mandatum are briefly stated in Heineccius, *Ad Inst.*, tit. 27, and by Gaius, iii. 155, &c. In England mandate in this simple sense is a department of the law of Bailment. [Bailment, P. C.] In Scotland there is a wide departure from the old Roman meaning of the word, and almost every instance where one person acts for another is said to be under the contract of mandate; thus the commercial agent buying and selling, and the solicitor conducting a litigation, are said to be 'Mandatories.' The case in which, by the practice of the law of Scotland, the word mandate in its old sense is best exemplified, is in trusts, which, instead of being subject to the complex legal peculiarities which characterise the system in England, are merely treated as simple mandates. The acceptor of a bill is held to be a mandatary of the drawer.

MANDRA'GORA. [Atropa, P. C.]

MANGANESE—*Medical Properties of.* During the prevalence of pneumatic medicine, preparations of manganese, particularly the binoxide, on account of the large quantity of oxygen it can yield, were much employed; but since the views of Beddoes and others, who recommended them, have become obsolete, the articles suggested to be used have fallen into oblivion. A rational ground for reviving some of them is to be found in the facts that oxide of manganese exists as a constituent of the bones, and may in some cases be deficient in these structures, and also that carbonate of manganese exists in some of the mineral springs of Carlsbad and Marienbad, and hydrochlorate of manganese exists in the waters of Kreutznach. The presence of these salts in waters much celebrated for their utility in various chronic diseases has suggested their employment in some of the complaints which are frequently benefited by them. But even if their curative properties are insufficient to establish them as valuable medicines, the deleterious effects of some forms of manganese justify a notice of them in this place. The extensive employment of black oxide of manganese in the preparation of bleaching-powder produces in some of the workmen a form of paralysis which should be early noticed, inasmuch as after it is thoroughly established it seems altogether incurable; and the only chance of escape is the complete abandoning of the occupation. It is limited to paralysis of the lower extremities, affecting the motor nerves only, for the sensibility is unimpaired. A staggering gait is the first symptom of its commencement. This is often perceived sooner by others than by the sufferer. No cholic, nor constipation, such as attends the use of lead, is manifested. (See Dr. Couper's paper in 'British Annals of Medicine.' i. p. 41.)

Binoxide of manganese has been used internally in pills, and also as a gargle; externally as an ointment in some obstinate cutaneous affections. It does not appear entitled to much attention. Hydrochlorate, and still more sulphate of manganese, deserve attention as chologogue cathartics, or promoters of the secretion of bile. The latter salt has a cooling and bitter taste, resembling that of Glauber salt. Dissolved in a considerable quantity of water, and taken in the morning, it produces several liquid stools. Its purgative action may be increased by giving it with infusion of senna or with rhubarb. Alkalies and their carbonates are incompatible with it, as decomposition occurs. Its power of augmenting the secretion of bile renders it a valuable agent along with mercury, or as a substitute for it where mercury cannot be borne. It is useful in gout.

MANGLE. [Calendering, P. C. S.]

MANGOSTA'NA. [Garcinia, P. C.]

MANIA. [Insanity, P. C.; Lunacy, P. C. S.]

MANNYNG, ROBERT, is more usually called Robert de Brunne. He owes this name to his having been a Gilbertine canon in the monastery of Brunne or Bourne in Lincolnshire. He lived in the reigns of Edward I. and his successor, and was the writer of one of the earliest of the Metrical Chronicles whose language can be called English. His work however is merely a translation from the French. It is in two parts: the first, translated from the 'Brut d'Angleterre' and 'Roman le Rou' of Wace and Gaimar, begins with Æneas and ends with Cadwallader; the second, from Cadwallader to Edward I., is translated from the Chronicle of Peter Langtoft. [Langtoft, P. C.] Robert's version was published by Hearne in 1725. The measure of it is octosyllabic in the first part, and Alexandrine in the second. Its poetical merit is very small; but it is interesting as an early monument of the language, and valuable for its information, both historical and literary. Robert made in English rhymes a translation, which has never been printed, of Saint Buonaventura's treatise 'De Cœna et Passione Domini.' He translated also, freely, into octosyllabic verse, the 'Manuel Peche,' or 'Manual of Sins,' which used to be attributed to Bishop Grosthead on insufficient grounds. Of this unprinted translation specimens are given in Warton's work and elsewhere. Hearne has supposed, with little reason, that Robert de Brunne was the author of the old English metrical romance called 'Rycharde Cuer-de-Lyon.'

MANTUA'NO, the common name of a family of artists of Mantua, of the sixteenth century. The proper name appears to have been Ghisi, but few particulars regarding the lives of its members are known.

Giovanni Battista, called Giovanni Mantuano, and also Bertano, was painter, sculptor, engraver, and architect, and author of a commentary on Vitruvius—'Gli oscuri e difficili Passi dell' Opera di Vitruvio,' fol., Mantua, 1558. He was the pupil of Giulio Romano, executed many designs, some engravings, and a few paintings; but his chief business was architecture, and he built the church of Santa Barbara at Mantua. It is not known what relationship he bore to the following artists.

Giorgio Ghisi, called Giorgio Mantuano, was born at Mantua about 1520. He was painter and engraver, and was still living in 1578. Bartsch describes seventy-one of his engravings, many of which are after the most celebrated works of the sixteenth century; they are well drawn and executed with great mastery, much in the style of Marcantonio. Among the most valuable are the Last Judgment, and the Prophets and Sibyls, by Michelangelo, in the Sistine Chapel; and the Dispute on the Sacrament and the School of Athens, after the frescoes by Raphael in the Vatican.

Bartsch describes 129 prints by Adamo Ghisi, called also Mantuano; and 46 by Diana Ghisi, called Mantuana. Those of the former are dated from 1566 to 1576, and those of Diana from 1575 to 1588. Diana was the daughter of Giovanni Battista Mantuano, and was married to Francesco da Volterra, architect; the date of her death is not known.

(Gandellini, *Notizie Istoriche degl' Intagliatori*; Bartsch, *Peintre-Graveur*; Brulliot, *Dictionnaire des Monogrammes*, &c.)

MANUEL, NICOLAS, sometimes called Deutsch, a celebrated Swiss painter, was born at Bern, in 1484. He is the Emanuelo Tedesco who studied under Titian at Venice about 1511, and he became very celebrated for a series of pictures (probably in distemper) of the Dance of Death, *Todtentanz*, painted between 1514 and 1522, in the cloister of the Dominican convent at Bern. The picture consisted of forty-six subjects, forty-one of which were the actual *Todtentanz*; it has been long since destroyed, but the compositions are preserved in prints and copies: the wall on which it was painted was pulled down in 1660. Manuel was an active reformer, and many of these designs are reflections upon the abuses of the Roman church: he was also a great politician; from 1523 he took an active part in an official capacity in the government of Bern. He died in 1530. His own portrait in oil and several drawings are in the library of Bern. There are a few other of his oil pictures at Basel and at Bern.

Of Nicolas Manuel, until recently, little was known beyond what Sandrart says of him in his 'Teutsche Académie.' He appears to have been a man of universal ability; he was painter, sculptor, wood-engraver, poet, soldier, and statesman; and he was lately made the subject of an elaborate work by Dr. Grüneisen—'Nicolas Manuel, Leben und Werke eines Malers, Dichters, Kriegers, Staatsmannes, und Reformators,' Stuttgart and Tübingen, 1837.

(Nagler, *Neues Allgemeines Künstler-Lexicon*.)

MANURES. [Manure, P. C.; Guano, P. C. S.]

MAPES, WALTER DE. [GEOFFREY OF MONMOUTH, P. C.]

MAPS AND CHARTS. [COPYRIGHT, P. C. and P. C. S.]

MARCELLUS, U'LPIUS, a Roman jurist, who lived under Antoninus Pius and his successors. He was employed by Pius as one of his legal advisers (Capitolinus, *Anton. Pius*, 12), and also apparently by Aurelius, the successor of Pius (*Dig.* 28, tit. 4, s. 3), for Marcellus speaks of the proceedings in a case before Aurelius, A.D. 166, in which the emperor delivered judgment. Marcellus (*Dig.* 26, tit. 2, s. 19), as quoted by Ulpianus, cites an oratio of the Divi Fratres, which proves that he survived Aurelius, if the word Divi was used by him, and is not introduced by Ulpianus. It is conjectured that this is the Ulpius Marcellus who commanded in Britain during the reign of Commodus, the successor of Aurelius, and by his military success excited the jealousy of the emperor. (Dion Cassius, lxxii. 8.) But it is doubtful if this Ulpius Marcellus is the jurist. (See the note of Reimarus on Dion Cassius.)

The writings of Marcellus mentioned in the Florentine Index are thirty-one books of Digesta, six books on the Leges Julia et Papia, and two books of Responsa. There are 159 excerpts from Marcellus in the Digest; and other works of his are cited besides those just enumerated. Marcellus is quoted by Marcianus, Ulpianus, and Paulus frequently, and by Modestinus.

MARCH, a market and post town in the chapelry of March in the parish of Doddington, in the northern division of Witchford hundred in the Isle of Ely, Cambridgeshire, 92 miles north of London, viz. 72 miles by the Eastern Counties Railway to Ely, and from thence 20 miles by coach-road through Chatteris to March. The area of Doddington parish is 38,240 statute acres, that of the chapelry of March 20,440 acres; the population of the parish in 1841 was 8648, of whom 5706 were in the chapelry of March. The population of the chapelry at the former enumerations was, in 1801, 2514; 1811, 3098; 1821, 3850; 1831, 5117. The number of houses in the chapelry in 1831 was 1016, inhabited by 1023 families; 42 uninhabited and 16 building; in 1841 it was 1163 inhabited, 32 uninhabited, and 12 building. In these returns the town is not distinguished from the rural districts of the chapelry.

The town consists principally of two streets, in the form of the letter T: the street which forms the stem of the letter runs north and south, and is lined with houses on both sides; the cross street runs in an irregular line on the north bank of the old river Nene, having scarcely any houses except on the north side of the street, the south side being for the most part closely skirted by the river, which is crossed by a bridge at the junction of the two streets. The church, or rather chapel, stands at the southern extremity of the town: it is dedicated according to some statements to St. Mary, according to others to St. Wendreda, and is said to have been erected in the middle of the fourteenth century; it is a handsome Gothic structure, with a spire at the west end. There is a modern and commodious town-hall, where manorial courts are held. The town is within the jurisdiction of a Court of Requests established in the Isle of Ely for the recovery of debts under 10*s*. There is a weekly market on Friday for butcher's meat, and there are two yearly fairs. Some trade in agricultural produce is carried on by means of the river Nene, which is navigable.

The chapelry of March is united with the vicarage of Doddington; the clear yearly value of the united benefices is 7306*l*., with a glebe-house; they are in the rural deanery, archdeaconry, and diocese of Ely. There were in the chapelry in 1833 nine day-schools, with 552 children of both sexes, giving not one in nine of the population (according to the census of 1831) under daily instruction. Two of the schools, with 304 children, were national schools supported by various endowments, and attended by the children on Sunday also; and there were two other Sunday-schools supported by Dissenters, with 170 children.

(*Ordnance Survey*; *Parliamentary Papers*; Lysons' *Magna Britannia*.)

MARCIA'NUS AELIUS, a Roman jurist, who was writing after the time of Septimius Severus, for he calls him Divus (*Dig.* 50, tit. 4, s. 7). He also survived Caracalla, the successor of Severus, for he names him Divus (*Cod.* 9, tit. 8, s. 8). He probably wrote chiefly under the reigns of Septimius and his son Caracalla. The works of Marcianus which are mentioned in the Florentine Index are sixteen books of Institutiones, four books entitled Regularia, two books on Appellationes, two books on Publica Judicia, a single book on Delatores, a single book on the Hypothecaria (formula), and a single book Ad Senatusconsultum Turpilianum. Marcianus is cited by Ulpianus and Paulus (*Cod.* 7, tit. 7). There are 275 excerpts from Marcianus in the Digest.

MARCUS GRÆCUS. Of this writer, and his *Liber ignium*, nothing is known but one old mention and a quotation. A certain Græcus is mentioned (about A.D. 800) by the Arabic physician whose name is latinized into Mesua. John Mesua's medical works were printed at Venice, 1581, folio. There is a surmise by Fabricius and Dutens, that this same Græcus is mentioned by Galen. His name first appears, as far as we can find, in Dr. Jebb's edition of Roger Bacon. In speaking (preface, sheet C, leaf 1) of Bacon's distinct reference to some sort of detonating powder, Jebb thinks he may have drawn his account from the *Liber Ignium* of a certain Marcus Græcus, of which work he (Jebb) had seen a manuscript in the possession of Dr. Richard Mead. Dutens, author of the 'Origine des Découvertes attribuées aux Modernes,' procured the account from Dr. Jebb, and ascertained that there was a manuscript in the Royal Library at Paris. But the work has never been printed, nor has any notice been taken of it, that we can find, except such references to Jebb and Dutens as that made by Dr. Hutton. [BACON, ROGER, P.C.] As the passage in question is not easily met with entire, and certainly describes gunpowder and its consequences, in the form of a rocket, we shall transcribe it, seeing that the early existence of some such thing as gunpowder is clearly indicated, not merely by the passage itself, but by Bacon's reference to it or a similar account:—

'Secundus modus ignis volatilis hoc modo conficitur: lib. i sulphuris vivi; lib. ii carbonis salicis; salis petrosi vi libras, quæ tria subtilissimé terantur in lapide marmoreo. Postea pulvis ad libitum in tunica reponatur volatili, vel tonitrum faciente. Nota quod tunica ad volandum debet esse gracilis et longa, et prædicto pulvere optimè conculcato repleta. Tunica vel tonitrum faciens debet esse brevis, grossa, et prædicto pulvere semiplena, et ab utraque parte filo fortissimo bene ligata. Nota quod in qualibet tunica primum foramen faciendum est, ut tenta imposita accendatur, quæ tenta in extremitatibus fit gracilis; in medio vero lata, et prædicto pulvere repleta. Nota quod ad volandum tunica plicaturas ad libitum habere potest, tonitrum vero faciens quam plurimas plicaturas. Nota quod duplex poteris facere tonitrum ac duplex volatile instrumentum, vel tunicam subtiliter in tunica includendo.'

MARGARITO'NE D'AREZZO, a celebrated old Italian painter, sculptor, and architect, was born at Arezzo, about 1215, or perhaps a little later, but he was probably at least twenty years older than Cimabue, who was born in 1240.

Margaritone was a painter of the Greek or Byzantine school, and of great reputation in his day. He executed many works in Arezzo, both in tempera and in fresco; in the latter style he painted the whole interior of the church of San Clemente, an old church which, with other buildings, was destroyed by the duke Cosmo de' Medici in 1547, to make room for improvement in the fortifications of Arezzo. Most of Margaritone's works have now perished; but one, which, according to Vasari, Margaritone considered one of his masterpieces, namely, San Francesco, painted for a convent in Sargiano, still exists, and is engraved in Lastri's 'Etruria Pittrice,' i. 7. Vasari speaks highly of a picture on canvas, illustrating the lives of the Virgin and John the Baptist, in small figures, and in which, says Vasari, Margaritone much surpassed his larger works; but this picture has also perished. There is still an old painted wooden crucifix by Margaritone in the church of Santa Croce at Florence, where it is placed by the side of a similar work by Cimabue. Margaritone's fame was very great in his time, but it was almost wholly eclipsed by the reputation of Cimabue and Giotto. He had a peculiar way of stretching and priming his canvases; they were primed with plaster mixed with size or glue made of strips of parchment, and were stretched and fastened with the same glue upon a pannel.

In sculpture, says Vasari, Margaritone was more successful than in painting. There is still by him, in the cathedral of Arezzo, a reclining marble statue of Gregory X. over the tomb of that pope, which was also constructed by Margaritone; in the upper part of the tomb was also Gregory's painted portrait, but this has been defaced by time: this monument, according to Vasari, is Margaritone's masterpiece. As an architect, Margaritone conducted the building of the cathedral of Arezzo, some time after the death of Jacopo

Lapo, but according to the design of that architect, from about 1277 until 1289, when a war broke out between Arezzo and Florence. He died at Arezzo, probably shortly after 1289, aged seventy-seven, and was buried in the old cathedral of that place, where his portrait was painted by Spinello Aretino, and the following epitaph was inscribed upon his tomb:—

Hic jacet ille bonus pictura Margaritonus,
Cui requiem Dominus tradat ubique plus.

(Vasari, *Vite de' Pittori*, &c., and the Notes to the German translation of Vasari by Schorn.

MARINERS' CONTRACT. [Ships, P. C.]

MARI'NUS TY'RIUS. [Ptolemæus, Claudius, P. C., p. 104.]

MARMION, SHAKERLEY, the son of a Northamptonshire squire, was born in that county, became a gentleman commoner of Oxford in 1617, and proceeded master of arts in 1624. He squandered a good fortune; took military service in the Low Countries; and in 1639 became one of the officers in the troop raised by Sir John Suckling for the king in his expedition against the Scots. But, becoming sick at York, he returned to London, and died there before the end of the year. Besides small scattered poems, he wrote three plays: 1, 'Holland's Leaguer, an excellent comedy,' 1632, 4to.; 2, 'A Fine Companion,' a comedy, 1633, 4to.; 3, 'The Antiquary,' a comedy, 1641, 4to., a drama of considerable merit, which is reprinted in the tenth volume of Dodsley's Collection.

MARQUOI'S RULERS. Among the methods which have been devised for facilitating the operation of drawing parallel lines, those which consist in making one ruler slide along the edge of another are in almost every case the most expeditious and accurate.

A triangular ruler having two of its edges at right angles to one another being made so to slide with one of its edges perpendicular to the length of a common rectangular ruler constitutes, apparently, one of the first contrivances of this nature. It is said to have been originally employed in Germany, from whence its use extended to other parts of Europe. A triangular ruler of the form just mentioned is called by the French artists an *équerre*.

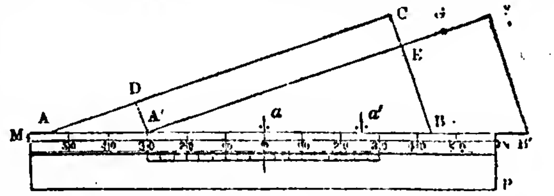
The most approved construction and application of a triangular ruler are due to an artist named Marquoi, who resided in London, and by his name only the instrument is now known. Where many lines are to be drawn parallel and perpendicular to one another, as in making plans or elevations of buildings, or the horizontal projections of the ramparts of fortresses, such an instrument is particularly useful. The right-angled triangle, as well as the rectangular rulers which accompany it, is made of box-wood, ivory, or some metal; and on the surfaces of the latter rulers are certain scales with graduations in equal parts.

The ratio of the hypotenuse to the shorter side of the triangular ruler is usually as three to one; and on one of the surfaces, about the middle of the hypotenuse, there is drawn a short line which serves as an index. The rectangular rulers which are used with the triangle are each about 12 inches long; they have scales on both surfaces, and the graduations are cut close to the edges in order that the coincidence of the index on the triangle with any required division may be accurately made.

Parallel to each scale there is generally cut another, each of its divisions having the same proportion to each division on the corresponding scale at the edge as the shortest side of the triangle has to the hypotenuse (1 to 3 usually). This second scale is used entirely as a plotting scale for the purpose of laying on paper lines of given lengths in feet, yards, or other measure, or of measuring them when traced; the former scale being intended wholly for the peculiar purpose of the sliding triangle.

The plotting, or, as they are called, the natural scales, are of various kinds, but usually from 20 parts to 60 parts in an inch; the others, which are called artificial scales, vary consequently from divisions equal to $\frac{3}{20}$ to such as are $\frac{3}{60}$ or $\frac{1}{20}$ of an inch.

When it is required to draw lines parallel to others at any given distance on a scale representing feet (for example), the apparatus is used in the following manner. Let M P be a rectangular ruler on the edge M N of which is the scale to be used: if, for example, the drawing is to be made on a scale of 30 feet to an inch, the scale is that whose divisions are each equal to $\frac{3}{30}$ of an inch: then, the edge A C of the triangle being made to coincide with a given line, the index a must first, by a movement of the ruler M N, be placed in coincidence with the zero of the scale (in the middle of the length of the ruler),



the triangle must then be moved along M N till the index a is (suppose at a') in contact with the number on the scale which expresses the number of feet in the perpendicular distance between the given line and that which is to be drawn. If the triangle be then in the position A′ B′ C′, a line drawn along its edge A′ C′ will be the line required; for it will be parallel to A C at a distance from it equal to the given number of feet on the natural scale. The reason is manifest; for imagine A′ D to be drawn parallel to B C, then the triangle A A′ D is similar to A B C: consequently, since A A′ is equal to the distance $a a'$ between the two positions of the index, A′ D will be the same part of A A′ or $a a'$ as B C is of A B; that is, by the construction of the triangle, A D, the interval between the parallel lines is one-third of the distance $a a'$ on the scale, or equal to the corresponding distance on the natural scale.

Lines may be drawn parallel to one another by means of the side B C of the triangle; and it is evident that the distance between them (E C′ for example) will bear the same proportion to A C as B B′ or $a a'$ bears to A B; that is as $\sqrt{8}$ to 3. But the edge B C is principally used in drawing lines perpendicular to given lines; if, for example, the edge B C were in coincidence with a given line, and it were required to draw, through a given point G, a line perpendicular to such line, the triangle must be moved along M N till A C passes through the given point; then the line A′ C′ will be perpendicular to that line.

When lines are to be drawn parallel to one another at considerable distances, the edge B C is made to coincide with an edge M N of the rectangular ruler; and, both ruler and triangle being moved together till A C, then perpendicular to M N, coincides with the given line, the triangle is moved along M N till the same edge A C is at the required distance from the original line; when the line may be drawn.

Marquoi's rulers have occasionally been formed and used in a different manner. Instead of one triangle with several scales, a single scale on the ruler M N has been made to serve the purpose by means of several triangles in which the lengths of the sides have different ratios to one another. Thus, if a scale of divisions each equal to one-tenth of an inch be formed at an edge of M P, and if a right-angled triangle in which the hypotenuse is twice the length of one of the sides be used with it; on sliding the index of the triangle over each division on the scale, the interval between the lines drawn contiguously to the longer side of the triangle will be $\frac{1}{20}$ of an inch: if the hypotenuse be four times the length of the shortest side, lines drawn contiguously to the longer side will, on sliding the index over one division of the scale, be equal to $\frac{1}{40}$ of an inch; and so on.

MAROCCO. [Algiers, P. C. S., p. 83.]

MARSH-MALLOW. [Althæa, P. C.]

MARSHALL, JOHN, Chief Justice of the United States of North America, was born in Fauquier County, Virginia, September 24, 1755. He was the son of Colonel Thomas Marshall, and the eldest of fifteen children. He received a little instruction in Latin and Greek, but went through no regular course of education, and was never at any college. On the breaking out of the American war, he engaged with enthusiasm in the cause of his country. In 1776 he was appointed a first lieutenant, and in 1777 was promoted to the rank of captain. He was present at the battles of Brandywine, Germantown, and Monmouth. There was however a redundancy of officers in the Virginian army, and Marshall having applied himself to the study of the law, was admitted to the bar in 1780, and in 1781 resigned his commission in the army. Thenceforward he devoted himself to the law, and rose rapidly to great distinction in the profession.

Marshall was a member of the Virginia Convention for the ratification of the constitution of the United States, and both then as well as subsequently in the Virginia legislature distinguished himself by his judgment and eloquence. He was twice offered the situation of attorney-general, and on both occasions declined on private grounds to accept the offer. In June, 1797, John Marshall, Charles Cotesworth Pinckney, and Elbridge Gerry, jointly and severally, were sent to France as envoys extraordinary and ministers plenipotentiary. Marshall returned to America in 1798. In 1799 he became a member of Congress, and on the 13th of May, 1800, he was appointed secretary of state. On the 31st of January, 1801, he succeeded John Jay as chief justice of the United States, and from that time till his death continued to fill the office with increasing reputation for ability and integrity. He died July 6, 1835, at Philadelphia, to which city he had gone from his residence at Richmond in Virginia, in hope that by medical advice and change of scene his declining health might be improved. Three of his children were with him, but his eldest son died suddenly at Baltimore, on his journey to attend his father's death-bed.

Judge Marshall was the author of the 'Life of Washington,' originally published in London, in 5 vols. 4to., the first volume in 1804, the fifth in 1807. The work was criticised by the 'Edinburgh Review' (October, 1808) severely, but perhaps not unfairly, as having been swelled out to an unreasonable bulk by historical matter unconnected with the life of Washington; as containing no details of his private character and habits, which Judge Marshall had ample opportunities of knowing; as diffuse and undiscriminating in narrative, and heavy and unanimated in style. This criticism seems not to have been thrown away. Marshall published a second edition of the work in 1832, compressed into two volumes, and greatly improved. The 'History of the American Colonies,' which in fact occupied the first volume of the original work, he had published in a separate form in 1824.

As a judge, it is admitted that he was one of the most distinguished that America has produced. Judge Story, who was twenty-four years his associate on the bench of the Supreme Court, wrote in 1828 an article in the 'North American Review' (vol. xvii.), 'On the Public Services of Judge Marshall,' in which he says:—'Splendid as has been the judicial career of this eminent man, it is scarcely possible that the extent of his labours, the vigour of his intellect, or the untiring accuracy of his learning, should be duly estimated except by the profession of which he was so great an ornament.' . . . . 'Many of those exquisite judgments which have cost days and nights of the most elaborate study, and for power of thought, beauty of illustration, variety of learning, and elegant demonstration, are justly numbered among the highest reaches of the human mind, find no admiration beyond the ranks of lawyers, and live only in the dusty repositories of their oracles.' . . . . 'We emphatically say of Chief Justice Marshall that his master-mind has presided in our deliberations, and given to the results a cogency of reasoning, a depth of remark, a persuasiveness of argument, a clearness and elaboration of illustration, and an elevation and comprehensiveness of conclusion, to which none others offer a parallel.'

(*American Almanac*, 1830, 1836; *North American Review*, vol. xvii.; *Edinburgh Review*, vol. xiii.)

MARSHMAN, JOSHUA, D.D. [SERAMPORE MISSION, P. C. S.]

MARTINO. [MEMMI DI MARTINO, SIMONE, P. C. S.]

MARY, SAINT, is the easternmost of the Azores or Western Islands, and lies near 37° N. lat. and 25° W. long. It is about seven miles in length from east to west, and five miles in breadth from north to south, and contains an area of 36 square miles, or 27,000 acres. The island consists of a plain and an elevated district. The plain occupies about one-third part on the west side of the island, the other part being formed of an elevated ridge running from north-west to south-east, which rises to a double peak (Pico Alto) 1889 feet above the sea, and of which the sides decline on the north, east, and south to mural cliffs, about 200 feet in height, with which it terminates on the shore. The plain is slightly undulating, and like the higher tract cut by ravines, terminating in cliffs more than 100 feet high. The aspect of St. Mary is therefore on all sides bold, and the coast abrupt or precipitous, and surrounded by the usual accumulations of fallen masses.

The surface on the west side is much overlaid with stones, and bears a spare vegetation of grasses and weeds. The most elevated part of the higher grounds is covered with common heath and some other shrubs; on the east side only is there any land which is fit for cultivation. The cultivation is limited to wheat, Indian corn, potatoes, and beans and peas. There are few plantations of trees, but those of oranges have been lately increased. Aloes and the prickly-pear cactus grow wild, and the Rocella tinctoria to a large size. Nothing is known respecting the climate of the island, except that there is much less rain in this island than in that of St. Michael's.

The population, according to the census of 1840, was composed of 4666 individuals, of whom about one-half belonged to the small town of Villa do Porto and two hamlets: the remainder were dispersed over the island in single farm-houses. There were then 2213 males and 2453 females. There are some public schools, established by government, but in 1840 they were only attended by fifty-two pupils, all males. The course of education does not comprehend more than the elements of reading and writing.

The whole quantity of agricultural produce is comprised in 2500 quarters of wheat, 2500 quarters of Indian corn, 200 boxes of oranges, and a small quantity of wine, potatoes, beans, peas, and other articles. About one-half of the wheat and all the oranges are exported to St. Michael's. This produce is derived from one-sixth of the whole area; the remainder is sterile. The greater part of the western plain is only fit for pasturage. There are about 2800 head of horned cattle, 2000 sheep, 1200 pigs, 600 goats, and 100 horses and asses. For these the grass and other fodder of the island does not afford a sufficient supply of food, and they are therefore fed in winter on the bruised leaves of the aloes, which are cultivated for that purpose on the stony ground and the otherwise unprofitable sides of the ravines.

St. Mary was discovered in 1431 by Gonsalvo Velho Cabral, a Portuguese, who was sent by the Prince Don Henrico to explore the part of the sea in which the Azores are situated, and the island received from him its name, because he discovered it on the 15th of August, the festival of the Assumption of the Virgin Mary. Soon afterwards it was settled by Don Gonsalvo.

(Hunt, *Description of the Island of St. Mary*, in *London Geogr. Journal*, vol. xv.; Birch, *Description of the Azores or Western Islands*.)

MARY, DUCHESS OF WÜRTEMBERG, or the Princess Marie d'Orleans, was born in April, 1813, during the exile of her father Louis-Philippe, then Duke of Orleans, and residing at Palermo with his wife Amelia, second daughter of King Ferdinand of Naples. The Princess Marie spent much of her childhood at Twickenham, near London; her youth was passed under the care of her mother at Neuilly, until her father was raised in 1830 to the dignity of King of the French. From her childhood a devoted love for art had been a distinctive feature of her character, and as soon as she was at an age to benefit by the instruction of masters, Louis-Philippe commanded some of the most skilful artists in their several styles to attend upon her. Ary Scheffer was her master in design and painting, Pierre Jean David instructed her in modelling and in sculpture, and Mr. Newton Fielding taught her drawing in water-colours. She was married to the Duke of Würtemberg in 1837, and she died at Pisa, in January, 1839, in consequence of injuries suffered from the conflagration of her palace at Stuttgart.

She is said to have left numerous designs, and to have executed many beautiful drawings. Some of her works in sculpture have already acquired her a European reputation; among these her marble statue of Joan of Arc is the most popular. Joan is standing with her eyes fixed upon the ground in deep meditation, her arms are crossed upon her breast, and in her right hand she grasps her sword; her costume is that of a female and a knight combined. The original statue, now at Versailles, is of the size of life, but it has been copied in many materials and in many sizes. She executed also an equestrian statue of Joan of Arc at the moment after having slain an Englishman with her battle-axe: there is also a small model by her of the Death of the Chevalier Bayard. And in a chapel at Fontainebleau there are some windows painted after her designs. Many contemporary journals, French and foreign, celebrated the character and ability, and deplored the untimely fate of this accomplished princess.

MARYGOLD. [CALENDULA, P. C. S.]

MASCARA. [ALGIERS, P. C., p 330.]

MASCHERO'NI, LORENZO, an Italian mathematician, was born at Bergamo in 1750. His studies were at first directed to the languages and literature of Greece and Rome, and to these subjects he applied himself with unwearied diligence. At eighteen years of age he was appointed professor of humanity in the university of his native city, and he attracted some notice at that time by a poetical dissertation on what he called the false eloquence of the pulpit. He afterwards became professor of Greek in the university of Pavia; and, having taken orders in the church, he acquired the title of Abbé.

It was not till he was twenty-seven years of age that he began the study of mathematics; but he rapidly acquired a taste for the sciences, which induced him to abandon his classical pursuits, and so great was his progress in this branch of learning that he was appointed professor of geometry in the college Mariano at Bergamo.

When the Revolution took place in the north of Italy, on the invasion of the country by the French, Mascheroni was chosen a member of the legislative body in the Cisalpine Republic; and soon afterwards he was sent to Paris to assist in the formation of the new system of weights and measures. He was at one time also engaged at Bologna, with other mathematicians, in the performance of experiments with a view of proving the rotation of the earth on its axis by the place at which a body struck the ground when let fall from the upper part of a lofty building.

Mascheroni published in 4to. a work entitled 'Sulle Curve che servono a delineare le Ore ineguali degli Antichi nelle superficie Plane,' Bergamo, 1784; and in the following year, at the same place, a tract, also in Italian, on the Equilibrium of Vaults, 4to. In this tract the higher branches of analysis are employed, and the investigations are extended to subjects beyond those which are treated in the works of the earlier writers on the applications of science to practical engineering. In 1795 he published at Milan, in 8vo., a work entitled 'Geometria del Compasso,' in which are ingenious solutions of several geometrical propositions by means of a pair of compasses only; that is, by the intersection of circular arcs, without the assistance of a ruler. Among these propositions is one in which it is required to find between or beyond two given points, and in the direction of a straight line joining them, other points whose distances from the former are in any assigned proportions. There are given in the work methods of finding points in lines perpendicular or parallel to, or making given angles with, a line joining two points whose positions are assigned; of determining a mean proportional between, and third, fourth, &c., proportionals to two given lines; and of inscribing polygons in circles. There are also approximative solutions of problems, such as the duplication or multiplication of a cube, and the trisection of an angle, which require, in the usual method of operating, applications of the conic sections or other curves.

Besides the mathematical works just mentioned, and a tract containing notes on Euler's 'Institutiones Calculi Differentialis,' Mascheroni published some verses which were addressed to the Countess Grismondi, an elegy on the death of Borda, and a poem entitled 'Invito di Dafni a Lesbia,' in which he introduced a precise description of the objects contained in the museums of natural history and philosophy at Pavia.

He died in July, 1808, in consequence, it is said, of too close application to his scientific studies, leaving several manuscripts, and among them one on 'Pyramidometry,' a subject which La Grange had previously investigated, but which Mascheroni had the merit of placing in a new light.

(*Biographie Universelle*; Montucla, *Hist. des Mathématiques.*)

MASSE'NA, ANDRE', Prince of Essling, Duke of Rivoli, and Marshal of France, was born at Nice, 6th May, 1758. 'Several of the French marshals,' says D'Israëli, 'and the most famous—Masséna, for example—was a Hebrew; his real name was Manasseh' ('Coningsby,' ii. 203). Left an orphan at an early age, his education was greatly neglected. He appears to have spent some years of his youth at sea with a relation who was captain of a trading vessel, but having taken a dislike to a sea-faring life, he abandoned it, and in 1775 entered the army as a private soldier in the regiment Royal Italian, in which one of his uncles was a captain. After a diligent discharge of his duties in that regiment for fourteen years, he only attained the rank of sergeant, which, when he afterwards became marshal, he declared was the step in his military career which had cost him the most to gain. Discouraged by this slow promotion, he retired to his native city, where he made an advantageous marriage. Events connected with the French revolution recalled him to his former profession, and he was appointed by the suffrages of his fellow-soldiers to the rank of adjutant-major of the battalion raised in the department of the Var, of which regiment he subsequently became colonel. In August, 1793, he was made general of brigade, and general of division a few months after. In the Italian campaigns of 1794 and 1795 he served under the generals Kellerman and Scherer, and it was chiefly owing to his skill as a tactician that the victory was gained in the defile of Saorgio (August, 1794), and on the Col de San Giacomo in 1795. Indeed the great success of these campaigns has generally been attributed to the ability of the plans which the influence of his talents caused to be adopted. When Bonaparte assumed the command of the army in Italy he employed Masséna actively on all occasions of importance, the brilliancy of whose military conceptions he so justly appreciated, that he surnamed him the 'favoured child of victory.' The scenes of his principal exploits were Montenotte (9-11 April, 1796), Millesimo (14 April), Castiglione (29 June—5 July), Arcola (15-17 Nov.), and Rivoli (9 January, 1797). At the peace of Campo Formio, October 17, 1797, Masséna was sent to France to present to the Directory the ratification of the treaty of peace by the Emperor of Austria. In February, 1798, he was appointed to the command of the army which, under General Berthier, was occupying Rome and the Papal States. His appointment to this office was equally disliked both by the French soldiers and the inhabitants of the subjected country, for they both became the victims of that insatiable avarice which on every occasion characterized this general. The multiplied complaints which his disposition gave rise to at last obliged him to resign his command and to return to Paris. He there published a 'Mémoire' in justification of his conduct, notwithstanding which he was left without employment till 1799, when the important command of the armies of the Danube and of Switzerland was confided to him. In the direction of this campaign he evinced a military talent of the highest order. The memorable battle of Zürich (5th and 6th of June, 1799), in which he obtained considerable advantages over the Russian army under Korsakow, saved France from the invasion of the allied powers, and led to the dissolution of the coalition which had been formed between the Russians and Austrians.

On the return of Bonaparte from Egypt, Massena was employed by him to defend Genoa, which was at that time invested by a large Austrian army, and closely blockaded by the English fleet under Lord Keith. He arrived there on the 18th of February, 1800, and defended it against immensely superior forces, and amidst the horrors of famine, till the 3rd of June, when, unable to prevent the rising of the inhabitants, he was compelled to agree to an honourable capitulation. Only eleven days after this capitulation, Bonaparte, conqueror at Marengo, stipulated the evacuation of this city, which was again re-entered by the French under General Suchet, on the 24th of June, 1800. [GENOA, P. C.]

Masséna's name does not appear connected with any event of importance till May, 1804, when, on the same day that Napoleon became emperor, Masséna was created a marshal of France. In 1805 he was again appointed to the command of the army in Italy, where he was opposed to the Austrian army under the Archduke Charles: he conducted this campaign with varying success, but he was at last enabled to drive back the Austrians into Germany, and to effect a junction with the grand army of Napoleon. After the peace of Presburg (20th Dec., 1805), Masséna had the command of the army which was to conduct Joseph Bonaparte [BONAPARTE, JOSEPH, P. C. S.] to Naples, which kingdom had been bestowed upon him by his brother (from whence he returned after having established by force of arms the authority of the new king). By his success over the insurgent Calabrians and the reduction of the fortress of Gaëta (18th July, 1806), he enabled Joseph to take possession of his new kingdom. In 1807 he was appointed to the command of the right wing of the army opposed to the Russians in Poland, and his services during this important campaign were rewarded by the title of Duke of Rivoli, in commemoration of the skill and bravery which he had displayed in that celebrated battle (1797) [RIVOLI, P. C.]: a large sum of money was at the same time given him to support his new dignity.

A singular and untoward circumstance occurred on his return to Paris. He, who had exposed his person in so many battles without receiving a wound, had the misfortune to lose the sight of his left eye while on a hunting-party, a portion of shot having accidentally struck it.

The Austrian campaign of 1809 shed considerable lustre on the already high military character of Masséna. He greatly distinguished himself at Landshut and Eckmühl. The rapid capture by storm of the strong castle of Ebersdorff, which, from its position on the river Traun, was deemed almost impregnable, especially attracted the admiration of Napoleon. At the battle of Essling [LANNES, P. C. S.] the defence of the village of Aspern was confided to Masséna, and it is generally believed that to his obstinate resistance in that village the French army was indebted for its preservation. His eminent services on that most critical occasion were rewarded by the rank and title of Prince of Essling.

The same success attended the operations of Masséna at Engerdorf and at Wagram. At the battle of Wagram he was obliged to direct the movements of the left wing of the army while seated in a carriage, on account of an injury produced by a fall from horseback. An incident there occurred which showed that in more than one respect he was 'the favoured child of fortune;' at one time success appeared doubtful, and to animate his soldiers he insisted on being placed on horseback; he had scarcely been so when a cannon-ball struck the vacant carriage and shattered the seat which he had occupied. In 1810 Marshal Masséna was appointed to the chief command of the army in Portugal, which was about seventy-two thousand strong: his commission was to drive the British, under Wellington, from Portugal. His exploits in this campaign, though in many instances marked by great military talent, have not added to his reputation as a general, while the frequent examples of his cruelty, avarice, and breach of faith, recorded in the histories of that period, have left a deep stain upon his memory. One achievement, however—his masterly retreat into Spain after the failure of his attempts on the lines of Torres Vedras—has been the subject of the highest praise and admiration, as far as military skill was concerned, by both English and French historians. (Sir W. Scott, *Life of Napoleon*, vol. vii. p. 136.)

Masséna was recalled from Spain in 1812, and the command of the army which he left was bestowed upon Marshal Marmont. His health having severely suffered, he was unable to join the expedition to Russia. In the latter end of 1813 he was sent to Toulon to take the command of the eighth military division, from which place he formally declared his adhesion to the Bourbons, on the 6th of April, 1814, and was by them confirmed in his command. On the return of Napoleon from Elba, after some hesitation, he recognised his government, but kept aloof from all active participation in the events which took place during the Hundred Days. After Napoleon's second abdication he was appointed commander-in-chief of the national guard of Paris. Being chosen a member of the Council of War which was assembled for the trial of Marshal Ney, he at first declined sitting as a judge on a fellow-soldier with whom he had been for some time at variance, and when this objection was over-ruled he joined the majority of members in pronouncing for the incompetency of the court. [NEY, P. C. S.] Some months after these events he was denounced in the Chamber of Deputies on the charge of having been at the head of a conspiracy for the return of Napoleon. He was however satisfactorily acquitted, and he afterwards publicly repelled the accusations which had been brought against him, in a 'Mémoire Justificatif,' to which a reply was published in a pamphlet entitled 'A Letter of a Citizen of Marseille to Marshal Masséna,' which was written in a spirit of such bitter invective that it produced a sensible effect on his mind and health, already enfeebled by bodily infirmities, and is said to have hastened his death, which took place on the 4th of April, 1817. His funeral eulogium, which was pronounced by General Thiébault, was inserted in the 'Mercure,' and afterwards published separately.

Masséna was gifted by nature with a powerful frame of body and with indomitable resolution. His bravery was rather characterised by perseverance than by impetuosity. He was considered the most skilful tactician among Napoleon's generals, and on the field of battle he was remarkable for the coolness and precision of his orders and for his penetrating insight into the intended movements of the enemy. He had moreover the invaluable quality in a commander of not being dispirited by defeat. His faults and vices we have already alluded to; they were principally rapacity and avarice, and they frequently brought down upon him the displeasure and punishment of his chief.

Hist. des Batailles*; *Biographie Moderne*; Pelet, *Mémoires sur la Campagne de* 1809, Paris, 1823-26, 4 vols. (this accurate military writer was aide-de-camp to Masséna); Napier, *Hist. of the Peninsular War.*)

MASSON, ANTOINE. This celebrated French engraver and painter was born at Loury, near Orleans, in 1636, and was originally an armourer and *damasquineur*, damaskenator, or ornamental engraver and inlayer of metals, an artist in much request in the days of armour and chivalry. Masson, who in engraving appears to have been self-taught, had extreme facility and certainty of execution, and he was one of the first artists who made a marked distinction in the textures of the objects which he engraved; he was also extremely successful in his mode of representing colour. The fantastic and eccentric mode however in which he sometimes engraved his portraits, has been condemned by some critics as mere bravura to display his own remarkable facility in handling the graver; in some heads the features are engraved in continuous and peculiar lines. He was very fond of displaying his skill also in executing hair, whether of man or beast, though he frequently sacrificed truth to his propensity for making these fine lines, and in draperies and animals he has gone so far beyond the truth, that this peculiarity is the most striking feature of some of his works. A print, after Titian, of the Disciples at Emmaus, is from the nature of the cloth on the table generally known as La Nappe, and there is a dog in the picture which is such a mass of hair, that upon a close inspection it appears, says Watelet, to be made entirely of straw; yet notwithstanding these peculiarities, says the same intelligent critic, this print is the best engraving after Titian. Watelet says that Masson's faults are faults which he would have, and that they are always compensated by his beauties. The print of the Disciples at Emmaus has an additional value beyond its merits as an engraving, for, with the exception of that of Christ, all the heads are portraits—the praying disciple is the Pope Adrian IV., the other is the Emperor Charles V., the host is the emperor's confessor, and the attendant is Philip II. of Spain. Masson died at Paris, in 1700, as engraver in ordinary to the king, and a member of the French Academy of Painting. He has executed many portraits, several after his own paintings, and some of them are nearly of the size of life. Masson's portraits have a peculiar interest also as representing a great portion of the most distinguished men during the reign of Louis XIV. His historical pieces are not numerous, but they are all excellent.

MAST. [SHIP-BUILDING, P. C.]

MASTER AND SERVANT. [SERVANT, P. C.]

MASTER OF A SHIP. [SHIPS, P. C.]

MASTERS IN LUNACY. [LUNACY, P. C. S.]

MAS'U'DI', ABU'-L-HASA'N 'ALI' BEN-HUSEI'N BEN-'ALI', one of the most celebrated Arabian writers, was born, according to his own statement, at Baghdád, in the 3rd century of the hejra, or the 9th of the Christian æra. He belonged to the illustrious family of 'Abdallah-ben-Mas'úd, of the tribe Hodzáíl, and one of his ancestors was among the few early followers of Mohammed who accompanied the prophet on his flight from Mecca to Medina. Mas'údí was gifted with great talents, which he applied at an early age to learned pursuits. He gathered an immense stock of knowledge in all branches of science, and his learning was not mere book learning, but he improved it in his long travels through all parts of the East, Turkey, Eastern Russia, and Spain. In A.H. 303 he visited India, Ceylon, and the coast of China, where the Arabs had founded numerous small colonies; thence he went to Madagascar and Southern Arabia; thence through Persia to the Caspian, and he visited the Khazars in Southern Russia. [TARTARS, P. C.] In A.H. 314 he was in Palestine; from 332 to 334 in Syria and Egypt, and he says that in 345, when he wrote his last work, the second edition of his 'Golden Meadows,' he was in Egypt, and had been a long time absent from his native country, Irák. He says that he travelled so far to the West (Morocco and Spain), that he forgot the East, and so far East, that he forgot the West. Mas'údí died probably at Kahirah (Cairo), in A.H. 345, (A.D. 956), and since he visited India as early as A.H. 303, it is evident that those who say he died young are mistaken.

No Arabian writer is quoted so often, and spoken of with so much admiration by his countrymen, as Mas'údí, and although only a small portion of his numerous and voluminous works is known to Europeans, it is sufficient to show that he deserves his reputation. The variety of subjects on which he wrote astonishes even the learned, and the philosopher is surprised to see this Arab of the middle age resolving questions which remained problems to Europeans for many centuries after him. Mas'údí knew not only the history of the Eastern nations, but also antient history and that of the Europeans of his time; he had thoroughly studied the different religions of mankind, Mohammedanism, Christianity, those of Zoroaster and Confucius, and the idolatry of barbarous nations. His geographical knowledge was no less extensive and correct than his acquaintance with history, and no Arabian writer can boast like him of learning at once profound and almost universal. In the introduction to Dr. Sprenger's translation of the 'Golden Meadows,' Mas'údí is thus compared with Herodotus—'If it is the warmth for his own nationality and tenets without prejudice against what is foreign; the elasticity of mind to receive impressions, and to appreciate opinions, without want of firmness and principles; the thirst for correctness of information without preconceived criticism, which rejects what is unknown if it differs from known facts; the vastness of experience and deep learning acquired through extensive journeys, frequent intercourse with men of all nations and opinions, without neglecting that self-knowledge which is acquired in solitary self-contemplation and the basis of history (?); and if it is that extensive knowledge and enlarged mind which embraces all past, reflecting on the present: and that sound criticism, which, entering into the feelings of nations, and penetrated by those ideas, imaginations, and tendencies which mankind feel at all times, select what is national and characteristic although it may not always bear the stamp of logical reasoning; if it is for these merits that Herodotus has acquired the name of father of history, and of the greatest of all historians—El-Mas'údí has a just claim to be called the Herodotus of the Arabs.'—A characteristic feature of Mas'údí is his want of method in arranging the prodigious number of facts which a rare memory never failed to supply him with while he was writing. He illustrates the history or geography of the West with analogies or contrasts taken from China or Arabia; he avails himself of his knowledge of Christianity to elucidate the creeds of the different Mohammedan sects; and while he informs the reader of the mysteries of the extreme North, he will all at once forget his subject and transfer him into the desert of the Sahara. In this respect the Arab has a striking resemblance to B. G. Niebuhr, although this peculiarity of the German historian is less apparent in his works than it was in his lectures.

The principal works of Mas'údí are: 1, 'Akhbár-ez-zemán,' or 'History of the Times.' This work, the wonder and delight of the learned in the East, was too voluminous to meet with popularity. According to Burckhardt there is a MS. of it in the library of the mosque of St. Sophia, which, incomplete as it is, consists of twenty large volumes in 4to., and ten at least are said to be wanted to make it complete. The 'Akhbár-ez-zemán' was a general history of all nations; it has never been printed; MSS. are very rare in the East, and there are none in Europe. In the royal library in Paris however there is a MS. fragment of it on Egypt, of which there is a MS. translation by Pétis de la Croix, which has been perused by later orientalists. The Arabic work 'Kitáb taríkh-al-júmán fí mokhtasár ákhbár-ez-zemán,' or 'The Book of Pearls gathered from the History of the Times,' of which there is a MS. copy in the Royal Library at Copenhagen, and another in that of Paris, is an extract from the 'Akhbár-ez-zemán,' according to the Danish orientalist Rasmussen. Saint Martin however doubts this. This extract was made in the 9th century of our æra, by Shehább-ed-dín Ahmed-am-Mokrí, a native of Fez in Morocco. 2, 'Kitáb-al-áúsat,' 'The Book of the Middle,' the word 'áúsat' the plural of 'wesat,' being probably taken in the sense of 'proportionate,' 'not exceeding a certain size.' This is the complement to No. 1, and treats of the most curious and important questions in history and geography. There is no MS. of it in Europe, and we know some of its details only through the quotations of other Arabic writers. Aware that his works were too voluminous, Mas'údí wrote, 3, 'Morúj-ad-dhehel we m'ádin-al-jewáhir,' his celebrated 'Meadows of Gold and Mines of Gems.' This is an extract with additions from No. 1 and 2. In the Leyden MS. perused by Dr. Sprenger, the work is divided into 132 chapters, of which the doctor gives the titles in the introduction to the first volume of his translation of the work; in a Paris MS. it is divided into 129 chapters, 65 of which treat on foreign countries, and the remainder on the Empire of the Arabs. Mas'údí wrote this work in A.H. 332, in the space of one year, according to the author, for each chapter bears the date when the author finished it. This seems, however, scarcely credible. In A.H. 345 the author issued a second edition containing 350 chapters, but this work was again too voluminous, and met with less favour from the public than the first edition, of which there are many MSS. in the East as well as in Europe; but there is no MS. extant of the second edition. A Spanish Arab, El-Shatíbi, a native of Xativa, made an extract from the 'Golden Meadows,' and so did Reiske during his residence at Leyden. The 'Historia Joctanidarum,' in Schultens' 'Monumenta Antiquissima Historiæ Arabum,' is a translation of a chapter of the 'Golden Meadows;' and it appears that the Arabic treatise of which Renaudot published a translation under the title 'Anciennes Relations des Indes et de la Chine do deux Voyageurs Mohammedans' is likewise a fragment of that work, though probably of the second edition. Dr. Gildemeister published a translation of a chapter of it on India, entitled 'De Indis,' Bonn, 1836, 8vo. The Oriental Translation Fund intends to publish a translation of the whole work, of which the first volume, containing the first seven chapters, translated by Dr. Aloys Sprenger, with the co-operation of the late Earl of Munster, appeared under the title 'El-Mas'údí's Historical Encyclopædia entitled Meadows of Gold and Mines of Gems,' 1st vol., London, 1841, 8vo. The 'Golden Meadows' treat on the history, geography, religion, manners, and politics of most of the Eastern and European nations, and are full of matter both important and curious.

The following are works of Mas'údí, some of which are extant in MS., but most of them are only known by being quoted by other writers:—

4, 'Kitáb fonún-al-m'árif,' &c., 'Different Branches of Science, and of what has happened in bygone times;' 5, 'Kitáb dekháír-al-'olum,' &c., 'Treasury of Science,' &c.; 6, 'Kitáb-al-ístib sár,' 'The Book of Consideration,' treats on a matter of the highest importance to all Moslems, namely on those who were entitled to succeed Mohammed as Khalif; 7, 'Kitáb-al-mesáíl,' &c., 'The Book of Questions on the Causes of Religion;' 8, 'Kitáb-al-ábánah,' 'On the Principles of Religion;' 9, 'Kitáb-as-safwah,' 'On Sincerity,' treats on the different Mohammedan sects. Mas'údí was a schismatic, and it is believed that he left his nativo town, and settled abroad, on account of some religious differences; 10, 'Kitáb sirr-al-háyáh,' 'On tho Secret of Life,' especially on the soul, and its transmigration; 11, 'Kitáb-al-d'áwí-ash-shenf'ah,' 'On Extravagant Opinions.' It is much to be regretted that there is no translation of this work; 12, 'Kitáb tabl-an-nofús,' 'The Physician of the Soul,' with a metaphysical digression on dreams; 13, 'Hadáík-al-ábazár,' 'Beds of Flowers,' contains historical information on the descendants of Mohammed and their virtues; 14, 'Al-mabádí we al-tarákíb,' 'On Principles and Compositions,' treats among other subjects on the influence of the sun and the moon; 15, 'Kitáb-ar-rús as-sehf'yah min as-síásah am-molúkíah,' 'The Book on the Seventy Chapters,' treats on the policy of kings, and is a very remarkable work. We close this list with, 16, 'An Account of the Establishment of the Fatemite Dynasty in Africa, from a MS. ascribed to Mas'údí,' with notes, by John Nicholson, Ph. D., Tübingen and Bristol, 1840, 8vo. According to Kosegarten and Silvestre do Sacy, this work is a fragment either of No. 1 or No. 2 in our list. The MS. used by Dr. Nicholson is one of those which the unfortunate Dr. Seetzen purchased at Damascus; it is now No. 261 in the library of the reigning duke of Saxe-Coburg-Gotha, at Gotha; it was written in A.H. 627, and is consequently of more modern date. An orientalist well acquainted with the works of Mas'údí would confer a great benefit on geographers by writing a commentary on the geographical system of the author. Mas'údí had thoroughly studied the systems of Ptolemy and Marinus of Tyre, and he distinguishes between the maps of Ptolemy and those of the Syrian geographer. There is consequently no doubt that the geography of Marinus was extant in the 10th century of our æra. Mas'údí speaks of the Arabic origin of the kings of Tibet, a fact which is likewise mentioned in the Chinese annals; of a Syrian empire anterior to that of Nineveh; of Wán in Armenia as the city of Semiramis; of cuneiform inscriptions, and other matters. And since the Arabic poem of which the Rev. Charles Forster has availed himself for deciphering the Himyaritic inscription of Husein Ghoráb and others, was taken from Schultens' 'Historia Joctanidarum' mentioned above, it seems that there is no small chance of finding a clue to the Himyaritic characters in the works of Mas'údí.

(Haji Khalfah, *Biographical Dictionary*; Herbelot, *Bibliothèque Orientale*; Quatremère de Quincy, *Mémoire sur Masoudi*, in 'Journal Asiatique,' 3ième Série, vol. 7 (January, 1839), a very valuable reference; the *Introductions* to the Translations by Dr. Sprenger and Dr. Nicholson mentioned above.)

MATCH, in Gunnery, is a material employed in firing military mines or in discharging pieces of ordnance. Before the invention of fire-locks, hand-guns or small-arms were fired by matches, which the soldiers carried with them on service; and match-lock fire-arms are still used in some parts of Asia.

What is called *slow-match* is only a piece of slightly twisted hemp which has been well soaked in a strong solution of saltpetre with boiling water. When fire has been communicated to it, it burns very slowly, and a piece one yard long is scarcely consumed in eight hours. In use, the end to which fire has been applied is blown upon by the breath, when it is capable of setting fire to gunpowder or to the cotton-wick inserted in the composition which fills a fuze.

The materials employed in the formation of *quick-match* consist of a mixture of saltpetre and mealed gunpowder with spirit of wine and rain-water. The water, in which the saltpetre is put, is made to boil for an hour in a copper vessel, a wick of cotton being coiled in the liquid; the alcohol is then added and the mixture is allowed to simmer over a slow fire for a quarter of an hour. Some of the powder is afterwards introduced, and the whole is left during twenty-four hours. The cotton is then wound on a reel and the remainder of the powder is sifted over it. The match is then left for several days in order that it may become thoroughly dry, after which it is fit for use.

MATHAM, JACOB, a celebrated Dutch engraver and painter, was born at Haarlem in 1571. He was the pupil of Golzius, who married Matham's mother, by whom he acquired considerable fortune. Matham's prints are very numerous; Bartsch describes nearly 300. He died in 1631.

(Bartsch, *Peintre-Graveur*.)

MATICA or MATICO,—*Medical Properties of.* This name is applied to an astringent plant brought from Peru, where it has long enjoyed a high reputation for its styptic properties. Doubts exist as to the botanical origin of the plant, some ascribing it to a Labiate plant, resembling a *phlomis*, while others refer it to a piperaceous plant, and even assert that it is the piper asperifolium, Ruiz et Pavon, a native not only of Peru, but also of Cayenne, and the Caribbean islands. The odour of the leaves, somewhat resembling a mentha, and the large quantity of volatile oil obtained from them, lend countenance to the former opinion; while the alternate position of the leaves in most of the specimens described, entirely negatives this notion. The probability is, that two distinct plants pass under the name of Matico, which, though they have a distinct origin, have similar properties. Frequent instances of this are found in Brazil, where numerous plants are called *caa-peba;* and several, reputed antidotes to the bites of serpents, are all termed *guaco*. The analysis of the leaves seems to have been made on the piperaceous plant, which is stated to yield a drink employed by the Indians to produce effects similar to the bang obtained from the Cannabis Indica. This fact strengthens the idea of its being a piper, since the piper methysticum yields a highly intoxicating beverage. Matico has been analysed by Dr. Hodges, who found it to contain 1, chlorophylle; 2, a soft dark-green resin; 3, a brown colouring matter; 4, a yellow colouring matter; 5, gum, and nitrate of potash; 6, a bitter principle, *Maticine*; 7, an aromatic volatile oil; 8, salts; 9, lignin.

Cold water extracts, in about four hours, all the medicinal virtues of the plant, and is an eligible means of administering it. A tincture is also employed, and the powdered leaves are given both internally and applied externally. It does not owe its astringent properties to tannin: and it seems to exert a vital action on bleeding vessels, so as speedily to arrest the hæmorrhage. It has been used to check other discharges, such as the profuse expectoration and also the night-sweats of consumptive patients. Few drugs exert more than a temporary influence over these symptoms; but among such, Matico seems well entitled to attention.

MATRICA'RIA, a genus of plants belonging to the natural order Compositæ, the suborder Corymbiferæ, the tribe Senecionideæ, and the section Anthemideæ. It has a nearly flat involucre with an elongated conical receptacle: the fruit angular, not winged; the pappus is either absent, or in its place there is a slight membranous border.

M. Chamomilla, Wild Chamomile, has bi-pinnate smooth leaves, capillary simple or divided segments, solitary heads of flowers, and a hollow receptacle. This plant is common throughout Europe, on dung-hills, in cultivated ground, and on way-sides and waste places. It was formerly used as a medicine, but its place has been taken by the common Chamomile and other plants of the same order. It is the ἀνθεμίς of Dioscorides, lib. 3, cap. 144. The *Pyrethrum Parthenium*, Fever-few, is by some botanists referred to Matricaria. This plant appears to be the ἀνθέμιον of Theophrastus, 'Hist. Plant.' lib. 14, cap. 7; and the παρθένιον of Dioscorides, lib. 3, cap. 135; and of Plutarch (*Sulla*, cap. 13). Other plants, as species of Parietaria, Chrysocoma, &c., were called παρθένιον by the Greek writers.

(Babington, *Manual of British Botany;* Fraas, *Synopsis Floræ Plant. Classicæ*.)

MAURICE, THE REV. THOMAS, was born about 1755, at Hertford, where his father was then head master of the Christ's Hospital school. After his father's death the family was impoverished by an unfortunate marriage of the widow: and his education proceeded irregularly till Dr. Parr, on opening his school at Stanmore, was prevailed on to receive him as a pupil, and treated him with great generosity and kindness. At the age of nineteen he was entered at St. John's College, Oxford, whence he removed next year to University College. After taking his degree of B.A., he was ordained by Bishop Lowth; and he held for some time the curacy of the large parish of Woodford in Essex, which in 1785 he resigned for a chapel at Epping, in order to obtain greater leisure for study. Next year he married; but his wife lived for no more than four years. He had already published a translation of the 'Œdipus Tyrannus,' and several other volumes of poems; and he long continued to publish volumes of verses. But his turn for historical studies had been fostered at University College by his distinguished tutor Lord Stowell; and before removing to Epping he had begun to concentrate his attention on the history of India, for dealing with which he made proposals in 1790 in a published letter addressed to the East India Directors. The irreligious spirit of the French revolution, alarming Mr. Maurice's mind, induced him to remodel his first work after it was nearly completed, and to devote a considerable proportion of it to dissertations on the Hindu mythology. His 'Indian Antiquities' began to be published in 1791, when two volumes appeared, in octavo: the rest were brought out at intervals, the completion of the work being mainly owing to the liberality of the Earl of Harborough; and the seventh and last volume appeared in 1797. Meantime he had undertaken his 'History of Hindostan,' the three volumes of which, in quarto, were published in 1795, 1798, 1799; and a second edition appeared in 1821. In 1798 Earl Spencer presented him to the vicarage of Wormleighton in Warwickshire: next year he was appointed assistant librarian in the British Museum: in 1800 Bishop Tomline obtained for him the pension that had been held by the poet Cowper: and in 1804 he received from the Lord Chancellor the vicarage of Cudham in Kent. His 'Modern History of Hindostan,' in two volumes, appeared in 1802 and 1804. Several other volumes on Eastern history and theology, and attempts in verse, succeeded this work: and one of his last undertakings was his 'Memoirs; comprehending the History of the Progress of Indian Literature, and Anecdotes of Literary Characters in Britain, during a period of thirty years.' Of this work the three volumes appeared in 1819, 1820, and 1822. Mr. Maurice died at his apartments in the British Museum, on the 30th of March, 1824.

MAURICIA'NUS, JU'NIUS, a Roman jurist, who appears to have been writing in the time of the emperor Antoninus Pius, from an expression which he uses (*Dig.* 33, tit. 2, s. 23); he was therefore a contemporary of Gaius. The only work of his that is mentioned in the Florentine Index is six books Ad Leges. There are four excerpts from Mauricianus in the Digest.

MAURY, JEAN SIFFREIN, Cardinal, was born on the 26th June, 1746, at Vauréas, in the Venaissin, of poor but respectable parents. He showed at a very early age a great disposition for learning, and, being destined by his parents for the ecclesiastical profession, he was placed at the seminary of St. Garde, at Avignon, to pursue his theological studies. At the age of eighteen he proceeded to Paris, in the expectation of earning a subsistence by the cultivation of his talents. Though he was without friends in that city, his first publication attracted considerable notice. Encouraged by this early success he took orders, and devoted himself to the study of pulpit eloquence. In 1772 an 'Eloge' on Fénélon, which he published, was favourably received by the French Academy, and caused him to be appointed vicar-general of the Bishop of Lombez. He however soon returned to Paris, where he became very popular as a preacher. A panegyric of St. Louis, which he delivered before the French Academy, and one of St. Augustine before an assembly of the clergy, met with so much success that the abbey of Frenade in the diocese of Saintes was bestowed upon him by the king, Louis XVI., who likewise appointed him preacher to the court. In 1785 he became a member of the Academy in the place of the lyric poet Lefranc de Pompignan; and the following year the valuable benefice of the priory of Lioris was conferred upon him. At the assembly of the States-General in 1789 he was named deputy of the clergy for the bailiwick of Péronne, and soon took a prominent part in the debates. From the first he enlisted himself on the aristocratic side, where his energetic eloquence and peculiar talent at reply rendered him a formidable antagonist to Mirabeau. [Mirabeau, P. C.] His impressive and impassioned oratory, though it expressed opinions hostile to the great majority of the assembly, was often listened to with admiration and greeted with applause. His great moral courage and firm adherence to the principles which he had adopted secured for him the respect and esteem of the more enlightened portion of his enemies. 'Opposed in debate by Mirabeau, Barnave, and Clermont-Tonnerre; interrupted at every step by the hisses or cries of one or two thousand spectators in the galleries; certain of being defeated in all his efforts by an overwhelming majority; in danger of being stoned, strung up to the lamp-post, or torn to pieces at the close of every interesting debate, by the furious mob which often surrounded the Assembly, he never deviated from his duty, but was ever to be found at his post. A true soldier of the church, he threw himself with undaunted valour into the breach, and it was hard to say whether, in oratorical contests, the vehement fervour of his declamation, the cutting force of his sarcasm, or the inexhaustible resources of his knowledge, were most conspicuous.' (Alison, *History of Europe*, vol. i. p. 539.) On the 27th of November, 1790, a decree was passed in the National Assembly, by which every ecclesiastic in the kingdom was required to take an oath to maintain with all his power the new constitution; and, in case of any priest's refusal, it was declared that he should be held to have renounced his benefices. To this constitution the pope had refused his sanction, on account of its hostility to the interests of the church, and the oath was indignantly refused by the great majority of the clergy. When the day arrived for the taking it by the bishops and clergy of the Assembly, an infuriated mob surrounded the hall, threatening death to all who should refuse. On this occasion also Maury displayed his usual intrepidity, and boldly advocated the independence of his order. 'Strike, but hear me,' was his exclamation, when the last efforts of his impassioned eloquence in that Assembly were interrupted by the incessant cries of his political antagonists. At the close of the stormy session of the National Assembly, Maury, who could lend no further aid to the prostrate cause of royalty and religion, quitted his native country, and, at the invitation of Pius VI., took up his residence at Rome. He was there received with the highest distinction, and the loss of his benefices in France was more than compensated by his speedy elevation to the highest situations in the Roman church. In 1792 he was named Archbishop of Nicæa 'in partibus infidelium,' and afterwards appointed apostolical nuncio to the diet held at Frankfort for the election of the emperor Francis II. This mission accomplished, in 1794 he was elevated to the dignity of a cardinal, and was instituted to the united sees of Monte-Fiascone and Corneto.

On the invasion of Italy by the French in 1798, though every effort was made to seize Cardinal Maury, he escaped under disguise to Venice, where he assisted at the conclave assembled for the election of Pius VII. In 1799 he returned to Rome upon the conquest of Italy by Suwarrow, and was accredited as ambassador to his exiled king, Louis XVIII., who was at that time residing at Mittau. This office he resigned on the reconciliation of the church of Rome with the government of France under Napoleon, on which occasion he addressed to the First Consul a letter, couched in the most submissive language, praying for permission to return to France. This letter, which was deemed not to be in unison with the tenor of his former conduct, subjected him in after-times to the reproaches and persecutions of the party whom he had served with so much personal hazard. Napoleon gladly received the proposal of a reconciliation with so distinguished a member of the church whose establishment he was restoring in France: an interview took place between them at Genoa, and in May, 1806, Maury reappeared at Paris. The flattering reception he there met with was calculated to attach him to the interests of this chief, who admitted him to his intimacy, and availed himself of his counsels in ecclesiastical matters. He received the pension assigned to the dignity of a French cardinal, and was appointed First Almoner of Jerôme Bonaparte. In 1807 he was elected a member of the Institute in the place of Target, one of the advocates of the unfortunate Louis XVI. His acceptance in 1810 of the Archbishopric of Paris subjected him to the displeasure of Pius VII., between whom and Napoleon there had arisen much disagreement. Cardinal Maury was a warm and sincere admirer of the emperor, and he not only espoused his cause in the disputes with the head of the church, but took every occasion, which the frequent victories of this chief afforded him, of testifying his gratitude by the expressions of admiration which were contained in his mandates to the clergy of his diocese. These mandates, written in a style of the most florid eloquence, do not remind us of the impressive and energetic orator of the National Assembly; they were severely criticised by the adherents of the antient régime and by the witty frequenters of the Parisian saloons, who styled them 'archiepiscopal dispatches,' in allusion to their military tone, and their imitation of the style and manner of Napoleon's bulletins.

After the capitulation of Paris on the 30th of March, 1814, Maury was deprived by the Bourbons of the administration of his diocese; and in their resentment for his adherence to Napoleon's fortune they forgot his former daring and powerful support of their tottering throne. He then returned to Rome, where he was imprisoned during one year by the orders of the pope; he was afterwards allowed to live in retirement on a pension which was given to him in compensation for his resignation of the see of Monte-Fiascone. In this retirement, deeply affected by the ingratitude of his former party and that of the pontiff, to whose elevation he had been instrumental, he died on the 11th of May, 1817.

'Notwithstanding his extraordinary eloquence,' says the Duchess of Abrantes, who knew him intimately, 'the Abbé Maury had been before the Revolution, what he was in proscription, what he continued under the empire, a man of talent rather than a man of sense, and a curate of the time of the League rather than an abbé of the reign of Louis XIV.' She adds that his figure was in the highest degree disagreeable, but the description she gives of it appears rather a caricature than a portrait.

His principal work, 'Essais sur l'Eloquence de la Chaire,' 3 vols. 8vo., published after his death by his nephew Louis Siffrein Maury, still maintains its well-merited popularity. His mind was formed to appreciate the eloquence of Massillon, Bossuet, and Bourdaloue, and his criticisms on the other French divines are in general as correct as they are temperate. In his review, however, of English pulpit oratory he manifests a want of acquaintance with the writings of our most celebrated preachers, such as Jeremy Taylor, Sherlock, and Barrow, and he selects Blair as the best model of English eloquence; the comparison which he draws between him and Massillon is necessarily most unfavourable to the former. His own Panegyric of St. Augustine is esteemed one of the finest pieces of French pulpit eloquence. He is also supposed, conjointly with l'Abbé de Boismont, to be the author of a work entitled 'Lettres sur l'Etat actuel de la Religion et du Clergé de France.'

There is a notice of the life of Cardinal Maury in 'L'Ami de la Religion et du Roi,' vol. xii.

(*Biographie Nouvelle des Contemporains*, vol. xiii.; Alison, *Hist. of Europe*, vol. i.; *Mémoires de la Duchesse d'Abrantes*; *Biographie Universelle Classique*, Deuxième Partie, Paris, 1829; *Biographie Moderne*, vol. ii.; and a curious work entitled *Dictionnaire des Girouettes*, Paris, 1815, in which are fully detailed the political variations of the most remarkable characters of the Revolution and the empire, though sometimes with more sarcasm than truth.)

MAXIMUM IN MACHINES. In all machinery there are certain relations between the motive powers and resistances to be overcome, which render the effect produced a maximum with respect to quantity of motion or velocity, or which render the time of the performance a minimum.

In investigations relating to this subject it is usual to consider that in every machine there is a certain point at which, if the moving power were immediately applied, and a certain point at which if the resistance to be overcome were immediately applied, the effect produced would be the same as that which is produced by the machine in its actual state. Thus, in a machine consisting of several wheels and axles with which weights are raised by means of ropes passing over their circumferences, the points at which the ropes immediately connected with the moving power and resistance are tangents to the circumferences are those at which the forces are conceived to be applied. Also, if several forces act at once as moving powers, and resistances are to be overcome at once at various points, the resultant of all the forces and that of all the resistances must be taken for the effective moving power and the effective resistance. The points of application of these resultant forces are to be found, and at these points such resultant forces are conceived to be applied: the effects of friction, the rigidity of ropes, and every other impediment to the action of the machine, are also to be estimated and applied as additions to the resistance which is to be overcome; and thus a complex machine is reduced to an equivalent mechanical power of a simple form. The velocities of the points at which these resultant forces are conceived to be applied are equal to the velocities of the power and resistance.

The motion in machines may be of two kinds. On the application of force to a machine previously at rest a certain movement is induced, and this movement for a time is accelerative; but in some machines, after a while, the resisting power and the friction of the materials destroy the acceleration, when, unless the machine is subject to variations of force, as is the case with those which are impelled by the wind or by the force of men or animals, the movement will become uniform. On the other hand, there are machines which are acted on by a constantly accelerative power, as when a weight at one end of a rope passing over a wheel descends from an elevated place and raises a weight attached to the other extremity.

If the velocities of the points of application of the equivalent forces are uniform, a simple equation will express the dynamical equilibrium of the machine; for, F representing the moving power, and V the velocity with which it moves, f the force of resistance and v its velocity, we have in the case of equilibrium

$$FV = fv\ ;$$

the first member of the equation is frequently designated the momentum of impulse, and the second the effect produced by the machine.

But the effect of a moving power on a machine in motion is different from that of an equal power on a machine at rest; for the effect produced by any constant power in the former case depends upon its relative velocity, or the difference between its own velocity and that of the machine, and, by Dynamics, it varies with the square of the relative velocity. Therefore, in order to introduce the absolute effect of a force into the equation of equilibrium in place of the efficient force, there must be given the velocity which would render the force quite ineffectual, as well as the actual velocity of the point of application: let the former be represented by V′, and the latter by V; then F′ representing the absolute force when the velocity is zero, and F the actual force when the velocity is V (F′ being determined by the weight or resistance which is just sufficient to prevent the power from communicating motion to the machine, and V′ by the velocity with which the machine can move when the resistance is zero),

$$F' : F :: V'^2 : (V'-V)^2\ ;$$

whence $F = F'.\dfrac{(V'-V)^2}{V'^2}$.

Then the first member of the equation $FV = fv$ becomes

$$F'\frac{(V'-V)^2}{V'^2}.V:$$

or, putting v' for $V'-V$, which gives $V = V'-v'$, it becomes

$$F'\left(\frac{v'}{V'}\right)^2(V'-v').$$

Now, in order to find the velocity which is consistent with the production of the greatest effect by the machine, this expression, which represents the equivalent of fv, the efficient action of the machine, is to be a maximum; therefore, differentiating that expression, v' being the variable, and making the result zero, we have

$$2V'-3v'=0\ ;\quad \text{whence } v'=\frac{2}{3}V'$$

and, by substitution, $V = \dfrac{1}{3}V'$.

Hence, if the resistance opposed to the machine is susceptible of being varied, it should be rendered such that the velocity V of the point of application of the equivalent force is one-third of the greatest velocity V′ which the power can produce if unresisted. Substituting this value of V in the above equation for F we get $F = \dfrac{4}{9}F'$; therefore F V, the momentum of impulse, or the effect of the machine, becomes $\dfrac{4}{27}F'V'$ when that effect is a maximum, the resistance remaining unaltered.

If two bodies are connected together by a flexible line (supposed to be without weight) passing over a pulley at the common summit of a doubly inclined plane, the parts of the line being parallel to the surfaces of the two planes; the relation between the weights may be determined so that the momentum of that which is to be raised by the descent of the other may be a maximum. Let p and w be the weights of the bodies, or the forces of gravity acting on them vertically, and let θ and θ' be the respective inclinations of the planes on which they are placed, to the horizon; then $p \sin.\theta$ and $w \sin.\theta'$ are the forces of gravity on the planes, and consequently $\dfrac{p\sin.\theta - w\sin.\theta'}{p+w}$ is the accelerative force by which p descends.

Now, by dynamics, the velocity of a body varies with the force and time; therefore, v representing the velocity of p or w, and t the time of motion,

$$v \propto \frac{p\sin.\theta - w\sin.\theta'}{p+w}\,t\ ,$$

and consequently the momentum wv varies with

$$\frac{pw\sin.\theta - w^2\sin.\theta}{p+w}\,t\ :$$

this expression is to be a maximum; therefore, differentiating it, w being the variable, and making the result equal to zero, the value of w may be found in terms of p by a quadratic equation: thus the required relation may be obtained.

If it were required to find, in any machine which when reduced to its most simple state may be considered as a lever or a wheel and axle, the ratio of the velocity of the moving power to that of the resistance to be overcome when the latter is a maximum, the following process may be used.

Let the arms of the supposed lever, or the semidiameters of the supposed wheel and axle, be represented by r and r', the power p being applied at the extremity of r, and the resistance w at that of r'. By the nature of the lever, $p = \dfrac{wr}{r}$ in the case of equilibrium; therefore, when the power is such as to produce motion, the motive force may be expressed by $p' - \dfrac{wr'}{r}$ if applied at the extremity of r. Now, in order that the momentum of the inertia of w at a distance r' from the fulcrum may be made equivalent to the momentum of inertia of a body at a distance r, on representing such body by p'', we have $p''r^2 = wr'^2$; whence $p'' = \dfrac{wr'^2}{r^2}$: the whole inertia to be overcome, if applied at a distance r from the fulcrum, will therefore be $p + \dfrac{wr'^2}{r^2}$, and the accelerative force at the extremity of r will be

$$\frac{p+\dfrac{wr}{r}}{p+\dfrac{wr'^2}{r^2}} \quad\text{or}\quad \frac{r^2p - wrr}{r^2p + wr'^2}\ .$$

But, by dynamics, the velocity of a body varies with the force and time; therefore, representing the velocity at the end of the arm r by v,

$$v \propto \frac{r^2p - wrr}{r^2p + wr'^2}\,t\ .$$

in order to obtain the velocity at the end of the arm r, the expression for v must be reduced in the ratio of r to r'; therefore the velocity at the latter extremity varies with

$$\frac{rr'p - r'^2w}{r^2p + wr'^2}\,t\ .$$

This expression is to be a maximum; therefore, on differentiating it, r' being the variable, and making the result equal to zero, there will be obtained the ratio of r to r' (which is the same as that of the velocities of p and w) consistently with the condition that the velocity of w is a maximum.

MAXIMUS, RUTILIUS, a Roman jurist, whose period is uncertain, but he probably wrote under Severus and Caracalla. The only work of his mentioned in the Florentine Index is Ad Legem Falcidiam, or a commentary on the Lex Falcidia (*Dig.* 30, s. 125). There is one excerpt from Maximus in the Digest.

Q. CORNELIUS MAXIMUS, a contemporary of Cicero, was the master of C. Trebatius Testa, the friend of Cicero and Horace (Cicero, *Ad Diversos*, vii. 8, 17; *Dig.* 1, tit. 2, s. 2, s. 45). There is no excerpt from his writings in the Digest, but he is once cited by Alfenus Varus (*Dig.* 33, tit. 7, s. 16), who prefers his opinion to that of Servius on the question that if a vinea (vineyard) was bequeathed with the 'instrumentum,' the word 'instrumentum' comprised the rakes, spades, poles, and stakes.

MAY-FLY, the popular name of the *Neuropterous* insects of the genus *Ephemera* and its allies. [EPHEMERA, P. C. S.] *Baetis* (referred to *May-fly* in P. C.) is one of the genera of *Ephemeræ*. The *Baetis venosa*, an insect inhabiting a great part of Europe, is the type.

MAYER, SIMONE, a composer of great repute during the later part of the last, and early in the present century, was born in Bavaria (at Sandersdorf, in 1760, according to Gerber; at Mendorf, in 1763, as stated by Lichtenthal), and at an early age sent to study music in Italy, in which country he passed the greater portion of his life, and drew his last breath. In 1802 he was chosen as Maestro di Capella to the church of Maria Maggiore in Bergamo. In 1799 appeared his first distinguished opera, now known under the title of 'Il Fanatico per la Musica.' In 1802 he produced his 'Misteri Eleusini,' which on the Continent has always been considered a work of the first class, though we believe it never reached this country. It is supposed to have prepared the way for the reception of Mozart's compositions in Italy, by the introduction of richer harmony and fuller and bolder accompaniments. In 1803 he brought out, at Vienna, 'L'Equivoco,' an opera buffa; and in the same year 'La Ginevra di Scozia,' founded on the episode of Ariodante, in the 'Orlando Furioso,' which yet keeps possession of the Italian lyric stage. So indeed do his 'Lodoiska,' 'Aleramo ed Adelasia,' and 'La Rosa Bianca, e la Rosa Rossa,' the subject of the latter from the history of our wars of the Red and White Roses. But the greatness of his conceptions, and the most striking proof of the energy of his mind, are evidenced in his serious opera, 'Medea,' first made known in London by Madame Pasta, whose personation of the Sorceress of Colchis was by all acknowledged to be one of the finest histrionic efforts that any stage in any country had exhibited, and who did no less justice to the vigorous music of the composer than to the classical taste of the poet, the living and well known Signor Rosetti, who built his drama on the foundations laid by Euripides and Corneille.

The bold determination of Mayer (and also of Paer) to draw more effects from the orchestra—to give to his compositions a higher colouring, as well as deeper contrasts of light and shade, than had been allowed by the Italian school—met at first with much opposition from the sturdy non-progressionists, and, through their influence, from the public generally. But the enlarged powers of the art thus obtained soon became apparent, overcame all resistance, and the Italy of our day adds another to the numberless instances of one extreme passing into its opposite; for the clamour of all kinds of braying instruments at present supplies the want of invention, nay even of taste in plagiarism. Hence what Gretry unjustly and captiously, if not jealously, said half a century ago—that Mozart 'placed the statue in the orchestra, the pedestal on the stage'—may now with the strictest propriety be affirmed of recent Italian composers; with this addition, that the statue exhibits nothing but distorted features and false proportions. Mayer died December 2nd, 1845.

MAYHEM. [MAIM, P. C.]

MAYNE, JASPER, was born in 1604, in Devonshire. After having continued at Westminster school till nineteen years old, he was entered as a servitor of Christchurch, Oxford; and in 1631 he commenced M.A. Taking holy orders, he became a popular preacher; and, being presented by his college to two livings in the neighbourhood, continued to reside in the university. He was created D.D. in 1646. Firmly devoted to the royal cause, he was deprived of his student's place in 1648, and soon lost both of his vicarages. But his spirit was unbroken; and in 1652 he held a public disputation with a noted Anabaptist preacher. Afterwards he resided, till the Restoration, as chaplain in the family of the Earl of Devonshire. In 1660 he was restored to his livings; he then became chaplain in ordinary to the king, a canon of Christchurch, and archdeacon of Chichester. He died at Oxford, in 1672, and was buried in the aisle adjoining to the choir of Christchurch. Dr. Mayne published, in 1662, a translation of a part of Lucian's Dialogues; and also several sermons and scattered poems. But he is now remembered only through the humour which marked his conversation, and which gave birth to two plays of his: 1, 'The City Match, a Comedy,' 1639, folio; 1658, 4to.; 1659, 8vo.; and in the ninth volume of Dodsley's 'Old Plays;' a work considerably more amusing than decorous, and especially lively in its satire on the Puritans; 2, 'The Amorous Warre, a tragi-comedy,' 1648, 4to.

MAZZOLI'NI, LODOVI'CO, a celebrated painter of Ferrara, sometimes called Lodovico Ferrarese, was born about 1481. Mazzolini, like several other distinguished painters not Florentines, owing to the silence of Vasari regarding them, has only recently received his due meed of praise. His name is sometimes confounded with Mazzolino, a name given by Lomazzo to Parmigiano, as the diminutive of Mazzuola, and Vasari has noticed him slightly under the name of Malini, whence, says Lanzi, he has been divided into two—Malini and Mazzolini, and treated as two distinct scholars of Lorenzo Costa, instead of one and the same; an error which is not corrected by Baruffaldi, the historian of the Ferrarese painters, who appears to have had very imperfect knowledge of him. Mazzolini was nevertheless, in pictures of small dimensions and small figures, one of the most successful of all the early Italian painters. His works are miniature altar-pieces, and are excellent in colour, light and shade, and expression; and even in composition they are equal to the best works of their style, the symmetrical. They are on the whole little inferior to the small works by Garofalo. Mazzolini generally painted architectural backgrounds, and these are remarkable for the beautiful detail of the ornaments and figures in basso-rilievo which are introduced into them. He died at Ferrara in 1530.

The works of Mazzolini are not numerous. There are several in the Capitol and in the Doria Gallery at Rome; four in the Gallery of Berlin, among which is a valuable large picture on wood, of Christ disputing with the Doctors; it is marked MDXXIV. Zenar Ludovicus Mazzolinus Ferrariensis. There are two also very characteristic works of this master in the National Gallery, in London; and two in the Gallery of Bologna. Besides these, there are very few authenticated works by this painter, many being no doubt ascribed to other masters, especially to Gaudenzio Ferrari, as is the case with a beautiful Nativity in the Florentine Gallery.

(Lanzi, *Storia Pittorica*, &c.)

MECCA, the birth-place of Mohammed, and the holy city of the Mohammedans, is situated in that part of Arabia which is called El Hedjaz or Hedj, about 21° 30′ N. lat. and 40° 20′ E. long., and seventy miles from the Red Sea, in a straight line.

This city is situated in a narrow and sandy valley, the main direction of which is from north to south. The breadth of the valley varies from one hundred to seven hundred paces: the chief part of the city is placed where the valley is widest. In the narrower part are single rows of houses only or detached shops. The town itself, or that part where the houses are contiguous to one another and constitute one mass, covers a space of about fifteen hundred paces in length, but the whole extent of ground comprehended under the denomination of Mecca amounts to three thousand five hundred paces in length. The mountains enclosing the valley are from two to five hundred feet in height, completely barren and destitute of trees. The valley slopes gently towards the south. Most of the town is situated in the valley itself, but there are some parts built on the sides of the mountains, especially on the eastern chain.

The streets of Mecca are in general broader than those of eastern cities, the houses lofty and of stone, and the numerous windows that face the streets give them a more lively and European aspect than the streets of Egypt or Syria, where the houses present few windows towards the exterior. Many houses are three stories high. In most towns of the Levant the narrowness of the streets contributes to their coolness, and in countries where wheel-carriages are not used, a space that allows two loaded camels to pass is considered sufficient. In Mecca it was necessary to leave the passages wide for the visitors who crowd here.

The only public place in the body of the town is the large square of the great mosque, which is only enlivened during the Hadj (Pilgrimage) by the great number of well-stored shops. The streets are all unpaved, and in summer the sand and dust are as great a nuisance as the mud is in the rainy season, during which they are scarcely passable after a shower.

Mecca is badly provided with water; there are few cisterns for receiving rain, and the well-water is too brackish except for culinary purposes, though during the time of the pilgrimage the lowest class of hadjis drink it. The famous well of Zemzem in the great mosque is indeed copious enough to supply the whole town, but the water is not well tasted. The best water is brought by an aqueduct from the vicinity of Arafat, six or seven hours distant. This aqueduct is wholly built of stone, and all those parts of it which appear above ground are covered with a thick layer of stone and cement. There are two places in the interior of Mecca where the aqueduct runs above ground, and in these parts it is let off into small channels or fountains, at which some slaves of the sherif are stationed to exact a toll from persons who fill their water-skins.

All the houses in Mecca except those of the principal and richest inhabitants are constructed for the accommodation of lodgers, and divided into numerous separate apartments, each consisting of a sitting-room and a small kitchen. Since the pilgrimage has begun to decline, numerous buildings in the outskirts have fallen into ruin, and in the town many houses are rapidly decaying. Except four or five houses belonging to the sherif, two *medresa* or colleges, and the mosque, Mecca has no public edifices, and in this respect is perhaps more deficient than any other Eastern city of the same size. Burckhardt thinks that the want of splendid buildings is to be attributed to the veneration which the inhabitants entertain for their temple, and which prevents them from constructing any edifice that might possibly rival it.

The mosque, called Beitullah (God's House), or El Haram, is only remarkable for the Kaaba, which it encloses; for there are several mosques in other places of the East nearly equal to it in size and superior in beauty. The Kaaba stands in an oblong square, surrounded by colonnades; on the east there are four rows of pillars and on the other sides only three. They are united by pointed arches, every four of which support a small dome, plastered and whitened on the outside. The number of these domes is one hundred and fifty-two, and that of the pillars is variously stated at four hundred and fifty and five hundred. The columns are from one foot and a half to one foot and three-quarters in diameter, and above twenty feet in height, but otherwise there is little regularity in them. No two capitals or bases are exactly alike. The capitals are of coarse Saracenic workmanship, and some, which had served for other buildings, have, by the ignorance of the workmen, been placed upside down upon the shafts.

Seven paved causeways lead from the colonnades towards the Kaaba, or Holy House, in the centre. The whole area of the mosque is upon a lower level than any of the streets surrounding it. There is a descent of eight or ten steps from the gates on the north side into the platform of the colonnade, and of three or four steps from the gates on the south side.

Towards the middle of this area stands the Kaaba, which, according to the belief of the Mohammedans, was constructed in heaven two thousand years before the creation of the world, and Adam, the first believer, erected the Kaaba upon earth on its present site, which is exactly below the spot which it occupied in heaven. It is an oblong massive structure, eighteen paces in length, fourteen in breadth, and from thirty-five to forty feet in height. It is constructed of the grey Mecca stone, in large blocks of different sizes, joined together in a very rough manner and with bad cement. It stands upon a base two feet in height, which presents a sharp inclined plane. As the roof is flat, it has at a distance the appearance of a perfect cube. The only door which leads into it is opened only two or three times in the year: this door is on the north side and about seven feet above the ground: it is entered by wooden steps. At the north-eastern corner of the Kaaba, near the door, is the famous Black Stone; it forms a part of the sharp angle of the building, and is four or five feet above the ground. It is an irregular oval, about seven inches in diameter, with an undulating surface, composed of about a dozen smaller stones of different sizes and shapes, well joined together with a small quantity of cement and perfectly smoothed. Every pilgrim kisses this stone. As its surface has been much worn by the kisses and touches of the pious, it is difficult to determine the nature of the stone. It appeared to Burckhardt to be a lava, containing several small extraneous particles of a whitish or of a yellowish substance. The colour is now a deep reddish brown approaching to black. The four sides of the Kaaba are covered with a black silk stuff, hanging down and leaving the roof bare. This covering is renewed annually at the time of the hadj, and is brought from Cairo, where it is made at the expense of the Turkish sultan. An opening is left for the black stone. The Kaaba remains without a cover for fifteen days before the new one is put on. The black colour of the covering spread over a large cube in the midst of a vast square, gives to the Kaaba, at first sight, a very singular and imposing appearance. As it is fastened slightly, the least breeze causes it to move with a slow undulation, which is hailed by the assembled congregation as a sign of the presence of the guardian angels, whose wings by their motion are supposed to produce the waving of the covering. Seventy thousand angels have the Kaaba in their holy care, and are ordered to transport it to Paradise when the trumpet of the last judgment shall be sounded.

There are several other buildings within the area of the mosque, mostly appropriated to reading prayers, preaching, or the performance of devotions. The Zemzem, or holy well, is supposed to be the spring found in the wilderness by Hagar, at the moment when her infant son Ishmael was dying of thirst. It seems probable that the town of Mecca owes its origin to this well; for many miles round no sweet water is found, nor is there in any part of the adjacent country so copious a supply. It is enclosed by a square building of massive construction, with an entrance to the north opening into the room which contains the well. This room is beautifully ornamented with marbles of different colours; and adjoining to it, but having a separate door, is a small room with a stone reservoir, which is always full of Zemzem water; this the hadjis get to drink by passing their hand with a cup through an iron grated opening, which serves as a window, into the reservoir without entering the room. From before dawn till near midnight the well-room is constantly filled with visitors. It is considered a miracle that the water of this well never diminishes notwithstanding the continual draught from it. Burckhardt learned that the water flows at the bottom of the well, and that it is supplied by a subterraneous rivulet.

The revenue of the mosque is considerable, there being few towns or districts of the Turkish empire in which it does not possess property in land or houses; but the rent of this property is often withheld by the provincial governors, or at least it is reduced by the hands through which it passes, to a small proportion of its real value.

The inhabitants of Mecca, with few exceptions, are Arabians from different countries; but they have amalgamated, and they wear the same sort of dress and have adopted the same customs. They have two kinds of employment, trade and the service of the Beitullah; but the former has the preference, and there are very few ulemas, or persons employed in the mosque, who are not engaged in commercial affairs, though they are too proud to pursue them openly. With the exception of a few potteries and dyeing-houses, the people of Mecca have not a single manufacture. During the hadj Mecca becomes one of the largest fairs in the East, and certainly the most interesting, from the variety of nations which frequent it. The merchants of the place make large profits during this time by their merchandise. They have also a considerable trade with the Bedouins, and especially with the inhabitants of the towns of the Nedj, who are in want of India goods, drugs, articles of dress, and corn. The greatest profit however is derived from supplying food for sixty thousand hadjis and twenty thousand camels. The consumption of grain is much greater in Arabia than in any of the surrounding countries, for the great mass of the population live almost entirely on wheat, barley, lentils, and rice, and use no vegetables, but a great deal of butter. The wholesale merchants are very rich, and have establishments at Jidda, whence they receive nearly all their merchandise.

Mecca was, up to recent times, governed by a sherif, who was raised to this station by force or by personal influence, and the consent of the powerful sherif families of Mecca. He held however his authority from the Turkish Sultan, who invariably confirmed the individual who had got possession of the government. When the power of the Turks in Arabia diminished, and the Porte was no longer able to send large armies with the hadj caravans, the sherifs of Mecca became entirely independent, and disregarded the orders of the Porte. But Mohammed 'Ali of Egypt has restored the authority of the Osmanlis in the Hedjaz, and usurped all the power of the sherif, allowing to the present sherif a merely nominal sway. The sherif is chosen from one of the many tribes of sherifs, or descendants of the Prophet, who settled in the Hedjaz; they were once numerous, but are now reduced to a few families of Mecca. The succession is not hereditary, but although it seldom takes place without some contest, there is little bloodshed in general; and though instances of cruelty sometimes have occurred in these contests, the principles of honour and good faith which distinguish the wars of the Desert have generally been observed.

(Burckhardt's *Travels in Arabia*; Ali Bey's *Travels in Morocco, Tripoli, Cyprus, Egypt, Arabia, Syria, and Turkey*.)

MECHANICAL POWERS is the name given to certain simple machines or engines, for these words are applied indifferently, either of which is occasionally used by itself in moving bodies or raising weights, or any of which are combined together in the formation of the complex constructions which are employed in manufactures and the arts. Frequently however, in investigations relating to statical equilibrium, the properties of the mechanical powers are introduced when no machine is contemplated; as when, at some part of a plane surface, the effect of a pressure at another part is determined by the ratio of the distances from a supposed point of support.

The several machines to which the name of mechanical powers is applied are the LEVER, the WHEEL AND AXLE, the INCLINED PLANE, the WEDGE, the SCREW, and the FUNICULAR MACHINE: the first five have been fully described under those words in the body of this work, and the last in the Supplement.

The object proposed in every machine is to transmit a force from the point at which it is immediately applied to that at which some resistance is to be overcome or some operation to be performed; and, in the transmission, the intensity of the motive power is to be increased so that effects may be produced which could not be accomplished by that power alone. The increase of the power is obtained by causing part of the resistance which is to be overcome to rest on the machine or on the fixed points which serve for its support, so that only the part which remains is opposed to the motive force. Thus, if it be required to raise a heavy body to a certain height from the ground, no exertion of human or animal strength may be sufficient, if directly applied, to accomplish the end; but if a plane inclined to the horizon and extending from the object to the spot to which the latter is to be raised be formed, and the object can be placed on its foot, the force of gravity in the vertical direction being resolved into two forces, one of which is destroyed by the reaction of the plane, the other may be overcome by a motive power less in intensity than that which would be required if a direct application of force were made; in fact the force which will suffice for the attainment of the end diminishes in proportion as the length of the plane is greater.

The manner of overcoming a resistance, which is specified in this example, will serve also to illustrate the well known fact that in every application of a mechanical contrivance to overcome a resistance, as much advantage is lost in respect of time or space as is gained in respect of power. For it is evident that, in order to raise the object vertically through a space equal to the height of the plane, it would be necessary to move it over a space equal to the length of the plane; that is, through a space which bears the same ratio to the vertical height as the weight of the object bears to the power required to move it up the plane.

An account of the applications of the mechanical powers in the construction of complex machines would involve descriptions of most of the engines by which human labour is abridged or dispensed with; and therefore the reader is referred to works in which machines or engines are expressly described, as Gregory's 'Mechanics,' vol. ii., and Barlow's 'Treatise on Manufactures,' in the 'Encyclopædia Metropolitana.'

In determining the efficacy of the mechanical powers it is evidently necessary to consider their parts as mathematical lines, to assume that the axles are without friction and cords without rigidity, so that a perfect equilibrium may subsist in the machine itself before the moving power is applied. The most simple lever, for example, of a physical kind, is a rod of wood or a bar of iron, the arms of which, on opposite sides of the fulcrum, are of unequal weights; and, in order to reduce such a lever to a state from which the exact relation between the opposing powers may be found, the weight of each arm must be computed, and being, in imagination, applied at the centre of gravity of the arm, the product of the weight multiplied by the distance of the centre of gravity from the fulcrum is to be added to the momentum of the weight actually applied to the same arm of the lever. The sums of these momenta, when the actual machine is in equilibrio, serve to determine the correct relation between the opposing powers. The conditions of equilibrium being determined, any excess of the motive power above that which enters into those conditions will evidently overcome the resistance, or produce motion in the machine.

MECKENEN, MEKENEN, or MECHELN, ISRAEL VAN, a celebrated old goldsmith, engraver, and painter of the fifteenth century, born probably at Meckenen near Bocholt, in the bishopric of Münster, though this is a matter of speculation, and his name is written in a great variety of ways, but the above form has met with most supporters, as it is found written in full on his tombstone and upon two of his prints: some however have supposed that the engraver and painter were two distinct artists, or that Israel van Meckenen is not Meister Israel the painter mentioned by several old writers. There are eighteen beautiful old oil-paintings in the Pinakothek at Munich, and some in other collections, which are attributed to Meister Israel; they are of the Van Eyck school, but most of them have been found in the neighbourhood of Cologne and Coblenz, which is one of the reasons for concluding that Meckenen in Westphalia was the artist's birthplace, notwithstanding Meckenheim near Bonn is in the very district in which these works have been collected. There is very good evidence in favour of Meckenen, as Israel was buried at Bocholt, and he appears to have resided there. In Ottley's 'Early History of Engraving' there is a print from a drawing in the British Museum, which was made from Israel's tombstone (since lost), which contains an inscription in the old Gothic character to the following purport:—'In the year of our Lord 1503, died Master Israel van Meckenen; his soul rest in peace. Indē: iear: unses: heeren: m: V: en: iij: up: sinte: mertijns: avend: starf de: erber: meister: Israhel: vā mecknē: sijn: siele: roste in: vrede.'

Israel Van Meckenen was evidently an engraver, from the signatures on his numerous prints, and we know him to have been a goldsmith, from accounts in the old Bocholt records in which his name occurs, from 1482 to 1498 inclusive; but he is on no occasion mentioned as a painter. Yet a painter of the name of Israel is mentioned by several writers, and among them by Jacob Wympfeling, in his 'Rerum Germanicarum Epitome,' c. 67, 'de pictura et plastice;' but from this very circumstance it is argued that the goldsmith and engraver Israel van Meckenen cannot have been the painter Israel Alemannus mentioned by this writer, as engraving was not known until the latter part of the fifteenth century, and subsequent to the time that Wympfeling appears to indicate. Wympfeling however does not say *picturae* or *tabulae depictae*, but *icones* Israëlis Alemanni, which may mean prints as well as pictures, and he certainly speaks of Israel as of his own time and contemporary with Albert Dürer, while he notices Martin Schoen, or Schongauer, an excellent engraver, as already dead, of whom he says, 'qui fuit tam eximius.' He therefore clearly writes at a time when engravings were not only known, but very generally spread over Europe: his book appeared first in 1505, at Strassburg, only two years after the death of Israel van Meckenen. From these facts it is evident that there are not, as far as Wympfeling is concerned, the slightest grounds for disputing the identity of Israel van Meckenen the engraver and Israel Alemanuus the painter.

Lomazzo, in his 'Trattato della Pittura,' which was published in 1584, also notices a German engraver of the name of Israel. He calls him Israel Metro (Meken?), and says he was the master of Martin Schön; but if we substitute pupil for master we shall probably have the truth, for Israel studied the engravings of Martin, and there are still extant forty copies by him of Martin's prints. It is remarkable that out of the three hundred prints and upwards, attributed with and without certainty to Israel, one only has the date fixed to it, and that is the Virgin Mary crowned by two angels and standing upon the half-moon, with the infant Christ on her left arm, and in her right-hand a crucifix; the whole surrounded by a glory of angels. On the margin of this print is 'Dns maculavit Adam propter me et matrem meam,' &c., with the following signature and date—'Israhel V. M. A 1502,' the 5 being reversed. It is No. 44 in Heineken's list. His prints are generally signed Israhel V. M.; I.V.M.; I. M.; and sometimes

Israhel alone. He has engraved his own portrait twice: in one, his name is signed in full 'Israhel van Meckenen, goldsmit;' the other, in which his wife is also engraved, is marked 'Figuracio Facicrum Israhelis et Ide ejus uxoris—I. V. M.' The pictures attributed to Israhel van Meckenen, upon what authority is not explained, are all upon gold grounds and upon pannel. They are some of them on a large scale, many of the figures being about half the size of life, and in execution are equal to any works of their style extant; their expression is often excellent, and the colouring very clear, forcible, and effective. The Ascension and Coronation of the Virgin, Joachim and Anne at the golden gate, and several pictures of Apostles, in the Pinacothek at Munich, are very beautiful works, and if by Van Meckenen, he is evidently entitled to rank with the Van Eycks, Wilhelm von Köln, Hans Burgkmair, Hans Memling, Lucas van Leyden, and other distinguished masters of that time and school. Some of these pictures were drawn in lithography, in 1822, by N. Strixner. The supposed signature of Van Meckenen, with date, on a picture in the gallery of Vienna, mentioned in the catalogue of Von Mechel, is according to Bartsch an error.

(Heineken, *Neue Nachrichten von Künstlern und Kunstsachen;* Fiorillo, *Geschichte der Zeichnenden Künste*, &c.; Bartsch, *Peintre-Graveur;* Becker, *Kunstblatt*, 1839; Nagler, *Neues Allgemeines Künstler-Lexicon;* Dillis, *Gemälde in der Königlichen Pinakothek zu München;* Brulliot, *Dictionnaire des Monogrammes*, &c.)

MECONO'PSIS (from μήκων, a poppy, and ὄψις, a resemblance), a genus of plants belonging to the natural order Papaveraceæ, and formerly referred to Papaver. This genus stands between Papaver and Argemone. It has 4 petals, numerous stamens, a short style, 5-6 radiating free stigmas, the capsule obovate, opening by pores beneath the apex.

There is but one species, *M. Cambrica*, the Welsh Poppy, and this is a native of Great Britain, but it is a rare plant. It is also found in many parts of Europe. It has yellow flowers which are very fugacious, and are seated on long peduncles which are inflexed before the opening of the flower, so that the flower-bud is drooping. It is an ornamental plant, and may be introduced into the garden. It will grow in a rich light soil, in a shady situation. It may be propagated by dividing the roots, or by seeds.

MEDICA'GO (from μηδική, the Greek name of one of the species), a genus of plants belonging to the natural order Leguminosæ, to the tribe Loteæ, and the subtribe Trifolieæ. It has the calyx somewhat cylindrical 5-cleft, the keel rather removed from the vexillum; the stamens diadelphous; the legume many-seeded, of various forms, reniform, falcate, or cochleate, but usually twisted in a spiral manner. The species are herbs or shrubs, with the stipules usually cut; the leaves triofoliate, the leaflet usually toothed, and the peduncles 1-2-many flowered. They are exceedingly numerous, upwards of eighty species having been described.

M. sativa, Lucern, has many-flowered racemes; the pods compressed, spiral, with two or three turns, downy, unarmed; the pedicels shorter than the calyx or bract; the leaflets obovate, oblong, dentate above, emarginate. This plant is a native of Europe, and is found wild in England and Scotland. It has an erect stem, with yellow or violet flowers. It is commonly cultivated in the fields of Europe [Lucern, P. C.], and Babington says that 'the wild specimens found are scarcely naturalised.' This is the μηδική of Theophrastus, 'Plant. de Caus.' lib. 2, cap. 20; and the Medica of Pliny, lib. 18, cap. 16.

M. falcata has the racemes many-flowered, the pods compressed, sickle-shaped, downy, unarmed; the pedicels shorter than the calyx, longer than the bract; the leaflets obovate-oblong, dentate above, emarginate, mucronate. It is a native of Europe on dry mountainous pastures. In England it is a rare plant, but is occasionally found on dry gravelly banks and old walls. This species is said to be the Lucern which is cultivated in Switzerland.

M. Lupulina, Black Medick, or Black Nonsuch, has many-flowered dense oval spikes; the pods compressed, kidney-shaped, with a spiral point rugged with longitudinal branched prominent veins; the stipules obliquely ovate, slightly toothed; the leaflets roundish-obovate, denticulate above, emarginate, mucronate. It has a procumbent stem with yellow flowers, and is a native of Europe in meadows, pastures, and waste grounds, and is plentiful in Great Britain. It affords excellent fodder for sheep, and must be treated in the same way as lucern.

M. arborea, Tree Medick, is a villous shrubby plant; it has obovate-cordate leaflets nearly entire; the stipules linear, acute, entire; the peduncles racemose; the legumes stipitate, twisted, reticulated from transverse veins; 2-3-seeded, the seeds somewhat kidney-shaped. This plant is a native of the south of Europe, and appears to be the κύτισος of Theophrastus, 'Hist. Plant.' lib. 4, cap. 5; lib. 1, cap. 9; 'De Caus. Plant.,' lib. 5, cap. 6; and the κύτισος of Dioscorides, lib. 4, cap. 113. It is also the Cytisus of the Romans: Pliny, lib. 13, cap. 24; Virgil, 'Ecl.' i. 79; 'Georg.' ii. 431.

Besides the first three species, described above, *M. maculata*, *M. minima*, and *M. denticulata* are natives of Great Britain. *M. muricata* was at one time admitted into the British Flora as growing on the sea-shore at Orford in Suffolk; Mr. Babington, in his 'Manual,' states that he is 'convinced, from personal observation, that no such plant now exists in that locality.'

In cultivation the species may be easily raised from seed, and the shrubby species propagated by cuttings. The perennial herbaceous species may be propagated by dividing their roots.

(Babington, *Manual Brit. Bot.;* Fraas, *Synopsis Plantarum Floræ Classicæ.*)

ME'DICI, GIA'N GIA'COMO, Marquis of Marignano, born at Milan in 1495, was the son of a steward of the Duke of Milan. He entered early the military profession, in which he showed great courage, accompanied with a want of all principle. In the war between the Italian powers and the French, for the disputed possession of Lombardy, Medici took the part of his countrymen, and served under Pescara in the campaign of 1522, in which the French were driven out of Lombardy. He acquired the confidence of the Duke Francis Sforza and of his chancellor Morone, who employed him to murder Astorre Visconti, a descendant of the former dynasty of the dukes of Milan, who gave umbrage to the actual occupant of the ducal throne. Medici, having committed the deed, was sent to assist in recovering the castle of Musso, situated in the mountains above the lake of Como, which was still held by the French. He succeeded in taking possession of it, and he kept it for himself for years after, defying from his stronghold the duke's authority, and making predatory incursions among his neighbours. When Francis I. again invaded Lombardy, in 1525, Medici made an incursion into the Valtellina which belonged to the Grisons, and took possession of Chiavenna. The Grisons, alarmed for their own country, recalled their troops which were serving as auxiliaries in the French camp, and this defection is said to have contributed to the defeat of King Francis at Pavia. In consequence of this service, Medici was acknowledged by the duke as feudatory of Musso and other places, with the title of Chatelain.

In the subsequent quarrel between Duke Sforza and his overbearing allies the Spaniards, Medici put himself at the head of the disaffected Milanese emigrants, and annoyed the Spaniards, but after a time, the Spanish governor of Milan succeeded in conciliating Medici, on whom he conferred the title of Marquis of Musso. The object of Medici was to carve out a principality for himself at the expense of his neighbours. He again invaded the Valtellina and took Morbegno. At last, in the year 1532, Duke Sforza, partly by force, and partly by offering him a sum of money with an amnesty for the past, made him give up Musso and his other strongholds. Medici then retired to Piedmont and entered the service of the Duke of Savoy. Here his career as an adventurer terminated. Medici afterwards served in the campaign of 1536 against the French in Piedmont. Having returned to Milan after the death of Duke Sforza, he was made Marquis of Marignano by Charles V. He then went to Spain, from whence he accompanied Charles in his expedition against the revolted Flemings. From thence he went to Hungary to fight for the emperor against the Turks, and afterwards he served in Germany under Charles himself against the Duke of Saxony. Returning to Italy, Medici was appointed to the command of the expedition against Siena, which city he took after a long siege in the year 1555. On his return he was received by Duke Cosmo I. of Tuscany at Florence, with great honour, and on this occasion his relationship to the Medici of Tuscany was acknowledged by Cosmo, notwithstanding which it is still greatly doubted, or rather disbelieved. On his return to Milan, Medici fell ill and died in November, 1555. The Duke of Alba, Spanish governor of Milan, attended him in his last moments. His body was buried at Marignano with great pomp, but afterwards his brother Cardinal Giovanni Angelo Medici having become pope, in 1559, by the name of Pius IV., built him a splendid monument in the cathedral of Milan, whither his remains were transferred. Gian Giacomo Medici was one of the most able and successful commanders of the age of Charles V., but was likewise one of the most unprincipled, rapacious, and cruel.

(Missaglia, *Vita di Jo. Jacopo Medici, Marchese di Marignano;* Verri, *Storia di Milano.*)

MEDINA, the second holy city of the Mohammedans, and the place where their Prophet was buried, is situated in that part of Arabia which is called El Hedjaz, or Hedj, about 25° 15′ N. lat. and 39° 30′ E. long., and about 110 miles from the town of Yembo on the Red Sea, which is the harbour of Medina.

Medina is built on the elevated plain of Arabia, not far from the eastern base of the ridge of mountains which divide the table-land from the lower country between it and the Red Sea. The town stands on the lowest part of the plain, in which the watercourses unite, which produce in the rainy season numerous pools of stagnant water, and render the climate unhealthy. Gardens and date-plantations, interspersed with fields, enclose the town on three sides; on the side towards Mecca the rocky nature of the soil renders cultivation impossible.

The city forms an oval about 2800 paces in circuit, ending in a point. The castle is built at the point on a small rocky elevation. The whole is enclosed by a thick wall of stone, between thirty-five and forty feet high, flanked by about thirty towers and surrounded by a ditch: it is well fortified for an Arabian town, and has always been considered the principal fortress in Hedjaz. Three well-built gates lead into the town. The houses are well built, entirely of stone, and generally two stories high. As the stone is of a dark colour, the streets have rather a gloomy aspect, and are for the most part very narrow, often only two or three paces across; a few of the principal streets are paved with stone. The diminution in the number of pilgrims of late years has caused a great part of the houses to fall into decay. There are only two large streets which contain shops. There are very few large buildings within the precincts of the city. The great mosque containing the tomb of Mohammed is the only temple. There are two fine medresses or colleges. The castle, standing at the western extremity of the city, is surrounded by strong walls and several high and solid towers. It contains sufficient space for 600 or 800 men, has many arched roofs, bomb-proof, and may be deemed impregnable against an Arabian force. It contains a deep well of good water.

The suburbs extend on the west and south of the city, and cover more ground than the city. They are separated from it by an open space, narrow on the south, but forming on the west a large public place. The side of the suburbs towards this open place has no walls, but on the outside they are enclosed by a wall of inferior size and strength to that of the city. Four gates lead through this wall from the suburbs into the open country. The greater part of the suburbs consist of large court-yards with low houses built round them, and separated from each other by gardens and plantations: they are inhabited by the lower classes of the town and all those who are engaged in agriculture. Each court-yard contains thirty or forty families, so as to form a hamlet by itself. The cattle are kept in the midst of the court-yard, where there is a large well, and the only entrance is shut at night. In the western portion of the suburbs are regular and well-built streets with houses resembling those of the city. There are two mosques in the suburbs, one of which is called Mesdjed Ali, or the mosque of the prophet's cousin.

The town is supplied with sweet water by a subterraneous canal which runs from the village of Koba, about three-quarters of a mile distant in a southern direction. The water is abundant, and in several parts of the town steps are made down to the canal, where the inhabitants supply themselves with water; for the water in the canal runs at the depth of twenty to twenty-five feet below the surface. The water however is bad, and, as it contains nitre, it produces indigestion when used by persons not accustomed to it. There are also many wells scattered over the town; every garden has one, by which it is irrigated; and when the ground is bored to the depth of twenty-five or thirty feet, water is found in plenty. During the rainy season many torrents descend from the higher grounds to the lower depression in which Medina is built, and part of the city is inundated. All these circumstances have united to make a plentiful supply of water in the environs of Medina, a circumstance which made this a considerable settlement of Arabs long before it became sacred among the Mohammedans by the flight, residence, and death of the prophet, to which it owes its name of Medina or Medinet el Neby (the City of the Prophet).

The mosque containing the tomb of Mohammed bears, like that of Mecca, the name of Haram, on account of its inviolability; but in other Mohammedan countries goes by the name of Mesdjed el Neby, the Mosque of the Prophet, who was its founder. It is situated towards the eastern extremity of the city, and its dimensions are much smaller than those of the mosque at Mecca, being a hundred and sixty paces in length and a hundred and thirty in breadth; but it is built much upon the same plan, forming an open square surrounded on all sides by covered colonnades, with a small building in the centre of the square. The colonnades are much less regular than those of Mecca. On the southern side of the square the colonnade is composed of ten rows of pillars behind each other; on the western side are only four, and on the northern and part of the eastern sides only three rows. The columns themselves are of different sizes. On the southern side, where the prophet's tomb stands, and which forms the most holy part of the building, they are of larger dimensions than in the other parts, and about two feet and a half in diameter. They have no bases and the shafts rest on the ground. The columns are of stone, but being all plastered white it is difficult to decide of what kind. The roof of the colonnade consists of a number of small domes, white-washed on the outside. The interior walls are whitewashed all around, except the southern one and part of the south-eastern corner, which are cased with slabs of marble, nearly up to the top. The floor under the colonnades on the western and eastern sides and part of the north, has a coarse pavement and is nearly covered with sand, as is likewise the open square. On the southern side the whole is paved with fine marble across the whole colonnade, and in those parts nearest the tomb of Mohammed this pavement is of mosaic, of excellent workmanship. Large lofty windows, with glass panes, admit the light through the southern wall; some of them are very well painted. On the other sides there are smaller windows along the walls, but they are neglected.

Near the south-eastern corner of the mosque stands the famous tomb, detached from the walls so as to leave between it and the southern wall a space of about twenty-five feet, and fifteen between it and the eastern wall. The enclosure which protects the tomb from visitors, forms an irregular square of about twenty paces, in the midst of the colonnade, several of its pillars being included within it; it is an iron railing painted green, about two-thirds of the height of the columns. The railing is of good workmanship in imitation of filigree, and is decorated with open-worked inscriptions in yellow bronze. It is of so close a texture that no view can be gained into the interior except by several small windows, about six inches square, which are placed in the four sides of the railing, about five feet above the ground. On the southern side, which contains the two principal windows, before which the visitors stand when praying, the railing is thinly plated over with silver, and the inscription 'There is no God but God, the evident truth,' is repeated in silver letters across the railing all round these windows. This enclosure is entered by four gates, three of which are constantly kept shut, and one only is opened every morning and evening to admit the eunuchs, whose office it is to clean the floor and light the lamps. The enclosure is called El Hedjra. Permission to enter it is granted gratis to people of rank, and may be purchased by other people, from the principal eunuchs, for about twelve or fifteen dollars; but on entering the enclosure nothing more is to be seen than what may be observed when peeping in at the windows of the railing. At the distance of only a few paces from the railing is a curtain carried all round; it is equal in height to the railing. It is made of a rich silk brocade of various colours, interwoven with silver flowers and arabesques, with a band of inscriptions in golden characters running across the middle of it. This curtain has a small opening at the northern end, which is always shut, no persons whatever being permitted to enter within its holy precincts, except the chief eunuchs, who take care of it, and who put on during the night the new curtain sent from Constantinople, whenever the old one is decayed, or when a new sultan ascends the throne. The old curtains are sent to Constantinople, and serve to cover the tombs of the sultans and princes.

According to the historians of Medina the curtain covers a square building of black stone supported by two pillars, in the interior of which are the tombs of Mohammed and his two earliest friends and successors, Abu Beker and Omar. These tombs are deep holes, in which the coffins are deposited; that of Mohammed is cased in silver. The floor between the curtain and the railings is inlaid with variously coloured marble in mosaic; glass lamps are suspended all round the curtains, which are lighted every evening and remain burning all night. The whole of the enclosure is covered with a fine lofty dome rising far above the domes which form the roof of the colonnades, and is visible at a great distance from the town. As soon as pilgrims to Medina catch sight of it they repeat some prayers.

Near the curtain, and within the railings, is the tomb of Setna Fatme, the daughter of Mohammed and wife of Ali; it consists of a catafalque forming a cube, covered with a richly embroidered black brocade, and without any other ornament.

Mohammedan tradition says, that when the last trumpet shall sound Aysa (Jesus Christ) is to descend from heaven to earth, and to announce to the inhabitants the great day of judgment; after which he is to die, and will be buried in this Hedjra by the side of Mohammed; that when the dead shall rise from their graves, they will both rise together and ascend to heaven, where Aysa will be ordered by the Almighty to separate the faithful from the infidels. In conformity with this tradition the spot is pointed at through the curtain of the Hedjra where the tomb of Aysa will be placed.

Four gates lead to the interior of the mosque; a few steps are to be ascended from the neighbouring streets up to the gates, the area of the mosque being at a somewhat higher level, contrary to what is the case at Mecca. About three hours after sunset the gates are regularly shut by means of folding doors coated with iron, and not opened till about an hour before dawn; but those who wish to pray all night in the mosque can easily obtain permission from the eunuch on guard, who sleeps near the Hedjra. During Ramadhan the mosque is kept open the whole night.

The inhabitants of Medina, like those of Mecca, are not Bedouins, but strangers, who have come to the place as pilgrims and afterwards settled there, or they are descendants of such strangers. Medina is not so great a place of commerce as Mecca, and the merchants are not so rich, but it has the advantage of having a considerable tract around which is fit for cultivation, and there are many wealthy landowners in the town, who let out their possessions to poorer people. Wheat and barley are cultivated, but the chief profit arises from the plantations of date-trees, the fruit of which is held in greater estimation than the dates of Egypt.

(Burckhardt, *Travels in Arabia.*)

MEDITA'TIO FUGAE WARRANT, in the law of Scotland, is a writ by which a debtor, supposed to be about to make his escape from the country, is arrested and kept in custody, until he pay the debt, or find security to pay it if he shall be judicially found liable to do so. It deserves notice from its being an old consuetudinary practice in Scotland, which happens to be in unison with the late legislation of England on the subject of debtor and creditor. In Scotland no such system as that of arrest on mesne process according to the law of England anterior to the 1 & 2 Vict. c. 110, appears to have ever been acknowledged; and it was only on the ground that he was about to flee the realm, that a debtor could be arrested, unless on the authority of a final judgment of a court of law, or on the extracted registration of one of those documents in which by 'a clause of registration for execution' or by commercial custom (as in the case of bills of exchange) the granter agrees to be put in the position of having a decree recorded against him. A meditatio fugae warrant may be granted by any judge having jurisdiction in questions of debtor and creditor, as by a sheriff, a magistrate of a burgh, a justice of peace, &c. When granted by a sheriff, it has, by a late act, the advantage that it may be executed in any part of Scotland, whether without or within the jurisdiction of the sheriff who grants it (1 & 2 Vict. c. 119, § 25). The ground on which the judge grants the warrant is, in the first place, the oath of the creditor, who must distinctly set forth the amount, nature, and origin of the debt. The debtor is then brought before the judge, who, hearing the statement of both parties, must act on his discretion. It is said that if a magistrate on a distinct oath of debt should refuse to commit, he is personally liable to the creditor for the consequences, and that if, on the other hand, he grant a warrant on an improbable or incoherent statement, he will be liable in damages to the person committed. At all events a person desiring a meditatio fugae warrant is liable to damages if he obtain it on a false statement. A person imprisoned on such a warrant must be liberated in six months, unless his further imprisonment be authorized by other judicial proceedings. By 5 & 6 Wm. IV. c. 70, imprisonment for any debt under 8*l.* 6*s.* 8*d.* (100*l.* Scots) was abolished in Scotland, and it was lately found by the court of session that meditatio fugae warrants come within the act.

MEGALI'CHTHYS, a genus of fossil Ganoid fishes, from the carboniferous strata of Edinburgh, Glasgow, Leeds, Manchester, Wigan, &c. (Agassiz, *Récherches sur les Poissons Fossiles.*)

MEGA'LODON, a genus of fossil Conchifera, proposed by Goldfuss. From the Devonian strata.

MEGA'PHYTON, a genus of fossil plants, from the coal-measures. (Artis, *Antediluvian Phytology.*)

MELALEUCA (from μέλας, black, and λευκός, white), a genus of plants belonging to the natural order Myrtaceæ. It has the calyx-tube nearly hemispherical, the limb 5-partite; the petals 5; the stamens numerous, combined into 5 elongated bundles, which alternate with the petals; the anthers incumbent; the style filiform, the stigma obtuse; the capsule connate with and enclosed in the thickened tube of the calyx, which is sessile on, and adnate at its base, to the flower-bearing branch, 3-celled, many-seeded; the seeds angular. The species are trees or shrubs with alternate or opposite entire leaves, equal at the base, with flowers perfectly sessile, or somewhat combined with the branch, arranged in spikes or heads, and of a white, yellowish, or purplish colour.

M. Cajuputi, Roxburgh, *M. minor*, Smith, has the leaves alternate, elliptic-lanceolate, acutish, rather falcate, 3-5-nerved; the flowers rather distant in spikes, the rachis and calyxes villous. This is the species which yields the chief part of the oil brought to Europe under the name of Cajeput oil. It is a native of Amboyna and other East India islands. [MELALEUCA CAJEPUTI, P. C.]

M. Leucodendron, White-tree, or Cajeput-tree, has alternate long lanceolate acuminated falcate 3-5-nerved leaves; the flower-bearing branches pendulous; the flowers in spikes rather distant, which, as well as the rachis, are quite glabrous. It is a native of the East India islands, and was at one time supposed to yield the oil of commerce. Roxburgh asserts that it possesses little or no fragrance in its leaves, and that it is seldom or never used for the distillation of the oil which is used in the European markets.

Upwards of thirty species of Melalenca have been described, the majority of which are natives of New Holland. Many of them are fine plants with beautiful blossoms, and very desirable for the conservatory or greenhouse. They grow well in a mixture of peat, loam, and sand, and may be propagated by cuttings, which will readily take root if planted in a pot of sand and placed under a hand or bell glass.

(Lindley, *Flora Medica*; Don, *Gardener's Dictionary.*)

MELAMPY'RUM (from μέλας, black, and πυρός, wheat), a genus of plants belonging to the natural order Scropbularineæ or Scrophulariaceæ. It has a tubular 4-toothed calyx; a ringent corolla; the upper lip compressed laterally with reflexed margins; the lower lip furrowed, trifid; the capsule oblong, obliquely acuminate, compressed; one or two seeds in each cell, smooth. The species are annual plants, with opposite lanceolate linear entire leaves, with opposite usually secund terminal flowers. Eight species are enumerated by Don, six of which are European and two American. Of the six European four are natives of Great Britain.

M. cristatum, Crested Cow-wheat, has the spikes densely imbricated, 4-sided, and the bracts heart-shaped. It is a native of woods and thickets in the eastern counties of England, and also generally of the north and middle of Europe.

M. arvense, Purple Cow-wheat, has lax conical spikes, and ovate lanceolate attenuated bracts. The bracts are of a purple rose-colour; the flowers yellow, variegated with rose-colour and purple. It is a native in fields of wheat in the south of Europe, and is found in Great Britain, though only rarely, in Norfolk and the Isle of Wight.

M. pratense has the flowers axillary, secund in distant pairs; the calyx closed; the upper lip protruded. It has large pale yellow flowers. It is a native of Great Britain, but not a common plant. There is one other British species, *M. sylvaticum*, with an open calyx, and lips equal in length. It is a rare plant, and is found in alpine woods.

(Babington, *Manual of British Botany*; Don, *Gardener's Dictionary.*)

MELA'STOMA (from μέλας, black, and στόμα, a mouth, because the berries when eaten stain the mouth black), a genus of plants, the type of the natural order Melastomaceæ.

It has the tube of the calyx ovate, half-adhering to the ovary, densely covered with scales or bristles; the limb 5- rarely 6-cleft, the segments alternating with the appendages, both deciduous; the petals 5-6; the stamens twice the number of the petals; the anthers oblong linear, a little arched, opening by a pore at the apex, each furnished with a stipe-formed connective, which is in some species elongated, and in others short, but always biauriculate or emarginate in front; the free part of the ovarium conical and bristly; the style filiform, somewhat thickened at the apex; the stigma a pruinose dot; the capsule baccate, 5-6-celled, opening irregularly; the seeds cochleate. The species of this genus are shrubs, which are usually covered with strigæ. The leaves are petiolate, and either quite entire or serrulated. The flowers are large, white, rose-coloured, or purple.

M. Malabathricum, Malabar Melastoma, is a shrubby plant with tetragonal branches rough from strigæ; the leaves elliptic-oblong, obtuse at the base, acute at the apex, quite entire, green on both surfaces, and scabrous from strigæ; the corymbs 1-5-flowered; the calyx clothed with adpressed strigose scales, with ovate acute lobes, the connectives of the anthers short, or very long. It is a native of the East Indies, and frequent in the Indian Archipelago. The leaves of this plant are employed by the natives, where it grows, as a remedy in diarrhœa, dysentery, and mucous discharges.

Between thirty and forty species of Melastoma have been described. They grow in the warmer districts of the Old and New World, and are found in South America, Asia, and Africa. Their flowers are very handsome, and all the species may be cultivated for ornament. They grow well in a mixture of loam, peat, and sand, and young cuttings root freely in sand in heat under a band-glass.

(Lindley, *Vegetable Kingdom*; Don, *Gardener's Dictionary*.)

ME'LICA, a genus of plants belonging to the family of Grasses. It has nearly equal glumes, with lateral ribs, nearly as long as the ovate spikelet of 1 or 2 flowers rounded on the back, and a club-like rudiment of one or two more; the paleæ hardening on the loose fruit; the styles terminal. There are two British species of this genus, *M. uniflora* and *M. nutans*, which are found in damp shady woods.

(Babington, *Manual of British Botany*.)

MELILO'TUS (from μέλι, 'honey,' and λωτός, 'lotus'), a genus of plants belonging to the natural order Leguminosæ. It has a calyx with five nearly equal teeth, the keel obtuse, the filaments filiform, the ovary straight, the pod subglobose or oblong, 1-celled, 1-4-seeded, longer than the calyx, the petals distinct, deciduous. The species are herbaceous plants with stipules adnate to the petiole, and trifoliate leaves with usually toothed leaflets. None of them are ornamental plants, and they are seldom cultivated except in botanical collections. Two of the species are used as fodder for animals. [MELILOT, P. C.] Two species are found native in Great Britain. *M. officinalis*, the common Melilot, has lax racemes, with the corolla twice as long as the calyx; the wings, keel, and standard equal; the pods ovate, acute, compressed, transversely wrinkled, hairy; the leaflets serrate, truncate, narrowly ovate; the stipules setaceous, entire. *M. vulgaris* has the wings and keel equal, but shorter than the standard; the pods ovate, obtuse, mucronate, reticulate, rugose, and glabrous. It is a rare plant, and is found in sandy and gravelly places near the sea.

M. Messanensis, Messina Melilot, has an erect stem, with obovate-cuneated denticulated leaflets; the stipules broad at the base, toothed, linear at the apex; the racemes few-flowered; the teeth of the calyx nearly equal, hardly shorter than the tube; the legume lanceolate, acute, very much nerved, 1-seeded; the seeds ovate, compressed, large, black, rugged from dots. This plant is a native of Barbary, Sicily, Piedmont, and the Straits of Messina. It is the Λωτός of Theophrastus, *Hist. Plant.*, lib. 7., cap. 9 and 14; the λωτός ἥμερος of Dioscorides, lib. iv., cap. 171. It is also the *Lotus* of the Romans (Pliny, xiii. 17; xxxii. 21; Virgil, *Georgic.* ii. 84, and iii. 394).

None of the species of this genus are worth cultivating as ornamental plants. They may be easily propagated by seeds, which should be sown in the open border in spring. A light dry soil suits them best.

(Fraas, *Synopsis*; *Manual of British Botany*; Don, *Gardener's Dictionary*.)

MELISSA (from μέλισσα, a bee), a genus of plants belonging to the natural order Labiatæ or Lamiaceæ. This genus has been variously defined according to the different views of systematic botanists. Bentham, in his monograph on the Labiatæ, has referred about 30 species to this genus. They are all known by the common name of Balms, and some of these species have been described under CALAMINTHA, P. C. S. The genus thus extended has the following characters:—The calyx is tubular, 13-nerved, usually striated, bilabiate; the upper lip generally spreading tridentate; the lower lip bifid; the throat naked or villous inside; the tube of the corolla straight or incurvedly ascending, naked inside, usually exserted, the throat generally inflated, the limb bilabiate, the upper lip erect, flattish, entire, or emarginate; the lower one spreading, with flat lobes, the middle lobe usually the broadest, entire or emarginate; the stamens 4, didynamous, ascending, approximate by pairs at apex, or rarely a little distant, lower two the longest, the superior two sometimes sterile, the filaments toothless, anthers free, two-celled, the connective often thickened, the cells distinct, parallel, diverging; the lobes of style sometimes equal, subulate with minute terminal stigmas; sometimes the lower lobe is elongated, recurved, flattened, with stigmatiferous margins; the achenia dry and smooth. The species are usually herbs, sometimes under-shrubs, with a variable inflorescence.

The only species of the old genus Melissa admitted into the British Flora is *M. officinalis*, common Balm. It has ovate crenato-serrato acute leaves, paler beneath, the calyx subcampanulate, slightly ventricose in front, distinctly 2-lipped, the upper lip flat truncate, with three short broad teeth, the lower with two lanceolate teeth. This plant, although it has a place in the British Flora, is a doubtful native. In its recent state it has a rough aromatic taste and a pleasant lemon-like smell. It is frequently used in infusion, under the name of Balm Tea, as a common drink in fevers. It was one of the medicines recommended by Paracelsus, but at the present day it is only used as a popular remedy.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

MELLAN, CLAUDE, a French painter and distinguished engraver, was born at Abbeville, in 1601. He studied in Rome under the then celebrated Vouet, but he soon gave up painting for engraving, which from that time became his chief business. He remained some years in Rome, and engraved many plates there, executed in the ordinary method of line-engravers. He did not altogether adopt his own peculiar method of engraving by a single line, until his return to France. He latterly executed all his plates by single lines, that is, instead of crossing one set of lines by a second or even a third set, where great depth was required, he accomplished a similar effect by merely thickening the single set of lines; the varieties of light and shade he produced wholly by varying the thickness of the line. Mellan carried this peculiarity to a great extreme on one occasion; he engraved a Sancta Veronica, or the Face of Christ, as large as life, by a single spiral line, commencing at the end of the nose; the execution is beautiful, and it is an extraordinary monument of patience and perseverance, but what it has gained in singularity it has lost in effect as a work of art: he made two preparatory drawings for this print; one is in the Royal Library at Paris.

Mellan's prints are very numerous: they amount, according to some accounts, to upwards of 500; many of them are after his own designs. His masterpieces are Rebecca at the Well, after Tintoretto; St. Peter Nolascus borne by two Angels, after a design by himself; and Pope Urban VIII., after Bernini. He enjoyed a great reputation during his lifetime; Charles II. invited him to England, and Louis XIV. granted him an annual pension, and gave him apartments in the Louvre. He died at Paris, in 1688, aged eighty-seven.

(Florent Le Comte, *Cabinet des Singularités*, &c.; Huber, *Manuel des Amateurs*, &c.)

ME'LOE. The Linnean genus *Meloe* included the several genera of heteromerous Coleoptera now forming the family *Cantharidæ*, interesting on account of its including those beetles known under the name of 'blistering flies,' and employed in medicine. The term *meloe* is now restricted to the apterous *Cantharidæ*, and the species are all beetles with large and swollen bodies, and short oval elytra, lapping over each other at the base of the suture. They are sluggish creatures and feed on various plants, especially the species of ranunculus. When alarmed they emit from the articulations of their legs an oily, yellow, or reddish liquid. Latreille maintained that this insect was the *buprestis* of the antients, to which noxious qualities were attributed. (See his paper on the subject in the 12th volume of the *Mémoires du Mu-*

eum d'Hist. Naturelle.) The nature of the larva of the *meloe* has been a subject of considerable discussion among entomologists, having been supposed to be a minute, active, parasitic animal found on bees and flies. Most entomologists have held this view since the time of Linnæus, but the observations of Geoffroy, Newport, and Westwood, go far to prove that it is a mistake, and that there is no anomaly in the case.

MELVILLE ISLAND is situated on the northern coast of Australia, between 11° and 12° S. lat. and 130° 20′ and 131° 34′ E. long. It is separated from Bathurst Island, which lies east of it, by Apsley Strait, which is forty-six miles long, and between two and four miles wide. East of the island lies Coburg Peninsula, where a British colony was established some years ago [ESSINGTON, PORT, P. C. S., vol. i. p. 345], and between them a strait, which at the narrowest place is fifteen miles wide. This strait is called Dundas Strait. The eastern end of Melville Island is only fifteen miles from the mainland of Australia, and the sea between them was called Clarence Strait by Captain King. It is studded with small islands, rocks, and reefs, between which run rapid currents. The area of the island may be about 1800 square miles.

The northern line of coast, and also the western, along Apsley Strait, are low, intersected by swamps, and covered by impenetrable woods of mangroves. The interior is more elevated, and has an undulating surface. In the centre it rises about 130 feet above the sea-level, but towards the southern side there are a few small elevations, which probably rise to 200 feet. The island is well clothed with wood, and presents one mass of thick green foliage. The surface of the elevated ground is covered with small shining masses of ironstone having a metallic lustre as if they had been ejected from a furnace. The sloping sides are less stony, and the flat ground is generally quite free from stone. Streams of water are scarce, but the swamp water is generally drinkable, and by sinking wells a constant supply of excellent water is obtained. The swamps are generally full of long grass and reeds, intermixed with small trees. Narrow gullies choked up with a kind of cane or rattan (Flagellaria indica, Linn.) lead into these swamps.

The soil of the island is of inferior quality, partaking of the character of the ironstone which is generally spread over it. The subsoil after digging two feet and a half is much better, being a brown mould of a saponaceous texture. Close to the shore the country is very rocky, and the soil is light and shallow, intermixed with sand and gravel. Bordering on the swamps it is richer and more productive, and it is supposed that some of the flats so situated are capable of producing rice.

Vegetation is very luxurious, and during the whole year there is plenty of grass for cattle. The timber is in general of good quality, and although trees which are small in the stem predominate, there are many of considerable dimensions, and applicable to house-building, furniture, ship and boat building, and to agricultural purposes. The average number of trees to an acre is about one hundred and twenty, but in some places they amount to one hundred and eighty. Among these forest-trees several species of eucalyptus are most abundant. The cabbage-tree is common. Ginger grows wild.

The most common quadrupeds are kangaroos, opossums, bandicoots, native dogs, a small brown rat, and a species of squirrel. The Ternate bat or flying fox is very numerous. The birds are mostly distinguished by their beautiful plumage, especially some species of cockatoos and parrots. There are also several varieties of king-fisher, among them the gigantic king-fisher (Dacelo gigantea), swamp pheasants, quails, curlews, wild ducks, sand-larks, wild geese, several kinds of cranes, and a wild fowl of the gallinaceous order of considerable size. Many beautiful small birds are very abundant. There is a great variety of snakes, measuring from one foot to twelve in length; some of them are venomous. There is also a great variety of lizards of beautiful colours: the largest are the frilled iguana (Chlamydosaurus Kingii), and the common iguana (Iguana delicatissima). Alligators abound in Apsley Strait, and turtles are found at some places on the coast. The most destructive of the numerous insects are the white ants.

The number of natives is rather large, considering that they lead a wandering life, and during the dry season live on kangaroos, opossums, bandicoots, iguanas, and lizards; and during the wet season on fish, turtles, crabs, and other shell-fish; their vegetables are the cabbage-palm and fruit of the sago-palm. They are evidently of the same stock as the natives of Australia, but they are more athletic, active, and enterprising. Their language is said to be so far different, that a native of the southern coast could not understand one word of what they said. In the construction of their canoes, spears, and waddies, they show much ingenuity, although the workmanship is rough from want of tools. Their canoes, water-buckets, and baskets are made of bark, neatly sewed together with strips of split cane. They are extremely diffident of strangers, and it was found impossible to enter into any friendly intercourse with them during the four years that the British colony existed on Aspley Strait.

The settlement on Aspley Strait, called Fort Dundas, was formed in 1824, for the purpose of attracting to it the commerce of the eastern part of the Indian Archipelago. But the inhabitants of these islands did not resort to the new colony, and it was ascertained that the soil was far from being fertile, and the climate very debilitating to Europeans, although not decidedly unhealthy. These combined circumstances led to the abandonment of the settlement in 1828, but in 1837 a new one was established in Port Essington on Coburg Peninsula, a place which is visited by the inhabitants of Macassar and other islands, to fish for trepang.

(Campbell's *Geographical Memoir of Melville Island and Port Essington*, in 'London Geogr. Journal,' vol. iv.)

ME'LYRIS, a genus of Coleopterous insects established by Fabricius, for the reception of certain species of the Linnæan genera *Cantharis* and *Dermestes*. It belongs to the family *Serricornes* of Latreille, and constitutes the type of the family *Melyridæ*. The *Melyridæ* are active and often gaily coloured little beetles, usually found on flowers, which they frequent for the purpose of preying on other insects. They have soft, oblong, or ovate depressed bodies; short, filiform, pointed palpi; exserted heads; dentated mandibles; and usually filiform and serrated antennæ. Some of the species of *Malachius*, a genus of *Melyridæ*, found in Britain, are furnished with red bladder-like appendages at the anterior angles of the thorax and base of the abdomen, capable of being contracted or dilated at the will of the insect, and usually exhibited when it is alarmed. Mr. Westwood regards these bodies as portions of an apparatus for emitting an offensive effluvium, and Curtis as means of enabling the insect to increase or decrease its gravity during flight. The larvæ, as well as the perfect insects, are carnivorous. The family is intermediate between the *Telephoridæ* and *Cleridæ*. The genera *Malachius*, *Dasytes*, *Enicopus*, *Dolichoroma*, and *Aplocnemus*, contain British species. See Westwood's *Modern Classification of Insects*.

MEMLING, HANS, or JAN, until recently more commonly called *Hemling*, and sometimes *Hemmelinck*, and *Memmelinck*: Memling appears to be the correct form. This admirable painter of the old Flemish or German school of the fifteenth century has been lately the subject of several inquiries, but even the correct spelling of his name is not yet agreed upon, though the majority of writers have adopted the form Memling. The place of his birth is likewise a matter of doubt. Dr. Boisserée writes his name Hemling, and upon the strength of a manuscript found by Herr von Lassberg at Eppishausen near Constanz, has assumed Constanz to be the place and 1439 to be the date of his birth. This date is later, though approximate to the common account, and accords with the dates on most of his pictures. Van Mander calls him Memmelinck, and a native of Bruges: according to some accounts he was born at Damme near Bruges, about 1425.

Regarding the spelling of his name, the correct form is apparently Memling, for, as shewn by M. de Bast of Ghent, the initial letter of the name on his pictures is the very same letter as the initial of Maria on a coin of Mary of Burgundy, and in many other names commencing with M in documents of the period. It is the capital M of that time, though more like the modern H: it very much resembles an H with an additional short stroke in the middle, reaching from the under side of the cross line to the bottom of the letter; or somewhat like a small Roman m, the two outside strokes being twice the height of the middle one. This peculiar letter however occurs in two instances as an H also; the question is therefore not absolutely decided. Because a Hans Hemling or Memling is mentioned in a German MS., it does not follow of necessity that he is identical with the celebrated painter of this name; nor, on the other hand, does Memling's residence in Bruges prove that he was a Fleming, as he may have been attracted there by the fame of John van Eyck. Marcus van Vaernewyck, in his 'Historie van Belgis,' 1565, notices a German painter of the name of Hans who lived at

Bruges, and he alluded very probably to Memling. Vasari also apparently alludes to Memling when he speaks of Ausse (Ansse) of Bruges. The dates of Memling's pictures range, according to the printed accounts, between 1450 and 1499. The date 1450 is found on the portrait, at Venice, of Isabella of Aragon, wife of Philip of Burgundy; this picture is mentioned in the anonymous Journal published by Morelli in 1800 —'Notizia d'Opere di Disegno nella prima Metà del Secolo XVI., esistenti in Padova, Cremona, Milano, Pavia, Bergamo, Crema, e Venezia, scritta da un Anonimo di quel Tempo,' in which the painter is called Mamelino or Memelingo. If this date be correct, Memling must have been born before 1439, and cannot have been the Hans Hemling of Constanz. The date 1499 is found on a small picture in the possession of M. van Ertborn at Utrecht; it is also the year in which he finished some paintings for the Carthusian convent of Miraflores near Burgos in Spain, in which he is said to have died not long afterwards: the account is given by Ponz, in his 'Viage do España.' This convent was destroyed by the French in 1812. Memling appears to have lived some years in Spain: he is supposed to be the Juan Flamenco of Flanders who was at Miraflores between 1496 and 1499, and perhaps later. He probably also visited Italy and Germany, and certainly Cologne; and he is said to have served Charles the Bold, Duke of Burgundy, both as painter and as warrior. The story is, that he was at the battles of Granson and Morat, in 1476; and in the beginning of 1477 was admitted, ill from wounds and destitute, into the Hospital of St. John at Bruges, a religious institution, into which, by provision of its foundation, none but inhabitants of Bruges or Maldeghem could be admitted. It was during his residence in this hospital that he painted the beautiful pictures which still adorn that establishment and Bruges, and have placed his name among the first of the painters of the fifteenth century.

The principal work by Memling in this hospital is the history, in minute figures, of St. Ursula and her companions, exquisitely painted in oil, in many compartments, upon a relic case of a gothic design, known as La Châsse de S. Ursule. This châsse, or shrine, has been made the subject of a special work by Baron von Keversberg, intituled 'Ursule, Princesse Britannique, d'après le Legende, et les Peintures d' Hemling,' Ghent, 1818. The paintings have been drawn in lithography by MM. Manche and Ghemard. Memling painted also during his stay in this hospital the small picture of the Adoration of the Magi, and the splendid large altarpiece of the Marriage of St. Catherine; both of which are still there.

The Marriage of St. Catherine, in which the figures are much larger than is usually the case in Memling's works, was painted in 1479, and is one of the most brilliant pictures of the fifteenth century. It is in three compartments, a centre and two revolving wings. In the centre is the marriage of St. Catherine, attended by angels and various saints; and in the background are painted episodes illustrating the lives and martyrdoms of the attendant saints and of St. Catherine herself. The left wing is the beheading of John the Baptist; the right wing is the vision of John the Evangelist in the island of Patmos: the last is a remarkably comprehensive composition. On the exterior of the left wing are two Hospital Brothers, the Apostle James, and St. Antony of Padua; on the right exterior are two of the Hospital Sisters, with saints Agnes and Clara. There is an inscription on this work, but as it has been renewed, it cannot be taken as an authority in a difference respecting the signification of letters: it is however variously reported. There are three other pictures by Memling in this hospital:—a Descent from the Cross, on wood, with two wings; the Madonna and Child, with a portrait of Martin van Nieuwenhoven, burgomaster of Bruges in 1497, on two pannels closing one upon the other, painted in 1487; and a female, inscribed 'Sibylla Sambetha quæ et Persica an: ante Christ nat. 2040.' There are other works by this painter in the Academy of Arts, and in other buildings of Bruges.

There is, or was in 1832, a small portrait of a young man in the costume of the hospital brothers of St. John, in the collection of Mr. Aders in London, which is said to be that of Memling himself, but the date on the picture is 1462, fifteen years before Memling is supposed to have entered that hospital, and the history of the picture is not positively known. Passavant has engraved it in his 'Kunstreise durch England und Belgien.' Dr. Waagen does not mention it. Another very interesting work, by Memling, in the collection of Mr. Aders, is the travelling altarpiece or altar of the Emperor Charles V., which was preserved in the cathedral of Burgos until the French invasion of Spain, when it was taken to Paris and sold, and it was again sold subsequently in London. It consists of three equal-sized pannels, joined together laterally by hinges, and shutting into one. They are semicircular at the top, and each measures 25 inches by 16 inches. The paintings are in honour of the Virgin Mary: they are described minutely by Dr. Waagen in his work on 'Arts and Artists in England.'

There are also pictures attributed to Memling at the Hague, at Antwerp, at Louvain, at Berlin, and at Munich. The nine works attributed to him at Munich are worthy of all the praise that has been bestowed upon Memling; they were nearly all formerly in the Boisserée collection. Of these nine the following are remarkable pictures:—Israelites collecting the Manna; St. Christopher carrying the infant Christ; Abraham and Melchisedek; the Seizure of Christ in the Garden: a Sancta Veronica, or Face of Christ; and above all, the Joys and Sorrows of the Virgin, and the Journey of the three Kings from the East, with their numerous retinues, six feet wide by two feet and a half high. Few pictures can have cost so great an amount of labour as this last mentioned. Besides an extensive and elaborate landscape covering almost the whole pannel, for the point of sight is very high, it contains about fifteen hundred small figures and other objects of various kinds, all executed with the minutest attention to detail, with extreme care, and with a clearness and brilliancy of colouring which could not easily be surpassed, and has certainly seldom been equalled. Memling, not satisfied with the mere representation of the epiphany or the adoration of the kings, has represented them in every stage of their expedition from the setting-out to the accomplishment of their mission; he has represented all the countries they journeyed through, and in the extreme distance, even their own kingdoms and homes, with their cities and their palaces. In the foreground are represented also, besides the nativity and adoration of the kings, the flight into Egypt, the murder of the Innocents, and the other principal events of the life of Christ, to his ascension, and to the descent of the Holy Ghost. The figures range in size from about six inches to one, and the whole is well modelled and arranged, and perfectly harmonious in light and shade and colour.

Rathgeber enumerates upwards of one hundred pictures which are attributed to Memling, but few of them can be authenticated. Some of them have been lithographed by Strixner. Memling also decorated missals and other books of church service: there is one in the library of St. Mark at Venice. There are other similar works attributed to him in different parts of Europe.

The date and place of Memling's death are as uncertain as those of his birth, but it probably took place in Spain, between 1499 and 1506.

(Descamps, *Voyage Pittoresque de Flandre*, &c.; *Notice des Tableaux qui composent le Musée de l'Hôpital Civil de S. Jean, à Bruges*, 1842; Passavant, *Kunstreise durch England und Belgien*, and in *Kunstblatt* for 1841; Schnaase. *Niederländische Briefe*; Johanna Schopenhauer, *Johan van Eyck und seine Nachfolger*; De Bast, *Messager des Sciences et des Arts*, Ghent, 1825, 1832, 1836; and the *Kunstblatt*, 1821, 1822, 1826, 1833, 1841; Rathgeber, *Annalen der Niederländischen Malerei*, &c.)

MEMMI, SIMONE, or SIMONE DI MARTINO, was a very celebrated Italian painter of the fourteenth century. Though he is called Memmi by Vasari and Lanzi, Martini appears to be the more correct name, as Martino was the name of his father, and he has inscribed his name as Simon Martini upon some of his works. Memmo, or Guglielmo (William), was the name of his father-in-law, and he is said to have also inscribed himself Memmi upon some of his pictures. The date of Simone's birth is uncertain, but he was born at Siena in 1284, or, according to Vasari, about 1285: he is supposed by some, upon the authority of Vasari, to have been the pupil of Giotto, which Rumohr and others consider scarcely possible. He was the rival of Giotto: Petrarch speaks of the two together in one of his letters in the following terms:—'I have known two excellent painters, Giotto, a citizen of Florence, whose fame among the moderns is immense, and Simone of Siena.' Simone now owes his fame chiefly to Petrarch: they were both living at the same time at Avignon during the residence of the popes there, and Simone painted the portrait of the celebrated Madonna Laura for the poet, who, through admiration and gratitude, wrote two sonnets on the painter (Son. 56 and 57), by which he has given him an undying name. Few of Memmi's works now remain, and these are dry and meagre performances. The principal are the frescoes of the chapter of the chapel degli Spagnuoli at Florence, painted in 1332: they consist of stories from the lives of Christ, San Domenico, Saint Peter Martyr, and part of the history of the order of the Dominicans or Predicants. In one of the last works are the reputed heads of Petrarch and Laura, but this story, as Lanzi says, is a mere fable, for Memmi did not paint Laura until four years after the completion of these works, in 1336, after he was invited to Avignon. [Gaddi, Taddeo, P. C. S.] There are also some stories by Memmi, from the life of San Ranieri, in the Campo Santo at Pisa: they are engraved in Lasinio's 'Pitture del Campo Santo.'

Simone painted also in miniature. There is a MS. of Virgil, with the commentary of Servius, now in the Ambrosian Library at Milan, but formerly in the possession of Petrarch, which is preceded by a miniature of Virgil seated with his pen in his hand, invoking the poetic muse; before him is Æneas in armour, with his sword, representing the Æneid; there are likewise a shepherd and a tiller of the soil, representing the Bucolics and Georgics; and Servius is also there, drawing a fine veil to himself, as symbolical of the elucidation of his commentary. This design, supposed to have been made at the instance of Petrarch, is inscribed with the following couplet:—

'Mantua Virgilium qui talia carmina finxit,
Sena tulit Simonem digito qui talia pinxit.'

Memmi died at Avignon in 1344, according to the necrology of the Dominicans at Siena, aged sixty, according to Vasari, but much older according to Della Valle and some others.

Notwithstanding Vasari's encomium upon the style of Memmi, which he said was worthy of one of the moderns, his remaining works are not at all beyond his age, and he was surpassed by the two Gaddi: his design is meagre and ugly. Of his portrait of Laura nothing whatever is known. The reputed head of Laura above mentioned is engraved in D'Agincourt's 'Histoire de l'Art par les Monuments,' Peint. pl. cxxii. 2, and in Cicognara's 'Storia della Scultura,' i. pl. 43. Cicognara has disputed the authenticity of this and some other reputed portraits of Petrarch and Laura, at considerable length in the third volume of his History. The only authentic portrait of Laura extant, of that age, appears to be a miniature in a MS. in the Bibliotheca Laurentiana at Florence, which however may have been copied from the original work by Memmi: there is an outline of this also in Cicognara's work, i. pl. 42.

Vasari gives the following as the inscription on Simone's tomb, but he does not say where:—'Simoni Memmio pictorum omnium omnis aetatis celeberrimo. Vixit ann. LX. mens. ij. D. iij.' His chief excellence was invention.

Lippo Memmi, the brother-in-law of Simone, assisted Simone in some of his works, and completed others which were left unfinished at his death. He was not equal to Simone, though a better colourist than he: there are a few of his works still extant. He was living in 1361.

(Vasari, *Vite de' Pittori*, &c., and the notes to Schorn's German translation of Vasari; Della Valle, *Lettere Sanesi;* Lanzi, *Storia Pittorica*, &c.; Rumohr, *Italienische Forschungen*.)

MEMMI DI MARTINO. [Simone, P. C. S.]

MENANDER, ARRIUS, a Roman jurist, of the time of Severus and Caracalla. The only work of his mentioned in the Florentine Index is four books on Militaria. There are six excerpts from Menander in the Digest.

MERCHANT SEAMEN. [Ships, P. C.]

MERCIER, LOUIS SEBASTIEN, a prolific writer on men and manners, politics, science, the drama, literary criticism, and many other subjects. The greater part of his works are sunk in oblivion, but several of them still deserve and obtain attention. He was born at Paris on the 6th of June, 1740. He was for some years professor of rhetoric in the college of Bordeaux. The works for which he chiefly deserves attention at the present day are his attacks on the manners and morality of his age. The first of these appeared in 1771, with the title 'L'An 2440; Rêve, s'il en fut jamais.' In 1781 he commenced the publication of the 'Tableau de Paris.' Having courted the attention of the authorities to his authorship of this book which, by its bitter remarks on all the social institutions of France, was sure to provoke their wrath, he found it prudent to retire to Switzerland, where he completed this remarkable work. Without holding with its author that the 'Tableau de Paris' produced the French Revolution, there is no doubt that it did much to open the eyes of mankind to the immoral and corrupt state of the social system of the French capital, and the inapplicability of the great national institutions of the country to supply their proper end of doing good to the nation at large. Mercier wrote with an animated, descriptive, and biting pen. He occasionally appealed to a high sense of morality, but his chief power lay in showing his readers the bad taste and the folly of the prevalent habits of the day. Wherever he had to depict honest industry struggling against false social laws, or the remains of pristine simplicity holding out against the inroads of corrupting manners, his tone has dignity and feeling. When he speaks of the profligate administration of the laws, of the artificial and vicious tastes of the leaders of fashion, of the tyranny over the free expression of opinion, he overwhelms with sarcastic ridicule. The work is a curious anatomy of Parisian society, and exposes many evils incident to large cities, of which the lapse of sixty years has not entirely enabled us to find the remedy. The sanatory regulations which have lately so much occupied the attention of society, and other means of social organization, are intended to supply deficiencies which Mercier points out in his own peculiar fashion: whether *he* could have devised remedies for the defects he discovers may be questioned. He was an avowed hunter after paradoxes. In 1801 he published 'Néologie, ou Vocabulaire de Mots nouveaux, à renouveller, ou pris dans des Acceptions nouvelles,' a work in which he announced such propositions as 'Les prosateurs sont nos vrais poètes.' He made war on the chief ornaments of French literature; seeming, wherever public opinion had unequivocally declared itself, to find that he had to perform the function of reversing the judgment. In philosophy he was equally paradoxical, raising his voice against the best-established truths in physical science. From these peculiarities his attacks on the social morality of his age have been received as chance blows struck in a right quarter by a man who struck at everything. The censure of his 'Tableau' has thus frequently been looked on as no more the result of just observation than the censorious remarks of a universal grumbler, who, living in a brothel or a gambling-house, should complain from morning to night of the improprieties by which he was surrounded. But Mercier deserves a better appreciation, and none can attentively read his censures without seeing that they proceed not only from a condemnation of what is wrong, but a sense of what is right. A list of his works would be much longer than the present article. He passed a life of cheerful vivacity, surrounded by friends who seem not to have been the less attached to him that he perpetually displayed with singular simplicity his sublime self-conceit. He died on the 25th of April, 1814.

MERCURIA'LIS, a genus of plants belonging to the natural order Euphorbiaceæ, has diœcious or monœcious flowers; the perianth 2-3-parted; with 9-12-stamens in the male flowers; the style short and forked in the female flowers; the capsule 2-celled; the cells 1-seeded, bursting at the back. The species are herbs; two of them are natives of Great Britain.

M. perennis, Perennial Mercury, has a simple stem, the leaves stalked, ovate-oblong, rough; the female flowers on long common stalks; the root creeping. It is a native of woods and thickets.

M. annua, Annual Mercury, has the stem branched, leaves stalked, ovate, or ovate-oblong, smooth, the female flowers nearly sessile, the root fibrous. It is a common plant in waste cultivated lands. It once had a place in the British Pharmacopœia on account of its supposed efficacy as an emmenagogue, but it is not now used for that purpose. The leaves abound in mucilaginous matter, and are cooked and eaten in Germany in the same way as we eat spinach. Professor Burnett has pointed out the peculiar instability of the stamens of this plant. At the period when they are fully developed, if they are touched they become loosened from their footstalks, and vault off elastically towards the pistilline flowers.

(Burnett, *Outlines of Botany;* Babington, *Manual of British Botany*.)

MERCURY, DEPRESSION OF. [Depression of Mercury, P. C. S.]

MERIAN, MATTHEW, a very distinguished German portrait painter, was the son of the eminent engraver of the same name, who was born at Basel, in 1593, where the son was born in 1621. He was the pupil of Sandrart, who was much attached to him; he studied also after Vandyck in London; became acquainted with Le Sueur and Vouet in Paris, and studied under Sacchi and Carlo Maratti at Rome. From about 1650, when the elder Merian died, Matthew conducted his father's book and print business, at Frankfort on the Main, but he did not give up his own profession. He painted the Emperor Leopold I. on horseback, and many other German princes and nobles. He also painted some historical pieces, and engraved a few plates, which are marked M. Merian, junior. He died at Frankfort, in 1687.

Matthew's sister Maria Sibylla Merian was an eminent insect and flower painter. She died at Amsterdam in 1717, aged seventy.

(Sandrart, *Teutsche Academie*, &c.; Fiorillo, *Geschichte der Zeichnenden Künste*, &c.)

MERIVALE, JOHN HERMAN, was born at Exeter in 1779, in which neighbourhood his father, John Merivale, Esq., resided, and was possessed of some landed property: his grandfather, the Rev. Samuel Merivale, was a Presbyterian minister at Exeter, and tutor at the dissenting theological academy there. Mr. Merivale entered St. John's College, Cambridge, in 1797, but took no degree, in consequence of the impediment of his dissenting persuasion, although at a later period he joined the Church of England. He married Louisa, daughter of the Rev. Dr. Drury, head master of Harrow School: was called to the bar in 1805, and practised in the Court of Chancery. He published three volumes of Chancery Reports from 1815 to 1817, of cases decided by Lord Eldon and Sir William Grant. In 1825 he was a member of the commission for inquiring into the state of the Court of Chancery, which was appointed in consequence of the attacks made at that period on Lord Eldon; and wrote a 'Letter on the Chancery Commission' in 1827, as well as some other pamphlets on law reform. He became a commissioner of bankrupt on the then newly organised system in 1831; and continued to hold that office till his death in April, 1844. From his early youth Mr. Merivale was addicted to literary and antiquarian pursuits, especially to the study of Italian and, in his later years, of German literature. He contributed a large proportion of the translations contained in the 'Collections from the Greek Anthology,' published in 1813 under the editorship of the Rev. Robert Bland; of which Mr. Merivale brought out a second edition, enlarged, in 1833. In 1814 appeared his poem of 'Orlando in Roncesvalles,' a tale in the ottava rima, being chiefly a free abridgment of part of the 'Morgante Maggiore.' In 1841 Mr. Merivale published two volumes of 'Poems, original and translated,' comprising most of his earlier pieces; and in 1844, shortly before his death, a volume of translations of the 'Minor Poems of Schiller, of the second and third periods, with a few of those of earlier date.' This was perhaps the most successful of his productions. It is an essay towards the rendering the lyrical pieces of the German poet in the same, or nearly the same, metres with the originals, and with an approach to close but not literal version. The more metaphysical or subjective poems of Schiller's later period—those which it is the most difficult to bend to this species of treatment—the Gods of Greece, the Feast of Eleusis, the Progress of Art (die Künstler), and others of the same character—are among the best executed parts of the work. Mr. Merivale was an extensive contributor to literary reviews, but none of his prose essays on these subjects are published in a separate form.

MESMERISM. [ANIMAL MAGNETISM, P. C. S.]

MESOLO'NGHI or MESSOLO'NGHI, perhaps the antient Olenus, Ὤλενος, in Aetolia, a small town in Greece, lies on the northern side of the Gulf of Patras, near its entrance, and right opposite Cape Kologria or Papas in the Morea. It became remarkable during the last Greek insurrection against the Turks, as is stated in the life of Bozzaris in the P. C., especially in consequence of the siege and capture of it by Ibrahim Pasha, the commander in chief of the besiegers. The heroic resistance of the Greek garrison, and their ultimate fate, made the name of Mesolonghi popular over all Europe.

Mesolonghi is built on the edge of a marshy plain, bounded on the north by the high ridge of Zygos, the antient Aracynthus, and is protected towards the sea by a lagune extending about ten miles along the coast and five in width; and hence perhaps the name of the town, which seems to be a contraction of the Italian (Venetian) words 'mezzo' and 'laguna.' With the exception of a few very tortuous channels, the lagune is impassable for any craft drawing more water than the 'monoxyla,' or small boats of the inhabitants. The main channel in the south is commanded by the mud-bank of Vassiladi, on which the Greeks had built a small fort; and the main channel in the north, by the islets of Poros and Anatoliko. At the time of the outbreak of the Greek revolution the town contained several thousand inhabitants, who derived wealth from their extensive fisheries. The fortifications were in such a neglected state that Lord Byron advised the Greeks to strengthen the place by additional works; but the Turks left them only time to add a rampart of earth faced with stones, and a ditch, which surrounded the town on the land side. After the progress of Reshid Pasha, the Turkish commander in Northern Greece, in the beginning of 1825, many Greek palikars and others flocked to Mesolonghi with their families, so that the garrison was increased to about 5000 fighting men. Their principal chiefs were the veteran Nothi-Bozzaris, Sornaris, Mitcho-Koutoyani, Liaketas, Lambro-Veikos, George Kizzos, Niketas, Iskos, Makrys, and others; and the body of officers was increased by many foreign volunteers, mostly German noblemen and gentlemen. On the 25th of April, 1825, Reshid Pasha appeared in sight of the town, with an army of 20,000 men and a numerous battering train, to which the besiegers could only oppose forty-eight bad iron guns of calibre varying from 4- to 48-pounders, two brass 10-inch mortars, one howitzer of 5 inches, and one mountain howitzer of 4⅗ inches. The Turks made the first trench on the 5th of May, and on the night of the 11th a terrible bombardment began. Bombardments and stormings now succeeded each other during two months, but the fire was well answered from the rampart, and the Greeks made frequent sallies, in which the besiegers were almost always defeated with great loss, especially on the 2nd of July. The Hydriotic fleet being stationed at the entrance of the lagune, there was no lack of ammunition and provisions in the town, till, on the 10th of the same month, the great Ottoman fleet appeared off the place, and, after having obliged the Hydriotic to avoid a certain defeat by a hasty retreat, landed a strong body of Turks, under Husein Bei. On the 28th of July, the 2nd of August, and in the night of the 3rd, the fortress was furiously assaulted, and a terrible cannonade carried destruction among the houses and their inhabitants; but the Greeks stood their ground, and were excited to hopes of certain victory when, a few days afterwards, the great Greek fleet under Miaulis and Sakhtouri came in sight, and after a severe conflict defeated and dispersed the Turkish fleet. The maritime blockade was now at an end, and in the beginning of September the garrison was still 4000 strong, with an additional population of 10,000 women, children, and aged or infirm men. Reshid Pasha, however, was far from being discouraged, and resolved upon still more vigorous attacks; but Sultan Mahmud, who was bent upon the possession of Mesolonghi, gave orders to Ibráhim Pasha, who commanded in the Morea, to take the chief command, while Reshid Pasha was to act as his first lieutenant.

The Egyptian forces consequently moved northward, and towards the end of November the combined fleet of Turkey, Egypt, and Barbary, drove the Greek fleet from the lagune, and kept a strict watch over its entrance. During the whole of the months of November and December scarcely a week passed without the Turks making an assault. In the first week of January, 1826, Ibráhim Pasha appeared in the Turkish camp with 14,000 Egyptians and an ample supply of provisions and ammunition. During the first fortnight he was nearly inactive, hoping that a strict blockade would compel the inhabitants to surrender for want of food, nothing having been introduced into the town since the end of November. Although the inhabitants were on the verge of starvation they would not capitulate, and continued their deadly sorties, when at last, Ibráhim, after having taken the islands of Poros and Anatoliko, made the town a heap of ruins by an uninterrupted bombardment from the 25th to the 27th of January. The fall of the fortress being now unavoidable, Sir Frederic Adam, the Lord Commissioner of the Ionian Islands, came to Krioneri, the land quarter of the Kapudan Pasha, for the purpose of offering his good services, and alleviating the lot of the Mesolonghians; but although he obtained an interview with the Turkish Admiral, Ibráhim Pasha declined any conference with him, and purposely avoided seeing him, so that he was obliged to depart without any prospect of saving the noble defenders of Mesolonghi. Ibráhim Pasha continued his terrible assaults. On the 6th of April, however, his forces were driven back with immense slaughter, and had the Greeks availed themselves of the confusion in the Egyptian camp, they might have escaped with their families without incurring great risk of being either driven back within the fortress, or made prisoners while in the midst of the enemy's army. Their ammunition and food being completely exhausted, so that even cats and rats were devoured with avidity, the garrison resolved to cut their way through the Egyptian camp, and effect a retreat into the neighbouring mountains. According to the best authorities the population consisted, in the month of April, of about 9000 persons. Three thousand fighting men were to rush headlong upon the besiegers and cut a way for 5000 women and children, while the retreat was to be covered by a thousand men, and the fortress guarded by a few devoted warriors who were ready to sacrifice their lives for the safety of their brethren. The 22nd of April was the day on which the Greeks were to try their last chance. But the plan was betrayed to Ibráhim Pasha by a Bulgarian deserter only a few hours before its execution, and when the heroes of Mesolonghi appeared outside their shattered stronghold, they were suddenly surrounded by the main body of the Egyptians. A dreadful conflict ensued. Five hundred men were cut down by the infuriated besiegers; 1800 persons, of whom 200 were females, escaped, of whom, however, 600 were starved to death in the mountains; and Ibráhim boasted of having taken prisoners 3000 soldiers, and from 3000 to 4000 women and children. Many of the captives were afterwards ransomed through the exertions of the Philhellenic societies in Europe. Nothi-Bozzaris and Mitcho-Koutoyani, though both upwards of seventy, escaped safely. Among the slain were Joseph, bishop of Rogon, the chief magistrato Papadiamandopoulos, the Generals Stornaris, Sadimus, and many other Greeks of note. Among the Germans, Baron von Riedesel and Lieutenant Rosser were killed during the siege; Colonels Dittmar and Delaunay, Captains Baron von Lützow and Stilzelberg, Lieutenants Klemp and Schipan, and several other gentlemen fell in the sortie. With them remained on the battle-field Dr. Meyer, another German, who was the editor of the 'Greek Chronicle,' and who was equally energetic with his pen and his sword: his wife and children were dragged into slavery. 'History will do us justice'—wrote the gallant doctor, a few days previous to the last sortie, to a friend—'and posterity weep over our misfortunes. May the relation I have drawn up of the siege survive me.' This relation was unfortunately lost.

Thus fell Mesolonghi after a siege of twelve months, and after 100,000 shot and shells had been exchanged between the besieged and the besiegers. Its melancholy fate excited the sympathy of all Europe, and there is scarcely a modern language in which poems were not written on the heroes of Mesolonghi.

(Gordon, *History of the Greek Revolution.*)

MESOPOTAMIA (from the Greek μεσος, 'middle,' and ποταμος, 'river'), 'the country between tho rivers,' is a term which was used by the Greek and Roman geographers (Strabo, and others) to comprehend all the countries which lie between the rivers Euphrates and Tigris, and it is still in use. The Arabs and Turks call this country by the corresponding name of Al Jesirah, or 'the island.' As Mesopotamia is not a political division, geographers do not agree as to the extent of the countries to be comprehended under this name. Somo confine it to the central countries, or those lying between 38° N. lat. and the Chalu or Median Wall (34° N. lat.), whilst others extend it northward to 40° N. lat., or the sources of the Euphrates, and southward to 30°, where the Tigris and Euphrates unite. We shall here givo a description of the countries included between tho parallels of 40° and 30° N. lat.

When a traveller departing from Trebizond or Rizeh, on the northern shores of the Black Sea, directs his steps southward, he passes over several mountain ridges running east and west, and is soon aware that the country rises rapidly. About seventy miles from the sea he finds himself on the most northern of the mountain ranges which traverse this portion of Asia from east to west, and which in antient times went by tho name of the Taurus and Antitaurus. This northern chain is traversed in its length by the parallel 40° N. lat., and is at present called Kop Dagh. Its highest part is always covered with snow, and many summits are 10,000 feet above the sea-level. From these mountains the view ranges southward over an elevated table-land, that of the Frat and Murad, which extends over two degrees of latitude, and whose surface varies from 3000 to 6000 feet above the sea-level, but several of the mountain masses attain 10,000 feet. On the south of it, between 38° and 36° 30′, lies the hilly region of Mesopotamia, or the subalpine region of the Taurus. The country here sinks gradually from 2500 feet to 1000 feet and less above the sea-level. It is succeeded on the south by the great desert plain of Mesopotamia, which embraces all the countries between the two rivers, or between 36° 30′ and 34° N. lat. This region is separated from the low plain of Babylonia by the Chalu or Median Wall, which begins on the banks of the Tigris, near 34° N. lat., and it terminates on those of the Euphrates, near 33° 30′ N. lat. This wall and the lower course of the two rivers up to their confluence, enclose the fourth region, the plain of Babylonia, or of Irak Arabi.

I. The *table-land of the Frat and Murad* lies between 40° and 38° N. lat., and between 38° and 44° E. long. In width from north to south it extends about 100 miles, and in length from east to west about 250 miles. This gives an area of 25,000 square miles, or somewhat less than that of Ireland. It constitutes the most elevated portion of the high grounds by which the table-lands of Asia Minor are connected with the great table-land of Iran or Persia.

The elevation of this table-land varies greatly. The highest part of it is on the north-east corner, where the lowest part of the country is about 6000 feet above the sea-level. Hence it descends rather rapidly along the banks of the Frat or Kara-su, for Erzerum is nearly 6000 feet, and Erzingan probably not more than 4000 feet, above the sea-level; where the Frat meets the Murad the elevation is less than 3000 feet. The descent along the Murad river is somewhat less rapid, as the town of Mush is still about 4000 feet above the sea; at Palu the level of the river is 2819 feet above the sea.

This table-land has a very unequal surface, but the inequalities constitute large masses. The Kop Dagh, which forms its northern boundary-line, rises, as already observed, to the height of 10,000 feet. Its northern face, or that which looks towards the Black Sea, is well wooded, but on its southern declivity there are no forests. Another mountain-chain, called the Kharzan Dagh, borders the table-land on the south. It begins on the east with the Nimrúd Tagh, a high peak west of the Lake of Van, and rises above the snow-line and more than 10,000 feet above the sea. Hence the Kharzan Dagh (the Niphates of the antients) runs nearly due west to the place where the Euphrates makes its great bend opposite the town of Malatiyah. Towards the east this range rises from 7000 to 8000 feet above the sea-level, for the mountain-passes which traverse it are from 6000 to 7000 feet high; but it appears to be lower towards the west; and that portion of it which surrounds the source of the Tigris is only 5000 feet high. This appears also to be the general elevation of this mountain-mass where it comes close to the bed of the Euphrates, where this river forms its three hundred cataracts between Isoglu or Fizoglu and Gerger. No mountain-range borders the table-land on the east, where it extends almost on a level between the Murad and Araxes rivers. But west of the source of the Murad the Ala Dagh rises above the snow-line, and it appears to be an isolated mass. Much farther to the west, and at nearly equal distances from the northern and southern border of the table-land, are two large mountain-masses, of which the eastern is called Bingol Tagh, and the western Dujik Tagh. The declivities of tho last-mentioned range approach the banks of the Frat above its confluence with the Murad. Tho two mountain-masses are probably separated from each other by a wide depression, and both rise above the snow-line.

Those parts of the region which are always covered with snow do not appear to cover a considerable space, but from their declivities mountain-streams descend, which are always copiously supplied with water. This circumstance, united to the great quantity of snow which falls during the winter months, makes this table-land one of the best-watered regions in Asia; and the whole surface, with the exception of tho most elevated parts, may be turned to useful purposes. The largest part however is unfit for cultivation, as tracts of considerable extent surrounding the highest grounds are so elevated that the summers are too short and too cold to bring corn to maturity. But as they are the whole year round clothed with excellent grass, they are used as pasture-ground, especially as sheep-walks. The number of sheep must indeed be great if there is no exaggeration in the statement that one million and a half of sheep are sent annually from this and the adjacent countries to Constantinople and Smyrna. They arrive at the place of their destination after a journey of eighteen months, and one-third of them are said to perish on the road. Large flocks are also sent to Diarbekr, Mosul, Aleppo, and Damascus, and even as far as Beirut on the shores of the Mediterranean. The value of this region as a pasture-ground is certainly increased by the total want of trees and even bushes, which peculiarity must be regarded as a characteristic of this as of many other table-lands on the globe. It is only in the most southern districts of the region, on the lower declivities of the mountains which enclose the valley in which the Murad river runs, that forests occur, and even there they consist only of underwood, especially willows and dwarf oak.

But a considerable portion of this region is fit for agriculture. The rivers do not always run in narrow valleys, but frequently traverse depressions, which on account of their extent may be called plains, as they are frequently thirty and even forty miles long, and from ten to twelve miles wide. Such are on the banks of the Frat, the plains of Erzerum, and Erzingan, and on those of the Murad, the plains of Mush and Kharpat, and a number of smaller plains. Near the banks of the rivers these plains are usually swampy, but in general they possess a considerable degree of fertility, except some of the higher grounds, which only yield abundant crops in wet seasons. These plains differ greatly in elevation, and consequently in climate and productions.

The Plain of Erzerum and some smaller districts in its vicinity are nearly 6000 feet above the sea-level. The winters, which are cold and long, commence in the beginning of November and continue to April. Snow sometimes falls in the commencement of June, and the corn is gathered in September. But during the summer months the heat is excessive and the weather very dry. At some places it is then found necessary to irrigate the fields. All the grains of Northern Europe grow very well, and yield rich crops, especially wheat and barley, but only a few of the hardier fruit trees are planted, and the grapes are very bad. All the domestic animals are very numerous, and the sheep of uncommon size. The plains of Erzingan, Mush, and Kharpat, are about 2000 feet lower. Though the winter here lasts four months, the climate is much more favourable to the growth of many plants and trees. The corn is ripe in the month of July, and the orchards and plantations of trees are numerous. Grapes and melons are exported to a considerable extent, and the fruit of the mulberry-trees is held in great esteem. These advantages, united to the extensive pasture-grounds on the higher portions of the table-land, have rendered these plains the abode of a numerous population. This region is politically divided into two pashalicks, those of Erzerum and Mush, and contains several populous places. The most important of them are the following:—

Erzerum. [Erzerum, P. C., vol. x., p. 8.]

Erzingan, on the Frat, is built on an extensive well cultivated plain, on which there are about one hundred villages, and is inhabited by 3000 families, or about 18,000 individuals. This place suffered greatly by an earthquake in 1667.

Egan is in a rather narrow valley, between steep mountain masses rising to 4000 feet above the Frat, whose declivities, however, to a considerable height are covered with orchards and plantations. It contains 2700 families, and some of the numerous villages in its vicinity from 400 to 500 families. The valley is too narrow to admit of cultivation on a large scale, and the population, which is great, lives almost entirely on the fruit of the white mulberry-trees, which here, as in some parts of Afghanistan, is dried and used as bread.

Kebban Maaden, on the Euphrates, a mile and a half below the place where the Frat and the Murad rivers unite, is built in a ravine enclosed by bare mountain masses. It owes its existence to the silver-mines in its vicinity, but they are not very productive. The population consists of between 400 and 500 families, all of them engaged in mining.

Mush, on the Murad river, in a well cultivated plain, has 8000 inhabitants, who are partly engaged in manufacturing iron utensils, carpets, stockings, and linen-cloth. It has some commerce with Erzerum, Bitlis, and Diarbekr.

Palú is built on a steep hill rising 473 feet above the level of the Murad river, which washes its base. It contains about 1000 families, some of which are engaged in weaving coarse cotton-cloth, for which there are 200 looms, and others in dyeing and tanning. This town is surrounded by extensive orchards. About twenty-four miles east of Palú, and about two miles from the southern banks of the Murad river, are the iron-mines of Sivan Maaden, where the mineral is very abundant, and the ore contains 75 per cent. of iron of good quality. The Turks began to work the mines some years ago.

Kharput is built on a cliff rising 1000 feet above the adjacent plain, and contained in 1835 about 9000 individuals. The surrounding country is very fertile, and considered the the most populous portion of the table-land.

II. The *Hilly Region of Mesopotamia*, or the *Subalpine Region of Mount Taurus*, lies to the south of the Kharzan Tagh, from which range it extends southward to the great caravan-road which runs from Bir-eh-jik on the Euphrates, to Mosul on the Tigris, past Urfah, or Orfah, Mardin, and Nisibin. This caravan-road lies along the base of the Hilly Region. This region lies between 38° 30′ and 37° N. lat., and between 38° and 43° E. long., and extends about a hundred miles from north to south, and two hundred and fifty from east to west, so that its area may be roughly estimated at 25,000 square miles, or equal in extent to the table-land of the Frat and Murad.

This country may be considered a continuation of the table-land of the Frat and Murad, or rather as a lower terrace of it. The northern districts are about 2500 feet above the sea-level, from which elevation it gradually descends to about 1000 feet, or somewhat more, where it is contiguous to the Great Desert Plain of Mesopotamia along the caravan-road. Only the most eastern part of this road between Tel Rumalah and Mosul is at a lower level, and runs through the Great Desert Plain.

The highest part of this region is that which on the west borders on the banks of the Euphrates between Izogln and Gerger, where the river forms its three hundred cataracts, and on the east on the upper course of the Tigris between its source and the town of Diarbekr, which is nearly 2500 feet above the sea: the sources of the Tigris are nearly 5000 feet. The level of the surface of the Euphrates near the confluence of the Frat and Murad is upwards of 2500 feet, and at Gerger probably less than 1800 feet. But the rocky mountain-masses which rise abruptly from the water's edge, at many places perpendicularly, generally attain near the river an elevation of between 2000 and 3000 feet, and a greater height at some distance from it. The highest portion of this tract must therefore be more than 5000 feet, and it may be 6000 feet. It does not, however, appear that any portion of it rises so far above the general level of the masses as to form conspicuous summits. This tract is little known. In the depressions are small villages surrounded by walnut-trees, and a little cultivation, but the inhabitants derive their subsistence chiefly from their cattle and sheep.

East of this mountain tract lies the Plain of Diarbekr, or of the Upper Tigris, which extends from some miles west of the town of Diarbekr to some distance east of the town of Sert, about 120 miles in length, and from the Kharzan Tagh on the north to the Karaja Daglieri on the south, from 40 to 50 miles; on the east it is shut up by the most elevated part of the mountains of Kurdistan. It is a most valuable part of Western Asia, especially that portion of it which lies on the southern declivity and at the base of the Kharzan Tagh. The declivity of this range is not so steep as that which descends to the banks of the Murad, and the slope is in many places interrupted by terraces from two to three miles in width. These terraces are generally used as pasture-grounds; but they are cut by wide valleys, which descend from the summit of the range to the plain below, and in which the waters collected on the top, which for many months of the year is covered with snow, find their way to the lower country. Rich crops of wheat and barley are obtained everywhere, and in some places, where irrigation can be practised, rice is grown. The sides of the hills which enclose the valleys, and the valleys themselves, are partly covered with orchards and plantations, consisting of walnuts, figs, vines, pomegranates, mulberries, and the fruit-trees of Northern Europe. In some places cotton, melons, and plantains are grown to some extent. The steeper portions of the mountains are chiefly covered with woods, in which two kinds of oak abound, one of which yields gallnuts, and the other a kind of manna, which is much used in the country. In some parts the steep declivities of the hills have been transformed into terraces, which are planted with fruit-trees and irrigated.

The Plain of Diarbekr itself is less fertile, and not cultivated with such care as these valleys. Its surface may at the lower part be about 1700 to 1800 feet above the sea-level. There are many tracts which are quite level, and others have an undulating surface; a few are hilly. The rivers, especially the Tigris, run in beds deeply depressed below the general level of the country, which renders it difficult and expensive to use the waters for irrigation, and as the summers are hot and dry, only those tracts can be cultivated which have a better soil. The others are only used as pasture-ground during the wet season, and until the grass is dried up by the heat. In some parts the surface is bare of mould and consists of naked rocks. There are no trees on this plain except mulberries and poplars, which are planted in some places. Corn and barley are grown, and some cotton, and also maize. In the vicinity of the town of Diarbekr cultivation is carried on with more vigour: flax is also grown.

A few miles from the southern banks of the Tigris, where the river runs from west to east, the plain is bordered by rocky masses, which rise with rather a steep ascent to 2000 feet above the general level of the plain. Though they appear to form a range, these masses constitute only the outer border of a table-land which occupies the whole country between the Euphrates and Tigris, north of 37° N. lat. and compels the Tigris to run eastward and the Euphrates west; near 38° N. lat. These two rivers are hardly thirty miles apart; but sixty miles farther south, between Rumkalah on the Euphrates and Jezirah Ibn Omar on the Tigris, they are more than two hundred and twenty miles from each other. The highest part of this table-land runs from north-west to south-east, beginning at no great distance north-east of the town of Severeck and terminating with the hill on which the town of Mardin is built. This ridge it appears is properly called Karaja Daghieri. This region has no watercourses, though a considerable quantity of snow appears to fall during the winter months. This must chiefly be attributed to the limestone, of which, according to Ainsworth, the upper surface of the country is composed, and which quickly absorbs all the water. Where this is the case the country generally presents bare rocks, or only a very scanty vegetation during the wet season. But there are some parts which are covered with basalt and trap, and these tracts have a soil fit for cultivation, or at least good pasture-ground. The whole country is imperfectly known, especially the portion contiguous to the Tigris, which has been visited by European travellers only in the vicinity of the river. Where the bed of the river is narrowed by the mountain-masses advancing to the water's edge on the east from the mountains of Kurdistan, and on the west by the Karaja Daghieri, the surface of the table-land is mostly broken by valleys and ridges, interspersed here and there with elevated plains. The valleys are well cultivated, and produce wheat, rice, cotton, tobacco, cucumbers, and melons; some of them have good vineyards. The ridges are well covered with oak, pine, holly, elm, and several bushes. The plains afford good pasture-grounds, and are also partly cultivated. Farther inland the country appears to be more uneven, as the inhabitants are able to defy the Turkish government and to maintain their independence; but according to the accounts of the natives there are many fertile valleys in it. If their accounts deserve credit, the eastern districts are much more fertile than the western, where the want of moisture in the summer is so great that nearly the whole is a desert, with the exception of some depressions, whose surface is formed of trap or basalt, and where a few villages occur with some cultivation surrounding them. In approaching the banks of the Euphrates where the mountain-masses have sunk down to 1200 or even 800 feet above the level of the river, the edge of the masses is split and indented, and numerous small valleys are found between the high ridges. In these valleys some corn is cultivated, but the largest part of them is covered with orchards, consisting of olives, pomegranates, mulberries, pears, peaches, and quinces; all of them have also excellent vine plantations. In some parts cotton is cultivated.

The country through which the caravan-road between Bir-eh-jik and Mosul runs, has great variety of surface and soil. Between Bir-eh-jik and Urfah it is hilly, and contains many cultivated tracts. Farther east, as far as Mardin, cultivated and wooded tracts, mostly situated in depressions, or valleys alternate with plains, which in some cases afford pasture, and in others are quite sterile. This tract is very uneven, and the ridges running south and north rise to high hills, generally of a conical shape. These ridges continue to Nisihin, but are less frequent. Between them run some watercourses, which are used for irrigation, and soon lost in the desert country which lies farther south. East of Nisihin cultivation ceases; but as in this part there are numerous watercourses, the adjacent country has pasture even during the summer months. After having passed Tel Rumaláh the road leaves the Hilly Region of Mesopotamia and enters the Desert.

This region has a more temperate climate than the table-land of the Frat and Murad, on account of its less elevation, the mountain-ranges which surround it on the east, north, and west, and its more southern situation. But the climate is much colder than that of Europe in the same parallel, because it lies much farther from the sea, and does not receive the warm western winds prevalent on the Mediterranean, as the elevated chain of Mounts Lebanon and Antilebanon prevent them penetrating so far eastward. The thermometer has been observed to descend as low as 12° of Fahrenheit. In January and February a great quantity of snow falls. The spring hardly exceeds six weeks, and in May the dry season begins, in which hardly any rain falls to the end of October, or the commencement of November. The thermometer rises to 90°, and all grass and minor vegetation dries up. Pasture is then only found in the vicinity of the pools and cisterns, which are common in many places of the table-land. Nature becomes reanimated in the month of November, when the Nile clouds appear, which proceed from Mount Lebanon eastward, and bring to the table-land very heavy rains, which about the beginning of the year are changed into snow.

If the Plain of Diarbekr is excepted, agriculture is limited to some tracts of moderate extent, to the numerous but narrow and short valleys, and a few plains and depressions which have a fruitful soil. The cerealia which are grown are wheat, beans, barley, rice (in very few places), lentiles, *cicer arietinum*, *Lathyrus sativus*, *vicia nissoliana*, *phaseolus maximus*, durrba (*holcus sorghum*), and *medicago sativa*. Other vegetables are several kinds of cucumbers, melons, *solanum melengena*, *hibiscus esculentus*, and pumpkins. The orchards and plantations contain olives, white and black mulberries, pomegranates, figs, cherries, Armenian plums (*prunus armeniaca*), three other kinds of plums, apples, pears, quinces, cornelian cherries, almonds, walnuts, hazel-nuts, chesnuts, and cembra kernels (the fruit of *pinus cembra*). Tobacco, sesamum (*sesamum orientale*), castor-oil (*rhicinus communis*), hemp, flax, saflor (*carthamus tinctorius*), cotton, and *trigonella foenum graecum*, are also cultivated. Among the wild plants are capers (*capparis spinosa*), mustard (*sinapis orientalis*), liquorice (*glycyrrhiza glabra*), asparagus, and *arum colocasia*—the leaves of the last are used as paper.

Sheep, cattle, and goats constitute the wealth of the nomadic tribes. There are two kinds of sheep, the Tartarian, with the fat tail, which often weighs fifteen pounds, and the Arabian, whose tail is not much thicker than that of our sheep. Horses are numerous, but not so good as in the table-land of the Frat and Murad, or on the desert plain: asses are also kept in great numbers. It does not appear that camels are bred, but they are used on the caravan road.

The most common wild animals are wild boars, deer of two or three different kinds, wolves, foxes, hyænas, jackals, bears, polecats, martens, marmots, hamsters (*cricetus vulgaris*), squirrels, porcupines, and hares. There are several kinds of vultures, falcons, and owls; ravens, crows, jackdaws, thrushes, beccafigues, and other smaller birds. Fish abound in both rivers, the Euphrates and the Tigris, and in several of their confluents. There are also several kinds of turtles, snakes, and lizards.

The Hilly Region of Mesopotamia constitutes the pashalik of Diarbekr; but the most south-eastern districts are sometimes placed under the pasha of Mosul. The most remarkable places are situated either in the Plain of Diarbekr or along the caravan road between Bir-ch-jik and Mosul. In the Plain of Diarbekr are

Diarbekr. [Diarbekr, P. C., vol. viii., p. 477.]

North of Diarbekr, on the southern declivity of the Kharzan Tagh, are very rich mines of copper, in whose vicinity are two towns, one of which is called Arghana (or Argunna) Maaden, and the other Maaden Kapur. Arghana Maaden is built round the summit of a high hill, 2887 feet above the sea-level, and contains according to some statements 1200, and according to others 600 houses. The declivities of the hill are partly cultivated with wheat and cotton, and partly planted with orchards and vines. The proper mining town, Maaden Kapur, is about 14 or 15 miles distant from Arghana, in a district destitute of vegetation, and contains about 4000 inhabitants, all of whom are employed in the mines. The produce of these mines formerly amounted to 400 tons, but in modern times they are not worked to such an extent, and the annual produce is only estimated at 75 tons. But even this is of great importance to the adjacent countries, for all the copper utensils which are used in the Asiatic provinces of the Turkish empire, and mostly also those used in Persia, are made of this copper. It is taken to Tokat and Erzerum, where it is manufactured, and to Trebizond, whence the metal is sent to Constantinople.

Farther east, but also on the southern declivity of the

Kharzan Tagh, is the town of Ilijeh, which contains 1000 families, and where some cotton-stuffs are manufactured: in the neighbourhood maize is cultivated.

At the eastern extremity of the Plain of Diarbekr, within the Kharzan Tagh, in a very alpine country, is the town of Bitlis, 5000 feet above the sea-level, which contains 12,000 inhabitants, and carries on an active commerce with the adjacent countries and with Persia. It exports wool, tobacco, gallnuts, and gum tragacanth, which are the produce of the country. From Persia it imports cotton for the manufactures of the town, which appear to be numerous; it has also several dyeing-houses and distilleries.

Sert is built near the eastern termination of the Plain of Diarbekr, not far from the base of the mountains of Kurdistan, 2750 feet above the sea-level. It contains about 5000 inhabitants, many of whom are engaged in dyeing red the cotton-stuffs of Bitlis and Ilijeh.

Along the caravan-road are the towns of Urfáh or Orfáh, Mardin, and Nisibin. Urfáh (Orfa, the antient Edessa), the most western, is at the base of a hill, and is a well-built large place, which is frequently compared with Damascus. It is surrounded by high and strong walls, seven miles in circuit, and has between 40,000 and 50,000 inhabitants. It is not said that any branch of industry is carried on. The most remarkable of its numerous mosques is the grand mosque, which in its exterior and interior exhibits a considerable degree of magnificence. With this building are united several medresses, where a number of young men are instructed in the Koran, divinity, and the law.

Mardin, which is nearly at equal distance from Bir-eh-jik and Mosul, is built on the summit of a steep limestone hill, which may be considered as the termination of the Kharaja Dághlieri; it is 2300 feet above the sea-level, and about 1000 feet above the plain lying south of it. The population is differently stated between 10,000 and 15,000 individuals.

Nisibin (the antient Nisibis), farther east, had sunk down to the condition of a miserable village, but in modern times the Turks have begun to rebuild the town.

The town of Suverek or Severek lies on the direct road between Urfah and Diarbekr, in a depression in the midst of the table-land. In the surrounding country wheat is raised to a considerable extent, and orchards are numerous. The place contains 2000 families.

The only place, except Diarbekr, built on the banks of the Tigris which requires notice is Jezirah Ibn Omar (the Island of the son of Omar), which is built on an island in the river. It has long been the seat of a rebellious chief of the Kurds, and contains a population of about 1000.

III. The third region, called the *Desert of Mesopotamia*, extends from the great caravan-road leading from Bir-eh-jik to Mosul to the Median Wall, or from 37° N. lat. to 33° 30′ N. lat., and between 38° and 44° E. long. At its northern extremity it is nearly 300 miles wide; but as the Euphrates and Tigris approach nearer to one another in their course to the south, the country grows narrower, and at its southern extremity it is hardly fifty miles wide. The length from north-west to south-east may be about 250 miles, and the average width about 150 miles. This gives an area of 37,500 square miles, or about 10,000 square miles more than Ireland.

This country has been called a desert, not on account of the sterility of the soil, but because till very recently we have been entirely unacquainted with its productive powers. That portion which has lately been seen by European travellers is far from being a desert, and has given rise to the opinion that in Mesopotamia there does not exist any tract of country of considerable extent which is covered with sand and utterly sterile, though a large part of it is covered with horizontal layers of sandstone, which only during a small part of the year are clothed with grass and plants. But, on the other hand, there are some districts which exhibit a considerable degree of fertility.

The level of this region at its northern extremity and in the vicinity of Mardin, is between 1300 and 1400 feet above the sea, but it decreases as it approaches the rivers; Mosul on the Tigris is only about 400, and Bir-eh-jik on the Euphrates 650 feet above the sea-level. The course of the rivers and streams shows that it descends towards the south. At its southern extremity near the Median Wall it probably does not exceed 200 feet above the sea.

The country is a plain, but there are a few isolated ridges of high hills, which however do not cover a great extent of country. The best known of these ridges are the Jebel Makhul on the banks of the Tigris, between 35° 30′ and 35° N. lat.; the Sinjar Hills, south of Nisibin, between 41° and 42° E. long., and north of 36° N. lat., and the Abd-al-aziz Hills, between 39° and 40° E. long. and near 36° 30′ N. lat. The precise situation of the last-mentioned range has not been determined.

The most fertile portion of this region is in the north-western corner, between the Abd-al-aziz Hills and the Euphrates: it is drained by the river Belik, which runs about a hundred miles, and falls into the Euphrates at Racca. This region comprehends the districts which are known by the names of Saruj and Harran. The fact of the fertility of this tract has only lately come to our knowledge in the last war between the Turks and Egyptians, when the army of the Turks drew provisions from this country. On this occasion Mr. Ainsworth was informed that in Saruj alone were more than forty large villages, inhabited by agriculturists, and that twenty of them cultivated rice. The country is considered as the granary of Syria, and no part of the last-mentioned province can vie with it in fertility and agricultural productions. Harran, which lies to the east of Saruj, is stated to contain a large portion of alluvial land, and to be equally fertile. The degree of fertility of the Abd-al-aziz Hills is not known, nor their extent and direction.

We are totally unacquainted with the tract between these hills and the Sinjar Hills, except that nearly all the upper branches of the Khahur river rise in this tract, and this leads to the presumption that this tract is well watered, and that it contains a fair proportion of land fit for cultivation. This is also stated to be the case with the valley in which the Khabur river runs southward and south-westward until it reaches the Euphrates, near the castle of Rehabeh, after a course of probably two hundred and fifty miles.

The country between the caravan-road and the Sinjar Hills is nearly a level plain, which even at the end of the dry season is mostly covered with coarse grass and prickly plants. In some places there are tracts of marshy ground, with long reeds, and interspersed with many large pools of sweet water; but at some places the soft soil is impregnated with salt. There are in this part many conical hills from 80 to 150 feet in height; they appear to be artificial. The portion of this tract which is under cultivation is small.

The Sinjar Hills run east and west with a slight inclination to the south. They extend in length about fifty miles, and in breadth from seven to nine miles. The highest part of the hills is near the eastern extremity, where they rise about 1500 feet above the plain. This is an agricultural district. Considerable quantities of wheat, barley, and cotton are raised in the lower and more level parts, and the sides of the hills are covered with plantations of fig-trees and vines, which yield articles of export. A portion of the hills is covered with oak trees, the acorns of which afford a plentiful supply of food to the numerous wild boars which frequent the hills. The number of the inhabitants, who are Yezidis, is stated to exceed 6000.

The plain between the Sinjar Hills and the Tigris has an undulating surface, and is for the most part barren, and covered with coarse scanty grass and thorny shrubs; there are large tracts of barren marshy soil, strongly impregnated with saline matter. The most common vegetable production is an oat-grass, which at many places covers tracts of several miles in extent, to the exclusion of all other plants, except a few flowers. Cultivation is only carried on in some of the beds of temporary watercourses, and between some low ridges of rocks, where wheat and barley are cultivated. Some tracts are covered with wormwood. In the vicinity of the Tigris the cultivated tracts are more extensive, not on the higher grounds, which rise with a rather steep ascent about 200 feet above the level of the river, but in the bottom of the Tigris. This river flows here in a valley from eight to ten miles wide: the projecting headlands of the higher country form large embayments called *hawis*, which have a fertile alluvial soil, overgrown in their natural state with grass and small tamarisks, but where cultivated giving abundant crops of grain or rice. In proceeding from Mosul southward the cultivated tracts decrease in number, as the agricultural inhabitants are too much subject to the predatory incursions of the Shammar Arabs who are in possession of the uncultivated interior of this part of Mesopotamia.

The Jebel Makhul extends about forty miles along the banks of the Tigris, and at a very short distance from the banks. It must be considered as the continuation of the Jebel Hamri, in Kurdistan, which near 35° comes close up to the banks of the Tigris from the south-east. The Jebel Makhul may rise about 600 feet above the level of the river: it consists mostly of two ridges, and is composed of one mass of transparent gypsum. In its present state it is a waste. At its western base is a large tract of country with a sandy soil, which contains a great number of bitter wells that are frequently visited by the nomadic tribes of the Arabs. The banks of the Tigris between the Jebel Makhul and the town of Tekrit are uninhabited on account of the neighbourhood of these tribes. Between Tekrit and the Median Wall the alluvial tract on the banks of the Tigris grows much wider, and appears to have been formerly a well cultivated country, which was irrigated from a large canal which still exists under the name of Ishaki, and extends from the town of Tekrit to Bagdad; a great number of smaller canals of irrigation are connected with it. But at present the canal rarely contains water, as the whole work has gone to decay from want of attention; and this tract, which has an exceedingly fertile soil, is without inhabitants, and almost without cultivation, except a few isolated spots.

The higher ground west of this alluvial tract, as far as the River Tharthar, has an undulating surface, consisting mostly of long ridges, and depressions between them, not unlike the waves of the sea. In the valleys between the higher grounds the soil is moist even at the end of the dry season, so as to afford pasture-ground nearly the whole year round. But the best pasture-ground is in the valley of the river Tharthar. This river is said to rise at the base of the Sinjar Hills. It runs parallel to the Tigris and about twenty miles from its banks. In May it was found to be between fifteen and twenty feet wide, and from five to seven feet deep. Its course may perhaps amount to one hundred and fifty miles. The water is brackish in summer, but not unpleasant to drink. The bottom in which this river runs is sometimes a mile wide, but in other places narrowed by the projecting headlands of the higher grounds to two or three hundred yards. It does not appear to be cultivated, but on the western bank are the extensive ruins of Al Hadhr (the antient Hatra), which must have been erected in a country which was well cultivated. The Tharthar falls into a salt lake, somewhat north of 34° N. lat. This lake is called El Milh, or the Lake of Ashlik; its extent is not known. The country west of the Tharthar river, as far as the banks of the Euphrates, is entirely unknown. It is said that at some places rock-salt is found in this desert.

The country contiguous to the banks of the Euphrates is much better cultivated than that which skirts the Tigris. Between Bir-eh-jik and Balis the Euphrates runs in a narrow bed between very high rocks; there is no bottom on the banks of the river, and the adjacent country is sterile and uncultivated. But between Balis and Racca the high grounds present themselves as low and rounded hills, and they are from one mile to six miles distant from the banks of the river. The bottom in these parts is an alluvium. On the banks of the river are tamarisk-bushes. A great part of the low plain is occupied by swamps, and the more elevated tracts between the swamps are either overgrown with tamarisk-bushes or used as pasture-ground. There is hardly any cultivation. In these parts the bed of the river is wider, and there are several islands in it. A few date-trees are planted.

At the mouth of the Khabur river are some extensive woods, composed of high trees, especially tamarisks and poplars. Lower down the low and level flats increase in extent, and here also cultivation is much more attended to, but still by far the greater part of the bottom is swampy, or only used as pasture. The number of islands increases as we proceed farther south; they are partly bare and partly well wooded with tamarisks. Before reaching Annah cultivation begins to be more general. Round this place a large tract is well cultivated; corn, cotton, French beans, and sesamum are raised to a great extent; the plantations of dates are extensive, and the numerous orchards yield oranges, lemons, pomegranates, figs, and olives. The olive-tree is not met with farther south; but the other trees and branches of agriculture are greatly attended to in the bottom of the Euphrates as far down as Hit. The banks of the river present a continual plantation of date-trees; and between them and the low, rounded, gently sloping hills at the back, the bottom is, with the exception of some swampy ground, in a high state of cultivation, and full of villages. The great fertility of this tract is mainly to be ascribed to the system of irrigation which has been introduced. A great number of canals traverse the river bottom in its width, extending from 200 to 2000 yards from the banks, and the water, raised by machines, is distributed over the adjacent lands. The numerous islands which occur in this part of the course of the Euphrates are mostly cultivated, and on some of them towns are built.

Opposite the town of Hit the bottom is only a mile wide, and nearly without vegetation, as the surface is mostly composed of gravel, intermixed with flint and pieces of chalk. There are only a few date-trees, poplars, and tamarisks; and at a few places are isolated fields of wheat, barley, or sesamum. Below this place the high grounds disappear entirely, and the whole country is very little elevated above the level of the river. The soil of this tract is extremely soft, and as the banks of the Euphrates are very low, it is annually subject to inundations, which leave behind them large pools and lagunes, the water of which is generally salt. There are no longer any canals, nor any cultivation. The whole tract is in possession of nomadic tribes, who find here during the dry season abundant pasture for their buffaloes and horses. The number of islands in the river decreases, and they are no longer cultivable; their soft soil consists of sand and mud. Such is the country between Hit and the Median Wall.

The Median Wall runs from the banks of the Euphrates to those of the Tigris. Its southern extremity is said to be on the Euphrates, a few hours above Felujah; but at this point it has not yet been recognised by European travellers. Its northern extremity is found somewhat north of 34° N. lat.; so that it runs in a straight line from N.N.E.½E. to S.S.W. ½W. It is an embankment or wall, 25 long paces thick, with towers or buttresses on its western face at every 55 paces; and on the same side it has a deep ditch, 27 paces broad. Near the Tigris it is built of the small pebbles of the country, imbedded in cement of lime of great tenacity. It is from 35 to 40 feet in height. The natives say that in places far inland it is built of bricks, and in some parts worn down level with the desert. According to their tradition it was built by Nimrúd (Nimrod) to keep off the people of Nínuwah (Nineveh), with whom he had an implacable feud; and they call it Sidd Nimrúd, or Chalú (embankment). We know nothing of the antiquity of this wall, except that it is mentioned as existing B.C. 401, when the Ten Thousand Greeks were commencing their retreat from the field of Cunaxa. Xenophon (*Anab.* ii. 4) describes it as built of baked bricks lying in asphalt, as 20 feet wide and 100 feet high: 'the length was said to be 20 parasangs (600 Greek stadia); and it is not far distant from Babylon.'

Our knowledge of the climate of this region is limited to a few general notices. The heat in summer is very great, and no rain falls up to the middle of November. During November and December the rain falls in frequent and heavy showers, but is not continual. In January and February there is a good deal of frost, and after the spring has commenced in March there are also occasional rains, but not so heavy as in December. The rains cease in the month of May, when the heat becomes soon so powerful as to dry up the pasture of the more elevated grounds, and to compel the nomadic tribes to descend with their herds to the banks of the Tigris and Euphrates, and to the valleys of the Tharthar and Khabur.

This region is divided between the pashaliks of Mosul and Bagdad. No remarkable places are found, except the towns built on the banks of the two rivers which enclose the region. On those of the Tigris are Mosul [P. C., vol. xv., p. 447] and Tekrit, which is built on a cliff, and occupies the eastern part of the site of an antient town, the ruins of which are very extensive.

The largest towns on the Euphrates are in the fertile tract which extends from Annah to Hit. Annah (the antient Anatho), which is partly built on the western bank, and partly on an island of the Euphrates, contains 1800 houses, and is considered the capital of the Arabic tribes inhabiting the country west of the river. Farther down lies Hedisah, on an island in the river, in the midst of date plantations, and contains more than 400 houses. El Uz is also a considerable place, and like Annah partly built on an island. Jibbah, another town built on an island, contains 500 houses, and is a thriving place. Hit (the Is of Herodotus, i. 179) contains bitumen springs, which are mentioned by Herodotus. It is built round a hill, and has good houses of stone. In the vicinity there is very little cultivation, and the inhabitants derive their subsistence from making salt, preparing bitumen, manufacturing woollen-stuffs, and building boats. The number of bitumen springs in the neighbourhood of this place is very great, and the produce of a single spring is sufficient to meet the demand, though it is used in these parts as fuel. A great number of river-boats of different sizes and forms are made here. They consist of wicker-work, made of branches from one and a half to two inches in thickness. The interstices are filled up with bark or straw, and then the whole is caulked with bitumen. In such boats the bitumen, salt, and prepared lime are taken to Hilla, Bassora, and even to Bagdad: in going to the last-mentioned place the boats pass through the canal of Saklάwiyah. The mode of navigating the river resembles that practised above two thousand years ago. (Herodotus, i. 194.)

IV. The plain of Babylonia, or of Irak Arabi, extends from the Median Wall (34° N. lat.) to the confluence of the Euphrates and Tigris at Kornah (31° N. lat.), and between 44° and 47° E. long. In length it does not much exceed two hundred miles, and in breadth it varies considerably. Between Felujah and Bagdad it is not more than forty miles wide, but lower down it widens to a hundred miles. Eighty miles may be the average width. This gives to this region an area of 16,000 square miles, or less than two-thirds the extent of Ireland.

This is the Babylonia which is described by Herodotus (i. 193) as a fertile tract, and as the seat of an immense population. At present this country is a desert. But when we consider the immense space over which the ruins of Babylon are scattered, and the large tracts in the interior of the country which are covered with continuous heaps of ruins, indicating the sites of antient towns and at short distances from each other, of the existence of which towns nevertheless not the slightest indications occur in the antient writers or the Arabian writers of the middle ages, we must come to the conclusion that this region was for centuries before the records of history the seat of a people who had attained a high degree of civilization, and that the famous city of Babylon was only the last of the numerous cities which successively were built there and fell into ruins. Its civilization probably goes as far back as that of Hindustan. Its destruction is chiefly to be ascribed to its situation between the two elevated table-lands of Iran in Persia, and of Nejd in Arabia, which are not adapted for arable cultivation to any great extent, but must remain the dominion of nomadic tribes, whose character and habits make them the scourges of cultivated countries, and the destroyers of civilization.

Babylonia attained its high degree of cultivation by a system of irrigation. The whole region was traversed by numerous larger and smaller canals running in every direction, by which abundance of water for irrigation was supplied to every spot. This circumstance, united to a summer heat which is not inferior to that between the tropics, enabled the soil, which is by no means of a superior description, to yield fifty or sixty fold the seed. The principal canals for irrigation extend across the whole country from the Euphrates to the Tigris. They occur chiefly in the northern and southern districts, and this is evidently to be attributed to the different level of the two rivers in these parts. It is certain that north of 32° the level of the Euphrates is considerably higher than that of the Tigris, and the water in the canals runs with a moderately strong current from west to east and falls into the Tigris. In the southern districts the contrary takes place: the level of the Tigris is higher than that of the Euphrates; and consequently the water in the canals runs from the Tigris to the Euphrates, from north to south.

The construction of these canals goes back to the remotest ages, but they have been made so substantial, that at present, after many centuries of neglect, a great number of them still impart a degree of fertility to the adjacent fields, and two of them have actually been navigated by steam-vessels; it is probable that several others which are known to exist would serve the same purpose. The most northern of these canals is the Saklάwiyah. It begins on the Euphrates about five miles north of the Castle of Felujah, and not far south of the place where, according to the accounts of the natives, the Median Wall terminates on the banks of this river, and reaches the Tigris below Bagdad. Though the direct distance between the two terminations of the canal is not more than 45 miles, its length is 70 miles, because for two-thirds of its course near the Euphrates there are many bends; the last third runs nearly in a straight line, and is frequently fifty yards wide. But where its course is not direct the canal is very narrow, so that the steam-boat navigated it with difficulty. This circumstance, the quickness of the current, which runs four miles an hour, and the lowness of the banks, which never rise above the level of the adjacent country, and are frequently lower, appear to prove that this part of the Saklάwiyah is a portion of a running stream and not a canal. Near the Euphrates the banks are thickly dotted with bushes of liquorice, which grow to the height of ten feet, and have roots of considerable thickness; these roots give consistence to the soft soil of which the banks are composed. Farther on the country adjacent to the canal presents a boundless prairie, on which numerous herds of cattle pasture, and among them are the black tents of the nomadic Arabs. By this canal the wicker-boats of Hit bring the produce of the country contiguous to that place to Bagdad, and it has twice been navigated by steam-boats. Before the Saklάwiyah reaches the Tigris it falls into a large lake called the Hor, which lies west of the town of Bagdad; a canal about five miles long called Mosadc, carries the waters of the Hor into the Tigris. It is also navigable.

The Saklάwiyah is considered to be the Isa canal of Abulfeda, who mentions three other canals farther south, which cross the whole width of Babylonia, and these canals still exist. They are called, from north to south, the Nahr Abu Gharib, the Nahr Melik, and Nahr Dhiyah. We have no particular account of these canals. These four canals leave the Euphrates between 33° 30′ and 30° N. lat. The mouths of some other canals are seen farther south, as far as the ruins of Babylon, but it is not known how far they extend inland.

The principal canal in the southern districts of the plain of Babylonia is the Shat el Hiyeh, which carries the waters of the Tigris to the Euphrates. It leaves the Tigris opposite Kut el Amara, a miserable village on the eastern bank of the river, nearly a hundred miles below Bagdad in a straight line, and 178 miles measured along the windings of the Tigris. The Shat el Hiyeh runs more than a hundred miles southward, and enters the Euphrates nearly opposite Arje or Arshe, about fifty miles above the confluence of the two great rivers, by two great branches, of which the western is called the But-je-Heïrat, and the eastern Sayid Nawain; their mouths are about five miles apart. The tide ascends the Euphrates as far as Arje. This canal is dry in summer, but during eight months it is navigable, and in winter it is 150 feet wide and rather more than two fathoms deep. In this period of the year it was navigated by a steam-boat during the late Euphrates expedition; but only the western branch is navigable, the country adjacent to which has many agricultural settlements, and a considerable traffic is carried on by it. At no great distance north of the western mouth of the Shat el Hiyeh is that of another large canal called the Shat el Kar. It runs also from north to south, but it is not known where it originates, and whether its northern extremity is connected with the Nahr Dhiyah. It was crossed by Fraser at a considerable distance above its mouth, where it was from 30 to 40 feet wide, and knee-deep in summer, but in winter it is fordable only in a few places. Like the Shat el Hiyeh, it is navigated by the river boats, which are made at Hit.

The banks of the Euphrates, from the place where the Saklάwiyah canal branches off, to the ruins of Babylon and the town of Hillah, are of moderate height. The country adjacent to them is of indifferent fertility, and is mostly overgrown with grass, thistles, and mimosas. Cultivation is limited to a few spots, and as the pasture-grounds are also indifferent, the number of cattle, sheep, and goats is not great. It appears to be little inhabited, and only from time to time a grove of datetrees is seen. Below Hillah the country improves greatly; a large portion of it is under cultivation, and the plantations of dates are more numerous. It is a populous country: between Hillah and Diwaniyeh a number of large villages are observed, the population of which was estimated by a traveller at 10,000 individuals.

A short distance below Diwaniyeh begin the marshes of the Euphrates, which lower down are called the marshes of Lemlun or Lamlun. They extend from Diwaniyeh to El Karayin or Grahim Inlet, a distance of upwards of 80 miles in a straight line, and they vary in width from 6 to 20 miles. This tract is the most productive and most populous on the banks of the Euphrates, and is inhabited by an Arab tribe called the Kasahel, who are estimated at half a million, which however is probably an exaggeration. The river runs between low banks, from which the country on both sides rises imperceptibly towards the interior, where it extends in level flats, between which are many extensive depressions which are swampy all the year round. The soil of this tract consists of a firm tenacious clay of a dark blue colour, in which numerous shells are imbedded. The soil is very fertile when irrigated, and the means of irrigation are abundant. The Euphrates divides into numerous branches, so as to convert a large tract of the marshes into islands. The marshes are also traversed by two large canals, one on each side of the river. That on the

Mesopotamia side is called the canal of Yusuf (Joseph). It begins about half an hour above Diwaniyeh and terminates at Grahim Inlet. At its upper entrance it is seventy paces wide, and its course lies nearly parallel to the Euphrates, at a distance of about 2 or 3 miles from its northern branch. The canal of the Arabian side is called the canal of Old Lamlun. It branches off from the Euphrates about 19 miles below Diwaniyeh, and rejoins it a short distance above the mouth of the Yusuf canal. The two canals are connected with the Euphrates by numerous other canals of smaller dimensions, and other canals carry the means of irrigation to those parts of the marshes which are more distant from the river. The numerous population derive their subsistence from their fields of rice, which extend over all the higher grounds, which are dry in summer, from their herds of buffaloes, which find abundant pasture in the more marshy tract, and from their plantations of dates, which cover the banks of the numerous canals. They have also a few plantations of fig-trees. During the inundations the whole surface of these marshes is under water, with the exception of those places which are enclosed by embankments, and some more elevated tracts on which the villages are built. The villages also are frequently inundated, and when this happens, the inhabitants convert the roofs of their reed-built huts into boats, or place their families on buffaloes, and in this way reach a more elevated spot. As it is very difficult to enter their country with any force, they are nearly independent, and rarely pay regard to the orders of the Pasha of Bagdad. The Euphrates in their country contracts very much in width, so as to be at some places not 200 feet across, and the Kasahel Arabs levy a very arbitrary toll on all the river boats which navigate between the lower and middle course of the river.

The marshy swamps terminate at Grahim Inlet, and with them the large canals for irrigation: farther downward only short narrow cuts are met with, which serve to irrigate the tracts adjacent to the banks of the river, and do not advance far inland. The banks are much more elevated, though not high, and in most places overgrown with bushes. This country inhabited by the Montefik Arabians, exhibits a mixture of cultivation and pastoral occupation: the inhabitants have begun to cultivate the ground, but they have not quite got rid of the habits of a nomadic life. The country is covered with villages and tents mixed together. As the country is rather fertile, it is well inhabited, but not so populous as the marshes of Lamlun. The date plantations are as numerous and extensive as at any place higher up the river, but less care is bestowed upon them and on the cultivation of rice and wheat. Those inhabitants who still adhere to a nomadic life have large herds and flocks of horses, camels, buffaloes, sheep, and goats. The tract of ground between the mouth of the two canals Shat el Kar and Shat el Hiych is swampy and well wooded, but little inhabited. But below the last-mentioned watercourse the country rather improves; the banks of the river present almost a continuous forest of date-trees, between which the villages and hamlets are so numerous that they almost touch one another: on approaching the place where the two rivers unite, the banks of the rivers sink lower, and large tracts are only swamps overgrown with reeds, but in many places extensive fields still occur, on which wheat, rice, and barley are grown. The uncultivated grounds are used as pastures for the numerous herds of buffaloes. From ten to twelve miles from the confluence of the rivers, the waters of the Tigris are so abundant that the country is converted into a swamp, which during part of the year is covered with water many feet deep, and in the dry season it is cut up by numerous watercourses. This district is nearly uninhabited.

The Euphrates fertilizes the low country which extends on both of its banks below the town of Diwaniyeh, as the Nile does the Delta of Egypt, but in a different way. The sediment which the Nile leaves on the fields, contributes as much to the fertility of Egypt as the moisture with which its soil is saturated during the inundations. The fertilizing power of this sediment is ascribed by Rüppel to the detritus which, during the rains, is collected in the mountains of Abyssinia in a volcanic region of great extent. The Euphrates does not pass through such a region, and the detritus which it brings down is formed by the abrasion of chalk, lime, and gypsum, which form a rather hard clay. This soil is not fertile itself, but becomes so when irrigated. This advantage is partly obtained by the inundations, and partly by machines of different descriptions, or by handwork. The water in the Euphrates is lowest from the middle of November to the end of the year. It then begins to rise slowly, and continues to rise to the middle of January. This rise is probably to be attributed to the great quantity of rain which falls in November and December in the countries watered by the Murad and Frat, and in the Hilly Region of Mesopotamia. No difference in the level of the water is observed between the middle of January and the vernal equinox, when the great rise begins, which continues to the end of May: the river attains its highest level between the 21st and 28th of that month. It is then found that opposite the town of Annah it is from 11 to 12 feet above the lowest level, and farther down to the marshes of Lamlun from 15 to 18 feet. Were this great volume of water permitted to rush down on the low country, it would entirely submerge it, and convert it into an immense swamp. To prevent this the great canals of Babylonia have been made, as they all occur above Hillah, or the place where the Euphrates enters the low country. The canals carry the superabundant water into the Tigris, and also give to the adjacent country the means of irrigation. They appear still in part to serve these purposes, but in a much less degree than in antient times. It is said that these canals do not always contain water, but that all of them, even the Saklâwiyeh, are either dry or nearly so during three or four months. As these canals at present are not kept in good order, they cannot carry away the great volume of water, and a larger quantity descends to the low country, and breaks through the embankments, which are not kept in good repair: this circumstance probably has converted a great part of the marshes of Lamlun and of the low country farther down into swamps. The great rise of the Euphrates is owing to the immense quantity of snow with which the table-land of the Frat and Murad is covered in the winter, which begins to melt as the sun approaches the equator. At the end of April or in the beginning of May the melting of the snow ceases, and shortly afterwards the waters of the Euphrates have attained their highest level. From the end of May to November they are continually but slowly on the decrease.

The Tigris also inundates the adjacent countries; but these inundations are more destructive than useful, on account of the great irregularity with which the inundations occur, and their difference in different years. On the 10th of April the waters of this river, at Bagdad, began to rise very quickly, and in twenty-four hours they had risen 27 feet above their common level. They rose still higher, and converted the whole country between Bagdad and Bassora into an immense lake, more than 300 miles in length. The damage and loss of life caused by this inundation were much less on the banks of the Tigris than on those of the Euphrates, which are well inhabited as far as the confluence of the two rivers, whilst those of the Tigris are nearly without inhabitants. In other years its rise is comparatively small. This irregularity in the inundations of the Tigris is chiefly to be ascribed to the numerous large rivers which originate in the mountains of Kurdistan, and join the Tigris in its middle course; while the Euphrates, after the junction of its two principal branches, the Frat and Murad, is hardly joined by any river of consequence. The affluents of the Tigris rise in the mountains of Kurdistan, which for many months being covered with deep snow, bring down an immense volume of water when the snow melts. The Zab Ala, or Greater Zab, at that time brings down a volume superior to that of the Tigris above the point of union. The other affluents, the Zab Asfal, or Lesser Zab, the Adhem, and the Diyalah, are also large rivers. The Tigris begins to rise in November, owing to the great rains which then fall in its upper basin. It rises and falls at intervals until the supply of water from the mountainous countries is stopped by the frost. In the middle of March begins the great rise, which continues to the end of May. After that period its waters alternately rise and fall during June, when they begin to decrease quickly, owing to the great rapidity of the current. Between August and November the volume of water has decreased so much that only vessels drawing four feet can navigate the river, and even such vessels encounter great difficulties. The Tigris and its great affluents flow in beds which consist of hard rocks, and a small quantity of detritus is brought down by them. It does not raise its bed by a deposit, but, on the contrary, scours it out deeper. This is probably the reason why the canals for irrigation are at present without water during the greater part of the year. Even the Shat Eidha, an antient bed of the Tigris in the plain of Bagdad, has very little water in it.

The country along the banks of the Tigris, from the northern extremity of the Median Wall to its confluence with the Euphrates, is nearly a desert, except in the immediate neighbourhood of Bagdad, which is not supplied with provisions from the lands in its vicinity, but from that part of Kurdistan which lies farther north. Bagdad is indeed surrounded with extensive gardens and some fields, but they extend only a few miles from the walls, and are surrounded by an uncultivated country. North of the town the plain is traversed by the great canal called the Ishahi, which extends from the neighbourhood of Tekrit to the Sakláwiyah canal, but is without water. There are also many other canals of smaller dimensions in the same state. The Shat Eidha probably has a small quantity of water all the year round, and in its vicinity are a few large villages, surrounded by orchards and plantations. The remainder of this tract is pasture-ground for the herds of the nomadic tribes during the summer. South of Bagdad there is still less cultivation. The country is quite flat, and in most parts a grassy prairie, well watered; in others, covered with extensive swamps. A few small cultivated spots appear at great intervals. Herds of buffaloes however, and the black tents of the nomadic Arabians, are common. There are hardly two or three villages which have a permanent population. As we approach the confluence of the Tigris and Euphrates, nothing is seen but stagnant water, swamps, and morasses, in which single families have settled, who live on the milk of their buffaloes and the little rice that they can raise.

The interior of the Plain of Babylonia is very imperfectly known. It appears to be considerably elevated above the tract adjacent to the rivers. The northern part, or that which lies north of the parallel of the ruins of Babylon, has an undulating surface. The soil is composed of sand and pebbles, and in most parts overgrown with coarse grass, mimosas, and thistles. The water is generally brackish. Between the higher grounds are swamps, which probably owe their origin to the inundations of the Sakláwiyah and other canals. Farther south the surface is less uneven, and the soil consists of clay covered with mud, intermixed with flint and small fragments of gypsum. In the middle is a row of sand-hills, which appear to cover a considerable space. In many parts efflorescences of nitré and other salts occur, which in some places form nearly a white crust on the ground. On the banks of some of the canals, especially on those of the Shat el Kar and Shat el Hiyeh, the number of settlements is considerable, and some of them are surrounded by fields of rice and other grain.

In the country just described occur the numerous groups of ruins which have been already mentioned. Many of them are seen by those who navigate the Euphrates in passing through the marshes of Lamlun. They appear to lie in a line, which begins at Al Hymer in the north [Babylon, P. C., vol. iii., p. 236], and extends from north-west to south-east, terminating at the lower course of the Shat el Hiyeh. Though the country has only been visited by two or three Europeans, we are already acquainted with nine or ten places where ruins cover a large tract of country. They form such masses that in the level country they are frequently taken for natural hills, until a closer examination shows that they contain a great number of pieces of glass, pottery, and bricks, like those found in the ruins of Babylon itself. In some of them fragments of columns have been found.

With respect to the climate of this region the reader is referred to Bagdad [P. C., vol. iii., p. 270], the remarks in which article may in some measure be applied to the whole region. Its productions are enumerated in the Pashalik of Bagdad [P. C., vol. iii., p. 268]. Besides the town of Bagdad, a few places occur on the banks of the Euphrates which require notice.

Hillah is a fortified place with about 25,000 inhabitants, Arabs, Persians, Turks, Jews, Armenians, and Indians, in the midst of a number of canals, which are partly filled up. It carries on a considerable commerce with all the towns on the Euphrates, mostly in river-barges of 50 to 80 tons. The imports consist especially of rice, dates, fish, oil, coffee, cotton-stuffs, and Indian goods, part of which are re-exported to Hit and Annah.

Diwaniyeh, lower down, a considerable place, with 1500 houses, is enclosed by a wall. Numerous river-barges are ployed in carrying the produce of the rich country in its vicinity to other places.

Suk el Sheyukh, the capital of the Montefik Arabians, contains from 6000 to 7000 families, whose habitations are dispersed among the large plantations of dates which cover the country. It is the principal if not the only market which is visited by the nomadic tribes of Nejd in Arabia. They bring to this place cattle, horses, wool, and gum, and take in return lead, fire-arms, ores of different kinds, and culinary utensils. From this place the British settlements in Hindustan are supplied with horses.

Mesopotamia is inhabited by nations of different origin. Owing to its position between two table-lands inhabited by nomadic nations, it has frequently been conquered by its neighbours, and it appears that they have expelled the original population, for the greater part of the country is inhabited by people whose ancestors have settled there within the period of recorded history. Those nations which claim to be aboriginal are the Armenians and the Yezídis. The Armenians are dispersed over the table-land of the Frat and Murad, and the Hilly Region of Mesopotamia. The first-named region they share with the Turks and Kurds; and it appears that until lately these three nations were almost equal in numbers in that country, but since the last war between the Turks and Russians many Armenians have left their country and gone to settle in Georgia. In the Hilly Region of Mesopotamia the number of Armenians is small in comparison with the Turks and Kurds. They are an industrious people, who occupy themselves with agriculture, the mechanical arts, and especially with commerce, by means of which they acquire wealth, and get into favour with the ruling nation, the Turks. They are Christians of the Greek church. [Armenia, P. C., vol. ii., p. 362.]

The Yezídis are a small nation, who exclusively inhabit the Sinjar hills, and also isolated tracts in the eastern districts of the hilly region of Mesopotamia and in Kurdistan. Though they are said to derive their name from Yezíd, the son of Móawiyah, the destroyer of the race of Ali, they are evidently different from the other nations of the country. They are of a middling size, and have a clear complexion, with regular features and black eyes and hair; their limbs are spare, muscular, and well proportioned. The hair is worn long and the beard and whiskers kept close shorn, but they are prohibited from cutting or dressing the mustachios. Their religion is a strange mixture of the worship of the devil with the doctrines of the Magi, Mohammedans, and Christians. They consider the devil as the chief agent in executing the will of God, and reverence Moses, Christ, and Mohammed, believing them more or less perfect incarnations of Satan. They adore the sun as symbolical of Jesus Christ. They have no fixed place for prayer or worship, but occasionally visit the Christian churches and monasteries, and present offerings there on recovery from sickness or escaping from danger. They are brave, hospitable, and sober, faithful to their promise, and much attached to their native soil, but cruel and vindictive: they consider their proper means of support to be robbery and theft, and they treat with great barbarity any unfortunate Mohammedans who fall into their power, especially Persians. They are industrious in cultivating the soil and managing their orchards and plantations.

The Kurds also may be partly considered as an aboriginal people. It is probable that when the Armenians generally adopted agriculture, those parts of their country which are unfit for cultivation, owing to the rigour of the climate, remained or passed into the possession of the Kurds, who had spread over these mountains from their own country. Where such tracts unfit for cultivation are extensive, the Kurds have adhered to their nomadic life, and are almost independent of the ruling nation. Where however agricultural and pastoral tracts of country are intermixed, they have partly acquired the habits of cultivators of the ground, but they still maintain an inclination to a roving life and to predatory excursions. They take great care of their cattle and sheep.

The inhabitants of Turkish origin are numerous in the table-land of the Frat and Murad, and in the Hilly Region of Mesopotamia, but a comparatively small number is found in the two southern regions. They doubtless settled in these countries at the different periods when Mesopotamia was conquered by the nations who inhabit the table-land of Iran, where nomadic tribes of Turkish origin have always been met with. In Mesopotamia they are agriculturists, and carry on different trades in towns and villages. It does not appear that any of the Turkish tribes in Mesopotamia still adhere to a nomadic life, as is the case with the Turkomans in Asia Minor. The Osmanli are only soldiers or employed by government as civil officers.

As northern Mesopotamia has derived a considerable part of its present population from the table-land of Iran, the southern regions, with the exception of a comparatively small portion, are occupied by tribes which have descended from the table-land of Nejd in Arabia; and this immigration, as it would appear, is from time to time renewed. Many of these Arab tribes have changed their mode of life, which appears always to have been the case when the immigrating tribes were not powerful enough to occupy large tracts of pastoral ground. In such case they selected a tract fit for cultivation, where they settled and became cultivators. There is a considerable number of small Arabic tribes in the desert plain of Mesopotamia, and they always cultivate only a small tract of ground. The more powerful tribes took possession of extensive regions, and even where the country was fit for cultivation they converted it into pasture-grounds for their horses, camels, and sheep. Some of them have preserved their nomadic habits to the present time; this is especially the case with the powerful tribe of the Shammar, which is in possession of the countries adjacent to the Tigris river from Mosul to Bagdad and nearly of the whole of the Great Desert. It is only in the vicinity of the Euphrates that a portion of an equally powerful tribe, the Aneizah, is found, but the principal seat of the last-named tribe is in the desert which extends from the Euphrates to Damascus. The cultivable tracts of the desert are in possession of some smaller Arab tribes, who are tributary to the Shammar. Other Arab tribes have been compelled by the physical nature of the country occupied by them to change their mode of life. This is most conspicuously the case with the tribe of Kasahel, which inhabits the marshes of Lamlun. This region does not afford pasture for camels, horses, or sheep; it is however fit for buffaloes, for the cultivation of rice, and plantations of date-trees. The inhabitants of the desert have thus been compelled to adopt the habits of the occupiers of swamps, but they have preserved their activity and their spirit of independence. The numerous tribe of the Montefik occupy along the banks of the Tigris the whole country between Bagdad and Korna, and on the Euphrates that tract which extends from the marshes of Lamlun to the confluence of the two rivers. At the back of the marshes some smaller tribes are settled. That portion of the tribe of Montefik which is settled on the Tigris lives almost entirely on the produce of their herds of buffaloes, cultivating occasionally a small spot of rice-ground. On the Euphrates the habits of the Montefik are much more agricultural: the date-plantations and rice-fields constitute their principal wealth, but the richer classes have not yet entirely got rid of their nomadic inclinations, as they still prefer to pass their time with their herds of horses and sheep in the interior of the country, whilst the poorer portion of them cultivate their rice-fields and manage the date-plantations. Travellers however observe that both the fields and plantations do not exhibit that careful cultivation which is observed in other parts of Asia where the habits of the people are entirely agricultural.

It would be an almost endless task to enumerate the political changes to which Mesopotamia has been subject since it was named in history as the birth-place of Abraham. There is no country on the face of the globe in which these changes have been so frequent and so great. From the sway of the kings of Babylonia Mesopotamia passed successively to that of the Assyrians and Medians, and then it was subjected by the Persians under the command of Cyrus. After the battle of Issus it fell into the power of the Macedonians, and after the death of Alexander his generals Antigonus and Seleucus successively got possession of it. Seleucus founded the kingdom of Syria, of which Mesopotamia formed a portion, until the countries belonging to the Syrian kingdom were divided between the Romans and Parthians. During many centuries Mesopotamia was the theatre of the wars in which these two nations contended for superiority, until the Parthians were supplanted by the Persian dynasty of the Sassanides, when Mesopotamia was disputed between them and the Greek emperor of Constantinople. But at last the Arabians appeared, and their caliphs established the seat of their wide-spreading empire in Mesopotamia. Since the destruction of the kingdom of Babylonia, the country had not enjoyed so much prosperity as under the caliphs; but after these princes had lost their power, Mesopotamia fell into the hands of the Turkish princes, the Seljuks and Atabecks. About the beginning of the twelfth century a portion of it was conquered by the Crusaders, who however did not keep it long, and after the country had been laid waste by the continual wars of the Mohammedan princes, it was invaded by the Mongols, who however soon left it, and then Mesopotamia again returned to a distracted state, until the Osmanlis, who had got a firm footing in Asia Minor, began to extend their conquests over this part of Asia. Their progress was for a time interrupted by the famous Timur, but after his death the Osmanlis again acquired the ascendancy, and subjected the whole of Mesopotamia to their dominion in the beginning of the sixteenth century. Since that time no political change of importance has taken place.

MESPILUS, a genus of plants belonging to the natural order Rosaceæ, and to the suborder Pomeæ. [POMEÆ, P. C. S.] It has the calyx 5-cleft, the segments foliaceous, the petals nearly orbicular; the disk large, full of honey; the styles 2-5 glabrous; the pome turbinate, open, 5-celled; the endocarp bony. The species are trees, natives of Europe, and in a wild state are furnished with spines, which all disappear on cultivation. The flowers are large, nearly sessile, and white.

M. Germanica, the common Medlar, has lanceolate undivided leaves, downy beneath, and solitary flowers. This plant is a native of Europe and Siberia. It is found in Great Britain in hedges and thickets in Surrey, Sussex, and Cheshire. It is cultivated on account of its fruit, which is eaten in a state of decay. Its taste and flavour are peculiar, and greatly esteemed by some persons. De Candolle describes three wild varieties of this species of medlar. The following are the garden or cultivated varieties:—

1. Blake's large medlar.
2. The Dutch, common, large Dutch, broad-leaved Dutch, or large German medlar. It bears the largest fruit of any of the cultivated medlars.
3. Stoneless or French medlar, has small obovate fruit, not much esteemed.
4. Nottingham, common, small-fruited, or narrow-leaved Dutch medlar. It has an obovate middle-sized fruit, and is the best of all the medlars.

M. Smithii, Smith's Medlar, has oblong elliptic serrated leaves, pubescent on the nerves beneath, the flowers usually solitary. The native country of this plant is unknown, but it seems to have the characters of a true species. It has white flowers, which are one-half smaller than those of the common medlar. The stipules of the sterile branches are large and foliaceous.

The medlar may be propagated by seeds or by layers, or by grafting upon seedling stocks of their own species or any kind of Pomaceæ. Forsyth remarks that the kinds of Mespilus do better by grafting on their own stocks. The soil best adapted to the growth of the medlar is a loamy rich earth, rather moist than dry, but not on a moist bottom. It may be grown either as a standard or an espalier. The general horticultural treatment should be similar to that of the apple-tree. For a further account of the pomaceous genera of Rosaceæ, see POMEÆ, P. C. S.

MESSENGER. [BANKRUPT, P. C.]

MESSENGERS AT ARMS are the officers who execute the writs issuing from the supreme courts in Scotland. The duty of executing the king's writs and injunctions appears to have rested with the Lyon King at arms, aided by the heralds or other assistants. To this day the Court of the Lord Lyon has authority in the admission of messengers at arms, in the impugnment of their conduct, and in their dismissal for misconduct. Each messenger must find security for the proper and legal performance of his official duties. Messengers require to perform their functions with great precision, as they are not only amenable to questions regarding the liberty of the subject, but have often to perform acts, on be legal accuracy of which the title to landed property may afterwards depend.

METAMORPHOSIS, VEGETABLE. [Vegetables, Metamorphosis of, P. C. S.]

METEOROLOGY. [Electricity, Atmospheric, P. C. S.]

METO'PTOMA, a genus of fossils (allied to Patella?), proposed by Professor Phillips. From the mountain limestone of the north of England.

METRODO'RUS, a distinguished antient painter and philosopher of Athens, born about two centuries before the Christian æra. After the defeat of Perseus by Paulus Æmilius, in Greece, B.C. 168, the Roman general ordered the Athenians to send him their most able painter to perpetuate his triumph, and their most distinguished philosopher to educate his sons. The Athenians paid Metrodorus the extraordinary honour of declaring to Paulus Æmilius that he was both their greatest painter and their most distinguished philosopher; and the Roman general is said to have been perfectly satisfied with their choice.

As Metrodorus was chosen to paint the triumph of Paulus Æmilius, and to educate his sons, and gave him satisfaction in both respects, we must infer that he did paint his triumph, though there is no actual mention of the picture. It must have been an undertaking of great magnitude, and indeed, if adequately represented, a very extraordinary performance, for in the procession of this triumph, which is partly described by Plutarch, there were two hundred and fifty waggons containing Greek works of art: the spectacle lasted the entire day.

(Pliny, *Hist. Nat.* xxxv. 40; Plutarch, *Paulus Æmilius*, 32.)

METRO'POLIS. [Colony, P. C., p. 359.]

METROPOLITAN. [Archbishop, P. C.]

METROPOLITAN STAGE-CARRIAGE. Before proceeding to give a brief notice of the law relating to hackney and stage carriages in London, we may quote, from two interesting papers on the 'Vehicular Statistics of London,' in 'Chambers's Edinburgh Journal' for 1845 (Nos. 76 and 78, New Series), some statements relative to such of the public vehicles of the metropolis as are not embraced in the article Hackney-Coach, P. C. S. These papers, we may observe, are founded on official though partly unpublished data.

The distinction between hackney and stage carriages is pointed out under Hackney-Coach; and the origin of that class of stage-carriages, which has almost entirely superseded the old stage-coaches in the streets of London, is noticed under Omnibus, P. C., p. 437. 'Fifteen years ago,' observes the writer of the papers above referred to, writing in 1845, 'a few very slow and unpunctual stages were the only means of transit provided for the citizens to convey them to their suburban residences.' 'A little earlier,' he adds, 'only one stage plied from Paddington to the Bank, along a road which an omnibus now passes every three minutes in the day; and this single vehicle, going in the morning and returning at night, was not always full. Its fares were two shillings inside, and eighteen-pence outside.' The old stage-coaches could only carry four, or at most six, inside passengers; and when an attempt was made, about the year 1800, to introduce a more commodious kind of vehicle, resembling an omnibus, the project failed, in consequence of a general prejudice against the hearse-like appearance of the carriage. The long-bodied carriage then tried was drawn by four horses, and had six wheels (Knight's 'London,' vol. i. p. 32.) When reintroduced from Paris, the omnibus had four wheels, but was much longer and heavier than at present, and was drawn by three horses abreast, an arrangement which, while advantageous as being the best mode of applying the power of the horses in drawing, was soon abandoned, it being found that the middle horse was distressed by the perspiration and the irregular stepping of those on each side. The first successful omnibus in London was started by a coach-builder named Shillibeer, in July, 1829, to run between Greenwich and Charing-Cross, at fares considerably less than those of the old short stages; in addition to which advantage, the greater part of the passengers were sheltered from the weather. By the judicious arrangement of making the same charge for inside and outside places, Shillibeer soon obtained extensive patronage, and began to break down the petty feeling of exclusiveness which formerly distinguished inside from outside passengers. Success in the first experiment led Shillibeer to establish omnibuses between Paddington and the Bank. After opposing the innovation most violently for a time, the old coach-proprietors followed his example, started omnibuses of their own, and by combined opposition succeeded in driving him entirely off the road; not however before the new system of travelling was fully established. It is to be regretted that the person to whose enterprise London is indebted for so great a boon, though thus prevented from reaping his reward, should never, so far as the writer is aware, have received a testimonial for his important services.

In the course of the contest between Shillibeer and the old proprietors, and of the subsequent quarrels and rivalries among themselves, the omnibus system fell into disgrace in consequence of the furious driving, want of punctuality, and general ruffianly conduct of the men employed as drivers and conductors, or, as they were popularly called, 'cads.' These evils led to the establishment, in 1836, of a joint-stock association called the 'London Conveyance Company,' which proposed to establish omnibuses along the principal lines of traffic, starting at short and regular intervals, and conducted by men of sober and respectable character, who were strictly forbidden to race, and bound to punctuality and civility. The result of this experiment was so successful, that on the lines which yet remained in private hands the proprietors found it to their interest to settle their differences, and to form themselves into associations of similar character. In the course of a few years the association system was almost universally adopted, and now, while on many lines of road the omnibuses belong to several different individuals, there is hardly an instance in which these individuals are not united in some compact which prevents competition, and secures community of interest among all the carriages running the same road, or rather among all running to and from the same termini. On the Paddington road, after a competition for some time between the London Conveyance Company and the association formed by the old proprietors, the two bodies united to 'work the roads' for their mutual advantage. Paddington is the suburban terminus of two very important lines of road, each of which has also a common City terminus at the Bank of England. One of these lines follows the course of the City Road and New Road, by Islington, Pentonville, and other northern suburbs of London; while the other takes a more direct course through the heart of the metropolis, by Holborn and Oxford Street. For working the last-mentioned line the London Conveyance Company have, according to the papers referred to at the commencement of this article, eighty-two omnibuses, and not less than a thousand horses. Each of the omnibuses performs, upon an average, six journeys (that is, double journeys) per day, and therefore requires at least ten horses to work it, independent of casualties. These horses are selected for strength and activity, and an experienced veterinary surgeon, with a staff of assistants and farriers, besides upwards of eighty horse-keepers or grooms, are employed to attend to them. These are independent of eighty-two drivers, and as many conductors, so that nearly three hundred persons are employed by the Company, for the service of this one line of road. The journeys are performed at intervals of from one and a half to three minutes, according to the time of day; and as each omnibus makes six double journeys, of about nine miles each, the total number of journeys run daily is 492, and the number of miles run daily is about 4428. 'Supposing,' observes our authority, 'we take as an average ten passengers for each trip, the gross receipts of the London Conveyance Company must, if that guess be an approximation to the truth, amount to 246*l.* per diem, or 89,790*l.* per year.' These statements may serve to convey some idea of the great extent of the omnibus traffic of London, and of the number of persons dependent upon it; especially when it is remembered that the eighty-two omnibuses to which they refer constitute the working stock of only one single route. The total number of omnibuses running to and from the suburb of Paddington alone is said to be nearly 200. The total number of stage-carriages plying in and from London during the year ending January 4, 1845, according to information obtained from the licensing office, was 1472, of which it is calculated that at least 1400 were omnibuses. By a rough calculation, the writer to whom we are indebted for the collection of the above facts, computes that about 2000*l*. are spent daily in omnibus fares, making a total of 730,000*l*. per annum. The number of licensed drivers in May, 1844, was 1740, and of licensed conductors, 1854; but of these about 300 took out licences in both capacities, and are therefore counted twice. By adding these numbers to those quoted under HACKNEY-COACH, our authority computes (without, we may observe, deducting the 300 cases of double licensing) that 8592 individuals were, in 1844, licensed as drivers and conductors of, or 'watermen' to attend to, the various public carriages used in the metropolis; that in all 3922 vehicles were in use, and that 'the cash annually circulated by all the metropolitan hired carriages exceeds 1,500,000*l*.' It is gratifying, as an evidence of the improving character of the class of men employed, to find that of the above large number only forty-two were refused new licences on account of misconduct.

The length of journey run varies from about four up to twelve or thirteen miles; but by far the greater part of the London omnibuses run a total distance, from end to end of their journey, of less than eight miles. With such the usual charge is sixpence per passenger, whether for the whole or a part of the journey; but a very large portion of their receipts arises from 'short' passengers, or such as are picked up and set down by the way. Omnibus proprietors are much exposed to peculation on the part of their servants, and various mechanical contrivances called 'tell-tales' have been tried to protect their interests by registering the number of passengers carried. None of these have come into general use; but in connection with the association system a method of checking the conductors, by a kind of secret police, has been adopted. When it is found that the returns made by one conductor fall short of the expected sum, spies are set to watch him by taking their places as passengers, and reporting at headquarters the numbers taken up, as a check upon him; and so systematically is this service performed, that any attempt at deception is pretty sure to be detected, and followed by suspension or dismissal. The power of applying such a check is one of the many advantages of the association system, in which, as commonly worked, each individual proprietor contributes a certain number of *turns-out* (a *turn-out* being the technical name for an omnibus with its complement of horses and men) to a common stock, which is worked, so far as regards the time of starting, speed, and other regulations, for the common benefit. The receipts of each omnibus are then paid into a common fund, from which each proprietor receives a portion proportionate to the number of *turns-out* contributed and maintained, without regard to the actual receipts of the omnibuses owned, by him.

The laws which relate to hackney-carriages and metropolitan stage-carriages are chiefly comprised in two acts of Parliament: 1 & 2 Wm. IV. c. 22, which came into operation January 5th, 1832, entitled 'An Act to amend the Laws relating to Hackney-Carriages, and to Waggons, Carts, and Drays, and to place the Collection of the Duties on Hackney-Carriages and on Hawkers and Pedlars in England under the Commissioners of Stamps;' and 6 & 7 Vict. c. 86 (22nd August, 1843), entitled 'An Act for regulating Hackney and Stage Carriages in and near London.'

In the former act are contained the greater part of the enactments which relate to hackney-carriages; in the latter, those which more especially apply to metropolitan stage-carriages (omnibuses).

The limits of hackney-carriages (hackney-coaches and cabriolets) are five miles from the General Post-office, London; and drivers of hackney-carriages are compellable to drive five miles from the place where hired or from the General Post-office; but if any hackney-carriage shall be discharged at any place beyond the limits of the metropolis (that is, beyond a circle of which the radius is three miles from the General Post-office), after eight in the evening and before five in the morning, back-fare may be demanded to the nearest part of the said limits or to any standing-place beyond the limits where the carriage may have been hired, at the option of the hirer.

The fares of hackney-carriages are fixed by the act 1 & 2 Wm. IV. c. 22. For every hackney-carriage drawn by two horses, for any distance not exceeding one mile, 1*s*.; for any distance exceeding one mile, at the rate of 6*d*. for every half-mile and for every fractional part of half a mile over and above any number of half-miles completed. By time, the fare is, for not exceeding thirty minutes, 1*s*.; not exceeding forty-five minutes, 1*s*. 6*d*.; not exceeding one hour, 2*s*.; and for any further time after the rate of 6*d*. for every fifteen minutes completed, and 6*d*. for any fractional part of fifteen minutes. The fares for hackney-carriages drawn by one horse (cabriolets) are one-third less, so that for the first mile they are 8*d*., for a mile and a half, 1*s*., and so on.

Every hackney-carriage and metropolitan stage-carriage is licensed by a registrar, deputy-registrar, or other officer appointed by one of Her Majesty's principal Secretaries of State; and every driver of a hackney-coach, and every driver and conductor of a metropolitan stage-carriage, and every waterman, at the time of granting the licence receives a metal ticket, which every such driver, conductor, or waterman is to wear on his breast in such manner that all the writing thereon may be distinctly visible. Watermen are the assistants of drivers of hackney-carriages and of metropolitan stage-carriages stationed at certain places to supply the horses with water, &c., and they also receive a licence. A stamp-duty of 5*s*. is charged on every licence, and 5*l*. is paid for it, and 10*s*. a week during the continuance of it. Plates are to be affixed to hackney-carriages with the name and abode of the proprietor and number of the licence; and 'Metropolitan Stage-Carriage,' or such other words as the registrar shall direct, are to be painted on omnibuses. Proprietors of metropolitan stage-carriages fix their own fares, but those fares are to be distinctly painted on or in the carriage, as well as the number of persons for whom the carriage is licensed.

Hackney-carriages standing in the street, though not on any stand, to be deemed plying for hire. Drivers may ply on Sundays, and, if plying, are compellable to drive when hired. Agreement to pay more than legal fare not binding, but driver may agree to drive any distance at discretion for a stated sum, and must not charge more than that sum, though less than legal fare. Deposit to be paid for carriage kept waiting, and driver must take the deposit and wait.

The act 6 & 7 Vict. c. 86, repeals a previous act (1 & 2 Vict. c. 79), and extends the enactments not specifically repealed of the 1 & 2 Wm. IV. c. 22, to the 6 & 7 Vict. c. 86. Other provisions of the acts relate chiefly to the restoration of property left in carriages, to furious driving, intoxication, insulting language, loitering, and other acts of misbehaviour; to proceedings of proprietors, drivers, and conductors, as to licences, payment of duties, contracts with each other; and to modes of granting summonses, powers of magistrates, punishments, penalties, &c.

METROSIDEROS (from μήτρα, the heart of a tree, and σίδηρος, iron), a genus of plants belonging to the natural order Myrtaceæ. It is distinguished from allied genera by the tube of the calyx not being angular, adhering to the ovarium, the limb 6-cleft; the stamens 20-30, free, very long, and exserted; the style filiform, and stigma simple; the capsule 2- or 3-celled, the cells many-seeded; the seeds wingless. The species are trees or shrubs, with opposite or alternate leaves, with the flowers pedicellate, not adnate to the branches, as they are in the genera Melaleuca and Callistemon. The last genus, with Angophora, has been recently separated from Metrosideros.

M. vera, true Iron-wood, has opposite ovate-lanceolate acuminated quite glabrous leaves seated on short petioles; the cymes axillary, pedunculate, many-flowered. It is a native of Java and Amboyna, among rocks. The Chinese and Japanese value the wood of this tree, which they apply to many purposes, as the making of rudders, anchors, &c. for their ships and boats. The bark is used in Japan as a remedy in mucous discharges, diarrhœa, and dysentery. It is usually mixed with some aromatic, as penang, cloves, or nutmeg.

M. polymorpha has opposite coriaceous leaves, of various forms, glabrous on both surfaces, but covered with a little silky tomentum beneath; the peduncles 3- or many-flowered, terminal and axillary, corymbose; the calyxes and branchlets glabrous or clothed with silky tomentum. This species is a tree, and grows in the Sandwich Islands, and is said to be the plant from which are made the clubs and other weapons employed in warfare by the South Sea Islanders. 'The Aki or Lignum Vitæ of New Zealand, the Rata and the Pohutu Kawa of the same country, are all hard-wooded trees belonging to the genus Metrosideros.' (Lindley.)

Several other species of Metrosideros have been described, natives of New Holland and the South Sea Islands. *M. lucida*, a beautiful tree, occurs as far south as Lord Auckland's Islands, in lat. 50½° south. The *M. buxifolia* of Allan Cunningham is the New Zealand plant called *Aki*, and is a rambling shrub, adhering to trees, and climbing by means of its lateral roots to the summits of the loftiest trees in the forests of Wangaroa and the Bay of Islands. In cultivation these plants may be grown in a mixture of loam, peat, and sand. They may be propagated by seeds or cuttings. Ripe cuttings will root in sand under a hand-glass.

(Don, *Gardener's Dictionary;* Lindley, *Vegetable Kingdom;* Burnett, *Outlines of Botany.*)

METZ, CONRAD MARTIN, a celebrated German engraver of Bonn, where he was born in 1755. He studied under Bartolozzi, in London, and remained altogether about twenty years in England. He published in 1790 a set of thirty-three engravings, including the title, after George the Third's collection of drawings by Parmegiano; and in 1791 a set of sixty-three plates in a similar style, after the designs by Polidoro da Caravaggio, in the possession of Sir A. Hume, Bart. He engraved many other imitations of drawings by the old masters. In 1801 Metz went to Rome, and commenced a series of engravings after the Last Judgment in the Sistine Chapel, by Michael Angelo. It is engraved in chalk manner in fifteen separate sheets, with an outline of the whole. Metz died at Rome in 1827, aged seventy-two. Dr. Nagler enumerates upwards of two hundred of his engravings in his *Künstler-Lexicon.*

METZU, GABRIEL, one of the most celebrated of the Dutch painters, was born at Leyden in 1615. It is not known under what master he studied, but he obtained a great reputation at Amsterdam while still young. Like Mieris and Terburg, Metzu belongs to the higher class of *genre painters.* He painted what are called conversation pieces; and often a lady at her toilet, or in her boudoir, with all the usual accessories; his scenes are occasionally taken from humble life, but generally from the middle classes of society. He excelled in light and shade, drawing, and colour, and his execution is always extremely careful; his pictures, though very small, are always finished with the minutest attention to detail. Metzu perhaps attained perfection in his style, and carried painting as a mere imitative art to its highest degree of excellence: the tone of his pictures is complete nature, every tint is perfectly true, and every object is accordingly in its proper place, for his drawing and linear perspective were equal to his light and shade, and colour. Beyond this he did not go; his works exhibit nothing choice or extraordinary either in subject or arrangement; and the faithful representation of familiar life appears to have been the end of his art, not for the sake of the scenes, but for the imitation's sake. He was essentially a materialist in art, and this is the distinguishing characteristic of the Dutch painters generally. He painted a few portraits; there is one of Admiral van Tromp in the Louvre. Some of his works realize very high prices; many of them have been engraved. Metzu died, according to D'Argenville, in 1658, in consequence of undergoing an operation for the stone: there is however a picture of a poulterer in the Gallery of Dresden, by him, dated 1662; the date therefore of his death is uncertain.

MEUM (from μείων, smaller), a genus of plants belonging to the natural order Umbelliferæ and to the tribe Seselineæ. It has an obsolete calyx; entire elliptical petals, acute at both ends, with an incurved point; the fruit elliptical, terete, or slightly dorsally compressed; the carpels with five sharp somewhat winged ridges; the interstices and commissures with many vittæ. There are two species of this genus.

M. Athamanticum, Common Bald-Money, has bipinnate leaves with multipartite leaflets, the segments thread-shaped, acute. This is a highly aromatic plant, with numerous white and yellow flowers. It is a native of Europe, in dry mountain pastures, and is found in England and the mountains of Scotland. The roots, seeds, and every part of the plant are aromatic, and are used in the countries where it grows as stomachics and carminatives. This and the other species, *M. Mutellina,* the Swiss Bald-Money, which is a native of the subalpine pastures of Europe, enters into the composition of the compound called Venice treacle.

(Babington, *Manual of British Botany;* Lindley, *Vegetable Kingdom.*)

MEYER, HEINRICH, a German designer and painter, and distinguished writer on art, known in Germany in his life time as 'Goethe-Meyer,' from his close intimacy with the great writer. For forty years Meyer was Goethe's consulting and confirming oracle in all opinions on art, and was even the author of many portions, especially of the critical parts, of Goethe's publications on art, as 'Kunst und Alterthum,' 'Winckelmann und sein Jahrhundert,' 'Propyläen,' 'Farbenlehre,' &c.

Meyer was born in 1759 at Zürich, and he was for some years the pupil of J. C. Füssly there. About 1786 he went to Rome, where he made the acquaintance of Goethe. In 1787 he was at Naples, lived there in the same house with Tischbein, and became acquainted also with Herder, then travelling in the suite of Amalia, Duchess of Weimar. In 1792 he visited, for some time, Weimar, and in 1797 established himself for the remainder of his life there. He became a great favourite with the court at Weimar, was intimate with all the distinguished literary men of the place, and held, from 1807, the office of director of the academy there, and enjoyed the titular rank of Hofrath. From 1794 until his death in 1832 Meyer was chiefly engaged on literary compositions relating to the history and theory of art, but chiefly the history of Greek and Roman art. He was the principal editor of the complete edition of the works of Winckelmann, which were published in 8 vols. at Dresden between 1808 and 1820 inclusive, and was the author of the greater part of the numerous notes by which they are illustrated. These notes be afterwards arranged and connected into a consecutive history of Greek art, under the title 'Geschichte der Bildenden Künste bei den Griechen,' 2 vols. 8vo., Dresden, 1824. A third volume, being the continuation of the history of Greek art in Rome, was edited by Dr. F. W. Riemer, after the death of Meyer, under the title 'Geschichte der Bildenden Künste bei den Griechen und Römern,' 1 vol. 8vo., Dresden, 1836. This work, though agreeably written, and containing a good general account of the progress and the remaining works of antient art, has failed to satisfy those interested in the subject, and has obtained little popular or general notice. In the first place its form is against it: the text and the author's remarks are separated, the latter being at the end of the volumes. The text is little more than a chronological catalogue of names and works; and the notes at the end of the volumes, besides being troublesome to refer to, as disconnected with their subject, do not clear up the obscurities, or reconcile the apparent contradictions of antient authors. Reflections are rare, and when they occur they are neither profound nor illustrative, nor does he in any case indulge in æsthetical remarks, or attempt to deduce or investigate theories. The work is also surpassed by other German works on the same subjects, though it is the only special work in the language that examines the progress of the two arts of painting and sculpture, throughout their whole course, from the earliest times until the decline of the Roman empire.

As a painter Meyer produced little. His works consist chiefly of water-colour and other drawings from antique remains, or from the works of the great Italian painters. His principal work is an allegory of human life, represented by children, as a painted frieze, in the palace at Weimar.

(Nagler, *Künstler-Lexicon.*)

MICHAEL, SAINT, the largest and most important of the Azores, or Western Islands, lies a little south of 38° N. lat., between 25° and 26° W. long. It is about 45 miles long, and from 6 to 9 miles wide; the area is about 220 square miles.

Nearly the whole of the island exhibits unequivocal signs of volcanic agency, and presents a great variety of surface. The greatest elevation occurs near its eastern extremity, which is formed by a mountain-mass terminating in several summits, the highest of which, the Pico da Vara, attains 3560 feet above the sea-level. Two other peaks rise respectively to 2927 and 2455 feet. The shores of this tract are very high, and in some places rise to more than 1200 feet. This part of the island has no traces of volcanic agency; is well watered and produces abundance of grain of all sorts, and the mountains are covered with woods. Contiguous to this tract on the west is a region of very uneven surface, but of less elevation. It comprehends the Valley of the Furnaces or Hot Wells. The large depression of the valley is partly occupied by a lake one mile long and half a mile broad. This lake is 995 feet above the sea-level, but the peaks which enclose the valley rise to between 1500 and 2300 feet. This division is abundantly watered by frequent showers in summer, and more continuous falls of rain at other seasons. As the soil consists of scoria, lava, and other volcanic matter, which has not been decomposed, the country has a barren aspect, but where cultivated it produces excellent fruit. In the centre of the island the country rises higher, and becomes mountainous. The Sierra da Agoa de Pao, which is 3060 feet above the sea, contains a great number of separate volcanic cones of great elevation, varying between 1800 and 2600 feet. They are chiefly composed of pumice and scoria. From want of cohesive power in the matter which composes these cones, the heavy rains cut deep gorges in their sides and frequently cause landslips. The lower part of this tract contains numerous vineyards, orchards, and orange plantations. Between the two largest places of the island, Ponte Delgada, on the southern coast, and Ribeira Grande, on the northern, lies the lowest part of the whole. The shores are here low, and rise almost imperceptibly towards the interior, where an irregular line of hills and craters occurs, beginning, on the east, with the Pico do Fogo, 1031 feet above the sea, and terminating on the west with the Sierra Gorda, 1574 feet. The soil of this tract is in general very fertile, but there are extensive patches of scoria and vitreous lava, which are only fit for vineyards. There are no hot springs or other signs of subterraneous heat, and the whole of this district is deficient in water, in consequence of its inferior elevation. The most western part of St. Michael's appears to have been more subject to volcanic changes than any other. It contains in its centre a valley of an elliptical form, called the Sete Citades, which is three miles long from south-east to north-west, and two miles and a half broad from south-west to north-east. The ridge which bounds it is of nearly equal height throughout, except where it runs into peaks. On the south-east is a short chain, two miles long, terminating in the Pico de Carvao, which is 2632 feet above the sea. The greater part of the interior of this valley is occupied by two lakes. In this tract are two hot springs which rise up in the sea below high-water mark. The soil varies much in character, being in some parts a yellow argillaceous earth, well suited for cultivation and of great fertility, in others a mixture of pumice and scoria, or a vitreous intractable lava which defies the efforts of the husbandman. Hot springs are frequent, except in the eastern districts and the country between Delgada and Ribeira Grande.

Although the climate is variable both as to heat and humidity, it is very temperate, and the changes do not materially affect health or comfort. In summer, clouds generally float in the atmosphere and mitigate the sun's heat; in winter, there are few days when heat is not felt, and during the whole year there is not one day in which agricultural labour may not be carried on.

Table of the Temperature of Air.

	Maxim.	Minim.	Mean.	Daily Range.
October	75°	58½°	66·6°	6°
November	71	50½	63·3	7
December	70	48½	59·1	7
January	69	48½	59	5½
February	69	48	58	6½
March	72	48½	60	6½
April	72	50	62	6½
May	75½	56	65·3	5½
June	78½	61	68·9	5½
July	82½	63½	73·1	5½
August	82½	65	74·4	5
September	80	64½	73	5½

The mean temperature in winter is 62° and in summer 69·5°. The extremes of the whole year are 46° and 84°, in winter 46° and 76°, and in summer 46° and 84°, in February 46° and 72°, and in August 64° and 84°. A much greater proportion of vapour exists in the air in all seasons than in England. The mean annual quantity of rain is 30 inches near the level of the sea, and the maximum 42 inches, while it is probably not less than 50 inches on the mountains. The prevailing winds are from the north-east and north-west. Northerly and easterly winds prevail over those from other points of the compass in the ratio of 37 to 26, which indicates that the island is not situated in that part of the Atlantic where westerly winds generally prevail.

The principal occupation of the inhabitants is the cultivation of the ground. The island contains 147,200 acres, of which 2100 are planted with orange-trees and 2400 acres with vines. The arable land amounts to 40,100 acres, and the remaining 102,600 acres are occupied by mountains, lakes, rivers, roads, and dwellings. The grains which are most extensively cultivated are wheat, Indian corn, and beans. Yams and bananas succeed in several places on the southern coast. Several kinds of vegetables are grown, but the common people cultivate only cabbages and potatoes to any extent. As two-thirds of the island are not cultivated, the pasture-grounds on the more rugged portions of the island are extensive. All the domestic animals of Southern Europe are kept, but the breeds are indifferent. Of wild quadrupeds only rabbits, ferrets, and weasels are noticed, with rats and mice. There are many kinds of birds, mostly those of small size; fish is rather abundant along the shores.

The inhabitants, who are Portuguese, are an industrious people; but nearly the whole of them, amounting to 80,000 individuals, are employed in agricultural labour. With the exception of the common mechanical trades, the manufacturing industry is limited to some coarse woollen stuffs, especially druggets, and to a coarse kind of red pottery, which is made at Villa Franca.

The capital of the island, Ponte Delgada, is built on the southern shore. It has an unsafe harbour, for when the wind turns to the south all the vessels in the road are obliged to slip their anchor, and they can only return after the wind has changed to another quarter. The town is surrounded by extensive orchards and orange plantations, and is rather a pleasant place, in which many English families have settled: the population is upwards of 20,000, and it is the largest town in the Azores. Alagoa, farther east, has a small port and 4000 inhabitants; and Villa Franca, still farther east, 5000 inhabitants. In the vicinity of these places are extensive plantations of oranges and vineyards. On the northern coast is the town of Ribeira Grande, with 12,000 inhabitants. It has no harbour, being hemmed in by reefs of rocks, which run out some distance from the shore. It is irregularly built, the houses being scattered over rocky uneven ground, and forming narrow irregular streets along the coast. It has some manufactures of coarse woollen cloth and common linen.

The foreign commerce was formerly confined to Portugal, but at present the island is visited by English, American, and Brazilian vessels. The number of English vessels which annually visit St. Michael's is about two hundred, and about the same number sail between St. Michael's and Portugal. The American and Brazilian vessels are few. The English take only oranges, of which about 90,000 boxes are annually exported. The other agricultural productions, especially corn and maize, are carried to Portugal. The Americans take only gold and silver coin in return for their imports. The importation from England consists of several kinds of textile fabrics, iron goods, and corn; those from Brazil, of hides and colonial produce; the Americans bring timber and whale-oil, and the Portuguese liquors, textile fabrics, colonial produce, silver coin, soap, and hats.

This island was discovered in 1444 by Cabral, and was settled in the following year. Since that period it has remained in possession of the Portuguese.

(Boid's *Description of the Azores, or Western Islands*; Hunt's *Description of the Island of St. Michael*, in *London Geogr. Journal*, vol. xv.)

MICHIGAN, since the article in P. C. was written, has become a State. A sketch of the new constitution and other particulars are given under UNITED STATES OF NORTH AMERICA, P. C. S.

MICIPSA. [JUGURTHA, P. C.; NUMIDIA, P. C.]

MICON (Μίκων or Μύκων), a distinguished Greek painter and sculptor, was the son of Phanochus of Athens, and was one of the most celebrated of the Greek painters for painting horses. He lived about the middle of the fifth century before Christ, and was the contemporary of Phidias and Polygnotus.

The history of Micon is less known than that of many others of the eminent artists of antient Greece. He was however one of the painters chosen by the Athenians to perpetuate their great victories in the Colonnades of the Ceramicus, which was enlarged or rebuilt by Cimon after his victories over the Persians; and he was also appointed to paint the walls of the temple of Theseus at Athens; an honourable distinction, indicating the highest eminence in his art.

Micon painted the battle of the Amazons and the Athenians under Theseus, in the gallery of the Ceramicus, which was called subsequently, in consequence of this and other pictures, the variegated gallery, or the Poecile (ἡ ποικίλη Στοά). He appears also to have assisted Panaenus in the picture of the battle of Marathon, in the same gallery, for it is said that he was fined 30 minae, or half a talent, for painting the Barbarians larger than the Greeks, in that picture.

In the temple of Theseus he painted another battle of the Amazons and Athenians; and opposite to it the battle of the Centaurs and the Lapithae. A third wall also was painted by Micon in this temple, but the picture was so much defaced through age, that Pausanias could not discover the subject of it. Micon also painted, together with Polygnotus, the temple of the Dioscuri; he painted there the return of the Argonauts to Thessaly with Medea and Æsteropea and Antinoe, the daughters of Pelias; they were so called according to this picture, on which their names were inscribed. This circumstance is noticed by Pausanias, who remarks also that the best part of these paintings was Acastus and his horses. It is observable that all Micon's pictures were of such subjects as admit of the introduction of horses, and some of them were the best subjects that could be chosen for the display of the painter's skill in painting these animals, as the battles of the Amazons and the Centaurs. Micon, as already mentioned, was one of the most celebrated of the Greek painters in this respect, yet he was not altogether perfect in his horses, for he gave some of them lashes to their under eyelids, which horses have not. His horses were objected to on this account by Simon, an Athenian well skilled in such matters, and who, according to Pliny, was the first writer on Equitation: a statue by a sculptor of the name of Demetrius was erected to Simon's memory at Athens. This nicety of criticism tends rather to establish Micon's reputation than otherwise, as this was the only error detected by so able a critic. According to another account, it was a fault that was found with some of the horses of Apelles. Great excellence however, in the drawing of the horse, is not at all inconsistent with the state of the art at the time that Micon lived, for we have actual remains of that very period in the beautiful horses of the frieze of the Parthenon, now in the British Museum, executed under the superintendence of Phidias, who was the uncle of Panaenus, with whom Micon worked in the Poecile.

A figure in one of Micon's battles of a certain Butes was the origin of an Athenian proverb: Butes was painted concealed or crushed by a stone, and all that appeared of him was his head and eyes, which seemed to the Athenians so very expeditious a method of painting a warrior, especially one it was necessary to give a name to, that 'Micon painted Butes,' and 'quicker than Butes,'—θᾶττον ἢ Βούτης—became sayings for expressing anything that was quickly done. Varro speaks of the style of Micon as crude and unfinished when compared with the works of Apelles and later artists. This is very probable, and the same might be said of many of the works of Michelangelo and Raphael compared with those of almost any of the scholars of the Carracci; yet the difference is a mere matter of execution, and is not at all essential, nor does it in the least interfere with the higher qualities of art, as form, expression, or composition.

Micon was also a sculptor: be executed, according to Pausanias, the statue of Callias, the Athenian pancratiast, at Olympia.

Micon appears to have been not an uncommon name among Greek artists. The father of Onatas of Aegina was Micon; and Pliny mentions Timarete, herself a painter, as the daughter of a painter of the name of Micon.

There was also a Syracusan sculptor of the name of Micon; be was the son of Niceratus, and made the two statues of Hiero II., which were placed by the sons of Hiero at Olympia.

(Pliny, *Hist. Nat.*, xxxiv. 19; xxxv. 35; Varro, *Lingua Latina*, viii.; Pausanias, i. 15-18; vi. 6; viii. 11; Aelian, *Hist. Animal.*, iv. 50; Sopator, *Rhet. Græc.*, p. 340, ed. Ald.; Böttiger, *Ideen zur Archäologie der Mahlerei;* Sillig, *Catalogus Artificum.*)

MICROMETER. [Divided Eye-Glass Micrometer, P. C. S.]

MIEREVELT, MICHIEL JANZEN, a celebrated Dutch portrait painter, was born at Delft in 1567, not in 1568, as in the first edition of Van Mander. His father was a goldsmith. Mierevelt was a very precocious boy; at eight years of age he could write better than any schoolmaster in Delft; at twelve be could engrave, and at fourteen he was a good painter, having studied for about two years under Antony Bloklandt at Utrecht.

Mierevelt painted almost exclusively portraits, and chiefly heads, but be attained great celebrity, even beyond the limits of his own country, and he could not be persuaded to leave it. The Duke Albert of Nassau, in consideration of his abilities, granted him the privilege of carrying on his Mennonite worship without molestation; and Charles I. of England invited him in 1625 to visit England, an invitation which Mierevelt declined because the plague was at that time in London. He died at Delft in 1641.

Mierevelt's portraits, though extremely numerous—Houbraken computes them at 5000—are generally well drawn and very elaborately finished. Many of them are engraved by various masters, and there are a few etchings by his own hand. He had two sons, who were likewise excellent portrait painters, Pieter Michielsz and Jan Michielsz; the elder was born in 1595, and died aged only twenty-eight in 1623: the younger also died young.

The following verses are under Mierevelt's portrait in the first edition of Van Mander, which was published during his lifetime:—

Pingendo au vivum, quo non praestantior alter;
Delphicus hinc Zeuxis dicitur esse novus.
Principibus magnis fuit invitatus: at ipsum
Ante alias urbes Patria culta tenet.

(Van Mander, *Het Leven der Schilders*, &c., ed. 1764; Houbraken, *Groote Schouburg der Nederlantsche Konstschilders*, &c.)

MIGLIARA, GIOVANNI, a very distinguished modern Italian artist, who invested architectural painting with a species of interest which it had not before possessed even in the ablest hands. He was born at Alessandria in Piedmont, October 15th, 1785, of poor parents, who placed him with Luigi Zuccoli of Milan, to learn wood-engraving; but on discovering his strong and peculiar talent, Zuccoli sent him to study architecture and perspective, under Albertolli and Levati, at the academy of the Brera. So prepared, he next studied scene-painting under Galiari, and practised that branch of art—for which Milan was then celebrated beyond any other place in Europe—about eight years, 1802-10, sharing in the fame reaped by Galiari, Perego, Landriani, and Sanquirico. This eminently successful career, one moreover which be pursued with such devotedness, was all at once arrested by a long and dangerous illness, occasioned partly by over-exertion, and partly by a pulmonary attack in consequence of cold caught while working in a damp place. This perhaps eventually proved a great advantage both to himself and to art, inasmuch as it compelled him to relinquish painting for the stage, and led him to produce works that are now treasured up for admiration in galleries. At the time however his illness was a serious calamity, for his family were reduced to very great distress. Owing to the care of a most affectionate wife, he recovered, and no sooner did he begin to do so, and was able to sit up in bed, than he employed himself in making pictures on a small scale of the various scenes—amounting to about a hundred—which he had painted for the theatres. Produced through necessity, as the only means of earning subsistence for himself and family, these subjects not only found purchasers, but there became even a demand for them. Thus encouraged he determined thenceforth to paint architectural scenery 'in small,' and also to combine the dramatist with the scene-painter, peopling his canvas not with mere figures as accessories, but with episodical groups of actors, either illustrating popular and local manners, or recording some historic incident; and among his numerous pieces of the latter class may be mentioned his Ildegonda, Adelaide dying in a *souterrain* of the Trappists, the Condemnation of a Templar, the Duchesse de la Vallière, and Charles V. at a Convent. In depicting the personages and manners of familiar and every-day life, he displayed a vein of strong humour; and his convent-kitchens and refectories, and incidents taken from Porta's dialect poems, rendered him an especial favourite with the public. Independently of the figures and stories—the great attraction for the many with which he baited his productions—he converted architectural painting itself, from mere actual portraiture of buildings into real picture, by the united mastery of perspective, chiaroscuro, and colouring. His pictures give the impression and sentiment of the edifices themselves, and are stamped by illusive yet anything but prosaic reality. Such was the reputation he acquired, that not only the King of Sardinia bestowed upon him the Order of Merit, but his native city Alessandria struck a medal in honour of him, in 1829. Honoured and prosperous in his profession while only in the meridian of life, be might, not unreasonably, look forward for years of uninterrupted happiness, when he was carried off very suddenly—in about half an hour after being seized by it—by an attack of his former pulmonary complaint, April 18th, 1837. He was followed to the tomb by the academicians, artists, and others to the number of upwards of three hundred; and his last work, his unfinished Interior of the Basilica of San Marco, was borne in the procession. His daughter Teolinda practises as an artist, in subjects of the same kind as her father.

(Giuseppe Sacchi, in Tipaldo's *Biografia; Westminster Rev.* vol. 35.)

MIKA'NIA, a genus of plants belonging to the natural order Compositæ, to the suborder Tubulifloræ, to the tribe Eupatoriaceæ, and the subtribe Adenostyleæ. It has a 4-flowered head, a naked narrow receptacle, 4 involucral leaves, with a bractlet added at the base or below it; the tube of the corolla short, with the throat dilated and somewhat campanulate; the anthers somewhat protruded; the achenium angular; the pappus in 1 row, rough and hairy.

M. officinalis has an erect, smooth, nearly simple stem, with leaves decussating somewhat triangular-ovate, cordate with a great sinus, toothed at the sides, entire towards the point, drooping; the panicles corymbose and terminal. This plant is a native of Brazil, where it is called *Coraçoa de Jesu.* It is a handsome plant. The leaves contain a bitter principle and an aromatic oil, and are used in the same way and for the same diseases as the Cascarilla and Cinchona barks. They are said to be an especially valuahle remedy in remitting fevers and in atonic dyspepsia. They are administered in the form of extract or decoction.

M. Guaco, Guaco plant, has an herbaceous twining stem; the branches round, sulcate, hairy; the leaves stalked, ovate, somewhat acuminate, shortly narrowed at the base, remotely toothed, netted, roughish above, hairy beneath; the corymbs axillary, stalked, opposite; the heads somewhat ternate sessile; the bractlets linear, shorter than the involucre; the involucral scales linear-oblong, obtuse, downy; the achenia smooth. This is one of the plants called *Guaco* in South America, and is used both internally and externally as a remedy against the bites of poisonous serpents. This plant is cultivated by the Indians for the purpose of being used. It is easily known from other plants by the large indigo blue spots that mark the under surface of its rough leaves. It is probable that the spotted character of the leaves of this and plants similarly employed, as the Calladium helleborifolium and a species of Aristolochia, have led to their use in the bites of poisonous snakes. 'The mode of using this remedy,' says Poeppig, 'is very simple: the wound is somewhat distended, and the fresh-pressed juice is dropped into it; the surrounding parts being repeatedly covered with the pressed leaves; and the juice is also taken hy the mouth. The tincture, made with common brandy, is also much celebrated, and recommended to travellers as a secure and portable means of cure. In Guayaquil little cakes are formed out of the fresh-bruised plants, which, when dried in the sun, retain their activity a long time. The effect of the Guaco is not in all cases alike quick and decided; but observations, both in Maranon and Ega, prove that after twenty-four hours' use the swelling had ceased, the pain vanished, and, with the exception of little ulcers, the cure had been effected. In Vurimaguas, and especially about Muniches, every year several persons are bitten by snakes; but the Guaco had acted so efficiently that in the memory of man only two children were known to have died of such wounds.' Although Poeppig has given so favourable an account of this remedy, he says in another place that 'the excision and cauterisation of the wound immediately after it is received is undoubtedly the safest plan.' Besides the guaco there are several other plants used in South America, some of which are called guaco, as the Herpestes colubrina, Dorstenia tubicina, Aristolochia cynanchifolia, &c. The guaco has been tried in this country as a remedy in hydrophobia, but without success. The Urali, or snake-poison of the Indians of British Guiana, is a compound, and contains in it strychnia. [STRYCHNOS, P. C.]

M. opifera is a smooth climbing plant, with an angular stem; it has stalked, cordate, acuminate, repand-toothed or nearly entire leaves, when full grown rather blunt; the heads stalked in corymbose panicles; the involucral scales ohlong, rather acute; the bractlets lanceolate; involucre rather shorter. This plant is a native of Brazil, where it is called *Eroa da Cobia.* It is also employed against the bites of snakes, and is said to effect a cure by its powerful diuretic action. An account is given of this plant by Gomez in the Memoirs of the Royal Academy of Lisbon for 1812, where it is described as the Eupatorium crenatum.

The genus Mikania is closely allied to Eupatorium, and they belong to a group of plants in the order Compositæ, the most remarkable for their activity. Dr. Lindley states, in his 'Vegetahle Kingdom,' that the famous styptic *Matico* is the produce of Eupatorium glutinosum, and not of Artanthe elongata, as has been usually supposed. Of this plant Mr. Hartwig says, in a communication to Dr. Lindley, 'Matico is the vernacular name applied by the inhabitants of Quito to Eupatorium glutinosum, or the Chussalonga in the Quichua language. It forms a shrub 3-5 feet high, and is common in the higher parts of the Quitinian Andes, where its properties were discovered some years back by a soldier called Mateo, better known under his nick-name Matico (little Matthew), who when wounded in action applied accidentally the leaves of some shrub to his wound, which had the immediate effect of stopping the bleeding. This shrub happened to be the Chussalonga, which has since been called, in honour of its discoverer, Matico. That it is the true Matico of the inhabitants of Quito and Riobomba I have not the slightest doubt; both leaves and specimens have been gathered hy myself, and upon comparing the latter with Kunth's description I found them to agree exactly with his Eupatorium glutinosum.' The Matico has been used in Europe, and is said to be an exceedingly efficient styptic, and of great value in stopping the bleeding from small wounds.

(Poeppig, *Reise in Chile, Peru*, &c.; Lindley, *Vegetable Kingdom*; Lindley, *Flora Medica.*)

MILITARY PUNISHMENTS. We have little knowledge of the manner in which offences against military discipline were punished hy the Greeks; but it appears that, for sedition or mutiny, the commander of an army had the power of causing the ringleaders to he seized and instantly put to death. Agamemnon, in the 'Iliad,' threatens such as may desert, that they shall die; and Alexander the Great, when a mutiny took place partly in consequence of the jealousy excited by the favour which he showed to the Persians, caused thirteen of his Macedonians to be executed without a trial. (Arrian, *Anab.*, vii. 8.) The military law of Athens prescribed the punishment of death for the crime of desertion while on service; yet occasionally, for this serious offence, the party was only imprisoned or sentenced to pay a fine. Whatever might be the power of an Athenian commander over his soldiers in the field, it is probahle that he would he very careful to act with a due regard to law; since, at the termination of a campaign, a man who might consider himself unjustly treated could compel his officer to answer for his conduct before a trihunal of his countrymen. Among the Lacedæmonians, cowards and deserters were either put to death or puhlicly disgraced: offenders who did not suffer the extreme penalty were made, when at home, to wear a party-coloured dress, and were ohliged to suhmit in silence to any insult which the meanest citizen might choose to offer. Disgrace also fell upon the soldier who, in action, had the misfortune to lose his shield.

The Romans punished crimes committed by the soldiery with great severity. For the gravest offences soldiers were beheaded or crucified; and under the Pagan emperors some, probahly such as professed the Christian religion, were burnt alive or exposed to wild beasts. On the occurrence of a mutiny, every tenth, twentieth, or hundredth man was sometimes chosen by lot, but generally only the ringleaders were selected for punishment. Deserters and seditious persons were frequently, after being scourged, sold for slaves; and occasionally the offender was made to lose his right hand, or was bled nearly to death.

If a soldier absented himself from the spot assigned to him for the night-watch, or if he was found asleep at his post, he was the next day hrought before the tribune, who having heard the evidence, on the fact being proved, sentenced him to suffer the hastinado. It appears from Polybius (vi. Ex. 2) that the tribune having gently touched the offender with his staff as a signal, the persons appointed to inflict the chastisement fell upon him and struck him repeatedly with sticks or stones, frequently with such violence as to cause his death: the culprit was allowed to escape hy flight if ahle; but in this case he was never permitted to return to his country, or, if he did return, no person dared to afford him shelter or relief.

Punishments of a like nature, hut less severe, were inflicted upon a soldier who was guilty of theft, or of giving false testimony either in his own favour or against a comrade. For certain hreaches of discipline the offender suffered a temporary deprivation of his pay, the forfeiture of his arms, or degradation from his rank. Sometimes he was sentenced to remain outside of the camp exposed to the chance of being taken hy the enemy, or he was made to stand for a certain time in an unmilitary dress before the prætorium. In some cases a culprit was sentenced to perform hard labour, to exchange into a corps of inferior rank, or to be entirely dismissed from the service with disgrace. Punishment was also inflicted on a soldier for cowardice or for losing his arms. A centurion guilty of a breach of discipline was deprived of the staff (a vine branch) which he carried as an emblem of authority.

A dictator could sentence to death any offender against military regulations; and the consuls had the power of exercising summary jurisdiction in capital cases. Punishments were ordered by the legionary trihunes, and by the præfects of the allies, with the concurrence of a council.

Among the nations of modern Europe the punishments for military offences were, till lately, no less severe than they were among the Romans. Besides the infliction of a certain number of lashes with cords, soldiers convicted of theft, marauding, or any other breach of discipline which was not punishable with death, were sentenced to run the gauntelope as it was called. For the execution of this sentence the regiment was drawn up in a double line; and each man being furnished with a small stick, generally of osier (except the grenadiers, who used their belts instead of the sticks), the culprit, naked to the waist, was either marched slowly or allowed to run as fast as he could, according to circumstances, from the head to the rear extremity between the two lines, each man striking him as he passed along. In certain cases the offender was afterwards expelled from the regiment, and sometimes also from the town or district with a charge never to appear there again under pain of death. The punishment of the knout, in the Russian army, consists in the naked back of the offender being struck with a leathern belt.

Cavalry soldiers were frequently punished by the *picket*, as it was called; this consisted in the man being made to hang by his hands from a beam during a certain time, a stake with its upper end made sharp being planted in the ground under him; so that, when from weariness he could no longer keep himself up, his foot was pierced by the stake: this kind of punishment has been long since abolished.

It has happened formerly that soldiers, being goaded to madness by the severities exercised on them, either from caprice or from a mistaken opinion that strictness in the minutest details of discipline is as necessary as in points of the highest importance, have murdered the officers, whom they considered as tyrants, and have afterwards, apparently without regret, suffered death for the crime.

Confinement in a dark room during a certain number of hours was, and still is, a frequent punishment for being absent without leave from parade, either on account of drunkenness or from any other cause; and soldiers so offending were formerly made to stand or rather to revolve in a cage or pillory which continually turned on its axis.

Besides the punishments of death and transportation, which, for great crimes, are within the scope of military law, in the British army, breaches of discipline are visited by flagellation, temporary imprisonment, extra drills, extra guards, and the performance of fatigue duties; but the punishments which consist in confinement to barracks and laborious employments, continued during long periods at the discretion of commanders of regiments, have been abolished by an express order from the present commander-in-chief.

While an army is in the field it is evident that breaches of discipline should be punished with extraordinary severity, and that the punishment should follow almost immediately on detection. It might be presumed that acts of treachery will seldom be committed; but unfortunately desertions to the enemy frequently take place; the more usual crime is however that of quitting the ranks for the purpose of plundering the country, a circumstance which is generally accompanied by gross acts of violence, often murders, committed on the defenceless people; and no doubt can exist that soldiers guilty of such crimes should be shot or hanged on the spot. Even when the crime is less heinous, the well-being and perhaps the safety of the army may be perilled in consequence of the spirit of resentment induced in the inhabitants of the country by injuries inflicted on them: such disorders should therefore be repressed by making signal examples of the offenders. It may be said also that the vice of drunkenness in soldiers deserves, in general, the heaviest punishment: the miscarriage of an enterprise, and defeat, with the loss of numbers of gallant men in an action, may be the fatal consequences of a failure, from inebriety, in the delivery of a report or order. That the trial and, on conviction, the punishment of an offender should be if possible immediate is also evident: the army may change its position or cantonments, when, if any delay takes place, it may be impossible for the necessary witnesses to arrive, or these may in the mean time be removed by the accidents of war. A long interval between the commission of a crime and its punishment diminishes the fear of the latter by opening to the culprit another chance of escape; it moreover diminishes the effect of the punishment as a warning: the impression produced by the crime wears off, and the punishment assumes, in some measure, the appearance of an act of cruelty.

The circumstances of an army in a time of peace and in a time of war, or rather when in the presence of an enemy, are very different: in the former case soldiers have no opportunity to commit treason or to pillage a country; and since the generality of the men who then enter the army are such as have a fair moral character, great crimes among them are as unfrequent as they are among an equal number of men in any other condition of life: the punishments for such offences as may then be committed may therefore with propriety be of the same nature and degree as those which would be adjudged for corresponding offences by the ordinary courts of justice. Imprisonment for a time, employment in laborious tasks, but particularly a forfeiture of pay and pension, where the offender is without a family depending on him for support, might, probably with advantage, be made the punishment for military offences.

The usual sentence now for breaches of discipline is that a certain number of lashes be inflicted with cords on the naked back of the offender; this kind of punishment is both cruel and disgusting, and, which is worse, it leaves on the skin during life the marks of disgrace which, if discovered by any accident, cannot fail to produce a prejudice against the individual, how well soever he may have conducted himself subsequently to the infliction. It falls, moreover, with unequal effect on different persons according to tho state of their health, or of their nervous systems at the time; and not unfrequently, according to the will of the person who administers or who superintends the punishment. It may be added that many of the soldiers who are drawn up to witness it, can neither avoid sympathizing with the culprit nor becoming dissatisfied with a service in which they are exposed to such disgrace and suffering.

The disadvantages under which, during his whole life, an individual may labour who has once suffered the punishment of being flogged, are strikingly related in General Sir Charles Napier's 'Remarks on Military Law,' p. 153, &c. This distinguished officer observes that such punishment, when inflicted only in a degree suited to the crime, and when circumstances prevent a different kind of punishment from being used, may occasionally be effectual; but he gives cogent reasons for considering it to be both wise and humane that the number of lashes which a court-martial was formerly allowed to prescribe is now diminished, and for abolishing the punishment entirely in times of peace.

Sir Charles Napier states that forty years before the time at which he wrote (1837), he frequently saw from 600 to 1000 lashes inflicted in consequence of sentences of merely regimental courts-martial; and in those days a man who had suffered a part of the punishment was often brought from an hospital when the wounds were barely healed, to receive the remainder. At present even a general court-martial cannot sentence a man to receive more than 200 lashes. The offence of inducing a soldier to desert, which in 1792 was visited with 1000 lashes, is, according to the present military law, punishable only by 'fine or imprisonment, or both, as the court shall adjudge.'

With respect to the effects of the law in its actual state, it may be observed that the discipline of the British army, during the time that it served in Spain and France, is acknowledged to have been more perfect than it had been in former times. Sir Charles Napier recommends, however, that the use of the lash be only gradually abolished; the milder punishments being substituted as often as possible. The practice of giving rewards for good behaviour, now so happily introduced in the military service, and the instruction obtained at the regimental schools, will in time, it is hoped, operate a beneficial change in the characters of such men as have not, from nature or from early education, a just sense of moral rectitude and of the obligations all are under of punctually and faithfully discharging the duties they owe to their country. It is indeed probable that such means will entirely supersede the necessity of a punishment which degrades a human being, by placing him below the level of a brute.

MILITARY TENURES. [Feudal System, P. C.]

MI'LIUM, a genus of grasses belonging to the tribe Agrostideæ. It has membranous glumes, nearly equal, unarmed; the paleæ 2, nearly equal, unarmed, about as long as the glumes, and hardening on the fruit; the spikelets convex on the back, or slightly dorsally compressed. There is but one British species of this genus, *M. effusum*. It has a diffuse panicle, with acute paleæ, a smooth stem, and linear-lanceolate leaves. It has a stem 3 or 4 feet in height, and is found in damp shady woods.

(Babington, *Manual of British Botany*.)

MILL, MILLWORK. [Wheels, P. C., p. 310; Windmill, P. C., p. 445; Windsails, P. C., p. 450; Coupling P. C. S., p. 433; Gearing, P. C. S., p. 643.]

MILLINGEN, JAMES, a very eminent English archæologist, was born in London, on the 18th of January, 1774. His father, who was a Dutch merchant, placed him at an early age at Westminster School; the boy showed a great partiality to everything connected with antient coins, having frequent opportunities of seeing a good collection in the house of one of his father's friends. His principal study in his leisure hours was the science of war, and he was anxious to enter the army in the engineer department; but as he was suffering from asthma, his father determined to send him from Westminster to one of the universities. However, the French revolution, which broke out at the time, changed his plans, for Millingen's father, an enthusiastic admirer of liberty, which seemed to dawn upon Europe, and to have chosen France as its favoured abode, went to reside at Paris, where his son James was received as a clerk in a banking-house. But as his new pursuits were not to his taste, he devoted all his leisure hours in the study of such works as Vaillant, Beauvois, Pinkerton, and Polybius, and his savings were spent in the purchase of antient coins, of models of cannon, pontoons, and other *matériel* of war, until after some time he obtained an employment better suited to his pursuits, and was appointed to the mint. In this capacity he became acquainted with several men of distinction and archæologists, among whom we may notice the Abbé Barthélémi, brother of the well-known author of the 'Voyage du Jeune Anacharsis en Grèce,' the geographer Barbié du Bocage, Walckenaer, D'Aumont, and others. The happy days which he spent in such company, however, were not of long duration, for when the National Convention ordered the confinement of every British subject until the peace, the young archæologist was arrested in the dead of night, and conveyed to prison. His father, being a Dutchman, escaped incarceration, but he was ordered to quit Paris under the surveillance of the police. In the Prison des Ecossais James Millingen became acquainted with Charles Este and Sir Robert Smith, who after their liberation established a banking-house at Paris, in which James Millingen became a partner. Shortly afterwards an event occurred which opened to Millingen a wide field of speculation. Some labourers, who were working in a field near Abbeville, discovered a Roman entrenchment, and dug up several earthen vessels filled with gold coins of Roman emperors down to Septimius, Severus, Caracalla, and Geta. Most of them were in a most excellent state of preservation, and some of them were extremely scarce. Millingen purchased them at the value of their weight, and soon after disposed of them in France and England to great advantage. From various circumstances the house in which Millingen was a partner failed, and he was thus thrown upon his own resources. His perfect knowledge of coins and the relics of antient art had in the meantime made his name known throughout Europe, and he would now have returned to England, but his asthmatic constitution rendered it necessary for him to reside in a southern climate, where he enjoyed comparative good health. During the last twenty-four years of his life he resided in Italy; at first in Rome and Naples, but latterly his permanent abode was Florence. He made occasional visits to Paris and London, where his arrival was always hailed by archæologists, as he was always the bearer of some precious relic of antient art. In 1845 he resolved to return to England, with a view of settling in London, when he was attacked by a severe catarrhal affection. At first he thought little of his illness, and wrote several letters even the day before his death, but on the 1st of October he died without a struggle, at the age of seventy-two, more from the effect of exhaustion than of disease.

What Millingen has done for practical archæology is of the highest importance, for there scarcely ever was a man of such experience, tact, and critical sagacity in antiquarian matters. The amount of knowledge which he possessed was a treasure which will not soon be found in one person. He was of the most studious habits, and most abstemious in his living; he was liberal in his opinions, and a perfect gentleman in his behaviour; but he was unfortunate in his domestic relations, for his wife and daughter both embraced the Roman Catholic religion (to which he was very hostile), which led to the separation from his wife and daughter. Both are still alive, as well as two sons. The following is a list of Millingen's works: 1, 'Recueil de quelques Médailles Grecques inédites,' Rome, 1812, 4to.; 2, 'Peintures Antiques inédites de Vases Grecs,' Rome, 1813, large folio, with sixty-three plates; 3, 'Medallic History of Napoleon,' London, 1819, 4to.; to which a supplement was published in 1822, with seventy-four plates. The same work was also published by the author in French. 4, 'Antient Coins of Greek Cities and Kings,' London, 1821, 4to., with figures; 5, 'Ancient unedited Monuments of Grecian Art,' London, 1822 and 1826, 2 vols. 4to.; 6, 'Remarks on the State of Learning and the Fine Arts in Great Britain,' London, 1831, 8vo.; 7, 'Sylloge of Antient Unedited Coins,' London, 1837, 4to. with figures; 8, 'Considérations sur la Numismatique de l'Ancienne Italie,' and a supplement, Florence, 1841 and 1844, with two plates. Besides these greater works, there are a considerable number of essays on antiquarian subjects by Millingen, in the *Annali* and the *Bulletino* of the Archæological Institute of Rome, and in the 'Transactions' of the Royal Society of Literature of London.

(*Classical Museum*, part xi. p. 91, &c.)

MINERALOGY. It will be seen by the number of substances now added under this head, that mineralogy has made considerable progress of late years. To the new substances which have been discovered, and which are now described, are added some which had before accidentally escaped insertion. In various treatises on mineralogy there will be found descriptions of some bodies which we have omitted to notice, and in these cases it is to be considered that the substances did not appear to possess the novelty ascribed to them, or had been previously described under other names. We mention this as a general rule, though we are not without apprehension that minerals may by mistake have been omitted which ought to have been inserted.

ABRAZITE. [PHILLIPSITE, P. C.]

ACHMITE. [EUCHYSIDERITE, P. C.]

AESCHINITE. [TITANIUM, P. C.]

AGALMATOLITE. [ZEOLITES, P. C.]

ALBITE. [CLEAVLANDITE.]

ALLOPHANE occurs reniform, botryoidal, globular, and massive. No cleavage. Colour blue, green, brown. Fracture conchoidal. Hardness 3·0 nearly. Lustre vitreous; transparent, translucent. Specific gravity 1·852 to 1·859. Found at Saalfeld in Thuringia, at Schneeberg in Saxony, and other places. Analysis, by Stromeyer:—Silica, 21·922; alumina, 32·202; lime, 0·730; sulphate of lime, 0·517; carbonate of copper, 3·058; hydrate of iron, 2·270; water, 41·301.

ALUMINA, SULPHATE OF, occurs in crystalline efflorescent masses. Colour white, occasionally yellowish. Translucent. Lustre silky. Taste similar to that of alum. Very soft. Specific gravity 1·66. Found at Araya near Cumana, and near Calama in Bolivia. Analysis:—Sulphuric acid, 36·4; alumina, 16; water, 46·6; peroxide of iron, 0·4. Dr. Thomson's analysis gives 2·26 per cent. of soda.

ALUMINITE (*Websterite, Subsulphate of Alumina*) occurs in reniform masses and botryoidal concretions. Colour white or yellowish white. Streak white. Fracture earthy. Soft, friable. Dull. Translucent occasionally, but more frequently opaque. Specific gravity 1·7. Found at New Haven, Sussex, Epernay in France, and at Halle in Prussia. Analysis:—Sulphuric acid, 23·27; alumina, 29·87; water, 46·76.

ALUMOCALCITE occurs massive. Colour white, inclining to blue. Streak white. Fracture conchoidal. Soft, may be crushed between the fingers. Adheres strongly to the tongue. Specific gravity 2·174. Found in the clefts of ironstone veins at Eybenstock in the Erzgebirge. Analysis, by Kersten:—Silica, 86·60; alumina, 2·25; lime, 6·25; water, 4·0.

AMBLYGONITE occurs massive and in rhombic prisms. Colour greenish white. Cleavage parallel to the sides of the prism. Fracture uneven. Hardness 6·0. Translucent or transparent in thin laminæ. Specific gravity 3·04. Found at Chursdorf near Penig in Saxony, and at Arendal, Norway. Analysis, by Berzelius:—Phosphoric acid, 54·12; alumina, 38·96; lithia, 6·92.

AMPHIBOLE. [AUGITE, P. C.]

AMPHIGENE. [LEUCITE, P. C.]

ANALCIME. [ZEOLITES, P. C.]

ANATASE. [TITANIUM, P. C.]

ANDALUSITE occurs crystallized. Primary form a right rhombic prism. Fracture uneven, conchoidal. Colour flesh-red to brownish and greyish red. Hardness 7·5. Lustre vitreous. Transparent to opaque. Specific gravity 3·104. Found in France, Spain, and North America. Analysis of a specimen from America:—Silica, 39·09; alumina, 58·56; protoxide of manganese, 0·53; lime, 0·21; water, 0·99.

ANHYDRITE (*Anhydrous Sulphate of Lime*) occurs massive and crystallized. Primary form a right rhombic prism. Cleavage very distinct parallel to the terminal planes and their two diagonals; parallel to the lateral planes indistinct.

Fracture uneven. Colour white, bluish, violet or reddish. Streak greyish white. Lustre vitreous, pearly on the cleavage surfaces. Hardness 3·0 to 3·5. Transparent, translucent. Refraction double. Specific gravity 2·5 to 2·9. Massive varieties amorphous, nodular, reniform. Found at Halle in the Tyrol, Bex in Switzerland, and in the salt-mines of Upper Austria and Salzburg, &c. Analysis of a specimen from Sulz:—Sulphuric acid, 57; lime, 42; silica, 2.

ANKERITE occurs crystallized. Primary form a rhomboid. Cleavage parallel to the primary planes. Colour white, sometimes yellowish or brownish from an admixture of oxide of iron. Fracture uneven. Hardness 3·5 to 4. Lustre vitreous. Translucent. Specific gravity 2·95 to 3·1. Found at Salzburg and in the Alps, &c. Analysis, by Berthier:—Carbonate of lime, 51·1; carbonate of magnesia, 25·7; carbonate of iron, 20·0; carbonate of manganese, 3·0 = 99·8.

ANORTHITE occurs crystallized. Primary form a doubly oblique prism. Colour white. Streak white. Fracture conchoidal. Hardness 6·0. Lustre vitreous, inclining to pearly on the cleavage faces. Translucent to transparent. Specific gravity 2·65. Found at Monte Somma. Analysis, by Rose: Silica, 44·9; alumina, 34·46; lime, 15·68; magnesia, 5·25; oxide of iron, 0·74.

ANTHOPHYLLITE occurs in crystalline masses with a fibrous columnar structure. Cleavage parallel to the lateral planes of a rhombic prism, and to both its diagonals. Colour brown and yellowish brown. Streak white. Fracture uneven. Hardness 5·0 to 5·5. Lustre pearly and inclining to metallic. Translucent, transparent on the edges. Specific gravity 3·0 to 3·3. Found at Kongsberg and Modum in Norway, and in the United States, &c. Analysis, by Gmelin: Silica, 56; protoxide of iron, 13; magnesia, 23; protoxide of manganese, 4; lime, 2; alumina, 3.

ANTRIMOLITE. [ZEOLITES, P. C.]

ARFWEDSONITE occurs amorphous. Cleavage parallel to the lateral planes and both the diagonals of a rhombic prism. Colour black. Fracture uneven. Hardness 6·0. Lustre vitreous. Opaque. Specific gravity 3·4 to 3·5. Found in Norway and Greenland. Analysis, by Dr. Thomson: Silica, 50·508; peroxide of iron, 35·144; sesqui-oxide of manganese, 8·920; alumina, 2·488; lime, 1·560; water, 0·960.

ATACAMITE (*Oxichloride of Copper, Muriate of Copper*) occurs massive, pulverulent, and crystallized. Primary form a right rhombic prism. Colour green of various shades, but chiefly emerald green. Streak lighter. Fracture uneven. Hardness 3·0 to 3·5. Lustre vitreous. Transparent to opaque. Specific gravity 4·4. Found at Remolenos in Chile; the pulverulent variety at Atacama in Peru. Massive variety reniform, with a fibrous structure. Analysis, by Proust: Muriatic acid, 10·6; oxide of copper, 76·6; water, 12·8.

AURICHALCITE occurs amorphous, sometimes granular, or in radiating masses. Colour green. Slightly transparent. Hardness but slight. Found at Loktewsk in Altai. Analysis, by Bottger: Oxide of copper, 28·19; oxide of zinc, 45·84; carbonic acid, 16·06; water, 9·93.

AUTOMALITE. [GAHNITE, P. C.]

BABINGTONITE occurs crystallized. Primary form a doubly oblique prism. Colour black or greenish black. Fracture uneven. Hardness 5·5 to 6·0. Lustre vitreous. Faintly translucent. Specific gravity 3·5. Found at Arendal in Norway, the Shetland Isles, and United States at Charlestown, Mass. Analysis, by Arppe, of a specimen from Arendal: Silica, 54·4; protoxide of iron, 21·3; lime, 19·6; magnesia, 2·2; protoxide of manganese, 1·8; alumina, 0·3; volatile matter, 0·9.

BALTIMORITE is composed of longitudinal fibres adhering to each other. Lustre silky. Opaque, but in thin pieces translucent on the edges. Hardness less than that of calcareous spar. Found at Baltimore, U. S. Analysis, by Dr. Thomson: Silica, 40·95; magnesia, 34·70; protoxide of iron, 10·05; alumina, 1·50; water, 12·60.

BARSOWITE occurs massive and in granular distinct concretions. Colour snow-white. Fracture splintery or imperfectly foliated. Hardness 5·5. Lustre of the compact dull; of the granular varieties feebly pearly. Translucent on the edges. Specific gravity 2·740. Occurs at Barsowskoj, in the Ural Mountains. Analysis: Silica, 49·08; alumina, 32·76; lime, 18·16.

BARYTOSTRONTIANITE. [STRONTIUM, P. C.]

BERTHIERITE (*Haidingerite*) occurs in masses confusedly lamellar, or composed of indistinct elongated prisms. Cleavage parallel to the axis of the prism. Colour dark steel grey, inclining to brown. Lustre metallic. Found at Chazelles in Auvergne, and at Braunsdorf, near Freyberg, Saxony. Analysis, by Berthier: Antimony, 52·0; sulphur, 30·3; iron, 16; zinc, 0·3.

BERZELINE occurs massive. Colour silver-white. Streak shining. Lustre metallic. Soft, and admits of being smoothed down and polished, assuming then the colour of tin. When exposed to the air, undergoes decomposition and becomes black, and frequently occurs of this colour in dendritic forms and thin seams. It is found at Smaland in Sweden. Analysis, by Berzelius: Selenium, 40; copper, 64 = 104.

BERZELITE. [LEAD, P. C.]

BERZELITE. [MAGNESIAN PHARMACOLITE.]

BOLSONITE. [PICROSMINE.]

BONSDORFFITE. [ZEOLITES, P. C.]

BORACITE occurs crystallized. Primary form a cube. Cleavage parallel to the planes of the octahedron, imperfect. Colour yellowish, greyish or greenish white; streak white. Fracture uneven or imperfectly conchoidal. Hardness 7·0. Lustre vitreous. Transparent, translucent. Specific gravity 2·56 to 3·0. Found at Segeberg near Kiel in Holstein, Luneburg in Brunswick, and near Tarapaca in Peru. Analysis, by Arfwedson: Boracic acid, 69·70; magnesia, 30·30.

BOTRYOGENE (*Red Sulphate of Iron*) occurs crystallized, the crystals being usually aggregated in globular, reniform, and botryoidal masses. Primary form an oblique rhombic prism. Colour deep hyacinth-red and ochre-yellow; streak yellow. Hardness 2·25 to 2·5. Lustre vitreous. Translucent. Taste slightly astringent. Specific gravity 2·039. Found in the great copper-mine of Fahlun in Sweden. Analysis: Sulphuric acid, 32·55; peroxide of iron, 23·86; protoxide of iron, 10·71; water, 32·85.

BOULANGERITE (*Sulphuret of Lead and Antimony*) occurs massive. Colour bluish grey. Fracture exhibits a crystalline structure. Lustre metallic. Specific gravity 5·97. Found at Molières in France and at Nertschinsk. Analysis of the ore from Molières, by Boulanger: Lead, 53·9; antimony, 25·5; sulphur, 18·5; iron, 1·2; copper, 0·9.

BOURNONITE, compound of the sulphurets of lead, antimony, and copper. Occurs massive and crystallized. Primary form a right rhombic prism. Cleavage parallel to the primary planes and to both the diagonals of the prism. Colour steel or blackish grey; streak similar. Fracture uneven, conchoidal. Hardness 2·5 to 3·0. Lustre metallic. Opaque. Specific gravity 5·79 to 5·83. Found in Cornwall, Clausthal, Pfaffenberg, Mexico, and Peru. Analysis, by Hatchett, of the mineral from Cornwall: Sulphur, 17; lead, 42·62; antimony, 24·23; copper, 12·80; iron, 1·20.

BRAUNITE. [MANGANESE, P. C.]

BREISLAKITE occurs crystallized in delicate capillary crystals of a reddish-brown or chesnut-brown colour, bent and grouped like wool. Fibres flexible. Lustre metallic. Found at Vesuvius and Capo di Bove, near Rome, forming woolly coatings in the cavities of lavas. Analysis:—It contains silica, alumina, and oxide of iron, but in proportions which have not been determined.

BREUNNERITE (*Carbonate of Magnesia and Iron*) occurs crystallized. Primary form an obtuse rhomboid. Cleavage perfect, parallel to the primary planes. Colour yellow of different shades, and black; streak white. Fracture flat conchoidal. Hardness 4·0 to 4·5. Lustre vitreous, sometimes inclining to pearly. Transparent, translucent. Specific gravity 3·0 to 3·2. Found at Zillerthal in Salzbourg and other places in the Tyrol. Analysis, by Stromeyer: Carbonate of magnesia, 86·05; carbonate of iron, 13·82; carbonate of manganese, 0·69.

BREWSTERITE. [ZEOLITES, P. C.]

BROCHANTITE (*Sulphate of Copper and Water*) occurs crystallized. Primary form a right rhombic prism. Cleavage obtained with difficulty in the direction of the lateral faces of the primary form. Colour emerald-green. Fracture uneven. Hardness 3·5 to 4·0. Lustre vitreous. Translucent, transparent. Specific gravity 3·78 to 3·87. Found in Siberia. Analysis, by Magnus: Sulphuric acid, 17·43; oxide of copper, 66·93; oxide of tin, 3·14; oxide of lead, 1·04; water, 11·91.

BRONGNIARTIN. [GLAUBERITE, P. C.]

BRONZITE occurs in massive aggregations of columnar crystals. Cleavage parallel to the lateral planes and both diagonals of a rhombic prism. Colour brown, ash-grey, or dark green; streak lighter. Fracture uneven. Hardness between 4·0 and 5·0. Lustre vitreous. Pseudo-metallic on cleavage planes. Translucent in thin laminæ. Opaque in mass. Specific gravity 3·3. Found in Upper Styria, the Harz, in Bayreuth, the Tyrol, the Lizard district of Cornwall,

&c. Analysis, by Kohler: Silica, 57·19; magnesia, 32·57; lime, 1·29; protoxide of iron, 7·46.

BROOKITE. [TITANIUM, P.C.]

BRUCITE. [MACLUREITE, P.C.]

BUCKLANDITE occurs crystallized. Primary form an oblique rhombic prism. Cleavage not observable. Colour nearly black. Fracture uneven. Harder than augite. Lustre vitreous. Opaque. Specific gravity 3·94. Found near Arendal in Norway, and at Laach on the Rhine. It does not appear to have been analyzed.

BUNTKUPFERERZ. [COPPER, *Purple*, P. C.]

BUSTAMITE occurs in irregularly disposed prismatic crystals, having a somewhat fibrous structure, and a pale grey, greenish, or reddish colour. Nearly opaque. Hardness 6·5 to 7·0. Lustre somewhat silky. Specific gravity 3·1 to 3·23. Found at Real de Minas in Mexico. Analysis, by Dumas: Silica, 48·90; protoxide of manganese, 36·06; lime, 14·57; protoxide of iron, 0·81.

CACHOLONG. [OPAL, P. C.]

CADMIUM, *Sulphuret of*. [GREENOCKITE.]

CALEDONITE occurs crystallized. Primary form a right rhombic prism. Cleavage parallel to the primary planes, and to the short diagonal of the prism. Colour blue and greenish blue; streak bluish or greenish white. Fracture uneven. Hardness 2·5 to 3·0. Lustre resinous. Transparent, translucent. Specific gravity 6·4. Found at Lead Hills in Scotland. Analysis, by Brooke: Carbonate of lead, 32·8; carbonate of copper, 11·4; sulphate of lead, 55·8.

CARBUNCLE. [GARNET, P. C.]

CARINTHITE. [LEAD, P. C.]

CHABASIE. [ZEOLITES, P. C.]

CHALCOLITE. [URANIUM, P. C.]

CHIASTOLITE. [MACLE, P. C.]

CHILDRENITE occurs crystallized. Primary form a right rhombic prism. Cleavage in planes parallel to the axis. Colour yellow, brownish yellow: streak white. Fracture uneven. Hardness 4·5 to 5·0. Lustre vitreous or inclining to resinous. Transparent, translucent. Found near Tavistock, Devonshire, and at Crinnis, Cornwall. Analysis: Wollaston has shown it to be composed of phosphoric acid, alumina, and iron, but the proportions have not been determined.

CHLORITE. [TALC, P. C.]

CHLOROPAL occurs massive, amorphous. Fracture conchoidal and splintery. Colour green, sometimes reddish brown. Structure compact, sometimes earthy. Hardness 3·0 to 4·0. Lustre of the compact, dull resinous. Opaque. Specific gravity 1·7 to 2·0. Found near Unghwar in Hungary. Analysis, by Brandes: Silica, 46·0; oxide of iron, 33·3; magnesia, 2·0; alumina, 1·0; manganese, a trace; water, 18·0.

CHLOROPHYLLITE (*Hydrous Iolite*) occurs crystallized in six-sided prisms, the edges of which are usually replaced by so many planes that the crystals appear almost cylindrical. Cleavage surfaces brilliant. Cross fracture conchoidal. Hardness 2 to 5. Colour green, greenish brown or dark olive-brown. Translucent. Specific gravity 2·705. Found in the neighbourhood of Abo, Finland, and also at Unity, N. H., in the United States. Analysis, by Bonsdorff, of the mineral from Abo: Silica, 45·05; alumina, 30·05; magnesia, 9·00; protoxide of iron, 5·30; water, 10·60.

CHONIKRITE occurs rounded in masses. Is not cleavable. Fracture uneven and imperfectly conchoidal. Colour white, with shades of yellow and grey. Hardness between 2·0 and 4·0. Lustre glimmering or dull. Translucent, often only on the edges. Found at Elba. Analysis, by Von Kobell: Silica, 35·69; alumina, 17·12; magnesia, 22·50; lime, 12·00; protoxide of iron, 1·46; water, 9·00.

CHRYSOCOLLA occurs massive. Sometimes in pseudomorphous crystals, botryoidal and reniform. No cleavage observable. Colour bluish and blackish-green; streak green. Fracture earthy or conchoidal. Hardness 2·0 to 3·0. Lustre vitreo-resinous. Translucent. Opaque. Specific gravity 2·031. Found in Cornwall, in the Bannat, Tyrol, Hungary, &c., &c. Analysis, by Kobell: Silica, 36·54; oxide of copper, 40·00; water, 20·20; iron, 1·00. It is more than probable, as shown by analysis, that calcedony and quartz, merely coloured by carbonate of copper, have been considered as chrysocolla.

CINNAMON STONE. [GARNET, P.C.]

CLEAVLANDITE (*Albite*) occurs massive and crystallized. Primary form a doubly oblique prism. Cleavage parallel to the primary planes. Colour commonly white, sometimes grey, greenish, bluish, or red; streak white. Fracture uneven. Hardness 6·0. Lustre pearly on the cleavage planes, vitreous in other directions. Transparent, translucent. Specific gravity 2·6 to 2·68. The massive varieties have a laminar structure. Found in Norway, Sweden, Dauphiny, St. Gothard, Scotland, and accompanying felspar in most of its numerous localities; from this it differs chiefly in containing soda instead of potash. Analysis, by Stromeyer: Silica, 70·68; alumina, 19·20; soda, 9·06; lime, 0·23.

CLINTONITE (*Seybertite, Xanthophyllite? Holmesite*) occurs crystallized, and in imperfectly crystallized masses. Primary form an oblique rhombic prism. Cleavage imperfect. Colour copper-red, reddish brown, yellowish brown, and reddish white; streak yellowish grey. Hardness 4·5. Lustre metallic and metallic pearly. Translucent to opaque. In thin laminæ sometimes transparent. Specific gravity 3·098. Found at Amity, Orange Co., N. Y. Analysis, by Clemson: Silica, 17·0; alumina, 37·6; magnesia, 24·3; lime, 10·7; protoxide of iron, 5·0; water, 3·6.

CLUTHALITE occurs in large nodules in amygdaloid, constituting a congeries of imperfect crystals with rough surfaces. Colour flesh-red. Hardness 3·5. Brittle. Lustre vitreous. Opaque or translucent on the edges only. Specific gravity 2·166. Found in the Kilpatrick Hills, near Dumbarton. Analysis, by Dr. Thomson: Silica, 51·266; alumina, 23·560; peroxide of iron, 7·306; soda, 5·130; magnesia, 1·233; water, 10·553.

COCCOLITE. [PYROXENE, P. C.]

COMPTONITE. [ZEOLITES, P. C.]

CONDRODITE. [MACLUREITE, P. C.]

CONDURRITE occurs amorphous. Colour brownish black; streak black. Fracture smooth. Hardness, scratched by glass. Brittle. Opaque. Specific gravity 5·204. Found in Condorrow Mine, Cornwall. Analysis, by Faraday: Arsenious acid, 25·94; copper, 60·50; arsenic, 1·51; sulphur, 3·06; water, 8·99.

COQUIMBITE (*Sulphated Peroxide of Iron*) occurs in granular masses, some parts of which are crystallized. The crystals are regular hexahedral prisms, terminated by six-sided pyramids. Entirely soluble in water. Colour white, and also of various shades of brown, yellow, red, and sometimes even of a deep blue colour. Found in the southern part of Peru near Calama in Bolivia, and near Copiapo in Chili. Analysis, by Rose: Sulphuric acid, 43·55; peroxide of iron, 25·21; alumina, 0·78; lime, 0·14; magnesia, 0·21; silica, 0·37; water, 29·98.

COUZERANITE occurs crystallized. Primary form an oblique rhombic prism. Cleavable parallel with the shorter diagonal. Colour usually perfectly black, sometimes indigo-blue, rarely light grey. Fracture conchoidal. Hardness about 6·5. Lustre resinous, vitreous, and rather brilliant. Specific gravity 2·69. Found in the valleys of the Seix, which border upon Saint Girons. Analysis, by Dufrénoy: Silica, 52·37; alumina, 24·02; lime, 11·85; magnesia, 1·40; potash, 5·52; soda, 3·96.

CRICHTONITE. [TITANIUM, P. C.]

CRONSTEDTITE (*Hydrous Silicate of Iron*) occurs massive and crystallized. Primary form a rhomboid; in small, thin, hexagonal prisms, and in radiating groups. Cleavage perpendicular to the axis distinct. Colour black and brownish black; streak dull green. Hardness 2·0 to 2·5. Lustre vitreous. Opaque. Specific gravity 3·3 to 3·36. Found in Cornwall, Brazil, and Przibram in Bohemia. Analysis, by Steinmann: Silica, 22·45; oxide of iron, 58·85; oxide of manganese, 2·89; magnesia, 5·08; water, 10·70.

CUBE ORE. [PHARMAKOSIDERITE.]

CUMMINGTONITE. [AUGITE, P. C.]

CYMOPHANE. [CHRYSOBERYL, P. C.]

DANAITE (*Arsenical Sulphuret of Iron and Cobalt*) occurs crystallized. Primary form a right rhombic prism. Colour silver white, inclining to steel grey; streak dark greyish black. Fracture uneven. Brittle. Hardness 5·5 to 6·0. Lustre metallic. Specific gravity 6·127. Found at Franconia, N. H., at Jackson, N. H., and other places in the United States. Analysis, by Hayes: Sulphur, 17·86; arsenic, 41·44; iron, 32·94; cobalt, 6·45.

DANBURITE occurs crystallized. Primary form an oblique rhombic prism. Colour honey-yellow, becoming nearly white by decomposition; streak white. Hardness 7·5. Lustre vitreous. Translucent, transparent. Specific gravity 2·83. Found at Danbury, Ct. Analysis, by Shepard: Silica, 5·6; lime, 28·33; alumina, 1·70; yttria, 0·85; potash, soda, and loss, 5·12; water, 8.

DAVYNE occurs crystallized. Primary form a rhomboid. Cleavage parallel to the planes of the hexagonal prism. Colour white, sometimes yellowish brown; streak white.

Fracture conchoidal. Hardness 5·0 to 5·5. Lustre vitreous. Transparent, translucent, opaque. Specific gravity 2·4. Found in the more antient rocks of Vesuvius. Analysis, by Covelli: Silica, 42·97; alumina, 33·28; lime, 12·02; peroxide of iron, 1·25; water, 7·43; loss, 3·11.

Dermatine occurs in reniform masses, rarely globular, and in thin coatings or crusts. Colour dark olive green or liver brown. Streak yellow inclining to grey. Fracture conchoidal. Feels greasy, but does not adhere to the tongue. Hardness about 2·0. Lustre somewhat resinous. Specific gravity 2·136. Found in the serpentine quarry near Waldheim in Saxony. Analysis, by Ficinus: Silica, 35·800; magnesia, 23·700, protoxide of iron, 11·333; protoxide of manganese, 2·250; alumina, 0·416; lime, 0·833; water and carbonic acid, 25·200.

Diallage. [Augite, P. C.]

Diaspore occurs massive and crystallized. Primary form a doubly oblique prism. Colour slightly greenish grey and yellowish brown. Hardness 6·0 to 6·5. Slightly translucent. Specific gravity 3·43. Found at Kosoibrod in the Orenburg government of Asiatic Russia. Massive variety occurs in slightly curvilinear laminæ of a shining pearly lustre and greenish grey colour; also in cellular masses, constituted of slender crystals, which have a pearly lustre and intercept each other in every direction; of a brown hue externally, but perfectly transparent and colourless when reduced to thin laminæ. Analysis, by Hess: Alumina, 85·14; water, 14·56. The brown variety, analyzed by Children, gave—alumina, 76·06; water, 14·70; oxide of iron, 7·78; loss. 1·46.

Dichroite (*Iolite, Peliome, Steinheilite, Cordierite*) occurs massive and crystallized. Primary form a right rhombic prism, commonly crystallized in six- or twelve-sided prisms. Cleavage parallel to the lateral planes. Colour blue in direction of the axis, and yellowish grey perpendicular to it; sometimes dull yellowish in both directions. Streak white. Fracture uneven and somewhat conchoidal. Hardness 7·0 to 7·8. Lustre vitreous. Transparent, translucent. Specific gravity 2·56. Massive varieties amorphous. Structure indistinctly granular. Found at Cape de Gatte in Spain, in Greenland, at Bodenmais, in Bavaria, Norway, the United States, &c. Analysis, by Stromeyer: Silica, 50·24; alumina, 33·42; magnesia, 10·84; protoxide of iron, 4·00; protoxide of manganese, 0·68; water, 1·66.

Dreelite occurs crystallized. Primary form a rhomboid, without any modifications. Presents three cleavages parallel with the faces of the primary crystal. Colour and streak white. Hardness 3·25. Lustre pearly. Specific gravity, 3·2 to 3·4. Found at Nuisière, near Beaujeu, France. Analysis, by Dufrénoy: Sulphate of barytes, 61·731; sulphate of lime, 12·274; carbonate of lime, 8·050; lime, 1·521; silica, 9·712; alumina, 2·404; water, 2·308.

Dufrénité occurs in small radiated masses. Colour olive or dull green. Slightly translucent and extremely fusible. Specific gravity 3·227. Found at Anglar, near Limoges. Analysis: Phosphoric acid, 24·8; protoxide of iron, 51·0; peroxide of manganese, 9·0; water, 15.

Dysluite occurs crystallized in regular octohedrons. Cleavage rather imperfect, parallel with the faces of the octohedron. Colour yellowish brown or greyish brown. Fracture conchoidal. Hardness 4·5. Somewhat translucent, opaque. Lustre vitreous, inclining to resinous. Specific gravity 4·551. Found at Sterling, New Jersey. Analysis, by Dr. Thomson: Alumina, 30·490; oxide of zinc, 16·800; peroxide of iron, 41·934; protoxide of manganese, 7·600; silica, 2·966; moisture, 0·400.

Edelforsite occurs fibrous or feathery and massive. Colour white or greyish. Hardness 6·(?). Lustre shining. Transparent. Specific gravity 2·58. Found at Aedelfors in Smaland, Cziklowa in the Banate, and in Norway. Analysis: Silica, 61·85; lime, 38·15; with small quantities of magnesia, alumina, and iron. Another compound under this name has also been called the Aedelfors red zeolite. It agrees in composition with stilbite, except that it contains two per cent. less of water.

Ekebergite (*Sodaite*) does not occur crystallized, but in compact or finely fibrous masses, and occasionally in thin laminæ. Colour green, greyish, or brownish. Lustre vitreous or resinous. Transparent. Analysis, by Ekeberg: Silica, 4·6; alumina, 28·75; lime, 13·50; soda, 5·25; oxide of iron, 0·75; water, 2·25.

Elæolite (*Fettstein*) occurs in amorphous masses, with cleavages parallel to the lateral planes, and both diagonals of a rhombic prism. Fracture conchoidal. Colour dark green, bluish grey, or greyish or brownish red. Hardness 5·5 to 6·0. Lustre resinous, frequently opalescent when cut. Translucent. Specific gravity 2·54 to 2·62. It is found at Laurvig, Stavern, and Frederickswärn in Norway. Analysis, by Vauquelin: Silica, 44·00; alumina, 34·00; soda, 16·50; peroxide of iron, 4·00; lime, 0·12. Gmelin found also 4·733 per cent. of potash, and only 0·651 of peroxide of iron.

Electrum. [Gold, Alloys of, P. C.]

Epistilbite occurs massive with attached crystals. Primary form a right rhombic prism. Cleavage parallel to the short diagonal of the prism. Colour white. Streak white. Fracture uneven. Hardness 4·0 to 4·5. Lustre vitreous. Transparent, translucent. Specific gravity 2·20 to 2·25. Found on Faroe Islands and in Iceland. Analysis of Iceland mineral, by Rose: Silica, 58·59; alumina, 17·52; lime, 7·56; soda, 1·78; water, 14·98.

Epsomite (*Sulphate of Magnesia*) occurs massive, botryoidal, and reniform, on the surface of other bodies, and in solution in sea and mineral waters. Colour white. Streak white. Structure fibrous, sometimes earthy. Brittle. Taste bitter and saline. Found originally in a spring at Epsom. It forms a large bed near Arequipa in Peru, and is often in fine crystals and silky fibres.

Erinite (*Arseniate of Copper*) occurs in concentric and mammillated layers, between which other arseniates are found. The layers have rough surfaces and a fibrous structure. Colour brilliant emerald green inclining to grass green. Streak paler. Fracture uneven or imperfect conchoidal. Hardness 4·5 to 5·0. Lustre slightly resinous. Slightly translucent. Specific gravity 4·0 to 4·1. Found near Limerick. Analysis, by Turner: Arsenic acid, 33·78; oxide of copper, 59·44; alumina, 1·77; water, 5·01.

Erinite. [Zeolites, P. C.]

Erlanite occurs massive and amorphous. Fracture in some specimens foliated, in others splintery. Structure granular, compact. Colour light greenish grey. Streak white, shining. Hardness 6·25 to 7·0. Lustre feebly shining, or dull. Opaque. Specific gravity 3·0 to 3·1. Found near Erla in the Saxon Erzgebirge, forming a bed of 100 fathoms in thickness. Analysis, by Gmelin: Silica, 53·16; alumina, 14·03; lime, 14·39; magnesia, 5·2; soda, 2·61; oxide of iron, 7·14; oxide of manganese, 0·64; water, 0·60.

Euchroite (*Arseniate of Copper*) occurs crystallized. Primary form a right rhombic prism. Cleavage indistinct, Colour bright emerald green. Streak pale apple green. Fracture uneven. Hardness 3·5 to 4·0. Lustre vitreous. Refraction double. Transparent, translucent. Specific gravity 3·38 to 3·41. Found at Libethen in Hungary. Analysis, by Turner: Arsenic acid, 33·02; oxide of copper, 47·85; water, 18·80.

Euxenite occurs massive without any trace of cleavage. Colour brownish black. In thin splinters has a reddish brown translucence, lighter than the streak. Streak reddish brown. Fracture subconchoidal. Hardness, scratches thorite. Lustre metallic, greasy. Specific gravity 4·60. Found at Jölster, in Norway. Analysis, by Scheerer: Columbic acid, with some titanic acid, 49·66; titanic acid, 7·94; yttria, 25·09; protoxide of uranium, 6·34; protoxide of cerium, 2·18; oxide of lanthanium, 0·96; lime, 2·47; magnesia, 0·29; water, 3·97=98·90.

Fassaite. [Pyroxene, P. C.]

Faujasite occurs crystallized in the form of an octohedron with a square base. Colour white, sometimes brown. Fracture vitreous or uneven. Fragile. Lustre brilliant. Found at Kaisarstuhls in Breisgau. Analysis, by Damour: Silica, 49·36; alumina, 16·77; lime, 5·00; soda, 4·34; water, 22·49.

Fibrolite. [Kyanite, P. C.]

Forsterite occurs in small brilliant crystals. Primary form a right rhombic prism. Colour white. Hardness about 7·0. Lustre vitreous. Translucent. Found at Vesuvius, with pleonaste and pyroxene. Analysis, according to Children—contains silica and magnesia.

Gadolinite. [Yttrium, P. C.]

Gedrite occurs in crystalline masses, having a fibrous, radiated, or lamellar structure. Colour clove brown. Streak grey or yellowish. Lustre submetallic, feeble. Hardness not above 5·0. Rough. Specific gravity 3·26. Occurs in loose stones near Gèdre in the Pyrenees. It has some resemblance to anthophyllite and hypersthene. Analysis: Silica, 38·811; alumina, 9·309; protoxide of iron, 45·834; magnesia, 4·130; lime, 0·666; water, 2·301.

Geokronite (*Kilbrickenite?*) occurs amorphous without cleavage Fracture lamellar in one direction, and in the other granular and conchoidal. Colour lead grey. Streak the same. Hardness between mica and calcareous spar. Lustre metallic. Opaque. Specific gravity 5·88. Found in the silver-mine of Scala in Sweden, and in the province of Galicia in Spain. Analysis of the mineral from the Scala mine, by Svanberg: Lead, 66·452; antimony, 9·576; arsenic, 4·695; copper, 1·514; iron, 0·417; zinc, 0·111; sulphur, 16·262.

GIGANTHOLITE occurs crystallized in six- and twelve-sided prisms. Cleavage parallel to the six sides of the prism. Colour greenish to dark steel grey. Lustre between vitreous and waxy. Hardness about 3·5. Specific gravity 2·862 to 2·878. Found near Temmela in Finland. Analysis, by Wachtmeister: Silica, 46·27; alumina, 25·10; peroxide of iron, 15·60; magnesia, 3·80; protoxide of manganese, 0·89; potash, 2·70; soda, 1·20; fluorine a trace; water with ammonia, 6·00.

GILBERTITE occurs in plates lying irregularly together. Colour white with a shade of yellow. Hardness 2·75. Lustre silky. Translucent. Specific gravity 2·648. Found near St. Austell, Cornwall. Analysis, by Lehunt: Silica, 45·155; alumina, 40·110; lime, 40·170; magnesia, 1·900; protoxide of iron, 2·430; water, 4·250.

GLOTTALLITE occurs crystallized either in cubes or four-sided pyramids, which seem to be regular octohedrons. Colour white. Hardness 3·5. Brittle. Lustre vitreous. Strongly translucent. Specific gravity 2·181. Found probably near Port Glasgow. Analysis by Dr. Thomson: Silica, 37·014; lime, 23·297; alumina, 16·308; peroxide of iron, 0·500; water, 21·250 = 98·299.

GMELENITE. [ZEOLITES, P. C.]

GORLANDITE. [LEAD, *Ores of*, P. C.]

GRAPHITE. [PLUMBAGO, P. C.]

GREEN IRON EARTH (*Hypochlorite*) occurs in reniform, botryoidal, and globular masses. Colour green, passing into black and yellow. Lustre resinous and dull. Brittle. Found at Schneeberg in Saxony. Analysis by Schülar: Silica, 50·24; oxide of bismuth, 13·03; alumina, 14·65; oxide of iron, 10·54; phosphoric acid with traces of manganese, 9·62.

GREENOCKITE (*Sulphuret of Cadmium*) occurs crystallized in six-sided prisms, with six-sided pyramids. Hardness 2·75. Lustre vitreous, sometimes almost adamantine. Translucent to transparent. Specific gravity 4·842. Found at Bishoptown, Renfrewshire, and on the Cochno burn, on the north side of the Clyde. Analysis by Connell: Sulphur, 22·56; cadmium, 77·30.

GREENOVITE occurs in small amorphous crystalline masses. Primary form a doubly oblique prism. Colour deep rose-red. Hardness greater than that of fluor spar; does not scratch glass. Some of the faces are brilliant, others often dull and tarnished. Specific gravity 3·44. Found at St. Marcel in Piedmont. Analysis, by M. Delesse: Silica, 30·40; oxide of titanium, 42; lime, 24·30; protoxide of manganese, 3·80. M. Delesse observes that this mineral is analogous to sphene.

GURHOFIAN. [DOLOMITE, P. C.]

HAIDINGERITE. [BERTHIERITE.]

HAIDINGERITE. (*Arseniate of Lime.*) [PHARMACOLITE, P. C.]

HALLOYSITE. [LENZINITE.]

HARTITE occurs crystallized. Primary form an oblique rhombic prism. Cleavage imperfect. Colour white. Lustre somewhat greasy. Translucent. Hardness 1·0. Specific gravity 1·046. Found at Oberhart in Austria. Analysis, by Schrötter: Carbon, 87·473; hydrogen, 12·048.

HAUSMANNITE. [MANGANESE, *Ores of*, P. C.]

HAYESINE (*Borocalcite*) occurs in globular masses of a fibrous structure, having externally a brown colour; when broken these masses appear to be formed of snow-white delicate fibres, interwoven, curved, and knotted; the lustre is satin-like, and the fibres so soft as to crush readily between the fingers. It encloses fragments of argillaceous slate, with brilliant and perfect crystals of glauberite, which are sometimes penetrated by the fibres of this mineral. Found in the province of Tarapaca, Peru. Analysis: after drying at 150° Fahr., boracic acid, 46·111; lime, 18·889; water, 35·000.

HAYDENITE. (*Heulandite.*) [ZEOLITES, P. C.]

HARRINGTONITE. [ZEOLITES, P. C.]

HEDYPHAN. (*Gorlandite.*) [LEAD, *Ores of*, P. C.]

HERRERITE occurs in reniform masses. Cleavage in three directions, affording rhomboidal fragments with curved faces. Colour pistachio, emerald, and grass green. Streak yellowish grey. Hardness 4·0 to 4·5. Brittle. Lustre vitreous to pearly, and shining on fresh surfaces. Translucent. Specific gravity 4·3. Found at Albarradon in Mexico. Analysis, by Herrera: carbonic acid, 31·86; peroxide of nickel, 12·32; tellurium, 55·58. This mineral is probably a mixture rather than a definite compound.

HETZEPOZITE. [MANGANESE, *Ores of*, P. C.]

HEULANDITE. [ZEOLITES, P. C.]

HISINGERITE. [THRAULITE, P. C.]

HONEY-STONE. [MELLITE, P. C.]

HOPEITE. [ZINC, *Ores of*, P. C.]

HORN-STONE, FUSIBLE. [FELSPAR, P. C.]

HORN-STONE, INFUSIBLE. [QUARTZ, P. C.]

HUMBOLDTILITE. [SOMERVILLITE.]

HURAULITE. [MANGANESE, *Ores of*, P. C.]

HYDROBORACITE occurs in small needle crystals, which appear to be flat six-sided prisms. Colour white, with spots of red from silicated peroxide of iron. Hardness similar to that of gypsum. Translucent. Specific gravity 1·9. Found in a collection of Caucasian minerals. Analysis, by Hess: Boracic acid, 49·22; lime, 13·74; magnesia, 10·71; water, 26·33.

HYDROTALCITE occurs massive, investing steatite in foliated masses. Colour white. Streak the same, with a pearly lustre. Transparent. Flexible, with a soapy feel. Hardness 2. Found at Snarum. Analysis: Magnesia, 36·30; alumina, 12·00; peroxide of iron, 6·90; carbonic acid, 10·54; water, 32·66; insoluble residue, 1·20.

HYDROMAGNESITE. [MAGNESITE.]

HYPOCHLORITE. [GREEN IRON EARTH.]

HYDROPHITE, a variety of green serpentine containing vanadium, occurs amorphous. Fracture irregular. Colour mountain green. Soft. Specific gravity 2·65. Found at Taberg in Smaland. Analysis: Silica, 36·195; oxide of iron, 22·729; oxide of manganese, 1·66; magnesia, 21·082; vanadic acid, 0·115; water, 16·080.

ICELAND SPAR. [CALCSPAR, P. C.]

IDRIALIN. [HYDROGEN, *Carburets of*, P. C.]

ILMENITE. [TITANIUM, *Ores of*, P. C.]

IRON, OXALATE OF (*Humboldtite, Humboldtine*), occurs crystalline and massive. Primary form a right prism with square bases. Cleavage in the direction of the primary faces, indistinct. Fracture uneven, earthy. Colour brightish yellow. Hardness, scratches sulphate of lime, and is scratched by mica. Opaque, dull. Specific gravity 1·3. Massive variety small, flattish, reniform pieces. Structure fine earthy. Found at Koloseruk, near Bilin, in Bohemia. Analysis, by Rammelsberg: Oxalic acid, 42·69; protoxide of iron, 41·40; water, 15·91.

ISERINE. [TITANIUM, *Ores of*, P. C.]

JASPER. [QUARTZ, P. C.]

JOHANNITE. [URANIUM, *Ores of*, P. C.]

JOHNSTONITE. [LEAD, *Ores of*, P. C.]

KAMMERERITE occurs crystallized and massive. Common form of the crystal a six-sided prism. Cleavage perpendicular to the axis only. Cleavage places have a pearly lustre. Colour, that of some crystals, which by daylight is so dark that their red colour is scarcely perceptible, appears by candlelight quite red. Massive variety, usually composed of fine laminæ. Colours sometimes dark violet blue, sometimes yellowish or greenish, or greenish white. Translucent on the edges, particularly after immersion in water. Fracture compact, fine-grained, becoming splintery or leafy on the less compact varieties; flexible. Dull, or of a greasy lustre, often glistening. When scratched gives a light peach-blossom red or almost white streak. Hardness 2 to 2·5. Specific gravity 2·640. Found in the Ural mountains. Analysis, by Hartwell: Silica, 37·0; alumina, 14·2; magnesia, 31·5; lime, 1·5; oxide of chromium, 1·0; water 13·0.

KEROLITE occurs massive and reniform. Structure lamellar or compact. Colour white, yellow, or green. Streak white. Fracture conchoidal. Hardness 2·0 to 2·25. Lustre vitreous or resinous. Transparent, translucent. Specific gravity 2·0 to 2·2. Feels greasy, but does not adhere to the tongue. Found at Frankenstein in Silesia, and at Zöblitz in Saxony, and also in New York and New Jersey, United States. Analysis, by Pfaff: Silica, 37·95; alumina, 12·18; magnesia, 16·02; water, 31·00 = 97·15.

KIRWANITE occurs filling cavities in a kind of basaltic rock. Texture fibrous, fibres diverging from a centre and forming brushes. Colour dark olive green. Opaque. Hardness 2·0. Specific gravity 2·941. Found on the north-east coast of Ireland. Analysis, by R. D. Thomson: Silica 40·5; protoxide of iron, 23·91; lime, 19·78; alumina, 11·41; water, 4·35.

KNEBELITE. [MANGANESE, *Ores of*, P. C.]

KOBELLITE resembles sulphuret of antimony, but is more brilliant. Structure radiated, crystalline. Streak and powder black. Specific gravity 6·29 to 6·32. Found in the cobalt-mine at Hucna in Sweden. Analysis by Setterberg: Sulphuret of lead, 46·36; sulphuret of bismuth, 33·18; sulphuret of antimony, 12·70; sulphuret of iron, 4·72; sulphuret of copper, 1·08; gangue, 1·45 = 99·49.

KOLLYRITE (*Hydrous Silicate of Alumina*) occurs massive. Colour white. Fracture earthy. Nearly opaque. Lustre somewhat vitreous. Hardness 3·25. Specific gravity 2·06 to 2·11. Found at Schemnitz in Hungary, and in a lead-mine on the bank of the river Oo, in the Pyrenees. Analysis, by Berthier: Silica, 19; alumina, 44·5; water, 40·5.

KROKYDOLITE occurs asbestiform, fibrous, and compact. Colour lavender or indigo blue. Streak lavender blue or leek green. Lustre silky. Opaque. The fibrous variety is flexible and elastic. Found on the Orange River in Southern Africa. Analysis of the fibrous variety, by Stromeyer: Silica, 51·64; protoxide of iron, 34·38; soda, 7·11; magnesia, 2·62; oxide of manganese, 0·02; lime, 0·05; water, 4·01.

KUPFERINDIG (*Indigo Copper, Blue Copper*) occurs in spheroidal masses, presenting superficial indications of crystallization. Colour dark blue. Fracture uneven. Hardness about 2·0. Lustre faintly resinous. Opaque. Specific gravity 3·8. Found at Sangerhausen in Thuringia, and also in the volcanic rocks of Vesuvius, in black or greenish blue incrustations. Analysis, by Walchner: Sulphur 32·64; copper, 64·77; iron, 0·46; lead, 1·04.

KUPFERSCHAUM occurs crystallized. Primary form a right rhombic prism. Occurs in rhomboidal plates, which present perfect cleavage parallel to the faces of the rhomb; generally in small aggregated and diverging fibrous groups of a pale apple green or verdigris-green colour. Streak paler. Hardness 1·0 to 1·5. Lustre pearly on the faces of the rhomb. Translucent. Flexible in thin laminæ. Specific gravity 3·0 to 3·2. Found at Matlock in Derbyshire, in the Bannat, at Lebether in Hungary, in Siberia, the Tyrol, and at Saalfeld in Thuringia. Analysis, by Von Kobell: Arsenic acid, 25·01; oxide of copper, 43·88; carbonate of lime, 13·65; water, 17·46.

LANARKITE (*Sulphato-carbonate of Lead*) occurs in long slender crystals, single or aggregated into fibrous masses. Primary form an oblique rhombic prism. Colour greenish, yellowish, or greyish. Streak white. Hardness 2·0 to 2·5. Lustre nearly resinous, but pearly on the cleavage planes. Transparent, translucent. Specific gravity 6·8 to 7. Found at Lead Hills in Scotland. A massive variety has been met with in Siberia. Analysis, by Brooke: Sulphate of lead, 53·1; carbonate of lead, 46·9.

LATROBITE occurs crystallized and massive. Primary form a doubly oblique prism. Cleavage parallel to all the primary planes. Colour pale rose-red or pink. Fracture uneven. Hardness 5·0 to 6·0. Lustre vitreous. Tranlucent. Specific gravity 2·72 to 2·80. Found at Amitok Island, Labrador, and in Finland. Analysis, by Gmelin: Silica, 44·65; alumina, 36·81; lime, 8·29; potash, 6·58; oxide of manganese, 3·16.

LAVENDULAN occurs amorphous. Colour lavender blue. Streak paler blue. Lustre greasy, inclining to vitreous. Hardness 2·5 to 3·0. Occurs at Annaberg in Saxony, with cobalt and iron ores. Analysis: According to Plattner, it contains arsenic, and the oxides of cobalt, copper and nickel, and water.

LEHUNTITE. [ZEOLITES, P. C.]

LENZINITE (*Halloysite*) occurs in compact and earthy masses of varioussizes. *Compact:* Colour yellowish milk white. Streak shining. Fracture conchoidal. Hardness 1·5. Nearly dull. Transparent on the edges. Feels rather greasy. Specific gravity 2·10. In water separates with noise into small fragments. *Earthy:* Colour snow white. Streak shining. Fracture earthy. Soft. Slightly translucent. Opaque. Dull. Specific gravity 1·80. Found at Kall in Eifeld. Analysis: *Compact*—Silica, 37·5; alumina, 37·5; water, 25, with a trace of lime. *Earthy*—Silica, 39; alumina, 35·5; water, 25; with a trace of lime.

Halloysite appears to be a variety of the above, its colour being bluish and greyish white.

LEONHARDITE occurs crystallized. Primary form an oblique rhombic prism. Cleavage very perfect, parallel to the lateral planes. Colour white, yellowish, and more rarely brownish. Streak white. Fracture uneven. Frequently coated with brownish or black powder. Hardness 3·0 to 3·5. Lustre pearly, especially on perfect cleavage planes; on the fractured surface vitreous. Translucent on the edges. Specific gravity 2·25. Found near Wolfstein in Rhenish Bavaria. Analysis, by Dr. Delf: Silica, 56·128; alumina, 22·980; lime, 9·251; water and loss, 11·641.

LEUCHTENBERGITE occurs in large but not perfectly developed crystals in the form of the rhomboid. Colour yellowish in masses, but in thin laminæ white. Texture lamellar. Lustre pearly. Transparent in small crystals. Hardness between calcspar and selenite; is impressed by the nail. Feels greasy. Specific gravity 2·71. Found in the Schischminsk mines in the district of Slatonst. Analysis, by Komonen; Silica, 34·23; alumina, 16·31; magnesia, 35·6; peroxide of iron, 3·33; lime, 1·75; water, 8·68.

LEUCOPHANE occurs crystallized in four-sided prisms, but is seldom regularly crystallized. Cleavage imperfect in three directions. Colour pale dirty green and deep wine yellow. Transparent and colourless in thin fragments. Lustre vitreous on cleavage surface. Hardness 3·50 to 3·75. Specific gravity 2·974. Found at Langesundfiord in Norway. Analysis, by by Erdmann: Silica, 47·82; glucina, 11·51; lime, 25·00; fluorine, 6·17; sodium, 7·59; protoxide of manganese, 1·01; potassium, 0·26.

LIBETHENITE (*Phosphate of Copper*) occurs in small octohedral crystals and in radiated masses. Primary form a right rhombic prism. Colour dark green. Streak green. Fracture uneven. Hardness 4·0. Transparent, translucent. Lustre resinous. Specific gravity 3·6. Found at Libethen in Hungary. Analysis, by Berthier: Phosphoric acid, 28·7; oxide of copper, 63·9; water, 7·4.

LIGURITE. Primary form an oblique rhombic prism. Colour apple green. Streak greyish white. Fracture uneven. Hardness above 5·0. Lustre of the surface of fracture, between vitreous and resinous. Transparent, translucent. Specific gravity 3·49. Found on the banks of the Stura, in the Apennines of Liguria. Analysis, by Viviani: Silica, 57·45; alumina, 7·36; lime, 25·30; magnesia, 2·56; oxide of iron, 3·00; oxide of manganese, 0·5 = 96·17.

LIME, OXALATE OF, occurs crystallized. Primary form an oblique rhombic prism, and from one-tenth to one-fourth of an inch long. Colourless. Fracture conchoidal. Hardness rather less than calcspar. Very brittle. Lustre similar to that of sulphate of lead. Transparent to opaque. Specific gravity 1·833. Supposed to have come from Hungary. Analysis, by Sandell, showed its composition to be oxalate of lime with one equivalent of water.

LINARITE (*Cupreous Sulphate of Lead*) occurs crystallized. Primary form an oblique rhombic prism. Colour deep azure blue. Streak pale blue. Fracture uneven. Hardness 2·5 to 3·0. Lustre vitreous or adamantine. Transparent, translucent. Specific gravity 5·3 to 5·4. Found at Linares in Spain, and at Lead Hills, Scotland. Analysis, by Brooke: Sulphate of lead, 74·4; oxide of copper, 18·0; water, 4·7.

LINSENERZ. Primary form a right rhombic prism, occurs in octohedral crystals. Cleavage parallel to the primary planes. Colour light blue and occasionally dull green. Streak pale blue or green. Hardness 2·0 to 2·5. Lustre vitreous. Transparent, translucent. Specific gravity 2·926. Found near Redruth, Cornwall, and in Hungary. Analysis, by Dr. Thomson: Arsenic acid, 43·39; oxide of copper, 30·10; water, 26·69.

LITHOMARGE occurs massive. Spheroidal. Colour white, grey, red, yellow, blue. Streak shining. Structure compact. Soft. Dull. Opaque. Unctuous to the touch. Adheres to the tongue. Specific gravity 2·2 to 2·5. Found in Cornwall near Redruth, in Saxony and some other places in Europe. Friable lithomarge occurs in scaly, glimmering particles, which are phosphorescent in the dark. Found at Ehrenfriedensdorf in Saxony. Analysis, by Klaproth: Silica, 32·00; alumina, 26·50; oxide of iron, 21·00; chloride of sodium, 1·50; water, 17·00.

MAGNESIA ALUM occurs massive. Structure fibrous, also compact. Colour and streak snow white. Lustre shining. Found at Cape Verd, in Southern Africa, where it covers the floor of a grotto to the depth of six inches. Analysis, by Stromeyer: Sulphate of alumina, 38·398; sulphate of magnesia, 10·820; sulphate of manganese, 4·597; chloride of potassium, 0·205; water, 45·739.

MAGNESIA, HYDRATE OF. [SHEPARDITE.]

MAGNESIAN PHARMACOLITE occurs massive. Cleavage foliated in one direction. Colour dirty white or honey yellow. Hardness 5 to 6. Brittle. Lustre waxy. Specific gravity 2·52. Found at Längbanshyttan in Wermeland. Analysis, by Kuhn: Arsenic acid, 58·52; lime, 23·22; magnesia, 15·68; protoxide of manganese, 2·13; iron, a trace; loss by ignition, 0·30.

MAGNESITE (*Carbonate of Magnesia*) occurs in acicular crystals, massive, and in powder. Colour usually white, occasionally greyish and yellowish. The *massive varieties* are found amorphous, reniform, nodular, and stalactitic. Fracture splintery or flat conchoidal. Hardness exceeds that of calc-spar. Dull. Nearly opaque. Specific gravity 2·8. Found in several parts of Europe, as Styria, Moravia, Spain and Silesia, in India, and at Hoboken in New Jersey, North America. Analysis, by Rammelsberg: Carbonic acid, 52·214; magnesia, 47·786.

MALTHACITE occurs in these plates and massive. Fracture uneven or conchoidal. Colour white or yellowish. Streak shining. Soft like wax. Lustre waxy, weak. Streak shining. Translucent. Specific gravity 1·99 to 2·01. Found at Stendorfal between Lobau and Bauzen, and near Beraun in Bohemia. Analysis, by Meissner: Silica, 50·2; alumina, 10·7; lime, 0 2; peroxide of iron, 3·1; water, 35·8.

MARGARITE (*Pearl Mica*) occurs in thin hexagonal crystals, and in masses of small thin shining laminæ. Primary form a rhomboid. Cleavage distinct parallel to the bases, indistinct parallel with the sides. Colour greyish, reddish, and yellowish white. Streak white. Fracture not observable. Hardness 3·5 to 4·5. Rather brittle. Lustre pearly on the terminal faces, vitreous on the others. Translucent. Specific gravity 3·0 to 3·1. Found at Sterzing in the Tyrol. No accurate analysis appears to have been made.

MARCELINE (*Anhydrous Silicate of Deutoxide of Manganese*) occurs crystallized in octohedrons with a square base. Colour greyish black. Lustre slightly metallic or vitreous. Found at St. Marcel in Piedmont. Analysis, by Berzelius: Silica, 15·17; oxide of manganese, 75·80; oxide of iron, 4·14; alumina, 2·80. The analysis by Berthier gives considerably more silica and less oxide of manganese.

MARMATITE. [ZINC, *Ores of* P. C.]

MARMOLITE (*Silicate of Magnesia*) occurs massive. Structure columnar, irregularly intersecting. Columnar portions foliated, having a cleavage in two directions intersecting each other. Colour greyish and greenish. Hardness 3·5. Lustre pearly. Translucent, opaque. Specific gravity 2·47. Found at Hoboken, New Jersey, and the Bare Hills, near Baltimore, United States. Analysis, by Nuttall: Silica, 36; magnesia, 46; lime, 2; water, 15.

MASCAGNIN (*Sulphate of Ammonia*) occurs stalactitic, pulverulent, or efflorescent. Colour yellow or greyish. Taste acrid, bitter. Translucent, opaque. Found in the fissures of the earth, and among the lavas of Ætna and Vesuvius, in the Solfatara, and near Sienna in Tuscany. Analysis, by Gmelin: Sulphuric acid, 53·29; ammonia, 22·80; water, 23·91.

MELANOCHROITE. [CHROMIUM, *Ores of—Subsesquichromate of Lead*, P. C.]

MELANTERITE (*Sulphate of Iron, Green Vitriol*) occurs massive, fibrous, earthy, and crystallized. Primary form an oblique rhombic prism. Cleavage parallel to the primary planes. Colour green, with shades of yellow or brown. Streak white. Fracture conchoidal. Hardness 2·0. Brittle. Lustre vitreous. Transparent, translucent. Taste astringent. Specific gravity 1·84. Massive varieties—Amorphous, structure granular, botryoidal, reniform, stalactitic. Structure fibrous. Formed the decomposition of iron pyrites frequently in coal-mines. Found at Hurlet near Paisley, and Campsie, Scotland. Analysis, by Berzelius: Sulphuric acid, 28·8; protoxide of iron, 25·7; water, 45·4.

MENGITE (*Monazite, Edwardsite*) occurs crystallized. Primary form an oblique rhombic prism. No regular cleavage. Colour hyacinth or brick-red. Streak white. Fracture uneven, and the fractured surface dull. Hardness 5·0. Lustre vitreous. Translucent. Specific gravity 4·924. Found near Miask in Siberia. Analysis, by Kersten: Phosphoric acid, 28·50; peroxide of cerium, 26·00; oxide of lanthanium, 23·40; thorina, 17·95; peroxide of tin, 2·10; protoxide of manganese, 1·86; lime, 1·68 = 101·49.

MESITINE SPAR (*Carbonate of Iron and Magnesia*). Primary form an obtuse rhomboid. Cleaves parallel to the faces of the primary. Colour yellowish. Hardness 4·0. Lustre vitreous. Translucent. Specific gravity 3·35 to 3·63. Found at Traversella in Piedmont. Analysis, by Stromeyer: Carbonic acid, 44·23; protoxide of iron, 35·13; magnesia, 20·64, with some protoxide of manganese.

MISPICKEL. [ARSENICAL MINERALS, P. C.]

MICA. It is remarked by Brooke 'that several distinct species of minerals are included under this name, merely because they may be easily split into *very thin shining* plates; but they cannot at present be distinguished by any characters which have been hitherto given.' He treats of the various substances belonging to this mineral, under the heads of Rhomboidal Mica; Oblique Prismatic Mica; Lepidolite, or Lilac Mica [P. C.]; Margarite, Pearl Mica; Rubellan, or Red Mica; Oderit, or Black Mica [P. C.].

Rhomboidal Mica occurs massive and in hexagonal prisms. Primary form a rhomboid. Cleavage very distinct, perpendicular to the axis. Fracture not observable. Hardness of the cleavage surfaces 2·0 to 2·5, that of the edges 4·5 to 5·5. Colour white, grey, black, brown, pale red, dull yellow, green. Streak white, grey. Lustre vitreous, pearly on the cleavage surfaces. Transparent, translucent. Massive varieties globular, structure fibrous, foliated. Amorphous, structure foliated, granular, fibrous. Found in primitive rocks.

Oblique Prismatic Mica. Primary form an oblique rhombic prism, and according to Brooke the preceding descriptions will probably apply to this variety, except as to the form. Analysis, by Rose: Silica, 47·19; alumina, 33·80; peroxide of iron, 4·47; oxide of manganese, 2·58; lime, 0·13; fluoric acid, 0·39; potash, 8·35; water, 4·07 = 100·88.

MIDDLETONITE occurs in rounded masses, seldom larger than a pea, or in layers a sixteenth of an inch or less in thickness, between layers of coal. Colour reddish brown by reflected light, and deep red by transmitted. Powder light brown. Transparent in small fragments. Hard and brittle. Lustre resinous. No taste or smell. Blackens on exposure. Specific gravity 1·6. Found about the middle of the main coal or Haigh Moor seam at the Middleton collieries near Leeds; also at Newcastle. Analysis, by Johnston: Carbon, 86·437; hydrogen, 8·007; oxygen, 5·563.

MONRADITE occurs massive. Cleavage, one distinct, and another imperfect. Colour pale yellowish, verging on red. Hardness nearly that of felspar. Lustre vitreous. Specific gravity 3·2673. Found at Bergen in Norway. Analysis, by Erdmann: Silica, 56·17; magnesia, 31·63; protoxide of iron, 8·56; water, 4·04.

MONTICELLITE occurs crystallized. Primary form a right rhombic prism. Crystals small, and have usually the aspect of quartz. Colour generally yellowish. No cleavage planes have been observed. Hardness 5·0 to 6·0. Sometimes nearly transparent and colourless. Found at Vesuvius. It has not been analyzed.

MOSANDERITE occurs massive and fibrous, and crystallized in flat prisms. Cleavage in one direction distinct, in others indistinct. Colour dull reddish-brown. Streak greyish brown. Hardness 4·0. Lustre of cleavage face between vitreous and greasy; of other surfaces resinous. Thin splinters translucent and showing a bright red colour by transmitted light. Specific gravity 2·93 to 2·98. Found at Lammanskaret in Sweden. Analysis: according to Erdmann it consists mostly of silica, titanic acid, and the oxides of cerium and lanthanium, with some oxide of manganese, lime, a little magnesia, potash, and water.

NEEDLE ORE occurs crystallized in acicular four- or six-sided prisms, indistinctly terminated and longitudinally striated. Cleavage parallel to the axis of the prism. Colour, when first broken, steel-grey or blackish lead-grey, soon acquiring a yellowish tarnish. Cross fracture small-grained and uneven, with a shining metallic lustre. Hardness 2·0 to 2·5. Opaque. Specific gravity 6·125. Found near Ekaterinburg in Siberia. Analysis, by Frick: Sulphur, 11·58; bismuth, 43·20; copper, 12·10; nickel, 1·58; tellurium, 1·32.

NEMALITE occurs in slender fibres, which are elastic, sometimes curved, and easily separated. Colour white, with a shade of yellow. Streak white. Lustre highly silky. Opaque. Some decomposed varieties have an earthy appearance. Hardness 2·0. Specific gravity 2·353. Found in veins at Hoboken, New Jersey, and other places in the United States. Analysis, by Dr. Thomson: Silica, 12·568; magnesia, 51·721; peroxide of iron, 5·874; water, 29·666.

NUSSIERITE. Occurs in crystals, which are almost lenticular. Primary form a rhomboid. It is generally found implanted in mammillary masses. Colour yellow, greyish or greenish. Streak yellowish white, greyish. Fracture somewhat conchoidal. Hardness 4·0. Lustre greasy, feeble. Specific gravity 5·0415. Found in the mine of Nussière, near Beaujeu, department of the Rhône, France. Analysis, by Barruel: Phosphate of lead, 56·40; phosphate of lime, 22·20; chloride of lead, 7·65; arseniate of iron, 6·50.

ŒRSTEDTITE occurs crystallized. Primary form a right square prism. Colour brown. Lustre splendent. Hardness 6·5. Specific gravity 3·628. Found at Arendal, Norway. Analysis: Titaniate of zirconis, 68·965; silica, 19·708; lime, 2·612; magnesia, 2·047; protoxide of iron, 1·136; water, 5·332.

OKENITE (*Dysclasite*) occurs in fibrous masses, having a radiated structure; also imperfectly fibrous, or composed of minute crystals. Hardness 4·5 to 5. Colour white. Specific gravity 2·28. Translucent. Exhibits double refraction. Found at Disco Island, Greenland. Analysis, by Kobell: Silica, 56·99; lime, 26·35; water, 16·65.

OLIGOCLASE occurs crystallized. Primary form an oblique rhombic prism. Colour white, yellowish, and greenish white. Fracture conchoidal, uneven. Hardness 6·0. Transparent, sub-translucent. Specific gravity 2·64 to 2·67. Found at Danvikszoll near Stockholm, Arendal in Norway, &c. Analysis, by Berzelius: Silica, 63·70; alumina, 23·95; lime, 2·05; magnesia, 0·65; soda, 8·11; potash, 1·20; peroxide of iron, 0·50.

OLEGON SPAR (*Carbonate of Iron and Manganese*). Primary form an obtuse rhomboid. Cleavage on the faces of the primary. Colour yellow, reddish-brown. Lustre vitreous. Hardness 4·0. Specific gravity 3·745. Found at Ebrenfriedensdorf. Analysis, by Magnus: Carbonate of iron, 59·99; carbonate of manganese, 40·66.

OLIVENITE (*Olivenerz*) occurs crystallized and massive. Primary form a right rhombic prism. Cleavage parallel to the primary planes. Colour green, generally inclining to olive-green. Streak paler. Fracture uneven. Hardness 3·0. Lustre vitreous. Transparent, translucent. Specific gravity 4·28. Massive varieties, globular, nodular, reniform. Structure fibrous, sometimes granular, compact. Found near Redruth, Cornwall, and near Alston Moor, Cumberland. Analysis, by Richardson: Arsenic acid, 39·9; oxide of copper, 56·2; water, 3·9.

ORPIMENT. [ARSENIC, P. C.]

OXALATE OF IRON. [IRON, OXALATE OF.]

OXALATE OF LIME. [LIME, OXALATE OF.]

OTTRELITE occurs in small rounded brilliant plates, with a perfect basal cleavage. Colour greyish or greenish. Streak pale green. Fracture uneven. Scratches glass with difficulty. Specific gravity 4·40. Found near Ottrez on the borders of Luxembourg. Analysis, by Damour: Silica, 43·34; alumina, 24·63; protoxide of iron, 16·72; protoxide of manganese, 8·18; water, 5·56.

OZOKERITE (*Carburet of Hydrogen*). Colour yellowish brown. Translucent; has a slight bituminous odour, and softens by the heat of the hand, so that it may be kneaded. Fuses readily, emitting a stronger bituminous odour; burns with a clear bright flame without residue. Insoluble in water, only slightly in alcohol, but readily in ether and oil of turpentine. Found in considerable masses at Slanik in the Buchau district of Moldavia, and used for fuel. Analysis: Carbon, 85·204; hydrogen, 13·787. It appears to be similar in composition to Hatchettine.

PARGASITE. [AUGITE, P. C.]

PEKTOLITE occurs on spheroidal masses which have a radiating fibrous structure. Colour greyish. Hardness 4·0 to 5·0. Lustre pearly. Nearly opaque. Specific gravity 2·69. Found in large masses on Monte Baldo, in the Southern Tyrol, and at Monzoni in the Fassa-thal. Analysis, by Von Kobell; Silica, 51·30; lime, 33·77; soda, 8·26; potash, 1·57; alumina and oxide of iron, 0·90; water, 3·89.

PERICLASE occurs crystallized on regular octohedrons. Primary form a cube. Cleavage in three directions parallel to the faces of the cube. Colour obscure green. Hardness equal to felspar. Lustre vitreous. Translucent. Specific gravity 3·78. Found in the lava of Vesuvius. Analysis, by Damour: Magnesia, 92·57; oxide of iron, 6·91; insoluble matter, 0·86.

PEROVSKITE. Primary form the cube. Cleavage parallel to the faces of the cube. Colour grey or iron black. Streak greyish white. Hardness 5·5. Lustre metallic. Opaque. Specific gravity 4·071. Found at Achmatoosk, near Slatoust in the Ural. Analysis, by Rose, shows that it consists principally of titanic acid and lime.

PHARMACOLITE, MAGNESIAN. [MAGNESIAN PHARMACOLITE.]

PHARMAKOSIDERIT (*Cubic Arseniate of Iron, Cube Ore*) occurs crystallized and sometimes massive. Primary form a cube. Cleavage parallel to the primary planes, indistinct. Colour of various shades between light and bottle green, and yellowish and brownish green; streak paler. Fracture uneven; cross-fracture uneven or imperfectly conchoidal. Hardness 2·5. Brittle. Lustre vitreous. Transparent, translucent. Opaque. Specific gravity 2·9 to 3·0. Massive variety amorphous, structure granular. Found in Cornwall, and more rarely at St. Leonard in France, Schneeberg, Schwartzenberg in Saxony, and Franklin, North America. Analysis, by Berzelius: Arsenic acid, 38·00; peroxide of iron, 40·56; phosphoric acid, 0·70; oxide of copper, 0·60; water, 19·57; insoluble matter, 0·35.

PHENAKITE occurs crystallized. Primary form a rhomboid. Cleavage parallel to the primary faces. Colourless; also bright wine-yellow, inclining to red. Hardness above 6·0. Lustre vitreous. Transparent to opaque. Specific gravity 2·969. Found near Freiberg and near Framont. Analysis, by Hartwall: Silica, 55·14; glucina, 44·47; alumina and magnesia, 0·39.

PHOLARITE, a hydrous silicate of alumina, probably similar to HALLOYSITE.

PHOSPHORITE. [APATITE, P. C.]

PHYLLITE. [GIGANTHOLITE?]

PICKENGERITE (*Magnesia Alum?*) occurs in masses composed of long parallel fibres of a silky or satin lustre. Colour white, or, viewed in the direction of the fibres, pale rose-red or light green. Compact, but easily divided parallel with the fibres. Brittle. Specific gravity 1·78 to 1·80. Found at Tarapaca in Peru. Analysis, by Stromeyer: Sulphuric acid, 36·770; alumina, 11·515; magnesia, 3·690; peroxide of manganese, 2·617; chloride of potassium, 0·205; water, 45·739.

PICTITE. [TURNERITE, P. C.]

PIMELITE. [NICKEL, *Ores of*, P. C.]

PINGUITE occurs massive. Colour siskin or oil green; streak lighter. Fracture conchoidal or uneven. Hardness under 2·0. Lustre slightly resinous. Specific gravity 2·315. Feels greasy. Does not adhere to the tongue. Emits a feeble argillaceous odour when struck. Found at Wolkenstein in the Erzgebirge. Analysis, by Kersten: Silica, 36·90; peroxide and protoxide of iron, 35·60; alumina, 1·80; magnesia, 0·45; oxide of manganese, 0·14; water, 25·10.

PISSOPHANE occurs amorphous. Colour pistachio, asparagus, or olive green. Fracture conchoidal. Hardness 1·5. Very fragile. Lustre vitreous. Transparent. Specific gravity 1·93 to 1·98. Found at Garnsdorf, near Saalfeld. Analysis, by Erdmann: Sulphuric acid, 12·593; alumina, 35·228; peroxide of iron, 9·769; water, 41·695.

PLACODINE (*Arseniuret of Nickel*) occurs in crystalline masses and crystallized. Primary form an oblique rhombic prism. Colour bronze-yellow; streak black. Fracture conchoidal, uneven. Hardness 5·0. Lustre metallic. Specific gravity 7·988 to 8·062. Found at the Jungfer mine, Müsen. Analysis, by Plattner: Arsenic, 39·707; nickel, 57·044; cobalt, 0·900; copper, 0·862; sulphur, 0·617.

PLAGIONITE occurs massive and crystallized. Primary form an oblique rhombic prism. Cleavage lateral, perfect, but seldom affording smooth surfaces. Colour blackish lead-grey. Fracture imperfectly conchoidal. Hardness 2·5. Brittle. Lustre metallic. Opaque. Specific gravity 5·4. Found at Wolfsberg in the Harz. Analysis, by Rose and Kudernatsch: Sulphur, 21·53; lead, 40·52; antimony, 37·94.

PLUMBO-CALCITE (*Carbonate of Lime and Lead*) occurs crystallized and in crystalline masses. Primary form a rhomboid. Cleavage parallel to the primary planes. Colour white; streak white. Hardness 3·2. Lustre vitreous, sometimes pearly. Transparent, translucent. Specific gravity 2·829. Found at Wanlockhead, Lanarkshire, Scotland. Analysis, by Johnstone: Carbonate of lime, 92·2; carbonate of lead, 7·8.

POLISHING SLATE (*Polier schiefer*) occurs massive, with a slaty texture. Colour white, yellowish white, or yellow. Brittle. Opaque. Specific gravity 0·59. Found near Bilin in Bohemia, at Zwickau in Saxony, and Auvergne, and is supposed to be a volcanic product. Analysis, by Bucholz: Silica, 83·50; alumina, 4·00; lime, 8·50; oxide of iron, 1·60 water, 9·00.

POONAHLITE occurs crystallized in long slender crystals. Primary form a right rhombic prism. Fracture uneven. Colourless. Hardness 5·0 to 5·5. Transparent, translucent. Lustre vitreous. Found at Poonah in the East Indies. Analysis, by Gmelin: Silica, 45·120; alumina, 30·446; lime 10·197; soda with a trace of potash, 00·657; water, 13·386

POTSTONE (*Compact Talc*). [TALC, P. C.]

PRASE. [QUARTZ, P. C.]

PRASEOLITE occurs imperfectly crystallized in prisms of several sides, with the edges rounded. Cleavage in one direction. Colour light or dark green; streak clear green. Fracture splintery and flat conchoidal. Hardness 3·5. Lustre weak. Specific gravity 2·754. Found near Brevig, Norway, Analysis, by Erdmann: Silica, 40·94; alumina, 28·79; protoxide of iron, 6·96; protoxide of manganese, 0·32; magnesia, 13·73; titanic acid, 0·40; oxide of lead, copper, and cobalt with lime, 0·50; water, 7·38.

Prasilite occurs massive. Composed of loosely adhering fibres. Colour dark leek-green. Hardness not sufficient to scratch selenite, and may be crumbled to powder between the fingers. Specific gravity 2·311. Found on the Kilpatrick Hills. Analysis, by Dr. Thomson: Silica, 38·55; magnesia, 15·55; peroxide of iron, 14·90; alumina, 5·65; lime, 2·55; oxide of manganese, 1·50; water, 18·00. The loss amounting to 3 per cent. is attributed to an alkali.

Psilomelane. [Manganese, *Ores of*, P. C.]

Purple Copper-Ore (*Buntkupfererz*) occurs crystallized and massive. Primary form a cube, the faces of which are usually curvilinear. Cleavage parallel to the faces of the regular octohedron, indistinct. Fracture uneven, conchoidal. Hardness 3. Colour purplish and reddish brown; tarnishes speedily after being cut. Streak greyish black. Lustre metallic. Specific gravity 5·0. Massive variety amorphous, structure compact. Found in Cornwall and most copper-mines. Analysis, by R. Phillips, of a specimen from Ross Island, Lake of Killarney, Ireland: Sulphur, 23·75; copper, 61·07; iron, 14·00; silica, 0·50.

Pyrope. [Garnet, P. C.]

Pyrosklerite. Primary form a rhombic prism, with one perfect cleavage, and another at right angles with this, imperfect. Colour emerald-green and apple-green; streak white. Fracture uneven and splintery. Hardness 3·0. Lustre dull. Translucent. Specific gravity 2·74. Found in the island of Elba, and at Aker in Südermanland. Analysis, by Von Kobell: Silica, 37·03; alumina, 13·50; magnesia, 31·62; protoxide of iron, 3·52; oxide of chromium, 1·43; water, 11·00.

Pyrrhite occurs crystallized in regular octohedrons. No cleavage observable. Colour deep orange-yellow. Hardness equal to that of felspar. Lustre vitreous, brilliant. Transparent on the edges. Found at Alabaschka, near Mursinsk, and at the Azores. It has not been analyzed.

Reussite (*Soda Sulphate of Magnesia*) occurs in flat six-sided prisms, acicular crystals, and mealy efflorescences. Colour snow-white. Fracture conchoidal. Taste saline and bitter. Found in the vicinity of Seidlitz and of Seedschutz in Bohemia. Analysis, by Reuss: Sulphate of soda, sulphate of magnesia, 31·35; muriate of magnesia, 2·19; sulphate of lime, 0·42.

Rhenite (*Hydrous Phosphate of Copper*) occurs crystallized and massive. Primary form an oblique rhombic prism. Cleavage indistinct, parallel to the horizontal diagonal. Colour blackish green, and green of various shades; streak light green. Fracture uneven. Hardness 5·0. Lustre vitreous. Translucent, opaque. Specific gravity 4·2 to 4·3. Found at Rheinbreitbach, near Bonn, on the Rhine. Analysis, by Lunn: Phosphoric acid, 21·687; oxide of copper, 62·847; water, 15·454.

Riolite. [Zinc, *Ores of*, P. C.]

Romeine occurs crystallized in square octohedrons, in groups of minute crystals. Colour hyacinth or honey-yellow. Hardness scratches glass. Found at St. Marcel in Piedmont. Analysis, by Damour: Antimonious acid, 79·17; lime, 16·65; protoxide of manganese, 2·16; protoxide of iron, 1·19; silica, 0·64.

Rosite occurs in small grains, without crystallization. Fracture splintery, and in the larger grains somewhat foliated. Surface of the fracture shining. Colour faint rose-red to brownish red; the former more common. Subtransparent. Hardness 2·5. Specific gravity 2·72. Found in Südermanland. Analysis, by Svanberg: Silica, 44·901; alumina, 34·506; peroxide of iron, 0·688; oxide of manganese, 0·191; potash, 6·628; lime, 3·592; magnesia, 2·498; soda, a trace; water, 6·333.

Rubellan (*Red Mica?*) occurs in small hexagonal plates, not elastic. Colour reddish brown. Hardness 2 to 2·5. Lustre pearly. Transparent, opaque. Specific gravity 2·8 to 3·1. Found at Schima in the Mittelgebirge, Bohemia. Analysis, by Klaproth: Silica, 45; alumina, 10; oxide of iron, 20; lime, 10; potash and soda, 10; volatile matter, 5.

Rutile. [Titanium, *Ores of*, P. C.]

Sahlite. [Pyroxene, P. C.]

Sapphirine occurs granular disseminated in anthophyllite. Colour pale blue or greenish; streak white. Fracture uneven, conchoidal. Hardness 7·0 to 8·0. Lustre vitreous. Translucent. Specific gravity 3·42. Found at Akudlek in Greenland. Analysis, by Stromeyer: Silica, 14·50; alumina, 73·11; magnesia, 16·85; lime, 0·38; oxide of iron, 3·92; oxide of manganese, 0·53; water, 0·49.

Sassolin (*Native Boracic Acid*). [Boron, P. C.]

Schorl. [Tourmalin, P. C.]

Semi Opal. [Opal, P. C.]

Seybertite (*Clintonite, Holmesite*) occurs in masses which are imperfectly crystallized, or present a foliated structure and crystallized. Primary form a right rhombic prism. Cleavage parallel with the primary planes imperfect. Colour copper-red, reddish brown, yellowish brown, and reddish white; streak yellowish grey. Hardness 4·0 to 4·5. Lustre metallic, pearly. Translucent, opaque, in thin laminæ sometimes transparent. Specific gravity 3·07 to 3·10. Found in Orange County, New York, near the village of Amity. Analysis, by Clemson: Silica, 17·0; alumina, 37·0; magnesia, 24·3; lime, 10·7; protoxide of iron, 5; water, 3·60.

Shepardite (*Hydrate of Magnesia*) occurs rarely in hexagonal prisms, generally in laminar masses, and fibrous. Primary form a rhomboid. Colour white, greenish white. Streak white. Lustre pearly. Transparent, translucent. Hardness 1·0 to 1·5. Specific gravity 2·33 to 2·63. Found at Hoboken, in New Jersey, North America, and in the island of Unst, Shetland. Analysis, by Bruce: Magnesia, 70; water, 30.

Sismondine. Crystalline characters not given. Colour deep green, brilliant. Cleaves readily, affording highly lustrous laminæ. Brittle, easily powdered; colour of the powder bright greyish green. Scratches glass. Specific gravity about 3·565. Found at St. Marcel in Piedmont. Analysis, by Delesse: Silica, 24·1; alumina, 43·2; protoxide of iron, 23·8; water, 7·6; trace of titanium.

Smaragdite. [Amphibolite, P. C.]

Smithsonite. [Zinc, *Ores of*, P. C.]

Soapstone. [Steatite, P. C.]

Soda Alum occurs in white fibrous masses. The outer fibres opaque by decomposition, internally transparent and exhibiting a glossy or silky aspect. Not scratched by the nail. Specific gravity 1·88. Found at St. Juan in South America. Analysis, by Thomson: Sulphuric acid, 38·5; alumina, 12·0; soda, 7·5; water, 42·0; with a little silica, lime, iron, and manganese.

Sodaite. [Ekebergite.] Humboldtilite of Monticelli.

Somervillite (*Humboldtilite*) occurs crystallized. Primary form a square prism. Cleavage perpendicular to the axis, very distinct. Colour pale dull brownish-yellow. Fracture uneven. Transparent, translucent. Found in the cavities of matter ejected from Vesuvius. Analysis, by Monticelli and Covelli:—Silica, 43·96; lime, 31·67; magnesia, 8·83; alumina, 0·50; protoxide of iron, 2·00. Kobell found 4·25 per cent. of soda.

Sordawalite occurs massive. Fracture conchoidal. Colour greyish, greenish, or bluish black. Structure compact. Hardness 2·5 to 3·0. Brittle. Lustre vitreous. Opaque. Specific gravity 2·50 to 3·0. Found near Sordawla in Finland, and at Bodenmais in Bavaria. Analysis, by Nordenskiold: Silica, 49·40; alumina, 13·80; peroxide of iron, 18·17; magnesia, 10·67; phosphoric acid, 2·68; water, 4·38.

Spherostilbite occurs in globular masses. Structure radiated. Fracture brilliant. Lustre pearly. Fibres flexible. Hardness above 3·0. Specific gravity 2·31. Found in Iceland and the Faroe Islands. Analysis, by Gehlen, of a specimen from Iceland: Silica, 55·61; alumina, 16·68; lime, 8·17; soda, 1·53; water, 19·30.

Stellite. [Zeolites, P. C.]

Sternbergite occurs crystallized. Primary form a right rhombic prism. Colour pinchbeck-brown, with occasionally a violet tarnish in some of the faces. Streak black. Flexible in thin laminæ. Lustre metallic. Opaque. Hardness 1·0 to 1·5. Specific gravity 4·2 to 4·25. Found at Joachimstal in Bohemia. Analysis, by Zippe: Sulphur, 30; silver, 33·2; iron, 36.

Stilpnomelan occurs in crystalline, lamellar, and fibrous masses. Cleavage in one direction. Colour greenish or black. Streak greenish to liver brown. Lustre vitreous. Hardness 3·0 to 4·0. Specific gravity 3·27 to 3·4. Found at Obergrund and Zinkmantel, in Silesia. Analysis, by Rammelsberg: Silica, 46·500; protoxide of iron, 33·892; alumina, 7·100; lime, 0·197; magnesia, 1·888; water, 7·00 = 97·477.

Stilbite. [Zeolites, P. C.]

Suzannite (*Sulphato-tricarbonate of Lead*) occurs crystallized in two forms, viz. an acute rhomboid and a right rhombic prism. Cleavage of both forms perpendicular to the axis, and very distinct. Colour white, grey, pale yellow, or green. Streak white. Hardness 2·5. Transparent, translucent.

Specific gravity 6·2 to 6·4. Found at Lead-hills, in Scotland. Analysis, by Brooke: Carbonate of lead, 72·5; sulphate of lead, 27·5.

Stromnite (*Barytostrontianite*). [Strontium, P. C.]

Tabular Spar. [Wollastonite, P. C.]

Tellurbismuth (*Telluret of Bismuth*). [Tellurium, *Ores of*, P. C.]

Troostite (*Ferruginous Silicate of Manganese*) occurs crystallized. Primary form a rhomboid. Colour greenish, yellow, grey, and reddish-brown. Fracture conchoidal. Hardness 5·5. Brittle. Lustre vitreous, inclining to resinous. Translucent to transparent. Specific gravity 3·014 to 3·034. Found at Franklin, New Jersey, U. S. Analysis, by Dr. Thomson: Silica, 30·650; protoxide of manganese, 46·215; peroxide of iron, 15·450; carbonic acid and water, 7·300.

Tryphiline occurs crystallized and massive. Primary form a right rhombic prism. Massive variety has a coarsely lamellar or crystalline structure, with cleavages parallel to the planes of a right rhombic prism. Colour greenish grey. Streak greyish white. Hardness 5·0. Translucent in thin pieces. Specific gravity 3·6. Found at Bodenmais in Bayern. Analysis: Phosphoric acid, 41·47; protoxide of iron, 48·57; protoxide of manganese, 4·70; lithia, 3·40; silica, 0·53; water, 0·68.

Uranotantalite (*Columbate of Protoxide of Uranium*) occurs in flattened grains, occasionally with traces of crystallization. Lustre of the surface of fracture shining and submetallic. Hardness 5·5. Streak dark reddish-brown. Opaque. Specific gravity 5·625. Found in the Ilmen mountains near Minsk, in the Ural.

Uwarowite (*Chromium Garnet*) occurs crystallized in rhombic dodecahedrons. Colour emerald green. Hardness 7·5. Lustre vitreous. Nearly transparent. Specific gravity 3·41. Found at Bessersk, in the Ural mountains. Analysis, by Komonen: Silica, 37·11; alumina, 5·88; oxide of chromium, 22·54; protoxide of iron, 2·44; limo, 30·34; magnesia, 1·10; water, 1·01.

Vauquelinite. [Chromium, *Ores of*, P. C.]

Villarsite. Primary form a rhombic prism. Colour yellowish green. Fracture granular. Hardness 3·0 to 3·5. Subtransparent. Found at Traversella in Piedmont. Analysis, by Dufresnoy: Silica, 39·61; magnesia, 43·37; protoxide of iron, 3·59; protoxide of manganese, 2·42; lime, 0·53; potash, 0·46; water, 5·80.

Volborthite (*Vanadiate of Copper*) occurs in small clusters of olive-coloured crystals, sometimes united into globular masses. Streak green, almost yellow. In thin splinters transparent, with a vitreous lustre. Hardness, scratches calcspar. Specific gravity 3·55. Found on examining some Siberian copper-ores. Von Volborth, who examined it, has not given an exact analysis.

Voltaite (*Iron Alum*) occurs crystallized in regular octohedrons. Colour brown or black. Found at the Solfatara near Naples. Analysis, by Dufresnoy: Sulphuric acid, 45·67; protoxide of iron, 28·69; alumina, 3·27; potash, 5·47, water, 15·77.

Wagnerite (*Fluophosphate of Magnesia*). Primary form an oblique rhombic prism. Fracture uneven. Colour yellow, of different shades; often greyish. Streak white. Hardness 5·0 to 5·5. Lustre vitreous. Translucent. Specific gravity 3·11. Found in the valley of Holgraben in Salzburg. Analysis, by Fuchs: Phosphoric acid, 41·73; hydrofluoric acid, 6·50; magnesia, 46·66; oxide of iron, 5·00; oxide of manganese, 0·5.

Warwickite (*Fluoride of Titanium and Iron*). Primary form an oblique rhombic prism. Cleavage parallel to the longer diagonal, perfect. Colour dark hair brown to iron grey, and often with a copper-red tinge on the face of perfect cleavage. Decomposing crystals are nearly iron black, with a faint tinge of purple. Fracture uneven. Hardness 5·5 to 6·0. Brittle. Lustre metallic-pearly on the cleavage surface; of other surfaces, vitreous or subvitreous, often nearly dull. Specific gravity 3·0 to 3·29. Found near Amity and Edenville, in the State of New York. Analysis, by Shephard: Titanium, 64·71; iron, 2·14; yttrium, 0·80; fluorino, 27·33.

Washingtonite (*Ilmenite*). [Titanium, *Ores of*, P.C.]

Websterite [*Aluminite*, P. C. S.]

Weissite occurs in oblique rhombic prisms. Colour ash-grey or brownish. Presents only feeble traces of cleavage. Fracture even or coarse granular. Hardness, scratches glass, but is scratched by steel. Lustre pearly or hazy. Scarcely translucent. Specific gravity 2·80. Found at Fahlun, Sweden. Analysis, by Wachtmeister: Silica, 53·69; alumina, 21·70; magnesia, 8·99; protoxide of iron, 1·43; protoxide of manganese, 0·63; potash, 4·10; soda, 0·68; oxide of zinc, 0·3; water, with a little ammonia, 3·20.

Wernerite. [Scapolite, P. C.]

Wichtine. Cleavage parallel to the sides of a rectangular prism. Scratches glass. Colour black. Fracture flat conchoidal. Found at Wichty in Finland. Analysis, by Laurent: Silica, 56·3; alumina, 13·3; protoxide of iron, 13·0; peroxide of iron, 4·0; soda, 3·5; lime, 6·0; magnesia, 3·0.

Willemite (*Anhydrous Silicate of Zinc*). [Zinc, *Ores of*, P. C.]

Wöhlerite occurs in angular grains, and in tabular crystals; form undetermined. Cleavage distinct in one direction. Colour light yellow, wine-yellow, honey-yellow, brownish yellow. Streak yellowish white. Fracture more or less conchoidal, splintery. Hardness 5·5. Lustre vitreous. Subtranslucent. Transparent. Specific gravity 3·41. Found in an island near Brevig in Norway. Analysis, by Scheerer: Silica, 30·62; columbic acid, 14·47; zirconia, 15·17; lime, 26·19; soda, 7·78; oxide of iron, 2·12; protoxide of manganese, 1·55; magnesia, 0·40; water, 0·24.

Worthite occurs in rolled masses, having a foliated crystalline structure, and sometimes presenting very small apparently 4-sided prisms or plates. Colour white. Hardness 8·5. Lustre vitreous. Translucent. Specific gravity, 3·1. Found near St. Petersburg, and on the shores of the Bay of Finland. Analysis, by Dr. Hess: Silica, 40·79; alumina, 53·06; magnesia, 0·88; water, 4·63.

Xenotime occurs crystallized. Primary form a right square prism. Cleavage lateral, perfect. Colour yellowish brown. Streak pale brown. Fracture uneven and splintery. Hardness 4·25 to 5·0. Lustre resinous. Opaque. Found at Lindesnaes in Norway. Analysis, by Berzelius: Phosphorio acid, 33·49; yttria, 62·58; subphosphate of iron, 3·93.

Yellow Copper-Ore (*Copper Pyrites*) occurs crystallized and massive. Primary form a square prism. Common form a tetrahedron. Fracture conchoidal. Colour brass yellow, frequently with a violet and purple tarnish on the surface. Streak greenish black. Lustre metallic. Hardness 3·5 to 4·0. Specific gravity 4·17. Found plentifully in Cornwall, and in most copper-mines. Analysis, by Rose: Copper, 33·12; iron, 30; sulphur, 36·52.

Yttrocerite. [Yttrium, P. C.]

Yttrotantalite. [Yttrium, P. C.]

Zeagonite [Phillipsite, P. C.]

Zoisite. [Epidote, P. C.]

Zurlite occurs crystallized and massive. Primary form a cube or square prism. Cleavage indistinct. Colour asparagus-green, inclining to grey. Fracture conchoidal. Hardness about 6·0. Lustre resinous. Opaque. Specific gravity 3·27. Found on Vesuvius.

MINES. Mines are properly openings in the ground from which any thing is dug. Until an opening is made, the name is not properly applied, though the term is now generally used to signify coal, lead, iron and so forth, before an opening is made for digging them out.

Mines belong to the tenant in fee-simple of the land, with the exception of gold and silver mines, which belong to the king by his prerogative, but by 1 W. & M. c. 30, a mine of copper or tin is not to be considered a royal mine, though silver be extracted from the ore. The owner of land in fee-simple is the owner of everything which lies in a perpendicular direction under the surface to any depth. A tenant for life, unless his estate is without impeachment of waste, cannot dig earth, lime, clay or stone, except for the repair of buildings or the manuring of the land. In fact the general principle is that the land, which term comprehends everything in it or that is permanently attached to it, cannot be taken away by any other person than the tenant in fee-simple or a tenant in tail. Accordingly a tenant for life cannot open a new mine, but he may work mines which are already open, and he may open new shafts for working veins of coals which have been already worked. A tenant in tail has an estate of inheritance, and incident to it the power of committing waste, as by cutting down timber or opening mines.

If a man who has an estate in fee leases the land with the mines upon it, the lessee is thereby empowered to dig for the minerals; and if he leases lands on which mines are already open, the lessee may work them.

The freehold of all copyhold lands is vested in the lord, and it is a legal consequence that he has the freehold of the mines. In some cases a copyholder of inheritance has by the custom of the manor a right to the timber, and the lord has no right to dig mines, unless there be a custom which gives him the right.

If a man works mines under his own land and follows the ore or other substance under his neighbour's land, he is a trespassor.

The act 7 & 8 Geo. IV. c. 30, § 6, 7, enacts certain punishments for malicious injuries done to mines. [MALICIOUS INJURIES, P. C.]

A partnership for working a mine is subject to the same legal rules as any other partnership. [PARTNERSHIP, P. C.]

MIREVELT. [MIEREVELT, P. C. S.]

MITCHELL, THOMAS, was born on the 30th of May, 1783, in London, and was the son of a riding-master. At the age of seven he was admitted into Christ's Hospital, where he remained until the year 1802, when he went to Pembroke College, Cambridge, on one of the exhibitions of the Hospital. In 1806 he took his degree of B.A., and the distinguished manner in which he acquitted himself at college induced the governors of Christ's Hospital to present him with a handsome silver cup. He did not however obtain a fellowship, as he had hoped, for no more than two persons educated at the same school are allowed to hold fellowships in Pembroke College at the same time. This regulation, which was then made and carried into effect for the first time, deranged all Mitchell's schemes, who had determined to devote himself to philological pursuits. A few years afterwards however his acquirements as a scholar procured him a fellowship at Sidney Sussex College, Cambridge. Mitchell never married, and if he had taken holy orders he might have remained in the enjoyment of that fellowship for life, and would have been spared the cares and anxieties for a livelihood to which he was afterwards exposed. But he never took orders from a fear of the great responsibilities of the pastoral office, and consequently, after a limited number of years, he was obliged by the statutes of the college to vacate his fellowship. He afterwards earned his livelihood by private tuition and by writing for the press: he was engaged for ten years as tutor in private families. In 1813 he commenced a series of essays for the 'Quarterly Review' on Aristophanes and Athenian manners, and this led him to translate some of the plays of Aristophanes into English verse: his translation appeared in 2 vols. 8vo., 1820-22. His articles in the 'Quarterly Review' impressed the patrons of a vacant Greek chair in one of the Scotch universities with so much respect for his classical attainments, that they invited him to accept the situation; but as he would have had to sign the Confession of the Scotch Kirk, which was to him an insurmountable obstacle, he declined the lucrative office, notwithstanding his poverty. During the last twenty years of his life Mitchell lived with some of his relations in the county of Oxford, and occasionally superintended the publication of the Greek works which were from time to time printed at the Clarendon press. During the years 1834-38 he edited, in separate volumes, five of the plays of Aristophanes, with English notes; and in 1839 he began an edition of Sophocles, likewise with English notes; but after the first three tragedies had appeared, the publication was suspended in 1842, because English notes were thought objectionable; and Mitchell now had no other employment but what the Clarendon press might casually offer. The almost entire cessation of literary income not only caused him great pecuniary difficulties, but broke down his health and spirits. His friends became alarmed about him, and made his condition known to Sir Robert Peel, who immediately placed at his disposal the sum of 150*l*. from the royal bounty fund. In 1843 the publication of Sophocles was resumed, and the remaining four plays were likewise edited by Mitchell, though with briefer notes than the preceding three. In 1844 he undertook the publication of a minor edition of a 'Pentalogia Aristophanica,' with short Latin notes, and had nearly completed his task when he died suddenly, on the 6th of May, 1845, at his house at Steeple Aston near Woodstock. His health had long been in a weak state, but his death was unexpected.

The works which Mitchell edited and commented upon contain evidence that he was a Greek scholar of considerable eminence; but his notes are often irrelevant, and the text of his author is seized upon to furnish opportunities of showing his strong political opinions: he had a passionate antipathy to the Athenian democracy and democratical forms of government in general.

(*Classical Museum*, vol. iii. p. 213, &c.)

MITE. [ACARUS, P. C.]

MITFORD, WILLIAM, the eldest son of John Mitford, Esq., of Exbury in Hampshire, was born in London on the 10th of February, 1744. In his boyhood he spent some time at the school kept at Cheam in Surrey by the well-known Mr. Gilpin, who afterwards owed to him the living of Boldre. Ill health caused his removal from school about the age of fifteen; and it seems to have been with very insufficient preparation that he became a student of Queen's College, Oxford. His time at the university was idly spent; and he left it without taking a degree. Perhaps the most important influence exercised on his mind by his academical residence was derived from the Vinerian lectures of Blackstone, which he attended regularly. He studied law for a time in the Middle Temple, but found the study distasteful; and, having succeeded to the family estate in 1761, on his father's death, he abandoned the profession to his younger brother, who afterwards became Lord Redesdale. In 1766 Mr. Mitford married; and for seven years afterwards his time was chiefly spent in the retirement of his country-seat, where his early predilection for the Greek language and literature grew into a settled passion. In 1769 he became a captain in the South Hampshire militia, of which the historian Gibbon was then major; and the conversation and advice of Gibbon confirmed, if they did not prompt, his resolution to undertake a history of Greece. His first work, 'An Inquiry into the Principles of Harmony in Languages, and of the Mechanism of Verse, Modern and Ancient,' appeared in 1774, and was reprinted in 1804. In this early part of his life, too, he published 'A Treatise on the Military Force, and particularly the Militia, of this Kingdom.' In 1776 he lost his wife, and was himself seized with a dangerous illness, on his recovery from which he left England to spend the winter at Nice. Before leaving home he had become acquainted with the French scholars Villoison and De Meusnier: the former introduced him to the Baron de Sainte Croix; and his intercourse with these young and ardent students matured his own literary ambition. On his return home, however, he allowed public duties to claim frequent precedence. He acted as a county magistrate, and in 1778 was appointed Verdurer of the New Forest. He retained his commission in the militia, succeeded to Gibbon's lieutenant-coloneley in 1779, and in 1805 was appointed to the coloneley, which he resigned in the course of the next year. From 1785 till 1790 he sat in the House of Commons as member for Newport in Cornwall; from 1796 till 1806 he represented Beeralston, a nomination borough of his maternal kinsman the Duke of Northumberland; and from 1812 till 1818 he was member for New Romney. His parliamentary appearances were chiefly confined to two or three speeches on the militia laws. In 1802 he succeeded, through his mother, to the Revely estates in Yorkshire. But his paternal estate on the borders of the New Forest continued to be his country residence. He died there on the 8th of February, 1827.

His 'History of Greece' was written and published in successive portions, the dates of the first edition, in quarto, being the following: vol. i., 1784 (second edition, 1789); vol. ii., 1790; vol. iii., 1797; vol. iv., 1808; and vol. v., 1818. It closes with the death of Alexander the Great; and the author, enfeebled by age and partly blind, was unable to execute his intention of continuing it to the subjugation of Greece by the Romans. In 1815 appeared an octavo edition of the volumes which had previously been published; and in 1829 there appeared a new edition of the whole work, in eight octavo volumes (since reprinted), with an introduction by his brother, Lord Redesdale, furnishing some particulars of the author's life, but chiefly taken up in vindicating the political opinions expressed in tho work. These opinions have exposed Mr. Mitford's History to much animadversion. He is determinedly anti-democratic; and this turn of thinking affects seriously the fairness of the estimate which he forms both of characters and of events. His partisanship is especially palpable in his account of the war between the Greeks and Philip of Macedon. Philip is with him a perfect king, hero, and statesman. Demosthenes is a dishonest and malignant demagogue, and the Athenians are a horde of treacherous miscreants. Yet tho author's research and perspicacity have thrown much light upon this as well as upon other parts of Grecian history. He has elucidated with remarkable success the state of political parties in some of the severest struggles of Greek politics; and he has suggested new and more accurate views of many particular events. He has been led to these results mainly by his severely critical way of estimating the antient authorities, and by his systematic endeavour to gain his knowledge from cortemporary sources. Accordingly his history will always be valuable to the classical student, notwithstanding the bias above noticed, and in spite also of its deficiency both in philosophical reflection and in animation of narrative. In style indeed the work is exceedingly faulty; and the few corrections made in the last edition have removed only the least of the technical faults, the perverse affectation of the orthography. A treatise on the religions of Antient Greece and Rome, which he published late in life, in a small octavo volume, was regarded by him as a supplement to his History, and would probably have formed a part of it had he been able to complete his original design.

MODELLING. Modelling in clay is so completely a practical art, and depends so much on the experience and formative skill of the modeller, that beyond a few remarks on the necessary consistency of the clay, nothing more can be given here than an account of the nature and uses of the tools, and some description of the sculptor's process.

The tools, called modelling tools, are made of wood and wire, but no tool is more useful than the finger; indeed tools have been invented as mere aids to the fingers, and are designed only to do what they cannot perform. Wire tools are the most useful, being fashioned into loups of various shapes and sizes, round and angular, and fixed into wooden handles. They accomplish any required form without driving the clay on to any already modelled part, the superfluous clay remaining in its place while the wire passes under it and until the tool is removed, when it either falls of its own weight, or is removed by the slightest touch of the modeller. The wire tools are most efficient when applied to concave surfaces, especially those in the close or narrow folds of draperies: the wire is sometimes notched or indented, to give a rough surface to the clay. The wooden tools are made of box and ebony, of various shapes and sizes—curved, straight, pointed, rounded, and flat and broad; the broad tools being notched, and designed chiefly for working the large convex masses, or large folds in drapery. In modelling a bust, especially the features, great nicety is required, and the modeller must be particularly careful not to injure what is already done, by retouching with the tool while clay is adhering to it, or he may risk the complete destruction of his work: the adhering clay will drive up the surface. A good method to guard against this accident is to keep the wooden tools which are used for the finer work soaked in oil; the clay is then not liable to adhere, and much time is accordingly saved in finishing the model. The above is perhaps, without practical demonstration, all that can be usefully said about the working tools.

The clay used is common potters' clay, but should be of the best quality. It must be so wet that it will not stand in a mass much higher than its own width without support. The clay adheres much more to the tools when wet, but it is at the same time much more easily and quickly worked, a matter of great consequence, as the patience of the artist is less tried, and some expenditure of time is saved. The supports for the clay are a most important consideration, for if not properly attended to, the finished work, the fruits of months of labour, might suddenly fall to pieces by its own weight. This accident happened to Don José Alvarez, a celebrated Spanish sculptor, while at Paris. He modelled, about the year 1805, a colossal statue of Achilles receiving the fatal arrow into his heel, which, owing to the insufficient support of the clay, fell to pieces shortly after it was finished: it was much admired by the connoisseurs of Paris, but Alvarez had not courage, or wanted opportunity, to restore it. This accident might certainly have been prevented by proper attention to the supports of the clay while the model was in progress, for though in large models this is a work of great care and labour, it is always practicable. The support of a figure of the heroic or ordinary size (seven feet) is comparatively easy, but this also exacts strict attention, especially if in any very active or unusual attitude. Sculptors generally model figures of the ordinary size upon a bench or stand called a banker, about thirty inches high, and about thirty inches square,—for a bust it must of course be much higher; above this a solid circular plinth is fixed on a wooden box, and is revolved upon six or more wheels, or what are better, short slightly conical rollers, fixed to the plinth near the circumference: the plinth moves more easily on such rollers than wheels, and the rollers afford a more solid support and last longer. A revolving plinth is necessary to enable the sculptor to see his work on all sides in any light, and it enables him to work on all parts, in one spot, or in the same light. On the centre of the plinth there must be fixed vertically a strong iron bar, about the height of a man, and from about six to ten inches in circumference, according to the weight of the figure; it must necessarily be strong and firmly fixed, as it is the main support of the whole skeleton of supports. In loosely draped figures, which are proportionally heavy, it is advisable to fix a vertical beam of wood to the main iron bar; for though the bar will keep the clay perpendicularly in its place, it is no provision against the sinking of a great mass; and the quantity used in some figures, even of the heroic size only, amounts to about two tons. Two cross pieces of wood must be fixed to the main bar at the shoulders and the loins, from which the supports of the arms and legs must be started; and a third piece may be fixed in the middle to diminish the weight of clay: the supports of the legs must be bars, straight or bent, according to the position of the legs; but the supports of the arms, when not detached from the body or drapery, may generally be made of twisted thick copper wire, small pieces of wood being twisted in with it at short intervals and at right angles, like the pieces of paper in the tail of a boy's kite. The fingers, if separated, will require similar care; indeed the clay should be gradually built up against a complete skeleton of supports, and sufficiently strong not to yield in the least to the weight of the clay when the model is finished. The building of such a skeleton for a figure of the heroic size is often the work of a week or more, and it would be always advisable for the young sculptor, in modelling his first figure, to procure some experienced hand to construct his skeleton of supports for him. If an arm is slightly elevated, and detached from the figure, the support might be so contrived as to allow the arm to be removed at pleasure, which would enable the sculptor to model the part beneath it with much greater ease, and would considerably diminish the risk of injury to the arm. The contrivance is easily accomplished, for nothing more is required than a pipe or tube in the shoulder support, which could receive and hold firmly the skeleton support of the arm, which might be a bar of wood or of metal; or merely thick or twisted wire, when of a small size. In modelling a bust very little support is necessary, an upright piece of wood with a cross bar at the shoulders being quite sufficient; but a small cross bar at the head would do no harm.

Another essential part of modelling is preserving the moisture of the clay, which should be always uniform if possible; it must never be allowed to dry, and it can be kept moist with very little trouble. While the modeller is at work, and the figure is exposed, especially in warm weather, he should repeatedly sprinkle it with water. A plasterer's brush is the best instrument for this purpose, and much superior to a syringe or the mouth, which some sculptors formerly used to apply as a squirt, even in the presence of their sitter, when modelling a bust: Nollekens, according to his biographer Smith, adopted this elegant method of keeping his clay moist while modelling the bust of George III., and in the king's presence. Bacon, on a similar occasion, used a silver syringe. At night time, or when the artist is not at work on the model, it should be covered over with a wet cloth or sheet. A figure may be kept moist for a long period without adding water, provided the air be kept away from it; this may be done by an oil-silk or any air-proof bag, which can be made fast to the plinth of the banker by clay. Sculptors generally model flowing draperies from lay-figures. When the model is complete, the next process is to take the cast, to work the marble from, or to make other casts from. The whole model, while wet, must be covered, in two or three masses, or more if necessary, with plaster of Paris; when this is fixed and dry, the whole may be separated at the joints, without any regard to the preservation of the model, for when the mould is taken the model is no longer of any value. When the clay is completely removed from the mould, the component parts of the mould must be again put together, and in the place of the original clay it must be filled with plaster of Paris, and when the cast is well set, the mould may be carefully broken off in fragments, and the cast is exposed, and complete, the finished work. If casts of it are required, a new working mould, or *safe mould*, as it is termed, must be taken, in many parts; and if the figure is to be executed in marble, it is copied by the carvers, with the assistance of the pointing-machine, of which the most complete is that invented and used by W. C. Marshall, A.R.A. It is so contrived that it can diminish or increase the scale of the model with perfect ease and nicety. It is always best to make the model of the size of the intended figure if practicable, because any error in a small model becomes multiplied in a larger one in proportion to the difference of size. Flaxman was in the habit of making small models, and he had in consequence sometimes immense labour to go through to diminish errors in the full-sized marble work: it is hardly possible to completely rectify them.

The antient sculptors used to bake their models, but this is not so good a plan as making plaster casts from them, though less troublesome and much cheaper: the clay in drying shrinks, and is apt to crack, and certainly never comes out of the oven the same shape that it was when put into it, or at least when originally modelled. These baked models are called terra-cotta (*baked earth*) figures, are extremely numerous, and are generally of small dimensions, but there are a few of a large size in various European museums. There are four at Naples which were found at Pompeii; and the inferiority of these works is some proof of the advantage of the modern method of taking plaster casts from the models over the antient system of baking them, for the errors in the proportions of these works are probably to a great extent due to the shrinking of the clay in the oven. The antients made also moulds of clay, which they likewise baked, and they formed their casts by the pressure of clay into these: this practice of pressing clay, or any malleable substance, into a mould is still occasionally had recourse to in works of fine art, and constantly in the potteries, and by frame-makers.

The antients used also wax for casting and in forming their models, especially those of the small bronzes, which are still so exceedingly numerous, and it is the common material used by goldsmiths and medalists. Modelling wax is prepared by melting virgin wax with a very small quantity of Venice turpentine and flake-white in fine powder: if coloured wax is required, a colour in fine powder must be substituted for the flake-white. The tools used in modelling in wax are made of wood and ivory, and have the same shapes as those of wood, already spoken of, for modelling in clay. Other processes in the art of sculpture will be found explained in the articles BRONZE; FOUNDING; SCULPTURE, P. C.; and WAX MODELLING, P. C. S.

MO'DENA or MU'TINA, TOMMA'SO DA, a painter of Modena, of the fourteenth century, who has been claimed by some German writers, without any better foundation than the possession of some of his works, for Bohemia. He appears to have been at Prague in the time of the Emperor Charles IV., who was a patron of the arts, but it is also quite possible that the emperor bespoke the works in his possession of the painter at Modena. The name of Tommaso da Modena is of more importance than it otherwise would have been on account of various pretensions which his works have given rise to. The altar-piece, in three compartments, of the Virgin and Child, with Saints Wenceslas and Palmatius, patrons of Bohemia, formerly at Carlstein, but now in the gallery of the Belvedere at Vienna, was said to be an oil painting, and, in Von Mechel's catalogue, to have been painted in 1297; it was therefore eagerly caught at by writers of Germany and Italy, to confute Vasari, to vindicate the title of their respective countries in opposition to the Flemish claim. This picture however bears no date, and more recent chemical analysis has shown that it is a *tempera*, and not an oil painting. The figures are half-length, about half the size of life, and are painted upon a gold ground; and the picture bears the following inscription:—

Quis opus hoc finxit? Thomas de Mutina pinxit,
Quale vides lector Barisini filius auctor.

Von Mechel read Rarisini, but some documents mentioned by Federici, Tiraboschi, and Lanzi show that Barisini should be the reading; Barisino being the name of Tommaso's father, and his own full name accordingly Tommaso di Barisino da Modena.

There is an extensive work, a series of many portraits, in the chapter-house of the Dominicans at Trevigi, which Fra Federici, a Dominican, has had engraved for his account of the antiquities of Trevigi—'Memorie Trevigiane su le Opere di Disegno.' They were painted in 1352, and are accompanied by the following inscription:—Anno Domini MCCCLII. Prior Travisinus ordinis prædicatorum depingi fecit istud Capitulum, et Thomas Pictor de Mutina pinxit istud. These works are completely in the style of their time, but rather above the standard than otherwise.

MODESTI'NUS, HERENNIUS, a Roman classical jurist, was apparently a pupil of Ulpianus. He lived under the Emperor Alexander Severus, and was one of his legal advisers (consiliarii); he also taught law to the younger Maximinus (Jul. Capitol., *Maximin. Jun.* 1). Modestinus often cites Ulpianus and Paulus. The Florentine Index enumerates the following works of Modestinus: nineteen books of Responsa, twelve books of Pandects, ten books of Regulae, nine books of Differentiae, six books of Excusationes, four books on Poenae. The work on Excusationes was written in Greek (*Dig.* 27, tit. 1, *De Excusationibus*). Nine other works by Modestinus, in single books, are enumerated in the Florentine Index.

The period of Modestinus is also determined by an inscription, which contains the judgment in a suit which was prosecuted some time between A.D. 227 and 245. The inscription was first printed by Fabretti, in his work on Inscriptions (p. 278). Modestinus is mentioned in a rescript, of the year A.D. 239, of the Emperor Gordianus. There are 345 excerpts from Modestinus in the Digest.

The compilers of the Digest have made a few excerpts from two writers posterior to Modestinus. These writers are Hermogenianus and Aurelius Arcadius Charisius. Modestinus is cited by Charisius (*Digest*, 50, tit. 4, s. 18).

MODUS. [TITHES, P. C.]

MOEHRINGIA, a genus of plants named after Paul Henry Gerard Moehring, a German physician, author of 'Hortus Proprius,' and other works. This genus belongs to the natural order Caryophylleæ, and has 5 sepals, 4 or 5 petals, either entire or slightly emarginate; 8 to 10 stamens, 2 or 3 styles, the capsule opening with 4 or 6 valves; the seeds numerous, with an appendage at the hilum. The species are alpine plants with the habit of Arenaria.

M. trinervia has ovate acute stalked 3-5-nerved leaves, the upper ones sessile, the petals shorter than the calyx, the sepals lanceolate acute 3-ribbed; the intermediate rib stronger and rough. This plant was formerly referred to Arenaria, but it may be distinguished from that genus by the appendage to the hilum of the seed. This plant is found in damp shady places, and is a native of Great Britain. Four other species of this genus are described by Koch in his 'Flora Germanica;' —*M. muscosa*, *M. prona*, *M. polygonoides*, and *M. villosa*.

The species are alpine plants, and adapted for cultivation on rockwork or in small pots. They may be propagated by dividing them at the root. They are best grown in pots, in a mixture of sand, loam, and peat.

(Babington, *Manual*; Don, *Gardener's Dictionary*.)

MOENCHIA, a genus of plants named after Conrad Moench, professor of botany at Marburg, who wrote several works on botany; amongst others, 'Enumeratio Plantarum Indigenarum Hassiæ, præsertim inferioris,' Cassel, 1777, 8vo.; also a work on the cultivation of North American forest-trees in Germany.

The genius Moenchia belongs to the natural order Caryophylleæ, and has 4 erect sepals, 4 entire petals, 4 stamens, a many-seeded capsule opening at the end with 8 teeth.

M. erecta is the only British species. It is a small glaucous plant growing in dry gravelly and sandy places.

(Babington, *Manual*.)

MOITTE, JEAN GUILLAUME, Chevalier, the son of the engraver P. E. Moitte, was a distinguished French sculptor, and was born at Paris, in 1747. He was first the pupil of Pigal, after whose death he studied under Lemoyne. In 1768 he obtained the grand prize in sculpture for a statue of David carrying the head of Goliath, and he went, as entitled in consequence, to complete his studies at the French Academy at Rome; the Roman climate however proved quite unfit for his constitution, and he was forced to return to Paris.

Moitte has executed many excellent bas-reliefs and figures, and some equestrian statues; but he left many models, and among them his principal works, unfinished at his death, as the great bassi-rilievi for the column of Boulogne, and the equestrian statue of General d'Hautpoul, a model in plaster, made for the French government. Moitte was a member of the old French Academy of Painting and Sculpture, and afterwards of the Institute of France, and a Chevalier of the Legion d'Honneur. He died in 1810.

The following are some of his principal works:—A marble statue of Cassini; another of General Custines; a basso-rilievo for the tomb of General Leclerc in the Pantheon; a Vestal sprinkling the holy water; Ariadne; a sacrificer; the large basso-rilievo of the front of the Pantheon, representing the Father-land, or La Patrie, crowning civic and military virtues, which was removed after the Restoration; a basso-rilievo in the court of the Louvre, representing History inscribing l'An VI. and the name of Napoleon with his French title of Le Grand; other bassi-rilievi for the barriers of Paris, and the Château de l'Ile Adam, and the colossal figures of Bretagne and Normandie at the barrier des Bons Hommes; an equestrian statue of Napoleon; and the basso-rilievo of the warrior devoting himself to his country, or France surrounded by virtues and calling her sons to her defence, now in the gallery of the Luxembourg: it was ordered in 1798 for the vestibule of the Luxembourg facing the garden.

(Gabet, *Dictionnaire des Artistes de l'Ecole Française*, &c.)

MOLI'NIA, a genus of grasses belonging to the tribe Festucineæ. It has unequal glumes without lateral ribs, shorter than the lanceolate spikelet of 2 or 3 semicylindrical flowers and a subulate rudiment of another. The paleæ hardening on the loose fruit, and the styles terminal. There is one species which is British—

M. cærulea, which has an erect elongate narrow panicle, spikelets from 1- to 3-flowered; the outer palea 3- rarely 5-nerved, downless, the upper part of the stem naked. The leaves are long, linear, and alternated. It grows on wet heaths in alpine situations. This species is the *M. depauperata* of Lindley.

(Babington, *Manual of British Botany.*)

MOLYN, PIETER. [TEMPESTA, P. C.]

MONCALVO. [CACCIA, GUGLIELMO, P. C. S.]

MONCREIFF, SIR HENRY, a divine, and ecclesiastical leader in the church of Scotland, was born at Blackford, in Perthshire, on the 6th of February, 1750. His father Sir William Moncreiff, though a cadet of the family, succeeded to the baronetcy by the failure of the elder line, when he was minister of Blackford, in 1744. Sir Henry was the sixth of his family that had belonged to the clerical profession. He studied at Glasgow and Edinburgh, and was ordained a minister on the 15th of August, 1771. Though he was probably the only man of rank who ministered in the church of Scotland, he was as strongly imbued with the spirit of the Presbyterian policy as those, by far the most numerous class in that church, whom the profession was the means of raising from the more humble grades of society. He had a commanding appearance, was gifted with a powerful argumentative oratory, and was zealous and learned. With such advantages, personal and social, he naturally occupied the first rank in the church. He was for some time his father's successor as minister of Blackford, and in 1775 he was appointed to the charge of St. Cuthbert's, in Edinburgh, where he remained till his death on the 14th of June, 1827. He was frequently moderator of the General Assembly, and his name was conspicuous in nearly all the ecclesiastical discussions connected with the church of Scotland during his ministry in Edinburgh. He was the author of many pamphlets connected with these questions. In 1815 he published 'Discourses on the Evidence of the Jewish and Christian Revelations, with Notes and Illustrations,' and in 1818 an 'Account of the Life and Writings of Dr. John Erskine.' [ERSKINE, JOHN, P. C. S.] His Sermons, of which there had been some separate publications during his life, were collectively published after his death (1829-1831) in three volumes 8vo., with a short memoir of the author, by his son Lord Moncreiff.

MONESES (from μόνος, sole, or alone), a genus of plants belonging to the natural order Ericaceæ and the tribe Pyroleæ. It has a 5-toothed calyx; 5-lobed corolla; 10 inclined stamens; the anthers dehiscing at the base by two holes, the cells elongated and tubular; the stigma 5-toothed; the capsule 5-celled; the valves dehiscing from the apex, destitute of tomentum. There is but one species of this genus, *M. grandiflora*. It has a creeping root; large solitary terminal drooping open white flowers, nearly an inch broad; very large stigmas. It is a native of Europe, Asia, and North America, in Alpine mossy woods. It is found in Great Britain, in the mountainous woods of Scotland. It may be cultivated in the same manner as the species of Pyrola. [WINTER-GREEN, P. C.]

MONEY is the medium of exchange by which the value of commodities is estimated, and is at once the representative and equivalent of such value.

Barter is naturally the first form in which any commerce is carried on. A man having produced or obtained more of any article than he requires for his own use, exchanges a part of it for some other article which he desires to possess. But this simple form of exchange is adapted to a rude state of society only, where the objects of exchange are not numerous, and where their value has not been ascertained with precision. As soon as the relations of civilized life are established in a community, some medium of exchange becomes necessary. Objects of every variety are bought and sold, the production of which requires various amounts of labour; these at different times are relatively abundant or scarce; labour is bargained for as well as its products: and at length the exchangeable value of things, in relation to each other, becomes defined, and needs some common standard or measure by which it may be expressed or known. It is not sufficient to know that a given quantity of corn will exchange for a given quantity of a man's labour, for their relative value is not always the same; but if a standard is established by which each can be measured, their relative value can always be ascertained as well as their positive value, independently of each other.

As a measure of value only money is thus a most important auxiliary of commerce. One commodity from its nature must be measured by its weight, another by its length, a third by its cubic contents, others by their number. The diversity of their nature, therefore, makes it impossible to apply one description of measure to their several quantities; but the value of each may be measured by one standard common to all. Until such a standard has been agreed upon, the difficulties of any extensive commerce are incalculable. One man may have nothing but corn to offer for other commodities, the owners of which may not have ascertained the quantity of corn which would be equivalent for their respective goods. To effect an exchange these parties would either have to guess what quantity of each kind of goods might justly be exchanged for one another, or would be guided by their own experience in their particular trades. Whenever they wanted a new commodity their experience would fail them, and they must guess once more. But with money all becomes easy; each man affixes a price to his own commodities, and even if barter should continue to be the form in which exchanges are effected, every bargain could be made with the utmost simplicity: for commodities of every description would have a denomination of value affixed to them, common to all and understood by everybody.

But however great may be the importance of money as a measure of value in facilitating the exchange of commodities, it is infinitely more important in another character. In order to exchange his goods it is not sufficient that a man should be able to measure their value, but he must also be able to find others who, having a different description of goods to offer as an equivalent, are willing to accept his goods in exchange, in such quantities as he wishes to dispose of. Not to enlarge upon the obvious difficulties of barter:—suppose one man to have nothing but corn to sell, and another nothing but bricks: how can any exchange be effected unless each should happen to require the other's goods? But presuming that this is actually the case, is it probable that each will require as much of the other as will be an exact equivalent; or in other words, as much as represents an equal amount of labour? Such a coincidence might occur once or twice, but it is not conceivable that it should occur often. Corn is consumed annually: but bricks once produced endure for many years; and their interchange between two persons in equal proportions, for any length of time, would therefore be extremely inconvenient. In order to dispose of his corn, the producer might buy the bricks and dispose of them to others; but in that case, in addition to the business of growing corn he must become a seller of bricks. But human labour has a natural tendency to a division of employments; and as society advances in wealth and in the arts of life, men confine themselves more and more to distinct occupations, instead of practising many at the same time. [DIVISION OF EMPLOYMENTS, P. C. S.] With this tendency a system of simple barter is obviously inconsistent; as by the one, a man is led to apply the whole of his labour to one business: by the other, he is drawn into many. By the one he has only to produce and sell; by the other he must also buy what he does not want himself, and become a trader.

But all these difficulties are removed if some one commodity can be discovered which represents a certain amount of labour, and which all persons agree to accept as an equivalent for the products of their own industry. If such a commodity be found, it is no longer necessary for men to exchange their goods directly with each other; they have a medium of exchange, which they can obtain for their own goods, and with which they can purchase the goods of others. This medium, whatever it may be, is Money.

When money has assumed the character of a medium of exchange and equivalent of value, the cumbrous mechanism of barter gives place to commerce. But what must be the qualities of an article which all men are willing to accept for the products of their own labour? It is now no longer like a weight or measure, the mere instrument for assessing the value of commodities; but, to use the words of Locke, 'it is the thing bargained for as well as the measure of the bargain.' A bargain is complete when money has been paid for goods; it has no reference to the price of other goods, nor to any circumstance whatever. One party parts with his goods, the other pays his money as an absolute equivalent. But though money as a medium of exchange thus differs from money as a mere standard of value yet in both characters it should possess, if it be possible, one quality above all others—an invariable equality of value at all times and under all circumstances. As a measure of value it is essential that it should always be the same, as that a yard should always be of the same length. And unless, as a medium of exchange, its value be always the same, all bargains are disturbed. He who gives his labour or his goods to another in exchange for a delusive denomination of value instead of for a full equivalent which he expects to receive, is as much defrauded as one who should bargain for a yard of cloth and receive short measure.

But however desirable may be the invariableness of money, complete uniformity of value is an impossibility. There is no such thing as absolute value. All descriptions of measures correspond with absolute qualities, such as length, weight, and number, and may be invariable. But as value is a relative and not an absolute quality, it can have no invariable measure or constant representative. The value of all commodities is continually changing; some more and some less than others. Their real value depends upon the quantity of labour expended upon them; but temporary variations in their exchangeable value are caused by abundance or scarcity —by the relations which subsist between supply and demand. No commodity yet discovered is exempt from the laws which affect all others. If precisely the same quantity of labour were required for a long series of years to produce equal quantities of any commodity, its real value would remain unchanged; but if it were at the same time an object of demand amongst men, variations in the proportion between its supply and the demand for it would affect its exchangeable value. It follows therefore, that to be an invariable standard, money must always be produced by the same amount of labour, and in such quantities as shall constantly bear the same proportion to the demand for it.

But even if any description of money could be invented which possessed these extraordinary qualities, the value of all other articles would still be variable, and thus its representative character would be disturbed. At one time, for example, a given denomination of money will represent a certain number of bushels of wheat; at another time, the same money, unchanged in real value or in demand, will represent a much greater number. Every application of machinery, every addition to the skill and experience of mankind, facilitates production, and by saving labour reduces the real value of commodities. Their value is also liable to temporary depreciation from other causes, from too abundant a supply, or from an insufficient demand. But if money maintain the same value, in relation to itself, notwithstanding the diminished value of other articles, its proportionate value is practically increasing. The consequences of a growing disproportion between the representative value of money and the value of commodities are these: 1st, a producer has to give a larger quantity of his goods than before for the same amount of money; 2ndly, those who are entitled to payments in money, receive the value of a greater quantity of commodities than they would have received if the relative value of money and of commodities had not been disturbed. It follows from these circumstances, that, as a general rule, all creditors whose debts have been calculated in money derive advantage from any increase in its value relatively to commodities; while debtors derive benefit from any circumstance which raises the value of commodities as compared with that of money, whether it be by increasing the value of the former, or by depreciating the value of the latter. To make these principles intelligible the following example may not be superfluous: Suppose a farmer to hold land under a lease for twenty-one years at a money rent; and that from any cause the value of agricultural produce is no longer represented by money in the same manner as when the arrangement was entered into with his landlord, but that the value of money has been relatively increased. In order to pay his rent, he must now sell a larger proportion of his produce, even though its production may have cost him as much as ever. On the other hand, his landlord receives the same money rent, but is able to purchase more commodities than before on account of the increased comparative value of money.

Thus far we have thought it convenient to confine ourselves to the abstract qualities and uses of money, and to explain such general principles only as are introductory to the consideration of particular kinds of money, and of the modes of using and regulating them.

In all ages of the world, and in nearly all countries, metals seem to have been used, as it were by common consent, to serve the purposes of money. It is true that other articles have also been used, and still are used, such as paper in highly civilized countries, and cowrie shells in the less civilized parts of Africa; but in all some portion of the currency has been and is composed of metals. We read of metals amongst the Jews, the Chinese, the Egyptians, the Persians, the Greeks, the Romans. In the earliest annals of commerce they are spoken of as objects of value and of exchange; and wherever commerce is carried on they are still used as money. But as they were introduced for this purpose in very remote times, it is not probable that they were selected because their value was supposed to be less variable than that of other commodities. More than two thousand years ago, indeed, Aristotle saw clearly (but what did he not see clearly?*) that the principal use of metallic money was that its value was less fluctuating than that of most other substances (*Ethic. Nicom.* v. 5). But however clearly this great philosopher may have observed the true character of money, many ages after the circulation of metals, those who first used them were men engaged in common barter, who considered their own convenience and security without reference to any general objects of public utility. They must have used metals not as a standard of value, but as an article of exchange, which facilitated their barter. All metals are of great utility and have always been sought with eagerness for various purposes of use and ornament: but gold and silver are especially objects of desire. Their comparative scarcity, the difficulty and labour of procuring them, their extraordinary beauty, their singular purity, their adaptation to purposes of art, of luxury, and display; their durability and compactness; must all have contributed to render them most suitable objects of exchange. They were easily conveyed from place to place; a small quantity would obtain large supplies of other articles; they were certain to find a market; none would refuse to accept articles in payment which they could immediately transfer to others: and thus gold and silver naturally became articles of commerce, readily exchangeable for all other articles, before they were circulated as money, and were acknowledged as such by law and custom.

The transition of the precious metals from the condition of mere articles of exchange, amongst many others, to that of a recognised standard of value by which the worth of all other articles was estimated, was very natural. Merchants carrying their wares to a distant market would soon find it necessary to calculate the quantity of gold and silver which they could obtain, rather than the uncertain quantities and bulk of other commodities. They would not know what articles it would be prudent to buy until they reached the market and examined their quality and prices: but a little experience would enable them to predict the quantity of gold and silver which would be an equivalent for their own merchandise. Merchants from different parts of the world, meeting one another in the same markets, and finding the convenience of assessing the value of their goods in gold and silver, would begin to offer them for certain quantities of those metals, instead of engaging, more directly, in bartering one description of goods for another; and thus, by the ordinary course of trade, without any law or binding custom, the precious metals would become the measure of value and the medium of exchange.

But when gold and silver had attained this position in commerce, they were not the less objects of barter; nor were

* Many important principles of political economy, the discovery of which is attributed to Adam Smith and other modern writers, may be found in the works of Aristotle, expressed with wonderful precision and clearness. Mr. M'Culloch, for example, refers to Locke as the first who laid it down that labour is the source of value; but the same principle was affirmed by Aristotle in more than one part of his works, and more accurately than by Locke (*Ethic. Nicom.* v. 5). Again, he perceived, perhaps as distinctly as any other writer, the distinction between productive and unproductive labour (*Metaph.* ix. 8). As another example we would refer to his account of the origin of barter, its development into commerce, and the connexion of the latter with the use of money (*Pol.* i. 6). And, lastly, any economist must be struck with his clear perception of the relations between a division of employments and the exchange of the products of labour (*Ib.* ii. 2).

they distinguishable in character from any other articles of exchange. They were weighed, and being of the required fineness, a given weight was known as a denomination of value, but in the same manner only as the value of a bushel of wheat may be known. In the earliest ages gold and silver seem to have been universally exchanged in bars, and valued by weight and fineness only. The same custom exists at the present day in China. There is no silver coinage, 'but the smallest payments, if not made in the copper *tchen*, are effected by exchanging bits of silver, whose weight is ascertained by a little ivory balance on the principle of the steelyard.' (Davis's *China*, c. 22.)

Notwithstanding the ease with which gold and silver are divided into the smallest portions, each of which is of the same intrinsic purity and value as the others, the trouble of weighing each piece, and the difficulty of assaying it, render these metals in bars, or other unfashioned forms, extremely imperfect instruments of exchange, especially when they are used in small quantities. However accurately they may be weighed, it requires considerable skill and labour to assay them, which in small pieces would scarcely be repaid. Even in large quantities the difficulty of assaying their fineness, in countries which have made considerable advances in the arts, is greater than might be expected. The Chinese affect much accuracy in the art of assaying. The stamped ingots of silver in which their taxes are paid are required to contain ninety-eight parts in a hundred of pure silver, and two per cent. only of alloy; and strict regulations for maintaining this standard are rigidly enforced. Hence we should naturally infer that the attention of merchants and of all persons dealing in silver would be particularly directed to the most accurate assays. Yet at Canton an enormous trade in opium has for a long series of years been conducted entirely in sysee silver, which has been found to contain so large an admixture of gold that it bears a premium of five or six per cent. for exportation to England. (Davis's *China*, § 22.)

If the Chinese have been unable to discover the presence of gold, which it would be their interest to appropriate, how difficult must it be to detect alloys of baser metals in gold or silver circulated amongst a people in the ordinary course of trade. To obviate this difficulty coinage was introduced, by which portions of gold, silver, copper, and other metals have been impressed with distinctive marks, denoting their character, and have become current under certain denominations, according to their respective weight, fineness, and value. These coins have always been issued by the government of each country as a guarantee of their genuineness; and the counterfeiting of them has been punished as a serious offence against the state.

In rich countries these three metals of gold, silver, and copper are very convenient substances for the manufacture of coins, on account of the differences in their relative value. Gold coins, containing a high value in small compass, are convenient for large payments, silver coins for smaller payments, and copper coins for those of the lowest value; while all the larger coins are multiples of the smaller. These several descriptions of coin serve the ordinary purposes of trade sufficiently well: they are universally received as money within the country in which they circulate, and the principal part of all payments of moderate amount is made in them. But payments of large amounts cannot conveniently be made in coins of any metal; and in this and other countries paper money and various forms of credit have been used as substitutes. Of these we shall speak presently; but it will first be necessary to consider the suitableness of gold and silver coins as standards of value.

Coins made of these metals are not exempt from the laws which govern the prices of other commodities. They have accordingly varied in their own value in successive periods, and are at no time secure from variation. In the sixteenth century new mines of extraordinary richness were opened in America which were worked with such ease, and were so unusually productive, that the value of the precious metals, as representatives of so much labour expended in their production, was lowered all over Europe to about a third of their previous value. And thus a revolution, so to speak, was effected in the gold and silver coins of that period as standards of value. Similar causes have produced the same effect at other times, though not in the same degree; and we cannot be secured against their recurrence.

If the production of gold and silver be free, like that of other commodities, the only circumstance which can permanently diminish their value, in relation to themselves at different periods, is a reduction in the quantity of labour required for their production. But they are also liable to fluctuations in their value by reason of variations in the demand for them in particular countries. Though fashioned into coins, they retain all their properties as articles of commerce: they are readily fused into other forms, and rendered available for all purposes of use and ornament; and the occasions of commerce often withdraw them from one country and attract them elsewhere. From these causes their value, instead of being always the same, is liable to permanent alterations, and also to occasional fluctuation.

Both gold and silver are alike subject to these general laws, and are therefore imperfect standards of value. If one be the standard independently of the other, it is liable to change in itself, and also in its relation to other commodities: if both be adopted as standards at the same time, they will not only each vary in themselves, and in relation to other commodities, but they will vary also in regard to each other. And thus another element of uncertainty is introduced into the coinage, which becomes still more imperfect as a standard.

But it is not customary for the state to allow coins to fluctuate in their legal value according to the circumstances which determine the market prices of gold and silver. Coinage does not merely authenticate the weight and fineness of a piece of metal, leaving it to find its own level in exchange for other commodities; but it attaches to it a definite value, by fixing the standard price of the metal as well as the weight and fineness of the coin. The object of this regulation is to maintain a greater equality in the standard; and as regards small fluctuations in the value of the precious metals, it will generally have that effect. But if any considerable disproportion should arise between the standard price of bullion and the market price, no such regulation can prevent a practical change in the standard. If the market price should become considerably higher than the standard price, the coins would be melted down for the sake of the profit arising from the difference. If it should become considerably lower for any length of time, the value of the coins, though nominally unchanged, would in fact be depreciated; for they would exchange for a less quantity of other commodities than they exchanged for before. And thus a currency composed exclusively of metals cannot be made an accurate standard of value by any expedients of law.

We may here remark however, that a seignorage, or charge by government to cover the expenses of coinage, acts as a protection, within certain limits, against the melting of coins, because unless their value be depreciated by over-issue, the whole charge will be added to their value as coins, and will be lost when they are melted. For this amongst other reasons a seignorage should always be charged by the state.

There is yet another imperfection in coins as standards of value. Notwithstanding their natural durability, they are subject to continual wear, and must be gradually diminished in weight. They are also exposed to the fraudulent experiments of men whose trade it is to rob them of a portion of their weight by artificial wear. The value of coins is therefore certain to be continually depreciated by loss of weight, apart from any other causes of variation.

From all these circumstances it is evident that gold and silver coins have qualities inherent in them which render them necessarily imperfect standards of value, with whatever care and skill they may be regulated. But, in addition to these natural causes of imperfection, others have been artificially produced by erroneous or dishonest political expedients. There is no country perhaps in which the coinage has never been debased by the government. Debasement of coins was formerly a common artifice for increasing the revenue of states, and it has been effected in three different ways:—1, by diminishing the quantity of metal, of the standard fineness, in coins of a given denomination; 2, by raising their nominal value and ordaining that they shall pass current at a higher rate; and, 3, by debasing the metal itself—*i. e.* by leaving the coin of the same weight as before, but reducing the quantity of pure metal and increasing the quantity of alloy. In all these ways have the coins of England been debased at different periods of our history; and to so great an extent were they debased by successive kings, that from the Conquest to the reign of Queen Elizabeth the total debasements of the silver coins have been estimated at 65 per cent. (Lord Liverpool, *On Coins*, p. 35.) By expedients of an opposite character the standard of coins may be artificially raised; and the result of measures connected with the coinage of this country was, that in a period of 115 years, from the 1st James I. to the 1st George I., the value of gold coins, as compared with silver coins, was raised 39 per cent. (Ibid., p. 84.) No further examples are needed to prove the inconstancy of coins as a standard, when they form the sole currency of a country.

But notwithstanding these imperfections, the convenience of gold or silver coinage, as money, has led to the universal adoption of one or the other, or of both conjointly, as the standard of value. The objections to a double standard have already been noticed, but throughout a long period of the history of this country we find gold and silver prevailing equally as standards. There appears to have been no public coinage of gold at the royal mints prior to the 41st Henry III. The gold pennies coined at that time were expressly declared not to be a legal tender, and never obtained a very general circulation. Silver was then the universal medium of exchange, and the people were unaccustomed to the use of gold as money: but as their commerce and riches increased gold naturally became more convenient for large payments. The results of this progress became apparent in the reign of Edward III., who established a general circulation of gold coins, which, though partially introduced nearly a hundred years before, by Henry III., had not been continued by his successors. From this time gold and silver coins circulated together, and were both legal tenders. To what an extent their relative value varied at different periods, has already been noticed; but they were equally recognised by law as authorised standards of value in all payments whatever, until the year 1774, when it was declared by statute (14 Geo. III. c. 42) that, in future, silver coins should not be a legal tender in payment of any sum exceeding 25*l.*, except according to their value by weight, at the rate of 5*s.* 2*d.* an ounce. This was a temporary law, but was continued by several statutes until the year 1816, when the legal tender of silver coins was further restricted to payments not exceeding forty shillings (56 Geo. III. c. 68). And thus, as all large payments were made and calculated in gold coins, they became the sole standard of value, so far as coinage alone was the real medium of exchange.

The expediency of adopting gold as the standard instead of silver, has been a question of much doubt and controversy amongst the highest authorities upon monetary affairs. It was the opinion of Locke, of Harris, and Sir William Petty (all great authorities) that silver was the general money of account in England, and the measure of value in its commercial dealings with other countries. Its general adoption for such purposes was urged as a proof of its superiority as money over gold; and of this opinion are many thinkers of high authority, at the present day. On the other hand it has been argued, that the metal of which the chief medium of exchange is fabricated, should have reference to the wealth and commerce of the country for which it is intended; that copper or silver coins of the lowest denominations suffice for the convenience of a very poor country; but that as a country advances in wealth its commercial transactions are more costly and require coins of corresponding value. As a matter of convenience this is undoubtedly true. Gold is the standard in England; silver is the standard in France; and the comparative facility of effecting large payments in the current coins of the two countries can admit of little doubt. Habit will familiarize the use of silver, and render a people insensible to its inconvenience; but it is certain that in England fifty sovereigns can be carried about in a man's waistcoat pocket, while in France the value of that sum in silver would weigh about 48 lbs. troy: so heavy and bulky indeed would it be, that a carriage would be required to convey it from one part of Paris to another.

But the convenience of coin for a certain class of payments is a question quite distinct from that of its fitness for a standard of value. It is not necessary to exclude gold from the coinage because it is not adopted as the standard; it may be circulated as freely as the people desire to use it, while, instead of being the legal standard, its value may be calculated in silver. If silver be the standard, a large gold coinage may circulate at the same time for the convenience of larger payments, just as silver circulates for small payments where gold is the standard. In either case, however, that metal which is chosen by the state as the lawful standard governs all calculations and bargains, while the other metal merely conforms to its standard, and is subsidiary to it. But even if the relative convenience of gold or silver as a standard were the sole question, it could not be determined by the modes of effecting large payments only. All payments are calculated as easily in the coins of one metal as of another, in whatever form they may be actually effected. But by far the greater number of bargains are made for articles of small value. It is in silver and copper that the consumption of all commodities is mainly paid for. The wages of the country are paid and expended in that form; and in that form the prices of nearly all the ordinary articles of daily use are calculated. However the wholesale bargains of merchants may be conducted, the goods bought and sold by them are ultimately distributed to the consumers in very small quantities, the prices of which are estimated in silver and copper. The aggregate value of the small bargains must be equal to that of the large mercantile bargains which relate to the internal trade of the country, and in frequency and number they are beyond all comparison more important. It is certain also that in the vast operations of commerce the bargains, in whatever medium they may be calculated, are very rarely paid for in any coin whatever, but are settled by various forms of credit; while all minor transactions—the bargains of daily life—can be adjusted by money payments only. It is for such purposes therefore that the metallic currency of a country is mainly needed; and it may be contended with much force that silver represents the value of commodities more universally than gold, and is consequently a fitter standard.

The fitness of a standard however cannot be determined solely by considerations of convenience; for we must chiefly regard its intrinsic qualities as a permanent measure of value. How shall uniformity of value be maintained as far as practicable in the money of a country? is the main question to be determined; and not, Which is the most convenient form in which to make bargains? In what medium shall the whole property of the country be valued, from one year to another? By what standard shall the relative value of all things be compared? How shall fluctuations be restrained in the value of this standard itself? These are the questions to be answered.

In favour of gold as a standard it is argued that being less extensively used for plate and other manufactures, it is less an article of commerce than silver, and is confined more specifically to the purposes of money. On the other hand, it is contended that gold is used in large quantities for jewellery, watches, and decorative purposes, and that being a comparatively scarce material, its consumption in this manner affects its quantity and value to a greater extent than the use of plate affects the price of silver.* And in this argument there is much weight, for it is estimated that the quantity of gold compared with the quantity of silver is as 1 to 50; and their relative value is as 1 to 15. (See *Bullion Report*, 1810, *Allen's Evidence.*) Now it is evident that any variation in the commercial demand for gold must be more sensibly felt than a similar variation in the demand for silver.

But it is not sufficient to consider the demand for the precious metals as articles of consumption only; they are suddenly sought for in large quantities for other purposes. If the exchanges be unfavourable to a country, its precious metals are in greater demand for exportation than its commodities; or if there be a foreign war, its metals are in demand for the payment of the troops and for the purchase of food and munitions of war. Here again gold must feel the demand to a greater extent than silver. If metals be required for exportation in payment of goods, gold is sure to be preferred by merchants; it is compact and portable; a large value can be exported at a small cost and without difficulty; while fifteen times as much silver must be taken to effect the same purpose. In war gold is even more in request than for the purposes of commerce: its facility of transport is so important that it must be obtained at any cost, and it is consequently drained from all countries in which it can be found. Thus not only is gold, from its limited quantity, more sensibly affected by any increased demand than silver, but it is more peculiarly liable to great and sudden drains from any country in which it forms the standard of value.

If it should happen that one country has a large gold coinage in circulation in addition to all the bullion which is required for the purposes of commerce, while all the adjacent countries use a silver currency, and possess very little more gold than is necessary for its consumption, it is clear that whenever a large demand for gold arises, it must be directed to the country in which there is a gold currency. That country will be immediately used by all others as a rich gold mine, whence abundance of metal without alloy, and assayed ready to their hands, may at once be grasped, without digging

* For an account of the consumption of gold and silver in various manufactures, see Jacob 'On the Precious Metals,' chap. xxvi vol. ii. p. 270.

in the earth. No laws and no vigilance can restrain its export: as soon as it is wanted abroad, it disappears like water through a sieve. And this has been the case with England. Every other country in Europe has a silver standard; and whenever gold is wanted, her coinage supplies it. The extent to which gold is exported when the foreign exchanges are unfavourable may be estimated from the returns of bullion retained by the Bank at different periods. On the 28th February, 1824, the Bank had in its coffers 13,810,060*l*. in bullion; at the same period, in 1825, it had 8,779,100*l*.; on the 31st August in that year its treasure was reduced to 3,634,324*l*.; and on the 28th February, 1826, to 2,459,510*l*. Again in March, 1836, the bullion amounted to 8,003,400*l*., but was reduced by the following February to 3,938,750*l*. A similar exhaustion of treasure was exhibited in 1838-9. In December, 1838, the Bank possessed 9,686,000*l*. of bullion; and in August, 1839, no more than 2,444,000*l*.

These are undoubtedly very strong objections to a gold standard, and in order to test them thoroughly it would be satisfactory to compare the actual prices of gold and silver, and estimate their relative variations. But such comparisons are extremely delusive, for there is no common standard by which to compare the price of each metal. If silver be purchased with gold, how shall we determine in which there has been variation? Or if gold and silver be both purchased alike with bank notes, there is a standard wanting; for the notes are made to conform to the value of the gold, and not to the value of the silver. These elements of uncertainty make all returns fallacious; but if reliance could be placed upon them, the fluctuations in the price of silver bullion would appear to be very slightly greater than those of gold. (See *Bank Charter Report*, 1832; *Sess. Paper*, No. 722, App. p. 98; *Banks of Issue Report*, 1841, No. 410, App. p. 316.) These results do not corroborate the objections to a gold standard; but it must be recollected that, independently of fluctuations in the prices of bullion, a diminution in the quantity of money circulating in a country raises the value of the remainder, and disturbs its relation to the prices of other commodities. It is in this form that the effects of an abstraction of gold must be felt rather than in the price of bullion; and though its influence upon prices is very injurious, the cause is not always perceptible. If a country had a circulation composed exclusively of gold, it might sometimes be deprived of all its money; if of gold and silver conjointly, it might sometimes be deprived of all its gold; but no country could be deprived of all or nearly all its silver by the operations of commerce. When paper money is added to gold and silver coins as part of the circulation, a country can always command a sufficient quantity of money; but the drain of its metals has an important influence upon the value of its circulating medium, and upon the operations of commerce; but of these matters more will be said hereafter.

The principal imperfections of the precious metals as standards of value have now been adverted to. Both of them are less liable to variation than any other known commodity which could be used for the purposes of money; but of the two, silver would appear to be, upon the whole, the most suitable for a standard of value.

But whatever metal may be chiefly used as money, there is a disadvantage attending the circulation of coins which remains to be noticed. To maintain a large circulation of them is the most expensive mode of furnishing a people with a medium of exchange. In the first place the whole value of the metals of which they are composed is subtracted from the productive capital of the country, in order to facilitate the exchange of other commodities. Unless this expense be absolutely necessary, it is an unwise extravagance. It is as if children should play at cards with gold counters instead of ivory fish. Secondly, the wear and abrasion of coins makes it necessary to supply their deficiency with more of these costly metals, in addition to the amount already coined. Thirdly, not only are coins diminished in weight, but great numbers are irretrievably lost and destroyed. They are buried in the earth by misers, and never found again; they are lost in the sea; they are wasted by fire; they are dropped in the roads, and trampled under foot with the dust and stones. Every accident of this kind diminishes the wealth of the country, and wastes the products of its labour. Some cheaper kind of money therefore should, as far as possible, be used as a substitute for gold and silver;—and such a substitute has been found in paper.

Not only is paper more economical than gold and silver, but it is more convenient than either for effecting large payments, or for transmitting sums of money to a distance. In this respect it excels gold more than gold excels silver. A million of money may be paid in bank notes as easily as ten sovereigns, and transmitted to a distance even more easily.

But notwithstanding these advantages, paper may be deemed an imperfect instrument of exchange, because it is subject to forgery. It shares this defect however with other kinds of money. Gold and silver coins are counterfeited in baser metals; paper-money is imitated by the forger. But the more exquisite the art with which a coin is struck, the more difficult it is to counterfeit its impression; and, in the same manner, the more elaborate the design of a promissory note, the greater will be the obstacles to forgery. No precautions perhaps can altogether prevent a spurious imitation of valuable articles; but the possibility of forgery can only be objected to the use of paper-money in the same manner as the danger of buying paste ornaments may be urged against the wearing of diamonds.

Paper is thus as well suited as any other material for the purposes of a currency; but its character is essentially different from that of other descriptions of money. Its cheapness, which renders its use economical, prevents it from being exchanged as an absolute equivalent for other commodities. Gold and silver have a value of their own, distinct from their value as money; but, except in its monetary character, paper is nearly worthless. To be accepted, therefore, in exchange for commodities, paper must represent some value besides its own.

In considering what that value may be, it will be convenient to describe the character and functions of a promissory note. The state, a bank, or some person of known wealth, instead of paying a sum of money in the ordinary coins of the country, issues a note promising to pay that sum, on demand, to any person who shall present it for payment. This is the form of promissory notes which circulate as money; but there are also promissory notes, payable at some particular period, which, for reasons which will be presently explained, do not form part of a monetary circulation. Now, in the ordinary transactions of life, no one will promise to pay a sum of money without receiving or expecting to receive an equivalent for it, and such equivalent, whatever it may be, is the value represented by the note. Suppose that A in London owes B at Edinburgh a thousand pounds, and that he has a thousand sovereigns to discharge his debt. Instead of transmitting the gold to Edinburgh, A takes it to the bank and exchanges it for a promissory note of that amount, which is accepted by B in payment of his debt. In this case it is clear that the note represents a thousand sovereigns; and any person in whose possession it may be can obtain them from the bank. Suppose again that C applies to D for a loan of 1000*l*., for the repayment of which he is able to offer security in the shape of goods or property; and that D, instead of advancing that sum in money, gives him his promissory note for 1000*l*. payable on demand. In that case, the promissory note, if issued by a solvent person, would be equally payable in coined money, but it would represent the security upon which it was given. The issuer of the note will suffer if that security be insufficient, for he has pledged his own property against it; but the interest which he expects to receive is a compensation for the risk he incurs in realizing, as it were, the property of another. A promissory note, it seems, may therefore represent either coined money or capital in any other form. But here an important question arises which affects the entire character of paper-money. Why do persons accept promissory notes instead of gold and silver? Why are they satisfied with the representative of value instead of receiving the value itself? For the explanation of this point it will be necessary to divide promissory notes into two kinds, viz.: 1, those issued by the state, or by a state bank; and 2, those issued by bankers, or other persons unconnected with the state.

1. Promissory notes issued by the state or by a state bank are under the protection of the law, and are made a legal tender. When once in circulation they discharge debts as completely as the current coin; they may not be refused in payment, although, if from any cause their value be depreciated, they may be taken in exchange for a less sum than they profess to represent. Such notes are therefore money, to all intents and purposes, just as if they were composed of gold and silver. Their value is liable to fluctuation, according to the regulations under which they are issued: but they are lawful money, coined by the state in paper, instead of in the precious metals. Such money will be current throughout

the country in which it is issued; but it differs from gold and silver, inasmuch as it cannot serve the purposes of an international currency. Gold and silver are current all over the world, and their value is everywhere understood; but paper-money is necessarily confined to the purposes of internal circulation.

2. Promissory notes issued by bankers or other persons unconnected with the state, not being a legal tender, may be refused in payment of any debt. They can only be circulated, therefore, with the entire concurrence of those who receive them. It is by means of banking accommodations, however, that they usually get first into circulation. A person who wishes to borrow money is not very particular concerning the form in which he obtains it, and he willingly accepts a note, if it be offered him instead of gold. He probably owes money to another, to whom he, in his turn, offers the note as payment. This third party will readily accept it, for he wishes to secure the payment of the debt, and if he distrust the value of the note, he may immediately call upon the party who issued it, for gold. When the credit and solvency of a bank are well known in any neighbourhood, its notes pass from hand to hand without any distrust, but they rarely circulate beyond the adjacent district. Within its own district they are received as money, as readily as a state bank-note is received all over the country; beyond its district they are sure to be returned for gold, just as a Bank of England note would be returned from Russia. A bank of issue is also a bank of deposit, and the people amongst whom its notes are circulated pay them into the bank whence they issued, and receive credit for them—not as notes only, but as current money: and when they draw again upon their deposits, they may receive the amount in gold and silver or in state bank-notes. In this manner the distinction between local notes and other descriptions of money is gradually lost sight of; they are readily convertible: they are universally circulated: habit familiarises the use of them; and at length, without the sanction or protection of any law, they become money: usage, and not the state, has coined them. Still any one may refuse to receive them, and the extent of their circulation depends upon the credit of the issuer. Let a whisper be heard against his solvency, and in a single day all his notes may be returned to him for immediate payment in the currency of the state.

The circumstances which occasion a large circulation of both these kinds of paper-money in a country are, the convenience of such a circulation, and the difficulty of obtaining a sufficient coinage for effecting the various purposes for which money is used. The demand for money is continually increasing in proportion to the increase of commodities in quantity and value: and in a rapidly improving country no coinage can keep pace with such an increase. When paper-money is issued it does not supersede gold and silver, but is used concurrently with them. Its denominations of value are the same as those of the coins; and if it be a properly regulated currency, its value will also be precisely the same as that of the coins of a like denomination. A hundred pound note should be of precisely the same value as a hundred sovereigns. But how is this equality of value to be maintained between two descriptions of money differing so materially in character? Gold and silver, as already explained, have a known value as articles of commerce, and their real value depends upon the quantity of labour required for their production. If this continue unchanged for many years, their exchangeable value may still be liable to fluctuation by reason of varying proportions between supply and demand. The supply of them may be the same with an increased demand: or the demand may remain the same, and the supply be either increased or diminished. But paper has scarcely any real value when used as money; the labour expended upon it compared with its denomination of value is merely nominal: and its value, supposing its credit to be good, must therefore depend entirely upon the proportion which the quantity issued bears to the requirements of commerce. If less be issued than there is a demand for, its value will rise; if it be issued in excess, its value will be depreciated. So strong is the operation of this principle, that promissory notes, which are a legal tender, may even be raised above the value of gold, though inconvertible into specie, if their amount be sufficiently limited. This result was actually produced, after the suspension of specie payments in 1797; when, so far from being depreciated in value, bank-notes bore a premium over gold, until they were issued in excess, and fell to a discount. It is evident, therefore, that the value of paper-money is independent of convertibility. If convertible, but issued in excess, its value will be depreciated; if inconvertible, but limited in amount, its value will be sustained. And further, if government paper and local notes be concurrently in circulation, and if either be issued in excess, the value of both will be depreciated, because the aggregate quantity of paper-money will be increased beyond the demand for it.

The mode of regulating the issue of paper-money so as to sustain its value and to prevent it from fluctuation, is one of those difficult problems which have perplexed theorists and statesmen, and still remain to be completely elucidated by experience; but the principles upon which any sound system of paper-currency must be founded are now agreed upon by the best authorities.

Let it be supposed that no paper-money is in circulation but government notes inconvertible into specie, and that it is the desire of government to maintain them at the same value as the gold and silver coinage. By what principle could the issue be regulated so as to effect this object? Gold and silver maintain a reasonable steadiness of price, as they are possessed of a real value, and being in demand all over the world, are distributed in quantities proportioned to the wants of each country. Without any standard price being fixed by the state, their value will, therefore, be self-regulated; but paper-money, not being possessed of any real value, has no element of stability in itself, and unless its issue be adjusted with the utmost nicety, its value will be constantly fluctuating. As the object to be secured is an equality of value between the precious metals and paper-money, and as the former have an element of stability which is wanting in the latter, it is clear that paper-money must be made, in some manner, to conform to the value of the precious metals. Now this can only be accomplished by making paper-money convertible into gold or silver, whenever its holders demand such a conversion. To regulate the issues of inconvertible paper is like filling a vessel with water in the dark, and without a measure: it is by the overflow only that the vessel is known to be full; while a convertible paper, under proper regulation, adjusts itself to the standard of the precious metals.

If convertibility be desirable when there is no other paper in circulation but that issued by government, it is indispensable when promissory notes are permitted to be issued by other parties; for, in that case, it is necessary to guard against an excessive issue of both descriptions of paper; and when government paper is convertible, other issues of paper will in some degree conform to its standard, as it, in its turn, conforms to that of the precious metals.

The manner in which convertibility restrains the over-issue of notes may be thus explained. If too much money be in circulation, its value is depressed, and the prices of commodities relatively raised. It thus becomes more profitable to export money than commodities in payment of the price of imports; but paper-money not being current abroad, gold or silver is taken, and whenever this occurs, the exchanges are said to be unfavourable. If a state bank issuing notes be required to give gold or silver in exchange for them, it must be constantly possessed of a large store of the standard metal. If it be the sole or chief bank of issue, it will be the principal depository of bullion in the country; and thus any drain caused by unfavourable exchanges will be first and chiefly felt by it. Persons wishing to export bullion will demand it of the bank in exchange for notes. In this way the bank is apprised of the state of the foreign exchanges, and learns that money is too abundant; while it has the power of immediately contracting its circulation by means of this very demand for bullion. It has merely to lock up those notes which it has received back in exchange for bullion, and every exportation of its bullion effects a proportionate contraction of the currency and restores the exchanges to a healthy state, by adjusting the quantity of money to the requirements of commerce. This is a simple mode of regulating the circulation of a country, and if all the paper-money were issued by one body only, it could not fail to be effectual. So far as the principle has been tested in England it has been successful; but its operation has been interfered with by the competing issues of many independent banks, and by the admixture of banking business with the issue of notes, in the bank itself. Both these causes of disturbance have been partially provided against by the recent Bank Charter Act (7 & 8 Vict. s. 32), and the experience of a few years will show if there be any imperfection in the principle, that the paper-circulation of the country must be regulated by the foreign exchanges.

Any further reference to the particular laws and practice by which the circulation of this country is regulated, in connection with a complicated system of banking, will be unnecessary for the explanation of principles, and these matters have already been treated under another head. [BANK, P.C.] But we cannot quit the subject of convertibility without adverting to a point of great importance. In order to regulate the issues of paper with reference to the exchanges, it is by no means necessary that gold or silver coins should be given by the issuing body in exchange for its own notes. Uncoined bullion would serve the purpose equally well, and would occasion a considerable economy in the coinage. It would be sufficient therefore to require the bank, or other issuing body, to give bullion in exchange for its notes, at the standard price, whenever a certain amount should be demanded. There can be no object in giving facilities to every person who possesses a 5*l.* note, to exchange it for gold, and much mischief is caused by such facilities, in times of panic; while, on the other hand, no impediment would be offered to the great operations of commerce by raising the minimum quantity of bullion to be demanded. By this arrangement whenever notes fell below the value of bullion, they would be brought in exchange for it, until the prices of both were again equalized; and if, by any undue limitation of issue, the value of notes should be raised above that of bullion, the bank should be obliged to give its notes in exchange for bullion. In this manner the circulation would be enlarged and the equilibrium between gold and paper restored. This excellent system was proposed by the late Mr. Ricardo in his able pamphlet entitled 'Proposals for an Economical and Safe Currency,' and was carried into effect, for a short period, on the resumption of cash payments, in 1819, but was succeeded by the present plan of convertibility into gold coin, which is more costly and less secure in its operation.

In regard to the issue of paper-money there are two antagonist theories, which remain to be noticed, although it will be impossible to enter fully into the arguments by which each is supported. By one it is proposed that all paper-money should, like gold and silver, be coined by the state alone, in order that its issue may be properly regulated and its convertibility secured. By the other it is maintained that the issue of paper-money should be open to all persons without restriction, like the drawing of bills of exchange, except in so far as securities may be necessary for the solvency of the issuers. In this country neither of these principles has been adopted singly, but the circulation has been founded upon the union of them both. It has however been the policy of the government gradually to contract the issues of private banks, and to replace them by the notes of the Bank of England, which, for the purposes of issue, now stands in the position of the government itself.

In considering the relative merits of a system of government issues and of free competition amongst issuing bodies, there are three main questions to be considered: 1st, the profits arising from the issue of notes; 2ndly, the solvency of the issuers; 3rdly, the convertibility of the notes and the securities against over-issue. If the two first questions were the sole consideration, it would be difficult to oppose the claims of those who insist upon the right of free issue.

1. The profits arising from the circulation of paper may be regarded as one of the many forms in which profits are realized by trade. It is true that the right of issuing money has ordinarily been claimed as a royal prerogative, and that promissory notes might be included in that category. If such a claim had been made on the first introduction of paper-money, it could undoubtedly have been supported by the analogy which paper-money bears to a coinage; and if the law had pronounced in favour of the claim, a lucrative prerogative would have been created, instead of a profitable branch of banking. But no such claim was advanced: the issue of notes has always been distinct from the coinage of money; and the state is now no more entitled to the profits arising from a paper-circulation, than to the profits of any other description of business.

2. The solvency of the issuers of promissory notes is a matter which can be provided for by law. There are few who will question the necessity of some security, when money is permitted to be issued by private parties. It is indeed contended by some that a promissory note is like a bill of exchange—that it represents capital and securities, and that, in its representative character, it is circulated instead of money, upon the credit of the issuer, and upon the responsibility of those who accept it. But there is an essential difference between a promissory note and a bill of exchange. The one is money and discharges a debt; the other leaves a debt outstanding until the bill becomes due and is paid. Again, a note passes from hand to hand upon the sole credit of the issuer; a bill of exchange passes not only upon the credit of the acceptor, but also upon the credit and responsibility of each indorser. A bill is circulated amongst merchants precisely as credit is given to persons of known solvency; but a promissory note, whatever may be the solvency of its issuer, if received at all, is received as money. It is obviously just, therefore, that when the state permits so important a privilege to be exercised as that of the issue of money, it should at the same time provide securities against its abuse. Such securities cannot be enforced without interfering, in some measure, with an unrestricted freedom of issue, but they are essential to the public safety, and they should on no account be neglected.

3. But the solvency of the issuers of notes concerns those parties only who may happen to hold the notes of a particular bank: it does not affect the whole country. If a bank fail, its creditors suffer like the creditors of any other bankrupt firm; but the general business of the country is not disturbed by its failure. On the other hand, however, the regulation of its issues had an influence upon the entire trade of the country. However effectual may be the securities against the insolvency of private banks—however complete the protection of the individual holders of their notes—the public interests are still in need of protection against the consequences of an ill-regulated currency. The securities against insolvency and the securities against over-issue are entirely distinct: the former may be complete; the latter may, at the same time, be inoperative. The mode of sustaining the value of paper-money on a par with the precious metals has already been explained. It is only by means of convertibility and by a reference to the foreign exchanges, that the issues of paper can be adjusted to the wants of the country; and this principle is incompatible with an unrestricted issue of paper by private banks.

If no control be exercised by government or by some central body over the issues of private banks, notes will be circulated, not according to any fixed principle, nor with reference to the exchanges, but to promote the business of banking. If too many should be in circulation, the action of the foreign exchanges cannot be brought to bear upon many independent banks with sufficient force and distinctness, and the convertibility of all the paper-money in the country is consequently endangered. This is the danger which is sought to be averted by restrictions upon the issues of private banks, and by the gradual substitution of the notes of one issuing body for those of many. No interference with the business of banking would be justifiable, except for the protection of the public interests; but the evils arising from the suspension of specie payments are so great, that every practicable precaution must be taken to avert it. It deranges all commercial transactions, it injures public credit, disturbs prices, and suddenly withdraws the standard of value by which all existing obligations and all future bargains are to be adjusted. When notes are issued by one body only, a limitation of its issues, as already noticed, may sustain their value; but when many independent bodies are issuing notes, during a period of inconvertibility, there is no principle at work to regulate or to limit their issues, and it is almost certain that their notes will not only be greatly depreciated, but also will be liable to constant fluctuations of value.

There are some political reasoners who have ascribed every commercial convulsion to an ill-regulated currency; while others deny its influence upon prices and upon the general arrangements of commerce. The opinions of both these parties are probably extreme, and their facts somewhat exaggerated; but the temperate view taken by Mr. S. Jones Loyd may be adopted with less hesitation. He says, 'The currency, in which all transactions are adjusted, has the same reference to the healthy state of trade, which the atmosphere in which we all live has to the physical constitution of our bodies; irregularities and disorders may arise from a variety of causes, but the duration and virulence of them will materially depend upon the pure, healthy, and well-regulated condition of the medium in which they exist. A well-managed currency cannot prevent the occurrence of periods of excitement and over-trading, nor of their necessary consequences—commercial pressure and distress; but it may tend very powerfully to diminish the frequency of their return, to restrain the suddenness of their outbreak, and to limit the extent of their mischief.' (*Remarks on the Management of the Circulation*, 1840.)

As yet such promissory notes only have been spoken of as are payable on demand: but a few remarks may be added concerning promissory notes and bills of exchange payable at some period more or less distant. These are regarded by some as paper-money, and are said to form part of the general circulation; but the essential distinction between them and paper-money has been more than once noticed above. They do not discharge obligations, but are merely written engagements to discharge them at a future period: they are one of the many forms of credit, and as such are used as substitutes for money; but they cannot be considered a part of the national currency. When transferred from one hand to another they do not pass as money, but as the transfer of a debt, of which the payment is guaranteed by each endorser in succession. It is true that that they are among the most efficient agents for economising the use of money, and that they leave the circulating medium more free for other purposes, in which payments are made in notes or specie. If this were not the case, the circulation of notes must be almost indefinitely increased in order to meet the various demand of commerce; but this economy in the use of money makes a comparatively small circulation sufficient. It is this circulation, however, of which the relative scarcity or abundance affects the prices of commodities and the foreign exchanges. The final settlement of a bill of exchange must be adjusted in the current money of tho country. If money be dear, the acceptor exchanges more goods for it in order to meet the bill when it becomes due; if money be relatively cheap, he makes a better bargain; but the bill of exchange itself is no more money than the goods which had been originally purchased with it. Every bill of exchange when first drawn and accepted, and subsequently endorsed, represents, at each transfer, a distinct commercial transaction, of which the bill is the immediate result. The number and amount of bills of exchange in circulation cannot therefore be added to the currency in order to compare the aggregate circulation with the aggregate amount of commodities; for those commodities which are exchanged by means of bills may be set off against the value of other commodities represented by the bills, while the notes and specie taken together may be compared with the aggregate of other transactions, added to the balances of accounts arising out of the final settlement of bills of exchange. It is undeniable that bills of exchange perform many of the functions of money, and they are regarded as a part of the circulation by some high authorities in monetary matters; but it appears to us that the balance of reason and of authority inclines to the other side and assigns to bills of exchange a distinct place as substitutes for currency instead of including them as part of the currency itself. (See tho Evidence upon this point before the Committee on Banks of Issue, 1840.)

A similar question arises in reference to the monetary character to be assigned to banking deposits: are they currency or not? The transfer of deposits pays debts and purchases commodities; it performs the functions of money, and so far would seem to be a part of the currency and to have an influence upon prices and upon the foreign exchanges. But it cannot be contended that the whole of the deposits are currency, for a large portion of them is invested by the bankers; and if every depositor were to call for his deposits at once, they could not be paid. Nor can the uninvested portion be properly called money; it is a form of credit which, like bills of exchange, economises the use of money and is a substitute for it, but is not the thing itself. It bears so close a resemblance to currency that to assign to it a distinct character is a matter of some difficulty; but still we are disposed to class all portions of banking deposits which are not actually held by the bankers in notes and specie, in the same category with bills of exchange, book-debts, and transfers in account. All these are modes of facilitating the exchange of commodities by a refined species of barter, without the intervention of any circulating medium. Each transaction is valued in the current medium of exchange, and final settlements of accounts are adjusted in money; but the estimated value of the transaction itself cannot be reckoned as a part of the circulation, for if it were, then commodities themselves would be money.

An ordinary case of barter would seem to offer a good illustration of the functions of all forms of credits as substitutes for money. Suppose a merchant, A, to have indigo to the value of 1000*l.* to sell, and that he wishes to purchase cotton of the same value, which B is willing to give in exchange for the indigo. The transfer is made at once between them: the transaction is complete without the passing of a shilling, for the indigo performs the functions of money. But can the indigo on that account be reckoned as a part of the circulating medium? Suppose again, that these merchants, at the time of the transfer, each drew a bill for 1000*l.* upon the other at three months, which each accepted. These bills would represent the value of the indigo and of the cotton; but no more money would pass between them until these bills became due, than if no part of their bargain had been committed to paper. When the bills became due, each would be indebted to the other to the same amount, and might write off one debt against the other; or each might transfer a portion of his bank-deposits to the other. In the case first supposed, no money would pass, but one commodity would be taken as an equivalent for the other. In the second case the credit of each party would be accepted as an equivalent for the goods without the intervention of a money payment: and this credit would afterwards be exchanged for another form of credit—a bank-deposit. In neither case, as it would seem, does the transaction involve the use of any portion of the circulating medium, nor call any new description of currency into existence.

It is of the utmost importance to form a clear opinion as to the distinction between various forms of credit and the circulating medium of a country; for if they be confounded one with another, all the established theories of currency are put into confusion. All hopes of regulating and controlling the circulation must be abandoned, for its variety and magnitude would be such as to defy tho operations of the government, or of a bank, by means of paper issues, which would form only one insignificant portion of the aggregate currency; and free trade in banking and free trade in the issue of notes must be recognised as the only reasonable principle for supplying commerce with a circulating medium.

We have now adverted to the main principles involved in the consideration of the character and functions of money. In treating of a subject which has been so fruitful of controversy, we have been obliged to touch lightly upon many points which to deep students of the 'currency question' may seem to have deserved more consideration. To examine them fully would add volumes to the many which have already been published upon that subject; and frequent allusions to the opinions of others, however deserving of attention, would give a controversial character to an inquiry after truth. We have endeavoured to state, as concisely as we could, the opinions we have formed, together with the grounds upon which we have formed them; and those who agree with us will think us right, while they who differ from us will pronounce us wrong. Upon currency questions unanimity is nowhere to be found; but the more men seek after truth in preference to quarrelling with one another, the more certainly will truth be found at last.

MONKSHOOD. [ACONITUM, P. C. S.]

MONNOYER, JEAN BAPTISTE, a very celebrated fruit and flower painter, was born at Lille, in 1635. He was educated as an historical painter at Antwerp, but he afterwards adopted flower painting and went very early to Paris, where he was noticed and employed by Le Brun, and in 1665 was elected a member of the French Academy of Painting. He was employed by Le Brun in the decoration of the palace of Versailles, in which he painted many festoons of flowers and other similar pieces. It was owing to the beauty of these works that he was invited, about 1680, to London by the Duke of Montague, then English ambassador at Paris, to decorate Montague House (the late British Museum) in a similar manner; and the free and beautiful flower decorations of this palace, which is now pulled down, must still be fresh in the recollections of many.

Monnoyer painted in many other noblemen's houses in London and at other places; at Burlington House, at Lord Carlisle's, at Hampton Court, and at the Duke of St. Albans' at Windsor. One of his most remarkable works is a looking-glass painted in Kensington Palace for Queen Mary, who took such delight in seeing him paint that she spent nearly all the time that he was at work in watching him. There are fourteen flower-pieces by Monnoyer, or Baptiste as he is now commonly called in England, in the apartment named George II.'s private chamber, at Hampton Court; they are however dirty and badly hung. Monnoyer was commonly styled 'the flower-painter' in England in his own lifetime. He paid a few visits to Paris after his first arrival in London, but his permanent abode was in London, where he died in 1699, and was buried in St. James's. The French offended him by allowing his son-in-law, who was a painter and living at Paris, to touch and alter some of his works.

Monnoyer's style, though not by far so minute or highly finished as that of Van Huysum, is infinitely more free and more brilliant, equally true and more effective. His selection of flowers, his grouping, his colouring, and light and shade, and touch, are all equally excellent and faultless: his works in their perfect condition must have rivalled nature herself. The brilliancy of his colouring is extraordinary. He was particularly fond of grouping roses, poppies, pionies, tulips, and a few white flowers together in a marble vase, and there are several etchings of such groups by his own hand: the vases are placed on pedestals or tables. His best works are in this country. The prints after his works amount to about 80, and make a good folio volume: his own etchings are marked J. Baptiste, sculp., whence probably his now common name of Baptiste. His son Antoine Monnoyer, likewise a good flower-painter, was called the younger Baptiste in England. There is a portrait of Monnoyer engraved by White from a picture by Sir Godfrey Kneller.

(*Essay towards an English School*, 1706; D'Argenville; Walpole; Huber.)

MONOTROPA (from μόνος, one, and τρόπος, a turn), a genus of plants belonging to the natural order Ericaceæ and the tribe Monotropeæ. It has a 4-5 parted calyx, a corolla of 4-5 petals each, with a hooded nectariferous base; 8-10 stamens with kidney-shaped 1-celled 2-valved anthers; a peltate stigma; the capsule 5-celled, 5-valved, many-seeded. The species of this genus are singular-looking plants, found growing at the roots of trees, and destitute of the green and bright colours which characterise the other forms of vegetation.

M. Hypopitys, Yellow Bird's-Nest, has the flowers in a drooping cluster, lateral ones with 8 stamens, the terminal ones with 10 stamens, the fruit erect, the bracts and flowers glabrous externally. The stem of this plant attains a height of 6 or 8 inches, is succulent, simple, clothed with ovate scales, terminating in a short cluster, dingy yellow, at length turning nearly black. The flowers with large scaly bracts. It is a native of Great Britain. This, with the other species of Monotropa, being constantly found at the roots of trees, was supposed to be parasitical upon them; recent researches have, however, led to the conclusion that in the case of this species such an opinion is erroneous. Mr. Rylands, in a paper published in the 'Phytologist,' page 341, has given the result of a very accurate investigation of this subject, and has proved that the fibrillæ of the roots of Monotropa possess spongioles and take up their nutriment in the same way as other plants. Most specimens of Monotropa, when recently dug up, present masses of a fibrous substance, which adhere to their fibrils and the roots of the plant near which they grow, so closely, that they were supposed to be portions of the roots of the Monotropa. On examining this fibrous substance with care, Mr. Rylands found that in all cases it consisted of a species of byssoid fungus which had been developed upon the roots of the Monotropa, having no organic connection with the plant. The species of fungus varied in different specimens, and were found to belong to hitherto undescribed forms of Cryptogamia. There can be little doubt that the other species of Monotropa are of the same nature as Hypopitys, and that their parasitism is imaginary. Some writers have referred the species here described, and two others, to a genus called Hypopitys. This includes the European species, whilst the old genus, Monotropa, embraces two American species, *M. Morisoniana* and *M. uniflora*. The last species have not the musky semi-fragrant odour of those belonging to the genus Hypopitys.

(Don, *Gardener's Dictionary*; *Phytologist*, vol. i.; Babington, *British Botany*.)

MONTAGUE, GEORGE, was descended from an antient family residing at Lackham, in the central part of Wiltshire, where he had an estate. He was distinguished for his love of natural history, and was one of the early members of the Linnean Society of London. In 1802 he published an 'Ornithological Dictionary, or Alphabetical Synopsis of British Birds,' 2 vols. 8vo. This work exhibited much research as well as an extensive knowledge of the department of natural history to which it was devoted, and may be consulted with advantage at the present day by the ornithological student. In 1803 he produced his 'Testacea Britannica; or Natural History of British Shells, Marine, Land, and Fresh-water, including the most minute; systematically arranged and embellished with Figures,' London, 4to. This work also contained a great mass of valuable information on the subject on which it treated. A 'Supplement' was published in 1809 containing several plates and descriptions of new species. Besides these two great works he published several papers in the Transactions of the Linnean Society. Of these the following are the principal—

1. Description of three rare Species of British Birds. Vol. iv. 1796.
2. Description of several Marine Animals found on the south coast of Devonshire. Vol. vii. 1802.
3. On some Species of British Quadrupeds, Birds, and Fishes. Vol. vii. 1803.
4. Of the larger and lesser Species of Horse-shoe Bats, proving them to be distinct, with a Description of Vespertilio Barbastellies taken in the South of Devonshire. Vol. ix. 1805.
5. On the Natural History of the Falco Cyaneus and Pygargus. Vol. ix. 1807.
6. Of several New or Rare Animals, principally Marine, discovered on the South Coast of Devonshire. Vol. xi. 1811.
7. Of some New and Rare British Marine Shells and Animals.—*Ib.*

During the latter part of his life Mr. Montague lived at Knowle, near Kingsbridge, in Devonshire, where he died in 1815.

MONTALEMBERT, MARC-RENE', MARQUIS DE, a distinguished military engineer of the eighteenth century, was born July 16, 1714, at Angoulême. He was descended from an antient and noble family; and, having received an education in which both literature and science were judiciously conjoined, he entered the army at eighteen years of age.

In the course of his first campaign (in 1733), he was present at the siege of Kehl, and in the following year he distinguished himself at the siege of Philipsburg. He served afterwards with considerable reputation in Bohemia, when a French army under Marshals Broglio and Belleisle was in that country; and, on the retirement of the army from thence, he returned to Paris, where he devoted himself to the study of subjects which have relation to the military art. He was admitted a member of the Académie des Sciences in 1747; and he wrote several 'Mémoires,' which were inserted in the volumes published by that body. About the same time he established a foundry at Perigord for the purpose of casting heavy ordnance, which was then much wanted for the French navy. During the Seven Years' War Montalembert was attached, as an agent for the French government, to the staff of the Swedish and Russian armies; and he appears to have been consulted by the allied generals respecting the arrangements of the plans for the different campaigns. In 1777 he published a small work entitled 'Correspondance pendant la Guerre de 1757,' which contains much interesting matter relating to that war. In 1779 he was appointed to construct a fort for the purpose of securing the isle of Aix against the English fleet; and this fort, which was built entirely of wood, is said to have borne, without experiencing any damage, the shock occasioned by the simultaneous firing of all the artillery which was mounted on it: the experiment seems to have been made in order to disprove the assertion of several engineers that the fort would fall in ruins by the fire of its own guns.

Montalembert published, in 1758, a small work in 4to., entitled 'Mémoire Historique sur la Fonte des Canons;' and, in 1766, one under the title of 'Cheminée-Poele.' He also published, in 8vo., a pamphlet designated 'Relation du Siège de Saint-Jean d'Acre.' But the work by which his name will be for ever remembered is his great treatise, entitled 'La Fortification Perpendiculaire, ou l'Art Defensif supérieur à l'Offensif,' which was published at Paris in eleven quarto volumes (1776 to 1796).

In the first volume, having shown the defects of the bastioned fortifications which are constructed according to the principles of Vauban, he proposes to suppress the flanks of the bastions, continuing the faces of those works till they meet in the middle of each front of fortification, and, at the place of meeting, to have a casemated work like a small ravelin. The advantage to be gained by this project is, chiefly, a diminution of the expense of construction; and, after proposing some other modifications of the existing fortifications, Montalembert dwells at length on that system which gives its name to the treatise. [FORTIFICATION, P. C.] The perpendicular fortification consists of four lines of rampart, the branches of which form right angles with one another at the re-entering parts, and three of these are defended by a powerful fire of artillery, which, being placed in casemates, is not liable to be dismounted by the enemy; while spacious terre-pleins at the foot of each rampart afford room for the troops of the garrison to engage the besiegers with forces superior to any which can be brought against them.

In the second volume, after giving an interesting account of the war in 1741, in which the importance of fortified positions is pointed out, he describes the construction of redoubts or small forts. In the third volume there is a project for the construction of a simple fortification, consisting of a crenelated wall covered by a rampart on which are constructed casemated traverses: this is proposed as a good kind of defensive work for sea-ports; and it is said that some of the forts which defend Cherbourg were executed on that principle. The fourth volume contains an abridged history of the reign of Louis XIV., together with sundry projects relating to the formation of lines of intrenchments for the defence of the frontiers of a state. In the fifth are some details concerning the construction of batteries for the defence of seacoasts; and the sixth and seventh volumes are occupied with refutations of the objections which had been made to his systems. The eighth contains some observations on the forts at Cherbourg and on the isle of Aix. The ninth volume, which is particularly entitled 'L'Art Defensif supérieur à l'Offensif,' contains sundry projects for circular redoubts and for a casemated star-fort. The tenth and eleventh consist of memoirs relating to fortification and artillery.

The leading principle on which the projects of this engineer are founded is, that a fortified post should contain an abundance of casemates for the security of troops and artillery: Montalembert considers that these alone will enable a small number of men to resist with success the attack of a numerous army, and that a few guns so protected are capable of dismounting all that an enemy can place behind parapets made merely of earth. His projects were severely criticised during his life; but, though some parts of his constructions are open to objections, the principles are unexceptionable; and it is important to observe that many of his ideas have been adopted by the Prussian and Austrian engineers in the works recently constructed for the defence of Western Germany.

In 1770 Montalembert married a lady who was distinguished by her talents as a performer on the French stage, and who wrote a novel entitled 'Elise Dumesnil,' which was printed in London in 1798. It is said that Montalembert composed for the theatre some small pieces which had a certain success; and his attachment to the Muses is proved from the fact that his biographer, Lalande, had in his possession a number of his songs and tales in verse which are said to have been characterized by grace, elegance, and imagination.

In publishing his great work, and in making his experiments for the improvement of the military art, he seems to have incurred expenses which injured his fortune. He had given up to the government his foundries at Perigord, and his applications for the sum of money which he claimed as an equivalent were fruitless; he was even deprived of a pension which he enjoyed for the loss of an eye in the service of the country. About the year 1790 he came to London; but, after remaining here a few months, he returned to Paris, leaving his wife in this country. It is said that, in order to save some of his property, he joined the revolutionary party; and it is painful to record that he entered so far into the prevailing spirit of the time as to divorce his wife in order to marry the daughter of an apothecary. He sold an estate for the purpose of satisfying his creditors, but receiving payment in assignats, which immediately afterwards suffered an enormous depreciation, he became involved in serious difficulties. He continued however, to employ an artist on a work with which he had long been occupied—the construction of a considerable number of models relating to fortifications and artillery, and the valuable collection, when completed, he presented to the Committee of Public Safety. At the same time, with other eminent engineers, he was constantly consulted by Carnot on subjects relating to the military affairs of the republic. He died of a dropsy, March 29, 1800, being then eighty-six years of age.

(*Eloge de Montalembert*, by Delisle de Sales; *Biographie Universelle.*)

MONTEN, DIETRICH, an eminent German battle painter, was born at Düsseldorf in 1799. He showed from his earliest youth a great love for accounts of wars and battles; and Homer, Tasso, and Ariosto were his favourite authors, from which he used to sketch the most striking scenes of arms. In order that he might have some practical knowledge in military matters he enlisted into the Prussian army as a volunteer in 1818, and served accordingly for twelve months. At the expiration of his term of military service, he entered the Academy of Arts of Düsseldorf, and after studying two years in that institution he removed to Munich, in order to benefit himself by the study of the works of Peter Hess, who almost rivals Horace Vernet as a battle painter, and is still resident in Munich.

Monten was not long in attracting the attention of Cornelius, then the Caposcuola of the painters of Munich, and the notice of the present king of Bavaria, Ludwig I. He was intrusted by Cornelius, in 1827, with the execution of three of the frescoes of the arcade of the Hofgarten—the storming of a Turkish entrenchment by the Bavarians at Belgrade in 1717, under the elector Carl Albrecht and his brother Ferdinand; the battle of Arcis sur Aube, in which the Bavarians under Wrede were engaged; and the granting of the Bavarian constitution by Maximilian Joseph I. in 1818. These works, though hard and much too positive in colour, have great merit, and allowance must be made for the comparative infancy of the then only reviving art of fresco-painting in Munich. After these works Monten painted for the king a picture of the battle of Saarbrück, 1815, for the Hall of Victory (Siegessaal) in the state apartments of the new palace; and for the same patron of the arts, the departure of the Poles from their fatherland in 1831. These were followed, in 1836, by the death of Gustavus Adolphus in the battle of Lützen, now in the King of Hanover's collection; in 1838, by George I. in the battle of Neerwinden; and in 1839, by the great camp in 1838 at Augsburg, for the Emperor Nicholas, at which that emperor was present. He painted besides these principal works many smaller pieces, which are all conspicuous for extraordinary spirit in the incidents and in the execution, and display much fine drawing and good colouring, though in many parts too sketchy and undefined; he wanted the necessary patience for elaborate modelling and uniform finish. But when the exact degree of this technical excellence is missed, its absence is more agreeable than its excess; and all Monten's works have a very agreeable effect: their greatest defect is an occasional extravagance of action. His horses are always very spirited. He died after a short but severe illness, in December, 1843, in the prime of life, being in his forty-fifth year only, universally regretted by all who knew him. Several of his works have been lithographed by Bodmer, Hanfstängel, and others.

(*Kunstblatt*, 1836-1844; Von Hormayr, *Geschichtlichen Fresken in den Arkaden des Hofgartens zu München.*)

MONTGOMERY, ALEXANDER, an old Scottish poet, was a younger son of a good family in Ayrshire. The Bannatyne Manuscript, written in 1568, contains some of his verses: but the very few events of his life which are exactly known fall within the reign of King James VI. of Scotland. He is described as having been a captain, probably in the guard of Morton the regent. King James quotes some of his poems in a work of his own, published in 1582; and he obtained a pension of five hundred Scottish marks, which led him into a troublesome law-suit on his return from a continental tour, begun in 1586. He appears to have died between 1607 and 1611. In the former of those years was published his principal work, an allegorical poem, called 'The Cherry and the Slae' (or Sloe). This poem is still popular in Scotland, and has been very frequently reprinted in a cheap form. It, and the author's sonnets and other poems, are both lively in fancy and pleasing in versification. In 1822 there appeared at Edinburgh a neat edition of all his poems, edited by Mr. Laing, with a biographical preface by Dr. Irving.

MONTIA, a genus of plants named in honour of Dr. Joseph Monti, professor of botany and prefect of the medical garden at Bologna. He paid much attention to the scientific arrangement of the Gramineæ and Cyperaceæ. He published also a catalogue of the plants in the botanic garden at Bologna, in which he described several new species. The following are the principal works which he published:—1, 'Catalogi Stirpium agri Bononiensis Prodromus, Gramina et adfinia complectens,' Bononiæ, 1719, 4to. 2, 'Indices Horti Bononiensis ad Usum Demonstrationum quæ in Horto Bononiæ quotannis habentur,' Bononiæ, 1724, 4to.

The genus Montia belongs to the natural order Portulaceæ, and has a persistent calyx of 2 sepals; a corolla 5-parted with 3 segments smaller than the others, with the tube split to the base in front; 3 stamens inserted in the throat and opposite to the smaller segments of the corolla; the ovary turbinate; the style very short; the stigmas 3, downy; the capsule of 1 cell with 3 valves and 3 seeds. There is but one species of this genus, *M. fontana*, which is a native of Great Britain. It is also found in North and South America in bogs, ponds, and ditches; and is commonly known by the name of water-chickweed. It closely resembles the species of the genus Claytonia.

(Babington, *Manual of British Botany*.)

MONTO'RSOLI, FRA GIOVANN' ANGELO, a celebrated Italian sculptor, was born in 1507, or about the beginning of the sixteenth century, at Montorsoli near Florence, on the road to Bologna, a villa belonging to his father Michele d' Angelo da Poggibonzi. He was first instructed by Andrea da Fiesole, with whom he lived three years. After the death of his father he found employment at Rome, at Perugia, and at Volterra, where he assisted in making the monument to Raffaello Maffei. He was next employed by Michelangelo in the church of San Lorenzo at Florence, and gained the admiration and lasting friendship of the great Florentine. In 1527 Montorsoli had a strong disposition to turn as it appeared to him to the only life in which peace was to be obtained; but after trying in vain several convents, he fixed, in 1530, upon the brotherhood of the Nunziata at Florence, and became a friar of the order dei Servi della Nunziata. Shortly after he had taken up his abode in this convent, he was called to Rome by Clement VII. to restore several antient monuments, much to the dissatisfaction of his brothers of the Nunziata: he had been recommended to the pope by Michelangelo. Montorsoli restored the Laocoon, to which he made the right arm, and he made the left arm of the Apollo, and executed other restorations. When these and a statue of the pope were finished, he returned to Florence with Michelangelo to complete the statues and other sculptures of the sacristy and library of San Lorenzo, of which his best is San Cosimo. After the death of Clement, Montorsoli again joined Michelangelo at Rome and assisted him in the works of the monument of Julius II.; but while engaged on this work he was invited by Cardinal Turnone, and advised by Michelangelo, to go with the cardinal to Paris, to Francis I., who commissioned him to make four great statues, but owing to difficulties with the treasury and servants of the court in Francis's absence, Montorsoli left Paris and returned to Florence without executing these works. After completing several good works in Florence and its neighbourhood, he went by Rome to Naples, and there constructed the tomb of Jacopo Sannazzaro. He next finished at Genoa the statue of Andrea Doria which was commenced by Baccio Bandinelli; and ornamented the church of San Matteo there with many works. Upon the completion of these works he returned to Michelangelo at Rome, but departed again soon afterwards, in 1547, for Messina, where he was employed to make a grand fountain for the place in front of the cathedral. The principal basin is thirty-four palms in diameter, and is ornamented on its twenty irregular sides with twenty bassi-rilievi illustrating the various antient fables connected with the watery element: it has besides the usual marine monsters and other designs contrived for jetting the water: the whole fountain is crowned by a figure of Orion with the arms of Messina engraved upon his shield. The successful completion of this great work induced the Messinese to commission Montorsoli to erect another fountain in the front of the Dogana (Custom-house) close to the sea. He designed also at Messina the church of San Lorenzo, a lighthouse, aqueducts, and many other considerable works in architecture and in sculpture. But in 1557 by a decree of Pope Paul IV., all religious persons, or all who had taken holy orders and were living at large in the world without respect to their religious character, were ordered to return to their convents and reassume their religious habits; and Montorsoli was accordingly obliged to leave many works unfinished, which he intrusted to his pupil Martino, and he returned to his convent at Florence. He was however shortly afterwards called to Bologna to construct there the high altar of the church of his own order dei Servi, which he completed with great magnificence in twenty-eight months. He returned to Florence in 1561, and being rich he built a common sepulchre for artists in the chapter-house of the convent of the Nunziata, with the requisite endowment for regular masses at appointed times, and gave the whole sepulchre, chapter, and chapel, to the then almost decayed society of St. Luke, or company of painters, &c., which upon the completion of the sepulchre, was at a solemn feast celebrated by forty-eight of the principal artists of Florence, re-established by the consent and authority of the Duke Cosmo I. upon a firmer and permanent basis; and the society still subsists as the Academy of Florence, though since that time it has been considerably enriched and endowed by successive Dukes of Tuscany. Montorsoli died, says Vasari, on the last day of August 1563, aged fifty-six.

(Vasari, *Vite de' Pittori*, &c.)

MORCELLI, STE'FANO ANTO'NIO, born at Chiari, near Brescia, in 1737, studied at Rome, entered the Order of the Jesuits, was sent to Ragusa, and afterwards returned to Rome, when he was made Professor of Rhetoric in the Roman College. After the suppression of the Order of the Jesuits in 1773, he became librarian to Cardinal Alessandro Albani, and then wrote his work 'De Stilo Inscriptionum Latinarum Libri III.,' Rome, 1781. In 1790 he was elected Provost of the Chapter of his native town, Chiari, where he busied himself in doing good to his townsmen, and for their sake he afterwards refused the see of Ragusa, which had been offered to him. He founded an institution for the gratuitous education of young girls; he gave in his life-time his own select library to the town of Chiari; he repaired and embellished the churches of the same town, and was very charitable towards the poor. He died at Chiari, in 1821. Besides his work on inscriptions already noticed, he wrote: 1, 'Inscriptiones Commentariis subjectis.' 2, 'Parergon Inscriptionum Novissimarum.' 3, 'Kalendarium Ecclesiæ Constantinopolitanæ cum Commentariis illustratum,' from an antient MS. anterior to the schism between the Eastern and Western churches. Morcelli translated the MS. from Greek into Latin, adding his own commentaries, and rendering it a valuable work on church history. 4, 'Explanatio Ecclesiastica Sancti Gregorii.' This Gregory was one of the earliest bishops of Agrigentum. 5, 'Africa Christiana,' 3 vols. 4to., Brescia, 1816. This is another important work on church history, from A.D. 197 till A.D. 697. It may be styled the Fasti of the Christian Churches in Northern Africa.

Morcelli's works on Inscriptions have been collected and published together: 'Opera Epigraphica,' 5 vols., Padua, 1818-25, and Professor Schiassi has added to them a 'Lexicon Epigraphicum Morcellianum,' in Latin and Italian.

Morcelli wrote also a book of epigrams—'Electorum Libri II.;' and various dissertations on Roman antiquities.

(Lombardi, *Storia della Letteratura Italiana*.)

MORDVINES. [RUSSIA, P. C.]

MORELLI, CO'SIMO, an Italian architect of considerable note among those of the last century, was born at Imola in 1732. He was the son of Domenico Morelli (an architect also), and studied under Domenico Trifogli, who executed several works of merit at Imola. It was Cosimo's good fortune to obtain powerful patronage at the very outset of his professional career,—first that of Gioan-Carlo Bandi, bishop of Imola, for whom he made designs for rebuilding the cathedral of that city, and through him, that of his nephew Giovanni Antonio Braschi, who was elevated to the papal throne in 1775, with the name of Pius VI. The new pontiff, who entertained a personal regard for Morelli himself, almost immediately appointed him city-architect at Cesena (the pope's native town), and among various other commissions commanded from him designs for a new sacristy at St. Peter's. If that and some other projects were not realized, the designs themselves obtained universal though transitory admiration. No art is more subject to blights than architecture, it being one in which the best ideas are often rejected. Yet as far as mere employment and number of works go, Morelli had no reason to complain,—rather to consider himself favoured beyond most of his contemporaries, as will appear from an enumeration of the principal structures executed by him, namely, the cathedral of Imola, the metropolitan church at Fermo, the duomo at Macerata, and the conventual church at Fossombrone, St. Petronio at Castel Bolognese, a church at Barbiano, that of the nuns of St. Chiara at Imola, and St. Maria in regola in the same city, and another church at Lugo, also some alterations in the metropolitan church at Ravenna. It happens, too, rather singularly, that Morelli was almost as much employed in theatrical as in ecclesiastical architecture. The buildings of this class erected by him are—the theatre of Imola (destroyed by fire a few years afterwards, but preserved in the volume of engravings of it published in 1780), Fermo, Jesi, and Osimo; also that of Ferrara, which is confidently claimed for him by some, although Foschini was likewise in some manner or other employed upon it. [FOSCHINI, P. C. S.] Besides the above works, he built the Palazzo Braschi at Rome, the Anguisola at Piacenza, the Berio at Naples, and the Cappi at Bologna; the façade of the Ridotto at Cesena, and the Hospital at Imola, the façade of the Palazzo Publico, and the Palazzo Vescovile. He would probably have done more, but for the unpropitious state of things in Italy for architecture towards the close of his life. He died, after a severe paralytic attack, in February, 1812.

(T. Papotti, in Tipaldo's *Biographia.*)

MORELLI, GIA'COMO, one of the most distinguished librarians of modern times, was born at Venice on the 14th of April, 1745. He was the son of poor parents, who were unable to give him a liberal education. It was against their will that he resolved to enter the church, although in all other respects he always showed the greatest deference to their wishes. He afterwards supplied the deficiencies of his education by private study; and the knowledge which he thus acquired was more substantial and extensive than that of any of his Italian contemporaries, though it was not till late in life that he became acquainted with the Greek and French languages. At an early period he pursued his private studies in the library of the family of the Zaniani, and his unremitting perseverance attracted the attention of the librarian de Rubeis, who soon became his adviser and faithful friend. After having read through the greater part of that library, his avidity to acquire knowledge led him to examine the other libraries of his native city to which he could gain access. His love of independence induced him to refuse several very advantageous offers that were made to him both by the church and by wealthy collectors of books at Venice, and he continued to live as a simple Abbé. He formed however an intimate friendship with the patrician Farsetti, of whose rich collection of MSS. he published a catalogue, under the title of 'Biblioteca Manuscritta del Bali T. G. Farsetti,' Venice, 1771-80, 2 vols. 12mo. While this work was in course of publication he also wrote 'Dissertazione Storica intorno alla Publica Libreria di S. Marco,' Venice, 1774, in which he discussed and solved a great many questions connected with the history of literature. He then prepared a similar work on the history of the library of the academy at Padua, whither he had accompanied his friend Farsetti; but the materials which he collected for that purpose were unfortunately left in the hands of Colle, the historiographer of that institution, through whose carelessness they were lost. In 1776 he published a catalogue of the MSS. of antient writers which were in the library of the Narni family; and somewhat later a catalogue of the MSS. of Italian works contained in the same library. These works alone would have sufficed to secure to Morelli an honourable place among the eminent bibliographers of modern times; but he acquired a still greater reputation as librarian of the library of St. Mark, an office which he received in 1778, and which he held until his death, which happened on the 5th of May, 1819. He devoted himself with the greatest zeal to the completion and arrangement of that famous library; but during the French rule in Italy he had, to his great vexation, to superintend the removal of the library from its venerable antient building to a new one, the splendour and convenience of which however consoled him in some measure for the loss of the former building. In 1795 he discovered a considerable fragment of the 55th book of Dion Cassius, which he published at Bassano, together with new various readings of other books of the same historian. This little work was afterwards (in 1800) republished at Paris, uniform with Reimarus' edition of Dion Cassius. The work which exhibits his extensive knowledge and his critical acumen in the strongest light is his 'Bibliotheca Manuscripta Graeca et Latina,' of which however only one volume was published at Bassano (1802), although he had collected materials for several more volumes. His last production was 'Epistolae Septem variae Eruditionis,' Padua, 1819. Abbé Morelli is acknowledged by all who had occasion to visit the library of St. Mark during the time that he was at the head of it, to have been the most amiable, kind, and obliging person, and his vast learning was equalled only by his extraordinary modesty. After his death there appeared, 'Operette ora insieme con Opuscoli di Antichi Scrittori,' Venice, 1820, 3 vols. 8vo.

(Bettio, *Orazione recitata nelle solenne Esequie nella Chiesa Patriarcale di Venezia*, Venice, 1819.)

MORETON BAY lies on the eastern coast of Australia, in New South Wales, and extends from north to south over more than a degree of latitude, chiefly between 27° and 28° S. lat.; one arm passes north of 27°. It is one of the most spacious bays on that coast, being probably more than 80 miles long, whilst the width of the main body, lying between 27° and 27° 30′, exceeds 10 miles. Those portions of the bay which lie farther south and north are comparatively narrow branches, being hardly anywhere more than three miles across. The bay is formed by two long islands, which extend lengthwise parallel to the shore of the mainland. The southern island, called Stradbroke, is about 40 miles long, and the northern, Moreton, 24 miles. In width these islands vary between two and four miles. They are moderately elevated above the sea-level, and contain some high hills. Of the three entrances leading between these islands to the bay, the most southern can only be passed by boats, but the two others admit large vessels. That between Stradbroke and Moreton islands is called South Passage, and that between the last-named island and the projecting cape of the mainland, North Passage. Two moderately large rivers fall into the bay: the northern, called Brisbane, may run more than a hundred miles, and the southern, Teviot, about seventy miles. A rather high range of hills lies between them, which appears to be connected with the high land situated at the distance of about eighty miles from the sea, and forming the eastern edge of the elevated table-land of the interior of New South Wales. The country between the ranges and on the banks of the river is clothed with woods which contain many large trees covered with climbing plants of various descriptions; the soil appears to be good. Since 1839 settlements have been formed on them, of which however no account has reached us lately. It was then supposed, that wheat, maize, tobacco, sugar, indigo, grapes, and many other articles would be raised in that part of the colony, as the climate approaches that of the inter-tropical countries. The elevation of the mountains at the back of the lower tract, screens this country from the hot winds that prevail during a great part of the year on the elevated table-land, and to the vicinity of the sea the frequency of showers may be attributed, which fall here when other districts are parched with drought.

(*Parliamentary Papers*, 1841.)

MORGHEN, RAPHAEL SANZIO, Cavaliere, one of the most celebrated engravers of recent times, was born at Florence, June 19, 1758, by his own account, according to the authority of Niccolo Palmerini, his pupil, who published a complete catalogue of his works.

Morghen's grandfather was a lace-merchant of Montpellier, who married a Genoese wife and settled in Florence, where he had two sons, Filippo and Giovanni. They both followed the arts: Filippo, the elder, and the father of the subject of this notice, was an engraver. He settled early in Naples, and married there the daughter of Francesco Lisni, court-painter to Charles III., and by her had several daughters and an only son, Raphael Sanzio, who became one of the most distinguished engravers of his own or any other time.

Filippo must have made a visit with his wife to Florence some time after his marriage, and before the birth of Raphael, as Florence was his birthplace by his own account.

Raphael Morghen's first works were small landscapes and prints of the neighbourhood of Naples: he was very early instructed by his father in the first principles of his art, and he could engrave a tolerable plate as early as his twelfth year. But his first engravings of consequence were seven plates from the masks of the carnival of 1778, the Pilgrimage of the Grand Signor to Mecca; a work of such extraordinary merit for a youth of twenty, that his father deemed it right that he should have the benefit of the best instruction that could be procured, and sent him accordingly to the celebrated Volpato at Rome, who gave him at first a print of E. Sadeler's, of Christ and Mary Magdalen in the Garden, to copy. He engraved also about this time Gavin Hamilton's allegoric figure of Painting, for the brothers Hackert. In 1781 he engraved Raphael's allegoric figures of Poetry and Theology, from the Vatican. In the same year he married Volpato's only daughter Domenica; and assisted Volpato on his plate of the Parnassus of Raphael, or the historical illustration of Poetry, in the Stanze of the Vatican. In 1787 he engraved the Aurora, painted in fresco by Guido for the garden-house of the Palazzo Rospigliosi; but this, though one of his principal works, is not one of his best. Though some of its parts are better, the Hours around the chariot of the Sun are less graceful and less buoyant than those in the print by Fry, executed long before it. The extremities, especially the hands, are in both badly drawn, but those of Morghen's print are inferior to Fry's, and the faces want regularity and beauty. This plate however was retouched by the school of Volpato, and is said to have been damaged. The impressions without the words 'In Aedibus Rospigliosis,' and those taken before the retouch, are much more valuable than any of those taken afterwards. In 1790 Morghen visited Naples, and engraved a portrait of his father. The Neapolitan court wished to persuade him to reside at Naples in 1792, and offered the inducement of a salary of 600 ducats; but Morghen accepted in preference an invitation from the Grand Duke of Tuscany to Florence, and established himself there in 1793, with a salary of 400 scudi and free apartments in the town, under the sole condition that he should keep a public school; with the privilege of engraving what he might choose, and his prints remaining his own property.

The first print engraved by him in Florence was the Madonna della Seggiola. In 1795 he commenced the celebrated Madonna del Sacco, after Andrea del Sarto, and Raphael's Transfiguration; but his time was much taken up by portrait commissions from the royal family of Florence. The first picture is in Florence; the second he engraved from a drawing by Tofanelli: he had commenced one from a copy by A. del Era; but upon comparing this with the original he found it very faulty, and he was forced to abandon what he had already done. This practice of engraving from copies and publishing the works produced as engraved from the original pictures, may be a custom with engravers, but it is a practice that cannot be justified, unless the original is not within the reach of the engraver, or unless the source be acknowledged upon the print. An engraver may commence his print from the print of another man if he has compared the copy with the original and found it to be exact; but an acknowledgment of the availed assistance is imperative in point of honour. A print which is sold as a faithful copy of a certain work of art, and is only the copy of a copy, without reference to the original, is virtually a forgery. Jordan, the Russian engraver, who has just completed a very large and excellent engraving of the Transfiguration, was actually engaged thirteen months in the Vatican making his chalk drawing from the picture, to execute his engraving from, and it was pronounced by all who saw it as exact a copy as could be made. All engravers cannot do this, but they can all ascertain whether the drawings they work from are approved copies or not.

Morghen's Transfiguration was not completed until 1812, when it appeared with a dedication to Napoleon, and the emperor invited the engraver to Paris, and honoured him with various presents. This print was originally sold at about twenty scudi, or four guineas, but the price afterwards very much increased, and reached, in some impressions, from 20*l.* to 30*l.* Jordan's print, however, will now materially interfere with the commercial value of Morghen's. The cast-away print was also finished by Morghen's brother, Antonio, but it is said that only two hundred impressions of it were ever printed: the plate came into the possession of Artaria and Co., at Mannheim. Though less correct, it has more technical effect as an engraving than the second print. Of the second print there are eight different kinds of impressions:—etchings, in five degrees of progress, in which additional portions are finished; fifteen impressions in which all is finished but the book in the hand of St. Andrew; impressions in the same degree of progress, with the inscription, 'Et transfiguratus est ante eos,' written with the needle; and, lastly, the completely finished prints. This engraving is a work of great labour, of great skill, and of extraordinary merit as far as the execution of the lines goes, yet it leaves much to be desired; it wants tone and aerial perspective, it is hard and metallic, and, as a whole, is flat, though the individual parts are beautifully rounded. Morghen was engaged while this work was in progress, three years, upon a print of the Last Supper by Lionardo da Vinci, and this is his masterpiece. The flatness and equality of his general execution is not perceptible or detrimental to this work, as the picture is comparatively in one plain, and it is sufficiently large to admit of great detail of expression: it was made from a drawing by Teodoro Matteini. Later impressions are retouched; the first and by far the most valuable have no comma after the word *vobis—dico vobis*, &c. The last impressions are also without the comma, which was removed.

Raphael Morghen died at Florence, April 8, 1833, and an extravagantly eulogistic inscription has been placed upon his tomb. His pupil Palmerini published at Florence, in 1824, a life and portrait of him, with a list of his works, 'Catalogo delle Opere d' Intaglio di Raffaello Morghen, raccolte ed illustrate da N. Palmerini, &c.' Morghen has engraved, according to this list, 73 portraits; 47 biblical and religious pieces; 44 historical and mythological pieces; 24 views and landscapes; and 13 vignettes and crests, &c.; in all 201 pieces: there are probably others omitted in the catalogue. Dr. Nagler has reprinted the list entire in his *Künstler Lexicon*.

MORHOF, DANIEL GEORGE, is well known as the author of a very useful work entitled 'Polyhistor.' A Life of him, extending to 78 closely printed quarto pages, is prefixed, under the title of 'Prolegomena,' to the second volume of that work, by the editor, John Moller, rector of the grammar-school of Flensburg in Schleswig. From this copious dissertation it appears that Morhof was born at Wismar, in the duchy of Mecklenburg-Schwerin, on the 6th of February, 1639. His father was Joachim Morhof, notary public, assistant-clerk to the town-council (Senatui urbano a judicii inferioris secretis), who had been born of humble parentage in the Mark of Brandenburg, and is described as distinguished both for his probity and his learning; his mother was Agnes, daughter of Daniel Hintzius, a respectable merchant. Young Morhof was taught his Latin rudiments at home by his father, who also made him early familiar with the Bible and with the elements of general history. Before he knew his alphabet he was fond of music, in which he afterwards made remarkable progress. When he was in due time sent to the Athenaeum, or academy, of his native town, he distinguished himself not only in Latin and Greek, but in history and in the mathematical sciences. In March, 1655, he was sent to the Royal Paedagogium of Stettin; whence after two years he proceeded to the university of Rostock to study law. He continued however to give a great part of his time to elegant literature, and especially to poetry, composing verses both in Latin and German with great facility and much to the admiration of his friends. In 1660 he obtained the professorship of poetry in the university. In the end of the same year, before commencing his public prelections, he visited Holland and England, remaining for some time in this country that he might have the use of the Bodleian Library. He also addressed a congratulatory Latin poem to Charles II. on his restoration. On his return to the Continent he was made doctor of laws by the University of Franeker, in Friesland, on the 26th of September, 1661. He greatly distinguished himself by the manner in which he performed the duties of his professorship; and in 1665 he was invited and induced to accept the appointment of Public Doctor of Eloquence and Poetry in the newly founded university of Kiel in Holstein. In the summer of 1670 he made a second journey to Holland and England; and stayed for a considerable time in London, where he enjoyed the society, among others, of Boyle, Isaac Vossius, and Oldenburg, the secretary of the Royal Society. On the 23rd of October, 1671, he married, at Kiel, Margaret, daughter of Caspar a Degingk, senator of Lübeck. She died in 1687, after having brought him four sons; of whom the second, George Marquard, and the fourth, Eric George, died young; the first, Caspar Daniel, and the third, Frederic, survived their father.

In 1673 Morhof succeeded to the professorship of history; and in 1680 he was appointed librarian to the university. The latter charge to so devoted a reader was peculiarly gratifying. From the time of the loss of his wife, however, his health began to break down. In 1690 he was attacked by a serious illness; and when he had partially recovered, in the spring of the following year he undertook an ill-advised journey to the mineral waters of Pyrmont, from which he never returned: he only got back as far as Lübeck, and there breathed his last, on the 30th of July, 1691, in the fifty-third year of his age.

Morhof was a very voluminous author. The account of his writings, published and unpublished, fills nearly fifty pages of the memoir by his friend Moller. His first production consisted of two Latin poems, published together in 1657. This was followed by an academical disquisition entitled 'Diatriba de Morbis et eorum Remediis Juridica,' in 1658; and afterwards, among other works, by an octavo volume entitled 'Epigrammatum et Jocorum Centuria Prima,' in 1659; 'Diatribe Philologica de Novo Anno ejusque Ritibus,' in 1663; a curious defence of the miraculous powers claimed by the kings of England and France in the cure of the king's-evil, under the title of 'Princeps Medicus,' in 1665; a volume of 'Miscellanea Poetica,' in 1666; another entitled 'Venerum, sive Epithalamiorum, Liber,' in 1667; another entitled 'Funerum Liber,' in the same year; several other volumes of Latin verse at various times; a translation into Latin of several of Boyle's tracts, in 1671; 'Disputatio de Sole Igneo Academica,' in 1672; in 1673 'Epistola de Transmutatione Metallorum,' (from which it is evident that he was a believer in the philosopher's stone); in 1682, an 8vo. volume, in German, on the history of the German language and poetry (*Unterricht von der Deutschen Sprache und Poesie*, &c.), with a collection of his own German verses (*Teutsche Gedichte*); in 1684, 'Liber de Patavinitate Livianâ;' in 1686, 'Otiorum Divinorum, seu Carminum Sacrorum, Liber;' and the first and second books of his 'Polyhistor,' in 1688. After his death appeared, among other works, in 1694, 'D. G. Morhofii CVIII. Quaestiones Chymicae, ex variis Autoribus Chymicis collectae;' in 1697, 'Morhofii Opera Poetica Latina omnia;' in 1698, 'Morhofii Orationes et Programmata;' in 1699, 'Morhofii Dissertationes Academicae et Epistolicae.' For the works which he left in manuscript, mostly in an unfinished state, and which have never been printed, we must refer to the ample pages of his biographer. They are far too numerous to be noticed here. So great a quantity of literary production in so short a life sufficiently attests Morhof's diligence and facility. His judgment, however, appears to have been hardly in proportion to his acquirements; and even his learning was more remarkable for its superficial extent than for its depth. Of all the mass of authorship to which his name is attached, his 'Polyhistor' is, we believe, the only portion that is still held in any esteem.

The full title of this work is 'Polyhistor Literarius, Philosophicus, et Practicus. Of the 'Polyhistor Literarius,' intended to form the first volume, Two Books, as already mentioned, were published by the author himself in 1688. They were brought out in 4to., at Lübeck. The First is entitled 'Bibliothecarius;' the Second, 'Methodicus.' As reprinted in the last edition of the work they make together 588 pages. A Third Book, entitled Παρασκευαστικος, was printed from Morhof's manuscript at Lübeck in 1692, with a re-impression of the two preceding Books. It extends to 156 pages. The remainder of the first volume, consisting of Book IV., entitled 'Grammaticus,' (206 pp.); Book V., entitled 'Criticus,' (20 pp.); Book VI., entitled 'Oratorius,' (60 pp.); and Book VII., entitled 'Poeticus' (72 pp.), was compiled from notes of Morhof's lectures, by Moller and John Frickius, professor of theology at Ulm; they also added the 'Polyhistor Philosophicus,' in Five Books; and the 'Polyhistor Practicus,' in Seven Books; and published the completed work in two vols. 4to. in 1704. A new edition of the whole work was produced in two vols. 4to., by John Albert Fabricius, in 1731; and another edition in 4to., by the same editor, in 1747. All the editions have been published at Lübeck. With the ample indexes which Fabricius has appended (though the plan of notation is rather complicated), and with the corrections and additions which it has received from his extensive and accurate learning, the 'Polyhistor' is still a useful survey of universal literature down to the middle of the last century. As in almost all such works, however, some subjects which happened to be favourites with the author or his editors, are treated at disproportionate length, while others of greater real importance are too summarily dismissed.

MORO, ANTO'NI, or Sir Antony More, was born at Utrecht, about the year 1525, and was the pupil of Joan Schoorel. He obtained, while still young, a great reputation at Rome, especially as a portrait painter, and when the Emperor Charles V. requested the Cardinal Granvelle to send a painter to Lisbon, to paint the future bride of his son Philip, the cardinal selected More. He was introduced to the Emperor, at Madrid, in 1552, painted Philip's portrait there, and, at Lisbon, painted besides the Infanta Mary, King John III., and the emperor's youngest sister, Queen Catherine of Portugal; for which he received 600 ducats and a very valuable gold chain as a present. Van Mander says that his usual price for a portrait was 100 ducats, which at that time was a very large sum.

After a short interval, in 1554, More was sent to paint another bride of Philip's, Queen Mary of England: for this picture he was also richly rewarded, says Van Mander, and had a salary of 100*l.* per annum settled upon him, as painter to the King and Queen (Walpole says 100*l.* per quarter). More remained in England during the reign of Queen Mary, by whom he was probably knighted, and he painted several portraits of her and many of the English nobility of the time, some of which are at Hampton Court, and many others are still in the private collections of the descendants of the families. Some of his works doubtless pass as Holbein's, but More was much inferior to Holbein. After the death of Mary, in 1558, More rejoined Philip in Spain, and appears to have lived on such terms of familiarity with the king, that, upon an occasion, in the year 1560, when Philip struck him with his open hand on the shoulder, the painter ventured to return a blow with his mahlstick, but he soon repented of his familiarity, and was heartily glad to escape with temporary banishment. Philip, however, sent to recal him, and the king's messenger overtook More on his way, but the painter excused himself, not daring to trust himself again within Philip's power. Philip wrote to him in the Netherlands, but, through the Duke of Alva, with a similar result. More had entered the service of the Duke of Alva, who sent for him from Utrecht, and he was appointed by the duke receiver-general of the revenues of West Flanders, an appointment, says Van Mander, which so elated him, that he made a bonfire of all his painting materials at Utrecht, and made presents to all his friends. Some suppose from this that he gave up painting; but so far from this, he was constantly painting, especially portraits of women, for the duke, at Brussels, whose high position enabled him to reward the painter with a public office for private services. The whole of More's family was also richly provided for, by Philip, or by the duke.

More died at Antwerp, in 1581, aged fifty-six, while engaged on a picture of the Circumcision, for the church of Notre Dame there, and it was left unfinished. More painted chiefly portraits; there are, however, also several good figure pieces by him, but they are painted in the prevailing dry style of that time in the Netherlands, and with its hard positive colouring. Yet he made a good copy for Philip, of Titian's Danaë, which is now at Madrid. There is much confusion about the dates of More's birth and death, some placing his birth in 1512; the above, however, is the account in the second edition of Van Mander, where it is fully explained in a note. More's portrait is in the Florentine gallery of painters' portraits.

(Van Mander, *Het Leven der Schilders*, &c., 1764.)

MORO'NI, GIAMBATTISTA, a celebrated Italian historical and portrait painter, was born about 1510, at Albino in the territory of Bergamo, and was the scholar of Moretto da Brescia, whom he did not equal in composition, but surpassed as a portrait painter. In this last branch he was inferior to Titian only in his time, and that great painter is said to have repeatedly recommended applicants to him to go to Moroni. The heads and draperies of his portraits are beautiful: the hands might be improved. In his historical pieces he belongs rather to the Milanese school than the Venetian. The date of his death is not known, but his works range, according to Count Tassi, from 1557 to 1578.

(Tassi, *Vite de' Pittori Bergamaschi*, &c.; Lanzi, *Storia Pittorica*, &c.)

MORPETH, a municipal and parliamentary borough in the township and parish of Morpeth, in the western division of Morpeth ward, in the county of Northumberland; 302

miles from the General Post-office, London, by the former mail-coach road through Ware, Huntingdon, Grantham, Newark, Doncaster, York, Thirsk, Northallerton, Durham, and Newcastle-upon-Tyne; or 331 miles—namely, 307 miles by railway through Rugby to Newcastle, and 24 miles from thence by coach: it is on the road to Berwick-upon-Tweed and Edinburgh. The parish of Morpeth comprehends an area of 7600 acres, and is partly in the east and west divisions of Castle ward, and partly in the western division of Morpeth ward. The population at the different enumerations in the present century was as follows:—1801, 3707; 1811, 4098; 1821, 4292; 1831, 4797; 1841, 4237. It is divided into eight townships—Hepscott or Liepscott and Morpeth Castle, (the latter having Catchburn and Stobhill united with it,) in the east division of Castle ward; Newminster Abbey, Shilvington, Tranwell and High-church, and Twizell in the west division of the same ward; and Morpeth and Buller's-green in the west division of Morpeth ward. The boundaries of the municipal borough include about half of the area, and nearly all the population of Morpeth township, and a small waste portion of the township of Newminster Abbey; the town is chiefly in the borough, but a portion of it is in the township of Buller's Green. The number of houses and persons in these two townships nearly coincides with the houses and population of the town. The return in 1831 and 1841 were as follows:—

		Houses.			Population.	
		Inhabit.	Uninhab.	Buildg.	Families.	Persons.
In 1831.						
Morpeth Township	Acres.	560	7	1	897	3890
Buller's Green ditto	900	52	7	0	57	203
	Total	612	14	1	954	4093
In 1841.						
Morpeth Township	Acres.	588	42	0	Not given.	3441
Buller's Green ditto	900	33	11	0	Ditto	169
	Total	621	53			3610

The diminution of the population, 483, or nearly 12 per cent., in ten years, and the circumstance that there were no houses building in 1841, show the decline which had taken place. The parliamentary borough, as regulated by the Boundary Act, comprises the parish of Morpeth, excepting the townships of Shilvington and Twizell (population of the two 151 in 1831, 137 in 1841), and the adjacent parish of Bedlington, or Bedlingtonshire (population in 1831, 2120; in 1841, 3155), a detached portion of the county of Durham. The population of the parliamentary borough in 1831 was therefore 6766; and in 1841, 7255.

Morpeth town stands in a sort of peninsula formed by the windings of the river Wansbeck, which surrounds the town on the west, south, and east sides, but is not navigable. The road from Newcastle enters the town from the south by an elegant bridge of three arches over the river, erected from the designs of Mr. Telford, and there is a suspension bridge on the west side. The streets are irregularly laid out, and, when the Municipal Corporations' Commissioners made their report (1835), were not lighted: they were formerly indifferently paved with pebbles, but in 1828 the pavement was taken up and the streets macadamised, to the great comfort of the townspeople and travellers. The town is supplied with water from a spring at Stob-hill. There are not many good houses in the town. The church is nearly half a mile from the town, on the south side of the river: it is in the style of the fourteenth century, and consists of a nave and chancel, and a western tower engaged with the nave: few old churches are more destitute of objects of interest, architectural or antiquarian. In the spacious churchyard is an antient octagonal cross, but little injured. In the town, close to the bridge, is an antient chapel, part of which is used for a grammar-school, and part is still used as a chapel-of-ease for performance of divine service. In a suburb of the town, on the south side of the bridge, on the east side of the road, is the gaol and house of correction for the county, erected about twenty years since, at a cost of 70,000*l.* It is an octagonal building, entirely of stone, in a dry and elevated site. The average number of prisoners in the year 1842-3 was 80, of whom 10 were debtors. The Gateway is an imposing mass of building and contains the chapel, the sessions-house or hall for county business, in which the Easter sessions for the county are held, and other apartments. Near the gaol, on the opposite side of the road, are the remains of Morpeth Castle, a rude and strong building, of which the gateway-house and the outer wall, now much shattered, are still standing; the area enclosed by them, 82 yards by 53, is occupied as a nursery-ground. The town-hall, a building by Sir John Vanburgh, was used as a sessions-house until the erection of the present gaol. There are a Roman Catholic chapel; and meeting-houses for Presbyterians, Independents, and Methodists. The Rev. John Horsley, the antiquary, author of the 'Britannia Romana,' was minister of the Presbyterian congregation from 1729 till his death in 1731, at the age of forty-six. The trade of Morpeth is not of much importance; but there is a good weekly market for live stock on Wednesday: the weekly sale of oxen is 200; of sheep and lambs, 2500. There are a dispensary, a savings-bank, a subscription library, and a Mechanical and Scientific Institution. Races are held yearly on the first week in September, on a course on Cotting-wood, north of the town. The race-course is about a mile and a quarter in circuit.

Morpeth is a borough by prescription. Under the Municipal Corporations' Reform Act, it has 4 aldermen and 12 councillors, and is not to have a commission of the peace except on petition and grant. The borough first sent members to parliament in 1553. It returned two down to the time of the Reform Act, when it was reduced to one. By the Boundary Act its limits for parliamentary purposes were enlarged from the existing municipal boundaries to the extent already described. The number of registered electors was in 1835-6, 354; in 1839-40, 363; in 1842-3, 428, namely 142 freemen and 286 ten-pound householders. Morpeth is a polling-station for the northern division of the county of Northumberland.

The town of Morpeth is not noticed in history till the reign of John (A.D. 1199), who granted a charter for a fair and market; it was burnt by John A.D. 1216, during his war with the barons. In the civil war of Charles I., Morpeth Castle was occupied by a body of the Scottish Covenanters, from whom it was taken in 1644 by the Marquis of Montrose. The late Dr. Morrison, the eminent Chinese scholar, was a native of Morpeth. The town gives the title of Viscount to the Earl of Carlisle, and by courtesy to his eldest son.

The living of Morpeth is a rectory, with the perpetual curacy of Ulgham, in the rural deanery of Morpeth, in the archdeaconry of Lindisfarne, in the diocese of Durham: the annual value of the benefice is 1611*l.*, with a glebe-house.

There were in the borough in 1833 thirteen day-schools with 448 to 458 scholars, viz. 260 to 270 boys and 188 girls; giving less than one-eighth of the population under daily instruction. Of the day-schools one, with 43 boys, was a free grammar-school founded and endowed by Edward VI.: two others were supported by the corporation. There were four Sunday-schools with 464 scholars, viz. 209 boys and 255 girls. Lending libraries are attached to two Sunday-schools; one (that of the Church school) is for the general use of the parish. A library of little value is attached to the grammar-school.

(*Parliamentary Papers*; Hodgson, *History of Northumberland.*)

MORTON, THOMAS, was born in 1764, in the county of Durham. His parents having died while he was young, his uncle, Mr. Maddison, a stockbroker in London, took him into his care. He was educated at the Soho Square Academy, celebrated for the annual theatrical performances of the pupils, several of whom became distinguished actors. He was afterwards entered a student of Lincoln's Inn, but the fondness for theatrical amusements which he had contracted at school was not to be subdued; he became a constant play-goer, and directed his studies to the drama rather than the law. Having written a dramatic piece which was favourably received, he abandoned the legal profession without having been called to the bar.

Morton thenceforward devoted himself entirely to play-writing, and became one of the most successful of modern dramatists. So great was his reputation and the confidence of managers in his power of pleasing an audience, that when his comedy of 'Town and Country' was to be brought out in 1807, Mr. Harris, the lessee of Covent-Garden Theatre, gave him 1000*l.* for the play before the parts were written out for rehearsal, taking on himself all risk of failure. Out of fourteen or fifteen comedies, comic-operas, and farces, five or six still continue to be stock-pieces at almost every theatre where the regular English drama is performed.

The following is a list of his plays, perhaps incomplete as to two or three of the later productions: 'Columbus,' 1792; 'Children in the Wood,' 1793; 'Zorinski,' 1795; 'Way to get Married,' 1796; 'Cure for the Heart Ache,' 1797;

'Speed the Plough,' 1798; 'Secrets worth Knowing,' 1798; 'The Blind Girl,' 1801; 'School of Reform,' 1805; 'Town and Country,' 1807; 'Roland for an Oliver,' 1819; 'School for Grown Children,' 1826; 'Invincibles,' 1828.

Morton was a respectable man, of regular and orderly habits. His conversation was sprightly, and abounded in anecdote. He was fond of cricket-playing, and was a constant attendant at the cricket-grounds, where he enjoyed his favourite exercise. He died March 28, 1838, in his seventy-fourth year, leaving a widow, three sons, and a daughter.

To those who are acquainted with Morton's plays only by reading them, his uniform and great success will probably be matter of surprise; to those who are engaged in dramatic writing, it must be no less a matter for investigation. Morton has no claim to the reputation of a great dramatist. He is deficient in the highest qualities of the art. He gives no true representations of character either in its broad and strong markings or in its nicer discriminations; he shows nothing of the real operation of motives, nothing of the genuine workings of feeling; his serious and his comic characters are alike artificial and exaggerated; they are strictly and peculiarly stage-characters, and anything resembling them in real life will rarely if ever be met with. But he has extraordinary dramatic tact: he foresees distinctly what may be effected in the performance, and the situations, as well as the characters are admirably contrived for displaying an actor's skill, abounding as they do in sudden transitions of feeling and bursts of passion, overflowings of excessive liveliness, or exhibitions of strange peculiarities, such indeed as have never been witnessed, but which, when well performed, are exceedingly amusing. His dialogue has no wit and little genuine humour, but is never languid or heavy; and the very speeches which when read produce a smile of contempt or a feeling of incredulous disgust, afforded to Lewis, Munden, Quick, Fawcett, Emery, John Kemble, and Edmund Kean, the medium by which they were enabled to exhibit the triumphs of the actor's art.

(*Gentleman's Magazine*, 1838; *Biographia Dramatica*, by Baker, Reed, and Jones; Inchbald's *British Theatre*.)

MOSER, GEORGE MICHAEL, R.A., gold-chaser and enameller, the first keeper of the Royal Academy of Arts in London, was born at Schaffhausen in Switzerland, in 1704. He came young to London, and was first employed as a chaser in gold and also of brass for the ornaments of cabinet-work, in which he obtained a great reputation. He was also an excellent medallist and a good painter in enamel, but he did not carry his works in this respect much beyond enamels for watchcases, in one of which he painted, for the king, George III., portraits of the Prince of Wales and the Bishop of Osnaburg. Moser's chief services were as keeper of the Royal Academy, who by virtue of his office is principal teacher of the students: the superintendence of and the instruction in the antique academy are the principal duties of the keeper. Before the foundation of the Royal Academy in 1768, Moser was for many years treasurer and manager of the private academy in St. Martin's Lane. He died in the beginning of 1783, and Sir Joshua Reynolds wrote an eulogium upon him, which is printed in Malone's Life of Sir Joshua. As a chaser in gold, says Sir Joshua, Moser was the first in his profession; and he had a universal knowledge in all branches of painting and sculpture. 'He may truly be said,' he continues, 'in every sense to have been the father of the present race of artists.' Hogarth, Rysbrack, Rouhilliac, Wills, Ellis, and Vanderbank, were Moser's early companions, all of whom he outlived.

Mary Moser, his only daughter, was a very distinguished flower painter, and is the only lady, besides Angelica Kauffman, who has ever been elected an Academician: she became afterwards Mrs. Lloyd. Miss Moser, says Smith, in his Life of Nollekens, was somewhat precise, but was at times a most cheerful companion: he has printed three of her letters, two to Mrs. Lloyd, the wife of the gentleman to whom she herself was afterwards married; and the other to Fuseli while in Rome, of whom she was said to have been an admirer. In one to the former, alluding to the absurd fashions of the beginning of the reign of George III., she says, 'Come to London and admire our plumes; we sweep the skies! a duchess wears six feathers, a lady four, and every milkmaid one at each corner of her cap. Fashion is grown a monster: pray tell your operator, that your hair must measure just three-quarters of a yard from the extremity of one wing to the other.' The second is chiefly on Lord Chesterfield's advice to his son: she says to her friend, 'If you have read Lord Chesterfield's letters, give me your opinion of them, and what you think of his lordship: for my part I admire wit and adore good manners, but at the same time, I should detest Lord Chesterfield, were he alive, young, and handsome, and my lover, if I supposed, as I do now, his wit was the result of thought, and that he had been practising the graces in the looking-glass.' In her letter to Fuseli she gives an account of the exhibition of the Royal Academy in the year 1770:—'Reynolds was like himself in pictures which you have seen; Gainsborough beyond himself in a portrait of a gentleman in a Vandyck habit; and Zoffany superior to everybody in a portrait of Garrick in the character of Abel Drugger, with two other figures, Subtle and Face. Sir Joshua agreed to give a hundred guineas for the picture; Lord Carlisle half an hour after offered Reynolds twenty to part with it, which the knight generously refused, resigned his intended purchase to the lord, and the emolument to his brother artist.—He is a gentleman! Angelica made a very great addition to the show, and Mr. Hamilton's picture of Briseïs parting from Achilles was very much admired; the Briseïs in taste, *à l'antique*, elegant and simple. Coates, Dance, Wilson, &c., as usual.'

Mary Moser decorated an entire room with flowers at Frogmore for Queen Charlotte, for which she received 900*l.*: the room was called Miss Moser's room. After her marriage she practised only as an amateur: she died at an advanced age in 1819. When West was reinstated in the chair of president of the Royal Academy, in 1803, there was one voice for Mrs. Lloyd, and when Fuseli was taxed with having given it, he said, says Knowles, his biographer, 'Well, suppose I did; she is eligible to the office; and is not one old woman as good as another?' West and Fuseli were ill-according spirits.

MOSQUITO COAST. This country, which has now taken a place among the independent countries of the American continent, is situated between 11° and 16° N. lat., and between 83° and 86° W. long. Along the coast of the Caribbean Sea it extends from the mouth of the Roman River (15° 57′ N. lat. and 85° 46′ W. long.) to Punta Gorda and the mouth of the Rama River (11° 30′ N. lat. and 83° 47′ W. long.). The sovereign of the country also claims the country farther south, lying between Punta Gorda and the Chiriqui Lagune, but the states of Costarica and Nicaragua dispute these claims. The line which separates the territories of the Mosquito Coast from the states of Honduras, Nicaragua, and Costarica, is not well determined; it is however presumed that it runs along the chain of mountains which traverse this part of America from south-east to north-west, and which is very imperfectly known. In such circumstances we must presume that the estimate of the area of the country, which without the disputed parts is stated to be 26,000 square miles, or nearly equal to Ireland in extent, and including the disputed districts, 34,000 square miles, is only to be considered as a vague approximation to the truth.

The most northern portion of the coast-line of this country, or that which extents from the Roman River to Point Patook, is high, but the remainder of the shore is low. Along this low line of coast a series of keys occur from ten to thirty-five miles from the shore. They are somewhat dangerous to inexperienced navigators, but shelter that narrow part of the sea which lies between them and the mainland from the oceanic swell, so that it can be navigated without danger by coasting vessels, as the depth of water varies between seven and fourteen fathoms. Vessels sailing from Jamaica to Cape Gracias a Dios pass between the islands of Old Providence and St. Andrews, and enter the above-mentioned channel by the wide opening in those parts between the keys.

From the mountain-range which forms the western boundary of the country several lateral branches run off, which terminate at the distance of eighteen to twenty-four miles from the sea. They do not appear to rise higher than from 1000 to 1500 feet above the sea-level, but they are very imperfectly known, with the exception of the most northern, which comes close up to the shore between the Roman River and Cape Patook. In these parts are several high peaks, as Carib Peak, which is about 4000 feet, the Poyas Peak, 3500 feet, and the Sugar-Loaf, 2000 feet above the sea-level.

Along the low coast the country is a level plain, slightly elevated above the sea, but on proceeding farther inland it rises in terraces, and here the plain is frequently interrupted by depressions and by elevated tracts which are connected with the mountain ranges. The terraces are furrowed by valleys scooped out by the currents of the rivers. The lower portions of the country are savannahs, without trees and frequently without bushes, but where the country rises and forms hills, it is overgrown with trees. In the vicinity of the sea the soil of the savannahs is light and lies on a layer of sea-sand, but nevertheless it produces excellent grass, which is ascribed to the waters which inundate this part of the country during the rainy season. Farther inland these plains have a richer soil, which consists of a light loam intermixed with a large proportion of black mould. The higher ground, especially near the banks of the river, and the lagunes, have a large mixture of sand, and these tracts are mostly overgrown with pitch-pine. But in other places they are composed of clay intermixed with mould, and in the woods which cover them a large number of mahogany-trees, cocoa-trees, caoutchouc, and other valuable trees are met with. The whole country, as far as it is known, presents a continual alternation of wooded lands and prairies.

The Mosquito Coast is drained by numerous rivers, which south of Cape Gracias a Dios run mostly to the east-south-east, but north of it they run north-east. Many of them are navigable to a considerable distance from their mouths, and it appears that rapids are only found near their sources. But the navigation is frequently impeded by the trees which are brought down during the rains, and when the waters decrease they are lodged in the bends of the river, where they are accumulated so as to form a dyke across the current. They are partly removed by the freshets, but are soon replaced by other trees. Most of the embouchures of the rivers form harbours, which however are only accessible to small vessels, as all those which do not fall into lagunes have bars across their mouths, on which at low-water there are in general only from three to four feet water during the dry season. In the rainy season the bars are partly removed, but the easterly trade-winds soon throw them up again, when the rivers have sunk to their lowest level, and the diminished force of the current cannot carry the matter far into the sea. Blewfields River, which falls into the lagune of the same name (12° N. lat.), and is said to run upwards of ninety miles, rises within the state of Nicaragua. Wanks or Segovia River also rises in Nicaragua, where it passes near the town of Matagalpa and Segovia. It is said to run 250 miles. Its mouth is near the Bay of Cape Gracias a Dios, and has a bar; but the river may be entered by a canal which unites it to the bay. It is said to be navigable to the boundary-line of Nicaragua.

The lagunes are a peculiar feature of this country. They are not shallow, stagnant collections of water, but deep lakes, connected with the sea by one or more straits, by which the tide enters them. They generally receive one stream, frequently several streams, and therefore a current is always observable, which sometimes runs strongly. Near the entrance of the lagunes the water is brackish, but in the interior, and especially near the mouths of the rivers, it is quite sweet. These sheets of water always extend parallel to the coast, and frequently approach one another, so that the natives in their light boats can travel to great distances, by hauling the boats over the narrow tracts of land which separate the lagunes. The lagunes form good harbours, but towards the middle of the dry season bars are found across the entrances, which however have much more water than the bars of the rivers. Owing to this circumstance, and because the lagunes do not exhale any dangerous vapours, the settlements have generally been made on their banks. The most extensive, from south to north, are Blewfield Lagune, into which the Blewfield River falls,—this lagune is upwards of fifty miles long, and from eight to fifteen miles across, and has from three to four fathoms water on its bar; Pearl Key Lagune, which is sixty miles long, and from sixteen to twenty miles wide; the bay at the Cape Gracias a Dios, which is of small dimensions, being only four miles long and three wide, but which forms a good harbour, with 22 feet water at the entrance and 17 feet in the interior, and excellent anchoring-ground; and Carataska Lagune, west of Cape Gracias a Dios, which is thirty-six miles long and from eight to ten wide, and from two to three fathoms deep: the bar across its mouth has only eight feet water, but close to the tongue of land which separates the lagune from the sea is a narrow channel, from two fathoms to two and a half deep. Four rivers of moderate size fall into this lagune.

The climate of the Mosquito Coast resembles that of Jamaica, in having two wet and two dry seasons, but they do not occur exactly in the same months, and differ somewhat in character. The autumnal rains, which in Jamaica occur in October and November, continue on the coast for four months, from November to February. They are heaviest in December, but even in that month only descend in showers: continual rains for twenty-four hours are of rare occurrence. In the middle of February these rains cease. Then follows the first dry season, which continues to the middle of June, and in which only slight showers are experienced, especially during the night. This season is succeeded by the summer rains, which continue to the end of July. They are not so heavy as in Jamaica, where they sometimes continue for several days and nights without intermission. On the coast the rains are heavy, but very short; they are however attended with heavy thunder-storms. From the commencement of August to the middle of October is the second dry season, in which only light showers occur at the beginning and towards the end of the season. The rainy months are November, December, January, and July; the dry months March, April, May, August, and September; and those in which showers alternate with dry weather, October, February, and June. The annual amount of rain which falls has not been ascertained, but it is certain that it exceeds the average of Europe, though the number of rainy days is not so large. In the coldest months (from September to February) the temperature varies between 66° and 70°, but descends occasionally to 62°, and even to 60°. In the three following months it varies between 70° and 80°, and rarely rises higher. In summer the thermometer ranges between 75° and 84°, sometimes rising to 86°. In autumn the range is between 72° and 84°. The difference between the temperature of the air in the day and night is very small. The eastern trade-winds, not being stopped by mountain-ranges near the shore, but passing over the inclined plane without impediment, impart to the air the same degree of heat which exists on the sea. To this circumstance, and to the absence of stagnant waters, the comparatively great salubrity of the climate is to be attributed, which is confirmed by all modern travellers who have resided for any length of time in the country, though contrary statements have been made by modern writers. During the long rains (November to February) northern winds prevail, but from the middle of February they decline to the east, where they constantly settle at the end of March, and during the three following months they blow with considerable force. In August and September they are light, variable, and interrupted by calms; and in October the wind passes between east and north, until it settles entirely in the last quarter. Dew is not frequent, and never heavy, but the thunder-storms are sometimes terrific. Hurricanes are not experienced, nor does it appear that earthquakes, even of a slight kind, have occurred, though most of the surrounding countries are frequently visited by them, especially Guatemala.

Vegetation is as vigorous as in any country between the tropics. The grasses with which the savannahs are clad often attain a height of five or six feet. The number of vegetables which are cultivated with success is great; the most common are plantains, bananas, arrow-root, Indian corn, yams, cacao, sugar-cane, rice, maize, tobacco, sweet potatoes, cotton, cassava or mandioc. Coffee, cocoa-nut trees, palm-oil trees, and orange and lime trees are planted; the woods contain a great number of trees whose fruits are edible, or which afford timber and cabinet-woods, or are useful in other respects. Such are the pine-apple tree, cabbage tree, fan palm tree, caoutchouc tree, avocado pear, pimento tree, live oak, sapotill tree, papaya tree, calabass tree, mameì tree, guajava tree, mangrove tree, cacao tree, silk cotton tree, mahogany tree, cedrele, yellow-wood tree, iron-wood tree, dog-wood, ebo tree, cashew tree, lassa tree, guaiaco tree, pock wood, rosewood tree, the castor-oil plant, brasilletto tree, and a few others. In the woods the indigo plant is found wild; vanilla and sarsaparilla are gathered, the last mentioned to such an extent as to afford a considerable article of export.

Cattle are very numerous and of a large size; horses abound, but they are not large; asses, sheep, and goats are not kept, but hogs are abundant. Fowls are numerous. Several kinds of monkeys are found in the woods on the banks of the rivers, where also the jaguar and the tiger-cat are met with. Other animals are the racoon, the opossum, grey squirrels, deer, and the manati. Alligators are found near the embouchures of all the rivers; lizards are common; the iguana is distinguished by its size, and is eaten by the natives. There are several kinds of snakes, four of which are stated to be poisonous. The land-turtles belong to the species Testudo tabulata, and are sometimes more than a foot long, but their flesh is less esteemed than that of the sea-turtles, of which great numbers are always to be met with on the keys opposite the coast, to which many boats from Jamaica and the Caymans resort, where they take especially green turtles (Chelonia midas) and hawks-bills (Chelonia caretta). The birds are imperfectly known. Among them are different kinds of parrots, the yellow-tail (Cassicus Montezuma, Less.), humming birds, the black vulture or John crow (Cathartes fœtens), and several kinds of pigeons. Several kinds of ducks and the pelican (Pelecanus fucus) have been noticed. Fish is abundant in the lagunes and rivers. Fifteen species are caught in the sea, thirteen in the lagunes, and perhaps more than ten in the rivers. The shark and the saw-fish (Pristis antiquorum) are frequent in the sea and the lagunes, and along the coast the flying-fish abounds. No shell-fish are noticed, except oysters. Crabs, crawfishs, and some kinds of lobsters are frequently met with. Honey is frequently used as sugar. Mosquitos are not common, which is ascribed to the strong winds that generally blow. Sand-flies, sand-fleas, and centipedes (Scolopendra morsitans) are common.

The majority of the inhabitants do not materially differ from the other savage tribes of America. But the ruling tribe, called Sambos, show evidently a strong mixture with the negro. The colour of the other tribes is a clear brown; but that of the Sambos is much darker, approaching sometimes to black; and whilst the black hair of the former is lank, that of the Sambos is curly, in some cases resembling wool. The Sambos have also thicker lips, and are stronger built. There exists a tradition, that a vessel containing a great number of negroes was cast away on this coast, that the negro males were killed by the natives, who married the negro women. Among them are also a few Caribbees, probably the descendants of those who, in 1797, were sent from the island of Dominica to that of Roatan, and who afterwards emigrated to the continent of America. They are shorter in stature than the other tribes, but stronger built, have a somewhat convex nose, and are distinguished by greater vivacity and industry. All the tribes, though they speak different dialects, distinguish themselves from other nations by the name of Misskitos, which the Europeans have changed into Mosquitos. The natives of this country live mostly on the produce of their fields, on which they cultivate maize, cassava, yams, plantains, pine-apples, cocoanut-trees, and some other fruits; but they eat also large quantities of fish, and the flesh of the wild animals which they kill, or of their cattle. They show considerable skill in making canoes, of which the larger kind, called dories, are frequently six or eight feet wide, and from thirty to forty feet long. They are made of a single trunk of a tree. Though in general very indolent, the natives are good seamen, and have frequently earned the praise of English naval officers, who have employed them and their canoes. They have also acquired some skill in weaving cotton-stuffs.

The commerce of the Mosquito Coast is carried on by a few English families which are settled there. They receive European goods for the market, commonly from Belize, but also by vessels sent from Jamaica and other English settlements in the neighbourhood. Vessels from Jamaica and the Cayman Islands to the keys along the coast to catch turtles, also import occasionally a few articles. In this manner the natives are supplied with some coarse linen and cotton stuffs, with very indifferent guns, gunpowder, balls and shot, some cutting instruments, as axes, knives, blades, iron kitchen utensils, fishing-hooks, glass beads, gossamer hats, American tobacco, pipes, flints, girdles, bows, and mugs of earthenware, rum, brandy, and liqueurs. These articles are exchanged for cattle, especially cows, turtle-shell, hides and horns, sarsaparilla, vanilla, caoutchouc, gummi, cacao, pimento, castor-oil-nuts, mahogany, fustic, and some articles from the central American states: as cochineal, silver, gold-dust, and silver and gold coin. Some of the tribes in the more remote districts have some intercourse with Honduras and Nicaragua.

This coast was one of the first places where the Spaniards tried to form a settlement. Alonso de Ojeda and Diego de Nicuessa visited this coast in 1512, with about a thousand adventurers; but the natives resisted the invasion with great perseverance, and the Spaniards were compelled to leave the country after having lost a considerable number of men. When the neighbouring countries Guatemala and Nicaragua had submitted to Davila (1522), and Pedro Alvarado (1523), the Spaniards again tried their arms against the natives; but they were not successful. They sent there in the seventeenth century several missionaries, some of whom died the death of martyrs. All these events increased the hatred of the natives to the Spanish name. When the buccaneers were in power in the seventeenth century, they were received by the Mosquitos with open arms, and resorted to the lagunes of the country as the safest retreat when they were pursued by the Spaniards. By means of the buccaneers it appears these people were brought into connection with the English, and the first protection tho English government granted them was confirmed by a treaty in 1670. The first settlement of Englishmen on this coast dates from 1730, when some families established themselves at Cape Gracias a Dios on Black River and Blewfield's River. As these settlements soon acquired a certain degree of prosperity, especially by smuggling with the inhabitants of the Spanish colonies, the English government sent there some persons invested with authority, and erected a few small forts, in 1741. But by the peace of 1763 England engaged to abandon these forts and to compel the colonists to leave the country. This was done, but several families established on Blewfield's Lagoon did not obey the order of their government, and remained there. It is stated that in 1770 the number of English settled on the Mosquito Coast amounted to 1400 individuals. These people were entirely abandoned by tho peace of 1783, and were obliged to go to Belize. Soon afterwards the Spaniards made the last attempt to conquer the coast, by taking possession of the fort on Black River, which the English had abandoned. But they were totally defeated by the natives. England again took the coast under its protection. In 1823, when the States of Central America acquired their independence, that of Nicaragua claimed the Mosquito Coast as a portion of its territories, but these claims were rejected by England and the king of the Mosquitos. It was then ascertained, that the Spaniards themselves had treated the king as an independent sovereign in 1817, when he paid a visit to the town of Guatemala. It appears that at present the claims of the state of Nicaragua have been given up, with the exception of those which refer to the country lying between Punta Gorda and the Lagune of Chiriqui. Meanwhile the king, whose power is absolute, has ceded different districts with almost sovereign power to some Englishmen, who have formed settlements on Blewfield's Lagune and on the banks of Black River, but other portions have not yet been settled. It is probable that in course of time this country will become an English colony, especially as the native population has lately greatly decreased, nearly half of it having been swept away by the small-pox.

(Henderson's *Account of the British Settlement of Honduras*, &c.; Robert's *Narratives of Voyages and Excursions on the East Coast and the Interior of Central America*; Young's *Narrative of a Residence on the Mosquito Coast during* 1839-1841; and *Bericht über die Untersuchung einiger Theile des Mosquitolandes von der dazu ernannten Commission*, Berlin, 1845.)

MOUFLON. [SHEEP, P. C.]

MOVING POWERS. The means employed to give motion to machinery, independently of the cases in which the force of gravity is applied directly, as in turning the cylinder of a clock, are the strength of men and animals, the pressure of the atmosphere, the expansive force of steam, and the action of wind or water; it is even probable that the recently proposed actions of the galvanic fluid and of fired gunpowder will in time be numbered among motive forces for impelling carriages, vessels, or machines. The first and second of the powers above named have been treated under ANIMAL STRENGTH, P. C. S. and ATMOSPHERIC RAILWAY, P. C. S.; and the force of steam under STEAM-ENGINE, P. C., p. 478 *et seq.*

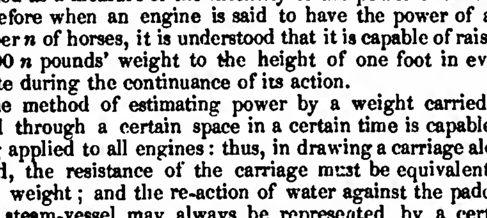
The intensity of a moving power is always estimated by the amount of the resistance which is overcome and the space through which the equivalent of that resistance is conveyed, or raised vertically, in a given time. Thus, in the article on Animal Strength [P. C. S.] it has been shown that a man, a horse, &c., can convey a certain weight, expressed in pounds, through a certain number of miles during a working day; and the continued product of the weight, the distance, and the time has been made to denote the intensity of the power, one pound being the unit of weight, one mile that of distance, and one hour that of time: in estimating, however, the power of an engine or machine it is usual to consider one foot as the unit of distance and one minute as the unit of time, one pound being the unit of weight; the action of the power is, moreover, supposed to be continued during all the time that the machine is at work.

Originally the larger kind of engines, except such as were impelled by wind or water, were moved by the power of horses; and when other agents were employed, the gross effect of the engine was estimated by the number of horses to whose action it was equivalent; but the intensity of horse-power is very variable, and some inconvenience was at first, on that account, experienced in estimating the relative values of engines. In order to establish, conventionally, this dynamical unit, Messrs. Boulton and Watt ascertained from trials purposely made that a strong horse can draw 125 lbs. at the rate of 3 miles per hour during 8 hours: therefore the measure of the power may be expressed by 3000 lbs. ($=125\times3\times8$) drawn or raised one mile in 8 hours; or, multiplying by 5280, the measure is 15,840,000 lbs. raised one foot in an equal time. This product, being divided by the number of minutes in 8 hours, gives 33,000 lbs. for the weight carried or raised one foot per minute continually; and the last number is now universally adopted as a measure of the intensity of the power of a horse. Therefore when an engine is said to have the power of any number n of horses, it is understood that it is capable of raising 33,000 n pounds' weight to the height of one foot in every minute during the continuance of its action.

The method of estimating power by a weight carried or raised through a certain space in a certain time is capable of being applied to all engines: thus, in drawing a carriage along a road, the resistance of the carriage must be equivalent to some weight; and the re-action of water against the paddles of a steam-vessel may always be represented by a certain weight which, if it were lifted by the wheel, would oppose a resistance equal to that of the water. For the useful force of steam-engines in terms of the volume of water evaporated, the pressure of the steam, the length of the stroke, &c., see STEAM-ENGINE, P. C.

Wind and water are employed as prime movers by means of the momentum arising from their velocity; and the latter, occasionally, by the pressure arising from its weight. The manner in which the force of wind is made to act in giving motion to vessels on the surface of water has been fully explained under SAIL, P. C., and, in producing the revolutions of windmill sails, under WIND-SAIL, P. C.; it is intended therefore, in this place, merely to explain the method of forming an equation of equilibrium for the power of an oar in giving motion to a vessel, and to show the force of water on the paddles or float-boards of wheels which are turned by that element.

Let M N represent one side of a vessel, A B the position of the oar when its blade enters the water, and E the fulcrum



or side of the rowlock against which it presses; then since the vessel will move forward during the time that a stroke of the oar is being made, let F be the position of the fulcrum and C D the position of the oar at the end of the stroke: if the vessel had remained at rest, the oar, at the end of the stroke, would have had the position $c\,d$, which may be considered as parallel to C D.

Now, B being the centre of percussion on the blade of the oar, the actual motion of B (supposed to be parallel to the keel of the vessel) may be represented by Bd while the movement of the vessel is E F ($=$ Dd); and therefore B D represents the relative movement of B. The lines B D and Dd being proportional to the velocities of the oar and vessel, which velocities we may represent by v and v'; $v-v'$ will express the relative velocity of the oar, and the effective power of the latter will vary with $(v-v')^2$. Let a, in square feet, be the area of the blade of an oar, and let the pressure of water against a square foot of surface be $1\frac{1}{2}$ lb. when the velocity is 1 foot per second; then $\frac{3}{2}a(v-v')^2$ will denote the force of the oar.

If, for simplicity, the prow of the vessel be supposed to have the form of a wedge with plane faces meeting in a vertical line, or cut-water, on putting a' for the area of the whole prow and θ for the inclination of each face to a vertical plane passing through the keel, we shall have

$$\frac{3}{2}a' \sin.^2\theta \,.\, v'^2$$

for the resistance of the water against the prow. Therefore, n being the number of oars all of which are supposed to act with equal forces; we have, when the vessel has acquired a terminal velocity,

$$n\,a(v-v')^2=a'v'^2 \sin.^2\theta,$$

from which v' may be found. The velocity of a vessel moved by oars is, however, found to increase in a less ratio than the number of oars.

The power of the oar in rowing appears to be diminished by the reaction of the feet of the rowers in pressing against the foot-boards; this has a tendency to force the vessel backwards, but it is compensated by the greater velocity which the centre of percussion in the oar thereby acquires. Some force, however, is lost in overcoming the inertia of the oar, and in bringing it forward against the air; this last force is considerable when the vessel is rowed against a high wind, though it is to a certain degree diminished by the practice of feathering the oars.

The above equation might be used to determine the velocity of a vessel impelled by steam, in which paddle-wheels are employed, if it were possible to determine, nearly, the value of $n\,a$, or the number of square feet of paddle which, on both sides of the vessel, are at every moment acting efficiently against the water: the value of v would be, of course, determined by the number of revolutions which the wheel makes in a given time; and it should be expressed by the number of feet per second which the centre of percussion in the paddle moves through in turning about the axle.

The momentum of water flowing horizontally against a plane, such as a float-board of an undershot wheel, depends on its velocity, on the area of the surface with which it comes in contact, and on the obliquity of that surface to the direction of its motion; and, in estimating the effect of water on such a wheel, it is necessary to determine from the dimensions of the channel and the velocity of the water in it the weight of water which descends vertically through a certain height, as one foot, in a given time. The product of this weight multiplied by the height actually descended, being compared with the product of the number of pounds which the wheel can raise to a certain height in the same time multiplied by that height, expresses the ratio of the power to the effect. From many experiments Mr. Smeaton concluded that, when the quantity of water expended is the same, the useful result varies nearly with the head of water, or with the square of its velocity.

The power of an overshot wheel is estimated by the product of the weight of water expended in a given time multiplied by the whole weight of its descent, that is, by the sum of the diameter of the wheel and the height of water in the reservoir above the top of the wheel. The useful effect of an overshot wheel is said to be nearly double that of one which is undershot.

In determining the power of water on breast-wheels, it is customary to consider such a wheel as one compounded of an undershot and of an overshot wheel; and its effect is conceived to be equivalent to that of an undershot wheel whose head of water is equal to the difference in height between the surface of the water in the reservoir and the point at which the water impinges on the wheel, together with the effect of an overshot wheel whose height is equal to the difference between the point of impact and the level of the tail-water.

MUCID ACID. [CHEMISTRY, P. C. S.]

MUCIUS SCAEVOLA. [SCAEVOLA, P. C.]

MU'CUNA, a genus of plants belonging to the natural order Leguminosæ. The calyx is campanulate bilabiate, with two very caducous bracteoles as long as the tube; the upper lip broad, entire, and obtuse; the lower lip trifid, with acute segments. The corolla is papilionaceous, with a cordate vexillum incumbent on the wings, much shorter than the wings and the keel, and without callosities. The stamens are diadelphous, with five of the anthers oblong, linear, and the other five ovate and hairy. The seeds oval, roundish, or reniform, with a narrow, oblong, or linear hilum. The species are climbing herbs or shrubs, with pinnately trifoliate leaves and axillary racemes, which hang down when bearing fruit.

M. prurita, Cowitch, has purple flowers in compact ovate racemes, leaflets hairy beneath, the middle one rhomboidal and obtuse, the lateral ones dilated on the outer edge. The legumes are oblong, curved, compressed, not keeled, and covered all over with a thick coating of erect, white, stinging hairs, which turn black in drying and brown when ripe. It is a native of the hedges and banks of the East Indies.

M. pruriens, Common or Stinging Cowitch, has entire ovate acute leaflets, smooth above, hairy beneath, the lateral ones oblique at the base, the middle one slightly rhomboidal

The racemes are from 1 to 1½ feet long, lax, and many-flowered. The calyx is hairy, pink, with narrow lanceolate segments. The flowers have a disagreeable alliaceous smell; the vexillum is flesh-coloured, the wings purple or violet, and the keel greenish white. The legumes about 3 inches long, the thickness of the finger, closely covered with strong brown stinging hairs. The seeds oblong, variegated with a white hilum. A mixture of the hairs of these two species form the Cowitch of commerce. The ripe pods are dipped in syrup, which is scraped off with a knife, and when the syrup has attained the thickness of honey, by means of the hairs becoming mixed with it, it is used as a medicine, and is considered a good anthelmintic, as it occasions no uneasiness. It is given from a tea-spoonful to a table-spoonful in the morning, fasting. The hairs, when applied to the skin, produce an intolerable and painful itching. A vinous infusion of the pods, twelve to a quart, is said to be a certain remedy for dropsy. A strong infusion of the roots, sweetened with honey, is used by the native practitioners in India in cases of cholera morbus. It is likewise considered a powerful diuretic.

M. urens has racemose flowers and legumes clothed with stinging bristles; the leaflets have a shining tomentum beneath. The flowers are large, white or yellow, with the lower edge of the wings red. The seeds, from their resemblence to an eye, are called by the French *Yeux bourrique*, or ass's-eyes, and for the same reason the seed has the name *ox-eye-bean* in our colonies in the West Indies, where the species is a native.

A rich soil suits these plants, and they are easily raised from cuttings, but are not worth the trouble of cultivation, excepting for botanical gardens.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany*.)

MULE, MULE-JENNY. [COTTON SPINNING, P. C., p. 96; COTTON MANUFACTURE, P. C., p. 98.]

MULGEDIUM, a genus of plants belonging to the natural order Compositæ, the suborder Liguliflore, the tribe Cichoraceæ, and subtribe Hieraciæ. It has many-flowered heads, a double involucre, the inner of one row, the outer of short lax imbricated scales; the fruit compressed, constricted above, and terminating in a ciliated disk; the outer rows of the pappus rigid and brittle. There are several species of this genus.

M. alpinum, has glabrous, lyrate at the base, arrow-shaped leaves, the terminal lobe large triangular-hastate acute; the stem simple, heads racemose, bracts, peduncles and involucres glandular, hairy; the fruit oblong, not attenuated, with many ribs. This plant has blue flowers in small numerous heads, with a stem about three feet high. It is a remarkably handsome plant, and is the only British species of the genus. It is the *Sonchus cæruleus* of Smith in the English botany. The only locality in which it grows in Great Britain is the mountains of Scotland.

M. floridanum is a native of America, and on account of its excessive bitterness, is called Gall of the Earth.

(Babington, *Manual*; Lindley, *Vegetable Kingdom*.)

MULIER. [BASTARD, P. C.]

MULINA'RI, or MOLINA'RI, STE'FANO, an Italian engraver, known for his numerous prints, after drawings by the early Italian masters. He was born at Florence towards the middle of the eighteenth century, and was the pupil of A. Scacciati, whom he assisted in a series of engravings after the most beautiful drawings in the Florentine Collection. Forty-one only were executed during Scacciati's life: the remaining fifty-nine were executed entirely by Mulinari. These were succeeded, in 1775, by a collection of prints after drawings of the earliest masters, from Cimabue to Pietro Perugino, under the title 'Istoria Pratica dell' Incominciamento e Progressi della Pittura, o sia Raccolta di 50 Stampe estratte da ugual numero di disegni originali esistenti nella Galleria di Firenze;' which was followed, in 1780, by a still more interesting work on the five great Italian schools of painting, 'Saggio delle Cinque Scuole di Pittura Italiana.' Mulinari died near the close of the eighteenth century, aged about fifty-five. Among the above-mentioned works are four after L. da Vinci, five after Michelangelo, twenty-two after Raphael, eight after Julio Romano, six after Polidoro da Caravaggio, twenty-six after Parmegiano, five after Daniele da Volterra, eight after Barocci, seven after Cesare Procaccini, three after Guido, three after Sacchi, thirteen after Guercino, and many others. Nagler has given a list of about two hundred of them in his *Künstler Lexicon*.

MÜLLER, the name of two very celebrated German engravers, father and son.

JOHANN GOTTHARD VON MÜLLER, the elder, was born at Bernhausen, near Stuttgart, in 1747. His father, who held an official situation under the government of his native country, wished to educate Müller for the church, but the youth showed so much ability for art in the (1761) newly established Academy for the Arts at Stuttgart, that the Duke himself urged him to follow art as his profession. Accordingly, in 1764, Müller, under the immediate patronage of the duke, entered the school of the court painter, Guibal, who recommended him to follow engraving, which he pursued for six years (1770-76), at Paris, under Wille, with such success that, in 1776, he was elected a member of the French Academy. He was recalled in the same year by the Duke Carl to Stuttgart. His last work in Paris was a good portrait of his master, J. G. Wille. The first work which he completed at Stuttgart was Alexander, Conqueror of Himself, after Flink, which he took, in 1781, to Paris to be printed, not venturing to work off so valuable a plate at the then inexperienced copper-plate press established by himself in Stuttgart. In 1785 he was invited to Paris to engrave the portrait of Louis XVI., painted in 1774 by Duplessis; but the picture from which Bervic engraved the same king was painted ten years later, and Bervic's is accordingly a more characteristic portrait of what he eventually was. In 1802 Müller was made professor of engraving in the academy at Stuttgart, where he instructed several of the best engravers of Germany, during the earlier part of the nineteenth century, among whom his own son, Christian Frederick, is the foremost. He was elected successively a member of the principal German academies; was presented in 1808, by the King Frederick of Würtemberg, with the Order of Civil Merit; and in 1818 was made a Knight of the Würtemberg Crown by Frederick's successor, King William. He died at Stuttgart in 1830, and in the same year a biography of him was published in the 'Schwäbische Merkur,' No. 71.

Müller engraved only thirty-three plates, a small number, but some of them are large and elaborate works; they are, however, chiefly portraits. His principal works, besides those already mentioned, are—the Battle of Bunker's Hill, after Trumbull, engraved in 1799; the Madonna della Seggiola, for the Musée Français, engraved in 1804, by many considered superior to the print of the same subject by Raphael Morghen; a St. Catherine, with two Angels, after L. da Vinci; and the portrait of Schiller, after A. Graf.

CHRISTIAN FRIEDRICH VON MÜLLER surpassed his father, but, owing to the extreme shortness of his career, his prints are even less numerous than those of the elder Müller. He was born at Stuttgart in 1783, and he died at Pirna, near Dresden, in 1816, aged only thirty-three. He was carefully educated by his father in all those branches of the arts which, by his own experience, he knew to be requisite to constitute an excellent engraver; and in 1802 he sent him to complete his studies in the great world at Paris, where at that time the majority of the finest works of art in Europe were collected together in the Louvre. Here, in 1808, Müller engraved the St. John about to write his Revelations, after Domenichino, in which the eagle brings him his pen; and Adam and Eve under the Tree of Life, after Raphael. He was commissioned shortly afterwards by Rittner, a printseller of Dresden, to engrave his last and greatest work, the most sublime of all the paintings of Raphael, the Madonna di San Sisto, in the Dresden Gallery. He was wholly occupied for the remainder of his short life on this plate, which he just lived to complete, but he never saw a finished print from it. He removed to Dresden in 1814, and was appointed professor of engraving in the academy there. His existence seems almost to have been wrapped up in the execution of this plate: he was occupied with it day and night, and, always of a sickly constitution, the infallible result of such constant application and excitement soon made its appearance; he was in vain advised to desist for a while from his work. He completed the plate and sent it to Paris to be printed; but with his plate the artificial excitement which supported him departed also: he had just strength enough left to admit of his being carried to the Sonnenstein, near Pirna, where he died in 1816, only a few days before the proof of his plate arrived from Paris. It was suspended over the head of his bier as he lay dead, thus reminding us of the similar untimely fate of the great master of the original, above whose head, as he lay in state, was hung also his last work, the Transfiguration. Müller left a wife and two young children.

Christian Müller engraved only eighteen plates, but the Madonna di San Sisto is in itself a host, and exhibits him at least the equal, if not the superior, of Raphael Morghen, to whose Transfiguration it serves as a good pendant: there are several lithographic copies of it. His other works are nearly all portraits: among them are—Jerome Bonaparte, Schiller, Jakobi the poet, Professor Hebel, Dr. Hufeland, William, King of Würtemberg as Crown Prince, and a medallion of Napoleon.

(*Kuntsblatt*, 1830; Nagler, *Allgemeines Künstler-Lexicon.*)

MÜLLER, CARL OTTFRIED, one of the most learned scholars of modern times, was born in 1797, at Brieg, in Silesia, where his father at the time held the office of preacher to a division of the Prussian army. Müller received his early education in the gymnasium of Brieg, and in 1813 he entered the university of Breslau, where he devoted himself to the study of philology. From 1815 to 1817 he studied at Berlin, and as soon as he had taken his degree and had given evidence of his mythological studies and researches in a little work entitled 'Aegineticorum Liber' (Berlin, 1817), he was appointed teacher of the antient languages in the gymnasium (called the Magdalenum) of Breslau. While engaged in teaching, he employed all his leisure hours in mythological inquiries, endeavouring to analyze the various mythical cycles and trace them to their earliest and simplest elements. The great work containing the results of these researches is a history of Hellenic races and cities ('Geschichte Hellenischer Stämme und Städte'), of which the first volume, on Orchomenos and the Minyans, ('Orchomenos und die Minyer') appeared at Breslau in 1820, 8vo.). It was in consequence of the advice of Heeren and a recommendation of A. Boeckh, that in 1819 Müller was invited to a professorship in the university of Göttingen, with the special object that he should lecture on archaeology and antient art. His activity created a new æra in the history of Göttingen, and under his and Dissen's auspices the study of philology and antient literature received an impulse, which was soon felt in all Germany, and was extended over a great part of Europe by the valuable works published by Müller in rapid succession. In order to acquire a more intimate knowledge of antient works of art than could be acquired from mere descriptions, he spent in 1819 some time at Dresden, and in 1822 he visited France and England. But although his attention was more particularly directed to antient art, he never lost sight of the fact that the arts of the antients represented only one side of their intellectual activity, and formed only one source among the many from which a complete knowledge of antiquity is to be derived. In order to show fully the connection of religion, manners, polities, and history, in the case of one of the Greek races, Müller wrote his work on the Dorians ('Die Dorier,' Breslau, 1824, 2 vols. 8vo.), which forms the second and third volumes of his 'Geschichte Hellenischer Stämme und Städte,' and was translated into English by H. Tuffnell and G. C. Lewis, Oxford, 1830, 2 vols. 8vo., with additions and corrections furnished by the author. A new edition of the 3 vols. of the whole work has been published since Müller's death by F. W. Schneidewin, Breslau, 1844, and a new edition of the English translation of the 'Dorians' appeared in 1840. Müller intended to continue this series of works by a history of Attica, but certain scruples induced him to defer the execution of this task, and it has unfortunately never been executed. The year after the publication of the 'Dorians' Müller published his Introduction to a scientific system of Mythology ('Prolegomena zu einer wissenschaftlichen Mythologie,' Göttingen, 1825, 8vo.), of which an English translation by J. Leitch was published in London, 1844, 8vo., and another work on the early history of Macedonia ('Ueber die Wohnsitze, die Abstammung und die ältere Geschichte des Makedonischen Volkes,' Berlin, 1825). These productions were soon followed by a great work on the Etruscans ('Die Etrusker,' Breslau, 1828, 2 vols. 8vo.), and a manual of the history of antient art ('Handbuch der Archaeologie der Kunst,' Breslau, 1830; a second edition appeared in 1835). This last work was the first of the kind that had been produced in Germany. About the same time he was requested by the Society for the Diffusion of Useful Knowledge, to compose a history of Greek Literature, of which the first volume appeared in 1840; of the second only a portion was published: since Müller's death all that had appeared in England has been published in Germany under the superintendence of his brother Julius Müller. Besides these greater works Müller also wrote 'Minervae Poliadis Sacra et Aedem in Arce Athenorum illustravit,' &c., Göttingen, 1820; 'De Phidiae Vita et Operibus,' Göttingen, 1827, and a great number of articles in periodicals and encyclopediac works. The only correct edition of Festus that we have is that of Müller (Leipzig, 1839, 4to.), and his edition of Varro's work 'De Lingua Latina' (Leipzig, 1833, 8vo.), and of the Eumenides of Aeschylus, are equally valuable.

In 1840 Müller, who had long desired to see the countries to the investigation of whose history, literature, and art his whole life had been devoted, resolved to visit Italy and Greece, partly to convince himself of the correctness of the results at which he had arrived, and partly to collect new materials. His activity in Greece was very great; one hot day in July, 1841, while engaged in making some excavation at Delphi, he was seized with a fever, in consequence of which he died soon after he had returned to Athens. He was buried in the Antient Academy at Athens, the most appropriate place for a scholar like Müller that could have been devised.

Müller was a man of the most extensive and varied acquirements, and of a keen and penetrating judgment. He acquired a European reputation at a comparatively early age. His numerous works, however, are not all of equal merit, and the two faults more particularly to be noticed are his great haste in the composition of his works, and a tendency to theorize and generalize on insufficient grounds. But in extent of knowledge and reading there scarcely ever was a scholar who surpassed him.

(*Neuer Nekrolog der Deutschen* für 1841; F. Lücke, *Erinnerungen an Karl Otfried Müller*, Göttingen, 1841, 8vo., which contains an admirable delineation of Müller's personal character.)

MÜLLER, WILLIAM JOHN, one of the best of the English landscape and costume painters, was born of a German father at Bristol, in 1812: his father was curator of the Bristol Museum. Müller's first instructor in art was the landscape painter J. B. Pyne, likewise a native of Bristol, but he owed his excellence to his own perception and powers of industry, and his great teacher was nature: he found an early and valuable patron in Mr. Acraman, of Clifton, for whom he painted many pictures. In 1833 and 1834 he made a tour upon the Continent, in Germany, Switzerland, and Italy, and made many admirable sketches. Sketching from nature was a department of art in which Müller had extraordinary power; nearly all his more considerable works of this class are in themselves complete; they require no elaborated copies to make them presentable as pictures; he did indeed elaborate very few of them into pictures, and some of these rather lost than gained by the process.

In 1836 he exhibited a picture of Peasants on the banks of the Rhine waiting for the Ferry-boat, but it was a piece of no pretensions, and attracted little notice.

In 1838 he started upon a long and arduous tour through Greece and Egypt: he went beyond the cataracts of the Nile, and visited the mummy-caves of Mahabdies, of which and many other interesting places in Greece and Egypt he made masterly drawings. He returned to England towards the close of 1839, took up his abode in London, and exhibited several admirable pictures of the remarkable scenes that he had sketched during this his first oriental tour. He had in the exhibition of 1840 Athens from the Road to Marathon, and the Memnon, or Ruins at Gornou in Egypt at Sunset, both pictures of the highest degree of merit, but in different styles. The Memnon, though hung high up in the dark octagon room in the Academy, commanded the attention of every one who could see so high; it is a master-piece of colour and effect, and is certainly a work of high poetic art. The view of Athens is equally excellent in its class; the picturesque, and at the same time the historical associations connected with the place make it an additionally interesting work: this picture, for which Müller received only thirty guineas, for his works had not yet attracted a moiety of the attention which they deserved, was lately purchased by a picture-dealer for nearly ten times the amount. The Memnon was sold for twenty-four guineas: ten times the amount is nearer its present value also.

In 1843 Müller joined on his own account Sir Charles Fellowes on his last expedition to Lycia, to remove to London the Xanthian marbles, now in the British Museum. He returned to London in 1844 with some dozens of very interesting and masterly sketches, which elicited the unqualified admiration of all who saw them at a meeting of the Graphic Society shortly after his return. About three hundred sketches and other works were lately sold by auction by Messrs. Christie and Manson, and they realized the enormous sum of

4360*l.*: a small sketch of his own apartment at Macri alone brought sixty-five guineas. These are curious facts: he himself receives only thirty guineas for his picture of Athens, a finished master-piece; he dies shortly afterwards, and a few months subsequently a small water-colour sketch of his own apartment, which probably he himself would not have valued at much more than thirty pence, is sold for more than double the number of guineas. The living artist would appear to be scarcely worth the shadow of his own body when dead.

The pictures, the fruits of Müller's second oriental tour, which were exhibited at the Royal Academy in 1845, appear to have been the primary causes of his early and unexpected death, though the fatal results of their bad hanging on the Academy walls betray an extraordinary degree of sensibility in the painter. He appears from his own words to have anticipated much honour and proportionate benefit from the exhibition of these works in the Academy; far indeed however was the result from the anticipation. Müller sent the following five pictures to the Academy exhibition of last year (1845):—Great Cannon formerly belonging to the Knights Templars, Rhodes; Head of a Cingari, Xanthus; The Burial-ground, Smyrna; Tent Scene, Cingaries playing to a Turkish family, Xanthus; and Turkish Merchants with Camels passing the river Mangerelii, in the valley of Xanthus. These works were, with one exception, what is called hung out of sight; that is, either so much below or so much above the line, that they could not be easily seen, and would very probably be altogether passed over by the majority of visitors to the exhibition. Müller felt this *condemnation* excessively, and notwithstanding his own professed resignation to his fate, he was evidently prostrated; he was seized with a severe illness in the month of May, which ended fatally at Bristol, on the 8th of September following. He died from enlargement of the left ventricle of the heart; and several of his friends have not hesitated to declare that the *hanging committee* of 1845 killed William Müller. In his own complaint however he was more moderate; he wrote as follows to his friends in the month of May, after the opening of the Exhibition:—'A man honourably leaves his country, he risks other and distant climates, spends large sums of money, and, after labour and fatigue, he returns to his home, and produces pictures acknowledged to be superior to his former works. His ambition leads him not to expect too high a reward—only places where his pictures may be seen. Such had been my hope; and I find my Turkish Burial-ground and Xanthian Tent Scene on the very top, (at least the first named) of the large room, conspicuously obscure. My large picture is not so badly hung (six feet or more above the ground), but in such a place that one may expect but little from it.' . . . . 'Such has been the reward I have received for the expenditure of large sums, of great labour, the risk of health, breaking up for a time a connection, &c., the fatigue and exhaustion of a long journey—such are the rewards, or post of honour, *a protected body* afford to the young English artist! the *top row* of the large room.' These and other extracts from Müller's letters are published in the 'Art Union Journal,' in which are also several letters written by him while in the East, containing a short account of his proceedings, and some interesting details relating to the ruins, and the customs of the people, in Asia Minor, illustrated with several sketches.

Müller exhibited several pictures at the British Institution, among which were, in 1845, a View of Rhodes with the Pasha's Palace, and a Dance at Xanthus. He exhibited also many excellent landscapes in the early part of his career at Bristol; and, besides what have been already mentioned, the following works at the Royal Academy:—In 1841, Sketch of an Egyptian Slave-market; Convent, Bay of Naples; and the Sphinx: in 1843, Arabs seeking Treasure; Prayers in the Desert; and Welsh Mill on the Dolgarey. He published in 1841 a beautiful work entitled 'Picturesque Sketches of the Age of Francis I.' A select series of his Sketches in the East will also shortly be published.

MUN, THOMAS, is the name of an English writer on political economy, who lived in the earlier part of the seventeenth century, but of whose personal history scarcely any thing appears to be known. His best known work, a small octavo volume, published at London in 1664, is entitled 'England's Treasure by Foreign Trade; or, the Balance of our Foreign Trade is the rule of our Treasure. Written by Thomas Mun of London, merchant, and now published for the common good by his son John Mun of Bearsted, in the county of Kent, Esquire.' This title-page comprehends nearly all the particulars we have been able to discover respecting Mun. The book is dedicated to Thomas, Earl of Southampton, in an address in which Mun's son says:—'It was left me in the nature of a legacy by my father, for whose sake I cannot but value it as one of my best moveables, and as such I dedicate it to your lordship. He was in his time famous amongst merchants, and well known to most men of business for his general experience in affairs, and notable insight into trade; neither was he less observed for his integrity to his prince, and zeal to the common-wealth. The serious discoveries of such men are commonly not unprofitable.' A passage which occurs in the body of the work may give some indication of the nature and extent of Mun's dealings. Having observed that Ferdinand I., the Grand Duke of Tuscany, was very rich in treasure, and enlarged his trade by lending to merchants great sums of money at a low interest, he adds:—'Myself had 40,000 crowns of him *gratis* for a whole year; although he knew that I would presently send it away in specie to Turkey, to be employed in wares for his country; he being well assured that in this course of trade it would return again, according to the old saying, with a duck in the mouth. By his thus encouraging of commerce, within these thirty years the trade of his port of Leghorn is so much increased, that, of a poor little town, as I myself knew it, it is now become a fair and strong city.' Ferdinand I. died, after a reign of twenty-two years, in 1609; it is strange, therefore, that Mr. Macpherson, who quotes this passage in his 'Annals of Commerce,' should place it under the year 1630, remarking that 'probably Mr. Mun was in Leghorn about this time, and may have written his book about 1660.' The conjecture of Mr. M'Culloch ('Principles of Political Economy,' p. 30), that the book was probably written about 1635 or 1640, is likely to be much nearer the truth. Mun, being, as we have seen, a foreign merchant of the highest eminence before 1609, can hardly have been born later than 1580, and most probably was dead long before 1660. His 'England's Treasure,' is addressed to his son, and begins:—'My son, in a former discourse I have endeavoured, after my manner, briefly to teach thee two things: the first is piety; . . . . the second is policy; . . . so am I now to speak of money.' But whether this former discourse was even published we do not know. Mun, however, has always been understood to be the writer of a work entitled 'A Discourse of Trade from England to the East Indies, by T. M.' 4to. London, 1621.

The object of this last-mentioned work is to defend the East India trade from the charge brought against it of exhausting the national wealth by occasioning an annual exportation of treasure, or of gold and silver. Mun does not deny, or for a moment doubt, that the true profit of the country upon any branch of commerce is to be measured by the balance of money which it annually brings into the country; but he contends, that, although the trade with the East Indies, considered by itself, would upon this principle be a losing trade, yet it became in reality profitable in consequence of the exportation of certain commodities which it enabled us to make to other European countries, from which in this way we drew back every year a much larger amount of treasure than wo sent out to India. The reasoning is the same that was afterwards employed by Sir Josiah Child in his anonymous pamphlet, 'The East India Trade, a most profitable Trade to this Kingdom,' published in 1677. The same doctrine is also expounded in Mun's other work, his 'England's Treasure by Foreign Trade,' the fourth chapter of which, principally relating to the East India trade, is headed, 'The exportation of our monies in trade of merchandize is a means to increase our treasure.' The fundamental principle of that work is stated in the second chapter:—'The ordinary means to increase our wealth and treasure is by foreign trade, wherein we must ever observe this rule—to sell more to strangers yearly than we consume of theirs in value.' Perhaps the principle of what has been called the mercantile or balance of trade system had scarcely before been so distinctly avowed, at least by any English economist. The work, which extends to 220 pages, contains twenty-one chapters in all. It was long looked upon as a great authority, and was reprinted at London in 1669, in 1698, in 1700, and in 1713; and a last edition was produced at Glasgow in 1755. A copy of the first edition in the British Museum, which is marked by its former possessor as 'E dono filii auctoris,' contains a few brief manuscript annotations on the margin, in general however expressing merely the writer's agreement or dissent.

MUNDAY, ANTHONY, must, according to his epitaph, have been born in 1553. His early life is almost totally unknown; but he was at one time abroad, and describes himsel' as having been 'the Pope's scholar in the seminary at Rome.' In 1582 he was one of the instruments in the detection of the Popish conspiracy; he was a witness against some of the prisoners; and he published 'A breefe and true Reporte of the Execution of certain Traytours at Tiborne the 28th and 30th days of May, 1582; gathered by A. M., who was there present.' He had, it appears, held a dispute at tho foot of the gallows with one of the victims. This pamphlet was not Munday's first publication. His tract called 'The Mirror of Mutabilitie' had appeared in 1579; and he published, after this date, a large number of pieces in prose and verse, originals and translations. Lists will be found in the 'British Bibliographer' and elsewhere. His dramatic productions are now more interesting than any of the others. He is said, but on equivocal authority, to have been a player and an unsuccessful one: ho was at any rate a frequent writer of plays, and also of pageants for the corporation and companies of London. Ben Jonson, in 'The Case is Altered,' written early in 1599, ridicules him and his city-shows, in his character of Antonio Balladino, making this personage to say of himself, that he 'supplies the place of pageant-poet to the city of Milan when a worse cannot be had,' and that he 'uses as much stale stuff as any man does.' Perhaps Ben's critical acumen was a little sharpened by the fact that Munday had just been called 'our best plotter' in Meres' 'Palladis Tamia,' in which Jonson's own name is not mentioned. Mr. Collier enumerates fourteen plays which Munday wrote or assisted in writing, desiring however to add to this list the recently discovered play called 'The Two Italian Gentlemen,' which he attributes to Munday, and infers to have been acted about 1584. The following other plays of Munday have been printed. 1, 2, 'The Downfal of Robert Earl of Huntingdon,' by Anthony Munday; 'The Death of Robert Earl of Huntingdon,' by Anthony Munday and Henry Chettle, both acted in February, 1598, and printed in 1601. Both are reprinted in Mr. Collier's 'Supplementary Volume to Dodsley's Old Plays.' They are rude and irregular pieces, possessing much vigour of painting, and presenting, in the scenes with Robin Hood's band in Sherwood Forest, some pleasing poetry. 3, 'The Widow's Charm,' acted in July, 1602; and supposed to be the comedy of 'The Puritan, or the Widow of Watling Street,' which was printed in 1607, and has been absurdly attributed to Shakspere. 4, 'The First Part of the Life of Sir John Oldcastle,' by Anthony Mundsy, Michael Drayton, Robert Wilson, and Richard Hathwaye; published twice in 1600, one of the editions attributing it to Shakspere. Munday died on the 10th of August, 1633, and was buried in the church of St. Stephen, Coleman-street.

MURAT. CAROLINA MARIA ANNUNZIATA BONAPARTE, sister of Napoleon, born at Ajaccio, in 1782, married in 1802 General Murat, then aide-de-camp to the First Consul, and became Grand Duchess of Berg, and afterwards Queen of Naples in 1808. She was the only sister of Napoleon who became a queen. She took a considerable part in the public affairs of the kingdom of Naples, and was several times regent in the absence of her husband, who was obliged to follow Napoleon in his never-ending wars. She displayed mnch ability, prudence, and firmness; she encouraged education and learning, and founded several useful institutions, among others one for the education of young ladies at Naples, which still remains. She had at various times a difficult task in acting the part of a conciliator between her spirited but imprudent husband and her imperious brother. After seven years of reign, during which she showed herself worthy of the crown, she was obliged, through the reverses of her husband in 1815, to leave Naples on board of an English man-of-war, and to retire to Austria, where she lived for many years under the title of Countess of Lipano (the anagram of 'Napoli'). After the tragical death of her husband, she busied herself with the education of her four children. In course of time the two sons went to settle in America, one daughter married the Italian Count Rasponi, and the other Count Pepoli of Bologna. Madame Murat made a journey to Paris after 1830 for some family interests, and was well received by Louis-Philippe and his family. She afterwards went to Italy, and died at Florence, in May, 1839. Napoleon had a very favourable opinion of his sister Caroline.

(Lesur, *Annuaire*.)

MURÆNA, an apodal malacopterygious fish of the family *Murænidæ*, and resembling the eel in form. It has no pectoral fins. The orifices of the gills are small and open, one on each side. In each jaw there is a single row of teeth. The dorsal and anal fins are very low, and are united. The *Muræna Helena* is the type of the genus. It is found in the Mediterranean and Portuguese seas, and in ono instance has been taken on the coasts of Britain. It grows to the length of between four and five feet, and even more. The body is smooth and glossy, beautifully mottled with salmon colour, yellow, and purple. Tho head is large and swollen, which gives the fish a disagreeable aspect. It is excellent eating, and was highly esteemed by the antients, who reckoned it among the best of fishes for the table, and kept the *Muræna* alive in *vivaria*.

MURPHY, ROBERT. No obituary has yet appeared, as far as we know, of this distinguished mathematician: and this, with tho interest attaching to so remarkable a rise by force of talent alone, may justify us in giving the facts we have been able to collect at length. The materials for his early life have been communicated by J. Dillon Croker, Esq., of Mallow, one of his first patrons.

Robert Murphy was the third of the seven children of a shoemaker, parish clerk of Mallow in Ireland: he was born in 1806. His father intended to have brought him up to his own trade; but the son's destination was changed by an accident which nearly cost him his life. When eleven years of age, while playing in the streets of his native town, he was run over by a cart, and lay on his bed for twelve months with a fractured thigh-bone. During this confinement, his family supplied him with such books and newspapers as they could procure; and among them there happened to be a Cork almanac, containing some mathematical problems. These attracted the child's attention, and made him desirous of possessing Euclid and a work on algebra. The books were procured with some difficulty, and before he was again able to walk, and before he was thirteen years of age, young Murphy was an extraordinary instance of a self-taught mathematician. A gentleman of the namo of Mulcahy, of Cork, who was the tutor of most of those from the south of Ireland who got fellowships at Dublin College, was in the habit of proposing problems (or *cuts*, as they are called in Cork) in the newspapers. At a certain time, he began to receive answers by return of post, from Mallow, without any signature. Surprised at the extraordinary talent displayed in these answers, Mr. Mulcahy went to Mallow to find out his unknown correspondent. After some difficulty, ho found that the asserted author of the answers was a boy on crutches, so young that he could not believe the story. A few minutes' conversation, however, put it beyond a doubt. On coming away, in amazement, he happened to meet the gentleman to whom we are indebted for this account, to whom he said, with natural exaggeration, 'Mr. Croker, you have a second Sir Isaac Newton in Mallow: pray look after him.' It was then agreed that the boy should give up learning his father's trade, and pursue his studies. Mr. Hopley, who kept a classical school in Mallow, had the generosity to take him as a pupil without any charge: and he, in after life, had the satisfaction of transmitting to the widow of his teacher, then reduced to poverty, the sum which an ordinary pupil would have paid.

When he attained the age of seventeen, great exertions were made to get him entered as a student of Trinity College, Dublin, but without success. The examinations for sizarships being classical, he had no chance: and some mathematical papers—which were sent to the authorities as the productions of a boy who had never had a teacher, and which, to judge by what we shall presently see, must have been of no common merit—received no attention. At this time Mr. Mackey, a Roman Catholic priest, published a duplication of the cube, the plausibility of which attracted attention, and, it is said, even obtained the assent of the teachers at Maynooth. Young Murphy, then eighteen years of age, answered this duplication in a pamphlet, entitled 'Refutation of a pamphlet written by the Rev. John Mackey, R. C. P. entitled "A method of making a cube double of a cube, founded on the principle of elementary geometry," wherein his principles are proved erroneous, and the required solution not yet obtained; by Robert Murphy, Mallow, 1824' (20 pp.). The matter and style of this production are really extraordinary under the circumstances: with the exception of a little too much acerbity of expression, and a mere slip in a point of history, a critic would not find anything to attack in it, even as the work of an educated person of mature age. The young author had a confusion in his head between Lord Brounker and Dr. Brinkley, when he says that 'Dr. Brounkley,' had expressed the circumference of a circle by a continued fraction.

The gentleman to whom we have several times referred now determined to try to get young Murphy sent to Cambridge. He applied to the clergyman who presented tho boy with his Euclid and algebra, Mr. Brown, who was then employed in a parish of which Mr. McCarthy, a Cambridge Master of Arts, was the proprietor. This last-named gentleman, being then about to visit England, promised to take some of Murphy's papers with him, and to do what he could to induce his old tutor, Professor Woodhouse [WOODHOUSE, P. C.], to interest himself in the matter. The first answer was not very encouraging. Mr. Woodhouse would say no more than that if they would send the boy he would look after him. On being requested to look over the papers, he declined, saying, that he had no time, and made it a rule not to do so. He desired that the papers might be taken away, and on being requested to allow them to remain, to meet the case of his possibly being able to look at them, he predicted for them the fate of waste paper, and the interview ended. In six weeks from that time, however, Mr. Woodhouse wrote a hurried letter to Mr. McCarthy, stating that at the moment when he was about to tear the papers, in fulfilment of his prophecy, his attention was struck by something that was almost new to him—that on turning page after page, he saw with delight so much talent that he was really unable to say how long he remained fixed to the subject that he intended should occupy him but a moment—that suddenly, recollecting it was the last day for entrance, he hastily went and placed the name of the writer on the boards of Caius College. He concluded by promising that if his friends would send him with fifty or sixty pounds in his pocket, he would take care that they should not be called on again: and this promise was faithfully kept. Mr. Croker immediately obtained about seventy pounds by subscription, and Mr. Murphy began his residence at Caius College, in October, 1825. During his residence, the college supplied him with money, in addition to the proceeds of his scholarship. In 1829 he took the degree of bachelor of arts, and came out third wrangler. The highest place is sometimes not to be gained by any amount of genius and industry, unaccompanied by strict attention to the University course of reading: and Mr. Murphy's time was much occupied by speculations of his own, which would not turn to much account in an examination. In May, 1829, he was elected Fellow of Caius; he shortly afterwards took deacon's orders (he did not proceed farther), and was made dean of his college (the dean is, at Caius, an officer who, under the master, regulates the chapel discipline) in October, 1831.

Of what he did in mathematics we shall presently speak: we could wish there were nothing more to say of his private life. He gradually fell into dissipated habits, and in December, 1832, left Cambridge, with his fellowship under sequestration for the benefit of his creditors. There is much excuse for a very young man, brought up in penury, and pushed by the force of early talent into a situation in which ample command of money is accompanied by even more than proportionate exposure to temptation. His college admitted the excuse to its fullest extent: and though it could not tolerate the continued residence of an officer who had shown such an example, yet it was understood that his ultimate promotion to one of the more valuable fellowships would take place, on the amendment of his excesses. After living some time among his friends in Ireland, he came to London in 1836, to begin life again as a teacher and writer. Among other things, he obtained from the Useful Knowledge Society an engagement to write the work on the Theory of Equations presently mentioned. In October, 1838, he obtained a small permanent income by his election to the examinership in Mathematics and Natural Philosophy in the University of London; but burdened as he was with debt, this was rather an addition to the instalments of his creditors than an increase of his own means of comfort. He submitted with resignation to the effects of his own misconduct, and showed himself most willing to make every exertion, though well knowing that many years must elapse before he could, by any effort, redeem the ground he had lost. He died March 12, 1843, of a disease of the lungs.

Mr. Murphy's writings were as follows:—*Cambridge Philosophical Transactions:* vol. iii. part 3, General Properties of Definite Integrals; vol. iv. part 1, On the Resolution of Algebraic Equations; part 3, On the Inverse Method of Definite Integrals, with Physical Applications; vol. v. part 1, On Elimination between an Indefinite Number of Unknown Quantities; part 2, second memoir on the Inverse Method of Definite Integrals; part 3, third memoir on the same; vol. vi. part 1, On the Resolution of Equations in Finite Differences. *Philosophical Transactions:*—1837, part 1, Analysis of the Roots of Equations; part 2, First Memoir on the Theory of Analytical Operations. *Separate works:*—Elementary Principles of the Theories of Electricity, Heat, and Molecular Actions, part 1, On Electricity, Cambridge, 1833, 8vo.; A Treatise on the Theory of Algebraical Equations, London, 1839, 8vo. (Library of Useful Knowledge): to these must be added some brief communications to the Philosophical Magazine, and various articles on subjects of physics in the Penny Cyclopædia, beginning with the letter D.

Mr. Murphy's character as a mathematician is too well known to require any comment of ours; while the facts of his life, and in particular those of his removal to Cambridge, have not been recorded: we have therefore preferred to devote our space to the insertion of the latter. What he might have been if the promise of his boyhood had not been destroyed by the unfortunate circumstances we have described, it is difficult to say: for he had a true genius for mathematical invention. Before however he had more than commenced his career, his departure from Cambridge, and the necessity of struggling for a livelihood, made it impossible for him to give his undivided attention to researches which, above all others, demand both peace of mind and undisturbed leisure.

MURRAY, LINDLEY, was born in 1745, at Swetara, near Lancaster, in the state of Pennsylvania, North America. His parents belonged to the Society of Friends, and he was the eldest of twelve children. He received the rudiments of education at Philadelphia, in the academy of the Society of Friends. In 1753, his father, who was an enterprising merchant, removed with his family to New York, where Lindley was sent to a good school. At an early age he was placed in his father's counting-house, in order to be trained up to the mercantile profession, but having taken a decided dislike to it, he prevailed on his father to allow him to have a private tutor to instruct him in classical learning, and afterwards to place him under an eminent lawyer, in order to receive instruction in the law, to which profession he had resolved to devote himself. John Jay, afterwards governor of the state of New York, was his fellow-student. About the age of twenty-one he was called to the bar, and having obtained a good practice he soon afterwards married. He was sedulous in his application to his business as a lawyer, and very successful till the disputes commenced between Great Britain and America. The law then ceased to be lucrative, and he entered into the mercantile profession, with such success that about the time of the establishment of American independence he had acquired sufficient property to allow him to gratify his wish of retiring from business.

Lindley Murray purchased a beautiful seat on the banks of the river about three miles from New York, but before he removed to it he had a severe attack of illness, which left him in a very debilitated state of body; the tone of his muscles was so much impaired that he could walk but little, and his debility continued to increase, in spite of change of scene, bathing, and every other means of remedy to which he had recourse. In 1784 he embarked for England, with his wife, in hope that a climate where the summers are more temperate and less relaxing than they are in the United States, might contribute to the restoration of his strength. He purchased a house and garden at Holdgate, a small village about a mile from the city of York, where he resided during the remainder of his life. For a short time his muscular strength increased, but afterwards diminished till he could no longer take exercise except in a carriage, or in a vehicle in which he was drawn about his garden, but for many years before his death he was entirely confined to his room. In the sedentary state to which he was reduced he occupied himself by reading and the composition of works chiefly intended for the instruction of youth.

Lindley Murray's first work, 'The Power of Religion on the Mind,' was published anonymously in 1787. It is a selection of passages from various authors, and was very favourably received. The first edition of his 'English Grammar' was brought out in 1795. A second edition was soon required, and the book was revised and enlarged by the author, and then reprinted. 'Exercises,' to correspond with the Grammar, and a 'Key' to the Exercises, were published in 1797, in which year he also published an Abridgment of the Grammar for the use of minor schools and those beginning the study of grammar. The four volumes were adapted to each other; and were soon introduced into many schools. The sale of them has been very large, and still continues to be so. Murray's Grammar and Exercises however are entitled to little praise beyond the care with which the materials have been arranged; they do not even approximate to a high standard in point of clearness of exposition, and are besides based on a wrong principle, that of teaching the pupil how to write good English by placing before him specimens of bad English. Definitions are given, which are frequently very obscure, and rules are laid down without explanation of the principles on which they are founded, and if the pupil commits the definitions and rules to memory, believes in them, and can apply them, his grammatical education, as far as these works are concerned, is considered to be complete. But grammars of this class ill supply the wants of the present age, even for the purposes of common school instruction, and ought to be superseded by others of a better kind, in which the principles of the language should be explained, as well as illustrated by specimens selected from the best writers. Murray's Grammar is altogether deficient in the etymological part, and the student can derive from it no knowledge of the true forms of words and their historical deduction from the early state of our language. His next publication was a series of extracts called 'The English Reader,' to which he soon afterwards added an 'Introduction,' and a 'Sequel;' the three volumes containing respectively selections suited to pupils of different degrees of maturity. The success which attended these publications induced him to publish the 'Lecteur François' in 1802, and in 1807 an 'Introduction au Lecteur François.' In 1804 he published a Spelling-Book. For the copyright of all these works he received a liberal price, and as he had no children, and his property was as much as he and his wife required, the entire sum was devoted to charitable purposes. All these editions were in 12mo. In 1808 he published an enlarged edition of the Grammar and Exercises, in 2 vols. 8vo., designed for the use of persons who might deem it worthy a place in their libraries. He also published a 'Selection from Horne's Commentary on the Psalms,' 12mo., and a little work, published in 1817, 'On the Duty and Benefit of a daily Perusal of the Holy Scriptures.'

Lindley Murray, though subject for so many years to bodily infirmity as well as to some severe attacks of disease, continued to live till his eighty-first year. He died Feb. 16, 1826, with the reputation of being an exceedingly kind and good man. His wife survived him.

(*Memoirs of the Life and Writings of Lindley Murray, in a Series of Letters written by himself; with a Preface and Continuation of the Memoirs*, by Elizabeth Frank, York, 8vo. 1826; *Journal of Education*, vol. viii. (1834), p. 308, &c.)

MURRAY, JOHN, publisher, born November 27, 1778, died June 27, 1843. His father, originally an officer of Marines, whose name was MacMurray, purchased (1768) the business of Paul Sandby, 32, Fleet-street. John Murray was educated at several schools—at the High School of Edinburgh, at Kensington, at Dr. Burney's at Gosport, where he lost the sight of an eye by the accident of the writing-master's penknife running into it, and finally at Loughborough House, Kennington. At the age of fifteen he lost his father, a great misfortune, as it left him without control and direction; his mother married again, and his guardians neglected him. He had commenced business as a medical bookseller, in partnership with Mr. Highley, but having dissolved the partnership in 1803, he soon devoted his attention to a wider field of literary business. The son of an old friend and neighbour, Dr. Rennell, Master of the Temple, Mr. Stratford Canning, with some other youths at Eton, had commenced a periodical called 'The Miniature,' which brought them some fame, but left them under loss. Mr. Murray, with a good-nature which always distinguished him, and with something of that tact which enabled him, in his subsequent career, to seize upon occasions of cultivating powerful friends, on hearing of their situation took the copies off their hands, paid their expenses, and, though he found little demand for the work, offered to print a new edition. Through the friends thus made, he became known to Mr. Canning. In September, 1807, he wrote to that gentleman opening to him the plan of the 'Quarterly Review,' as a means of counteracting the political influence of the 'Edinburgh.' While maturing his project—the most important undertaking of his life—it chanced that a severe criticism on Scott's 'Marmion' (condemning the author for writing for money) appeared in the 'Edinburgh Review.' Mr. Murray instantly started for Scotland, was introduced to Scott at Ashiestiel, in September, 1808, found in him a warm supporter of his intended review, and with Scott's co-operation and that of his friends, the Hebers, George Ellis, Canning, Barrow, and Mr. Gifford, the editor, the publication commenced in 1809, and soon attained a circulation of 12,000 copies.

The closest alliance of business and friendship long subsisted between Mr. Murray, and Constable of Edinburgh, and the Ballantynes; but he early perceived the result of the reckless mode of business to which they had resorted, and foregoing the great advantages of the connection, after repeated and strong warnings and remonstrances, he separated from them. He published, however, 'The Tales of My Landlord,' and had no difficulty in discovering the real author of 'Waverley,' nor did he ever entertain any doubts on the subject.

In 1810 he sought and made the acquaintance of Lord Byron, giving 600*l.* for the two first cantos of 'Childe Harold,' which had been refused by another publisher. In 1812 he removed to Albemarle Street, where, increasing the number of his friends and literary connections, he soon surrounded himself with a circle of distinguished literary characters. In the afternoon might be found in his drawing-room, Scott, Byron, Campbell, Wm. Spencer, R. Heber, Gifford, D'Israeli, Mr. Ward (Lord Dudley), Canning, Hallam, Croker, Barrow, Madame de Staël; and, a few years later, Crabbe, Southey, Belzoni, Washington Irving, Lockhart, and many more.

His acquaintance with Byron extended over a period of more than ten years, and the poet's correspondence with him is printed in Moore's Life of Byron, where will be found more than one proof of his liberal mind. Having heard in 1815 that Lord Byron was in pecuniary difficulties, he sent him a draft for 1500*l.*, promising another for the same amount in the course of a few months, and offering to sell the copyright of Byron's works for his use, if that were not sufficient. He abandoned the publication of Lord Byron's Autobiography, at a considerable sacrifice, because it was thought that parts of it might hurt the feelings of the living, and not do credit to the dead. The MS. and the only existing copy of it were consequently committed to the flames in 1824. Soon after Mr. Murray commenced printing a series of cheap works in parts, consisting of 'Modern Voyages,' the publication of which was delayed by circumstances;—a specimen however given by him to Captain Basil Hall was taken to Edinburgh, and suggested to Constable the notion of his Miscellany. In 1826, trusting to others more sanguine than himself, and allowing his own good judgment, perhaps, to be misled by partiality for the projector, he commenced 'The Representative,' a daily newspaper—almost the sole undertaking of his life which proved a failure. It was attended with considerable loss, which fell entirely on him, and was soon given up. Among his valuable and successful publications were the expeditions of Mungo Park, Belzoni, Parry, Franklin, Denham, and Clapperton—the Family Library, begun April, 1829—the Domestic Cookery, of which nearly 300,000 copies have been sold, the fortunate title having been suggested by himself—Markham's Histories—the Sketch Book—and Deathbed Scenes. The three last works, originally published by others, proved failures until Mr. Murray, perceiving their merits, took them into his own hands.

Further particulars redounding to his credit as a liberal-minded man of business and a gentleman, will be found in the Lives of Byron, Scott, and Crabbe, and especially in his modest 'Answer to the Calumnies of Captain Medwin,' appended to Byron's works.

The 'Quarterly Review,' always the object of his pride and solicitude, was conducted from 1809 to 1825 by Mr. Gifford, since which, with the exception of one year (March to December, 1825), during which Mr. (now Justice) Coleridge was editor, it has been directed by Mr. Lockhart. Although the principles on which it was established and conducted, excluded the publisher from any interference in its management, yet his tact and perseverance in catering for it, in suggesting subjects for review, and in enlisting contributors, tended much to its popularity. He was an excellent man of business; and, when he really applied, could get through more work than most men. No one better understood how to measure the calibre of an author's genius, or the extent of his popularity, and few could be more skilful in timing a publication, so as to secure its favourable reception. His eminent merit—that which distinguishes him above the majority of his class—was that he dealt with the commercial department of literature in a spirit far above that of the mere dealer and chapman. Had he thrown away his capital and his talent upon the idle scheme of patronising every literary adventurer—a design which some think the especial duty of every publisher—a few years would have conducted him to ruin. But he did better than this. He indirectly encouraged all literary effort by dealing honourably and generously with authors whose reputation was established, or of whose success there could be no doubt. This was not patronage, but equitable distribution of the rewards of the capitalist and the labourer. He was distinguished too, by his careful avoidance of the low arts of puffing; he published, for the most part, books of worth, and his imprint alone gave a recommendation to a book which raised it above the necessity of advertising quackery. Mr. Murray continued to take an active share in his business until within a short time of his death. Although his health had been in a precarious state for some months preceding it, no danger was apprehended until two or three days before this occurred. Mr. Murray married in 1807 the daughter of Charles Elliot, bookseller, of Edinburgh, by whom he left one son, who continues his business, and three daughters.

MUSCA, a genus founded by Linnæus for the reception of the Dipterous insects, commonly known as Flies. The Linnæan genus has been broken up by subsequent entomologists into many genera and even families. Of the typical family *Muscidæ* no fewer than 1700 European species have been described by Meigen, and nearly as many more extra-European have been described by Robineau Desvoidy in a quarto volume of 812 pages, devoted entirely to this subject.

Many of the *Muscidæ* are interesting on account of their habits. Some of the species of *Myobia* deposit their eggs in the nests of Hymenoptera, so that their larvæ when hatched may feed on the stores of provisions there collected. The larvæ of *Tachina* are parasitic on other larvæ. Those of some other genera are only found in the dead bodies of particular species of animals, as *Cynomyia*, which reside in the carcasses of dead dogs. The blue-bottles and blow-flies, species of *Lucilia* and *Calliphora*, lay their eggs in meat, which becomes fly-blown. *Anthomyia* deposits its eggs in manure or in the roots of vegetables, and *Tephritis* in growing plants. The cheese-maggot is the larva of an insect of this family named *Piophila casei*. *Drysophila cellaris* deposits its eggs in fermented liquors.

Most of these flies are extremely prolific; the ovaries of the female flesh-fly (*Sarcophaga carnaria*) have been found to be arranged in spiral fashion and to contain as many as 20,000 eggs.

(Westwood, *Introduction to the modern Classification of Insects;* and the writings of Meigen, Haliday, Desvoidy, and Macquart.)

MUSCA'RI, a genus of plants belonging to the natural order Liliaceæ. It has a globose or subcylindrical perianth narrowed at the mouth and 6-toothed. The stamens are inserted at about the middle of the tube, the filaments not decurrent.

M. racemosum, Grape Hyacinth, is the only British species of this genus. It abounds in Suffolk near Pakenham, and is found in some other parts of Great Britain. It has ovate nodding crowded flowers, the upper ones nearly sessile, abortive; the leaves linear, flaccid, and recurved. The flowers are of a dark blue colour. It grows most abundantly in sandy fields.

The bulbs of *M. moschatum* are, according to Lindley, emetic.

(Babington, *Manual of British Botany;* Lindley, *Vegetable Kingdom.*)

MUSCOVADO SUGAR. [SUGAR, P. C.]

MUSCULAR TISSUE. [TISSUES, ANIMAL, P. C. S.]

MUSEUM OF ECONOMIC GEOLOGY. This institution owes its origin to the suggestions of Sir H. T. De la Beche, who in 1835 submitted to the Chancellor of the Exchequer, that the persons employed in the Ordnance Geological Survey had constant opportunities afforded them of collecting specimens illustrative of the application of geology to the useful purposes of life, and of the mineral wealth of the kingdom. The advantages which would arise from such a collection, and its exhibition to the public, under the care of the Board of Public Works, were also briefly pointed out.

The Museum now occupies the houses Nos. 5 and 6, Craig's Court, Charing-Cross, the former containing the Mining Record Office, and the latter the specimens; the establishment is open daily to the public, between the hours of ten and four in summer, and ten and five in winter. The principal officers to the establishment are Sir H. T. De la Beche, already named as the Director, Mr. Richard Phillips, Curator, who is also chemist to the Museum, conjointly with Dr. Lyon Playfair; Mr. Robert Hunt is keeper of the Mining Records.

The objects contemplated in the arrangements which have been effected were—to obtain specimens of the various mineral substances used for the construction of public works or buildings, or for road-making; of such as are employed for useful or ornamental purposes in the arts, or from which the useful metals are extracted; these being arranged with reference to the instruction of those to whom such knowledge would be advantageous, either in a scientific or practical point of view.

With respect to building-stones it may be observed in illustration of the utility of the establishment, that there exists in it a collection, described by appended tickets, of the various specimens of building-stone, procured by the commissioners appointed in 1838, to visit the quarries and examine the qualities of the stone to be used in building the New Houses of Parliament. These specimens, with the very elaborate report in which their properties are described, cannot fail to be a source of great and lasting utility to the architect who seeks for information.

In addition to these specimens there are also exhibited numerous polished granites, porphyries, and marbles from various parts of the kingdom: some of the specimens are turned into columns, and others formed into vases.

Another object intended to be effected by the formation of the Museum is the promotion of improvements in agriculture, by exhibiting sections of strata, with specimens of soil, subsoils, and the rocks from the decomposition or disintegration of which they have been produced. It is intended, by this department of the Museum more especially, to exhibit the relations of geology to agriculture by imparting such a knowledge of the material composing the substrata as may suggest the means of permanent improvement on the surface. As constituting a large and most important proportion of the mineral riches of the empire, the Director has been especially careful in collecting specimens of coal from every part of the kingdom, and the public have liberally contributed to this and indeed to every part of the institution.

An annual grant is voted by Parliament for geological sections of railway cuttings, a service of much importance, especially in the mineral districts.

The Museum contains an extensive collection of the various metalliferous ores of Great Britain, with specimens of the results of the metallurgic processes by which the metals are extracted, accompanied with illustrations of many of the purposes to which the metals are applied.

The application of various earths and metallic oxides to enamelling, and the manufacture of glass and of porcelain, is illustrated by specimens of the art of different ages.

It is to be further observed that a laboratory forms another department of the Museum; in this the analysis of soils and minerals is performed for the public on very moderate terms, and pupils are admitted into the laboratory for instruction in analytical and metallurgic chemistry.

In the Mining Record department are deposited plans and sections, and models of mines, and of the machinery by which they are worked; it also contains workshops in which many of the models have been constructed; and collections of mining tools used in several of the different countries are also exhibited. This department having for its objects matters which concern particular parties, rather than the public generally, is, from the nature of its contents, not open to indiscriminate admission, but every reasonable facility is afforded to all operative miners as well as the owners or agents of mineral properties, by application to Mr. R. Hunt.

In concluding this brief sketch of the Museum, we may observe that, owing to the great liberality with which it has been supported by the government and by the public, it has been for some time past impossible to exhibit the accumulated specimens for want of room. It is understood that, on this account, Government is building a larger and more commodious house for the purpose, which will extend from Piccadilly through to Jermyn-street.

MUSHROOM. [AGARICUS, P. C.]

MUSIS, A DE. [VENEZIANO, AGOSTINO, P. C.]

MUSOCA'RPUM, a genus of fossil plants, the fruits only known. From the coal measures of Lancashire. (Brongniart.)

MUSSOWA, or MASSOWA. [ABYSSINIA, P. C. S., p. 24.]

MUTI'LLIDÆ, a family of Hymenopterous insects corresponding to the Linnæan genus Mutilla. These bees belong to Latreille's division *Fossores*, and some of the species are remarkable for the power of their stings.

MUZIA'NO, GIRO'LAMO, an eminent Italian painter, was born at Acquafredda near Brescia, in 1528. He was first instructed by G. Romanino at Brescia; he then turned his attention to the colouring of Titian, and particularly to his landscape backgrounds. About 1550 he went to Rome, where he first attracted notice as a landscape-painter, and he was known there as the Giovane de' Paesi, or Girolamo de' Paesi, 'landscape Jerome.' He however soon showed that he was equally capable not only in all departments of painting, but in other kindred arts likewise; and he became one of the first painters of his time, and even in the characteristic grand style of the Roman school he obtained a place in the ranks of the greatest masters. Michelangelo himself pronounced Muziano to be one of the first painters of the age, when he saw his large picture of the Resurrection of Lazarus, which he painted for the church of Santa Maria Maggiore. This picture was afterwards removed to the Appartamento de' Principi in the Quirinale, or papal palace of Monte Cavallo, where it still was, according to Titi, in 1763, but it was not seen there by Ramdohr a few years afterwards. There was a Resurrection of Lazarus by Muziano in the Orleans Gallery at Paris, but as this piece was engraved by S. Vallée for the 'Cabinets de Crozat,' in 1729, as a part of the Orleans collection, it cannot be the picture so much approved of by Michelangelo, unless the account of Titi is incorrect. When the part of the Orleans collection, of which it was one, was sold by auction in London in 1800, it fetched only fifty-six guineas: who the purchaser was, or where it is now, is not publicly known.

There are many of Muziano's works in the churches and palaces of Rome, in oil and in fresco; there are also works by him in the cathedrals of Orvieto and Foligno, and in the church of the Madonna at Loreto. There is likewise a very celebrated picture by him of Christ washing the feet of his disciples, in the cathedral of Rheims: it has been engraved by L. Desplaces. Muziano painted many historical landscapes, or landscapes with historical personages or events so introduced into them as to be secondary objects, and of little service beyond affording subject for a title to the landscape. Several of these pictures have been engraved by C. Cort, who executed also some prints after other works by Muziano.

Muziano superintended the Roman mosaic-works, and executed some parts of pictures himself in this style. He performed great services in the art of working in mosaic: what was merely a crude and ornamental art of inlaying coloured stones, he brought almost to the perfection of painting. As an architect, he built the Capella Gregoriana, or the chapel of Gregory XIII. in St. Peter's, in which are two of his best pictures, which however he did not live to complete; they were finished by his most distinguished scholar Cesare Nebbia, a painter of Orvieto. Muziano also completed the series of drawings which Giulio Romano had commenced from the sculptures of the Colonna Trajana at Rome, and the first prints of these bassi-rilievi were made from these drawings: the prints of Bartoli were engraved from drawings by himself. The foundation of the Academy of St. Luke at Rome is also due chiefly to the exertions of Muziano: he procured the brief of its establishment from Gregory XIII., and it was confirmed by Sixtus V.

Muziano died at Rome in 1590, according to Baglione (Ridolfi says 1592), and was buried in the church of Santa Maria Maggiore, near the spot where his picture of the Resurrection of Lazarus was placed. His style was severe, and more than ordinarily correct for his time, though he may be reckoned among the imitators of Michelangelo, whose anatomical display seems to have had its due share of influence on the taste of Muziano. Many of Muziano's works have been engraved by some of the best engravers of the seventeenth and eighteenth centuries, and by his contemporaries Ch. Alberti and C. Cort.

(Baglione, *Vite de' Pittori*, &c.; Titi, *Pitture, &c. di Roma;* Ramdohr, *Mahlerei und Bildhauerarbeit in Rom;* Lanzi, *Storia Pittorica*, &c.; Waagen, *Kunstwerke, &c. in England.*)

MY'GALE, a genus of spiders, the species of which have their eyes placed closely together at the anterior extremity of the thorax. They spin their webs in the form of tubes, in which they reside concealed in holes in the ground, or under stones, or the bark of trees. In consequence of the representations of Madame Merian, some kinds of *Mygale* have become celebrated as bird-catching spiders. Mr. W. S. Macleay has however shown that Madame Merian's drawing is not to be trusted, since the *Mygale* there figured is a subterranean spider, and makes no net in which to entrap small birds. The same distinguished naturalist has observed a spider belonging to the genus *Epeira* eating a young bird of the genus *Zosterops*, which had been entangled in its net in a garden in Sydney, New Holland. In a communication of Mr. Macleay's, published in the 'Annals of Natural History' for 1842, he remarks on the subject of bird-catching spiders as follows:—'My conviction is that Madame Merian has told a wilful falsehood respecting *Mygale*, or rather has painted a falsehood; and that her followers have too hastily placed confidence in her idle tales. My conviction is that no *Mygale* can catch birds in its net; for, as I have said in the paper printed in the Zoological Transactions, it makes no geometrical net. Nay, further, I have proved that the genus *Nephila*, which lives in a geometrical net, does not catch birds either here or in the West Indies; and moreover, I have ascertained that birds are not the proper food of this New Holland *Epeira.*' The *Mygale Ionica*, a Grecian species, forms a very ingenious trap-door with which to close up the mouth of its tube.

MYOSU'RUS (from μῦς, a mouse, and οὐρά, a tail, the seeds being seated on a long receptacle 'which looks exactly like the tail of a mouse'), a genus of plants belonging to the natural order Ranunculaceæ. It has a calyx of 5 sepals, prolonged into a spire at the base; the petals 5, with a filiform tubular claw; the capsules closely imbricated upon a long filiform receptacle, not bursting; the seed pendulous; the embryo inverted with the radicle superior. The only species of this genus is *M. minimus*, which has a simple leafless single-flowered stem 2 to 5 inches high. It has a very long receptacle, numerous carpels, and linear leaves. It grows in damp places and in fields. It is a native of Europe and America. The American plant has been described as *M. Shortii*, but there is every reason to believe it is the same as the British and other European plants.

(Babington, *Manual.*)

MYOSO'TIS (from μῦς, a mouse, and ωτ, the crude form of οὖς, an ear), a genus of plants belonging to the natural order Boragineæ. It has a 5-parted calyx, the corolla salver-shaped, contorted in æstivation; the throat closed with scales, the limb 5-fid, obtuse; the stamens included, with filaments very short; the style simple, the nuts smooth, externally convex, keeled within, attached by a minute lateral spot near their base. This genus is distinguished from all the other Boragineous genera, by the possession of a contorted æstivation of the corolla. The species are annual or perennial, rough or smoothish plants, with blue flowers in terminal racemes, which are revolute before expansion. About fifty species have been described, which inhabit the more temperate parts of Asia, Africa, and America, and are found abundant in Europe. Eight species are found in Great Britain.

M. palustris, Great Water Scorpion-Grass, or Forget-me-Not, has the calyx open when in fruit, and shorter than the pedicel, with straight adpressed bristles; the teeth short, triangular, the limb of the corolla flat, longer than the tube, the lobes slightly emarginate, the pubescence of the stem spreading. It is a native throughout Europe, and also of Asia and North America. In Great Britain it is found in humid meadows, bogs, banks of rivers, rivulets, and ditches. This plant has a large bright blue corolla with a yellow eye. It is a beautiful plant, and when once seen will be seldom forgotten. It is probably on this account that it has obtained its common name Forget-me-Not. Amongst the young it is regarded as emblematical of true affection. A variety is described with white flowers.

The following are the remaining British species of this genus:—

M. repens, Mouse Ear, with narrow lanceolate teeth; lobes of the corolla slightly emarginate, the pubescence of the stem spreading. Found in boggy places.

M. cæspitosa with narrow lanceolate teeth; the limb of the corolla equalling the tube, the lobes entire, the pubescence of the stem adpressed. Found in watery places.

M. suaveolens has an attenuated calyx; the limb of the corolla longer than the tube, the root-leaves on long stalks pointed. Only found in Scotland on the summits of the Breadalbane mountains.

M. sylvatica has a calyx rounded below, deeply 5-cleft, closed when in fruit; the limb of the corolla longer than the tube, flat; the root-leaves bluntish. Found in shady places.

M. arvensis, Field Scorpion-Grass, has the calyx half 5-cleft; the limb of the corolla equalling the tube, concave. Grows in cultivated land and thickets.

M. collina has the calyx open and ventricose when in fruit. Found on dry bank·

M. versicolor has the calyx closed and oblong when in fruit. It has small flowers, at first pale yellow, afterwards blue. Found in meadows and on banks.

None of the species are used in medicine or the arts. The British species are most desirable for cultivation, especially *M. palustris* and *repens*. All the perennial species require moist situations, as the edges of ponds or ditches. Some of the species may be grown in pots among other alpine plants. The annual species will grow in a dry sandy soil or on old walls, where the seed may be sown. The other species may be propagated by dividing the roots.

(Babington, *Manual of British Botany*; Don, *Gardener's Dictionary*.)

MYRIACA'NTHUS, a genus of fossil fishes, from the lias of Dorsetshire. (Agassiz.)

MYRIANI'TES, a genus of fossil Annelida, from the lower silurian strata of Lampeter, in South Wales. (Murchison.)

MYRICA (the Greek μυρίκη), a genus of plants the type of the natural order Myricaceæ. It has its flowers in catkins, which are composed of concave scales; 4 to 8 stamens. The fruit a 1-celled 1-seeded drupe, and no perianth. There are several species of this genus, which are shrubs or small trees.

One species, *M. Gale*, the sweet Gale or Box Myrtle, is a native of Great Britain. It has lanceolate serrate leaves broader upwards, with a shrubby stem. It is a bushy plant, about 4 feet in height; the catkins are sessile and erect; the fruit is covored with resinous glands, and the leaves are fragrant when bruised. This plant is found on the Continent of Europe, and also in North America, under the same circumstances as in Great Britain. The leaves, on distillation, yield a yellow æthereal oil, of a feeble odour, and mild taste, which after a little time becomes slightly warm. The leaves were formerly used as a remedy against the itch, and when bruised are placed amongst furs for the destruction of the moth. In decoction they are employed for the destruction of bugs and other vermin. In Sweden they are used as a substitute for hops in brewing.

M. cerifera, Wax-myrtle or Bay-tree, has cuneate lanceolate leaves, sometimes entire, but more frequently toothed, particularly toward the end, somewhat pubescent, a little paler beneath, and generally twisted or revolute in their mode of growth; has a branching half evergreen stem, from one to twelve feet high. The small flower is formed by a concave rhomboidal scale, containing 3 or 4 pairs of roundish anthers, on a branched footstalk. The pistilliferous catkins which grow on a different shrub are less than half the size of the staminiferous ones, and consist of narrower scales, with each an ovate ovary, and two filiform styles. To these catkins succeed clusters or aggregations of small globular fruits, which are at first green, but finally become nearly white. They consist of a hard stony covering, which incloses a dicotyledonous seed. The hard covering is studded on its outside with small black grains, and over these is a coating of hard white wax, fitted to the grains, and giving to the surface of the fruit a granulated appearance. This plant is a native of woods in the United States of America. The bark of the root of this plant is acid and astringent; in large doses it produces vomiting, accompanied by a burning sensation in the throat. It is used as a stimulant and astringent. The wax of the fruit is collected and purified, and used for many of the purposes for which bees-wax and candles are employed. The wax has been occasionally used in pharmacy in the same way as common bees-wax.

The fruit of *M. sapida*, a native of Nepal, is about the size of a cherry, and is pleasantly acid and eatable.

(Lindley, *Flora Medica*; Lindley, *Vegetable Kingdom*; Babington, *Manual of British Botany*.)

MYRIOPHYLLI'TES, a genus of fossil plants, from the coal measures. (Artis.)

MYRIOPHYLLUM (from μυρίος, numerous, and φύλλον, a leaf), a genus of plants belonging to the natural order Halorageæ. It has monœcious flowers; a 4-parted calyx; 4 petals fugitive, longer than the calyx in the staminiferous flowers, small and reflex, or none in the pistilliferous flowers; the stamens 8, styles 4, villose; the fruit tetragonal, separable into 4 hard nuts. The species are floating aquatic herbs, rising above the water to blossom. The leaves are finely cut opposite or verticillate; the flowers are small, disposed in axillary whorls or in whorled spikes, the upper leaves being almost all abortive.

M. verticillatum, verticillate water milfoil, has the flowers all axillary whorled, the bracts pinnatifid. It is a native of Europe, in ponds, ditches, pools, and lakes, but never in running water. It is found in Great Britain, but is a rare plant.

M. spicatum, spiked water milfoil, has the flowers whorled, forming a leafless spike, the bracts small entire, the spike erect when in bud. It is a native of Europe and North America, in ditches, lakes, and pools, never in running water; it is found abundantly in Great Britain.

M. alternifolium has the spike drooping when in bud, and the fertile flowers in axillary whorls. It is found in ponds and ditches in Europe, in Great Britain rarely.

About ten other species of this genus from various parts of the world have been described. There are none of them employed in medicine and the arts, and they are only worth cultivating in botanical gardens. When it is wished to grow the tropical species, G. Don recommends that small parts 'should be taken up in the autumn, planted in a pan of water and then to be placed in the stove in order to preserve them in a living state during the winter, and in the course of the April or May next season, may again be returned to the pond in the open air, where they will thrive much better than if grown all the year round in pans of water or cisterns in a hothouse.'

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

MYRIPRISTIS, a genus established by Cuvier for certain tropical fishes of the family of Perches.

MYRME'LEON, a genus of large neuropterous insects, the larvæ of which are remarkable for their habit of entrapping their prey by means of pitfalls. Among the many accounts which have been published of their operations, one of the best and most recent is that given by Mr. Westwood, in the 'Magazine of Natural History' for 1838, and in his Introduction. 'Some larvæ of the common species, *Myrmeleon formicaleo*,' writes that naturalist, 'which I brought alive to this country from France, afforded me ample opportunities for watching their proceedings. It is in very fine sand that the larva makes its pitfall. When placed upon the surface, it bends down the extremity of the body, and then pushing or rather dragging itself backwards by the assistance of its hind legs, but more particularly of the deflexed extremity of its body, it gradually insinuates itself into and beneath the sand, constantly throwing off the particles which fall upon, or which it shovels with its jaws or legs upon its head, by suddenly jerking them backwards,

Ossaque post tergum magnæ jactata parentis.

Proceeding in this manner, in a spiral direction, it gradually diminishes the diameter of its path, and by degrees throws so much of the sand away as to form a conical pit, at the bottom of which it then conceals itself, its mandibles widely extended being the only parts that appear above the surface; with these any luckless insect that may happen to fall down the hole is immediately seized and killed. When the fluids of the victim are exhausted the ant-lion, by a sudden jerk, throws the dry carcass out of the hole: should, however, the insect by chance escape the murderous jaws of its enemy, the latter immediately commences throwing up the sand, whereby not only is the hole made deeper, and its sides steeper, but the escaping insect is probably hit, and again brought down to the bottom of the pit. It is chiefly upon ants and other soft bodied insects these larvæ feed. They are however capable of undergoing long fasts, for one of my larvæ remained from October till March without food. Previous to assuming the pupa state, the larva forms a globular cocoon of less than half an inch in diameter of fine sand, glued with silken threads spun from a slender telescopic-like spinneret, placed at the extremity of its body, and lined with fine silk. The pupa is small, not being half-an-inch long, inactive, and with all the limbs laid at rest upon the breast. When ready to assume the perfect state, it uses its own mandibles, which are quite unlike those of the larva and imago, to gnaw a hole through the cocoon, and pushes itself partly through the aperture in which it leaves the pupa skin. Immediately on assuming the perfect state, the abdomen is almost immediately extended to nearly three times its previous length.'

(See also the writings of Rösel, Reaumur, and Bonnet and Guilding.)

MYRON, one of the most celebrated artists of antient Greece, and the sculptor of the Discobolus, or Quoit-thrower, of which that among the Townley Marbles in the British Museum is supposed to be an antient marble copy, was born at Eleutheræ in Bœotia about 480 B.C. Myron was the fellow-pupil of Polycletus under Agelades; he was therefore in the prime of life at about the time that Phidias died; and he lived at the height of his fame in Athens, where he was domiciliated, at the commencement of the Peloponnesian war.

Pliny gives the following account of Myron:—he first obtained reputation by a brazen heifer, much celebrated by the poets, which gives Pliny occasion to reflect that men derive more good from the wit of others than from their own. He made also a dog; a quoit-thrower; Perseus killing Medusa; and, as Böttiger explains *pristæ*, sea-monsters; also a satyr admiring a flute; Minerva; Delphic pentathletes; pancratiasts; a Hercules which was in the temple of Pompeius in the Circus Maximus; and also a statue of Apollo which Marcus Antonius brought from Ephesus, and Augustus restored to the Ephesians, being warned to do so in a dream.

Myron is said to be the first who represented in sculpture Nature in her multiplicity of forms: he represented man and animal with equal success; he almost, says Petronius (*Satyric.* c. 88), gave the souls of men and animals to brass. He was, says Pliny, more numerous and various than Polycletus, but was not so exact in his proportions: he was curious in all corporeal detail, but paid little regard to expression: whether Pliny means this or not by the words 'ipse tamen corporum tenus curiosus, animi sensum non expressisse,' it is a characteristic which would very probably distinguish a sculptor who was excellent in representing animals, a quality indicating a strong love of the variety of forms. Myron seems to have adhered in the head and face to the earlier type, as rendered sacred by age, for he kept the hair, beard, and features in the formal manner of the earlier artists, which he much more probably did from taste than from any want of perception, as Pliny seems to imply.

From an observation of Pliny's, Winckelmann placed Myron back to the time of Anacreon and Erinna: Pliny supposed that an epigram of Erinna spoke of a monument to a grasshopper and a locust by Myron; this epigram is in the Greek Anthology, and is ascribed to Anyte, but the Myro, not Myron, there spoken of, says Sillig, is a virgin whose charms were sometimes fatal to her rivals. Myron executed many works besides those mentioned by Pliny, though some of them were preserved at Rome. Augustus placed four oxen in the portico of the temple of Apollo on the Palatine Mount, and a statue of Hercules is mentioned by Cicero as one of the works plundered by Verres. A statue of Apollo also, with the name of Myron on the thigh in silver letters, was plundered by Verres from the temple of Æsculapius at Agrigentum, where it had been consecrated by Publius Scipio: Pausanias mentions the Perseus killing Medusa. A great work by Myron was a group in the Heræum at Samos, of Jupiter with Minerva and Hercules, one on each side, of which the figures were colossal: it was removed to Rome by M. Antonius, but the Minerva and Hercules were restored to their place again by Augustus: the Jupiter he placed in the Capitol. A Bacchus is mentioned by Pausanias, which, he says, after his Erectheus, was Myron's best work at Athens. The Athletes by Myron must have been very numerous, as he was particularly distinguished for works of this class; there is mention of several in Pausanias and other antient authors; as Ladas, a celebrated Lacedæmonian runner; two of Lycinus, a Lacedæmonian charioteer, at Olympia; Timanthes of Cleonæ, a pancratiast; Philippus of Pallene, a juvenile pugilist; and one supposed to be Chionis of Lacedæmon, also an Olympic victor, but denied by Pausanias to be Chionis (vi. 13).

All the above works were executed in bronze of Delos; Polycletus used the Ægina bronze. But Myron was also a sculptor in marble, a carver in wood, and an engraver of metals. Pliny mentions a celebrated marble statue of a drunken old woman, at Smyrna, by Myron; and Pausanias describes by him a single-bodied Hecate with one head, in wood, which he saw on the island of Ægina: she was the chief divinity of the Æginetans according to Pausanias (ii. 30).

The most celebrated of all Myron's works was his Cow, lowing, and according to some suckling a calf; there are no less than thirty-six epigrams on this work in the Greek Anthology. No human figure has attracted so much notice, and doubtless much of the admiration this work excited was owing to its novelty. Athens was full of gods and men, but bronze animals were certainly rare, and this Cow may have been the first good work of its class that was set up at Athens: the horses of Phidias were mere bassi-rilievi placed under a colonnade and of a small size, and, however excellent, would have little effect compared with an isolated bronze, perhaps gilded, figure of the natural size, and fixed upon a marble pedestal in the centre of a public place. So according to Cicero it still stood in his time, though it was removed before Pausanias visited Athens, for he did not see it: in the time of Procopius it was in the temple of Peace at Rome. Ausonius wrote the following beautiful epigram on this work:

> Bucula sum, cælo genitoris facta Myronis
> Ærea; nec factam me puto, sed genitam.
> Sic me taurus init; sic proxima bucula mugit;
> Sic vitulus sitiens ubera nostra petit.
> Miraris quod fallo gregem? gregis ipse magister
> Inter pascentes me numerare solet. (*Epig.* 58.)

The same idea is still more happily expressed in an old Greek epigram, incorrectly attributed to Anacreon; the following English version of it is from an old translation of Anacreon printed by Curl, and is adopted by Fawkes:—

> This heifer is not cast, but rolling years
> Hardened the life to what it now appears:
> Myron unjustly would the honour claim,
> But Nature has prevented him in fame.

Sonntag has collected all the numerous epigrams on this work of art. The Discobolus by Myron was one of the most celebrated works of antient art: the original was in bronze, but there are still several antient copies of it in marble, though not one entire: one in the Campidoglio, one in the Vatican, and a third was in the Villa Massimi at Rome; that in the British Museum was found in the villa of Hadrian near Tivoli, in 1791, and passed into the possession of Mr. Townley through the hands of Mr. Jenkins, a well-known dealer in works of art of that time. Some other trunks of antient statues, which have been variously restored, are also said to be marble imitations of this work of Myron. The Townley copy according to some critics has been incorrectly restored, and the head is said not to belong to it. In Lucian's description of the Discobolus of Myron the head is noticed as being turned and looking back, as it does in some other of the reputed copies of this celebrated work. It must be observed however that there is no proof whatever that any of these marbles are copied from the celebrated Discobolus of Myron. The Abbate Fea appears to have been the first to suggest the identity, which occurred to him from the similarity between the Massimi Discobolus found in the Villa Palombara in 1782, and a Discobolus by Myron as described by Lucian and in part by Quintilian. Quintilian (ii. 13) merely alludes to its distorted position and elaborate execution; Lucian (Philopseudes 18.) describes it more in detail: he says—'The Discobolus, in the twisted posture with the hand reversed and one knee bent, as if about to vary his attitude and rise with his throw, his head being turned to τὴν or τὸν δισκοφόρον—the quoit-bearer,' which Fea interprets by 'the hand in which he has the quoit.' These words are however sometimes rendered 'the girl or boy who holds the quoit;' implying that the thrower was not yet in action, having only assumed his position, turned his head back, and extended his hand to receive the quoit from the bearer in attendance, who is implied only by the attitude of the Discobolus, not expressed. The Townley marble is however throwing the quoit, both knees are bent, and the toes of the left foot, on which the figure partly rests, are turned back: the action is perfectly momentary, and he is already giving the impetus to his throw. Barry preferred the forward direction of the head, as in this statue, to the turn spoken of by Lucian and seen in other statues of this subject, as much more consistent with the necessary impetus of the throw: he says—'The position of the head, hanging down in the same direction as the body, is very remarkable in Mr. Townley's figure, as it is a deviation from the original of Myron, as described by Lucian, and consequently from the Massimi copy, which corresponds perfectly with that description. In all other respects these figures agree, and this deviation appears to have been not unwisely made, as in this way all ambiguity in the intention of the figure, by the direction of the eyes (which are not wanting in the action), is ingeniously avoided; and in finishing the action, at least an equal acceleration of impetus is produced by the head shooting upwards and forward, along with the other extremities.'

Myron had a son Lycius who was likewise a sculptor. He is mentioned by Pliny, and Pausanias (i. 23.) says he saw in the Acropolis at Athens a brazen boy holding a laver, by Lycius the son of Myron (Kühn and Amasaeus read Λυκίου instead of Λυκίου in this passage): Pliny calls Lycius the pupil of Myron.

sichten und Geschichte der Plastik bei den Griechen, in his *Andeutungen zu Vorträgen über die Archaeologie;* Göthe, *Propyläen;* Barry, *Works*, vol. i. See also *Specimens of Antient Sculpture, published by the Society of Dilettanti*, vol. i., and vol. i. of *The Townley Gallery* of the Society for the Diffusion of Useful Knowledge, in both of which the Discobolus is engraved.)

MYRRHIS, a genus of plants belonging to the natural order Umhelliferæ, and to the tribe Scandicineæ. It has an obsolete calyx; obcordate petals, with an inflexed point; the fruit not beaked; the carpel covered with a double membrane; the outer membrane with elevated keeled ridges hollow within, the inner one close to the seed; no vittæ. The species have leaves three times decomposed, the leaflets pinnatifid; the involucrum wanting; the involucels of many lanceolate ciliated leaves, the central flowers of the umbel staminiferous; the petals white.

M. odorata, Sweet Cicely, or Great Chervil, has the leaves downy beneath, the leaflets of the partial involucres lanceolate acuminate. This plant has a stem 2 or 3 feet high, round, leafy, and hollow. It is a native of Middle and South Europe and Asia, from Spain to Asia Minor, also of Germany, Switzerland, Austria, the South of France, and the North of Italy. In Great Britain it is found in pastures and hilly districts. This plant was formerly much used in medicine. It yields a volatile oil, which has a pleasant odour. The young leaves and seeds were used in salads, and the roots were boiled or eaten cold, or in tarts or in a variety of sauces. In Germany the seeds were added to soups, and in the North of England they are employed for polishing and perfuming old oak floors and furniture. *M. sulcatum* has hoary leaves, and is a native of Spain. Both species may be grown in any common garden soil, and propagated by seeds or division of the roots.

(Babington, *Manual of British Botany;* Burnett, *Outlines of Botany.*)

MYRTUS (Greek, μύρτος), a genus of plants, the type of the natural order Myrtaceæ. It has the calyx-tube somewhat globose, with the limb 5- or very rarely 4-partite; the petals 5, or very rarely 4; the stamens distinct; the berry 2- or 3-celled, somewhat globose, crowned with the segments of the calyx; several seeds in each cell, or very rarely solitary; uniform, with a bony testa; the embryo curved, cotyledons semicylindrical, very short, the radicle twice the length of the cotyledons. The species are shrubs with opposite quite entire pellucid-dotted leaves; peduncles axillary 1- or rarely 3-flowered.

M. communis, Common Myrtle, has solitary 1-flowered pedicels about the length of the leaves, bearing 2 linear bracteoles under the flowers; the calyx 5-cleft; the leaves ovate, lanceolate, or acute. This beautiful plant is a native of the south of Europe; it is found wild in France about Marseilles, and extends from that city along the sea-coast to Genoa, and throughout Italy. In these districts it forms thickets which sometimes grow within reach of the spray of the sea. This plant has been in all ages a great favourite in Europe. It was called by the Greeks μύρτος. Μυρσίνη is the name under which Hippocrates refers to this plant (*Morb. Mul.* i. 599). Theophrastus also uses this word and μυρρίνη and μυρρίς, in speaking of the myrtle. The Romans knew this plant by the name of 'Myrtus' (Plin. 12-13). This name has been adopted in most European languages: it is *Myrto* in Italian and Spanish; *Murte* in German; *Myrter* in Danish; *Myrten* in Swedish; *Mirte* in French; *Murta* in Portuguese.

The leaves of the myrtle, like the whole order, contain a volatile oil which possesses medicinal properties, and they were used as stimulants by the antients. The buds and berries of this plant also contain volatile oil, and were used by the antients as a spice, and are at this day, in Tuscany, employed as a substitute for pepper. The Tuscans also prepare a kind of wine from the myrtle called myrtidanum. The berries are used at the present day in Greece as a remedy in the diarrhœa of little children. The mode of administering them is to soak them in red wine. The flowers of the myrtle have an agreeable scent, and when distilled they form the perfume sold in France under the name of 'Eau d'Ange.' In addition to a volatile oil the myrtle contains tannin, so that in medicine its various parts have an astringent action, and have been used for this purpose. In Greece, Italy, and the South of France, the bark is used for tanning.

The myrtle is a half-hardy plant in this climate, although many individuals have lived and borne our winters for above a hundred years. The myrtle appears to have been introduced into England in the sixteenth century. There are at the present time many fine myrtle-trees in Great Britain and Ireland. At Cobham Hall, in Kent, there are several specimens 30 feet high. In the Isle of Wight it forms the hedges of many gardens. It cannot however be relied on, but may be easily cultivated by protection during the winter. Several varieties of the Myrtus communis are found in gardens, of which the following, from Don's 'Gardener's Dictionary,' may be regarded as the principal.

M. melanocarpa (D. C. Prod. iii. p. 239), fruit blackish. This variety of myrtle is frequent in the south of Europe and in gardens, where there are varieties of it with double flowers and variegated leaves.

Var. α. *Romana* (Mill. p. t. 184. p. 1), leaves ovate; pedicles longer. The common broad-leaved or Roman myrtle. It is sometimes called flowering myrtle, because it flowers more freely in England than any other variety.

Var. β. *Tarentina* (Mill. Dict.), leaves ovate; berries rounder. The box-leaved myrtle. Flowers small, and open late in the autumn. Leaves small.

Var. γ. *Italica* (Mill. Dict.), leaves ovate-lanceolate, acute; branches more erect. The Italian or upright myrtle.

Var. δ. *Bœtica* (Mill. Dict.), leaves lanceolate, acuminated. The orange-leaved myrtle.

Var. ε. *Lusitanica* (Lin. Op.), leaves lanceolate ovate, acute. (*M. acuta*, Mill. Dict.) The Portugal myrtle. The nutmeg myrtle appears to be only a variety of this.

Var. η. *Belgica* (Mill. Dict.), leaves lanceolate acuminated. The broad-leaved Dutch myrtle. Leaves crowded; dark green. The double flowering myrtle appears to be of this variety.

Var. θ. *mucronata* (Lin.Op.), leaves linear, lanceolate, acuminate. *M. minima* (Mill.), rosemary or thyme-leaved myrtle.

M. leucocarpa (D. C. Prod. iii. p. 239). Fruit white. Native of Greece and the Balearic Isles. The fruit of this is rather large, edible, with a grateful taste and smell.

The above varieties are constant; but there are others in the garden which are more variable. It will suffice to give the names of a few of these.

1. Gold-striped broad-leaved myrtle.
2. Broad-leaved Jew's myrtle. This variety frequently has its leaves in threes, on which account it is said to be in esteem among the Jews in their religious ceremonies.
3. Gold-striped leaved orange-myrtle.
4. Silver-striped Italian myrtle.
5. Striped box-leaved myrtle.
6. Silver-striped rosemary-leaved myrtle.
7. Silver-striped nutmeg myrtle.
8. Cockscomb, or bird's nest myrtle.
9. Spotted-leaved myrtle.

About forty other species of myrtle besides those of the old genus myrtus now referred to the genera Myrcia, Syzygium, Eugenia, &c., have been described. None of them yield products used in arts or medicine, and only a few of them have been cultivated.

M. tomentosa is a native of Cochin China. It is a handsome shrub, and has been found to grow well against walls in the south of England.

M. nummularia is a creeping species found at the Straits of Magellan; and *M. myrsinoides*, a native of the colder parts of Peru, would probably be found to be half-hardy in this climate.

The species of the genus Myrtus grow well in sandy loam and peat; and cuttings readily strike root either in sand or mould.

(Don, *Gardener's Dictionary;* Loudon, *Arboretum Brit.;* Fraas, *Synopsis Floræ Classicæ;* Burnett, *Outlines of Botany;* Lindley, *Flora Medica.*)

MYTENS, DANIEL, a native of the Hague, where he was born about 1590, was the best portrait-painter in England during the reign of James I., and previous to the arrival of Vandyck, to whom he was little inferior. He was in England in the time of Van Somer, but he did not attain to great celebrity until he was appointed one of his court painters by Charles I. in 1625, with a salary of 20*l.* per annum, and in the following year he received in addition 125*l.* for pictures painted for the king. Mytens now executed many portraits of royal and distinguished personages, some of which are at Hampton Court; and he was in great favour until about 1632, when he was so much disconcerted at the favour shown by the king to Vandyck, that he solicited Charles for leave to retire to his own country, but the king, learning the cause of his dissatisfaction, entreated him to remain, and told him that he should have work enough both for him and Vandyck. Mytens remained, but apparently for a short time only, as none of his works in England bear a date subsequent to the arrival of Vandyck. The two rivals however parted apparently on good terms, for Vandyck painted the portrait of Mytens, and it is engraved in the collection of Vandyck's portraits, by Pontius. Mytens returned to the Hague, and was still living there in 1656, when he painted a portion of the ceiling of the town-house of that place. His style was bold, firm, and natural, his colouring mellow and harmonious, and his pictures are frequently enriched by warm landscape backgrounds. There are many of his portraits at Hampton Court, of which the full-length of James, first Marquis of Hamilton, is an excellent picture: there are here also Prince Rupert when a boy, and the dwarf Sir Jeffrey Hudson, who, when seven years old, was served up in a pie at Burleigh, at an entertainment given by the Duke of Buckingham to Charles I. and Henrietta, and was presented by the duchess to the queen, who kept him as her dwarf. Hudson was then only eighteen inches high; he grew, after he was thirty, to the height of three feet nine inches. Mytens introduced this dwarf in a large portrait of Charles and his queen, which was in the possession of the Earl of Dunmore. Sir Jeffrey died a prisoner in the Gate-house, Westminster, in 1682, aged sixty-three: he was imprisoned upon suspicion of being concerned in the Popish Plot.

(Walpole, *Anecdotes of Painting*, &c.)

MYXI'NE, a genus of cartilaginous fishes, of the order *Cyclostomi*. It is synonymous with the *Gastrobranchus* of Bloch. The *Myxine glutinosa*, or glutinous Hag, is the type. This curious animal is shaped like an eel, and measures when full grown about one foot and a half. The head is scarcely distinguishable from the body, and is obliquely truncated in front, terminating in a large round mouth, the frame work of which is a membranous maxillary ring, furnished above with a single tooth. The tongue is furnished on each end with two rows of strong teeth. Eight filaments surround the mouth. In the middle of its superior margin there is a single round spiracle. It has no eyes. The branchial openings are two, and are estimated at about one-fourth the length of the body, below the mesial line. The skin is naked, and very slimy. Along each side of the belly there is a row of pores, which furnish the mucous secretion. An obscure fin runs along the hinder portion of the back, is continued round the compressed tail, and beneath the anal opening, which is placed near the tail. It is of a dark bluish brown colour above, and whitish beneath. The *Myxine glutinosa* is not uncommon in the Scandinavian seas, and is frequently taken off the north-east coast of Britain. It enters the mouths of fishes caught in the lines of the fishermen, and eats up all the fleshy parts of their bodies, leaving only the skin and bones.

The very anomalous characters of this fish have at different times caused naturalists to place it in more classes than one. Thus Linnæus classed it among *Vermes*; Modeer, among *Amphibia*; and O. F. Muller among *Mollusca*. That it is a true fish, though very low down in the series, has now been placed beyond doubt. It has furnished the subject of many elaborate essays. The most valuable is the celebrated memoir on the Anatomy of Myxinoideæ, by Professor John Müller, published in the Transactions of the Berlin Academy for 1834, illustrated by admirable anatomical drawings.

In that memoir the author proposes the following arrangement of the cartilaginous fishes, in which the exact position of *Myxine* and its allies in the series is well shown

CHONDROPTERYGIA.

Skeleton cartilaginous, cranium without sutures.

1st Order, BRANCHIOSTEGA.

1st Family, *Cataphracta*. Cartilage of the cranium, and skin of the trunk covered at intervals with cartilaginous tubercles.

Sturiones. Genus 1. *Sturio*.

2nd Family, *Nuda*. Body without tubercles.

Spatulariae. Genus 2. *Spatularia*.

2nd Order, HOLOCEPHALA.

Genus 1. *Chimaera*.

Genus 2. *Callorhyncus*.

3rd Order, PLAGIOSTOMATA.

1st Family, *Squali*. The bronchial apertures not attached to the head.

Genus 1. *Squalus*.

Subgenera.

Scyllium.	*Notidanus*.
Carcharias.	*Selache*.
Lamna.	*Cestracion*.
Galeus.	*Spinax*.
Mustelus.	*Centrina*.
Scymnus.	

Genus 2. *Zygaena*.

Genus 3. *Squatina*.

Genus 4. *Pristis*.

2nd Family, *Raiae*. The bronchial apertures attached to the head.

Genus 1. *Rhinobatus*.

Genus 2. *Torpedo*.

Genus 3. *Raia*. (Subgenera *Raia*, *Trygon*, and *Anacanthus*.)

Genus 4. *Propterygia*.

Genus 5. *Myliobates*, (subgenera, *Myliobates* and *Rhinoptera*).

Genus 6. *Cephaloptera*.

4th Order, CYCLOSTOMATA.

1st Family, *Hyperoartia*, palate imperforate.

Genus 1. *Petromyzon*.

Genus 2. *Ammocaetis*.

2nd Family, *Hyperotreta*, with the palate perforate. *Myxinoidea*.

Genus 1. *Myxine*.

(Müller enumerates only one species, the *Myxine glutinosa* of the northern seas. A representative species has since been made known from the Antarctic seas.)

Genus 2. *Bdellostoma*. (The fishes of this genus differ from the *Myxine* in having eyes, and more than one bronchial spiracle.)

(Müller enumerates four species as certain, viz.: *B. hexatrema* and *B. heterotrema* from the Cape of Good Hope; *Heptatrema* from the South Seas, and *Forsteri* from New Zealand. *B. Dombeyi* is regarded as doubtful.)

INDEX TO THE LETTER M.

VOLUME II.

N.

NAGPOOR, a district formerly included in the province of Berar, in Hindustan, but now in the adjoining province of Gundwana, of which the city of Nagpoor is the capital. Ellichpoor is the capital of Berar. The palace and seat of government of the raja of Berar is at Nagpoor, and hence he is as frequently styled the raja of Nagpoor as the raja of Berar. The state of Berar, or Nagpoor, is one of those over which the British authorities hold full political sway, with right of interference in case of mismanagement of the public revenue; and they have a political agent resident at Nagpoor. The British government is bound by treaty to protect the raja of Nagpoor, and he is bound to pay the British an annual subsidy of 80,000*l.*, to maintain five regiments of infantry and four regiments of cavalry, and a contingent force of 1000 cavalry to co-operate with the British in case of war. The area of the state is about 64,000 square miles, the population about 2,500,000, and the estimated revenue 350,000*l.* That portion of Berar which lies to the west of the river Wurdah is included in the territory of the Nizam of Hydrabad; and the title of raja of Nagpoor is consequently now perhaps a more appropriate title than raja of Berar, a large portion of the territory of Berar having been transferred to the Nizam after the termination of the Mahratta war.

(Hamilton's *East India Gazetteer;* Malcolm's *Central India;* Appendix to *Report on East India Produce.*)

NAIL. The use of nails being illustrated under JOINERY, P. C. S., p. 121, it will be sufficient here to notice the various modes by which they are manufactured.

Until a comparatively recent period almost every kind of nail was produced by hand-labour: each nail, however minute, was separately forged from a thin rod of iron, a process which is still followed in the production of what are technically known as *wrought* nails; and as nails so formed possess certain advantages, for particular kinds of work, over those formed either by casting, or by cutting or stamping out of rolled sheet metal, there is no reason to anticipate the total abandonment of this process, notwithstanding the continual improvement of nail-making machinery.

The making of wrought nails, which retains, in most places, the character of a domestic manufacture, forms the employment of a peculiar class of blacksmiths called nailors, who are very frequently assisted by the female members of their families. The nailor receives his iron in the form of narrow square rods, of various sizes, according to the kind of nail to be forged from them. Putting the ends of three or four such rods into the forge-fire at once, the nailor commences his work by withdrawing one when it is properly heated, and forging its end upon a small but very firmly bedded steel anvil to a tapering point. The pointed end is then cut off to the proper length, which is adjusted by a gauge, by laying it across a fixed chisel or *hack-iron,* and giving it a smart blow with the hammer. In some cases, as in making the kind of nail used for fixing horseshoes, this operation completes the nail; but in most cases a subsequent process is necessary to form the head. For this purpose the red-hot spike just cut off from the nail-rod is taken up and dropped, point downwards, into one of the holes of an instrument called a *bore,* which is a piece of iron, ten or twelve inches long, with a perforated knob of steel at each end. The holes of this instrument are made to fit the upper or thicker part of tho nail, and so countersunk at their upper ends as to form a kind of mould for the head of the nail. When dropped into one of these holes, a few well-directed strokes of the hammer upon the thick projecting end of tho spike or nail converts it into a head of any required shape. In making small nails it is sometimes practicable to forge and cut off two lengths from the nail-rod with one heating; but where this is not the case the nailor is enabled to proceed with his work without interruption by the convenient plan of having several rods in the fire at once, so that as soon as one is cool another is ready to his hand. In many cases, for tho sake of economy, two or three nailors work at one hearth, using the same fire and the same bellows in turn; and Holland, who, in his treatise on 'Manufactures in Metal,' in Lardner's 'Cabinet Cyclopædia,' vol. i. pp. 192-218, gives much curious information on the nail manufacture, describes a very simple, cheap, and convenient circular forge, patented in 1824 by Mr. Spencer, of Belper, around which five or six persons may work at the same time, and which possesses the further advantages of allowing the use of pure wood charcoal, by which the quality of the iron heated in it is improved, of having no back, and of having a grating to keep the fire clean, and to prevent the accumulation of clinkers. Though adapted also for some other purposes, this forge is especially intended for the use of nailors. The hammer used by nailors is larger or smaller, according to the size of the nails to be formed, and its usual form, according to Holland's description, is 'the frustum of a cone, the smaller end being the base, which, instead of forming a horizontal plane, as in the case of an ordinary round hammer, is inclined or sloped considerably towards the handle.' 'The degree of this obliquity, the weight of the hammer head, the size and shape of the handle,' &c., he adds, 'are matters of nice consideration, one nailor being rarely able to work comfortably with another man's hammer;' and hence, he observes, 'as they are somewhat given to tramping from place to place, each workman generally carries with him a favourite hammer, which, like the fabled mallet of Thor, is both the symbol and the agent of the owner's power.' Of the astonishing dexterity of some of this class of operatives Holland quotes a remarkable illustration from the 'Mechanics' Magazine' for 1828, in the case of a nailor who undertook and accomplished the task of making, in each of two successive weeks, seventeen thousand (1200 to a thousand of 20 lbs.) of double flooring nails; in performing which task, as each nail required about twenty-five strokes of the hammer, which weighs about two pounds, he made, including the cutting up of the nail-rods into convenient lengths, and re-uniting them when they became too short, no less than 1,033,656 strokes, and moved to and from the fire at which the rods were heated 42,836 times. This task is, Holland states, allowed to have been as much as three ordinary men could perform without difficulty.

For some purposes nails formed by the much cheaper process of casting have been long used instead of those wrought in the manner above described. Common cast nails are, however, so clumsy and so brittle that they can only be used for a few coarse purposes, as in plasterer's work, and in the nailing up of fruit-trees. By the introduction of great improvements in the manufacture, however, a very useful kind of cast nail, of an exceedingly pure material called malleable cast iron, has been successfully introduced for certain descriptions of woodwork. Nails of this kind are very neat and regular in their appearance, being cast with great accuracy; and they are annealed to such perfection that the metal will bear far more bending than ordinary wrought-iron without injury. This extraordinary degree of tenacity is, however, obtained at the expense of rigidity, such nails being often nearly as soft as copper, and therefore quite unsuitable for use in hard woods.

The comparatively high price of wrought nails, owing to the great amount of manual labour required in making them, and the insufficiency of cast nails as a substitute for them, has led to the introduction of many highly ingenious machines for forming nails by cutting, stamping, or compression, out of plates or rods of rolled-iron, and with such success that, for the ordinary purposes of the carpenter and joiner, cut-nails, varying in size from the smallest tack or brad up to spikes of six inches or more in length, have almost superseded those wrought by hand. According to Barlow's 'Treatise on Machinery and Manufactures,' in the 'Encyclopædia Metropolitana,' the earliest machine for nail-making was that contrived by Mr. French, of Wimborne, Staffordshire, in 1790, in which no material departure was made from the ordinary process of making nails by the hammer, but labour was saved by working hammers by water-power, so that women and children might perform work which would otherwise have required men. Barlow describes several contrivances of later date, in which the various processes of rolling, pressing, stamping and cutting are introduced; but for the details of such machinery we must refer to his work, that of Holland, above quoted, Dr. Ure's 'Dictionary of Arts,' and Hebert's 'Engineer's and Mechanic's Encyclopædia.' Dr. Ure attributes the invention of cut nails to the citizens of the United States, observing that, according to a report by the secretary of the state of Massachusetts, so long since as the year 1810 they possessed a machine which performed the cutting and heading at one operation, with sufficient rapidity to turn out more than 100 nails per minute. In the process now most commonly followed nails are cut from sheet-iron of suitable thickness, which is first reduced, by cutting transversely, into strips or ribands of a breadth equal to the intended length of the nails. These strips are then applied to a machine in which a chisel-shaped cutter descends with sufficient force to cut off from the end of the strip, at each downward stroke, a narrow piece sufficient to form one nail. As the nails are required to be of a tapering form, the cutter must be so fixed as to form a slightly oblique angle to the direction in which the strip is pushed into the machine, and this obliquity must be reversed or varied between each stroke, by means similar to those adopted in comb-cutting machinery. [COMB, P. C. S., p. 398.] If the nails are to be of any of the kinds to which the term *nail* is specifically applied, as distinguished from *brad*, the action of the cutter is simply reversed, so as to reduce the strip of iron into long wedge-shaped pieces, and the pieces thus separated are subsequently headed by pressure or stamping, so as to form finished nails; but if the nails are to be of the *brad* kind, the action of the cutters must be so modified as to produce cuts alternately at right and oblique angles with the edges of the strip. Nails of this kind need no subsequent heading, but are completed by the action of the cutter. The accuracy with which this operation is performed may be seen by laying together side by side, heads and points alternately, a number of cut nails or brads, when it will be found that they range exactly, so as to compose a regular strip. In some machines the cutters do not vibrate or vary their position, but the strip of iron is turned between each cut, so as to produce the same effect. Brads are frequently cut out of hoop-iron instead of transverse strips of sheet-iron, as above described; but the practice is much to be deprecated, although the brads so formed have a rather neater appearance than others; for it is evident that as, in the operation of rolling, the fibres of the iron are laid longitudinally in the strip, they must lie across instead of along the nails cut transversely from it, thereby rendering them very weak and brittle. The advantage derived from the superior squareness of cut nails, as compared with wrought, is alluded to under JOINERY, p. 121; and another peculiarity of considerable importance is that, as such nails are usually tapered in one direction only, their points are somewhat chisel-shaped, and, though sharp, as broad as the body of the nail. If, therefore, such a nail be placed with its chisel-shaped point across the grain of a piece of soft wood, it may be driven in without boring, and without the risk of splitting, which would arise if the nail were, as most wrought-nails are, tapered on every side.

In some of the coarser operations of carpentry nails are secured by *clenching*, or bending down their points with the hammer, after they have been driven completely through what they are intended to hold together. Hebert notices a very neat and secure substitute for this rather clumsy expedient, which consists in placing on the projecting end of the nail a little perforated plate of iron called a *rove*, resembling a very small nut, and then clenching or riveting the end of the nail down upon it. He states that this mode of fastening appears, though without reason, to be almost entirely confined to boat-building.

Nails of iron with ornamental brass heads are much used for hanging pictures upon, and for other purposes in which the heads of ordinary nails would be unsightly; and nails wholly formed of brass, copper, or metallic alloys, are used in ship-building, and for a few other purposes. For the mode of coating small iron nails or tacks with tin, for use in cases where rusting would be injurious, see TINNING, P. C., p. 482.

NAKHITCHEVAN. [EKATERINOSLAF, P. C.]

NANTEUIL, ROBERT, a celebrated French engraver and draftsman, was born at Rheims, in 1630, and was the pupil of his brother-in-law, N. Regnesson. He engraved chiefly portraits, in which class he is one of the most distinguished engravers, though he generally engraved the head only, without accessories; but he frequently executed them of the size of life. He also took portraits from the life in pastel in a very able manner; but as he used these chiefly to engrave from, few of them have been preserved. He engraved in line and in stipple, and generally combined both styles, stippling the middle tints; and he contrived to express colour to a considerable degree in his prints. Nanteuil died in 1678, and though he lived to the age of forty-eight only, he has engraved nearly 300 plates, almost exclusively portraits, and comprising many of the princes of Europe, and most of the celebrated men of France during the reign of Louis XIV., of whom alone he engraved nineteen portraits, all in different periods of his life. His master-pieces are J. B. van Steenberghen, after Duchatel, known as l'advocat de Hollande, 1668; M. de Pomponne, after Le Brun; F. M. la Mothe le Vayer, 1661; and Marshal Turenne, besides some others.

(Watelet et Levesque, *Dictionnaire des Arts*, &c.; Huber, *Manuel des Amateurs*, &c.)

NARDOSTACHYS, a genus of plants belonging to the natural order Valerianaceæ. The limb of the calyx is 5-parted; the lobes ovate, oblong, acute, leafy, somewhat toothed and permanent. The corolla is regular, ecalcarate, obtusely 5-lobed and bearded in the throat. There are four stamens, which are attached to the bottom of the corolla. The species are herbs with sweet-scented perennial roots, which are beset with erect fibres at the neck.

N. Jatamansi is a dwarf herbaceous plant with a long hairy tap-root. The stems are perennial, very short, and simply divided into a number of shaggy, scaly crowns, from which the leaves are produced. The branches erect, downy, and a few inches high. Leaves obovate, lanceolate, 5-ribbed, downy; those at the base acute, the upper ones obtuse. The flowers are of a pale pink colour, clustered in the axils of the upper leaves, which form a kind of involucre for them. It is native of Nepaul, on the Himalaya mountains, and in Delhi, Bengal, and Deccan. This species is the true Spikenard of the antients, and is esteemed not only as a perfume, but as a stimulant medicine. Oriental writers give it as a remedy for a multitude of diseases, and it seems to be really valuable in cases of epilepsy and hysteria.

N. grandiflora has a glabrous stem, oblong glabrous leaves, with solitary terminal flowers. The capsule is downy, and the lobes of the calyx evidently denticulated. It is native of Nepaul and Kumaon.

These plants should be grown in pots, in a mixture of loam, peat, and sand, and placed among other Alpine plants. They may be propagated by dividing at the root, or by seed.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

NARTHECIUM, a genus of plants belonging to the natural order Juncaceæ. The perianth is partly coloured, of 6-lineal lanceolate persistent leaves. The filaments are woolly, and the style undivided. It has a simple obtuse stigma. The capsules pyramidal, 3-celled and 3-valved. The placenta extends only a short distance up the inner edge of the dissepiment. The seeds have a long filiform appendage at each end.

N. ossifragum, the only British species, has lineal sword-shaped leaves, pedicels with one bract at the base, and another above their middle. The perianth longer than the stamens, and considerably shorter than the capsules. The flowers are bright yellow. This species is distinguished especially by its seeds. It is found in turfy bogs.

(Babington, *Manual of British Botany*.)

NASIREANS. [NAZARENES, P. C.]

NASMITH, DAVID, was born in Glasgow, on the 21st of March, 1799, of respectable parents, who educated him with a view to his entering upon a course of college study at the University of that city. Finding, however, that he was averse to the study of the learned languages, this intention was abandoned, and he was early placed in a mercantile establishment. In 1813 he commenced the efforts by which he subsequently became so eminently distinguished, by taking an active part in the formation of a Youths' Bible Association at Glasgow, of which he became secretary; and at the age of sixteen he made a public profession of religion by joining the church in Nile-Street, under the pastoral charge of the late Rev. Greville Ewing. He shortly afterwards made great exertions to prepare himself for the Christian ministry; but as his friends did not encourage the attempt, he returned to secular employment, but engaged with great zeal in Sunday-school teaching, in the establishment of adult-schools, the religious instruction of prisoners, and other philanthropic efforts. In the autumn of 1821 an event occurred which, by affording enlarged scope for his benevolent desires for the religious and temporal welfare of his fellow-men, led to the fuller development of a character which, for disinterested devotedness, has been rarely equalled. 'The conductors of the various religious and benevolent societies in Glasgow,' observes Nasmith's biographer, 'with a view to concentration, economy, and efficiency, had procured a large and commodious edifice, which was divided into rooms and offices, suitable to their respective objects;' and the completion of their plan required the services of an active secretary, who should be common to them all. In answer to an advertisement for such an officer, Nasmith offered himself, and was elected at the low salary, for the first year, of sixty pounds, though the interests of twenty-three societies thus dovolved upon him. In this office he was brought into frequent communication with committees composed of ministers and laymen of all sects and parties, in religion and politics, and bo gained the personal esteem of many of the most eminent men of Glasgow; and the remarkable course of mental training thus afforded had the effect of fitting him for the singular career he was subsequently to pursue. To it his biographer attributes 'the free, easy, and noble air' by which he was distinguished in after life, and to which he appears to have been largely indebted for his influence over men who were strangers to his person, and who, in many cases, were inclined to regard his projects with prejudice and distrust. 'Even on the first interview,' observes Dr. Campbell in the 'Memoirs' upon which this article is chiefly based, 'no stranger could escape the impression that he was a man of extraordinary integrity and sagacity, piety and benevolence.' 'Mr. Nasmith,' observes Mr. Asthury, 'was a man of consummate ability and tact in the formation of societies.' 'It was,' he remarks, 'his great talent;' and it was manifested in his power of 'directing a committee without assumption on his own part, patiently attending to the various opinions of members of provisional committees in the discussion of rules, &c., and gently intimating his own judgment, which, being founded on great experience, was generally adopted.' In this office he also, to return to Dr. Campbell's account, 'obtained a very deep insight into the true condition of city society, and thus discovered its wants; he saw directly before him the amount and character of the agency provided for the supply of those wants; and hence he ascertained how much of those wants remained still unsupplied.'

While faithfully discharging his onerous duties in connection with the existing philanthropic societies of Glasgow, Nasmith applied himself also to the formation of such new associations as appeared needful for the moral and religious welfare of that and other populous places. Young Men's Societies, or associations for promoting the religious interests of young men, for protecting them from the temptations incident to a residence in large towns, and for directing their united energies into channels of benevolent exertion, occupied then, as in his later years, a large share of his attention; and in a letter upon the subject addressed by him to Professor Buchanan in February, 1826, he states that he had been the means of forming about seventy such societies, in the United Kingdom, France, and America, since the close of the year 1823. A still more important project, and one which has proved far more extensively successful in practice, was the formation of city and town missions, or societies for carrying religious instruction, by means of lay agents wholly devoted to the work, into the homes of the neglected poor, and even into the very haunts of vice and dissipation. Attempts had been previously made in a few instances, and on a small scale, to accomplish this object; but the difficulties of the task, especially those arising from the mutual jealousies of various sections of the Christian Church, had impeded their success. In spite of such difficulties, Nasmith succeeded in establishing, at the commencement of 1826, the 'Glasgow City Mission,' which, though commenced by the congregation to which he belonged, was constituted on so catholic a footing that, before the end of its first year, eight evangelical denominations of Christians were united in its management, and eight missionaries were employed. The success of this society encouraged Nasmith to print and circulate widely, not only in the British Islands and America, but also in France and other parts of the continent of Europe, a brief account of its design, with testimonials of its usefulness. In the same year Nasmith married Miss Hartridge, a native of Kent, who was then residing in Glasgow, and who became a most valuable coadjutor in his benevolent designs. In 1828, his health being impaired by the arduous duties of his office, Nasmith resigned his connection with the Institution House at Glasgow, and from that time until his death he devoted himself wholly to the exercise of what he deemed his peculiar vocation, that of a kind of moral agent or missionary, travelling from place to place to promote the establishment of city and town missions, young men's societies, and other kindred associations. The self-denial and moral courage necessary for such an undertaking was of no ordinary character, since it involved the relinquishment of any settled means of obtaining a livelihood, and of all prospect of attaining a station to which his talents entitled him; while he had no property on which to rely even for travelling expenses, nor any society on which to fall back for support. His first removal was to Dublin, where he succeeded in establishing a prosperous city mission. Having subsequently visited London, and his wife's family in Kent, he returned to Glasgow, and thence again to Dublin, where he formed a society for promoting the establishment of local missions in Ireland, and whence, in 1829, he proceeded on a tour through the south of Ireland, establishing missions in Cork, Limerick, Waterford, and several other places. In the following year he performed a similar journey, with the like results, in the north of Ireland, after which he returned to Glasgow, and prepared for a voyage to the United States on the same benevolent errand. Arriving at New York in September, 1830, he formed a city mission there, and performed a journey of about three months' duration, visiting and establishing similar societies at many towns in the United States, after which he returned to New York, sailed to New Orleans, made some stay in Philadelphia, and afterwards, pausing for a third time at New York, proceeded to Canada. How completely disinterested Nasmith was in these travels may be seen from the fact that while his necessary expenses from May, 1828, when he first left his native country for Ireland, to December, 1831, when he returned from America, where he travelled about 3000 miles, amounted to rather more than 671*l.*, a sum wonderfully moderate when it is considered what he accomplished during the three years and seven months over which the expenditure was spread, the sums received by him from friends who took an interest in his efforts amounted only to 439*l.*, leaving a deficiency of 232*l.* to be provided from his own very scanty resources. Pecuniary difficulties, however, could not repress his ardour, and it was not long before he visited Paris and established a city mission there, and set on foot a similar institution at Hâvre. He subsequently resided for some time in Glasgow, and in March, 1835, fulfilled a long-cherished intention of removing his residence to London, for tho purpose of establishing a city mission. 'His enterprise,' observes Dr. Campbell, 'to all but himself, seemed hopeless, if not preposterous.' Many of the best friends of the object at which he aimed deemed it utterly hopeless to effect that object by the union or co-operation of different sects, and especially by the joint efforts of churchmen and dissenters. Nasmith, who was of too catholic a spirit to care to what section of the Christian Church his fellow-labourers belonged, so that they were real Christians and united in the desire to impart the highest benefits to their fellow-men, and who, indeed, in answer to inquiries respecting himself, would say 'I am a Catholic Christian,' neither suffered objections or difficulties or impediments to deter him from his aim, nor to induce him to lessen its moral grandeur by identifying it with sect or party. The London City Mission was therefore commenced in conformity with the design of its founder, but without the active support of many influential individuals, who shortly afterwards, finding their fears groundless, heartily united to carry it on. Operations were commenced with only four missionaries, with salaries amounting in the whole to 297*l.* per annum; but so rapid has been the progress of the institution that in 1845, at the date of the tenth annual report, the number of missionaries employed was 121, and the expenditure in salaries alone for the preceding year had been 7400*l.*, exclusive of all other expenses incident to the mission. In the same year the number of domiciliary visits, and visits to hospitals, asylums, and other places where the poor and ignorant are congregated together, paid by the missionaries, amounted to 544,089, of which 39,469 were to the sick and dying. In a large majority of the latter class of visits the agents of the city mission were the only individuals by whom religious instruction and consolation were carried to the bed-side of the sufferers. The distribution of Bibles and religious tracts, the holding of religious services in neglected neighbourhoods, and various other benevolent operations, are also carried on by the missionaries, and special provision has been made, by the appointment of agents suited to their peculiar necessities, for the spiritual wants of cab-drivers, and of the numerous Lascars, Germans, and other foreigners in the metropolis. By gaining the confidence even of the most wretched and abandoned, the missionaries have obtained access, and often with the best results, to haunts of misery and vice which no other agency has been able to reach. They therefore constitute a kind of moral police, of the efficacy of which the reports of the society and the documents published monthly in the 'London City Mission Magazine' afford abundant proof. One missionary alone, in Clerkenwell, has, according to the report above quoted, succeeded either in marrying or separating no less than 74 couples who had lived, some of them for many years, in a state of illicit cohabitation. The establishment of so noble an institution might have been supposed sufficient to satisfy the desires even of Nasmith; but such was not his feeling. He could not rest without desiring further means of usefulness, and therefore he set on foot several kindred societies, of which perhaps the most important is the 'London Female Mission,' a society which has begun to operate successfully upon the condition of prostitution in the metropolis, both by reclaiming women, and by preserving destitute females from degradation. The 'English Monthly Tract Society' and the 'Adult School Society' also appear on the long list of philanthropic institutions established by him; but that to which he appears to have been most personally devoted in his latter years was a society originally called the 'British and Foreign Mission,' and intended to promote the establishment of city missions and other similar associations. The name was afterwards altered to 'The British and Foreign Town Mission,' but which has latterly, under the modified title of the 'Town Missionary and Scripture Readers Society,' chiefly confined its efforts to the establishment of local missions. In connection with this society Nasmith visited and formed missions at Cambridge, Birmingham, Manchester, Leeds, Bradford, Halifax, Huddersfield, Wakefield, and York; and subsequently visited Scotland for the same purpose. He afterwards travelled in Wales, re-visited Dublin, and made several other tours in various parts of England, of which Dr. Campbell gives full particulars. During these efforts he was supported, but in a very humble and precarious way, by the contributions of a few friends who appreciated his character and services, but he was often reduced to great pecuniary difficulties, the effect of which, coupled with incessant exertion, undermined his health; and at length he was seized at Guildford, whether he had gone with the intention of establishing a Town Mission, with a sudden illness, of which he died on the 17th of November, 1839. His body was brought to London, and interred in the presence of a large assemblage of ministers and others of various denominations, in Bunhill-Fields burying-ground; and a subscription of 2420*l.* was very shortly raised by his friends for the benefit of his surviving widow and children. A very full account of his extraordinary career, accompanied by remarks which tend to throw light upon a character which cannot be correctly judged by ordinary rules, is given in Dr. Campbell's 'Memoirs of David Nasmith; his labours and travels in Great Britain, France, the United States, and Canada,' 8vo., 1844, to which volume a portrait of Nasmith is prefixed, and in which will be found testimonials from many eminent men of various religious sects, respecting the disinterested efforts to which he devoted his life.

NASMYTH, ALEXANDER, a distinguished Scotch landscape painter, was born at Edinburgh, in 1758; he came early to London, where he was the pupil of Allan Ramsay, painter to George III. He studied afterwards several years in Rome, where he studied portrait, history, and landscape. He settled in Edinburgh as a portrait painter, and Robert Burns was among his sitters. Having however a decided taste for landscape painting, he ultimately confined himself to this branch; but much of his time was occupied in teaching, in which he was very successful. He died at Edinburgh, in 1840, aged eighty-two. His landscapes are very numerous; Italy was one of his most favourite themes. His style is picturesque and simple, and though 'some of his competitors may have far excelled him in the heroic grandeur of landscape composition, in that sweetness and beauty which depend upon a skilful selection of subject, combined with a minute and artistlike execution, at once elaborate and simple, no one has surpassed him.'

(*Art-Union Journal*, May, 1840.)

NASMYTH, PETER, son of Alexander Nasmyth, was born in Edinburgh in the year 1786. He showed an early decided predilection for landscape painting, and his zeal in the pursuit of his favourite art left him little opportunity of acquiring other instruction. Early in life he injured his right hand, and learned to use the pencil and brush with his left. At the age of twenty he went to London, and his productions soon became very popular, obtaining for him the designation of the English Hobbima. It cannot be said however that he had much in common with the great Flemish master, excepting the minuteness of his details in landscape scenery. He had not the same firmness of touch as Hobbima, producing his results by an apparent multiplicity of detail. He improved on the style of his father, and his pictures have less of the spotted chalky character, which, from its having been followed by other members of this clever family, is characteristic of what is called 'The Nasmyth School.' Notwithstanding a certain air of feebleness, Peter Nasmyth's landscapes are eminently pleasing. Though he often painted Scottish scenes, and his works are perhaps more admired in his native country than elsewhere, the character of his landscapes is eminently English. His style was not sufficiently massive properly to represent the wild mountain scenery and striking atmospheric peculiarities of Scotland. Light clouds, sunshine, smooth water, or small pattering brooks, meadows, gentle rising ground, and green trees, are the objects which his style was best calculated to represent. He died in lodgings in South Lambeth, London, on the 17th of August, 1831, during a memorable thunder-storm, which—his ruling passion for the contemplation of natural objects 'strong in death'—he was lifted up in his bed to behold. (*The dates and incidents are taken from Memoir in Lit. Gazette*, 1831.)

NASTURTIUM. [TROPÆOLUM, P. C.]

NAU'CLEA, a genus of plants belonging to the natural order Rubiaceæ. It has a calyx with an oblong tube and a short truncate or 5-toothed limb. The corolla is funnel-shaped, with a slender tube, a naked throat, and 5 spreading oval oblong lobes. Tho anthers are inclosed, and always shorter than the lobes of the corolla. The capsules are 2-celled, sessile upon the receptacle, but gradually attenuated to the base. The seeds numerous, imbricate, winged, fixed to oblong placentæ, which are adnate to the dissepiment. The embryo is invested in a fleshy albumen. The leaves are opposite or 3-4 in a whorl, petiolate, or sessile. The bracts wanting at the base of the head of flowers, but with linear paleæ among the flowers, which are crowded and sessile. The species are unarmed trees, rarely shrubs, and natives of India and Africa.

N. Cadamba has brachiate branches, petiolate, coriaceous, ovate leaves, triangular stipules, terminal solitary peduncles, usually shorter than the heads, which are globose. The flowers are orange-coloured, collected into heads about the size of a small apple. The style is white and exserted. The seeds not winged, the leaves from 5 to 10 inches long.

Kudumba is the native name of the tree; it flourishes about Calcutta and Malabar, where it grows to be a very large tree, and is ornamental and very useful from the extensive shade it affords.

N. parvifolia has petiolate obovate obtuse leaves, oval stipules, and terminal solitary peduncles; sometimes the peduncles are in triplets, when the middle one is the shortest. It is native of the East Indies and all the coast of Coromandel, but chiefly in the mountains of the Philippines. The flowers are light yellow, and globular, about the size of a plum. The wood is of a pale chesnut colour, firm, and close-grained; it is useful for purposes where it can be kept dry, but when exposed to wet it soon decays.

N. cordifolia is prized on account of its wood, which is light and durable where it can be kept dry. It answers well for furniture. There are thirty-seven species of this genus enumerated, all of which are natives of the East, but do not possess any peculiar qualities which entitle them to particular notice. They are of easy culture. A mixture of loam, sand, and peat is the best soil for them, and they readily take root under a hand-glass in the same kind of soil.

The Nauclea Gambia of Hunter (*Linnæan Transactions*, vol. ix.) is now Uncaria Gambia. [UNCARIA, P. C.]

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

NAU'CRATES, a genus of fishes of the mackarel tribe having fusiform bodies, tails heeled at the side, and two free spines before the anal fin. The *Naucrates ductor* is popularly known as the Pilot Fish, and is remarkable for its habit of following vessels often for many hundred miles. Mr. Crouch, in the 14th volume of the 'Linnean Transactions,' has recorded an instance of two individuals of this species which accompanied a ship from the Mediterranean to Falmouth, where they were taken by a net. The *Naucrates ductor* is about a foot in length, and is remarkable for the beauty of its colour, being of a silvery pale blue banded by broad and deep transverse dark blue belts.

NAUCY'DES (Ναυκύδης), a Greek sculptor, who was born at Argos, and was in repute, according to Pliny, about Ol. 95; he was the son of Mothon and the brother and master of the younger Polycletus of Argos, and, says Thiersch, was one of the most important artists between Alcamenes and Praxiteles. Pliny mentions a Mercury, a Discobolus, and a man sacrificing a ram, by him. Pausanias notices six other of his works: a Hebe, in ivory and gold, placed near the celebrated chryselephantine statue of Juno at Mycenae by Polycletus; the rest were in bronze—a Hecate at Argos, and four victors at the Olympic games, one of Eucles at Rhodes, two of Chimon, one of which was at Olympia, the other in the Temple of Peace at Rome, and the fourth of Bacis the wrestler. A tenth work by Naucydes, a bronze statue of Erinna, is mentioned by Tatian. The two statues of Chimon were, according to Pausanias (vi. 9), his best works. He was the master of Alypus of Sicyon. The well-known Discobolus in repose, standing with the quoit in his hand, is sometimes called the Discobolus of Naucydes, but without the slightest foundation.

(Junius, *Catalogus Artificum;* Thiersch, *Ueber die Epochen der Bildenden Kunst unter den Griechen.*)

NAUNTON, SIR ROBERT, a diplomatic statesman, was born in 1563, and was the son of Henry Naunton of Alderston, in Suffolk. He studied at Trinity College, Cambridge. He attended his uncle, William Ashby, when he was sent as ambassador by Queen Elizabeth to Scotland in 1589, and being sometimes trusted with the management of important business connected with the mission, he was thus initiated in diplomatic life. In 1596, he was sent by Essex to France, with letters to Antonio Perez, formerly Spanish secretary, probably with a view of securing the services of that statesman to the English government, or at least of sounding his intentions. Returning home, he was, in the same year, appointed tutor to a young gentleman named Vernon, of whom the Earl of Essex was guardian. He proceeded with his pupil to the Hague, and thence to France, in company with the French ambassador, the Duc de Bouillon; and it is manifest that the object hidden under his appointment, and his journey, was to give Essex the services of so able a man as a spy on the French court. He seems to have been naturally of a candid disposition, which did not easily mould itself into the pliant morality necessary for successfully conducting the flagitious diplomacy of that age. He wrote many complaining letters to his patron. 'The best allowance of credit I can have,' he says in one of them, 'is but in nature of betwixt a pedagogue and a spy; both trades I know not whether more odious or base, as well in their eyes with whom I live as my own.' After the fall of Essex, little seems to be known of him, until 1614, when he reappears as member of Parliament for Helstone, a favourite of King James on account of his scholarship, and one of the persons patronised by Buckingham. He was sworn Secretary of State, on the 8th of January, 1618. Having afterwards opposed the favourite's friend, Gondomar, the Spanish ambassador, he was deprived of office, but he was subsequently appointed Master of the Court of Wards. He died on Good Friday, 1635. His '*Fragmenta Regalia;* memoirs of Elizabeth, her court, and favourites,' was greedily perused in manuscript and frequently copied over, until it was printed in 1641. It has passed through several editions. This little book is remarkable as one of the very few which in that age noticed political events and characters in their relation to the progress of the constitution; a purpose on which the writer brought to bear a sagacious spirit and animated style. (*Memoir prefixed to Fragmenta Regalia*, 1824.)

NEALCES (Νεάλκης), probably of Sicyon, a celebrated Greek painter, contemporary with Aratus of Sicyon, about 213 B.C. Few of his works are mentioned, but he was the most celebrated painter of his time. Pliny mentions a Venus by him, and a battle between the Egyptians and Persians on the Nile. To show the locality of his battle Nealces painted an ass drinking at the side of the river and a crocodile lying in wait for him, an ingenious application of accessories, of which there are also many other examples in the history of Greek painting. Nealces is one of the painters whom tradition represents as having succeeded by accident in painting the foam on a horse's mouth with his sponge.

Aratus, in his zeal against the tyrants, waged war even against pictures, and resolved to destroy all their portraits which were preserved at Sicyon. This he did with one exception; Nealces saved the portrait of Aristratus by Melanthius and Apelles from the common destruction, but only partially. Aristratus was represented standing by a chariot of Victory; Nealces painted out the figure of Aristratus, and substituted a palm-tree in its place. 'The piece was so admirable,' says Plutarch, 'that Aratus could not avoid feeling the art that was displayed in it; but his hatred of tyrants soon overruled that feeling, and he ordered it to be defaced. Nealces the painter, who was honoured with his friendship, is said to have implored him with tears to spare that piece; and when he found him inflexible, said, 'Aratus, continue your war with tyrants, but not with everything that belongs to them. Spare at least the chariot and the Victory, and I shall soon make Aristratus vanish.' Aratus gave his consent, and Nealces defaced the figure of Aristratus, but did not venture to put anything in its place except a palm-tree. We are told however that there was still a dim appearance of the feet of Aristratus at the bottom of the chariot. (Langhorne's Translation.)* Such a dim or faint appearance of the feet here spoken of may have arisen some time after Nealces altered the picture; such accidents frequently happen in painting out, unless a considerable body of colour is used.

Anaxandra, the daughter of Nealces, was likewise distinguished for her paintings; and his colour-grinder, Erigonus, became a painter, and acquired great honour through the celebrity of his pupil Pasias.

(Pliny, *Hist. Nat.*, xxxv. 11, 40; Plutarch, *Aratus*, 13.)

NE'BULÆ. [STAR, P. C., pp. 449, 450.]

NECTANDRA, a genus of plants belonging to the natural order Lauraceæ. It has a 6-parted rotate calyx, deciduous segments, the three outer rather the broadest. There are 9 anthers which are ovate, nearly sessile, with 4 cells, arranged in a curve, and distinct from the tip of the anther, the cells of the interior anthers inverted. The glands are in pairs, globose, sessile at the base of the three interior stamens next their back. The fruit is succulent, more or less immersed in the tube of the calyx, which is changed into a truncated cup. The flowers are panicled or corymbose, axillary lax and pretty ample.

N. cymbarum is a tree nearly 100 feet high, growing in the woods of the Orinoco, near S. Fernando de Atabasso, where it is called Sassafras, and also in the ancient forests of the Rio Negro in Brazil. The branches are smooth, the leaves oblong, lanceolate, papery, and shining above. The cup is large with a double edge. The bark aromatic, bitter, and stomachic. Martius suspects that it is one of the ingredients in the famous Woorary poison of Guiana.

N. Cinnamomoides has oblong leaves tapering into a fine point, acute at the base, between papery and leathery, naked, smooth, and shining above; finely downy beneath, with numerous distinct narrow costal veins. The bark has the smell and flavour of cinnamon, as which it is used in New Granada.

N. Puchury major has oblong or elliptical leaves tapering to a narrow point, smooth, reticulated, and of the same colour on other side. The cup of the fruit is very large and spongy. Martius assigned the Pichurim bean to this plant. In the early months of the year the fruits drop from their cups to the ground, and are collected by the natives, cleaned and dried by a gentle heat. They are prescribed in dysentery, diarrhœa, cardialgia, strangury, &c. The bark has the smell of fennel mixed with cloves.

N. Puchury minor, according to Nees, yields seeds similar in their qualities to the above. Its bark is said to resemble sassafras when fresh, but tasteless and scentless when dry. According to Humboldt it yields the sassafras nuts sold in the London shops. It is a native of the woods of Jabatinga, in the province of Rio Negro in Brazil.

(Lindley's *Flora Medica*).

NECTARINE. [AMYGDALUS, P. C.; PEACH, P. C.]

NECTARY, in Botany, a term used by Linnæus to designate those appendages of the corolla which secrete honey. The term has however, since the time of Linnæus, been used in a general sense to express any organ existing in the flower between the corolla and pistil, and which could not be rightly assigned to these or the stamens. Such parts or appendages of the flower have had many other names applied to them, and some much more commonly than nectary. A common form of appendage of the corolla is called *corona*. This organ is formed at the base of the limb of the corolla, and forms sometimes an undivided cup, as in the Narcissus, when it is called by Haller a *scyphus*. When it is separated into several parts, as in Silene and Brodiæa, it forms the *lamella* of some writers. In Stapelia this organ forms a thick solid mass, covering over the ovary and adhering to the stamens. It is here called the *orbiculus*. When this appendage is accompanied with little projecting processes, they

* These are not the words of Plutarch; he says the feet were under the chariot, and 'as they say' διαλαθεῖν, when the figure was painted out. The exact meaning of διαλαθεῖν is doubtful. Aristratus was not in the chariot: he was standing by it. The old version of Amyot is right. That of North, who translated Amyot, is partly wrong.

are called *cornua*, or horns; the upper end of these is the beak or rostrum, and their back, if dilated and compressed, is called *ala* or *appendix*. Occasionally there is a second set of horns, which alternate with the first, and are called *ligulæ*; the circular space at the top of the orbiculus is the *scutum*. When the lamellæ are small and scale-like, and overarch the orifice of the tube, they are called a *fornix*.

Link proposes to call all appendages which are referable to the corolla *paracorollæ*, or, if they consist of several pieces, *parapetala*, and all appendages referable to the stamens *parastemon*. The peculiar filiform appendages of Passiflora he calls *paraphyses* or *parastades*.

The real nature of these appendages is a point of some interest. In some instances they appear to be simple expansions of the cellular tissue and epidermis of the part on which they are seated, and in others they are evidently abortive stamens or petals. Thus the little bodies found in the claw of the petals of Ranunculus may be regarded as an expansion of the tissue, whilst the filamentary appendages seen in the genus Passiflora are evidently metamorphosed petals. The various forms of corona may be assigned to one or other of the above causes. This subject requires investigation, and it would be well if a more simple and intelligible nomenclature could be applied to these parts of the flower; for, however unimportant at first sight such organs may appear, they nevertheless constitute some of the most valuable distinctive marks for species, genera, and even orders, which the botanist possesses.

The original name, nectary, of these appendages was applied on account of the honey which the tissues of these organs frequently secrete. They were on this account called by Meyen compound glands. It was supposed by Knrr that the function of these glands was vicarious, and that they only secreted honey till the fruit began to develop itself. But that the function of the nectary has no direct relation with the object of the function of the fruit, that is, the development of the seed, is proved in an experiment by Kurr himself, in which he found that the seeds of plants became perfectly maturated, although he had in the early stages of the growth of the flower removed the nectaries. As to what may be the determining cause of the secretion of sugar in these organs any more than in other parts, no examination of their structure has hitherto pointed out. They do not however possess the power of secreting sugar and other secretions in any greater degree than the petals and other parts of the flower and fruit.

(Lindley, *Introduction to Botany*; Schleiden, *Grundzüge der Wissenschaftlichen Botanik*; Meyen, *Pflanzen Physiologie*.)

NEEDLE-ORE. [MINERALOGY, P. C. S.]

NEGOTIABILITY. [BILL OF EXCHANGE, P. C.]

NEJD, or NEDJD. [ARABIA, P. C. and P. C. S.]

NELUMBIUM, a genus of plants belonging to the natural order Nymphæaceæ. It has many distinct carpels, half immersed in the profoundly honey-combed, obconical, elevated torus, each bearing a style with a solitary seed in each carpel, which is exarillate, and destitute of albumen. The flowers are large and showy, white, red, or yellow. Both leaves and flowers rise from the surface of the water.

N. speciosum, Pythagorean Bean, has a polypetalous corolla and anthers drawn out beyond the cells into a club-shaped appendage. It is native in slow running streams and tranquil waters, in the warmer parts of Asia. The flowers are very beautiful, smelling of anise, and generally of a rose colour, seldom white. A variety of this species, *Tamara*, has its outer stamens sterile, dilated at the top, winged, obcordate, the appendage rising from a notch at the apex. It is native of Malabar. The fruit resembles an instrument once used in play by the French, called Lotos, and is one of the plants supposed to be the celebrated Lotos of antiquity, formerly found in Egypt. It was known to the Greeks, and is mentioned as growing in Egypt by Herodotus (ii. 92), Theophrastus, and others. Although not now to be mot with in that country, there can be no doubt as to its having actually existed there, either naturally or in a cultivated state, for these authors speak of it in clear and decisive terms, and their accounts are confirmed by the sculptures still preserved, which testify that this species, as the proper Lotos, has obtained religious reverence. It is spoken of as having been used as food by the Egyptians. Both roots and seeds are esculent, and are accounted cooling and strengthening, and to be of service in extreme thirst, diarrhœa, vomiting, &c. In China it is called Lieuwha, and the seeds and slices of the hairy root, with the kernels of apricots and walnuts, and alternate layers of ice, were frequently presented to the British ambassador and his suite, at breakfasts given by the principal mandarins. The roots are laid up by the Chinese in salt and vinegar for winter use. Thunberg says this plant is held sacred in Japan, and is considered pleasing to the deities, the images of which are frequently made sitting on its large leaves. The seeds are somewhat of the size and form of an acorn, and of a taste more delicate than that of almonds.

N. luteum has a polypetalous corolla, and greatly resembles *N. speciosum* in structure. It is native of North America, in lakes and ponds: it has been naturalized as far as Philadelphia. The flowers are yellow, and resemble a double tulip. The seeds are very agreeable to eat, and are much relished by the Indians and children.

The species of this beautiful aquatic genus should be grown in cisterns, tubs, or large pots, in a rich loamy soil; they require a strong heat to flower to perfection. The pot they are in should be kept full of water while they are growing, but may be allowed to get dry when the flowering season is over. They may be increased by dividing the roots, but are obtained more readily from seeds, which vegetate freely. None of the species have flowered in this country excepting the *N. speciosum*; they all require a very warm situation in a stove.

(Don, *Gardener's Dictionary*; Burnett, *Outlines of Botany*.)

NEMACA'NTHUS, a genus of fossil fishes from the oolite and liassic strata. (Agassiz.)

NEMERTI'TES, a genus of fossil Annelida, from the lower silurian strata of Lampeter, in South Wales. (Murchison.)

NEMO'CERA, the first family of Dipterous insects in the arrangement of Latreille, includes such species as have antennae composed of many joints, an exserted head, a a sheathed sucker, and either simple or toothed tarsal hooks. It includes the species of *Culex* and of *Tipula*, the names given by naturalists to the Mosquitoes and Craneflies. These Linnean genera are now greatly subdivided.

NEO'TTIA (νεοττία, 'a nest with the young in it,' 'the young themselves'), a genus of plants belonging to the natural order Orchideæ. It has a hooded perianth, a deflexed 2-lobed lip saccate at the base; the stigma transverse; rostellum flat, broad, prominent, entire, and without an appendage.

N. Nidus-avis, bird's nest orchis, is the only British species of this genus. The whole plant is of a pale reddish-brown; the root formed of many thick fleshy fibres, from the extremities of which young plants are produced. The stem is about a foot high, with sheathing brown scales. It has no leaves. The spikes are dense, cylindrical, and many-flowered. It is the original *Neottia* of Linnæus, and is native of Great Britain in shady woods.

(Babington's *Manual of British Botany*.)

NEPA, a genus of hemipterous insects of the family *Hydrocorisa*, the species of which are popularly known as water-scorpions. Their bodies terminate in two long setæ, by means of which they acquire a supply of air for respiration, when immersed in the water or mud.

NE'PETA, (a name used by Pliny from *nepa*, scorpion, being supposed to be efficacious against the bite of a scorpion, or from Nepe or Nepete, a town in Tuscany,) a genus of plants belonging to the natural order Labiatae, and the tribe Nepeteae. It has diverging anther cells, a ringent corolla, the upper lip flat, straight, emarginate, or bifid. The calyx is 5-toothed.

N. Cataria, catmint, has stalked cordate acute leaves, deeply crenated and clothed with a whitish pubescence beneath, dense many-flowered whorls, smooth and glabrous nuts. The stem is from 2 to 3 feet in height, downy or mealy. It is native throughout the whole of Europe and middle Asia, and is plentiful in Britain. The corollas are white, with a tinge of red spotted with purple. The whole plant has a strong smell between mint and pennyroyal. Cats are said to be fond of it, and hence it derives its name; they roll themselves on it and tear it to pieces apparently with much pleasure. Ray noticed that the plants he removed from the field into his garden were always destroyed by cats, unless he protected them with thorns until they had come into flower; but they never meddled with plants raised from seed; hence the old saying 'if you set it the cats will eat it, if you sow it the cats won't know it.' Ray accounts for this from the fact that by transplanting the leaves become bruised, and the powerful odour is exhaled which attracts the cats to it. It appears to act as a real aphrodisiac upon cats. Sheep are said to eat it, but all other domestic animals refuse it.

N. Glechoma (*Glechoma hederacea*, Smith), Ground Ivy, has uniform cordate crenate leaves, axillary stalked whorls, ovate aristate teeth, and oblong nuts with impressed dots. The corolla is a light bluish grey, three times as long as the calyx. It is native of Europe and the north of Asia, in hedges and ditches, in woods and waste places, and is plentiful in Britain. The leaves of the ground ivy were formerly thrown into the vat with ale to clarify it and give it a flavour; this was called gill ale, Ground Ivy being named Gill or Gell, and Creep-by-Ground in some places. From this use of the plant and the form of the leaf, it has also the names Ale Hoof and Tun Hoof, but it has gradually grown into disuse since the introduction of hops.

N. Nepetella, Small Catmint, is an erect pubescent plant, clothed with hoary tomentum, the leaves lanceolate, crenate, rounded or cordate at the base, clothed with hoary tomentum or pubescence on both surfaces, the racemes many-flowered, nearly simple; the bracts scarcely longer than the pedicels, the calyx tubular, incurved with an oblique mouth, the corolla twice as long as the calyx. It is a native of the South of Europe, and is found in Spain, Provence, Switzerland, and Italy. It is a very variable plant, especially in gardens. Many varieties have been described.

There are about seventy species of Nepeta known to botanists. Some of them have pretty blossoms, and may be cultivated in the garden. They grow well in any garden soil, especially when light and dry. They may be propagated by dividing the root or by sowing the seeds.

(Koch, *Flora Germanica*; Babington, *Manual of British Botany*; Don, *Gardener's Dictionary*.)

NEPHRO'DIUM. [ASPIDIUM, P. C. S.]

NER'ATIUS PRISCUS, a Roman jurist who lived under Trajanus and Hadrianus. Spartianus (*Hadrianus* 4) states that there was a general opinion that Trajanus once intended to make Neratius Priscus his successor in the empire, instead of Hadrianus. However, Priscus was employed by Hadrianus as he had been by Trajanus. A case is mentioned (Dig. 37, tit. 12, s. 5) in which Trajanus acted on the advice of Neratius Priscus and T. Aristo. Pomponius (Dig. 1., tit. 2, s. 2, § 47) states that Neratius was elevated to the consulship, but the year of his consulship is not certain.

Neratius succeeded Celsus the father, and was therefore of the school of Proculus. His writings, which are mentioned in the Florentine Index, are fifteen books of Regulæ, seven of Membranæ, and three books of Responsa. There are sixty-four excerpts from Neratius in the Digest. Neratius is often cited by the subsequent jurists. He is also mentioned by Gellius (iv. 4) as the author of a treatise De Nuptiis, but in place of Neratius some MSS. have Veratius in this passage of Gellius.

NEREI'TES, a genus of fossil Annelida, from the lower silurian strata of Lampeter, in South Wales. (Murchison.)

NERIUM (from νηρός, humid, the habitat of species), a genus of plants belonging to the natural order Apocynaceæ. It has a hypocrateriform corolla, the orifice surmounted by lacerated multifid processes: segments of the limb contorted. The filaments are inserted into the middle of the tube, the anthers sagittate, adhering by the middle to the stigma. It has two ovaries, a filiform style, dilated at the apex, and an obtuse stigma.

N. odoratum has linear lanceolate leaves three in a whorl; the segments of the calyx erect; appendages of the corolla filamentous; the anthers bearded at the point; the flowers red or white with an agreeable musky scent. The bark of the root and the sweet smelling leaves are supposed by native Indian doctors to act as powerful repellants applied externally: the root, taken internally, acts as a poison.

N. Oleander, Common Oleander, has lanceolate leaves, three in a whorl being beneath, the segments of the corona trifid. It is native of the Indies, in humid places, but has now become wild in the South of Europe, by the side of streams and the sea coast. The flowers are rather large and of a bright red colour. This species contains a great quantity of gallic acid, and a decoction of the leaves or bark forms an acrid stimulating wash, much employed by the poor people in the South of France to cure cutaneous disorders. The peasants in the neighbourhood of Nice use the powdered bark and wood of the Oleander to poison rats. Several cases are also recorded of death from having eaten meat roasted on a spit of Oleander wood.

All the species of Oleander are very showy when in blossom; they thrive well in a light rich soil, and cuttings strike root freely in a moist situation. All of them require a good deal of heat to flower well in this country.

NET AND LACE. [WEAVING, P. C., p. 179.]

NEUTRIA. [COYPOU, P. C.; FURRIERY, P. C. S.]

NEWCASTLE, DUKE and DUCHESS OF. [CAVENDISH, MARGARET, P. C. S.]

NEWGATE, London. [DANCE, P. C. S.]

NEWTON, GILBERT STUART, R. A., was born in 1794, at Halifax, in Nova Scotia, where his father was collector of the customs. He came to England about 1820, and, after making a tour in Italy, entered as a student of the Royal Academy. He adopted Watteau in some degree as his model, and produced several excellent small pictures much in the style of that master as regards the figures, yet at the same time displaying great expression and character. His first works which attracted notice were the Forsaken, and the Lover's Quarrel, engraved in the 'Literary Souvenir' of 1826. He painted the Prince of Spain's Visit to Catalina, for the Duke of Bedford for 500 guineas; it was engraved in the 'Literary Souvenir' for 1831. In 1830 he painted Shylock and Jessica, from the 'Merchant of Venice,' Yorick and the Grisette, from the 'Sentimental Journey,' and the Abbot Boniface from the 'Monastery;' all in the exhibition of the Royal Academy in 1830. In 1831 he exhibited Portia and Bassanio, another scene from the 'Merchant of Venice;' and Lear attended by Cordelia and the Physician. In 1832 he paid a visit to America, and married there; and in the year following, in which he was elected an academician, he exhibited a small picture of Abelard sitting in his study, a work full of expression and sentiment. Besides these he painted the Vicar of Wakefield restoring his daughter to her mother, Macheath, and a few portraits. His Macheath was purchased by the Marquis of Lansdowne for 500 guineas.

His Abelard was the last picture that he exhibited in the Royal Academy, 1833, and it was about this time that he evinced signs of aberration of mind, and these were followed by unequivocal insanity, which however he recovered from four days before his decease, and he died with calmness and resignation August 5, 1835, at Chelsea, aged forty. His wife returned with her child to America a few months before his death. He painted slowly, and was laborious and fastidious in his execution. He was also, says a friend, extremely neat and fastidious about his dress, though 'he was far from paying the same attention to his chambers, for his compositions were scattered carelessly around; the finished and unfinished were huddled together, and broken models and bits of ribbon and withered flowers abounded.' This was in 41, Great Marlborough-street, where his principal works were painted.

(*Gentleman's Magazine*.)

NEY, MICHAEL, Prince of the Moskowa, Duke of Elchingen, and Marshal of France, was born at Sarre-Louis in Lorraine, on 10th January, 1769. At the age of thirteen he was articled to a notary of that town, but this occupation not being suited to his disposition, he enlisted in 1787 in a regiment of hussars. He there soon distinguished himself by his courage and activity, and, after passing through the inferior grades, he became a lieutenant in 1793, and a captain the year following. The skill which he displayed in conducting some partizan warfare in 1794 attracted the attention of General Kleber, by whom he was sirnamed 'The Indefatigable,' and raised to the rank of adjutant-general. In 1796 he greatly contributed to the victory obtained at Neuwied, and distinguished himself in the engagements of Altenkirchen [LEFEBVRE, P. C. S.], Montabour, and Dierdorf, in which last he was made a prisoner. After his exchange he served in 1796 with the army of the Rhine, and after a brilliant exploit at Würzburg, where with a small body of cavalry he took two thousand prisoners, and obtained possession of that town, he was nominated general of brigade. In the course of this campaign his courage was enhanced by his humanity towards the French emigrants who had been taken prisoners, and he enabled them to elude the sanguinary decrees of the Directory. In 1799 he again served as a general of division with the army of the Rhine under General Moreau. We can only enumerate the principal achievements which in this memorable campaign added to his celebrity. They are the capture by surprise of Mannheim (12th March, 1799), the engagements at Worms and Frankenthal, and the seizure of all the enemy's artillery at the battle of Iller (5th June, 1800). He was also present at the battle of Hohenlinden [MOREAU, P. C.], and his bold attack of a column of the Austrians, which he drove back into the forest, greatly contributed to the victory. At the peace of Luneville he returned to Paris, where he was received with distinction by Bonaparte, who, the better to attach him to his interests, caused him to marry Mademoiselle Augnié, a friend of Hortense Beauharnais. In 1803 he was appointed minister plenipotentiary of the French Republic in Switzerland; on leaving that country the inhabitants presented him with a medal in testimony of their esteem for his character and conduct, and the moderation with which he carried into effect the measures of his government. On his return to Paris the command of a division of the army encamped near Boulogne was given him, and in 1804 he was raised to the dignity of a Marshal.

On the renewal of hostilities with Germany in 1805 the direction of the eighth corps of the army was confided to Marshal Ney. A brilliant achievement in this campaign, the capture by storm of the village of Elchingen (October 4th, 1805), in which the Austrians, under General Laudon, lost fifteen hundred men killed and wounded and two thousand taken prisoners, was attended with the most important results. The impetuous courage and persevering skill which this marshal displayed on that occasion had been witnessed by Napoleon, who in commemoration of it afterwards bestowed upon him the rank and title of Duke of Elchingen.

But it was perhaps during the Prussian campaign of 1806 that Ney's military reputation rose to its greatest height. Of the many splendid actions by which he distinguished himself, the chief are, the capitulation of the towns of Erfurt (October 15th, 1806) and Magdeburg (November 11th, 1806) in which 23,000 prisoners were taken and 800 pieces of cannon fell into his possession; the passage of the Vistula, the taking of Thorn, the total destruction of a Prussian corps at Deppen (February 5th, 1807), the combat of Schmoditten, by which the retreat of the Russians on Königsberg was cut off, and, finally, the defeat of the left wing of the enemy at the battle of Friedland [BONAPARTE P. C.], which more than any other movement contributed to the victory. In September, 1808, he was appointed to a command of the army in Spain, and he distinguished himself in the various engagements by which Gallicia and the Asturias were subjected. In Portugal, though under the orders of Marshal Masséna, the merit of the capture of Ciudad-Rodrigo (July 10th, 1810) and of Almeida (August 27th, 1810) have generally been attributed to him. He was also of great assistance to Masséna in conducting his skilful retreat, after his failure in attempting to force the lines of Torres Vedras. [MASSENA, P. C. S.] The different dispositions however of these two great generals soon brought on differences of opinion, which ended in a serious dispute. The result was unfavourable to Ney, who was deprived by Napoleon of his command and recalled to France.

In 1812 he joined the disastrous expedition to Russia, and had the command of the third corps of the grand army. In the course of it he appears to have freely expressed to Napolean his dissatisfaction at some of his movements, and advised him to winter at Smolensko. At the taking of this city (August 17th, 1812), at the combat of Valentina (August 19th), and, above all, at the sanguinary battle of the Moskowa (September 14th), from which he derived his title of Prince of the Moskowa, he eminently proved himself worthy of the sirname by which he was known to the army, of 'Bravest of the Brave.'

But it was during the calamitous retreat of the French army that he rendered it the most important service. The details of it are amply described in the histories of Ségur, Chambray, and Labaume; the first of these, however, though one of the finest models of historical style, should be read in conjunction with the Memoirs of General Gourgaud, who, with military bluntness, and perhaps some personal hostility, corrects several erroneous statements of Ségur. One incident in this retreat is peculiarly characteristic of Ney's intrepidity and perseverance. General Dumas relates that as he was sitting down to breakfast at Gumbinnen, a man in a brown coat, long beard, and a weather-beaten countenance, entered his room, exclaiming, 'I am at last here; General Dumas, do you recognise me?' The general having answered that he did not; 'I am the rear-guard of the grand army,' he continued; 'I have fired the last musket-shot on the bridge of Kowno; I have thrown the last of our arms into the Niemen, and have come here through the woods. I am Marshal Ney.' (Colonel Mitchell's 'Fall of Napoleon,' vol. ii.)

In the campaign of 1813 Ney displayed his usual courage and ability, and was chiefly instrumental in obtaining the victories of Bautzen, Lützen, and Dresden. He met however with some severe reverses, and at the battle of Dannewitz (September 6th, 1813) he was signally defeated by the Prussians and Swedes under Bernadotte, then Crown Prince of Sweden [BERNADOTTE, P. C. S.], with a loss of thirteen thousand men, forty-three pieces of cannon, and three standards. After this disastrous engagement Napoleon had an interview with Ney's aide-de-camp, whom he interrogated respecting the particulars of this misfortune, and explained the causes which led to it to the generals present, without giving expression to any feeling of dissatisfaction at the conduct of his lieutenant. 'The Emperor,' says St.-Cyr, who is quoted by Alison ('Hist. of Europe,' x. 535), 'explained at once lucidly and satisfactorily the causes of the reverse, but without the slightest expression of ill-humour, or any manifestation of displeasure at Ney or any of the generals engaged. He ascribed the whole to the difficulties of the art of war, which he said were far from being generally known. He added that, one day or other, if he had time, he would write a book in which he would demonstrate its principles in a manner so precise they should be within the reach of all military men, and enable them to learn the art of war as they learn any other science.'

After the abdication of Napoleon, in 1814, Ney withdrew from public life and retired with his family to his country-seat. It was there that, on the 6th of March, 1815, he received orders from the Minister of War to join the eighth military division, of which he was commander, and which was stationed at Besançon. Ignorant of the motives of the order, he immediately proceeded to Paris, where for the first time he learned the return of Napoleon from Elba. He then willingly undertook the duty which had been imposed upon him to lend his aid for the purpose of opposing the invasion of his former chief; and on taking leave of Louis XVIII. he assured him that he would bring back Bonaparte in an iron cage. As some doubts have been cast upon the truth of this boastful assertion of Ney, it may be well to state that he himself acknowledged on his trial that he used the expression. On leaving the king he travelled rapidly to Auxerre, where he alighted at the residence of his brother-in-law, the prefect of the department, who had zealously joined the cause of Napoleon, and who made Ney acquainted with all the difficulties likely to attend any support of the Bourbon dynasty, and his own doubts on this subject increased as, advancing towards Lyon, he became more aware of the popular feeling in that part of France. The character of Ney was more fitted for the field of battle than for a political struggle, and it was only in the presence of danger that he showed resolution. Of this Napoleon was well aware, and he skillfully threw the weight of his influence and entreaties into the balance of Ney's already vacillating opinions. An earnest appeal to the early and glorious reminiscences of the prosperous days of the Empire, coming from his antient chief, the creator of his fortunes, completely overcame the pledged loyalty of this marshal. 'In the night of the 13th of March,' said he at his trial, 'down to which time I solemnly declare my fidelity, I received a proclamation drawn by Napoleon, which I signed.' On the ensuing morning this fatal proclamation was publicly read to the troops, who received it with the most enthusiastic approbation. His defection was speedily followed by that of his whole army.

On the 10th of June he joined the army at Lille, and was soon actively but unsuccessfully engaged with the British at Quatre-Bras. His conduct at Waterloo elicited equal praise both from friend and foe. His fruitless but resolute attempts at the head of the columns of the guard to overwhelm the British before they could receive succour from the Prussians, are well known. Five horses were shot under him in this terrible conflict: still, on foot, his clothes pierced with balls, he gallantly headed the impetuous charge. In the disastrous retreat which ensued, he was among the last to leave the field, and, as on the plains of Russia, he was the rear-guard of the last Imperial army.

After the defeat of Napoleon at Waterloo, Ney returned to Paris, and remained there after the capitulation of that city to the allies, considering himself safe by virtue of the twelfth article of that capitulation, which contains the following clause: 'All the individuals who are at present in the capital, shall continue to enjoy their rights and liberties, without being disquieted or prosecuted in any respect, in regard to the functions which they occupy, or may have occupied, or to their political conduct or opinions.' (*Convention*, July 3rd, 1815.) On the 24th of July however appeared a Royal ordinance, in which, among several others, he found himself proscribed as a traitor to his country. To escape the danger he endeavoured to leave France, but was arrested on 5th August, at the château of Bessoms near Aurillac. He was at first cited before a council of war, which declared its incompetency to sit in judgment on a peer of France. His trial was then removed to the Chamber of Peers by another Royal ordinance of 12th November. His defence was most ably conducted by his eloquent advocates, Berryer and Dupin, and chiefly rested on the article of the capitulation above alluded to. The result however was that be was found guilty, and condemned to death by a very large majority of the peers.

On 7th December, 1815, the day after his condemnation, an officer presented himself to Ney to communicate to him the sentence, which was to be carried into immediate execution. On hearing his titles enumerated, he exclaimed, 'Call me simply Michael Ney, now a French soldier, and soon about to be a heap of dust.' A spot in the garden of the Luxembourg was selected for the execution; he there met his fate at eight o'clock in the morning with calm courage. 'He who had fought five hundred battles for France—not one against her—was shot as a traitor.' (Napier, *Hist. of the Peninsular War*, vol. ii. p. 406.)

The reflections of Alison on this event are creditable alike to his impartiality as an historian and his feelings as a man. 'The death of Ney,' he says, 'is a subject which the English historian cannot dismiss without painful feelings. His guilt was self-evident; and never perhaps was the penalty of the law inflicted upon one for a political offence who more richly deserved his fate. The question of difficulty is, whether or not he was protected by the capitulation of Paris. The clause in that treaty has already been given which expressly declares that no person should be molested for his political opinions or conduct during the Hundred Days; and it is very difficult to see how this clause could be held as not protecting Ney, who was within the city at the time of the treaty. Wellington and Blücher concluded the capitulation: their Sovereigns ratified it: Louis XVIII. took benefit from it. How then can it be said that he, as well as the allied sovereigns, were not bound by the treaty, especially in so vital and irreparable a matter as human life—and that the life of such a man as Marshal Ney? It is very true a great example was required; true, Ney's treason was beyond that of any other man; true, the Revolutionists required to be shown that government could punish; but all that will not justify the breach of a capitulation. To say that Louis XVIII. was not bound by the capitulation; that it was made by the English general without his authority; and that no foreign officer could tie up the hands of an independent sovereign, is a quibble unworthy of a generous mind, and which it is the duty of the historian invariably to condemn. This was what Nelson said at Naples, and what Schwartzenburg said at Dresden; and subsequent times have unanimously condemned the violation of these two capitulations. Banished from France, with his double treason affixed to his forehead, Ney's character was irrevocably withered; but to the end of the world his guilt will be forgotten in the tragic interest and noble heroism of his death.' (*Hist. of Europe*, vol. x. p. 975-977.)

(The following works may be consulted for a full detail of the life of Marshal Ney: *Vie du Maréchal Ney, avec Hist. de son Procès*, Paris, 1816; *Biog. des Généraux Français*, par Courcelles; *Hist. de Napoléon et de la Grande Armée*, par Segur; *Hist. de l'Expédition de Russie*, par Chambray; Alison, *Hist. of Europe*, vols. iii. iv. v. ix. x.; *Court and Camp of Napoleon; Mémoires de Rapp;* Napier, *Hist. of the Peninsular War;* Mitchell, *Fall of Napoleon; Examen critique de l'Hist. de Ségur*, par le Gén. Gourgaud. The arguments in favour of his condemnation may be seen in the works of Bellart, the crown prosecutor, *Affaire du Maréchal Ney*, Paris, 1827.)

NIBELUNGEN LIED. [GERMANY, P. C., p. 194.]

NICERON, JEAN-PIERRE, was born at Paris in 1685. He entered the regular order of Barnabites, and devoted himself to the study of languages and biography. He led a life without incident, and died at Paris on the 8th July 1738. He is chiefly known as the author—or in some parts rather the compiler—of 'Mémoires pour servir à l'Histoire des Hommes Illustres dans la République des Lettres,' of which thirty-nine volumes were published by Niceron, and four were added after his death. All who have had occasion to study the earlier literary history of France must be under obligations to this laborious and meritorious work. Its merits are never very high in criticism, philosophy, or the essential elements of spirited and descriptive biography. Niceron was however a curious and laborious reader, and in those instances where he exhibits the fruit of his own original research, his matter is highly valuable. Many of the lives however are mere compilations from other sources, and appear to have been hastily prepared to suit the order of publication. There is little attempt at a proportional distribution of space, secondary authors sometimes receiving notices as elaborate as the most distinguished men of their age. This is a defect sometimes not unpleasing, as it generally attends enthusiasm in some particular walk of literature, and marks the original investigator. Niceron published some translations from the English. (*Mémoires*, tom. xl. 379-396; *Nouveau Dictionnaire Historique*.)

NICHOLAS, ST., situated in 51° 9′ N. lat. and 4° 8′ E. long., is a large and well-built market-town in the province of East Flanders, of the kingdom of Belgium. It has a large market-place surrounded with good houses, a handsome town-hall, a prison, a tribunal of commerce, and a Latin school. The number of inhabitants is about 18,000, who manufacture cotton and woollen goods of various kinds, hats and ribbons; there are tanneries, potteries, dye-houses, brick and tile kilns, soap-works, salt-works, &c. There is a great weekly market for corn, flax and yarn, and horses. St. Nicholas is in fact one of the richest and most flourishing towns, not only of Flanders, but of all Belgium. The surrounding country is highly cultivated.

(Stein, *Lexicon*; Cannabich, *Lehrbuch*; Hassel, *Handbuch*.)

NICI'AS (Νικίας) of Athens, the son of Nicomedes, and the pupil of Antidotus, was one of the most celebrated painters of antiquity. He was, though probably younger, contemporary with Apelles. His particular excellence was in the general effect of the picture: in elegant design, in beautiful colour, and in effective chiaroscuro; in fact in the characteristic qualities of the Bolognese school subsequent to the Carracci. He also excelled in painting females; but this would be the necessary result of his mastery over the instrumental and technical parts of art.

It is remarkable, that though Athens was so long the principal seat of the arts among the Greeks, about two centuries, Nicias and Apollodorus are the only two Greek painters of the greatest fame who were natives of Athens. Yet the case is very similar with modern Rome; of all the great painters of that central city of art, two only were natives—Giulio Pippi, called Romano, and Carlo Maratti.

The most celebrated work of Nicias was the Νεκυία, or the region of the shades, of Homer (*Necromantia Homeri*); from the passage of the Odyssey where Ulysses invokes the shades of the dead. Nicias, says Plutarch, refused to sell this picture to Ptolemy I., of Egypt, who offered him sixty talents for it; he presented it to his native city, Athens. If Plutarch speaks here of the Attic talent, the price offered was enormous, though not unprecedented in antient times—about 15,000*l.* according to some computators of Attic money; but if the Egyptian talent is signified, which is very unlikely, the amount would be diminished to nearly one-fourth.

Nicias must have been old when Ptolemy was king of Egypt; and from his refusal of this offer, probably very rich also, as Pliny says he was. Ptolemy ascended the throne of Egypt in 306 B.C., and Nicias, about half a century earlier, was employed by Praxiteles to colour some of his statues. Pliny intimates a doubt whether the same artist in these two cases is alluded to; and Sillig, in his 'Catalogus Artificum,' has concluded that they cannot be the same. Only one Nicias, however, is known and spoken of by antient authors; and the only reason for doubting the identity of these two is founded on Pliny's method of assigning their dates to artists and their scholars, mentioning only a single year or olympiad for each, which, vaguely expressed as it always is, need not give us the exact time of an artist within half a century. If we consider such a given date as the commencement of his career, we make him probably contemporary with a generation of artists who succeeded him; and if as the end of his career, as probably with one which preceded him; but if we assume such date to be the middle of his career, he may still have been born half a century before it, and may have painted pictures a quarter of a century after it. Thus if we suppose Nicias, when he refused to sell his picture to Ptolemy, to have been about seventy years of age, and he was doubtless old, with such a reputation and such independence, he may very easily have many years before painted the statues of Praxiteles. Praxiteles flourished, according to Pliny, in Olymp. 104; and if this date is to be understood as the beginning of his career, he was essentially the contemporary of Nicias; and if as the middle, he was about one generation his senior. This is in all probability the case;

for it reconciles all the facts recorded of Nicias, and it is much more probable that Praxiteles would employ a young man to colour his statues for him who was only rising in his profession, than a great painter, his equal in age and reputation. Statue-painters, ἀγαλμάτων ἐγκαυσταί, constituted apparently a class of themselves, and Nicias may have been one of these in his youth: this is more probable than that one of the greatest painters of his time should be thus employed. One of Sillig's difficulties in identifying these two as one, is, that Nicias was the pupil of the pupil of Euphranor, who was the contemporary of Praxiteles. It is a mere assumption, however, to suppose that there must necessarily be a generation between master and pupil: the master is frequently only a very few years older than his pupil, and is sometimes even younger. But if we suppose that Nicias was a generation younger than Praxiteles, there is not the slightest difficulty in the way of his having been the pupil of the pupil of a contemporary of Praxiteles.

Nicias painted in encaustic, and besides the one already mentioned Pliny notices the following pictures by him:—an Alexander (Paris), a sitting Calypso, an Io, an Andromeda, and another Calypso, in the hall of Pompey; a Bacchus, a Diana, and a Hyacinthus, in the temple of Concord. The Hyacinthus was brought to Rome by Augustus from Alexandria, and was consecrated afterwards by Tiberius in the temple of Augustus, on account of his great delight in it: it is mentioned by Pausanias (iii. 19), who says that the figure of Hyacinthus was very elegant.

Augustus dedicated and fixed in the wall also a picture by Nicias in the Curia Julia, of Nemea sitting on a lion, holding in her hand a palm twig; and by her side was standing an old man, resting upon his staff; above him was hanging a picture of a Biga. It was brought from Asia by Silanus, and was most probably the same of which a Teutonic ambassador, being asked his opinion, said, according to Pliny, 'That he would not have him even if he were real and living,' alluding to the old man with his staff: entirely overlooking the art which embodied the picture, and measuring the man apparently by his sinews. Lessing (*Laocoon*, p. 280, note) proposes to substitute in the place of the *picture of the Biga*, (*tabula bigæ*) hanging above the man's head, which he supposes to be a corruption of the text, a *name tablet*, called by the Greeks πτυχίον. Nicias wrote on this picture that he had burnt it in, Νικίας ἐνέκαυσεν, that is painted it in encaustic. These words were, in the opinion of Lessing, written upon the small painted tablet which was hanging over the head of the old man—cujus supra caput tabula bigæ dependet. Nicias scripsit se inussisse; tali enim usus est verbo. The passage is obscure; only one picture is spoken of; the words *tabula bigae* may be corrupt; it is certainly difficult to give them a suitable meaning. The Biga, says Lessing, can have no respect to the Nemean games, because in them four-horse chariots were used. (Schmidius, *in Prol. ad Nemeonicas*, p. 2.)

Nicias painted also the interiors of tombs, as that of Megabyzus, high priest of Ephesus, and one at Tritaea. Pausanias says, before you come to Tritaea from Pharae there was a sepulchre of white marble, which was particularly worthy of inspection on account of the paintings of Nicias upon it—a beautiful young woman was represented seated on an ivory chair, and behind her was a female servant holding an umbrella; a beardless youth also was standing near her, dressed in purple; by the youth was an attendant with hunting spears and a leash of dogs (Nicias was, according to Pausanias, the most excellent animal painter of his time); the names of these people were not known: Pausanias supposed them to be man and wife. Nicias was honoured with a public burial, and was interred in the road from Athens to the Academy, the cemetery of all great Athenians: Pausanias notices his tomb there. He appears to have been a very studious and absent man. Aelian says he used to forget to take his meals (*Var. Hist.*, iii. 31).

It has been said above that Nicias painted some of the statues of Praxiteles: this requires some explanation. Pliny relates that Praxiteles being asked which of his marble statues he preferred, answered, 'those which Nicias had had a hand in; so much did he attribute to his *circumlitio*.' This word *circumlitio* has been variously interpreted: Fuseli supposed it signified the outlining of the clay model; but Pliny is speaking of marble statues, and the circumlitio must have been some superficial application, and cannot be applied to a correction of form; the question is also about a process which the marble statues have undergone at the hands of a painter. Cicero has 'Persae mortuos cera circumlitos condunt.' (*In Tusc.*, i. 45.) There is a prejudice against the idea that the Greeks painted their statues; that they did so however is an indisputable fact, though it was not a universal practice. The statue-painters, οἱ ἀνδριάντας γράφοντες, as Plato calls them, are definitely spoken of by Plutarch (*De Glor. Athen.* 6,) as Ἀγαλμάτων ἐγκαυσταί—the encaustic painters of statues—and the art itself as ἀγαλμάτων ἔγκαυσις. Statues seem to have been sometimes entirely painted, which appears from the following words of Plato (*De Republ.* iv. 420. c.). He observes, in speaking of statue painters—'It is not by applying a rich or beautiful colour to any particular part, but by giving every part its local colour, that the whole is made beautiful.' That it was not however the common practice to paint the marble entirely is evident from the conversation between Lycinus and Aristratus, in the dialogue of the *Portraits*, or *Panthea*, in Lucian; from which it is plain the Venus of Cnidus, by Praxiteles, and other celebrated statues, were not painted, though parts may have been coloured, and the whole body covered with an encaustic varnish. (Lucian, *Imag.* 5-8.)

We may infer therefore in this case that the *circumlitio* of Nicias, applied to the marble statues of Praxiteles, was the ἀγαλμάτων ἔγκαυσις of Plutarch, and that Nicias was himself an ἀγαλμάτων ἐγκαυστής, or painter of statues, in his youth. In his *circumlitio* the naked form was probably merely varnished, the colouring being applied only to the eyes, eye-brows and lips, to the hair, the draperies, and the various ornaments of dress; and there can be little doubt that marble statues, especially of females, must have had a very beautiful appearance when carefully coloured in this way.

(See *Dictionary of Greek and Roman Antiquities*, article Painting, by the author of this article; Pliny, *Hist. Nat.*, xxxv., 10. 36-40; Pausanias, i. 29, iii. 19, vii. 22; Plutarch, *Mor.* 'Epicurus,' c. II.; Junius, *Catalogus Artificum*.)

NICOLE, PIERRE, one of the distinguished recluses of Port Royal, was born at Chartres on the 19th of October, 1625. At the age of fourteen, when he is said to have had an ample command over Greek and Latin, he was sent to study at Paris, where he was persuaded to join the community of the Port Royal. There he occupied himself in instructing the pupils confided to the institution. He formed an intimate acquaintance and a species of alliance with Anthony Arnauld, with whose fiery zeal and restless energy his placid disposition and clear systematic mind afforded a strong contrast. [ARNAULD, P. C.] The angry disputes regarding the five points of the Jansenists prompted him to remain for several years a simple clerk, but in 1676 he was induced to seek holy orders. He was refused the necessary consent however of the Bishop of Chartres, who disliked his opinions; and he was evidently rather rejoiced than saddened by an excuse for remaining in a position where he was not too near the van in the battle of controversy. In his own province, however, of a clerical or polemical logician, he was bold and uncompromising, and it was not from the defence of his principles but their too conspicuous championship that he shrunk. He was obliged in 1679 to retire from France, but returning soon afterwards, he entered with some keenness into two of the celebrated disputes of his age—that of the studies suited to monastic institutions, where he joined Mabillon in defending a devotion to science and learning in place of pure asceticism; and the discussion regarding quietism, in which he opposed the devotees of that mental epidemic. He was a man of simple habits and candid mind, and some ludicrous incidents have been told as arising out of his absent habits. He died on the 11th November, 1695. His works are many and voluminous. He was the principal author of 'La Logique, ou l'Art de Penser' (1668), known as the Port Royal Logic. Of the first three volumes of 'La Perpétuité de la Foi de l'Eglise Catholique touchant l'Eucharistie,' which is generally associated with the name of Arnauld, he is known to have been the principal writer. Hume admired the logical clearness with which Nicole in this work showed the impossibility of one mind sufficiently examining all subjects connected with religion to form a creed for itself on the principle of private judgment; and stated that the difficulty so ingeniously set forth suggested to him the sceptical argument in his Dialogues on Natural Religion. He wrote also 'Traité de l'Unité de l'Eglise;' 'Les Prétendus-Réformés convaincus de Schisme;' 'Les Lettres imaginaires et visionnaires,' &c. He was eminent as a translator and composer in Latin, and in 1659 published 'Epigrammatum Delectus.'

(Niceron, *Mémoires*, t. xxix. 285-333; *Nouveau Dictionnaire Historique*.)

NICOLL, ROBERT, a poet distinguished by the precocity of his talents, was born at Tullybeltane, in Perthshire, on the 7th January, 1814. His parents were in too humble circumstances to afford him any education beyond the rudiments of reading and writing; and at a very early age he was set to the occupation of herding cattle. At the age of seventeen he was apprenticed to a grocer in Perth, and at the conclusion of his service endeavoured to earn a livelihood by keeping a circulating library in Dundee. During this interval he had been acquiring the elements of knowledge. He was a devourer of books, and at the age of twenty had acquired both knowledge and cultivation without being educated. In 1835 he published a small volume of 'Poems,' which became very popular, were extensively noticed by the newspaper press, and passed through three editions. They are less remarkable for energy or originality than as the fruit of a fine-toned and sensitive mind. In prose his writing was of a different character. In 1836 he undertook the editorship of the 'Leeds Times,' a paper of strongly liberal sentiments; and by the spirit and energy of his political articles, and their adaptation to the feelings of the surrounding community, he soon more than tripled the circulation of the paper. His early struggles had probably undermined his constitution, and he soon sank under the excitement of his editorial labours. When on his death-bed he was removed to the neighbourhood of Edinburgh, where, amidst tho attentions of kind friends, he died on the 9th of December, 1837, in his twenty-third year.

(*Memoir*, by Mrs. Johnstone, prefixed to a third edition of his Poems; *Westminster Review*, No. 76.)

NICO'MACHUS (Νικόμαχος) of Thebes, son and pupil of Aristodemus, was a celebrated Greek painter, who lived between 360 and 300 B.C. He is classed by Cicero with Apelles and Protogenes, and his paintings are compared by Plutarch with the lines of Homer: he was the most celebrated of all the Greek painters for rapidity of execution. In illustration of the rapidity of his execution, Pliny mentions the decorations of the monument which Aristratus, tyrant of Sicyon, had erected in honour of the poet Telestes, which were executed in a few days by Nicomachus, with remarkable beauty, and to the entire satisfaction of Aristratus, who shortly before was exceedingly angry with him, for, as he supposed, neglecting his contract, which was to have the tomb finished by a certain day. Nicomachus had deferred the commencement of the tomb so long, that Aristratus concluded he did not intend to meet his engagement: the painter, however, was a better judge of the required time in his own case.

The notices of Nicomachus are few, and what there are contain but little information about him. Pliny mentions by him—a Rape of Proserpine in the Temple of Minerva on the Capitol, hanging above the niche or shrine of Juventus or youth; a Victory in a quadriga, in the Capitol, which was dedicated by Plancus; also Apollo and Diana; a Cybele, the mother of the gods, sitting upon a Lion; Bacchantes, with Satyrs creeping up to them; and a Scylla, which was in the Temple of Peace. Pliny notices also an unfinished picture of the Tyndaridæ by Nicomachus; he instances it as an example of the unfinished works of painters being in greater repute than their finished works, when left unfinished through death, or perhaps other circumstances impeding their completion: he mentions four pictures—the Tyndaridæ of Nicomachus, the Iris of Aristides, the Medea of Timomachus, and a Venus of Apelles. Nicomachus is the first who represented Ulysses with the pileus or cap of liberty. He is one of the painters who from an error of Pliny's is said to have used only four colours. (See Dictionary of Greek and Roman Antiquities, article *Colores*.) Cicero, in speaking of the cruder performances of the early artists, notices that in the works of Echion, Nicomachus, Protogenes, and Apelles, all things are perfect. He is, however, enumerated by Vitruvius among those artists who though of the greatest ability met with little substantial success in life. Stobaeus relates of Nicomachus that, hearing some one say that he saw no beauty in the Helen of Zeuxis, he observed—'Take my eyes, and you will see a goddess.' He had several scholars: Aristides, the celebrated painter, his brother; Aristocles, his son; Philoxenus of Eretria; Nicophanes; and a certain Coryhas. Philoxenus imitated Nicomachus in celerity. Nicophanes was notorious for licentious pictures.

(Pliny, *Hist. Nat.* xxxv., 10, 36; 11, 40; Cicero, *Brutus*, 18; Plutarch, *Timol.* 36; Vitruvius, iii. *in proœm.*; Stobaeus, *Serm.* 61.; Junius, *Catalogus Artificum*.)

NIGELLA (from niger, black, because of the colour of the seeds), a genus of plants belonging to the natural order Ranunculaceæ. It has 5 coloured petal-like spreading sepals. The petals small, from 5 to 10, bilabiate, with a hollow nectariferous claw. The capsules more or less connected together, terminated by the elongated styles opening in the inside, many-seeded. The leaves are capillary, multifid, often surrounding the flowers like an involucre, and finely cut like fennel. The flowers are solitary on the tops of the stems or branches. The species are erect annual smoothish herbs.

N. sativa has ovate obtuse anthers, capsules muricated, united up to the very point into an ovate fruit, terminated by five erect styles; the stem erect and rather hairy; flowers naked. The seeds are angular, aromatic, subacid, and were formerly used instead of pepper; and have also been employed as carminatives. It is the Μελάνθιον of Hippocrates, 'Steril.' 675, and of Dioscorides, 3, 93; the Githex of Pliny, 20, 17.

N. arvensis has pointed anthers; from 5 to 7 styles circinately revolute, outwardly smooth; capsules connected below the middle into an obconical fruit, which is narrowest at the base. It has a smooth stem, with diverging branches. It is native of middle and southern Europe in corn-fields, also in the north of Africa. The seeds are sometimes used instead of those of N. sativa, but they are not so aromatic, neither have they so pleasant a smell. Both species are employed in the adulteration of pepper. All the species of Nigella are plants of easy culture, only requiring to be sown in the open border. They are curious and ornamental.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*; Fraas, *Synopsis Plantarum*; *Floræ Classicæ*.)

NIGRITIA is a term, which was formerly applied by geographers to that part of Africa which at present is known by the name of Soodán of which Arabic expression it is only a translation, meaning the country of the blacks. [SOODAN, P. C., vol. xxii.]

NILE. Since the article NILE was printed in the P. C. the course of the western branch of the river, the Bahr-el-Abiad, has been traced to 4° 42′ N. lat., which is nearly nine degrees south of Aleis, to which place it had been explored by Linant. In 1840, 1841, and 1842, the pasha of Egypt sent three expeditions for the purpose of exploring the course of the river to its source, and the two last expeditions were accompanied by several scientific Europeans.

South of Khartun (15° 17′ N. lat.) and as far south as Aleis the Bahr-el-Abiad is in general from one to two miles wide, and runs in a bottom, which is generally four miles wide, but sometimes even six miles. The bottom is covered with grass and the higher grounds at the back are partly covered with trees. There occur a few low hills in this part of the country. The western banks of the river are occupied by the Hussaniyeh, a nomadic tribe of Arabian origin, the most southern of this description. This tribe is frequently at war with the black tribes who live farther south, especially the Shillucks.

South of Aleis begins the country of the Shillucks, which extends to about 10° N. lat. The river is here three miles wide and contains a great number of low islands. They are frequently several miles long and a quarter of a mile wide, and nearly all of them overgrown with high trees and bushes. On the western side is a mountain group, called Arasholl, which is crowned with seven peaks; between this high ground and the banks of the river are extensive forests. In these forests are numerous villages, which when seen from the river appear to be regularly arranged in three rows parallel to tho river. They are inhabited by the Shillucks, a piratical nation of blacks, who frequently descend with their boats in great numbers to the countries lower down the river, and formerly extended their predatory incursions as far as Khartun, but at present they are kept in awe by the pasha of Egypt. Near the southern limits of their territories the country is interspersed with numerous isolated conical hills, among which one called Defa Fungh (10° 20′ N. lat.) appears to be an extinct volcano, consisting partly of tufa and red-brown porous lava.

Near 9° 11′ the Bahr-el-Abiad is joined from the east by a large tributary, the Sobat, which is supposed to rise in the mountains of Abyssinia, and brings down a volume of water nearly equal to that of the principal river. The lower course of this tributary was explored, and it was found that it runs between banks, which are much higher than those of the Bahr-el-Abiad itself, and well wooded. From the mouth of this river to Khartun the Bahr-el-Abiad flows from south to north, but higher up it runs from west to east for about a hundred miles, through a country inhabited by another black nation, the Dinkas, who are divided into seven tribes and speak a language different from that of the Shillucks. In this part (between 8° and 9° N. lat.) the river appears to traverse an immense swamp interspersed with many smaller and larger lakes, one of which is stated to cover an area of 420 square miles. The current of the river through these low grounds is imperceptible, and its water divided into so many branches, that it is difficult to find out the main channel. It is supposed that the great quantity of water which collects in those parts is brought down by a river running from north-west to south-east, perhaps that river which by the Arabian geographers is called Kailack. It is also possible that the course of this river has induced them to adopt the opinion that the Bahr-el-Abiad rises far to the west. The Dinkas inhabiting this swampy region are a nomadic tribe, who live principally on the produce of their herds of cattle, distinguished by large horns like those of antient Egypt. They are less strongly built than their northern neighbours, the Shillucks, and it appears that their health suffers from their residence in the swamps. In this region elephants, giraffes, and hippopotami are met with in great numbers.

Before the Bahr-el-Abiad enters this swampy region it runs from south to north, but farther upwards (south of 7° N. lat.) from south-east to north-west. The country traversed by it is a plain. The river is completely navigable, without cataracts and even without rapids. Its eastern banks are occupied by the Nuerres, and its western by the Kyks or Kekes. Both nations are cultivators of the ground, but have also numerous herds of cattle, sheep, and goats. The Nuerres are not negroes. The colour of their skin inclines to the red, and their hair is smooth and lank, not woolly. They have enclosures round their huts, and others for their cattle. The Kyks have also numerous herds of cattle, but live chiefly on fish, grain, and roots. Both nations received the expeditions with confidence and joy, and presented to them a great number of cattle. It appears that these tribes speak a language which is understood by the Dinkas.

Farther upwards other tribes are named, as tho Heliab, Bhor, and Chir. At last the expeditions arrived in the country of a black nation called the Barrys, where their progress was stopped by a ledge of gneiss, which traversed the river in all its width near 4° 42′ N. lat. and 30° 58′ E. long. In approaching 5° the bed of the river, which up to these parts appears to be formed by alluvial soil, begins to be rocky, and at the same time mountains become visible, which extend from east to west. The river by degrees acquires such a velocity as to run six knots an hour. According to the information obtained from the *matta*, or king of the Barrys, persons must walk for a month before they arrive at a country called Anyan, where the river is formed by the confluence of four rivulets, the largest of which comes down from the east.

The Barrys are described as a very interesting nation. They consist of five tribes, and speak a peculiar language. Their country is well cultivated and exhibits the richest crops, their fields being irrigated by numerous canals. They enjoy a considerable amount of ease, which appears to have a great influence on their character, and to render them peaceable and humane. They are in general more than six Paris feet in height, and are well built. They inhabit a great number of villages, consisting of huts built of reeds, and situated either on the banks of the river or at a distance from them; some are built on hills. They cultivate dhurra, sesamum, tobacco, and several kinds of melons. No horses, camels, or asses are found in their country, but their cattle are of great size and very numerous; they have also fowls in abundance. Among the wild animals, elephants, giraffes, and antelopes are very numerous. In the mountains lying towards the east iron-ore is abundant, and they make agricultural implements, lances, and arrow-points. They are also acquainted with the art of tanning and making some cotton fabrics, and with working copper and ivory, which they employ as ornaments. The king is said to live in a palace built on an island, to which his subjects can only arrive by swimming. He is surrounded by a guard composed of women. It was observed by the persons who composed the expedition, that the inhabitants were in possession of several articles brought from India, as calicoes, and several fabrics made at Surat, as also swords and other arms of iron. The natives stated that all these articles were brought to them from a commercial place which they called Berry, and which, as they said, was fifteen days' journey farther east, at the foot of a range of mountains.

Thus we learn by the accounts of these expeditions that the interior of Africa is much more populous than was supposed, and that several of the nations inhabiting it have attained a considerable degree of civilization.

(Werne, *Ueber die zweite Expedition welche auf Befehl des Paschas von Aegypten Mehemed Ali zur Erforschung der Quellen des Weissen Nils unternommen wurde. In den Monatsberichten der Gesellschaft für Erdkunde zu Berlin*, New Series, vol. ii., and Ritter, *Ein Blick in das Nil Quelland.*)

NIMA, a genus of plants belonging to the natural order Simarubaceæ. It has hermaphrodite flowers, a 5-parted permanent calyx, 5 oblong petals, 5 stamens with filaments dilated at the base; the 5 ovaries are connected together, pilose, and seated on the thick disk beneath the petals. The embryo is large, without albumen. The species are trees, with alternate imparipinnate leaves, having four pairs of serrated leaflets. The flowers are disposed in panicle corymbs.

N. quassioides is a native of Nepaul, in a valley near the town called Thankot. It has elliptical oblong leaflets, which are acuminated and serrated. The corymbs are trichotomous. It is as bitter as the quassia of South America.

(Don, *Gardener's Dictionary;* Lindley, *Flora Medica.*)

NINEVEH. Since the publication of the article NINEVEH in the 'Penny Cyclopædia,' discoveries of the highest importance have been made, if not on the precise site, yet in the immediate vicinity of that city, of which the following are some of the most interesting particulars.

For these discoveries we are indebted to M. Botta, consul of France at Mosul on the Tigris, opposite to the presumed site of Nineveh. M. Botta, leaving Paris in the spring of 1843, announced to his friends his intention of employing what leisure the duties of his office might allow him in making excavations at Nineveh. He began with some operations in the inclosure on the river, which have been long conceived to be the rampart of Nineveh, but which we must now suppose to have contained only tho palace of the Assyrian kings, as intimated by Mr. Rich. M. Botta found only some bricks and fragments of no value. Meantime the inhabitants of the environs, seeing the consul engaged in these researches, brought him bricks with inscriptions, and other remains of antiquities, which induced him to send his workmen to the village of Khosabad, Khorstabad, or Khortabad (for, says M. Botta, 'the name, which is certainly not Arabic, is pronounced in all these ways'*), distant about five hours (caravan reckoning) north-east of Mosul, on the left bank of the little river called the Khauser (Khosar). M. Botta's researches in this place not only proved more successful, but have led to discoveries of the highest importance, which, if the numerous cuneiform inscriptions can be deciphered, will doubtless throw great light on the antient history of Asia. Commencing his excavations in a small mound, his workmen soon came to a monument, remarkable for the number and stylo of the sculptures with which it is adorned, and which appears to have been a royal palace. M. Botta regularly communicated, during the progress of the work, with M. Julius Mohl, at Paris, to whom he wrote sixty letters, with drawings of the sculptures and copies of the inscriptions. M. Mohl published the most important letters, and the drawings and inscriptions, in the 'Journal Asiatique;' and they have since appeared in one volume, with fifty-five plates. M. Botta regretted that he was not a competent draughtsman, and wished the government to send him a good artist; and as soon as the French ministry were aware of tho great importance of the discoveries, they sent him M. Flandin, an able artist, who had lately returned from Persia, and granted sums of money to enable M. Botta to prosecute his researches. The following particulars are extracted from M. Botta's letters, and such parts have been selected as may be understood without the plans. He had great difficulties to encounter, and impediments wero thrown in his way by the ill-will of Mehemet, tho Pasha of Mosul. All are now happily surmounted, and the excavations are terminated (in 1845). M. Flandin has

* With respect to the name of this village, it is noted by an English traveller as *Hor-'sabad*, 'which,' says he, 'viewed as an Arabic and Persian compound, would designate—what it is—a city in a marsh. As to the more ancient name of the place I am quite at fault, but cannot at all admit that it constituted part of ancient Nineveh—the distance is too great.' M. Mohl says, 'Mr. Rawlinson, English consul-general at Bagdad, lately wrote to me that he has found in Yakould that this place was called by the Syrians *Sar'oun*. A letter from Constantinople, written June, 1844, says, however, 'Botta's most recent discovery is that the hill was connected with Nineveh. On the direct road from Nineveh to Chorsabad there is a series of similar hills covered with fragments of bricks and marble tablets with inscriptions, and it begins to seem probable that Chorsabad was a royal palace, situated at the end of the city. In this case the quadranglo which is still surrounded with a wall, and has generally been taken for the whole city of Nineveh, was probably only the great palace, while tho city extended to tho hill of Chorsabad, a distance of five caravan leagues.'

returned, with drawings of 130 bas-reliefs; and the greater part of the sculptures (weighing it is said above 300 tons) have been sent to Bagdad, to be embarked on board a vessel to be conveyed to France, where they are to form an Assyrian museum. M. Botta is we believe now at Paris, with copies of 200 inscriptions, and will publish an account of his great discoveries, with engravings of all the sculptures and inscriptions.

*From M. Botta's third letter, dated Mosul, June 2nd, 1843.**—'I return with increasing astonishment from my discoveries at Chorsabad. My operations have again brought to light a great number of bas-reliefs and inscriptions. . . . On the north wall of the apartment there are, first, some figures, of which only the feet remain; then a bas-relief, on which there are two archers standing and two kneeling, who wear coats of mail, and have an inscription over them. These archers are shooting at a fortress, which is taken by storm. The fortress consists of an embattled wall, strengthened by projecting towers; at the bottom there are undulating lines, probably representing a river or the water of the moat. Within this wall there is an eminence with a castle upon it, from which arise what I suppose, from their red colour, to be intended to represent flames. At the other extremity there are three warriors armed with pikes, holding their shields over their heads, and ascending a ladder; others have already reached the top; and in the intervals between the towers others are mounting scaling ladders. At the other end there are the remains of a similar scene, but this part is much damaged; we only see that one of the soldiers pursues an enemy with his sword; a man pierced with an arrow is seen falling from the top of the wall; and on several parts of the fortress others are lifting up their hands to heaven; at the bottom there is a row of wretches impaled. On the top of the hill there is a short inscription, probably containing the name of the fortress. The whole is very animated. The attitudes are perfect, and though the heads of the figures are scarcely an inch long, the expression of the features is excellent.

'After this bas-relief there are on the same wall five war-chariots following each other, turned to the fortress, and evidently meant to represent a battle. These chariots are all alike. The horses are in full gallop, and trample with their hoofs on a man lying on the ground. There are five persons in each. The principal figure wears a pointed tiara, and is discharging arrows; beside him is the driver, and behind them two warriors, armed with darts and wearing bucklers. Above there is a man who seems to be wounded, and thrown into the air with the head downmost. The singular position of this figure is perhaps meant to indicate the confusion of the battle, or the rapidity of the chariot, which violently throws to a distance whatever it encounters in its course. The scene is extremely animated; the horses in particular are very spirited. The harness of the horses is very rich, and has evidently been coloured. These five bas-reliefs are each sculptured on one of the large slabs which form the walls; and over them is a long inscription, which at first seems to be continuous, but it is certain that it is divided into parts, each bounded by the edge of the slab on which it is sculptured; in fact a perpendicular line at the edge of each slab separates the inscriptions, which differ in the number of lines.'

M. Botta describes several other figures, and proceeds:—'This description of these newly discovered sculptures is very incomplete; to describe them in detail would require a volume. I doubt whether more richly decorated walls are to be found even in Egypt. In the whole monument there is scarcely a square foot which is not covered with sculptures and inscriptions. The mode of building is everywhere the same. The walls are formed of enormous slabs of gypsum or alabaster ten or twelve feet square, and scarcely a foot thick. . . . The figures are in relief, and often lower than in Greek sculpture, but higher than the Egyptian. Though rather stiff they are well designed, the attitudes admirable, the muscles strongly marked, and the hands, feet, and ornaments very carefully executed. I have no doubt that the building has been destroyed by fire; on the ground were found a quantity of charcoal and some remains of burnt beams. The surface of the slabs is in many places calcined by fire and friable. . . . . As persons better informed than myself will probably be desirous to determine the age of the monument, I shall refrain from all discussion on the subject, and merely state some particulars which may aid them in their researches. Though the hair, the beards, and the costumes resemble the Sassanide modes, I have found no trace of any inscription in a different character from that of the bricks found at Nineveh itself: all the mythological emblems are Babylonian. I have not met with any trace of iron being employed in the monument, but many remains of articles of copper (query brass or bronze); nails, rings, and even part of a small wheel, a foot or a foot and a half in diameter. These facts indicate the antiquity of the monument; but on the other hand I have discovered that the stones with which it is built belong to a more ancient edifice. In fact, some of the slabs of gypsum have on the back cuneiform inscriptions evidently injured by time, in characters exactly resembling those on the present monument.'*

M. Botta in his fourth and fifth letter continues to give an account of the progress of his discoveries; among the most interesting are two colossal statues of bulls fifteen feet high, with human heads, and between them a passage seven feet and a half wide, forming, as he presumes, a portal of a striking character and of great magnificence. These bulls were winged; they are not properly statues, but in high relief. On clearing the passage it was found that the bodies of the bulls were continued on the walls in low relief. These figures are of large dimensions, 18 feet in length and high in proportion. They have five legs, so contrived that from whatever side you look at them, one leg being hid by another, four legs are always to be seen. On each of the walls of the passage to which this is the entrance, there is a figure with the head of a bird of prey; the hair is regularly braided, on the head is a sort of cap which comes down to the shoulder. The figure has a necklace, armlets, and bracelets, and wears a short tunic, with a fringe girdle. On the opposite side of the chamber, M. Botta afterwards found a similar portal. M. Botta resolved to send two of these bulls to Paris.

This discovery cannot fail to engage the attention of the learned; but unfortunately the greater part of these remains has already disappeared. The walls are not solid, but formed of slabs of gypsum or alabaster, with an intervening space which is filled up with earth. 'This earth,' says M. Botta, 'has caused the walls to bulge in many places, and broken the sculptures into a thousand fragments since I have cleared them. Having nothing to support them, they would fall did I not take the precaution to shore them up as I proceed; but as these supports will last only during the operations that I am carrying on, the monument will necessarily perish entirely if the enlightened munificence of the French government does not furnish me with means to save the most interesting portions.'

In a report to the Minister of the interior, M. Botta says, that on visiting the ruins of Khorsabad (after the excavation had been suspended for two months on account of the heat), 'I much regret that a great part of the sculptures is already destroyed. The inhabitants have stolen the props which I had placed to support them; the rains have caused many walls to fall. I am extremely sorry that M. Flandin has not yet arrived.'

'I am still in doubt,' says M. Botta to M. Mohl, 'respecting the destination of this monument; whether it was a palace or a tomb. The latter seems the more probable, because the interior must have been completely dark; for there is no appearance whatever of windows. At all events, the extreme richness of the decorations, and the number of battles represented, prove that it must have been built by a rich and powerful monarch.'

It is to be hoped that the 300 tons weight of the sculptures sent by M. Botta to France, the 200 inscriptions, and the drawings of M. Flandin, will enable the learned antiquarians of Europe to throw much light on the history of those remote ages.

The writer of a private letter from Constantinople says, 'M. Flandin's drawings, which we had the good fortune to see a few days ago, will greatly interest the public in general as well as antiquarians—the manners and customs, the religion, the art of war, the costumes and the instruments of the people

* M. Mohl has published only five of M. Botta's letters.

* A letter from Constantinople, of the beginning of 1844, says, "M. Botta has entirely given up his opinion that the slabs had belonged to another building. The reason is, that these plates which form the angle of all the apartments, have the two faces forming the corners hewn out of one piece, and have always at the back, an inscription which runs round the corner. To account for these inscriptions being so placed that they could never be seen while the building remained entire, we need only suppose that their contents are of a talismanic, religious, or mystical nature, and were purposely concealed, like the idols which M. Flandin found in deep recesses in the walls; which could not be got at as long as the walls remained entire."

who built Khorsabad, are here delineated in faithful copies of the bas reliefs. The principal figure in most of them is a sovereign, king, or hero; on his head he wears the tiara, his forehead is low and prominent, his eyebrows thick; his hair and beard falls straight on the shoulders and breast, terminating in large ringlets. The dress, which appears to have been extremely magnificent, consists of a richly embroidered tunic, and an upper garment, resembling the surplice of a Roman Catholic priest. This figure appears, sometimes engaged in combat, driving his enemies before him; sometimes seated at an entertainment; and sometimes in a solemn procession, guiding a chariot with four horses abreast. Among the many figures of combatants, there is frequently a shield-bearer, under whose protection another warrior draws his bow or poises his lance.—There are no female figures, except one, which is not very distinct.' M. Botta at first took several figures for females, but afterwards changed his opinion, and thought they might perhaps be meant for eunuchs.

(*Lettres de M. Botta, sur ses Découvertes à Khorsabad près de Ninive, publiées par* M. Julius Mohl, Paris, 1845.)

NIPADI'TES, a genus of fossil fruits, from Sheppey. (Bowerbank.)

NISI. [RULE (in Law), P. C.]

NISSO'LIA (in honour of William Nissole, a French botanist), a genus of plants belonging to the natural order Leguminosæ. It has a campanulate calyx, a papilionaceous corolla, and ten monadelphous stamens. The legume is stipitate, one- or few-seeded. The species are climbing shrubs, with imparipinnate leaves.

N. ferruginea has from 7 to 11 leaflets, which are alternate, oblong, mucronate, and clothed with rusty velvety down; beneath the flowers are panicled, monadelphous, and the legume straight and rather velvety. The flowers are violaceous. It is native of Guiana, and exudes from its stem a red transparent gum that has a powerful astringent flavour. It is also known by the name of *N. quiriata.*

None of the species of this genus are European, nor are they of use in art or science. A mixture of loam and peat is the best soil for them, and young cuttings will strike root in sand under a bell glass in heat.

(Don, *Gardener's Dictionary;* Burnett, *Outlines of Botany.*)

NITELLA, a genus of plants belonging to the natural order Characeæ. It is characterised by the whole plant being more or less pellucid; the cells are tubular, not invested with a secondary layer of smaller cells as in Chara; the reproductive organs consist of globules and nucules, mostly seated on the terminal whorl and axillary.

Four species of this genus have been described inhabiting Great Britain.

N. translucens has an elongated flaccid pellucid glossy stem, with the branches of the whorls spreading, elongated; the nucules and globules approximate, on the smaller ramuli scarcely bracteated. It grows in deep and stagnant ponds, but is by no means a common plant in Great Britain. It is the largest of the British species, and best adapted for the examination of the curious currents, which are obvious in the whole of the family to which it belongs. [SAP, P.C.]

N. flexilis has a stem one to two feet long, smooth, flaccid, somewhat glossy and pellucid. It is not unfrequent in lakes and still waters. The nucules are often solitary. The stem, like that of Chara, is often incrusted with carbonate of lime. Hassall thinks this constitutes the only distinction of Agardh's *N. opaca.*

N. nidifica, has single stems, smooth below, flaccid, somewhat glossy and pellucid: the nucules and globules separate. It is a native of the salt water ditches in the south and east of England.

N. gracilis has smooth, glossy, pellucid stems, with whorls of the branches compound, the segments acute, the bracts wanting. This is a small delicate and elegant species, but probably not distinct from N. flexilis. In fact, it may be questioned whether all these species are not varieties of one.

(Hassall, *Freshwater Algæ;* Smith, *English Botany.*)

NODAL POINTS AND LINES. The former are those points in the length of a string extended between two fixed objects, or in a column of air confined at one or at each extremity, which, when the string or column is put in a state of vibration, are found to remain at rest; and the latter are corresponding lines which exist on the surface of an elastic body, usually a plate, whose parts are in a state of vibration.

It is well known that if a string or a metallic cord be attached at its extremities to a board or plate, on causing it, when in a state of tension, to vibrate transversely, there may be distinguished, besides the principal sound, which is due to the length of the string, several others which have a greater degree of acuteness; these are called *harmonic sounds,* and they are conceived to result from some property of the extended string, by which, when in a state of vibration, it becomes a sort of moving axis, having on it points, at distances from one another equal to some aliquot part of the whole length of the string, at which points a contrariety in the directions of the vibrations of the particles keeps the latter in a state of rest. Such are called *nodal points;* and they may be conceived to form themselves in consequence of inequalities in the thickness or density of the string, or of different degrees of flexibility in its different parts. The string between every two such points is in the same condition as if it were attached at those points to fixed objects; its partial vibrations are consequently such as are due to the distance between the points, and hence arise the secondary or harmonic sounds.

A string of considerable length, on being made to vibrate, will be found to have several such nodal points, and the curves which the intervals assume in consequence of the vibrations, though alternately on opposite sides of the axis of the string, are equal and similar to one another. The situations of the nodal points may be made evident by placing, at intervals, across the string, pieces of paper notched or bent in the form of an inverted V; those which are at the places of the nodes remaining at rest, while the others experience considerable agitations, or are thrown entirely off.

If a string, in a state of tension, have its extremities attached to a board or a plate of metal, and be made in some part of its length, to pass over a bridge resting in the centre of the board or plate, the vibrations of the string, when a violin-bow is drawn across it, will be communicated to the plate; and if over the latter light dust be strewed, that dust will be agitated and made to arrange itself on lines at which the surface of the plate is in a state of rest: these are called *nodal lines,* and the figures which they form are called Acoustic figures. Again, if a glass rod be cemented at one end to the centre of a disk of the like material, and be excited by being rubbed, for example, with a wet cloth, so as to be put in a state of vibration longitudinally, those vibrations will be communicated to the disk, and light dust strewed over the latter when in a horizontal position will arrange itself in acoustic figures. Or, if a glass rod be connected at each extremity to a glass disk at right angles to its length, on exciting one of the disks by drawing a violin-bow across its edge, the vibrations of that disk will, by means of the rod, be communicated to the other; and if light dust be strewed over both it will arrange itself in figures: when the disks are equal and similar to one another, the figures are alike on both; otherwise they differ.

If a column of air in a cylindrical tube which is closed at either, or at each end be acted upon by the force of the breath, for example, applied at an aperture in any part of its length; it will spontaneously divide itself into portions in which the particles are subject to equal and similar vibrations [ACOUSTICS, P. C.; VIBRATION, P. C.]: these portions are separated from one another by sectional areas in which the particles are at rest; the condensations, or rarefactions, of the air being, in those areas, greater than in any other parts of the tube in consequence of the particles moving in contrary directions, and with equal velocities towards, or from, them. Such areas are called *nodal sections,* and several may exist at the same time in the tube. Their existence is rendered evident by boring small holes in different parts of the sides of the tube and covering them with pieces of thin paper slightly adherent to the surface: at the nodal sections the papers will be scarcely affected, while, in the intervals, they will be greatly agitated.

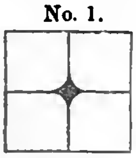
If, in the side of a tube containing a column of vibrating air, any aperture exist by which that air is enabled to communicate with the atmosphere, the air in that section becomes in equilibrio with the latter, and, in that section, there is consequently neither condensation nor rarefaction: this section corresponds to the middle point between two nodes in a vibrating string.

Vibrations corresponding to those which are produced in strings or rods and in columns of air may be conceived to take place in any solid bodies or in any elastic fluids whatever be the figure of their mass: in such a mass there may be several places at which the vibrations are performed in contrary directions so as to produce nodal lines; and these, when they occur on the surface of the mass, may become sensible by means of light dust strewed over it. Some of the vibrations are found to take place parallel to the surface, and others perpendicular to it: the former being called tangential, and the latter normal vibrations. In one case the particles of dust glide upon the surface in directions which tend alternately towards and from the nodal lines (the movements in the former direction being always more rapid than those in the other) till they come to a state of rest on those lines: in the other case the particles alternately rise from and fall back upon the surface at the places where the latter is in a state of vibration; and, dispersing from those places, they become quiescent in the lines of no vibration.

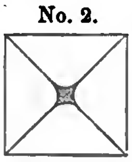
Galileo was the first who observed (*Dialoghi delle Scienze Nuove*) that the vibrations of elastic plates might be rendered visible by covering the plates with fine sand; and he remarked that the sand became accumulated at the parts where the vibrating plate was in a state of rest: but this subject was extensively investigated by Dr. Chladni of Wirtemberg, who first discovered the longitudinal vibrations of solid bodies; and, in 1787, published, in a work entitled *Entdeckungen über die Theorie des Klanges*, an account of numerous experiments which he had made on the nature of the vibrations produced in plates of glass of different forms.

The plates with which such experiments may be performed should be of good window glass; and, if square, from 4 to 8 inches on each side; if circular, their diameters may be within the same limits: in making an experiment the plate must be held horizontally between a finger and thumb, or it may be fixed within the lips of a clamp screw; and when it is required to prevent any particular part of the plate from vibrating, that part, if on the edge, may be pressed against a fixed object, or, if at any part of the surface, one of the fingers of the hand may be pressed gently upon that part. The plate being in a horizontal position, it must be covered with a layer of fine dust; and it may be put in a state of vibration by drawing a violin-bow across its edge: the dust will then arrange itself in figures which will vary with the form of the plate, the place at which the bow is applied, and that at which the plate is held. If, for example, a square plate be held at its centre, and the bow be applied near one of the angles, the dust will arrange itself in lines so as to divide the plate into four equal squares (No. 1). If the plate be held as before,

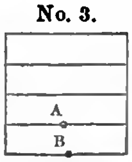
No. 1.



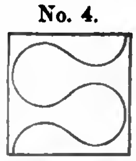
No. 2.



No. 3.



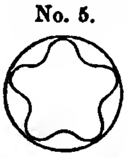
No. 4.



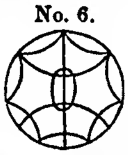
and the bow be applied at the middle of one of the sides, the vibrations will be such as to make the dust lie in the directions of the two diagonals (No. 2). Again, if the plate be held at A (No. 3) and the bow be applied at B, the dust will assume the positions of three lines parallel to one another: and if the plate be held at a point nearer the edge, the lines will become curves, as in No. 4.

If a circular plate, held at the centre, be pressed against a fixed object at any point on its circumference, and the bow be applied at 45 degrees from that point, the lines will take the positions of two diameters at right angles to one another, one of them passing through the point at which the circumference touches the object. A greater number of radiating lines than four will be produced if the bow be drawn more rapidly and with less pressure against the edge of the plate than in the former case. If the centre of the circular plate be free, various curve lines will be assumed by the dust, according to the position of the point which is held; and one of them is represented in No. 5. The figures represented in

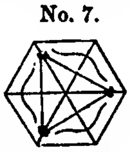
No. 5.



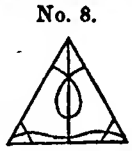
No. 6.



No. 7.



No. 8.



Nos. 6, 7, and 8, are selected from the great number which Chladni has obtained with glass plates of a circular, a polygonal, and a triangular form.

M. Felix Savat, has observed, that if a rectangular plate of glass about 27 inches long, $\frac{3}{4}$ inch broad, and $\frac{1}{16}$ inch thick, be held horizontally between a finger and thumb at the middle of its opposite edges, and it be put in a state of longitudinal vibration, either by rubbing its under side, near one of the ends, with a wet cloth, or by striking it gently at one end, the dust on the upper surface will arrange itself in lines perpendicular to the length of the rod. It is remarkable, that if the plate be turned with its upper face downwards, being held as before, and vibrations be produced in like manner, the places of the nodal lines will be opposite to the middles of the intervals between the lines observed in the other position of the plate—a circumstance which proves that the motions of the particles in one-half of the thickness of the lamina of glass are directly contrary to those in the other half. A like effect has been observed when cylindrical rods of glass have been made to vibrate longitudinally; the line of nodes then assuming a spiral form about the cylinder, and the curves consisting of portions which run alternately in contrary directions: the points of greatest and least inclination to the axis of the cylinder are at 90 degrees from each other with respect to a line drawn on the surface parallel to the axis, and the effect is such as would arise if the cylinder were divided longitudinally into four quadrantal portions, having opposite qualities. The places of the nodes on that part of the rod which was uppermost were found, the rod being held in a horizontal position, by annular pieces of paper loosely encircling it.

In 1822, M. Savart read to the Académie des Sciences at Paris, an account of some curious experiments in which acoustic figures were produced in consequence of vibrations communicated through the air to elastic membranes. (Brewster's Edinburgh Journal of Science, vol. ii. p. 296.) A sheet of thin paper was slightly stretched over a glass vessel four or five inches in diameter, and on it was strewed light dust. A thin circular plate of glass, in a state of vibration, was then brought within a few inches of the paper, when the vibrations were communicated to the latter, and, the paper being of uniform thickness and well stretched, the dust assumed figures which were perfectly regular. M. Savart, having rendered the glass plate immoveable at opposite points on its circumference by holding it there between the thumb and a finger of each hand, placed the tip of another finger at a point on the surface, at a distance from the centre equal to about one-fifth of the diameter, and caused the plate to vibrate by drawing a violin-bow across its circumference. In these circumstances, on presenting the plate to the stretched paper, the following appearances were observed. The nodal figures on square paper were analogous to those formed on a square plate of glass or metal, and on circular plates their general character was circular. The circular lines were sometimes cut by diametrical lines which formed nodal points, or stars, and the number of these increased with the acuteness of the sound produced by the bow. When the plate of glass was parallel to the paper, the nodal lines were similar on both, as when two plates were connected with each other, by a rod fixed perpendicularly between them. When the plane of the glass plate was held vertically, the nodal lines on the paper became parallel to one another; and the figures on the paper changed as the glass plate was made to decline from the vertical position.

NODIER, CHARLES, was born at Besançon, in France, on the 29th of April, 1780. Under the care of his father, a man of stern principles and of a cultivated mind, he evinced in early life a considerable disposition for the acquirement of knowledge. At the age of twelve he entered on a course of classical study, which was, however, soon interrupted by the events of the Revolution, the principles of which his father, at that time mayor of Besançon, warmly espoused. During the Reign of Terror young Nodier employed himself in writing poetry and composing tragedies on classical subjects. These early compositions he was accustomed to read to an aged friend, who judiciously advised him to devote himself to more serious pursuits. The beneficial consequence of his advice became manifest, when five years afterwards he published a work of considerable research and great critical acumen, entitled 'Le Dictionnaire des Onomatopées,' that is, a dictionary of words which derive their signification directly from the action which they represent (ὄνομα, 'a name,' and ποιέω, 'to make'), as the verb 'to hiss' in our language, and 'siffler' in French. At the suggestion of Fourcroy [FOURCROY, P. C.], it was used as a class-book throughout France, and a copy of it, by order of government, was placed in the library of every Lyceum or public school. The preface of this remarkable work on philology evinces great grammatical knowledge, and is not inferior in style to any of his later productions. During the same period of the Reign of Terror he formed an acquaintance which terminated in the most intimate friendship with Mons. de Chantrans, a Royalist officer, who was compelled to seek for safety in a retired country-life; through him Nodier acquired a taste for the study of natural history, to which he afterwards devoted a considerable portion of his time; it was especially to the minute examination of insects and flowers that he attached himself, and his taste for them is strongly marked in all his after-productions. He published in 1798 the result of his studies in a dissertation on the organs of hearing in insects, and in 1801 in a small work entitled 'Bibliothèque Entomologique.' In 1796 Nodier had gone to Paris, where, furnished with numerous recommendations, he had been introduced into the best literary societies of that time. Two years afterwards he retired to his native town; but soon becoming wearied of the monotony of a provincial life, he sought for novelty in the society of the political prisoners and suspected Royalists, who at that time abounded at Besançon. His imprudence, however, became the fortunate means of bringing his talents more prominently into notice. The company he was keeping brought him under the suspicions of the government, and his room was one night forced open and searched by the police agents, and his papers placed in the hands of the prefect, Jean Debry, one of the deputies of the French Republic, who was imprisoned at Rastadt by the Austrians. While searching among his papers for some traces of a political plot, Debry met with the manuscript of 'Le Dictionnaire des Onomatopées,' and was surprised to discover the deep research and learned disquisitions contained in a work of a young man whose habits were apparently so frivolous. With just discernment he perceived to what important uses might be applied the power of a mind so brilliant in imagination and so persevering in study. Under his influential auspices the work was published, with the success already mentioned.

At the Revolution which placed Napoleon on the throne, Nodier, who during the most turbulent periods of the Republic had expressed opinions favourable to the Royalists, became under Napoleon a stern Republican. Indeed, in the strict acceptation of the term, he had no political opinions. The disposition of his mind always prompted him to oppose the prevalent tendencies of the age. Thus, under the Republic, which discountenanced religion, Nodier professed openly the most religious sentiments; under the Consulate, he was at one time a Girondist, at another a Vendean; under the Empire, he was a discontented Liberal; under the Restoration, he sung the praises of the political party which had brought to the scaffold the brother of the reigning king. The following remark made to a young friend, who has lately published a most interesting relation of his life, is the best index of his disposition: 'My child,' he one day said to him, 'of whatever political struggles you may become witness, always abide by the side of the conquered; their cause is almost invariably the most just.'

His first poem, 'Napoleone,' is consecrated to the defence of liberty, and appeared in 1800, when military power was assuming the ascendant; the last lines are a tribute of praise to 'the martyred Sidney.' The author of a poem filled with unseasonable praise of democratical institutions, was sought for among the ranks of the suspected republicans; and several had already been arrested, when Nodier acknowledged the poem as his own. An imprisonment of some months was the result, at the expiration of which he was sent back to his native town, and placed under the inspection of the police. These measures of the government, as they were the means of secluding him from society, enabled him to devote more time to literature, and he especially attached himself to a critical study of his own language. It was during this period that appeared his 'Examen critique des Dictionnaires de la Langue Française;' a work replete with the most learned and instructive remarks. To this period also is to be assigned his 'Peintre de Saltzbourg,' which he composed while wandering over the country to avoid the watchful persecution of the government agents. After some years spent in this manner of life, he retired to Dôle, where he gave public lectures on French literature, which met with success unprecedented in a small country-town. It was there that he first became acquainted with Mademoiselle Desirée Charvés, a lady of great accomplishments and personal attractions, whom he afterwards married.

Nodier spent the first years of his married life at Quintigny, near the Jura; it was amongst the picturesque woods and meadows which adorn the neighbourhood of that town that most of the poems which have added so much to his celebrity were composed. The necessity of providing for the subsistence of his family obliged him to abandon the charms of a country life in order to settle in Paris. Previous to leaving Dôle he had solicited the vacant situation of public librarian of that town, to which was attached the small salary of 1000 fr., about 40*l.* a year, but the corporation, with a singular want of discernment, had refused it to him. In Paris he soon made himself known by his numerous publications, and became a regular contributor to the 'Journal des Débats.' A short interruption to his residence at Paris was caused by the acceptance of the office of librarian at Laybach in Illyria, with a salary of 1800 fr., half of which he generously bestowed upon an aged German who had been his predecessor. The restoration of the Bourbons produced little change in the fortunes of Nodier; he continued attached to the 'Journal des Débats,' which paper he afterwards left to undertake the direction of the 'Quotidienne.' This period of Nodier's life was rich in literary labour; each successive year he produced a work, which, taken by itself, was sufficient to confer celebrity on the author. In 1818 appeared his 'Jean Sbogar,' in which he displays an intimate knowledge of German literature; in 1819 'Thérèse Hubert,' a short romance remarkable for the unaffected beauty of its style and the simple development of its plot; in 1820 'Adèle,' another imitation of the German; in 1821 'Smarra,' derived from the writings of Apuleius, and 'Trilby' in 1822.

Nodier was shortly after this nominated to the important situation of librarian to the Arsenal at Paris. Nodier's rooms at the Arsenal soon became the resort of the most distinguished literary men of the capital, who were attracted thither by the amiable affability of the librarian, and by the charms of his brilliant and learned conversation. Among the most constant of his visitors were Victor Hugo, Lamartine, Alexandre Dumas, and Ste. Beuve. It is not the least surprising fact connected with the life of this remarkable writer, that amidst the incessant occupations of his situation, and the time which he devoted to the society of his friends, he should have produced so many works, all of which bear the stamp of original genius. It would be here impossible even to enumerate all his productions. He was a contributor to the 'Biographie Universelle' and other publications, and the originator of the 'Grand Dictionnaire Historique,' while almost daily publishing various works of a more popular character, such as his 'Souvenirs de la Jeunesse,' 'Inès de las Serras,' 'Les Fantaisies du Docteur Néophobus,' 'Dernier Banquet des Girondins,' and 'Franciscus Columna,' his last and perhaps most remarkable novel. In 1834 the French Academy did him the tardy justice of electing him a member of their body in the place of Mons. Laya.

At length, under the effects of constant application, Nodier's health gradually gave way. The evening before Christmas, 1843, was the last in which he was permitted to enjoy the society of his literary friends. Three days after he was taken with a serious illness, more lingering than painful, and expired on the morning of the 27th of January, 1844.

Nodier's character is described by those who enjoyed the privilege of his acquaintance as peculiarly amiable and unaffected. With more than an ordinary disposition to raillery and sarcasm, he ever tempered the sallies of his wit with kind consideration to those against whom they were directed. The father of a family, which he maintained by the most incessant literary labour, he had none of that irritability of temper too often the accompaniment of genius. When he was placed under the necessity of administering reproof, it was disarmed of offence by the simple modesty of his manner: to an acquaintance who had brought him a work for his perusal, in which he had made a bad imitation of his style and method, he remarked: 'My friend, what you have given me to read cannot be very good, for, at first sight, I mistook it for my own.'

His peculiar characteristic as a 'littérateur' is that he devoted the energies of his mind to no special subject, but to write on almost every subject, and that in a way which leads one to suppose that, had he attached himself to it, he might have attained the highest eminence. As a poet his merit consists in the purity of his style and diction, his hostility to the innovations which have been introduced in French literature, and his faithful adherence to their best classical models. In one respect he deserves especial praise, the substance and moral of his writings are as pure as his style.

There is a short but most interesting biography of Nodier by his friend Francis Wey, Paris, 1845; and also in the 'Portraits littéraires de Ste. Beuve;' to these two works we are chiefly indebted for the materials of this article.

NOLA'NA (so named by Linnaeus, from nola, a little bell, on account of the bell-shaped form of the corolla), a genus of plants belonging to the natural order Solanaceæ and the tribe Nolaneæ. It has a 5-cleft calyx, a campanulate 5-lobed 5-plicate corolla; 5 stamens adhering to the tube of the corolla, nearly equal. The anthers are 2-celled, dehiscing lengthwise. The seeds are roundish, with a membranous testa, and fleshy copious albumen. The species are herbs, natives of Peru and Chili, usually annual. Leaves alternate, quite entire. The flowers are solitary, pedunculate, and of a showy blue colour.

N. prostrata, prostrate Nolana, has a prostrate stem, ovate oblong leaves, a pyramidal calyx, with triangularly sagittate segments, furnished with spur-like processes at the base. It is a native of Peru, but grows freely in this country in the open air. In France poultry are fed upon it, and are so fond of it that Persoon proposed to call it *N. gallinacea*.

N. paradoxa has prostrate hairy stems, ovate obtuse pilose leaves, the segments of the calyx triangular, the corolla campanulately funnel-shaped, the drupes cumulated, 1-seeded. It is native of Chili, on the sea-shore about Concepcion. The flowers are blue.

The species of Nolana are only valuable as ornamental plants; they are showy when in blossom, and are much like some of the trailing species of Convolvulus. The seeds should be sown in a gentle hotbed in the spring, and the plants when of sufficient size or about the middle of May should be finally transplanted to the open ground, where they will flower and ripen seed; or the seeds may be sown at once in the open border in a warm sheltered situation.

(Don's *Gardener's Dictionary*; Burnett's *Outlines of Botany*).

NOLLET, JEAN ANTOINE, a distinguished French philosopher, was born at Pimpré, in the Noyonnais, in 1700. It being the intention of his father, who held a farm in that part of France, that he should embrace the ecclesiastical profession, he was sent to the college of Beauvais, in order that he might prosecute the study of theology; but his taste inclining him to cultivate the physical sciences the intention was abandoned, and he was never otherwise connected with the church than by holding deacon's orders with the title of Abbé. On leaving the college he went to Paris, where he attended a course of lectures on natural philosophy, the subjects of which he studied with great diligence, repeating in his humble dwelling the experiments which he had seen performed in public. He passed many of his leisure hours in the practice of enamelling; and he is said, at one time, to have superintended the education of a son of M. Taitbout, who held the post of recorder.

The Abbé Nollet applied himself particularly, in conjunction with M. Dufay, to the subject of electricity; and he soon became distinguished by the number as well as the ingenuity of his experiments with relation to that science, performing them in the laboratory of M. Réaumur, who generously permitted him to make use of his valuable apparatus. He was the first who observed that pointed bodies, when electrified, gave out streams of light, but did not exhibit in other respects such powerful indications of electricity as were shown by blunt bodies; and he found that the smoke of burnt linen and wood, and the vapour of water, were better conductors of electricity than the smoke of gum-lac, turpentine, or sulphur. He ascertained that an excited tube lost none of its electricity by being placed in the focus of a concave mirror when the sun's light was concentrated in that point; that glass and other non-conductors were more strongly excited in the air than in vacuo; and that oil of turpentine on a woollen cloth was capable of producing the electric fluid in abundance: he observed also the diffusion of the electric light in vacuo. He discovered that electricity augments the natural evaporation of fluids, and that the effect is the greatest when the fluids are contained in non-electric vessels.

In repeating the experiments of M. Boze on the effects of electricity in promoting the discharge of fluids through tubes, Nollet found that no acceleration took place when the bore of the tube exceeded $\frac{1}{12}$ inch in diameter: he ascertained however that if the bore was very small the electrified fluid divided into several streams and acquired considerable velocity, presenting a brilliant appearance when the experiment was performed in the dark. He electrified, during several days, the mould in a garden pot, in which seeds had been sown, continuing the operation three or four hours each day; when it appeared to him that the plants grew faster and produced shoots earlier than the plants obtained from the like seed in a pot containing the same kind of mould, but which was not electrified. Nollet electrified in the like manner cats, pigeons, sparrows, &c.; and he imagined that the animals were lighter than those of the same kind which were not so treated: from thence he concluded that electricity increases the insensible perspiration of animals. Accounts of these experiments will be found in the Philosophical Transactions for 1748; but it ought to be observed that experiments relating to the effects of electricity on plants and animals have, since, been frequently repeated without verifying the conclusions of the French philosopher; and it may be added, that the attempts which have recently been made to promote the growth of vegetables by an apparatus for conveying to the ground the electric fluid in the atmosphere, have signally failed.

In 1734 the Abbé Nollet, accompanied by his friend M. Dufay, made a visit to England, when he was elected a Fellow of the Royal Society of London: he went from hence to Holland for the purpose of conversing with the philosophers of that country; and, on his return to Paris, he delivered a course of lectures on physics, which was well attended. In 1739 he was elected a member of the Académie des Sciences: and, during the same year, he went to Turin, where he repeated his electrical experiments in presence of the Duke of Savoy. In 1742 he went by invitation to Bordeaux, where he delivered a course of lectures; and he subsequently delivered a course at Versailles in presence of the dauphin of France, the son of Louis XV.

Nollet made many experiments to ascertain, at various depths under water, the intensity of sounds excited in the air; and he perceived that the striking of a clock and the blowing of a hunter's horn were heard distinctly, but very faintly, at two feet below the surface. He was not fortunate however in his hypothesis concerning the nature of the electric fluid: he imagined that this fluid has two motions, viz. an afflux to the electric body and an efflux from it, and he supposed that, in consequence of the former, all light bodies are attracted or carried towards the electric; while, in consequence of the latter, they are repelled from it. Hence he considered that all bodies have two different kinds of pores, one kind for receiving and the other for emitting the electric fluid. This hypothesis has never been admitted by philosophers.

In 1747 Signor Pivati, of Venice, published a pamphlet in which it was stated, that a man who had suffered from a pain in his side had by him been cured on being electrified with a machine in the glass cylinder of which was contained some balsam of Peru; and that two persons of great age had been cured of the gout by the like means: the benefit was supposed to have arisen from the effluvium of the balsam, which was stated to be so great that the bed and even the whole apartment of one of the patients who had received it was strongly perfumed with it. Professor Winkler of Leipzig also stated, about the same time, that he had performed similar experiments with equal success, by means of sulphur or cinnamon enclosed in the globe of the machine. These extraordinary reports induced the Abbé Nollet to make a journey to Italy for the purpose of obtaining information respecting the nature of the experiments; and the result of his inquiry was that, though in some cases the patients might find relief from electricity, its effects had been greatly exaggerated. All attempts in England to obtain results corresponding to those which were said to have been produced on the continent entirely failed; and the reports of the pretended cures soon ceased to obtain credit.

In 1756 the king of France founded a chair of experimental philosophy at the college of Navarre, and he appointed the Abbé Nollet to superintend it: the zeal and ability with which the latter fulfilled the duties of his post gave full satisfaction to the king, who conferred on him the title of Master of Philosophy and Natural History to the Royal Family. Nollet was subsequently appointed Professor of Experimental Philosophy to the School for Artillery, which then existed at La Fère, and which was afterwards removed to Mézières.

He died April 24, 1770, in the Louvre, where the king had assigned to him a suite of apartments: the amiability of his character was equal to his talents; and it is said that he devoted nearly all the profits of his labours to the support of his parents while they lived. Besides being a Fellow of the Royal Society of London and a Member of the Académie des Sciences at Paris, he was a Member of the Institut of Bologna and of the Académie of Erfurt.

The Abbé Nollet published at Paris, in 1743 and the succeeding years, a work entitled 'Leçons de Physique Experimentale,' in 6 vols. 12mo.; this is considered as the most methodical work on that subject which had till then appeared, and it was the first in which the discoveries of Newton respecting the phenomena of light were stated in a popular form. His second work is entitled, 'Recherches sur les Causes particulières des Phénomènes électriques,' in 12mo., 1749; and the third, 'Essai sur l'Electricité des Corps,' 12mo., 1750. He also published, in 1753, his 'Recueil de Lettres sur l'électricité,' in 3 vols. 12mo.: and a work by him entitled 'L'Art des Expériences,' was published in 1770, also in 3 vols. 12mo.; this work contains the elementary principles and the practice of the mechanical arts.

(*Biographie Universelle; Philosophical Transactions* for 1748.)

NONATE'LLIA, a genus of plants belonging to the natural order Rubiaceæ, the tribe Guettardeæ, the subtribe Morindeæ. It has a calyx with an ovate tube, and a 5-toothed permanent limb; a tubular funnel-shaped corolla, with the tube as if it were gibbous, and a 5-lobed limb; the stamens five, almost inclosed; the stigmas (2?) obtuse; the fruit a globose drupe, furrowed, containing 5 coriaceous 1-seeded pyrenæ; the albumen horny. The species are shrubs or small trees with glabrous downy oval-oblong leaves, and the stipules combined together more or less or free. The flowers are white and arranged in a panicle-formed or corymbose thyrse.

N. officinalis, Asthma Bush, has ovate, acute, glabrous leaves, the stipules combined into a 4-toothed sheath, the panicles corymbose; the involucrum small, 3-leaved under each flower. It is a native of Guiana, in forests and sterile places. All the parts of this plant, when bruised or dried, give out a slight aromatic odour. The creoles in Guiana call this plant *Azier à l'asthme*, and it is said to have a powerful influence in subduing attacks of asthma.

There are several other species of Nonatellia, all natives of America, but none are used in the arts or as medicines.

(Lindley, *Flora Medica;* Burnett, *Outlines of Botany.*)

NONIONI'NA, a genus of foraminifera. It occurs fossil in the coralline crag. (Morris's Catalogue.)

NORD, DEPARTEMENT DU. In our notice of this department of France, [NORD, P. C. vol. xvi. p. 253, &c.] references were given to articles CASSEL and GRAVELINES, from which in their places, references had been given to the article NORD. We here supply a brief notice of those two towns.

Cassel is situated on an isolated eminence, the summit of which, Mont Cassel, close to the town, rises to the elevation of from 300 to 350 feet, in the midst of a level country; and commands a prospect of great extent, comprehending more than thirty towns, and extending to the ocean. Two streams, (one of them the little river Peene,) which flow into the Yser, rise near the town and furnish the inhabitants with a constant supply of water. The town, which was antiently fortified, is neat and clean, with a large '*place*,' irregularly laid out. The population of the commune by the census of 1831 was 4234; by that of 1836, 4495; about three-fifths in the town, the rest in the neighbourhood. Some lace, stockings, hats, and coarse earthenware are manufactured; there are oil-mills, and a considerable trade in cattle is carried on. Cassel has one yearly fair of seven days. The town has some historical interest. It is thought to have been one of the strongholds of the Morini, and was known in the Roman period by the name of Castellum Morinorum, whence the modern name Cassel. In the middle ages it was the scene of two severe conflicts. In A.D. 1071, Philippe I., King of France, was defeated by Robert Le Frison, who had usurped the county of Flanders from his nephew Arnulphe, whom Philippe supported, and who was killed in the battle. In A.D. 1328, Philippe VI. de Valois, King of France, defeated, with dreadful slaughter, the Flemish insurgents who had surprised him in his camp. In later times A.D. 1677, William, Prince of Orange, afterwards William III. of England, was defeated here by the French under the Duke of Orléans. Cassel is in the arrondissement of Hazebrouck, 148 miles from Paris by Amiens, Doulens, Lillers, Aire, and Hazebrouck.

Gravelines is near the coast between Calais and Dunkerque, in the arrondissement of Dunkerque, on the river Aa, twelve miles N.E. of Calais, and 170 N. of Paris by Beauvais, Abbeville, Boulogne, and Calais. It is a small town, but strongly fortified with a good citadel; but has very little trade. The Aa is navigable up to the town for small vessels, and some fishing is carried on, and small vessels are built. The town is laid out with tolerable regularity with wide streets. There are a church, a nunnery, a military hospital and barracks. The population of the commune was by the enumeration of 1831, 4193; by that of 1836, 4642. It is the chief place of the canton of Gravelines. The town has some historical interest from the defeat of the French in A.D. 1558 under the Maréchal De Termes, by the Spaniards under Count Egmont, assisted by some English ships that were off the coast.

NORFOLK ISLAND PINE. [ARAUCARIA, P. C.]

NORMANDY, CUSTOMARY LAW OF. Previous to the first Revolution the several provinces into which France was divided [FRANCE, P. C.] were chiefly governed by a system of laws which, originally arising from the local usages and customs of the people, became in after time embodied in a code which, after it had received various modifications, obtained the sanction of the sovereign, and became the written and established law of the province. These codes were styled customs, 'coutumes,' and have been largely and learnedly commented upon by the various jurists of the period; their commentaries were often received as law; thus we have the customs of Burgundy, Brittany, &c., commented upon by Bouhier, D'Argentré, &c. The customary of Normandy, if not the most ancient, ranks certainly among the most ancient of the French provincial customaries. According to it laws, customs, and usages, were regulations of a very different order and authority: the laws were enacted by the sovereign power, reduced to writing, and registered by the exchequer, afterwards denominated the parliament of Rouen; its customs originated with the people, and in time were compiled and reduced to writing by the supreme authority. Hence the difference between 'loi,' 'us,' and 'coutume,' as understood in the ancient provinces of France. By 'loi' or law was understood the royal ordinances and Roman law; by 'coutumes' or customs those regulations which had been reduced to writing and received the sanction of the sovereign; by 'us' or usage, such regulations as had not been reduced to writing. Normandy, as an independent state, and after its annexation to the crown of France under Philip Augustus [NORMANDY, P. C.], may be said to have had three distinct codes; 'le grand coutumier' or ancient customary, 'la charte aux Normands,' or Norman charter, and the modern custom. The ancient and modern custom related more particularly to property, &c.; 'la charte aux Normands' to the political liberty of the subject. The Norman charter was granted by Louis X., and its principal object was to restrain the kings of France from imposing too heavy burdens on their Norman subjects: this charter was confirmed six times from its promulgation to the reformation of the customary by Henry III., which fact affords a fair presumption that it had been often violated. The customs of Normandy were first reduced into writing by a private hand in the reign of Louis IX., about the year 1229, which corresponds with 14 Henry III. of England. Being subjected to examination under Charles IX., many of its reforms were sanctioned by the high authority of the Chancelier L'Hôpital, and the modern reform dates from 1585 under Henry III. This custom was known thoughout France by the appellation of 'la sage coutume.' The number of provincial customs of France before the Revolution were reckoned at eighty, and its local usages at nearly three hundred. In Normandy there were no less than twenty-two different modes of devising patrimonial estates, which corresponded to the number of vicomtés or districts of which the province was composed.

The oath of a Norman duke so late as the thirteenth century differed very little from that of a king of France: he swore to protect the church and the property of the different orders of the community by the impartial administration of justice, and more particularly to govern according to the Norman charter.

'L'Ancien Coutumier' is divided into 125 chapters, nearly two-thirds of which are devoted to regulate the duties of the judicial officers, the proceedings in the different courts, and the respective rights and obligations of the kings of France, the dukes of Normandy, the feudal lords and people. The power of the kings of France was very inferior to that of the dukes of Normandy, and even to that of the counts and great territorial barons, who in those days monopolised the land, and with it all local influence. The transmission of property by wills and inheritance, which occupy so large a portion of modern law and of the reformed Norman law in the sixteenth cratury form a very small portion of the 'Ancien Coutumier.'

The modern or reformed 'Coutumier de Normandie' is divided into 24 chapters, which are subdivided into 622 articles. The modern 'Coutume' was reformed at Rouen on 1st July, 1585, by commissioners appointed by Henry III. of France with the concurrence of the provincial authorities known as 'les gens des trois états,' or three orders representing the nobility, clergy, and people.

Among the peculiar customs of Normandy was 'la clameur de Haro,' which custom still prevails in the Channel Islands, where the Norman ancient customary is the principal law. [ALDERNEY, P.C.; GUERNSEY, P. C. and P. C. S.; JERSEY, P. C.] The 'Clameur de Haro' may be denominated a call upon the supreme authority for justice, 'appellatio ad principem ad opem in lite ferendam.' The term is considered to be derived from Duke Rollo, or as the name is variously spelt, Raoul, Roul, and Rou, to whom Normandy was ceded by Charles the Simple of France, in 912. (Du Moulin's Hist. de Normandie, lib. i. c. 9, and lib. vii. cap. 20.) So that 'Haro' is a corruption of the cry Hal, or Ha Rou, by which this prince, who was remarkable for his justice, is said to have been invoked. It is thus practised in the Channel Islands: when an individual considers that another is making a trespass, or is infringing upon his right of property, in the presence of two witnesses he protests against the proceedings, and, crying out three times 'Haro,' in the queen's name summons the trespasser to desist. He then applies to the judicial authorities, declaring what he has done, and proceeds to the register, or record office, where note is taken of the particular circumstances of the case; he afterwards brings an action against the trespasser. If he neglects to do so, then the person against whom the 'Haro' was cried may bring his action against him who cried it, and oblige him, if he cannot justify his proceedings, to desist and submit to the judgment of the court. Upon the action of either of the parties the decision is generally referred to what is termed 'une vue de justice,' or an examination by the court of all the circumstances on the spot itself. Whichsoever of the parties is condemned, he is subjected to a small fine to the queen and pays all costs; in addition to which he was formerly punished by what was termed 'un regard de château,' that is, twenty-four hours' imprisonment; the imploring the aid of the prince without cause and the invasion of another's possession being accounted equally criminal. In ancient Normandy parties resorted to the 'Clameur de Haro' in cases of assault and battery, but that part of the custom has never prevailed in the Channel Islands.

The president or chief judicial officer in Guernsey is still styled bailiff,* the name by which he is designated in the ancient 'Coutumier de Normandie.' In Jersey he is styled bailly, by which name he is designated in the modern customary of the same island. In Alderney this officer is styled juge. In each island they are appointed by the crown to administer justice; and their authority continues to this day much the same as laid down in the ancient 'Coutumier,' wherein it is stated that the bailiff is intrusted by the prince or duke with power to administer justice to the people who owe him allegiance. It is his duty to maintain order, to decide according to law and usage all disputes arising between parties residing within his jurisdiction; and to put down all thieves, incendiaries, and other malefactors.

It was remarked at the commencement of this article that the different provincial customaries had been frequently commented upon. The first commentary on the Grand Coutumier of Normandy was written by Rouillé, a jurist of Alençon (Guillaume de Rouillé, *Commentaire sur la Coutume de Normandie*, fol., 1534, reprinted in 1539). It was followed by that of Terrien of Dieppe, which was published in 1574, after his death (Guillaume Terrien, *Commentaire sur les Coutumes anciennes de Normandie*, fol.). The former is more generally received as an authority in Jersey, and the latter in Guernsey. These commentaries, though they have not given to their authors the reputation of a Bouhier, the president of the parliament of Burgundy, or a D'Argentré of Brittany, were held in high authority by the parliament of Rouen. After the revision of the customary in 1585, several modern commentaries appeared, such as those of Bérault, Basnage, Godefroy, Flaust, Pesnelle, and Houard.

This last-named commentator has, at the end of the fourth volume of a work entitled 'Dictionnaire Analytique, &c., de la Coutume de Normandie,' Rouen, 1782, published, we believe, for the first time, from a manuscript lent him by the Marquis de Paulmy, a poetical version of the customary of Normandy. Several manuscripts of this poem then existed; in one of them there was the following prologue, which, if authentic, determines its date and the name of its author:—

'Mil deux cents quatre fois vingt (1280)
Après ce que Jésus Christ vint
En terre pour humain lignage
Pour rendre nous son héritage,
Et nous donner le Paradis
Qu' Adam nous tollit jadis,
Quand de mauvais venin fut yvre;
Mit Richard Dourbault ce livre
En rimes en mieux qu'il put
Pour commun et propre salut.'

There appear however at the end of the MS. of the Marquis de Paulmy, which did not contain the above prologue, the following lines:—

'Qui mon nom veult apperesvoir
Par aiguille et pour me voir,
Le saura, et le sournom sache
Cil y met C, A, U, P, H.'

This interesting relic of ancient poetry is of considerable length, and is divided into 147 chapters; the language and details afford internal evidence of its having been composed in the thirteenth century.

The following definition of 'coutumes' may be taken as a specimen of the style and correctness.

'Coustumes ce sont vieux usages
Approuvés par les Princes sages,
Du peuple gardé qui font rendre
A chacun ce qu'à soy doibt prendre;
Eulx apprennent possessions,
Des droits font introductions,
Et se mutacions respolvent,
Les droits aussi muer se doivent;
Si varient ou renouvellent
Les droits si lient et appellent,
Et des coustumes, sont les unes
Especiaulx, aultres communes.'
CHAP. XV.

The following are the best editions of writers on the subject of the Customary of Normandy:—'Décisions sur chaque article de la Coutume de Normandie, et observations sur les usages locaux de la même Coutume par Pierre de Merville,' Paris, 1731, fol.; Bérault, Josias, an advocate of the parliament of Rouen, born 1563, died 1640, 'Commentaire sur la Coutume de Normandie,' Rouen, 1684, in fol.; Basnage, Henri, born 1615, died 1695, 'Commentaire sur la Coutume de Normandie,' Rouen, 1678-1681; Godefroy, Jacques, 'Coutume du Pays et Duché de Normandie avec les Commentaire de Bérault, Godefroy et d'Aviron,' Rouen, 1684, 2 vols. fol.; Flaust, Jean Baptiste, born 1711, died 1783, 'Explication de la Jurisprudence et de la Coutume de Normandie,' 2 vols. fol.; Pesnelle, 'Coutume de Normandie avec la observations de Roupnel,' Rouen, 1759, in 4to.; Houard, David, born 1725, died 1803, 'Traité sur les Coutumes Anglo-Normandes,' Rouen, 1776, 4 vols. 4to.

Hale, in his 'History of the Common Law of England' (chap. vi.), maintains that the 'Coutumier of Normandy' was written long after Glanville's tract, which was written in Henry the Second's time; and that the Norman collection was made after the time of Henry II. appears from its mentioning his coronation, and appointing it for the limitation of actions ancestral, which must at least have been thirty years after. 'Nay, the "Coutumier" appears to have been made after the act of settlement of Normandy in the crown of France, for therein is specified the institution of Philip king of France, for appointing the coronation of king Richard I. for the limitation of actions, which was after the said Philip's full possession of Normandy.' Hale's opinion is, that 'this similitude of the laws of England and Normandy was not by conformation of the laws of England to those of Normandy, but by conformation of the laws of Normandy to England.'

NORONHA, FERNANDO DE, is a small group of islands, belonging to Brazil, and situated in the Atlantic Ocean. The fort Concepçaõ on the principal island is situated 3° 50′ N. lat. and 32° 25′ W. long. The group consists of two islands of moderate size, Fernando de Noronha and Dos Ratos, and a few rocks. Fernando de Noronha is about ten miles long and about three across, in the widest part. The surface is mountainous, and there is a peak, which resembles a steeple or tower, which is two or three thousand feet high. The soil is stony, and there are only a few small spots susceptible of cultivation. As there is no harbour, and the surf runs high on its shores, landing is difficult and sometimes dangerous. It has good water, which however is difficult to be got on board the vessels, which visit this island for a supply, on account of the surf. To the north, and separated from it by

* i. e. Guardian.

a narrow channel, is the Island dos Ratos (of the rats), which is three miles long, less stony and more wooded. These islands are used by the Brazil government as a place of deportation, to which exiles and criminals are sent. Their numbers amounts to about eight hundred, and the garrison consists of two hundred black soldiers. They cultivate a small quantity of mandioc, a few fruits, and a little corn, and keep some cattle, sheep, and goats. Rats and wild cats, the descendants of those which have fled from the houses, are numerous. No boats are kept on the island, and no intercourse is held with shipping, without permission and the strictest inspection.

(Henderson's *History of the Brazil*; *Narrative of the Surveying Voyages of the Adventure and Beagle*.)

NORTH, SIR THOMAS, Knight. We regret that we have been unable to obtain any materials for a biographical notice of Sir Thomas North, the first translator of the Lives of Plutarch into English. North had previously published two other works:—1, 'The Diall of Princes; compiled by the Reverend Father in God, Don Anthony of Guevara, and Englyshed out of the Frenche; right necessary and pleasaunt to all gentlemen and others which are lovers of vertue,' London, 1557, folio; 1568, folio; 1582, 4to.; 'Reformed of faultes in the first edition, with an amplification also of a fourth book annexed to the same, entitled the Favoured Courtier; never heretofore in our vulgar tongue; right necessary and pleasaunt to all noble and vertuous persons.' 2, 'The Morall Philosophie of Doni, drawne out of the auncient writers; a work first compiled in the Indian Tongue, and afterwards reduced into divers other Languages; and now lastly Englyshed out of tho Italian,' London, 1570, 4to. Watt observes that 'the word Doni seems to be of like import with that of Magi,' a strange blunder of the learned bibliographer. Doni is the name of an old Italian writer, and the original work is called 'La Filosofia Morale del Doni, tratta dagli antichi Scrittori, ovvero, La Filosofia de' Sapienti Antichi, scritta da Sendebar, moralissimo Filosofo Indiano,' Venice, 1552, 4to.

North's translation of Plutarch was made, as he states in the title, from the French version of Amyot, which is generally very exact, and has considerable merit in point of expression. Indeed it is said that Amyot's translations did much towards fixing the French language. Amyot's dedication to Henry II. of France is dated 1559. North's dedication to Queen Elizabeth is dated January 6th, 1579; his address to the Reader is dated January 24th, 1579. North's version is often inaccurate, where that of Amyot's is correct, which is somewhat strange, for he tells us that he translated Amyot. The book, besides tho Lives of Plutarch, contains 'The Lives of Epaminondas, of Philip of Macedon, of Dionysius the Elder, and of Octavius Cæsar Augustus, collected out of good Authors; also the Lives of Nine excellent Chieftaines of Warre, taken out of Latine from Emylius Probus, by S. G. S., by whom also are added the Lives of Plutarch and of Seneca; gathered together, disposed, and enriched as the others. And now translated into English by Sir Thomas North, Knight.' This part of his book is also dedicated by North to Queen Elizabeth, to whom he seems to have been indebted for some kind of pension or means of subsistence, for he says, 'The princely bounty of your blessed hand (most gracious Soveraigne), comforting and supporting my poore old decaying life, of right challengeth the travel of my study, the labor of my body, and the prayers of my devotions, to be wholly imployed for your Highnesse, and altogether dedicated to your service.'

(Watt's *Bibliotheca Britannica*; *Biographie Universelle*, article 'Doni.')

NORTH, FRANCIS, BARON GUILDFORD, lord keeper of the great seal of England, the immediate elder brother of the following, was born, as Lord Campbell has discovered from the inscription on his tomb-stone, on the 22nd of October, 1637. He acquired the rudiments of education at a school at Isleworth, where he appears to have been taught some rigid Presbyterian principles, which left very little trace on his mind in subsequent life. In 1653 he was admitted fellow commoner of St. John's College, Cambridge. He afterwards became a member of the Middle Temple. He passed his time gravely and studiously, and appears early to have resolved not to leave any plan untried, whether by intellectual exertion or less commendable means, to obtain wealth, power, and distinction. His relaxation consisted of music meetings, hearing Hugh Peters preach, and occasional convivial suppers with fellow-students—very small items of dissipation, the nature of the times and the habits of the young lawyers of the Restoration considered. He was well connected, and received some aid and auspices from his relatives in his early struggles. His practice however was for some time insufficient to satisfy his expectations, and he was sunk in despondency when he was taken in hand by Sir Jeffrey Palmer, the attorney-general, who saw in the character of the young barrister something for which the crown lawyers of such times might find use. Sir Jeffrey's son dying about this time, much of the business destined for him fell to the lot of his father's favourite, young Francis North. He went on the Norfolk circuit, which brought him into the neighbourhood of his family interest; but he was careful to let no influence that seemed likely to aid him slip from his hands. 'He was exceeding careful,' says his brother, 'to keep fair with the cocks of the circuit, and particularly with Serjeant Earl, who had almost a monopoly. The serjeant was a very covetous man, and when none would starve with him in journeys, this young gentleman kept him company.' The memoir of the lord keeper by his brother, Roger North, is one of the most ample developments of private life and habits during the seventeenth century which our literature possesses. We are let into all the hopes and fears of the young aspirant—his paltry and dishonest tricks, his intense selfishness, his moral cowardice, his trimming politics, and his readiness to do any work that persons well intrenched in power might set before him. The book is all the more curious because its author treats these qualities as prudential virtues, and exhibits them as that patient perseverance in well doing which finally brought him who practised them to solid honour and wealth. Standing between a Shaftesbury and a Jeffreys, North's character had some features which may well have appeared commendable, and perhaps the honest indignation which his character has elicited from Lord Campbell seems rather disproportionate when the nature of the times is considered. The brother is particularly instructive in describing his attempts to obtain a rich wife, bestowing hearty commendation on the skill and intrepidity with which he foiled every effort to ally him to anything under the desired standard of wealth. Other qualifications appear not to have given him much concern. One of his negotiations is thus told:—'There came to him a recommendation of a lady, who was an only daughter of an old usurer of Gray's Inn, supposed to be a good fortune in present, for her father was rich; but, after his death, to be worth nobody could tell what. His lordship got a sight of the lady, and did not dislike her: thereupon he made the old man a visit, and a proposal of himself to marry his daughter. There appeared no symptoms of discouragement; but only the old gentleman asked him what estate his father intended to settle upon him for present maintenance, jointure, and provision for children. This was an inauspicious question, for it was plain that the family had not estate enough for a lordship, and none would be to spare for him. Therefore he said to his worship only "that when he would be pleased to declare what portion he intended to give his daughter, he would write to his father, and make him acquainted with his answer." And so they parted, and his lordship was glad of his escape, and resolved to give that affair a final discharge, and never to come near the terrible old fellow any more. His lordship had at that time a stout heart, and could not digest the being so slighted, as if, in his present state, a profitable profession and future hopes were of no account. If he had had a real estate to settle, he should not have stooped so low as to match with his daughter; and thenceforward despised his alliance.' He brought himself into notice at court by pleading against the privileges of parliament in the Writ of Error brought into the House of Lords upon the judgment of the King's Bench in the old case of the prosecution of the five members for holding the Speaker in the chair. On this occasion he was rewarded with a silk gown. On the 20th of May, 1671, he was made solicitor-general; and on the promotion of Sir Heneage Finch to the woolsack, he succeeded him as attorney-general on the 12th of November, 1673. On the 25th of January, 1675, he was made lord chief justice of the Common Pleas. This was at the period of the curious disputes for jurisdiction conducted between the Common Pleas and the King's Bench, founded on no higher motive than the fees paid by the suitors. The King's Bench had engrossed so much business by the fictitious use of the writ of 'latitat,' that 'the proper court sat idle, and had scarce enough to countenance their coming to Westminster Hall every day in the term.' North retaliated by a dexterous use of the 'capias,' and wo are told that 'after this process came into common use, it is scarce to be conceived how the court revived and flourished, being, instead of vacation in term, rather term in vacation; so large was the increase of trials by *nisi prius* out of the court, as also of motions and pleas in the court.' These struggles are well known to have had great influence in the practical extension of the jurisdiction of the three courts of Westminster Hall to all ordinary questions of civil right.

On the death of Lord Nottingham, the great seal was confided to North's keeping on the 20th of December, 1682. On this occasion, and in the presence of the king and some of the most accomplished courtiers of the age, he was not so much dazzled as to lose sight of his own ultimate interest. Knowing that, from the difficulty felt by the king in obtaining parliamentary supplies, it was intended that the new lord keeper should have no salary beyond the fees of his office, and conscious that he was the only person who had at that juncture a substantial claim on the appointment, he refused to touch the seals until, 'for his majesty's honour,' they were accompanied by a pension of 2000*l.* a year. As a judge, he was almost invariably in favour of the prerogative, and seldom if ever endangered his influence at court by his independence. A bolder and a still less scrupulous instrument of power was however gradually undermining him in his latter days in the person of Jeffreys, whose ascendancy and presumption seem to have completely broken the spirit of the lord keeper. His brother gives him credit for having attempted to mitigate the cruelties of 'Jeffreys's campaign;' but Lord Campbell, in a comparison of dates, finds that the lord keeper's death occurred at too early a period in the history of the massacre to admit of his having offered any effectual intervention. He died on the 5th of September, 1685. He was, in private life, a moral man even for an ordinary age, and a miracle in the reign of Charles II. On his professional merits, Lord Campbell emphatically says, 'He had as much law as he could contain, but he was incapable of taking an enlarged and commanding view of any subject.'

(North's *Lives of the Norths*; Campbell, *Lives of the Chancellors*, iii. 431-496.)

NORTH, SIR DUDLEY, the third son of Dudley, Lord North, Baron of Kelting, was born on 16th May 1641. In childhood he was lively and active, and having strayed from his custodiers, he was stolen away by a gipsey or beggar, and with difficulty recovered. He made little progress in literary education, and his brother and biographer tells us that he 'had a strange bent to traffic, and while he was at school, drove a subtle trade among the boys by buying and selling. In short, it was considered that he had learning enough for a merchant, but not phlegm enough for any sedentary profession, which judgment of him was made good by the event.' Being 'bound to a Turkey merchant upon the ordinary terms to be sent abroad,' he was sent as supercargo to Archangel and Smyrna. He left an animated and curious journal of his voyage to Archangel, and his subsequent progress by Italy to Smyrna, published by his biographer. It is not the production of a scholar, but it is full of amusing descriptions and sagacious remarks. After a residence for some time in Smyrna, where he suffered from disease, he removed to a factory at Constantinople. He acquired a knowledge of Turkish, of which he said "that for scolding and railing it was more apt than any other language." He left some curious information about Turkish manners, particularly as to the administration of justice, with which he had some practical experience. His experience and observations are generally printed in his memoir as he wrote them; but on some occasions, when his brother professes to render them in his own language, the biographer being a practising English barrister, makes a singular jumble of the Turkish administration by putting his allusions to it into the technical phraseology of the English law.

Very few dates are given in his biography, but it is stated that Dudley on his way home having touched at Smyrna, left that place on 25th March 1680. He wrote, as to his journey homeward, a 'Voyage from Smyrna, with an Account of Turkey, containing matters little known in Europe,' left unfinished. He spent his latter years in London. Soon after his return he was chosen sheriff, and knighted, and was afterwards elected alderman of Basinghall. By the interest of his brother, the lord keeper, probably as much as by his own merits, he was made a Commissioner of the Customs. Towards the end of the reign of Charles II. he was made a Commissioner of the Treasury, but on the accession of James II. he was sent back to his office in the Customs. He made himself somewhat unpopular in his office by suggesting a tax on sugar and tobacco. In the mean time he had been chosen member of Parliament for Banbury, and took considerable interest in politics, with, apparently, a far more independent spirit than his brother, the lord keeper. His biographer claims for him the merit of having offered resistance to the crown under the operation of 'closeting.' He lost his office at the Revolution, and was subjected to a pretty rigorous examination by both Houses of Parliament. He died on 31st December, 1691. (North's *Lives of the Norths.*)

NORTH, ROGER, the sixth son of Dudley, Lord North, was born about the year 1650. He studied in the Middle Temple, and became steward of the courts to Archbishop Sheldon. It is stated in Rees's Cyclopædia that he was Attorney-General to James II., but his name does not appear in the list of Attorney-Generals in Beatson's Political Index. He died in 1733. He left, in manuscript, some 'Memoirs of Music,' which met with approbation from Dr. Burney. In 1740, a quarto volume was published called 'Examen, or an Enquiry into the Credit and Veracity of a pretended complete History, showing the perverse and wicked design of it, and the many Falsities and Abuses of Truth contained in it, together with some Memoirs occasionally inserted, all tending to vindicate the Honour of the late King, Charles II., and his happy Reign, from the intended Aspersions of that foul Pen.' The work against which this volume is levelled is Kennet's 'Complete History.' Notwithstanding its purely partisan object, much insight may be had into the state of society and politics during the reign of Charles II., by a perusal of the Examen, and when measured by a higher tone of public feeling, the author, in his vindications, often, in pure simplicity, embodies the severest censures. In professing to point out the course he intended to pursue, he indicated that which he avoided. 'Is it fit,' he says, 'that, upon pretence of candour and impartiality, good and evil should stand upon equal pretence or level of choice? Therefore, when bad dealings occur, whereof the facts are apparently evil, let them be branded with infamy, and the contrary adorned with terms of fitting approbation. And this seems to be so far from a fault, that it is incident to the work of a good writer, and whoever, on pretence of impartiality, in that distinction is mealy-mouthed, may be accounted not only a sneaking neutral in the cause of good and evil, but a positive traitor to goodness itself. And herein let the fruit declare the tree, and the works the author. Upon these reasons the writer here is fortified, and declares himself no trimmer between right and wrong, virtue and vice, fidelity and treachery, or in any moral difference of good and evil; but will be positively and plainly declared, let it concern whom it will.' But a clause which immediately follows this bold declaration very distinctly accounts for the utter abandonment of this rule in practice. He is to follow it out, 'saving only the not speaking evil of dignities, that is, of men in regal exaltation and magistracy.'

The work by which Roger North is now best known was published after his death—1740, 1742—in two volumes quarto, with the title, 'The Lives of the Right Hon. Francis North, Baron Guilford, Lord Keeper of the Great Seal under King Charles II. and King James II.; the Hon. Sir Dudley North, Commissioner of the Customs, and afterwards of the Treasury, to King Charles II.; and the Hon. and Rev. Dr. John North, Master of Trinity College, Cambridge, and Clerk of the Closet to King Charles II.' The Life of the lord-keeper was republished in 8vo., and the whole work was re-edited in 1826. It will be seen, that besides the two of whom notices are given above, he commemorated a third brother, John, who lived the life of a retired student. The nature of the book has been already characterised, and it only remains to be stated that whatever opinions may be formed of the author's general notions of right and wrong, it is a memorial of very strong fraternal affection.

(*Article* by Burney, in Rees's *Cyclopædia*; Collins's *Peerage*; *Works referred to.*)

NORTHUMBERLAND INLET, is a large bay on the eastern coast of North America, running nearly parallel to Davis' Strait and entering the continent to a distance of more than 150 miles from the open sea. Its entrance lies between 64° and 65° N. lat. and is more than 60 miles wide. Hence it extends in a north-north-western direction with a width varying between 40 and 50 miles to the north of 66° N. lat., where it begins to grow narrower, and it terminates in an inlet not more than three or four miles wide, which extends from 66° 30′ to 67° N. lat. Though by its geographical situation this bay appears to be placed without the general course of the icy masses, which during the summer are met with along the coast of this part of America, the prevailing southerly and south-easterly winds, and the tides, which rise to twenty-five feet and more, bring during that season large masses of floating ice into the bay, which circumstance renders its navigation rather difficult. The country along the shores of the inlet is very rocky, and in the vicinity of the ocean mountainous. Near the western shores is Mount Hecla, whose summit rises to 2000 feet above the sea-level, according to an estimate. Farther inland the country appears to be less elevated. The shores of the bay, especially on the western side, are beset with numerous rocky islands and cliffs. It does not appear that this inlet is much visited by whales, nor are other fish abundant. But as it is pretty well peopled by Esquimaux, wild animals probably are numerous. The Esquimaux have also several stations, at which great numbers of salmon are caught. This inlet was first explored or discovered in 1841 by Captain Wareham.

(*London Geographical Journal*, vol. xii.)

NOSO'LOGY, (from νόσος and λόγος), is the term applied to the classification and arrangement of diseases. It was early found in the observation of the symptoms of disease, that many of them recurred again and again, and this led to the assigning to such groups of symptoms particular names. Thus we find that the term fever was early applied to designate a certain set of symptoms, and, as any of these symptoms preponderated, the fever obtained a specific name, as putrid fever, petechial fever, &c. But not only were symptoms had recourse to for the purpose of distinguishing peculiar forms of fever, but the causes and the locality were frequently employed; thus marsh, jail, hospital, and other fevers have been described. In this way the materials were early accumulated for the formation of a system of nosology. It was not, however, till comparatively modern times, that anything like a scientific system of arrangement was proposed. One of the earliest of these was that of Sauvages, who, taking the most prominent symptoms of diseases as his guide, divided them into ten great classes which he named Vitia, Febres, Phlegmasiæ, Spasmi, Anhelationes, Debilitates, Dolores, Vesaniæ, Fluxus, and Cachexiæ. Under these classes were arranged various orders: thus, under the first class Vitia, he arranged the orders, Maculæ, Efflorescentiæ, Phymata, Excrescentiæ, Cystides, Ectopiæ, Plagæ. The order Maculæ was divided into the diseases Leucoma, Vitiligo, Ephelis, Gutta rosea, Nævus, and Ecchymoma. This classification of diseases was followed by those of Linnæus, Vogel, Sager, and Macbride, but in their arrangements they all recognised the same principle of classification as Sauvages, and made their division of diseases to depend on the greater or less prominence of particular symptoms. All these systems, were, however, supplanted by that of Cullen, which he promulgated in the second edition of his 'Synopsis Nosologicæ Methodicæ.' The following plan will give an idea of its structure:—

CLASS I.—PYREXIÆ.

ORDER I.

FEBRES.

§ 1. *Intermittentes.*

1 Tertiana
2 Quartana
3 Quotidiana

§ 2. *Continuæ.*

4 Synocha
5 Typhus
6 Synochus

ORDER II.

PHLEGMASIÆ.

7 Phlogosis
8 Ophthalmia
9 Phrenitis
10 Cynanche
11 Pneumonia
12 Carditis
13 Peritonitis
14 Gastritis
15 Enteritis
16 Hepatitis
17 Splenitis
18 Nephritis
19 Cystitis
20 Hysteritis
21 Rheumatismus
22 Odontalgia
23 Podagra
24 Arthropousis

ORDER III.

EXANTHEMATA.

25 Variola
26 Varicella
27 Rubeola
28 Scarlatina
29 Pestis
30 Erysipelas
31 Miliaria
32 Urticaria
33 Pemphigus
34 Aphtha

ORDER IV.

HÆMORRHAGIÆ.

35 Epistaxis
36 Hæmoptysis
37 Hæmorrhois
38 Menorrhagia

ORDER V.

PROFLUVIA.

39 Catarrhus
40 Dysenteria

CLASS II.—NEUROSES.

ORDER I.

COMATA.

41 Apoplexia
42 Paralysis

ORDER II.

ADYNAMIÆ.

43 Syncope
44 Dyspepsia
45 Hypochondriasis
46 Chlorosis

ORDER III.

SPASMI.

47 Tetanus
48 Convulsio
49 Chorea
50 Raphania
51 Epilepsia
52 Palpitatio
53 Asthma
54 Dyspnœa
55 Pertussis
56 Pyrosis
57 Colica
58 Cholera
59 Diarrhœa
60 Diabetes
61 Hysteria
62 Hydrophobia

ORDER IV.

VESANIÆ.

63 Amentia
64 Melancholia
65 Mania
66 Oneirodynia

CLASS III.—CACHEXIÆ.

ORDER I.

MARCORES.

67 Tabes
68 Atrophia

ORDER II.

INTUMESCENTIÆ.

§ 1. *Adiposæ.*

69 Polysarcia

§ 2. *Flatuosæ.*

70 Pneumatosis
71 Tympanites
72 Physometra.

§ 3. *Aquosæ.*

73 Anasarca
74 Hydrocephalus
75 Hydrorachitis
76 Hydrothorax
77 Ascites
78 Hydrometra
79 Hydrocele

§ 4. *Solidæ.*

80 Physconia
81 Rachitis

ORDER III

IMPETIGINES

82 Scrofula
83 Syphilis
84 Scorbutus
85 Elephantiasis
86 Lepra
87 Frambœsia
88 Trichoma
89 Icterus.

CLASS IV.—LOCALES.

ORDER I.

DYSÆSTHESIÆ.

90 Caligo
91 Amaurosis
92 Dysopia
93 Pseudoblepsis
94 Dysecoea
95 Paracusis
96 Anosmia
97 Agheustia
98 Anæsthesia

ORDER II.

DYSOREXIÆ.

§ 1. *Appetitus erronei.*

99 Bulimia
100 Polydipsia
101 Pica
102 Satyriasis
103 Nymphomania
104 Nostalgia

§ 2. *Appetitus deficientes.*

105 Anorexia
106 Adipsia
107 Anaphrodisia

ORDER III.

DYSCINESIÆ.

108 Aphonia
109 Mutitas
110 Paraphonia
111 Psellismus
112 Strabismus
113 Dysphagia
114 Contractura

ORDER IV.

APOCENOSES.

115 Profusio
116 Ephidrosis
117 Epiphora
118 Ptyalismus
119 Enuresis
120 Gonorrhœa

ORDER V.

121 Obstipatio
122 Ischuria
123 Dysuria
124 Dyspermatismus
125 Amenorrhœa

ORDER VI.

TUMORES.

126 Aneurisma
127 Varix
128 Ecchymoma
129 Scirrhus
130 Cancer
131 Bubo
132 Sarcoma
133 Verruca
134 Clavus
135 Lupia
136 Ganglion
137 Hydatis
138 Hydarthrus
139 Exostosis

ORDER VII.

ECTOPIÆ.

140 Hernia
141 Prolapsus
142 Luxatio

ORDER VIII.

DIALYSES.

143 Vulnus
144 Ulcus
145 Herpes
146 Tinea
147 Psora
148 Fractura
149 Caries

It was the simplicity of this system which recommended it to general adoption, and which has caused it to exercise so great an influence over other systems of pathology. At the same time it will be seen that this and the previous systems are purely artificial, and frequently bring together diseases of a very dissimilar character. Such systems have also led to the impression that diseases have a character as definite as the objects of natural history, and that a species in the one car. be as easily defined as the species of another. But it becomes evident, after a little inquiry, that, with the exception of those diseases that depend on a specific contagion, no part of the idea of a species as applied to plants or animals can be made use of to designate particular diseases.

With tho progress of a sound knowledge of physiology and pathology, many attempts have been made to give a more natural arrangement of diseases than that of Cullen. Dr. Mason Good divided diseases into the following six classes:—

Class I.—*Cœliaca.* Diseases of the digestive functions. Class II.—*Pneumatica.* Diseases of the respiratory function. Class III.—*Hæmatica.* Diseases of the sanguineous function. Class IV.—*Neurotica.* Diseases of the nervous function. Class V.—*Genetica* Diseases of the sexual function. Class VI.—*Eccritica.* Diseases of the excernent function.

This system, however successful it may be regarded in its primary divisions, was too technical in its details to be very generally employed. One of the most simple of natural classifications founded on pathological distinctions is that of Pinel, who divides diseases into fevers, inflammations, hæmorrhages, nemoses, and organic affections. The great objection to a physiological system is the imperfection of our knowledge of the functions of many parts of the human body, whilst the symptoms of diseases, being very evident, lead to the assumption of causes of disease and pathological states which probably do not exist.

(Cullen, *Systema Nosologiæ Methodicæ;* Williams, *Principles of Medicine;* Mason Good, *Study of Medicine.*)

NOSTOC. [Zoocarpes, P. C.]

NOTHOSO'MUS, a genus of fossil fishes, from the lias of Dorsetshire. (Agassiz.)

NOTI'DANUS, a genus of fossil fishes from the chalk of Kent. (Agassiz.)

NOY, WILLIAM, a lawyer, whose professional career had a considerable influence on British History, was born about the year 1577. 'He was,' says Fuller, 'for many years, the stoutest champion of the subjects' liberty, until King Charles entertained him to be his attorney.' He was made Attorney-General on 31st October, 1631. He had for some years been member of Parliament, first for Helston, and subsequently for St. Ives. He was a profound lawyer and juridical antiquary; but, as Clarendon says, 'he could not give a clearer testimony that his knowledge in the law was greater than all other men's than by making that law which all other men believed not to be so.' It was to his researches in the older constitution, conducted in this perverse spirit, that the court owed the project of ship-money. Noy drew the writ for levying this illegal tax, but he did not live to see the momentous effects of his exertions, and died on 6th August, 1634. In private matters he seems to have been fond of startling novelties adverse to received opinions and feelings. Thus he bequeathed a fortune to his son, 'to be squandered as he shall think fit—I leave it him for that purpose, and I hope no better from him.' The young man responded to the anticipation, and, after a brief and wild career, was killed in a duel. There are several traditionary anecdotes of Noy's ingenuity as a lawyer. He was the author of several legal works, which seem generally to have been published posthumously. Among these are 'A Treatise of the Principal Grounds and Maximes of the Lawes of England,' 4to., 1641, which has passed through several editions; 'The compleat Lawyer; or a Treatise concerning Tenures and Estates in Land of Inheritance for Life, and other Hereditaments and Chattels, real and personal; together with Observations on the Author's Life,' 1674, 8vo.; 'A Treatise on tho Rights of the Crown; declaring how the King of England may support and increase his annual revenues,' 1715, 8vo. He collected 'Reports and Cases taken at the time of Queen Elizabeth, King James, and King Charles,' 1669, folio.

(Fuller's *Worthies of England*; *Life prefixed to Compleat Lawyer.*)

NU'CLEUS. [Seed, P. C.]

NULLITY OF MARRIAGE. [Marriage, P. C.]

NUMBERS, OLD APPELLATIONS OF. The student of books verging on the middle ages will occasionally meet with some designations of numbers, or rather of the ratios of numbers to numbers, which may need explanation in a work of reference. Corresponding terms are found in the Greek writers, particularly in those on music, and they seem to have obtained universal currency in the middle ages by means of the work of Boethius on Arithmetic, which was a general object of study up to the middle of the sixteenth century.

These words illustrate a fault which has been avoided in our day by the adoption of the opposite extreme. The antients often overloaded a subject with terms; the moderns cannot prepare them as fast as they want them. The higher analysis now abounds with objects of thought for which there are no names except complex algebraical symbols; the old arithmeticians strove to find names for all the varieties of numerical ratio.

In describing these words, we shall, where we can, use the English form of the Latin adjectives, to avoid overloading our article with Latin words: the adjectives accompany the word *numerus*, not *ratio*. The ratio of the greater integer number to the less was one of the following five, multiple, superparticular, superpartient, multiple superparticular, or multiple superpartient. The ratio of the less to the greater was either submultiple, subsuperparticular, subsuperpartient, multiple subsuperparticular, or multiple subsuperpartient.

The term multiple has been preserved, and its species, duple (double), triple, quadruple, quintuple, &c. Thus 10 to 2 is a multiple ratio, namely quintuple: that of 2 to 10 is submultiple, namely subquintuple.

Superparticular ratio (part, that is, aliquot part, over) is when the greater contains the less and a submultiple of the less: its varieties are sescuple or sesquialter, sesquitertius, sesquiquartus, &c. Thus the following ratios are superparticular: 15 to 10, which is sesquialter; 16 to 12, which is sesquitertius; 15 to 12, sesquiquartus; and so on. But the ratio of 12 to 15 is subsuperparticular, namely subsesquiquartus. One of these names is still preserved in our language, in the *sesquialter* stop of an organ. The ratio of 3 to 2 (a sesquialter ratio) is that of the length of a pipe to the length of a pipe which sounds the fifth above the note of the first. Accordingly when a stop was made to sound with the ordinary stop, but a fifth above it, the name sesquialter was given to the stop which gave the higher note.

Superpartient ratio, according to Boethius, is that in which the major term is twice the minor all but an aliquot part. Its varieties are superbipartient (ratio of 5 to 3), supertripartient (ratio of 7 to 4), superquadripartient (of 9 to 5), and so on. Thus the ratio of one and *four*-fifths to one is super-*quadri*-partient. According to Boethius, then, the intermediate ratios of one and two-fifths and one and three-fifths to one have no names. Some of his followers extend the name of superpartient to these, and some would invent the adjectives superbiquintus and supertriquintus to signify them; others used superbipartiens quintas and supertripartiens quintas. Multiple superparticular and multiple superpartient ratios have in the major term a multiple of the minor together with the fraction which gives the remaining adjectives. Thus, the ratio of $7\frac{1}{4}$ to 1 is multiple superparticular, being septuplus sesquiquartus; and $7\frac{3}{4}$ to 1 is multiple superpartient, being septuplus supertripartiens. The preposition *sub* serves as before, prefixed to *super*, to denote the inverse ratios. The reader may fancy for himself, if he can, the beauty of a treatise in which the ratio of 4 to 11 is expressed by *duplus subsupertripartiens.* Not that the writers of these works were ignorant of more simple phrases; and we remember one place in which the example of Aristotle is brought forward to show that it would not be wrong to use them.

Of means, or *medieties*, Boethius discusses ten, to which Jordanus added an eleventh. The first three bear the names which have descended to us, arithmetic, geometric, and harmonic; and all are as follow. Let a, b, c, be three numbers, of which a is the greatest and c the least.

1	a—b : b—c : : a : a	7	a—c : b—c : : a : c
2	a—b : b—c : : a : b	8	a—c : a—b : : a : c
3	a—b : b—c : : a : c	9	a—c : b—c : : b : c
4	b—c : a—b : : a : c	10	a—c : a—b : : b : c
5	b—c : a—b : : b : c	11	a—c : a—b : : a : b
6	b—c : a—b : : a : b		

The works of Boethius and his followers consist in dissertations on what would now be called the most obvious properties of the ratios of numbers, enriched with comments of every species, from numerical to theological. It is not right that they should be utterly lost sight of, for they form a dark background on which the merits of Sacrobosco, Bradwardine, Regiomontanus, and afterwards Tonstall and Recorde, are very distinctly seen.

NUMBERS, THEORY OF. We are here to supply an omission in the article on this subject, or rather in filling up the references which were made from it.

Euclid's geometry, assuming only the use of his three celebrated postulates, enables him, a linear unit being given, to construct the length represented by any algebraical expression which involves only additions, subtractions, multiplications, divisions, extraction of the square roots, or combinations of all these. But a cube or fifth root is beyond the power of the system. Again, from the theory of equations it is soon made obvious that the solution of the equation $x^n-1=0$, and the division of a circle into n equal parts, are one and the same problem. One solution of the preceding is $x=\cos\theta+\sqrt{-1}.\sin\theta$, where θ is the nth part of four right angles. [ROOT, P. C.] Euclid, in his fourth book, shows how to cut a circle into three, four, five, and fifteen equal parts; and analysis shows that the sines and cosines of the angles so involved can be obtained by formulæ which involve no roots except the square. But except into halves, thirds, fifths, or fifteenths, or parts obtainable from these by one or more bisections, Euclid was not able to cut a circle into equal parts.

So the matter rested for about 2000 years, until Gauss, in his 'Disquisitiones Arithemeticæ' (1801), not only pointed out how to extend Euclid's conclusions, but also in a manner how to account for them. The statement of his results, even without demonstration, is instructive to the learner, and we shall give it accordingly: referring for the demonstration to the works of Gauss or Legendre [NUMBERS, THEORY OF, P.C.], or to Murphy's 'Theory of Equations.'

The expression $a+\sqrt{b}$, a and b being rational, is the solution of a quadratic equation with rational efficients. But if a and b themselves have the form $c+\sqrt{d}$, in which c and d have themselves the same form, and so on; then $a+\sqrt{b}$ is the solution of a quadratic equation in which the coefficients are themselves the solutions of quadratic equations, whose coefficients are again the solutions of quadratic equations, and so on. Consequently, any equation, the root of which is capable of construction by Euclid's postulates, must be reducible to a system of quadratics; and the converse. Now if n be a prime number, $n-1$ is an even number, and therefore has factors. Let its prime factors be 2, a, b, c, &c., and let them severally enter p, q, r, s, &c. times: so that

$$n-1=2^p a^q b^r c^s \ldots.$$

Gauss succeeded in showing that when n is a prime number, the solution of the equation $x^n-1=0$, can be made to depend upon the solution of p equations of the second degree, q of the ath degree, r of the bth degree, and so on. Consequently, whenever 2 is the only prime factor of $n-1$, or when $n-1=2^p$, n being prime, or when 2^p+1 is a prime number, the solution of x^n-1 is reducible that of p quadratic equations, and the division of the circle into n equal parts can be accomplished by Euclid's geometry. And further, it is easily demonstrated that 2^p+1 can never be a prime number, except when p itself is a power of 2 (2^0 included) though 2^p+1 is not then always prime. Nor has it been shown that other divisions are impossible: Gauss's theorem merely points out cases in which the thing can be done, without pronouncing the exclusion of others. Gauss, indeed, does assert that be can demonstrate all other cases to be impossible to be constructed by geometry, that is, reducible to quadratic equations: and the thing is highly probable. If we now construct the series $2^1+1, 2^2+1, 2^4+1, 2^8+1$, &c., among which all our chances lie, we have 3, 5, 17, 257, 65537, 4294967297, &c. The first five are prime numbers: Euclid has disposed of the two first divisions; Gauss has added that a circle can be geometrically divided into 17, 257, and 65537 equal parts. But 4294967297 is not a prime number, being divisible by 641. Euclid's mode of obtaining the division into 15 parts can also be extended.

From $\frac{1}{3}$ and $\frac{1}{5}$ we get $\frac{2}{15}$ by their difference, as in Euclid; and thence $\frac{1}{15}$. From $\frac{1}{15}$ and $\frac{1}{17}$ we give $\frac{2}{255}$, and thence $\frac{1}{255}$. From $\frac{1}{255}$ and $\frac{1}{257}$ we get $\frac{2}{65535}$, and thence $\frac{1}{65535}$. From $\frac{1}{65535}$ and $\frac{1}{65537}$ we get similarly $\frac{2}{4294967295}$. Consequently the circle is divisible geometrically into the following numbers of equal parts.

3	4	5
15	16	17
255	256	257
65535	65536	65537
4294967295	4294967296	——

NUMERAL CHARACTERS. In the article under this name, P.C., we have stated that the mode of accounting for the Roman numerals there given is an antient suggestion. We were not then prepared to lay our hands on the works which contain it. The account of it was revived in our day by Leslie, in an article in the Edinburgh Review, and afterwards in his Philosophy of Arithmetic. But it may be found almost entire in the 'Cursus Mathematicus' (1690, vol. i. p. 28) of Dechales, who gives it as the opinion of several of his time. And the earliest hints (by no means complete, and mixed with some absurdities) which we have found are in the 'De Numeris Libri Duo' of John Noviomagus, Paris, 1539, 8vo.

NUNCUPATIVE WILL. [WILL AND TESTAMENT, P. C.]

NUPHAR. [WATER-LILY, P. C.]

NUTRIA. [COYPOU, P. C.]

NUTTAINIA, a genus of Trilobites, from the Silurian strata of Tyrone. (Portlock.) It occurs also in England and Wales.

NYCTERI'BIA, a genus of parasitic insects of the order *Diptera*. They are closely allied to the horse-flies (*Hippoboscidae*). They have neither wings nor balancers. Their intermediate legs are connected at the base by a pair of comb-like organs supposed to represent wings. They live on the bodies of bats.

NYMPHÆA. [WATER-LILY, P. C.]

INDEX TO THE LETTER N.

OATMEAL. [AVENA, P. C. S.]

OBLIQUE ARCH. [SKEW BRIDGE, P. C.]

O'BSEQUENS, JULIUS, the author of a small work in Latin which is entitled 'De Prodigiis.' Nothing is known about the author. Scaliger concludes that Obsequens lived before Hieronymus, because Hieronymus in a particular passage appears to have copied a fact from Obsequens. This passage of Hieronymus was written in the time of Valens, who died A.D. 379. The work of Obsequens is a record of wonderful things that happened during the period from the foundation of Rome to the time of Augustus. The first part of the work is lost, but it has been supplied by Lycosthenes, whose supplement commences with the time of Romulus and extends to the year of the City 563, when the extant work of Obsequens begins. There are various gaps after 563, which Lycosthenes has also supplied. The method of the author is to enumerate the wonderful occurrences under any given year, and then to state what happened thereon. The following is an example (No. XCI.):—'It rained milk on the Græcostasis. At Croton a flock of sheep with a dog and three shepherds were killed by lightning. At Satura a calf with two heads was born. There was an uproar in the city owing to Gracchus proposing his laws.' Obsequens chiefly followed Livy, for he uses pretty nearly Livy's words, as appears from a comparison of Obsequens with those parts of Livy which are extant. His work also terminates with an event relating to Drusus, the son of Livia, and the history of Livy terminates with the death of Drusus.

Lycosthenes in his preface argues that the attention which the Romans paid to wonderful occurrences and signs proved their religious feeling, while their blindness is shown by their worship of false deities; and he adds that if they had been acquainted with the true religion, they would have surpassed in religious zeal their posterity, who are Christians rather in name than in fact, and disregard the signs of the times foretold by Jesus Christ (Luke xxi.) as to happen when the end of the world was approaching. Among the signs then recently witnessed the author mentions three or four eclipses happening in a year, stars with hair (comets), burning meteors, and earthquakes and convulsions of the earth in Italy, all which made no impression on the people of that day, to such a height of impiety and wickedness were men come. The consequences of all this were pernicious errors, horrible blindness, and persevering blasphemy; and the divine vengeance showed itself in civil wars, strange diseases, and famine. The author thought that an edition of Obsequens at such a time would be suitable, and would show men that dreadful signs always portended evil to men, and that by this example they might take warning. The author supplied what is wanting in the MSS. of Obsequens from Livy, Dionysius of Halicarnassus, Orosius, and Eutropius, and other most esteemed authors, so that nothing should be omitted. If his labours should find favour with his readers, he promises to complete his chronicle which he had written of wonderful events from the creation of the world to his own time. The author's preface is dated Basle, 1552.

The edition of Obsequens by F. Oudendorp, Leiden, 1720, contains the notes of Scheffer and the Supplements and Preface of Lycosthenes.

ODEVAERE, JOSEPHUS DIONISIUS, the most celebrated historical painter of the Flemish school of recent times, was born at Bruges, October 2, 1778. He was brought up in the college of the Augustines of that city, and was destined by his parents for mercantile pursuits, though he had always displayed a decided ability for the graphic art. In 1794, in consequence of the French invasion of Belgium, Odevaere was removed by his parents, and accompanied them into Holland, where he remained fourteen months. They returned to Bruges, and as Odevaere had a confirmed dislike to a mercantile pursuit, he was placed in the Academy of Bruges, in which he obtained the first prize for drawing in 1796. He went, towards the close of the following year, to Paris, and studied in the school of his fellow-townsman Suvee until he was appointed director of the French Academy at Rome, when Odevaere entered the school of David. In 1804 he obtained the grand prize of the French Academy of Painting, for a picture of the death of Phocion, and had the honour of being presented to the emperor. He returned in the same year to Bruges, and in 1805 he went as a pensioner for five years of the French government to Rome, but he remained there altogether eight years. According to the regulation of the French government, he sent, after his residence of five years in Rome, an historical picture to the French Academy; the subject was the Coronation of Charlemagne, and it was generally admired. In 1812 he received a commission in Rome to paint two large frescoes for the palace of Monte Cavallo, but political events which followed prevented the execution of these works. He left Rome at the close of 1812, and returned to Paris, and obtained the gold medal for a picture in the exhibition there. He returned finally to Bruges, where he executed several public and private commissions. In 1814 he established himself in Brussels, where he painted his pictures of the Peace of Utrecht, and the Battle of Waterloo at the moment the Prince of Orange was wounded, for the King of the Netherlands, who had created Odevaere his court painter in the spring of 1815. The Battle of Waterloo was exhibited in 1817 and 1818 in many of the provinces of the Netherlands, together with a portrait of the Prince of Orange, which is engraved by Lignon, and a picture of Bramante introducing Raphael to Julius II. Odevaere was the commissioner appointed on the part of the Netherlands to reclaim the pictures which had been taken by the French to Paris from the collections of Holland and Belgium. Upon the completion of this commission, the King created him a Chevalier of the Lion of the Netherlands, and several Flemish cities presented him with medals struck expressly in commemoration of the restoration of their respective works.

The Battle of Waterloo was followed, in 1820, by the Battle of Nieuwpoort, and a Narcissus, engraved by Vlamynck. In 1821 he exhibited at Brussels his Triumph of Cimabue: and subsequently David in his studio; the Establishment of the Power of the House of Orange; the Inauguration of the King at Brussels in 1815; besides others from classical history, and many scripture-pieces for various churches in the Netherlands, in some of which are excellent altar-pieces by Odevaere. He died at Brussels, in February, 1830, not having completed his fifty-second year. Van Eynden and Vander Willigen, in the third volume of their 'National History of Painting since the Middle of the Eighteenth Century,' published in 1820, have given December 2, 1775, as the date of Odevaere's birth, which is corrected in the fourth volume of appendix, published in 1840, to the date given above. His portrait is published in the work of Eeckhout and Burggraaff, 'Portraits des Artistes modernes,' &c., Brussels, 1822; and several of his works are engraved in the 'Annales du Salon de Gand'—as the Coronation of Charlemagne; the Confession of Phaedra to Theseus; Narcissus; and the Battle of Nieuwpoort. Some of the pictures of Odevaere are of very large dimensions. He was a member of the Academy of St. Luke at Rome, and of several other institutes of the fine arts.

(R. Van Eynden en A. Van Der Willigen, *Geschiedenis der Vaderlandsche Schilderkunst, sedert de helft der* xviii. *Eeuw*, Amsterdam, 1842.)

ODO'METER (from ὁδός, a road, and μέτρον, a measure) is an instrument used for measuring the distances passed over in travelling, and is very nearly the same as that which is called a Pedometer: the latter is carried in the pocket of a person on foot or on horseback, and the former is attached to a carriage. [PEDOMETER, P.C.]

OECUMENICAL COUNCILS. [COUNCIL OF THE CHURCH, P. C. S.]

ŒDE'MERA, a genus of beetles belonging to the third family of heteromerous Coleoptera, the Stenelytra.

ŒNOTHE'RA, a genus of plants belonging to the natural order Onagrariæ or Onagraceæ. It has a 4-cleft calyx, 4 petals, a filiform style, with a clavate or cruciform stigma, linear capsules of 4 cells, with 4 valves, and numerous seeds.

Œ. biennis, Evening Primrose, has ovate lanceolate flat-toothed leaves, a rough hairy stem, petals longer than the stamens and about half as long as the tube of the calyx. The flowers are large, numerous, and of a bright yellow colour. It abounds on the Lancashire coast, and covers several acres of ground near Woodbridge, Suffolk. The roots are eatable, and were formerly taken after dinner to flavour wine as olives now are; therefore the generic name was changed from Onagra, the ass-food, to Œnothera, the wine-trap. This plant was once cultivated for the sake of its tubers, which might in some measure have stood instead of the potato had they not been superseded by the introduction of the latter. This is the only British species of the genus. There are 85 species enumerated by Don, growing chiefly in North America. They are handsome border flowers, and deserve to be cultivated, but are not valuable on account of any properties they possess. They will grow in any common garden soil. The perennial kinds are easily propagated by seed, by dividing the plants at the root, and some of them by cuttings. The seeds of the annual and biennial kinds only require to be sown where the plants are intended to remain.

OFFERINGS, OBLATIONS, and OBVENTIONS are not only those small customary sums paid at Easter, but also the customary payments for marriages, christenings, churchings, and burials. By 2 & 3 Ed. VI. c. 13, 'all persons which by the laws and customs ought to make or pay their offerings, shall yearly well and truly content and pay the same to the parson, vicar, proprietor, or their deputies or farmers, of the parishes where they shall dwell or abide; and that at such four offering-days as at any time heretofore within the space of four years last past hath been used and accustomed for the payment of the same; and, in default thereof, to pay for the said offerings at Easter then next following.' The four offering days above spoken of were Christmas, Easter, Whitsuntide, and the feast of the dedication of the parish church. It is directed by the rubric, at the end of the Communion Service, that 'yearly at Easter, every parishioner shall reckon with the parson, vicar, or curate, or his or their deputy or deputies, and pay to them or him all ecclesiastical duties accustomably due then at that time to be paid.' Easter offerings are due of common right, as well as by custom. (Bunb. 173, 198.) Thus, in Carthew *v.* Edwards, Trin. 1749, it was decreed by the Court of Exchequer that the Easter offerings were due to the plaintiff of common right, after the rate of 2*d.* a-head for every person in the defendant's family of sixteen years of age and upwards. But by custom the sum may be more. In London 4*d.* a-head is usually claimed. By the Small Tithe Act, 7 & 8 Wm. III. c. 6, offerings, oblations, and obventions may be recovered before justices of the peace.

Surplice-fees are payable for every marriage, whether by banns or licence; and for every funeral, churching, or christening, according to the custom of the parish. Mortuaries are claimed on the death of each person in a parish, according to value of property left, but not to a greater amount than 10*s.*

(Burn, *Ecclesiastical Law.*)

OGGIO'NE or UGGIO'NE, MARCO DA, a Milanese painter and distinguished scholar of Leonardo da Vinci at Milan about 1490; he was born therefore about 1470, at, as his name imports, Oggione, in the Milanese. He painted in oil and in fresco, and is on the whole one of the best of the Milanese painters. His frescoes of the church della Pace at Milan, which are much praised by Lanzi, are now in the Brera at Milan; they were removed from the wall by Barezzi. Oggione is however now chiefly known for his copy of the 'Last Supper' of Leonardo da Vinci, now in the Academy of Arts in London. This copy is painted in oil, and was executed about 1510 for the Refectory of the Certosa di Pavia; and as it was copied when the original was in a perfect state, the now almost total decay of the latter renders it very valuable. The opinions regarding its merits are various. Giuseppe Bossi does not wholly approve of it; but as the original has been virtually decayed since 1726, when it was first restored, all subsequent judgments of the merits of the copy with respect to the original must be received with due reservation, as they are certainly the result of individual fancies of what the original might have been, rather than of what it by actual comparison was found to be. Marco da Oggione's copy must be a better criterion of what the original was, than the remains of the original itself, or the speculations of all the critics combined; they have no right to assume a deviation from the original, when they cannot possibly demonstrate it. Oggione made two large copies, both, it is said, from a small copy made by himself for the purpose, that in oil, in the Royal Academy, and one in fresco for the Refectory of the convent of Castellazzo, which was copied by the Cav. Giuseppe Bossi, though Bossi's picture was taken chiefly from a copy in the Ambrosian Library made by Andrea Bianchi called Vespino in 1612, when the original was already much decayed. There is an older copy at Ponte Capriasca, made in 1565, and attributed to Pietro Luini. Bossi's copy was made in 1807 for Eugene Beauharnais, viceroy of Italy, to be worked in mosaic; the cartoon is now at Munich, and the mosaic is at Vienna. But this work, made partly from one copy partly from another, from studying other works of Da Vinci, and from the artist's own feeling of Da Vinci's style, is essentially a restoration or translation, and not a copy: it may have no resemblance to the original beyond size and composition; and to the true lover of art can have little value, compared with the old unassuming copy of Oggione. The mere fact that Oggione's copy was painted for people who must have been well acquainted with the original, and by a distinguished pupil of Leonardo's from the original when in its perfect state, ought to be sufficient guarantee for its fidelity, notwithstanding its imperfections, making of course due allowances for the different capacities of the two men. Marco da Oggione died in 1530.

(Lanzi, *Storia Pittorica,* &c.; Göthe, *Propylaeen.*)

OHMACHT, LANDELIN, an eminent German sculptor, was born at Dunningen near Rottweil in Würtemberg, in 1760. He was the pupil of J. P. Melchior. His first public works were some sculptures for the Kreuzkirche at Rottweil, which still decorate the choir. Among his other earlier works is a good bust of Lavater. In 1790 he went to Rome, where he remained two years, and after his return to Germany he was employed on several important monumental works, the first of which was the monument to the Burgomaster Rhode, in the cathedral of Lübeck; but his principal works are at Strassburg, where he settled in 1801. His first work there was the monument of General Desaix, who was killed at Marengo, erected on the Rheininsel near Strassburg: there are four monuments also by him in the church of St. Thomas, of which that to Professor Oberlin (1810) is one of his principal works; that to the historian Koch (1815) is likewise much admired. He executed also a beautiful monument in the new church to Dr. Blessig; another to General Kleber, in the cathedral; and a colossal figure to Adolph von Nassau, in the cathedral of Speyer. There are also several classical figures by Ohmacht—a Venus; Psyche; Flora; Hebe; the Judgment of Paris (at Nymphenburg), and others. Among his busts are several of Klopstock, with whom he was intimate. He died at Strassburg, in 1834: his portrait is in the Vogel collection of portraits in the possession of the king of Saxony. The celebrated sculptor David, upon seeing the works of Ohmacht at Strassburg, is reported to have said that one could not sufficiently admire them, and that Ohmacht was the Correggio of sculptors.

OIL-PAINTING. [Eyck, John Van, P. C., p. 133; Painting, P. C., p. 142.]

OIL-COLOURS. [Painting, House, P. C., p. 145; Syringe, P. C., p. 479.]

OILS, MANUFACTURE OF. An account of the properties of the more important oils, and of the materials from which they are procured, is given in the articles Oils, P. C., p. 415, and Oils, Vegetable, P. C., p. 417; and further information may be found under the names of some of the principal oils, as Croton Oil, Linseed Oil, and Olive Oil, or in articles which treat on the materials from which oils are made, such as Elæis, Madiá, Linseed, Olea Europæa, Ricinus Communis, and Guacharo Bird. Under Fisheries, also [P. C., pp. 288, 289], is given much information on the produce of whale oil. We may here add a few words on the processes of the manufacture of such oils as are of the greatest commercial importance.

The manufacture of animal oils requires very little notice beyond what is given in the articles Oils and Fisheries above referred to. The *blubber,* or fat from which the oil is procured, is usually cut into small pieces and packed in casks soon after it is taken from the whale; it is then brought home in a half-putrid state, and is emptied into a large wooden vessel or receiver, capable of holding several tons. From this receiver the decomposing fat is conducted, after settling for a few hours, into a copper boiler, in which the separation of the fluid from the solid portions of the blubber is completed by the application of heat. From the boiler the oil flows through a kind of filter of brushwood, which detains the grosser impurities, into coolers, from which, when quite cold, it may be drawn off into casks. Various chemical processes are employed for purifying whale oil and diminishing its unpleasant smell. The quantity of oil obtained is about four-fifths that of the blubber used. In the South-Sea fishery it is found advisable to boil the blubber on board the whaling vessels, and to bring home the oil alone in casks. In this process, as commonly performed, the oil is very imperfectly extracted from the blubber, and the *scraps*, or solid portions which remain, are used as fuel under the *try-pots*, or boilers; by which arrangement the oil that remains in them is not only destroyed, but also becomes, from its great inflammability, a source of serious danger. To obviate these evils some ships are provided with powerful screw-presses for squeezing out whatever oil may remain after the process of boiling the blubber, and thus materially increasing the produce. Hebert, in the 'Engineer's and Mechanic's Encyclopædia,' vol. ii. pp. 206, 207, gives an engraving and description of such a press, in which the blubber-scraps are put into a hollow cylinder, while yet warm, and compressed by a piston brought down upon them with a great force. The oil escapes through holes in the bottom of the cylinder, between which and the blubber is laid a mattress of wicker-work, to prevent the blubber from choking up the holes. This press is the invention of Mr. John Blythe, of Limehouse.

Olive oil, as explained under OLEA EUROPÆA, in P. C., differs from most vegetable expressed oils in being extracted from the soft fleshy pericarp, whereas such oils are usually procured from the seeds only. The manufacture is very simple, and is usually conducted with very rude machinery; but writers differ in their accounts of the process, in some important particulars; some stating that the fruit should be gathered a little before it is ripe, and spread on the floor of a room for several days to dry and ferment slightly, while in the volume on 'Vegetable Substances used as Materials of Manufactures,' in the 'Library of Entertaining Knowledge,' it is stated on the authority of an English gentleman who had resided at Gallipoli, where much excellent olive oil is made, that the Gallipolitans never gather the olives, but allow them to drop in their maturity from the tree to the ground. In the 'Dictionnaire de l'Industrie,' published at Paris in 1795 (vol. iii., p. 73), in an account of the manufacture of olive-oil in Provence, however, it is stated that fallen olives should not be mixed with those which are gathered, for fear of imparting an earthy odour to the oil, and a caution is given against allowing the heap of gathered olives to heat or ferment, coupled with the remark that the sooner the olives are taken to the mill the better will be the oil. According to this authority, also, all leaves should be carefully removed, as their presence would give a bitter taste to the oil. But Dr. Ure, in the 'Dictionary of Arts,' &c., p. 898, writing of the same district, states that it is usual in the neighbourhood of Aix, in Provence, 'to preserve the olives for fifteen days in barns or cellars, till they have undergone a species of fermentation, in order to facilitate the extraction of their oil.' 'If,' he adds, 'this practice were really prejudicial to the produce, as some theorists have said, would not the high reputation and price of the oil of Aix have long ago suffered, and have induced them to change their system of working?' 'In fact,' he proceeds, 'all depends on the degree of fermentation excited: they must not be allowed to mould in damp places, to lie in heaps, to soften so as to stick to each other, and discharge a reddish liquor, or to become so hot as to raise a thermometer plunged into the mass up to 96° F. . . . A slight fermentation, however, is useful towards separating the oil from the mucilage.' The first and finest oil is obtained by crushing the olives in a kind of mill, termed by Dr. Ure an edge-mill, in which the crushing-stones are so mounted as not to break the stones of the fruit, but simply to crush the pulp. The mass thus bruised is put into *cabas*, or bags made of bulrush-matting, or of coarse canvas, which are piled or laid upon one another to the number of eighteen, and exposed to gradual compression in a screw-press; and the oil which flows from the cabas, which is the pure virgin oil, is conducted by channels into casks or stone cisterns partly filled with water, on the surface of which it floats so that it may be readily collected by skimming. When the oil ceases to flow, the mass of pulp is taken out of the bags, mixed with boiling water, and treated as before, but with an increase of pressure. The second quality of oil thus procured is quite fit for table use when fresh, but is apt to become rancid by keeping. After skimming off the oil which accumulates on the surface, the subjacent water still retains a good deal of oil, by the intervention of the mucilage; but after long repose in a large cistern the oil and water separate, and the water may be drawn off from below. This oil, however, is of very inferior quality, and can only be used for factory purposes. A still coarser kind of oil is finally procured by crushing the marc, or solid residue, in a mill, so as to break the stones, boiling it with water, and re-pressing it. All the oil, Dr. Ure observes, must be *fined* by keeping in clean tuns, in an apartment heated to at least 60° F., for twenty days, after which it is run off into strong casks, cooled in a cellar, and then sent into the market.

Dr. Ure, in the article and page above referred to, gives the following useful directions for refining olive-oil for the use of watchmakers:—'Into a bottle or phial containing the oil, a slip of sheet-lead is immersed, and the bottle is placed at a window, where it may receive the rays of the sun. The oil by degrees gets covered with a curdy mass, which after some time settles to the bottom, while itself becomes limpid and colourless. As soon as the lead ceases to separate any more of that white substance, the oil is decanted off into another phial for use.'

Passing over the processes of manufacture of many kinds of oil of less importance, we proceed to take linseed-oil, or the oil extracted from the seeds of the flax-plant, as an illustration of the manufacture of oil from seeds. 'Linseed, rape-seed, poppy-seeds, and other oleiferous seeds were,' Dr. Ure observes, 'formerly treated for the extraction of their oil, by pounding in hard wooden mortars with pestles shod with iron, set in motion by cams driven by a shaft turned with horse or water-power; then the triturated seed was put into woollen bags, which were wrapped up in hair-cloths, and squeezed between upright wedges in press-boxes, by the impulsion of vertical rams driven also by a cam mechanism.' In the best mills on the old construction, he adds, the cakes of crushed seeds obtained by this first wedge-pressure were ground anew upon the bed of an edge-mill, and subjected to a second pressure, with the aid of heat. 'These mortars and presses,' he states, 'constitute what are called Dutch mills: they are still in very general use both in this country and on the Continent, and are by many persons supposed to be preferable to the hydraulic presses.' A good account of the modern English process of making linseed-oil, as practised at the Walker oil-mill, near Newcastle-upon-Tyne, is given in Dodd's 'British Manufactures; Chemical,' (forming No. xxv. of 'Knight's Weekly Volume,') and in No. 802 of the 'Penny Magazine,' where also are some interesting details respecting the mode of cultivating and preparing hemp-seed and rape-seed for the oil-manufacture. When flax is cultivated for its seed, the plants, after being pulled up, are either laid on the ground in handfuls, with the seed end towards the south, or else several plants are tied together at the top, and placed upright with their roots spread out. When they have been thus dried by exposure to the air, the seeds are separated from them by means of a *ripple*, or comb with long wire teeth, through which the plants are drawn, and by which the capsules containing the seed are separated from the flax. [FLAX, P. C., pp. 303, 304.] The seeds and pods are then spread thinly upon a cloth to dry in the sun, when the ripest will separate from the pods of themselves, while such as are less ripe will need to be lightly trodden or thrashed. The whole is then carefully sifted, winnowed, and cleaned from dirt and chaff.

As the hardness and smoothness of the seed gives it a tendency to slide away unbroken under the rolling action of the millstones by which they are ground, it is well, before taking it to the grinding-mill, to bruise or crush it by causing it to fall from a hopper between two iron crushing-rollers, placed side by side, and capable of being pressed against each other with any determinate degree of force; but the use of such rollers is by no means universal, the seeds being, in many cases, submitted to the grinding-mill without any such preparation. This mill, which is sometimes called an *edge-mill*, consists of a pair of stones, technically called *running-stones*, or *runners*, usually made of granite, resembling grindstones in shape, and from five to seven feet or upwards in diameter, so mounted as to roll round in a circular path of small diameter upon a solid horizontal bed of stone or iron laid beneath them. Those stones, which roll round the bed from thirty to thirty-six times in a minute, are sometimes hooped with iron, though many prefer the rough surface of the granite, which may be re-dressed with a hammer as often as is needful. They grind the seed partly by their weight, which often amounts to three tons each, and partly by the peculiar rubbing motion which arises from the circumstance that the outer edge of the stone has to perform a larger circuit than the inner, although the two must of course revolve round the axle at one and the same speed. The action is therefore similar to that of a cone when forced to roll onward in a straight path. The two running-stones are mounted on the same horizontal axis, but at rather different distances from the central vertical shaft or axis round which they roll, so that they do not follow one another in precisely the same path on the bed of this mill. The bed is surrounded by a rim which prevents the seeds from being scattered, and the revolving framework in which the running-stones are mounted carries also two rakes or sweeps, which collect and lay the seeds in a ridge along the circular path of the runners. By this means the seeds are reduced, by the partial expression of the oil, to a pasty mass, from which a limited quantity of very fine *cold-drawn* oil may be obtained by the simple action of the press.

Owing to the extreme hardness and smoothness of the seeds of flax and hemp, and to the circumstance that the fragments of their shells, however broken, form minute concavities which will retain the oil unless a greater pressure be applied than could be given by an ordinary screw-press, the presses employed for extracting oil from such seeds differ materially from those used in crushing olives and other comparatively soft oleaginous substances. Hence it is that the wedge-press and Bramah's hydraulic press have been introduced for the purpose, and that of these two powerful machines some manufacturers prefer the former, believing that the same degree of pressure is more efficient when imparted by means of sudden impulses or blows upon the end of a wedge, than when it is applied gradually and steadily as in the hydraulic press. In the wedge-press, of which there are many varieties, the crushed seeds are put into bags of hair-cloth or some similar material, and these bags are then placed between plates of iron united together like the covers of a book, or between boards or blocks of wood, within a very strong and massive framework. The small end of a wedge is then introduced in such a way between the plates or boards that, when it is driven down by the blows of a ram or pestle, it may compress the bags with enormous force. Barlow, in his 'Treatise on Manufactures and Machinery,' in the 'Encyclopædia Metropolitana,' in which work (sections 504—513) is much important information on the subject of this article, states that the driving of the wedges is continued until they 'are so tight that the pestle rebounds from them three times, when they are judged to be sufficiently driven.' The use of the hydraulic press instead of this apparatus needs no minute explanation. In Barlow's work, just referred to, is an account of such a press which acts horizontally, the bags being, as in the wedge-press, placed vertically, and separated from one another by cast-iron plates; but in Dodd's account, above noticed, of the Walker oil-mill, the bags are represented as piled upon one another in cast-iron cases, and placed in a vertical press. Dodd speaks of the bags in which the seeds are contained as of flannel, and Barlow as of woollen, 'unfolded (enfolded?) by horse-hair mattresses, enclosed in leather wrappers.' The last-mentioned writer states that the first oil-mill in which the hydraulic press was thus applied was constructed at Bremen, in 1821, and that its proprietor is satisfied of the superiority of the plan to any other then in use. Among other advantages it is stated that the hydraulic or hydrostatic press requires less space than a stamping-mill which could do the same work, and that the hairs and bags are found to last longer with it than with the old machine. Since the above date the Bramah press has been successfully applied in the manufacture of cocoa-nut oil, and several presses have been exported to Ceylon and other places for that purpose. Mr. John Hall, of Dartford, patented in 1823 an ingenious oil-press in which the power of a steam-engine or other prime mover might be applied through the medium of cams or eccentric rollers: but Barlow states that the plan has not been generally adopted.

We have hitherto spoken only of the extraction of the finest oil, without heat. The application of heat before pressing is however necessary for obtaining the principal supply of oil. The precise order of the several operations, as well as the nature of the machinery employed, differs in different manufactories, but in the process detailed by Barlow the oil-cakes, or solid contents of the bags, which remain after the first cold pressing, are taken out of the bags, broken to pieces, and put into mortars to be pounded by pestles worked by machinery. 'There,' he observes, 'the paste is again broken down, and the parenchyma of the seed reduced to a fine meal; thus free egress is allowed to the oil from every vesicle in which it is contained, but it is now rendered much more clammy by the forcible mixture of the mucilage, and even of the fine parts of the meal.' When sufficiently heated it is removed to a *chauffer*, or circular copper-pan, in which, while it is kept continually stirred by machinery, it is heated to about the temperature of melting bees-wax, either by a charcoal fire, or, according to a more recent practice, by steam. It is then, while hot, put into the bags and subjected to a second pressing; and in some cases the like operations are repeated a third time, by which a further quantity of oil, but of inferior quality, is produced. Sometimes the produce of oil is increased by mixing a little water with the paste; but this practice is considered to impair the quality of the oil. The oil-cake which remains after the last process is used as food for cattle, and for various other agricultural purposes; but of course they vary greatly in richness according to the degree in which they have been divested of oil. Barlow states, indeed, that 'there are small mills in Holland which have no other employment than extracting oil from the cakes which they purchase from the French and Brabanters, after passing the process of their mills: a clear indication of the superiority of the Dutch practice.' In some of the Dutch mills, we learn on the same authority, the produce is increased by the application of moderate heat during the grinding process, by enclosing a little furnace in the bed upon which the running-stones roll; but it is observed that 'the utmost care is necessary to prevent the heat from becoming too considerable, as it causes the oil to dissolve too much of the fermentable substance of the seed, and exposes it to the risk of soon growing very rancid. When the seed is very dry the process of grinding may be facilitated by the addition of a little water. The oil produced by the above process needs little further attention. If left in a cistern, as it is by the Dutch manufacturers, the parenchymatous part, which inevitably passes away with the oil in some degree in the operation of pressing, will gradually subside, and the oil may be drawn off at various levels, of different degrees of purity; the bottom being at length removed to a deep and narrow cistern, where it should be left a considerable time for the dregs to subside.

Linseed oil is used principally as a vehicle for mixing oil-colours for painting, but it is also valuable in several branches of manufacturing industry, and, in a refined or purified state, in some medicinal preparations. Being a fat or unctuous oil, it is slow in drying, and as this is a great inconvenience for some purposes in painting, it is sometimes converted into *drying oil* by boiling it with sugar of lead, white vitriol, red lead, or other substances which possess similar properties. The common kinds of drying oil are generally known by the name of *boiled oil*.

Very full details of the improved modern machinery used in the manufacture of oil from seeds are given by Barlow, in the work above quoted, in Dr. Ure's *Dictionary of Arts*, and in the *Supplement* to that work; and some ingenious presses of simpler character are described in Hebert's *Engineer's and Mechanic's Encyclopædia;* and in both of these works additional details may be found respecting the manufacture of oils of a less generally important character. The process of making castor oil is detailed under RICINUS COMMUNIS, P. C., p. 5, 6.

O'KEEFFE, JOHN, was born at Dublin, on the 24th of June, 1747. Being designed for a painter, he was placed, when only six years old, under the charge of Mr. West at the Royal Irish Academy; and his literary education, in Greek, Latin, and French, was received from Father Austin, a learned Jesuit, he and his family being Roman Catholics. Two years of his youth, beginning when he was about fifteen, were spent in London with an uncle. From early boyhood he had dabbled in versification: at the age of sixteen he had composed a comedy: and when he was no more than eighteen another comedy of his was brought out by Mossop, at the Smock-alley Theatre in Dublin. His dramatic turn now took entire possession of him. He obtained an engagement from Mossop as an actor, and continued for some years to be a member of the company; acting both in Dublin and in other towns of Ireland. At the same time he exercised himself in dramatic writing, often producing small pieces for his own benefits and on other occasions. In 1774 he married a daughter of Mr. Heaphey, proprietor of the Theatre Royal in Dublin, by whom he had three children. Domestic disagreements arose: after seven years of union Mr. O'Keeffe and his wife separated; and the separation lasted for the remainder of their lives.

In 1778 Mr. Colman brought out successfully, at the Haymarket, the farce of 'Tony Lumpkin in Town,' the first piece by which O'Keeffe became known in England. In 1781, on his separation from his wife, he removed to London; and he never again visited his native country. From that time he was a play-writer by profession. The greater number of his pieces were composed for Colman's company at the Haymarket; but he wrote frequently also for Covent Garden under the management of Harris. His dramatic career may be said to have closed in 1798, after which date no new play of his was brought upon the stage. The fruit of his labours was a collection of dramatic pieces, amounting, on his own list, to no fewer than sixty-eight, of which fifty-six were acted, and many of these with great success. Some of them still keep possession of the stage. Such are his comedy of Wild Oats, and his operatic farces of The Agreeable Surprise and The Highland Reel.

O'Keeffe's works do not belong to a high class. Their diction is coarse, and in incident and character they are merely farcical; but the best of them have a flow of spirits, a kindliness of feeling, and a richness of whim and eccentricity, which account adequately for the popularity they so long enjoyed. They were composed in circumstances calling for much indulgence. They were the constant efforts of a very poor man to preserve himself and his children from beggary. And, further, from his twenty-eighth year, when a neglected cold brought on inflammation of his eyes, he suffered under a gradual decay of sight, which speedily made reading and writing alike impossible. He was never entirely blind; but for many years he could do little more than distinguish light from darkness.

In 1798 twenty-one of his pieces were published together, in four volumes octavo. The subscription for the edition scarcely paid the expenses. In June, 1800, Mr. Harris gave him a benefit at Covent Garden, at which he himself appeared on the stage and delivered an address: and the receipts enabled him to spend 300*l.* in purchasing a small annuity. In 1803 he received a life-annuity of twenty pounds from Covent Garden, nominally as the purchase-money of his dramas still unprinted: but this annuity ceased to be paid in 1826. In 1808 he began to receive a pension from the crown, to which another pension of a hundred guineas was added in 1826. From these combined sources he was, during the latest years of his life, in receipt of an income little exceeding two hundred a-year; and, in an honourable spirit of independence, he refused a donation sent him by the Literary Fund Society. In 1826 he published 'Recollections of the Life of John O'Keeffe, written by himself:' two volumes 8vo. In 1828 he removed from the neighbourhood of London to Southampton, and there resided thenceforth, attended by a daughter, who was his only surviving child, his eldest son, a clergyman of the Church of England, having died of the yellow fever at Jamaica, in 1804. O'Keeffe himself was a Roman Catholic to the last. He died at Southampton, on the 4th of February, 1833. In 1834 appeared a small volume of his versified pieces, entitled 'O'Keeffe's Legacy to his Daughter,' and prefaced by notices of his character and domestic circumstances.

OLBERS, HENRICH WILHELM MATHIAS, an able physician and a distinguished astronomer of Germany, was born October 11, 1758, at Arbergen, near Bremen. Of his private life few particulars have yet been made public; and almost all that can be stated respecting the history of this celebrated individual consists only of a few brief notices relating to his discoveries in the heavens. He studied medicine at the University of Göttingen, and, during all his life, his time appears to have been divided between the exercise of his profession and his astronomical researches: it is said that, in 1830, he celebrated, by a public festival, the fiftieth anniversary of his medical labours; and his observatory is described as the most complete of those which, at the time of its construction, existed in Germany. It consisted of three rooms in the upper part of the house, which was situated in the heart of Bremen: three great windows in the south front gave a view of the heavens almost to the horizon on that side, and one in a closet enabled the observer to look towards the north: openings in the ceiling and roof permitted observations to be made near the zenith. Olbers possessed a five feet achromatic telescope, with a position micrometer by Dollond, and a reflecting telescope of equal length by Schröter: he had, also, an astronomical clock by Carsten, a quadrant by Bird, and a reflecting sextant by Troughton, but he had neither a transit instrument nor a mural circle; and, apparently, he determined his time by extra meridional altitudes. Attached to the observatory was an astronomical library containing, among other valuable works, an extensive collection of documents relating to cometography: this library was, after the death of Olbers, purchased by the Emperor of Russia, and deposited in the observatory of Pulkowa.

Dr. Olbers wrote but little on the subject either of medicine or astronomy; but, in 1780, he printed a thesis entitled *De Oculi Mutationibus Internis*, in which he showed that the eye accommodates itself to the different distances of objects from it by means of a variable action of the muscles, in consequence of which changes are produced in the convexity and the focal length of the cornea; and in 1832, he published in the *Annuaire du Bureau des Longitudes* a mémoire entitled 'De l'influence de la lune sur les saisons et sur le corps humain.'

In 1779 he became known to astronomers by a series of observations which he made on the comet of that year, and by his determination of the elements of its orbit: the computations were founded on a method which had been given by Euler; but, at a subsequent period, Olbers discovered a method of calculating the orbits of comets from three observations, which, with respect both to facility and accuracy, he considered as having great advantages over the methods before in use. An account of this method, with a preface by the Baron de Zach, was published at Weimar in 1797. It is entitled *Abhandlung über die leichteste und bequemste methode die Bahn eines Cometen aus einigen Beobachtungen zu berechnen*, and it affords sufficient evidence that the talents of the author as a mathematician were considerable. An outline of the method, with its application to an example is given in Delambre's *Astronomie* (tom. iii. Nos. 184, 223, &c.) Olbers computed also the orbits of the comets which appeared in 1781 and 1795; those of two comets which appeared in each of the years 1798 and 1799, of one in 1802 and of the great comet of 1811.

The interval between the orbits of Mars and Jupiter, which appears disproportionably great when compared with the intervals between any two of the other planets belonging to our system, had suggested to the original and inquisitive mind of Kepler the idea that a planet, too small to be seen from the earth, existed in that region: the idea appears to have been little regarded till M. Bode, of Berlin, obtained his empirical formula, for the distances of the planets from the sun, which except with respect to the interval between Mars and Jupiter, was found to hold good for all the known planets, including the Georgian; when that which was before considered as the vision of an enthusiast was found to be deserving of serious consideration. With a view, therefore, of ensuring, as far as possible, a complete examination of the heavens in the parts where the supposed planet might be expected to be found, M. Schröter was induced to form an association of twenty-four astronomers, who, having divided the heavens into as many zones, were each to confine his observations to one of them. That distinguished individual was chosen President, the Baron Zach secretary; and among the members was Dr. Olbers: the labours of the association were not, however, immediately rewarded; and M. Piazzi, of Palermo, who was not one of the number, had the good fortune to discover January 1, 1801, a planet, to which he gave the name of Ceres, and which was found to be between the orbits of Mars and Jupiter, at a distance from the sun nearly equal to that which, in conformity to the law discovered by Bode, it ought to have.

This planet soon afterwards became invisible, from its vicinity to the sun; but Dr. Olbers and M. Gauss, having calculated its orbit approximatively from such observations as had been obtained, sought for it at the time when it was expected again to appear, and the former was the first to re-discover it. The idea of Kepler and the formula of Bode seemed now to be fully confirmed; but the harmony conceived to exist in the planetary distances was almost immediately, in appearance, deranged; for on the 28th of March, 1802, Dr. Olbers, being engaged in examining the northern part of the constellation Virgo, discovered a star which was not in any of the catalogues: this was ascertained to be a new planet, and it received the name of Pallas. Its orbit was soon calculated, and it was found to describe a very excentric ellipse about the sun at a mean distance from it which is nearly equal to that of Ceres: the time of its periodical revolution is also nearly the same as that of the last-mentioned planet, but it has a much greater inclination to the plane of the ecliptic. Dr. Olbers was led, from the fact that these two planets are nearly in the same part of space when they arrive at the places where the planes of the orbits intersect one another, to imagine that they might be dispersed fragments of a large planet which revolved, at one time, about the sun at nearly the same distance from that luminary; but which, in consequence of an internal convulsion or from some other cause, had been broken up. Pursuing this idea, he considered that there might be other fragments, or small planets, in the same region; and the idea was strengthened when, in September, 1804, a third planet of a like kind was discovered by M. Harding of Bremen. This planet, which was named Juno, has the nodes of its orbit nearly coincident with those of Pallas; the excentricities of the two planets are also nearly equal to one another, and both planets revolve about the sun at nearly the same distance. Dr. Olbers now determined to make the discovery of new planets a particular object of research; and, from 1804 to 1807, he persevered in examining with the most minute attention, at the times of their opposition to the sun, the parts of the heavens which were near the nodes of the three other planets. On the 29th of March, in the latter year, his sagacity and diligence were rewarded by the discovery of a fourth planet: on the 3rd of April he sent intelligence of the event to his friend M. Bode, and he transmitted the series of his observations to M. Gauss. The latter astronomer immediately computed the figure of the orbit, and, Olbers having requested him to give a name to the planet, he designated it Vesta. This is the smallest of the four new planets, or asteroids, as they have been designated, and the time of its revolution about the sun is the shortest.

It may be proper to mention, in this place, that additional confirmation of the opinion of Olbers has been afforded by the discovery of a fifth planet: this was made on the 8th of December, 1845, by M. Hencke of Drissen, and it has received the name of Astræa; it is a small planet, and revolves about the sun, between the orbits of Juno and Vesta, in about four years.

In 1815 (March 6th) Dr. Olbers discovered, near the constellation Perseus, a comet which presented the appearance of an attenuated nebulosity without any visible nucleus; and he continued to observe it till the end of August, when it ceased to be visible: its orbit was calculated by Bessell and Gauss, and it was found to accomplish its revolution about the sun in 73 years. In 1826, he published a dissertation on the probability that a comet may come in collision with the Earth:—a subject which then engaged the attention of astronomers on account of the near approach of the comet Biela when in one part of its orbit. In 1841 he made a proposal for a re-formation of the constellations and a revision of the nomenclature of the stars; recommending, as models, the figures in Flamsteed's Atlas, but better drawn than they are in that work, and also that the representations of persons and machines which have no relation to astronomy should be cancelled.

Dr. Olbers was elected a fellow of the Royal Society of London in 1804, and a Foreign Associate of the Académie des Sciences at Paris in 1829: he was also a corresponding member of several other learned societies, a knight of the order of Danebrog and of the Red-Eagle of Prussia. He died at Bremen on the 2nd of March, 1840; and, as a proof of the esteem in which he was held during his life, his fellow-citizens of Bremen placed his bust in the public library of the city.

(*Biographie Universelle, Supplement*. Monthly Notices of the Royal Astronomical Society.)

OLDMIXON, JOHN, one of the heroes of the Dunciad, was born in 1673. The place and kind of his education are unknown. His authorship appears to have begun with the drama, in which he was thoroughly unsuccessful; and his principal productions were historical, political, and critical. He superintended, carelessly and unfaithfully, the first edition of the collection of English historians which bears the name of Bishop Kennett. He himself wrote also 'A Critical History of England,' 'The History of England during the reigns of the House of Stuart,' and 'The History of England during the reigns of William and Mary, Anne, and George I.' These dull and unlearned works are chiefly remarkable for their strong spirit of Whig partisanship. In criticism Oldmixon was distinguished for his unscrupulous abuse of Pope and other eminent men of his day. He found abundant opportunity for venting his bile, not only in contributions to periodical prints, but in his 'Prose Essay on Criticism,' and his 'Arts of Logic and Rhetoric' (a clumsy adaptation from Bouhours). His party-services were rewarded by an appointment to the place of Collector of the Customs at the port of Bridgewater. He died in London, in 1742.

OMBRO'METER. [Rain Gauge, P. C.]

OMNIBUS. [Metropolitan Stage Carriage, P.C.S.]

OMNIUM, a term used in the Stock Exchange, to express the value, taken as an average, of the different stocks in which a loan is usually funded. Thus, a loan having been contracted for on a certain day, an average is made of the stocks in which such loan is contracted, at the price which they bore on that day, and the fund thus formed as an average of the whole is called Omnium. (M'Culloch's *Dict. of Commerce*.)

ONA'GRA. [Œnothera, P. C. S.]

ONA'TAS (Ὀνατᾶς) of Aegina, the son of Micon, was alike distinguished as a painter and a sculptor: he was contemporary with Polygnotus, and lived accordingly in the early part and about the middle of the fifth century before the Christian æra. His name does not occur in Pliny, and, with the exception of an epigram upon a statue of Apollo by him, in the Greek Anthology, he is noticed only by Pausanias, who however mentions several of his works and speaks of him in terms of great praise. Pausanias speaks of a group of Homeric heroes near the great temple at Olympia, which were dedicated by the Achaeans in common; Thiersch attributes them all to Onatas, but his name was inscribed on one only. Pausanias says that the Achaean people in common dedicated those statues which represent the Greeks who drew lots for the challenge of Hector; they stood armed with spears and shields near the great temple; opposite to them was Nestor with the lots in a helmet. There were eight besides Nestor; the statue of Ulysses, which made the ninth, had been removed by Nero to Rome. Of the remaining eight, only one, that of Agamemnon, had his name inscribed upon it, and it was written from right to left. On the shield of another was represented a cock, and this, says Pausanias, was Idomeneus, the grandson of Minos. In the interior of the shield was the following inscription, which appears to apply to the statue of Idomeneus alone:—

Πολλὰ μὲν ἄλλα σοφοῦ ποιήματα καὶ τόδ' Ὀνατᾶ
Ἔργον, ἐν Αἰγίνῃ τὸν τέκε παῖδα Μίκων.

'As well as many others, this is the work of the skilful Onatas; Micon was his father, his birth-place Ægina.'

The Thasians also dedicated a bronze statue of Hercules by Onatas at Olympia, with a club in his right and a bow in his left hand; it measured ten cubits, and the name of Onatas with his birth-place and parentage was inscribed upon it. Pausanias observes with respect to Onatas that he was not surpassed by any artist that had appeared in the school, or from the workshops, of Attica, since Daedalus; that is, from Daedalus to Onatas's own time, which was shortly before Phidias.

Pausanias mentions further, by Onatas, at Olympia, a Mercury carrying a ram under his arm; he had on a helmet and a cloak besides a tunic or under robe; he was assisted by Calliteles, whom Pausanias supposes to have been the son or pupil of Onatas.

Onatas cast also in bronze a statue of Ceres the Black, or Demeter Melaina, for the Phigalians, in the place of an old wooden image which was destroyed by fire. Onatas cast the new statue from a picture or wooden image of the former one, assisted by a vision in a dream: it had a horse's head. He made also a statue of Apollo, at Pergamus, magnificent for its size and its workmanship.

Onatas made also the bronze chariot of Hiero, dedicated by his son Deinomenes at Olympia in honour of his father's victories in the games: the horses and riders were by Calamis. He made also, together with Calynthus, an artist otherwise unknown, the monument dedicated by the Tarentines at Delphi: they sent a tenth of the spoils taken from the Peucetii, a neighbouring barbarous people. The offerings consisted of several figures of warriors on foot and on horseback: Opis, king of the Iapyges, who assisted the Peucetii, was represented dying; near him stood the hero Taras, and Phalanthus, by whom was a dolphin; Phalanthus was saved from shipwreck in the Crissaean sea and brought on shore by a dolphin.

Onatas is mentioned only once as a painter: he decorated with Polygnotus the walls of the vestibule of the temple of Minerva Areia at Platsea. Onatas painted the first expedition of the Argives against Thebes. He probably also painted at Plataea the picture of Euryganea lamenting the death of her sons Eteocles and Polynices killed by each other's hands; which, according to Sylburgius, is by a MS. error, attributed to Onasias, otherwise not mentioned. Böttiger supposes Micon the father of Onatas to be the celebrated Athenian painter of that name.

(Pausanias, v. 25, 27, viii. 42, vi. 12, x. 13, ix. 4, 5; Junius, *Catalogus Artificum*; Thiersch, *Epochen der Bildenden Kunst unter den Griechen*; Böttiger, *Ideen zur Archäologie der Mahlerei*.)

ONGOLE, or ANGOLE, a town of Hindustan, in the Presidency of Madras, and Northern Carnatic. [CARNATIC, P. C.] Ongole is the chief town of the district of Ongole, and is situated in 15° 31′ N. lat., 80° 1′ E. long., 173 miles N. by W. from Madras. The sovereignty of the district and town of Ongole was acquired by the East India Company in 1801, by treaty with the Nabob of Arcot, to whom it previously belonged. The town was then strongly fortified, but the fortifications have been suffered to fall into decay or have been destroyed.

(Hamilton's *East India Gazetteer.*)

ONOBRY'CHIS (from ὄνος, an ass, and βρύχω, to gnash the teeth), a genus of plants belonging to the natural order Leguminosæ. It has a calyx with five nearly equal subulate teeth; the keel obliquely truncate, longer than the wings; the pod one-celled, compressed, indehiscent, one-seeded, upper suture straight, lower curved, toothed, winged or crested. The species of this genus are natives of Europe or Asia, with unequally pinnate leaves, and axillary elongated peduncles having spikes of flowers red or white at their tops. The most common, as well as only British species is *Onobrychis sativa*, common Sainfoin. [SAINFOIN, P. C.; HEDYSARUM, P. C. S.] About forty other species have been described, but none of them possess useful properties. Many are showy plants when in bloom, and are adapted for flower borders or rockwork. They may be propagated by seeds.

(Don's *Gardener's Dictionary*; Babington's *Manual of British Botany.*)

O'NONIS (from ὄνος, an ass, and ὄνημι, to delight, some of the species being said to be grateful to asses), a genus of plants belonging to the natural order Leguminosæ. It has a five-cleft campanulate calyx, narrow segments, the lower ones longer. The keel is beaked, the style filiform and ascending, the stigma terminal and subcapitate.

O. arvensis, trailing Rest-harrow, has a procumbent uniformly hairy stem, axillary stalked solitary flowers, broadly oblong leaflets, ovate pods shorter than the calyx. It is usually without spines. The stems root at their base, and the seeds are tubercular and scabrous.

O. antiquorum has an erect or ascending stem, bigariously hairy; axillary solitary stalked flowers, oblong leaflets, and ovate, erect pods longer than the calyx. It is doubted by many botanists as to this being the true *O. antiquorum*. Koch and Reichenbach both describe quite a different plant, with smooth seeds.

O. reclinata has a viscid pubescent stem, axillary flowers with one flowered pedicles shorter than the leaf flower, a pod without bracts, the corolla about equal to the calyx, obovate cuneate leaflets serrated at the lip, ovate stipules, and cylindrical reflexed pods. It is found in sandy places in Galloway and the Channel Isles, and in the south of France by the sea coast.

There are 107 species of this genus described, but none of them are used in medicine or the arts. They are chiefly natives of Europe; about twelve species are found in Africa, and a few on the coast of Asia. They are generally handsome when in flower. The hardy shrubby kinds are increased by seeds and layers, the hardy perennial kinds by dividing the roots in the spring, or by seeds. These are well fitted for flower borders. The seeds of the hardy annual kinds only require to be sown in the open border in April. The greenhouse and frame species thrive well in a mixture of loam, peat, and sand; these are usually increased by seeds which ripen in abundance.

(Don's *Gardener's Dictionary*; Babington's *Manual of British Botany.*)

ONOPORDUM, a genus of plants belonging to the natural order Compositæ. It has a honeycombed receptacle, a four-ribbed fruit, and an imbricated involucre, with simple spinous pointed scales.

O. Acanthium, Cotton-Thistle, has an erect many-headed stem, elliptic oblong leaves, woolly on both sides; serrate, spinous, and decurrent; the outer involucral scales lanceolate, subulate, recurved, and spreading. The stem is from four to five feet high; woolly, with broad spinous wings; the involucre nearly globose, large, and somewhat cottony; the scales fringed with spinous teeth; the florets are purple. This plant is found on waste ground in Great Britain and Spain. Another name for the same species is Wild Artichoke, or *Alcachofa* of the Spaniards, on account of the fleshy receptacle being once cultivated as an esculent vegetable. The expressed juice of this plant is said by Eller to be a serviceable application to cancer of the breast, and to cleanse foul ulcers; and a decoction of the root, which is astringent, has been used to restrain discharges from the mucous membranes. The seeds are oleiferous; and M. Durand reports, as the result of experiments, that 22lbs. of onopordum heads will yield 12lbs. of seeds, from which 3lbs. of oil fit for burning may be extracted by heat.

(Babington's *Manual of British Botany*; Burnett's *Outlines of Botany.*)

ONOSMA (from ὄνος, an ass, and ὀσμή, smell: grateful to the ass), a genus of plants belonging to the natural order Boragineæ. It has a five-parted calyx, a tubularly campanulate corolla, and a naked throat. The anthers are sagittate, and connected together by the bases of the lobes. The nuts are ovate, strong, and fixed to the bottom of the calyx, unperforated at the base. The species are small scabrous canescent plants, with crowded lanceolate or linear leaves, and terminal racemes of large yellow secund and usually drooping flowers.

O. Emodi has lanceolate triple nerved leaves, less hairy beneath, terminal solitary racemes, linear bracts, not half so long as the flowers; the calyx is five cornered with ovate segments, a ventricose five-keeled corolla contracted towards the mouth, and the anthers longer than the filaments. It is native of Nepaul, in Gosaingsthan, where it is called by the natives *Moharanga*. The root is branched, of a dark purple colour, and is used in dyeing.

O. echinatum is a hispid plant, covered with white pungent hairs. It has terminal racemes and pedicellate flowers. The corolla is yellow, a little longer than the calyx, tubularly campanulate with reflexed teeth.

O. tinctorium is native of Tauria, in the vicinity of the Bosphorus. The root is simple, blackish, and covered with a red pigment, which stains paper a violet colour.

All the species of this genus, which exceed thirty in number, are extremely handsome when in blossom, but are not valuable on account of any peculiar properties. Most of them are natives of rocks and sandy places in Europe and Asia, and answer well to grow in rock work or wall tops. They are short-lived, and apt tu rot. They do well, however, in pots among other alpine plants.

(Don's *Gardener's Dictionary.*)

OOSTERHOUT, situated in 51° 30′ N. lat. and 4° 52 E. long., is a market-town in the province of North Brabant, in the kingdom of the Netherlands. The population is about 8000 inhabitants. There are numerous potteries, brick-kilns, and three annual fairs for cloth, linen, and shoes.

(Stein, *Lexicon*; Hassel, *Handbuch*; Cannabich, *Lehrbuch.*)

OPACITY is a condition of bodies by which they are incapable of transmitting light through them. It seems to depend upon the nature or disposition of the particles of bodies, but its precise cause is, at present, far from being understood. According to Newton, opacity may arise from the unequal densities of the particles of certain substances, in consequence of which the rays of light on entering those substances suffer such refractions and reflexions as compel them there to remain, and cause them to be finally absorbed; while, in bodies of a homogeneous nature, as glass, diamond, &c., the light experiences so much less of these irregular actions that, except when the thickness of the medium is very great, it is enabled to pass quite through them.

The entire absorption of all the light which enters a substance, merely by the multiplied refractions or reflexions which it undergoes within the mass, is difficult to conceive; and the advocates of the undulatory theory ascribe opacity to the unfitness of the pores, or intervals between the particles of a body, for permitting the vibrations of the particles of æther, and consequently for continuing in the interior the existence of the waves which are incident on its surface. The same persons consider transparency to consist in such a dispositiun of the particles of a body that the incident waves of æther can be propagated with a certain degree of freedom through the mass: some impediment to the propagation of the waves may exist in the most transparent substances; and hence when such substances have more than a certain thickness, the waves cease to be transmitted through them. [TRANSPARENCY, P. C.; ABSORPTION OF LIGHT, P. C. S.]

OPERATION. In this article we intend to point out the principal steps of the application of the calculus of operations [OPERATION, P. C.] to the solution of differential equations and equations of differences. The article just cited must be carefully read before the present one, and also the general principles laid down in ALGEBRA, P. C. S.

However much the calculus of operations may throw light upon the character and principles of algebra, it would at one time have been thougnt unlikely that it should much facilitate actual processes. It does this, nevertheless, and nowhere more than in the subject we are now going to describe. Solutions which by the usual method [VARIATION OF PARAMETERS, P. C. S.] would never have been considered fit examples for an elementary work, on account of their complexity, may be represented with ease, and obtained in full with very little trouble.

When rules of algebra are true of the meanings of any symbols, all consequences of the use of these rules, all relations which are legitimate deductions from them, also represent truths. Not that these truths are always intelligible without subsequent interpretation: nor do we mean to say that, in the present state of the science, the interpretations are always attainable. And further, it may happen that theorems can be pointed ont, derived from processes in which *some* only, and not *all*, of the fundamental rules of algebra are true. This does not prevent our right to deduce conclusions from such theorems, as long as we use no fundamental rules except those which are true of the expressions in question. For instance, we have seen that the operations of our calculus are not convertible with the operation of multiplying by a function of the variable. Thus if E stand for the direction to change x into $x+1$, Δ for that of forming the difference thence arising, and D for the direction to take the differential coefficient with respect to x, we have no right to say $E\phi x(\psi x)=\phi x E(\psi x)$, or $\Delta\phi x(\psi x)=\phi x\Delta(\psi x)$, or $D\phi x(\psi x)=\phi x D(\psi x)$; in which ψx is the function operated upon. But, when we thus use another function, ϕx, besides the one operated on, ψx, this convertibility of operations is the only rule of algebra which fails; it is therefore the only one the use of which we must avoid.

The operations E, Δ, and D, are closely connected with $E+a$, $\Delta+a$, $D+a$, of which they are particular cases; a being a constant, positive, negative, or nothing. We have

$$(E-a)\,.\,\phi x=a^{x+1}\Delta(a^{-x}\phi x)$$
$$(\Delta-a)\phi x=(a+1)^{x+1}\Delta\big((a+1)^{-x}\phi x\big)$$
$$(D-a)\phi x=\epsilon^{ax}D(\epsilon^{-ax}\phi x).$$

The first sides of these equations being representatives of $\phi(x+1)-a\phi x$, $\Delta\phi x-a\phi x$, and $\phi' x-a\phi x$. If these operations be repeated, we have

$$(E-a)^m\phi x=a^{x+m}\Delta^m(a^{-x}\phi x)$$
$$(\Delta-a)^m\phi x=(a+1)^{x+m}\Delta^m\big((a+1)^{-x}\phi x\big)$$
$$(D-a)^m\phi x=\epsilon^{ax}D^m(\epsilon^{-ax}\phi x).$$

These results will also be found to be true when m is negative, by which means we are enabled to interpret $(D-a)^{-1}$, $(\Delta-a)^{-1}$, and $(E-a)^{-1}$ and their repetitions.

These same forms may be extended, as follows:—Let E_x and E_y severally denote the operations of changing x into $x+1$ and y into $y+1$; and let D_x, D_y, Δ_x, Δ_y, be similarly interpreted with respect to the differentiations and differences. We have then

$$E_x-a)^m\,(E_y-b)^n=a^{x+m}\,b^{y+n}\,\Delta_x^m\,\Delta_y^n\,a^{-x}\,b^{-y}$$
$$(\Delta_x-a)^m\,(\Delta_y-b)^n=(a+1)^{x+m}\,(b+1)^{y+n}\,\Delta_x^m\,\Delta_y^n$$
$$(a+1)^{-x}\,(b+1)^{-y}$$
$$(D_x-a)^m\,(D_y-b)^n=\epsilon^{ax+by}\,D_x^m\,D_y^n\,\epsilon^{-ax-by};$$

in which the function first operated upon is left out to save room. Here m and n may be either positive or negative integers. And even a or b may be symbols of operation, but not with respect to x or y. Thus

$$(D_x-a\,D_y)^m=\epsilon^{axD_y}\,D_x^m\,\epsilon^{-axD_y},$$

in which the second side is to be thus interpreted. Changing y into $y-ax$, differentiate m times with respect to x, and then change y into $y+ax$.

We shall now give the heads of some methods of solution, observing that this article is intended only for those who can already master the same solutions by other methods.

Take the common linear equation—

$$a\frac{d^my}{dx^m}+b\frac{d^{m-1}y}{dx^{m-1}}+\ldots=X,$$

in which a and b are constants, and X a function of x. The operation performed upon y is $aD^m+bD^{m-1}+\ldots$: if this be called G, then y is the result of performing the inverse operation G^{-1} upon X. By the method explained in FRACTIONS, DECOMPOSITION OF, P. C. S., transform $(aD^m+bD^{m-1}+\ldots)^{-1}$ into $A(D-\alpha)^{-1}+B(D-\beta)^{-1}+$, &c., where α, β, &c. are the roots of the algebraical equation $ax^m+bx^{m-1}+\ldots=0$ Then y is

$$A(D-\alpha)^{-1}\,X+B(D-\beta)^{-1}\,X+\ldots$$
$$\text{or } A\epsilon^{\alpha x}\!\int\!\epsilon^{-\alpha x}\,X dx+B\epsilon^{\beta x}\!\int\!\epsilon^{-\beta x}\,X dx+\ldots.$$

substituting for D^{-1} its usual mode of expression. The arbitrary parts of the solutions will be obtained by the constants of integration in the usual manner. But the arbitrary part will always be obtained, in all inverse operations, by considering the function operated upon as $X+0$, and operating separately npon X and 0. Thus $(D-a)^{-3}$ X may be completely expressed by

$$\epsilon^{ax}(\textstyle\int dx)^3\,\epsilon^{-ax}\,X+\epsilon^{ax}(\int dx)^3\,\epsilon^{-ax}\,0,$$

the second term of which is $\epsilon^{ax}(P+Qx+Rx^2)$, P, Q, and R being any constants.

Suppose that there are equal roots in the above equation, say three roots equal to a. The resolution of the fraction gives terms of the form

$$K(D-a)^{-3}+L(D-a)^{-2}+M(D-a)^{-1},$$

which contribute to the general value of y,

$$\epsilon^{ax}\{K(\textstyle\int dx)^3+L(\int dx)^2+M\int dx\}\epsilon^{-ax}\,X,$$

and the arbitrary part $\epsilon^{ax}(P+Qx+Rx^2)$.

The lincar equation of differences corresponding to the above is

$$au_{x+n}+bu_{x+n-1}+\ldots=X,$$

where u_x is a function of x to be determined. The operation performed on u_x on the first side is $aE^n+bE^{n-1}+\ldots$

Every single root a, contributes to the solution a term of the form

$$A(E-a)^{-1}.X \text{ or } a^{x-1}\,\Delta^{-1}(a^{-x}\,X),$$

in which $\Delta^{-1}\,a^{-x}$ X may be any function of which the difference is a^{-x} X. If x be an integer, what is called $\Sigma(a^{-x}\,X)$ will do. Any set of equal roots contributes terms of the form

$$A(E-a)^{-k}\,X \text{ or } Aa^{x-k}\,\Delta^{-n}(a^{-x}\,X).$$

Any linear equation being given, in which either of the operations E_x, Δ_x, or D_x is combined with either E_y, D_y, or D_y, the form of the solution may be found. Take for example

$$\frac{d}{dx}u_{x,y}-au_{x,y+1}=X,$$

the operation performed upon $u_{x,y}$ on the first side is D_x-aE_y, and accordingly we have

$$u_{x,y}=\epsilon^{axE_y}\!\int\!\epsilon^{-axE_y}X dx,$$

which is one form of the solution, and must be interpreted by expanding

$$\epsilon^{\pm axE_y}\text{ into } 1\pm axE_y+\frac{1}{2}a^2x^2E_y^2\pm\ldots.$$

Another form can be obtained from

$$(E_y-\frac{1}{a}D_x)u_{x,y}=-\frac{1}{a}X.$$

We can only touch very briefly upon these points, and rather to show the existence of the system than to enter into it. Further details will be found in the *Library of Useful Knowledge*, in the 'Treatise on the Differential Calculus,' pp. 751-758.

The theorems answering to that of integration by parts, when $D-a$ and $E-a$ are used, are as follows. To save room let $D-a$ and $E-a$ be denoted by Θ and Λ. Then

$$\Theta^{-1}(PQ)=P\Theta^{-1}Q-\Theta^{-1}\{P'\Theta^{-1}Q\}$$
$$\Lambda^{-1}(PQ)=P\Lambda^{-1}Q-\Lambda^{-1}\{\Delta P.\Lambda^{-1}EQ\}$$

P and Q being functions of x, to which D and E refer, and P$'$ meaning $dP:dx$. If $a=0$, the first becomes

$$\int PQdx=P\!\int\! Qdx-\int\{P'.\textstyle\int Qdx.dx\},$$

which is the formula for integration by parts. And if Q be of the form Θ^nR, or Λ^nR, and P be a rational and integral function of a lower degree than the nth, the preceding operations carried on will show that $\Theta^{-1}(P\Theta^nR)$ and $\Delta^{-1}(P\Delta^nR)$ can be performed without leaving any trace of inverse operation in the result. Of the first of these it is a particular case that

$$\int P\frac{d^nR}{dx^n}dx$$

can be found whenever P is a rational and integral function of a lower degree than the nth. Thus, P being of the second degree

$$\Theta^{-1}(P\Theta^4R)=P\Theta^3R-P'\Theta^2R+P''\Theta R$$

$$\Delta^{-1}(P\Delta^3R)=P\Delta^2R-\Delta P.\Delta ER+\Delta^2P.E^2R.$$

By help of these theorems the intermediate equations of any linear equation can be readily discovered. Suppose, for instance, we have

$$(D-1)^5(D-2)^3y=X,$$

an equation of the eighth degree. There are eight equations of the seventh degree. Two of them are discovered at once by performing the operations $(D-1)^{-1}$ and $(D-2)^{-1}$ on both sides, giving

$$(D-1)^4(D-2)^3y=\epsilon^x\int\epsilon^{-x}Xdx,$$

$$(D-1)^5(D-2)^2y=\epsilon^{2x}\int\epsilon^{-2x}Xdx.$$

To find the other six, multiply separately by x, x^2, x^3, x^4, the simplest functions of their several degrees, and perform $(D-1)^{-1}$ upon all four results, and $(D-2)^{-1}$ upon the first two. This, by the preceding theorems, can be done. Thus, multiplying by x we have

$$(D-1)^5\{x(D-2)^2y-(D-2)y\}=\epsilon^{2x}\int\epsilon^{-2x}xXdx,$$

$$(D-2)^3\{x(D-1)^4-(D-1)^3y\}=\epsilon^x\int\epsilon^{-x}xXdx,$$

which are two more of the required equations. To find the equations of the sixth degree, those of the seventh degree must be selected which admit of a repetition of the operation without leaving the inverse form $(D-2)^{-1}y$ or $(D-1)^{-1}y$: and the operation must be repeated; and so on.

(See the *Cambridge Mathematical Journal*, vol. iv., pages 60, 96. This work abounds in uses of the calculus of operations; it was here in fact that the late D. F. Gregory first introduced this branch of it. See also the *Examples of the Differential Calculus*, by the same author. Mr. Boole, in a recent volume of the *Philosophical Transactions*, has given great and ingenious extensions to the subject.

OPHI'DIUM (from ὄφις, a snake), a genus of malacopterygious fishes of the Eel tribe. The species have smooth heads; long slender bodies, margined by the united dorsal, anal, and caudal fins. The jaws, palate, and pharynx are all furnished with teeth. The branchial aperture is large. The species vary in form and colour, and in the presence, absence, and number of filamentous appendages or beards attached to the under jaw. Two species inhabit the British seas, but are both very rare. In the Mediterranean, the bearded ophidium is common, and is used for food.

OPHIOCE'PHALUS (from ὄφις, a snake, and κεφαλή, head), a genus of fishes belonging to the division of *Acanthopterygii*, characterised by having labyrinthiform pharyngeals, and capable of living for a long time out of the water. The species inhabit India and China. [ANABAS, P. C. S.]

OPHIOGLOSSUM (from ὄφις, a snake, and γλῶσσα, the tongue), a genus of plants belonging to the natural order Filices and the tribe Ophioglosseæ. The thecæ are connate, disposed in a simple distichous spike attached to an undivided frond.

O. vulgatum, Adder's Tongue, is the only British species. It has an ovate obtuse frond, and is from 4 to 12 inches in height. The spike is club-shaped, usually rather longer than the frond, sometimes very long. This plant is generally distributed over England, and in many places is exceedingly common, covering large plots of ground, and is highly injurious to the crop of grass. It is less frequent in Wales, Scotland, and Ireland. It is a common plant on the continent of Europe, and is said to occur in Africa and North America. Like most singular-looking plants, it has been used in medicine. Ray recommended an ointment composed of oil and adder's-tongue. Gerarde says that the 'Adder's Tongue is dry in the third degree. The leaves of Adder's Tongue stamped in a stone mortar and boiled in oile olive vnto the consumption of the juice and until the herbes be dry and parched, and then strained, will yeeld a most excellent greene oyle or rather a balsame for greene wounds comparable to oile of St.-John's-wort, if it do not far surpass it by many degrees, whose beauty is such that very many artists have thought the same to be mixed with verdigris.' Lightfoot says that the common people in Scotland make an ointment of the green leaves, and use it as a vulnerary. It is also used in the same way in many parts of England.

(Newman, *British Ferns*; Babington, *Manual of British Botany*.)

OPHIO'XYLON (from ὄφις, a serpent, and ξύλον, wood, because it has a twisted root and stems), a genus of plants belonging to the natural order Apocynaceae. It has a 5-cleft permanent calyx, a funnel-shaped corolla with a long tube, thickest in the middle, and a 5-cleft oblique limb. The anthers are subsessile, inserted into the middle of the tube. The ovary is double, each lobe with one ovule, a filiform enclosed style and a capitate stigma. The drupes are baccate, black, about the size of a pea, twin, or solitary by abortion, each containing a one-seeded wrinkled nut.

O. serpentinum, Serpentine Snake-Wood, is native of the East-Indies. In rich soil it becomes a climbing plant, but in poor soil it is a small erect shrub. The leaves are in threes or fives; they are short-stalked, oblong, pointed, wavy, and smooth. The peduncles are long, smooth, round, sometimes nearly erect, sometimes drooping. The pedicels and calyxes are of a bright red colour, and the corollas white. In India the root of this plant is employed by the Telinga physicians as a remedy in many diseases. It is given inwardly as a febrifuge and after the bite of poisonous animals. The juice is also expressed and dropped into the eye for the same purpose, and it is likewise given to promote delivery in tedious cases of labour. This plant is of easy culture and beautiful appearance. A mixture of loam, peat and sand is the best soil, and cuttings will readily strike root under a glass in heat.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany*.)

OPHRYS, a genus of plants belonging to the natural order Orchideae. It has a patent perianth, a variously-lobed lip without a spur. The glands of the stalks of the pollen masses each in a distinct pouch.

O. apifera, Bee Orchis, has a tumid 5-lobed lip, the two lower lobes prominent and with a hairy base, the two intermediate reflexed, truncate, terminal, acute, elongated and reflexed; the anthers with a hooked point, the petals oblong, bluntish, downy. It is about a foot high, and has large, few, and rather distant flowers. The sepals are whitish tinged with purple. The lip is velvety, brown, variegated with yellow. It is one of the handsomest species of orchidaceous plants, native of Great Britain, and grows on chalky calcareous soils.

O. arachnites, late Spider Orchis, is distinguished by a terminal, inflexed, flat, rather heart-shaped appendage, and deltoid downy petals. The sepals are pink, the lip dark purple variegated with yellow and velvety, the appendage green, never reflexed. It is found on chalk downs near Folkstone and Sittingbourne in Kent.

O. aranifera, Spider Orchis, has 3 obscure lobes, the middle lobe large, emarginate, without an appendage, the petals linear and glabrous. This species is smaller than the preceding, and with fewer flowers. The petals and sepals are green and quite glabrous. The lip is of a dark brown colour, hairy, and covered with pale or yellowish lines. It is found in chalky places in Kent and Sussex.

O. muscifera, Fly Orchis, has an oblong trifid lip with a large pale spot in the centre, the middle lobe is elongated, bifid, the anthers short and obtuse, and the petals filiform. It is a slender plant and grows about a foot high. The petals are very narrow, and of a purple colour, the sepals green, and the lip of a purplish brown colour, the spot in the centre of a bluish tinge. It is found in damp calcareous thickets and pastures in Great Britain.

(Babington, *Manual of British Botany*.)

OPORINIA, a genus of plants belonging to the natural order Compositae. It has a subimbricated involucre, the exterior scales much smaller in several rows, a punctured receptacle, attenuated uniform fruit; the pappus of all the fruit in one row, feathery, dilated at the base.

O. autumnalis has radical leaves, linear, lanceolate, toothed, or pinnatifid, nearly glabrous; stalk branched, scaly, and thickened upwards, the involucre glabrous or hairy. This is the *Apargia autumnalis* of Smith, and the *Leontodon autumnalis* of Koch. It is a native of Great Britain in meadows and pastures and on lofty mountains.

(Babington, *Manual of British Botany*.)

OPOPANAX, a genus of plants belonging to the natural order Umbelliferæ; it has an obsolete calyx, roundish entire petals rolled inwards, with a rather acute lobe; compressed fruit with a dilated convex border, bipinnate leaves with unequally cordate segments, crenated and obtuse. The umbels are compound; the involucre both universal and partial, and the flowers yellow.

O. Chironum is a native of the south of Europe and Asia Minor, on dry hills, margins of fields, and thickets. It is a plant six or seven feet high, of a dull yellowish colour, and resembling a parsnip. The stem is strongly furrowed; the leaves from one to two feet long, or more, flat, bipinnate, with ovate cordate leaflets, which are usually oblique at the base, often confluent, and surrounded by a cartilaginous crenated border. The calyx is inconspicuous, the styles rather short and stout. Although this plant is a native of the south of Europe, the resinous gum which exudes from the stalk or root when wounded is brought from the Levant and East Indies in roundish drops of a reddish yellow colour, with specks of white. It is supposed to be an emmenagogue, but it is seldom used; it is similar in its effects to assafoetida. This is a plant of easy culture, and may be propagated either by seeds or dividing at the root.

(Don's *Gardener's Dictionary*; Lindley's *Flora Medica*.)

OPTO'METER (from the Greek words ὄπτομαι, to see, and μέτρον, a measure) is an instrument devised for the purpose of ascertaining with precision the refractive powers of lenses, and the distances at which minute objects may be distinctly seen. The idea originated with Scheiner; but such an instrument was constructed by Dr. Porterfield for the purposes just mentioned, and was afterwards improved by Dr. Thomas Young.

Dr. Porterfield's contrivance consisted of a convex glass lens affixed by its frame to a slip of wood about two feet long: a pencil of light, diverging from a radiant point in the axis of the lens, was suffered to fall on a plate of metal in which were two small perforations; and the rays which passed through these, after being refracted in the lens, were received on a screen, where they formed in general two bright spots, but in certain positions of the lens and screen the spots united so as to form but one image. The distance of the single image from the lens, being measured by a scale of inches, constitutes the focal length of the lens for rays diverging from the radiant point. Dr. Porterfield used the instrument to determine the distance at which distinct vision of a small object takes place in the eye; the latter being substituted for the screen, to receive the rays coming from the object through the two perforations.

The instrument constructed by Dr. Young consisted of a slip of ivory, unpolished, or of wood covered with white paper, about eight inches long and half an inch broad, on which, in the direction of its length, was drawn a narrow and well-defined black line. At one extremity of the slip was fixed a plate of ivory, or a piece of card, nearly perpendicular to its length, and this was perforated either with a single aperture or with two apertures at distances from one another varying from $\frac{1}{40}$th to $\frac{1}{8}$th of an inch, but not exceeding the diameter of the pupil of the eye.

On applying the eye to a single aperture, and looking in the direction of the line drawn on the instrument, the line appears to have a certain breadth, and to be ill defined, at the nearest extremity: the breadth gradually diminishes at points successively more remote till it becomes a minimum, when the line becomes distinct; beyond that point the line gradually increases in breadth, becoming again ill defined. On applying the eye to a double aperture, the line appears to be double, the parts seeming to cross one another at a very acute angle, and the intersection is at the place where a single line would have had the minimum breadth: beyond this intersection the two lines appear to diverge from one another, and to become indistinct. The point of intersection is that at which a minute object being placed, its image would be distinctly seen by the eye at the aperture, and its distance from the eye may be immediately found by means of a scale of inches on the instrument, a sliding index being, at the time of making the observation, moved to the point of intersection.

This distance affords, evidently, a measure of the refractive power of the observer's eye; since rays of light diverging from a small object at that distance are, by the lenses of the organ, made to converge accurately to a point on the retina, so as to form there a single and well defined image. If the object were brought either nearer to or removed farther from the eye, the rays, after passing through the two apertures, would form two images, both of which would appear to be less perfectly defined than the single image.

It being assumed that a person whose sight is perfect sees a small object distinctly at the distance of 8 inches from the eye, Dr. Young obtained by computation a series of numbers which he placed on the scale of the optometer, at such distances from the plate containing the apertures, that a spectator having a *presbyopic* eye (or one which, like those of most persons who are advanced in life, has distinct vision of small objects only when they are at greater distances than 8 inches) on looking through the slits and observing the place where the two images of the line cross each other, might ascertain at once, by the number at the place, the focal length of a convex lens which would enable him to see distinctly at 8 inches. He also computed a series of numbers which he placed on the scale in such situations that a person having a *myopic* eye, or one which has distinct vision of objects at less than that distance from it, on observing the place at which the lines appeared to intersect one another, might ascertain the virtual focus of a concave lens which would enable him to see distinctly at 8 inches. The optometer thus became a means of enabling persons to make choice of the proper lenses for spectacles which would correct the imperfections of their natural vision.

But the scale of Dr. Young's optometer being, for convenience, only 8 inches long, and the inferior limit of distinct vision in a presbyopic eye being beyond that distance, Dr. Young applied to his instrument a convex lens 4 inches focus, by which the point of distinct vision for such an eye was reduced within 8 inches from it: the numbers on his scale were therefore computed for the instrument when furnished with such a lens.

Dr. Young used the optometer for the purpose of determining the refractive powers of the eye, not only in its usual state, but also when, in cases of cataract, the crystalline lens had been displaced or extracted, and when the effect of the cornea had been rendered null by immersing the anterior part of the eye in water, which was contained in a cell of a proper form, and having a plane glass in front. By such means he endeavoured to ascertain in what manner the eye accommodates itself to distinct vision for objects at different distances from it; and his conclusion is that the faculty depends entirely (*Lectures on Natural Philosophy*, vol. ii. pp. 575-603) upon changes of figure which take place in the crystalline lens.

ORCA'GNA, or **L'ARCA'GNUOLO**, is the name by which Andrea di Cione, a celebrated old Florentine artist, is generally known; he is by Rumohr first called L'Archagnuolo, which appears to be his proper name. Vasari calls him Orgagna. He was painter, sculptor, and architect; was born at Florence in 1329, according to Vasari, or according to other accounts about 1315 or 1320, and was probably first instructed in art by his father Cione, who was a celebrated goldsmith; from him he passed into the school of Andrea Pisano.

He painted several works, together with his brother Bernardo, in the churches of Florence, and also in the Campo Santo at Pisa, where the Triumph of Death and the Last Judgment were by Andrea, and the Hell by Bernardo; the Last Judgment and the Hell are engraved by Lasinio on a single plate in his 'Pitture del Campo Santo di Pisa:' Orcagna repeated them in Santa Croce at Florence: he had painted previously in the Strozzi chapel in Santa Maria Novella, a picture of Hell from Dante's 'Inferno,' in which he introduced the portraits of several of his enemies. As an architect, he built the elegant Loggia de' Lanzi in the Piazza Granduca at Florence, which is still in perfect condition — it and its sculptures are engraved by Lasinio in Misserini's 'Piazza del Granduca di Firenze, con i suoi Monumenti,' Florence, 1830. He built also the church of the monastery of Or' San Michele, and designed the celebrated tabernacle of the virgin of that monastery. It is a high Gothic pyramidal altar to the Virgin, free on all sides, is built of white marble, and is richly ornamented with figures and other sculptures. The following words are inscribed on the base: 'Andreas Cionis pictor Florentinus oratorii archimagister extitit hujus, MCCCLIX.' It is engraved in Richa's 'Notizie delle Chiese di Firenze,' after a drawing by Andrea himself. Orcagna generally signed himself painter upon his sculptures, and sculptor upon his pictures; on his pictures he wrote 'Fece Andrea di Cione, Scultore;' on his sculptures, 'Fece Andrea di Cione, Pittore.' He was also a poet. Vasari mentions some sonnets which he addressed to Burchiello; and in the works of Burchiello, published in London in 1757, there is a sonnet addressed to Orcagna. He died at Florence according to Vasari in 1389, but according to Manni in 1375.

He was a man of great taste in architecture, and has the credit of having been the first in those ages to adopt the semicircular arch in preference to the pointed; but to this merit, if one, he is not entitled, though his elegant 'Loggia de' Lanzi' may have contributed greatly towards the subsequent popularity of that form of the arch in Italy: Arnolfo di Lapo, however, and other earlier architects, used the semicircular arch. Those, says Lanzi, who are fond of minute detail in minute things, may consult Baldinucci, Bottari, and Manni, concerning Andrea di Clone; Rumohr, however, was the first to show his real name, of which Orcagna is a contraction, Lo Archagnuolo Lo 'rchagnio l' orchagno. In painting, Orcagna did not go beyond Giotto; in sculpture he was a worthy follower of the Pisani. According to his epitaph, which is given by Vasari in the first edition only of his work, he was chiefly excellent as a sculptor, or rather statuary:—

Hic jacet Andreas, quo non praestantior alter
Aere fuit; patriae maxima fama tuae.

His portrait, published in Vasari's work, was taken from one of the figures of the apostles in the above mentioned tabernacle of the Virgin, which is understood to be his own.

(Vasari, *Vite de' Pittori*, &c., and the Notes to Schorn's German translation of Vasari; Rumohr, *Italienische Forschungen*.)

ORDER IN COUNCIL. This expression is chiefly known in connexion with the measures taken by the British government in 1807 and 1809, in retaliation of the Berlin and Milan decrees of Napoleon, by which Great Britain and her colonies were declared in a state of blockade. The measure of retaliation had the effect of treating as enemies, not only France and its dependencies, but all who, either voluntarily or by compulsion, gave obedience to the decrees. A full account of the matter will be found under the head BLOCKADE, P. C. There has been much dispute as to the legality of these orders. The law of nations has acknowledged the blockading of lines of coast against the commerce even of neutral or friendly powers, when the object is to punish the state so blockaded, and the belligerent power has a force on the spot sufficient to make the blockade actual and physical. But where a belligerent power goes beyond this, and declares some place at which it has no armed force under a state of blockade, it simply issues an edict against the freedom of commerce, authorizes its cruisers to seize vessels which are not impeding any warlike operations, and covertly declares hostilities against the states affected by the fictitious blockade. The law of nations has never countenanced such a licence, and it came to be a question whether these orders in council, being thus not of an executive but of a legislative character, were legal, the Privy Council not having any legislative authority in this country, except in so far as it may be authorized by act of parliament. In favour of the orders, it was maintained that they were merely part of the execution of the royal prerogative of declaring and conducting war, and that they were methods of legitimate retaliation, by which individuals undoubtedly suffered, as individuals always must where warlike operations are conducted on a large scale. Analogy was taken from the exercise of the crown's prerogative during war, in prohibiting the supplying of the enemy with commodities contraband of war—an interference with the freedom of commerce justified by the necessity of the case. But these arguments did not satisfy the country generally that the measure, if it was a right one, should not have been accomplished by Act of Parliament instead of Order in Council.

It is difficult to draw the line between what may and what may not be accomplished by Order in Council. There have been various occasions on which, in cases of emergency, orders in council have been issued contrary to law, and those who have been concerned in passing, promulgating, or enforcing them have trusted to legislative protection, and taken on themselves the personal responsibility of the proceeding. In the year 1766, when there was a deficient harvest and the prospect of famine, an order in council was issued prohibiting the exportation of corn from the British ports. In the immediately ensuing parliament the act 7 Geo. III. c. 7 was passed for indemnifying all persons who had advised the order or acted under it, and for giving compensation to all who had suffered by its enforcement. The act in reference to the order declared, 'which order could not be justified by law, but was so much for the service of the public, and so necessary for the safety and preservation of his majesty's subjects, that it ought to be justified by act of parliament.' All orders restricting trade—unless when they are within the justification of the national war policy—and all orders suspending the operation of any act of parliament, would require an act of indemnity. There are some matters affecting trade and the revenue, as to which orders in council are specially authorized by act of parliament. Thus in the Customs' Duties Act, when there is any scale of duties to be paid by the subjects of a state having a treaty of reciprocity with Britain, it is enacted that the treaty of reciprocity, and consequently the right to import at the lower duties, shall be declared by order in council. By the International Copyright Act, 1 & 2 Vict. c. 59, the countries which, by their conceding a term of copyright to works published in Britain are to enjoy a similar privilege here, may be declared by order in council.

OREGON QUESTION. The country known by the name of Oregon is bounded on the south by the parallel of 42° N. latitude, being the northern boundary of Mexico. On the north this territory is bounded by the parallel of latitude 54° 40′, or, more strictly, this is the northernmost point on the coast, for in this latitude the irregularly shaped boundary of the Russian possessions in America terminates. On the east of it are the Rocky Mountains, and on the west the Pacific Ocean. It occupies a space of about thirteen degrees of latitude and fifteen degrees of longitude. Besides the Rocky Mountains, there are two other ranges, one called the Far West or Cascade Range, and the other the Blue Mountains, dividing the country into three divisions, which are distinguished by peculiarities of soil and climate. The country between the Rocky and the Blue Mountains is almost uninhabitable by those who depend on agriculture. In the middle district rain never falls from April to November, and the soil is unpromising. The western district may be calculated, from latitude 42° to latitude 48° 30′, to be 6½ degrees in its extreme length, or less than 450 miles, and its average breadth about 100 miles, that is, 45,000 square miles is the superficial extent of this westernmost region of Oregon, or rather more than the extent of the state of Pennsylvania, to which it is much inferior in fertility. Indian corn does not succeed in any part of Oregon, from deficiency of rain. The valley of the river Willametty, a tributary of the Columbia, which is the most fertile district, is about 150 miles long and 60 broad. Wheat produces here about 20 to 30 bushels an acre. The winters are wet and stormy.

The territory north of the Columbia river and south of the parallel of N. latitude 49°, is that which is in dispute between the governments of Great Britain and the United States. It is bounded on the east and the south by the Columbia river, on the north-west by the Straits of Juan de Fuca, on the west by the Pacific Ocean, and is roughly estimated to be a little larger than the state of New York. Nine-tenths of the eastern half of this 'disputed territory' is described to be 'a worthless desert,'—the other half has a very large proportion of bad land. President Polk has claimed for the United States the territory between 49° N. latitude and 54° 40′, as well as south of 49° to latitude 42°. Between Frazer's river, or latitude 49° and 54° 40′, Captain Wilkes states, that nowhere on the coast could a settlement be formed that could supply its own wants.

The claims of Great Britain and of the United States are both founded on an alleged title derivable from discovery, settlement, and treaty. Some writers have added to these elements of title, what they call 'contiguity,' but this is of no importance in the dispute.

I. The discoveries along the coast have been as follows:—

Navigator's Name.	Flag.	Date.	Latitude reached.
Ulloa	Spanish	1539	30°.
Cabrillo	„	1542	37° 10′.
Ferrelo (Cabrillo's 'pilot')	„	1543	40° 20′ or 43°.
Drake	English	1579	48°.
Gali, or De Gualle . .	Spanish	1584	37½° or 57½°.

[The 57½ is an alteration of a translator; the origiual account is 37½, *in words*, not figures.]

Viscaino	Spanish	1596	42°.
D'Aguilar	„	1596	43°.
Perez	„	1774	55°.
Heceta	„	1775	49° 30′.

[Inferred the existence of the Columbia from the general appearance of the embouchure or bay, and named it San Roque.]

De La Bodega . . .	Spanish	1775	58°.

[These last three voyages were kept secret by the Spanish Government.]

Navigator's Name.	Flag.	Date.	Latitude reached.
Cook	English	1778	44° to beyond 60°.

[Exact discovery scarcely began till Cook.]

Commercial Expedition	Russian	1783	60°.

[Planned from information obtained from King, Cook's successor. It started from the North, and proceeded no lower than 60°.]

Various commercial enterprises, chiefly English, then took place, which ended in the seizure of English vessels by the Spanish Officers at Nootka Sound in 1789. In these enterprises were the well-known names of Dixon, Portlock, Duncan, Colnett, Barclay, Douglas, and Meares; the last of whom may fairly stand next to Cook and Vancouver as a discoverer, in the immediate region north of the Columbia.

Vancouver	English	1792	Surveyed the Coast.

[Inferred the existence of the Columbia from the *river-coloured* water.]

Gray . . .	American merchant	1792	Entered the Columbia.
Baker . . .	English merchant	1792	Entered the Columbia.

[Broughton found Baker there, who stated that he had also been there in the earlier part of the year.]

Broughton, Vancouver's Lieutenant, surveyed the Columbia for upwards of 100 miles above the æstuary, and *took possession*, with the consent of the Indians.

The following are romances.

Lorenzo Maldonado . .	Spanish	1588	
Juan de Fuca	„	1592	Professed to have discovered the North-west passage by sailing *through* the Continent of North America.
Fonte, or De Fuentes . .	Spanish	1640	77°.

This last is a palpable forgery—and was first published in 1708, in London, in 'The Monthly Miscellany, or Memoirs of the Curious.' Neither Fuentes nor Fuca was ever noticed by Spanish writers. Fuca invented his story with a view of getting employed by Elizabeth; Fuentes never existed.

Hakluyt, in his 'Collection of Voyages,' published in 1589, states that Drake merely reached the lat. 42°, but his account is interpolated in the volume which contains it, and he appears to have intended to suppress it. In the edition of 1600 Hakluyt places the northern point of Drake's voyage in latitude 43°.

The authorities for the higher latitude are: 1, 'The World Encompassed,' printed in 1628, under the superintendence of Francis Drake, a nephew of the admiral, which states that the coast 'was searched diligently even unto 48°.' 2ndly, Fletcher, who accompanied Drake, and whose MS. is in the British Museum. 3rdly, the celebrated navigator John Davis, in 'The World's Hydrographical Discovery,' printed in 1595, says, that Sir F. Drake 'coasted all the Western shores of America until he came in the septentrional latitude of forty-eight degrees, being on the back side of Newfoundland.' An authority which ought to decide the question of the limit of Drake's discoveries. 4thly, Admiral Sir W. Monson, who had served under Drake, and who says that Drake 'ventured upon an unknown sea in forty-eight degrees.'

In the account of the Spanish expedition under Galiano and Valdes, published by the order of the King of Spain, at Madrid, in 1802, is this passage—'The true glory which the English navigator (Drake) may claim for himself is, the having discovered the portion of coast comprehended between the parallels of 43° and 48°, to which consequently the name of New Albion ought to be limited, without interfering with the discoveries of preceding navigators.'

The discovery of the coast was, therefore, made by the British. But even if Drake had not discovered it, still, according to the principles laid down by jurists, the exploration of Cook would be treated as conferring a title by discovery, since the voyages of Perez, Heceta, and Bodega were not made known until 1802. (Wolff, 'Institutes du Droit des Gens,' § 213; Vattel, book I. l. xviii. § 207.) The discovery must be made public, otherwise the presumption is against it, or that it was a mere passing act, or that occupation not being intended, the territory was abandoned. Publicity is essential to enable foreign nations to recognise and respect the title founded on it.

Such was the condition of the title by mere discovery when the Spanish officer, Captain Martinez, in May, 1789, seized the British vessels the 'Iphigenia,' 'North-West America,' and in July the 'Argonaut,' Captain Colnett, and the 'Princess Royal.' A correspondence ensued between the governments of Great Britain and Spain, which occasioned a message from the king to both Houses of Parliament, delivered May 25, 1790, stating that 'no satisfaction was made or offered for the acts of seizure, and that a direct claim was asserted by the court of Spain to the exclusive rights of *sovereignty*, navigation, and commerce in the territories, coasts, and seas in that part of the world.' The claim of *sovereignty* made by Spain was objected to, and Mr. Pitt stated that 'it was indefinite in its extent, and had originated in no treaty nor formal establishment of a colony, nor rested on any one of those grounds on which claims of *sovereignty*, navigation, and commerce usually rested.'

This dispute was terminated by the Convention of the Escurial, dated October 28, 1790, the third article of which declared that 'the respective subjects of the contracting parties should not be molested in navigating or carrying on their fisheries in the Pacific Ocean or in the South Seas, or in landing on the coasts of those seas in places *not already occupied*, for the purpose of carrying on their commerce with the natives of the country, or of making *settlements* there.' Great Britain then renounced its title to exclusive possession, founded on mere discovery—and any similar claim on the part of Spain was abandoned. The Convention was condemned by the opposition in parliament, the chief speakers asserting that Great Britain ought to have excluded Spain, and not to have conceded to it the right to settle on the coast. When it was asked where settlements could be made, Mr. Pitt replied that he should esteem the government highly culpable if it neglected to ascertain by actual survey.

Captain Vancouver was sent by the British government to take possession of Nootka Sound, and to ascertain among other things how far to the north Spanish settlements had been established. He sailed from Deptford, January 6, 1791. Nootka Sound was delivered to him, but having a discussion on the extent of his instructions with the Spanish officer, Quadra, Lieut. Mudge was sent to England for further orders. Ultimately, in March, 1795, Nootka was delivered up to Lieut. Pierce of the marines.

It was while Vancouver was on this voyage that he received information that in May, 1792, Captain Gray, of the ship Columbia, from Boston, had entered the æstuary of the river now known by the name of this ship. Vancouver had on the 27th of April observed the 'river-coloured' water of the sea, but he did not attempt to enter the river in consequence of being directed by his instructions not to pursue any other inlet or river than should be navigable by vessels of a burden safely to navigate the Pacific. Shortly afterwards Lieut. Broughton in the Chatham, the consort of Vancouver's vessel, entered the æstuary, and found there the 'Jenny' of Bristol, Captain Baker, who had been there before in the early part of the year. Lieut. B. explored the æstuary, discovered where the river entered it, which Gray had not done, and ascended the river above 100 miles—'taking possession' in the name of his sovereign. Gray, it must be observed, was a mere private trader, without a commission from his government: the coast had been previously discovered, and his own government never noticed his proceedings until 1814. But if he had had a commission, the discovery of the entrance to the river was a geographical merit conferring no rights, for rivers follow the title to the coast, and their discovery does not affect or impair such a title.

After Nootka Sound was delivered up in 1795, the Spaniards never made any settlement north of Cape Mendocino. They abandoned the country, and left the British to perfect their title by discovery, through occupation and settlement.

The subsequent expeditions to Oregon were as follow:—

Name of Traveller.	Flag.	Date.	
Mackenzie . . .	English	1793.	Crossed the Rocky Mountains and discovered Frazer's River.
David Thompson.	English	1800.	Crossed the Rocky Mountains, discovered and named the McGillivray River.
Thompson. . . .	English	1806.	First Settlement West of the Rocky Mountains, in 54°, speedily followed by other settlements among the head-waters of the Columbia.
Lewis and Clarke	American	1805-6.	Explored the Southern branches of the Columbia, and descended the main stream.

Name of Traveller.	Flag.	Date.	
Missouri Fur Company.	American	1808.	Established a post on the Southern arm of the Columbia or Lewis river.
Astor's Company . .	American	1811.	Established Astoria, at the Southern mouth of the Columbia, which was subsequently sold to the English North-West Company.
Thompson, North-West Co.	English .	1811.	Descended the Northern branch of the Columbia and main stream to the mouth.

The expedition of Mackenzie was the first made by civilized men west of the Rocky Mountains.

The posts and settlements made by Thompson were the first established by civilized men west of the Rocky Mountains, and Thompson and his followers were the first white persons who navigated the northern branch of the Columbia or traversed any part of the country drained by this branch of the river.

Astor's Pacific Fur Company consisted of Mr. Astor himself, six British subjects, and three citizens of the United States. Before those who were British subjects started, they asked for and received an assurance from the British minister at Washington—'that in case of a war between the two nations, they would be respected as *British subjects and merchants*.' The expedition received no sanction or support from the government of the United States. In 1813, the persons resident on the Columbia, having full power to do so, sold their establishment to the North-West Company. Subsequently in the same year, Captain Black, R.N., in the Racoon, took possession of Astoria in the name of his Britannic Majesty.

After the war the American government claimed Astoria, under an article of the Treaty of Ghent, made in December 1814, as a post *captured* during the war. This was not the fact; but in 1818 possession was formally delivered up, the British government having previously stated that the post had not been captured, and that the territory had early been taken possession of in his majesty's name (as it had been by Broughton); but that the question of title should be discussed in the negotiation on limits and other matters, which was soon to be commenced.' (Greenhow, 307, 310, 312.)

On the delivery of this post the United States for the first time exercised any act of sovereignty in Oregon. It was put into possession, but not relieved from proving its title, for its possession was derived from Great Britain.

In October, 1818, a treaty between Great Britain and the United States declared that the country should be open to the subjects of both powers for ten years, without prejudice to the claims of either power or to the claims of any *other* power.

In February, 1819, the United States made the Florida Treaty with Spain, which declared part of the west boundary of the United States to be along the parallel of latitude 42° to the sea, both parties ceding to each other, and respectively renouncing, all claims on either side of this line. The Americans pretend that this treaty confers a title to the coast north of 42°, though Spain never completed or obtained a title by occupation.

In August, 1827, a treaty between Great Britain and the United States extended indefinitely the provisions of the treaty of 1818, until determined by notice of a year, and it was not to impair the claims of *either* party. This treaty is still in force, but the Congress of the United States in April 1846, authorised the notice to terminate it to be given.

1. The government of the United States contend, notwithstanding their treaty of 1818, that Spain alone was entitled to Oregon until 1819. In reply it is said that the British title was acknowledged by the Convention of the Escurial—that Spain never made a settlement in the territory, but totally abandoned it—that Spain had no title either by discovery or occupation—that all the rights or claims which it had were derivable from the treaty of 1790—and that official Spanish writers admit the British title by discovery to New Albion.

2. It is contended that Gray discovered the Columbia, and that this is of itself a sufficient title to Oregon. In reply it is said that rivers follow the title to the coast—if the coast was discovered, the rivers follow the title to it—that Gray was not acting under a public commission, and could not, as a private person, extend the territory of the United States—that his discovery was never noticed by his own government for upwards of twenty years—and that in the negotiation with Spain in 1819 it was not set forth.

3. The settlement of Astoria is called a national settlement. In reply it is said that the only sanction the adventurers received was from the British minister—that it was a mere private speculation by a party of men, the majority of whom were British subjects, who had asked for British protection—that the application to the United States government to sanction it was not complied with—and that a colony could not be planted beyond the limits of the United States without the authority of an Act of Congress.

The British title depends on original discoveries made by Drake, Cook, and Vancouver, whose acts were sanctioned and approved of by their sovereigns, and notified to the world—on the acknowledgment of the title made by Spain in 1790—on the restoration of Nootka in 1795, as evidence of the acknowledgment of territorial rights—on the possession taken by British officers, which by our law, when done with the sanction of the sovereign, is alone sufficient to make a country part of the dominions of the crown—on the numerous settlements and posts which our government has allowed the North-West Company and the Hudson's Bay Company to establish—on the recognition of the claims of the British government made by the United States in 1814, in 1818, and in 1827—on the sovereignty which those acts of recognition proclaimed, and which was recognised by the United States before its treaty with Spain in 1819, as well as subsequently in the treaty of 1827.

Great Britain does not assert claims beyond the terms of the treaty of 1790. The United States some time since claimed the whole territory, without ever having obtained any legal authority over any part of it, and they now allege the extent of this bare claim as evidence of having a better title.

In the course of the early negotiations the United States government offered the boundary of 49° to the sea and the navigation of the Columbia river. Great Britain required that the line should run along 49° to the Columbia river, then along the Columbian river to the sea, agreeing not to erect any fort at the mouth of the river. Subsequently it offered part of the territory between the river and the coast. In the last negotiation carried on by Mr. Pakenham and Mr. Buchanan, the United States offered a boundary along the parallel 49°, withdrawing the former proposal respecting the Columbia river; and the correspondence closed with an assertion of an exclusive right to the entire west coast from 42° to 54° 40′, thus denying every claim made by Great Britain and hitherto recognised by the government of the United States. There are signs that this violent policy and disregard of the admissions made in former negotiations will not be supported by the people of America, and it is to be hoped that they will not be indifferent to what is just and honourable in the affair. The British government has twice offered to refer the question to arbitration, and the last offer was very remarkable for proposing that the arbiters should be civilians, in order to avoid the apprehension which republicans might have of a monarchical tribunal. The offers have been refused, and the last refusal was accompanied with most objectionable reasons.

(Greenhow, *History of Oregon and California*, Boston, 1844; Falconer, *On the Oregon Question*, 2nd ed., 1845; Wallace, *On the Oregon Question*, London, 1845; *The Oregon Question examined in respect to Facts and the Law of Nations*, by Dr. Travers Twiss, D.C.L., London, 1846; *Tracts on the Oregon Question, by an American*, New York, 1846. *Spectator*, No. 921.)

OREODAPHNE, Mountain Laurel (from ὄρειος, mountainous, and δάφνη, a laurel), a genus of plants belonging to the natural order Lauraceæ. It is hermaphrodite, diœcious, or polygamous, with a 6-parted nearly equal calyx, the limb eventually disappearing. It has 9 stamens, oblong anthers, with narrow filaments, 4-celled, the 3 inner looking outwards. The fruit is succulent, more or less immersed in a deep thick cup formed out of the altered tube of the calyx. The flowers are panicled or racemose, axillary, and occasionally umbellulate.

O. opifera is native of the woods of Para and the Rio Negro. It has oblong cuspidate leaves, tapering into the petiole, silky on the under side. The panicles are compact, divaricating, and silky. The fruit is oval in shape, and yields upon distillation a volatile oil, of a yellow colour and peculiar smell. It is used in Brazil as a remedy in pains and contractions of the limbs.

O. cupularis is a very large tree, with a strong-scented wood; it has ovate elliptical leaves, acute at both ends, sometimes blunt at the apex, ending in a channelled stalk, obsoletely netted, smooth; the axils of the costal veins without pores. The flowers are in clustered few-flowered rough hoary racemes below the axillary and terminal bud. The calyx of the fruit is nearly globose. This species is the cinnamon of the Isle of France, where it grows, and also in Bourbon and Madagascar.

(Lindley, *Flora Medica.*)

ORGANIC CHEMISTRY. [TISSUES, ANIMAL, P.C.S.]

ORGANON. The article ORGANON in the P. C. contains a general view of the nature and object of logical science; and the article SYLLOGISM contains all that is necessary on that part of the subject. But something is still wanted to complete what has been already given.

The 'Elementa Logices Aristotelicae,' by Professor Trendelenburg, Berlin, 1842, 2nd edition, consists of passages selected from the works of Aristotle, which passages may be considered as containing the elements of the science. These passages are so arranged as to present a kind of outline of the whole logical system of Aristotle. They are intended for the use of the higher classes in gymnasia, and as a preparation for philosophical studies.

The following article is simply a translation of these extracts, which are retained in the order given to them by Trendelenburg; and the references to the original places in Aristotle have also been retained. The original terms of Aristotle are also given in brackets the first time that each is mentioned.

In the preface to another useful work (*Erläuterungen zu den Elementen der Aristotelischen Logik*, Berlin, 1842, by the same author), he has more fully explained his views in making these extracts from Aristotle, and the following remarks are his: At the time of the Reformation Luther saw clearly the advantage of logical instruction in the higher schools, and he viewed it correctly as the completion of the grammatical instruction. The circle of studies in modern times has been wonderfully enlarged, and it has been found necessary to extend the school instruction to meet the wants of the present age. But the great variety of subjects with which our present systems of education occupy us, only render it the more necessary to discipline the mind in such a manner that it shall see a unity in all that is presented to it, and not be bewildered by the variety of objects whose connection escapes us, when they are contemplated separately. Such a discipline is furnished by a good course of elementary instruction in logic. For this purpose the author has adopted the genuine words of Aristotle, in which the philosopher has laid down his elementary logical principles. The logic of Aristotle is not antiquated, though it is both misunderstood by some, and blamed by others who do understand it. It is not the formal logic of Kant, which would confine us to the forms of thought without any reference to the object into which the thought penetrates. Such a limitation of the subject is entirely at variance with the system of Aristotle, and opposed to its real character. 'We have,' says Trendelenburg, 'attempted to restore this real character, and thus brought Aristotle nearer to the objective demands of modern times.' Those who view logic as purely formal, view it differently from Aristotle, and they may consider their mode of viewing the subject to be better than his. Those who say that Aristotle has, in some matters, erroneously extended the province of logic to things beyond its limits, and has not always kept close to the real subject, appear to have conceived that he viewed it merely as formal, and sometimes transgressed the boundaries of the science which he recognised. This is however an erroneous view of Aristotle's system.

The advantage of studying these elementary principles in the words of Aristotle is, that in his writings the language of philosophy is formed into a scientific terminology, which is the basis of that which we now use. We cannot therefore lay a sure foundation for our logical and philosophical studies on any other basis than a full comprehension of the meaning of Aristotle's terms.

The author remarks that a learner of logic there meets with those fundamental notions (begriffe) in their simple nakedness, which lie hidden in all our knowledge and govern it. As these notions are hid or concealed in our knowledge, they appear dry and lifeless when they are produced in their naked form. It is therefore the business of the teacher to show to the pupil their real significance, to make him see their actual value in their application. Now the instruction in the German Gymnasia, as in the higher schools in Great Britain and Ireland, is in the learned languages and in mathematics; and accordingly the teachers in both these departments, if they are to make use of such a work as Trendelenburg's, must be able to apply logical principles to instruction in language and in mathematics. To facilitate this method of instruction is the object of the learned author in the 'Illustrations (Erläuterungen) to the Elements of Aristotle,' not, as he modestly observes, that this is precisely the form in which he supposes that they ought to be presented to the pupil, but 'merely to render clear the fundamental notion of the logical relationship in the objects of scientific observation.'

The mode in which the author suggests that his two works should be used is probably the best; but they cannot be used at all in ordinary instruction, except under the guidance of a competent teacher. They will however be useful to those who have a competent knowledge of the Greek and German languages, and possess some elementary notions of logic; and those who cannot read Greek with facility will probably find the following translation sufficiently exact to give them the meaning of Aristotle. A translation of such extracts is not easy, and it is possible that there may be some errors in it. A careful study of these extracts however will convince a student how meagre and unsatisfactory an exhibition of the elementary principles of logic even our best works on the subject contain.

Outlines of Logic.

(1.) In things in which there is both falsehood and truth, there is a composition of ideas as though they were one. (*De Anim.* iii. 6.) For falsehood and truth are concerned with composition and separation. Accordingly nouns and verbs by themselves resemble the idea without composition and separation, as 'man' or 'white,' when nothing is added: for there is so far neither falsehood nor truth. (*De Interpret.*) Consequently he thinks truly who considers that which is separated to be separated, and that which is compounded to be compounded; but he thinks falsely whose thoughts have a different relation from that which the things have. (*Metaph.* ix. 10.)

(2.) All speech (λόγος) is significative, but not all enunciative (ἀποφαντικός), but only that in which there is either truth or falsehood. But it is not in all; for example, prayer is speech, but neither true nor false. The enunciative alone belongs to the present inquiry. (*De Interpr.* c. 4.)

(3.) Of things said with no connexion, each signifies either substance (οὐσία) or quantity, or quality, or relation, or where (space), or when (time), or position, or possession, or acting, or being acted on. And substance (οὐσία) is, to give an example, such as 'man,' 'horse:' and quantity is, such as two cubits, three cubits: and quality, such as white, grammatical: and relation, such as double, half, greater: and where, such as in the Lyceum, in the agora: and when, such as yesterday, last year: position, such as he is lying, he is sitting: and possession, such as he has shoes on, he is armed: and acting, such as he cuts, he burns: and being acted on (πάσχειν), such as he is cut, he is burnt. (*Categ.* c. 4.)

(4.) Simple enunciative speech is firstly an affirmation, secondly a negation. And affirmation (κατάφασις) is an enunciation of something towards another thing; and negation (ἀπόφασις) is the enunciation of something away from another thing. And the speech is true in like manner as the things are true. (*De Interpr.* c. 5. 6. 9.)

(5.) 'Not-man' is not a noun; for indeed there is no name to call it by; for it is neither affirmative speech nor a negation. But let it be called 'name or noun indefinite,' because it can be said equally of anything, both of what is and what is not.

Every affirmation and negation will consist either of a noun and a verb or of an indefinite noun and a verb. But without a verb there is neither affirmation nor negation. (*De Interpr.* c. 2. 10.)

(6.) Of things some are universal and some particular. I call that universal which can be said of more things (than one); and I call that particular which cannot: thus, man belongs to the universal, and Callias to the particular. (*De Interpr.* c. 7.) A Proposition (πρότασις) then is speech either affirming or denying something about something. And this speech is either universal or particular or indefinite. I call that universal which belongs either to all or to none; I call that particular which belongs either to some one, or not to some one, or not to all; and I call that indefinite which either belongs or does not belong, without the universal or particular, as, for instance, of opposite things that there is the same science, or that pleasure is not a good. (*Analyt. Pr.* i. 1.)

It is very evident that the universal is more efficient, because, knowing the first of two propositions we know in a manner the second also and have it potentially; for example, if a man knows that the angles of every triangle are together equal to two right angles, he knows in a way that the angles of an isosceles triangle also are together equal to two right angles potentially (δυνάμει), even if he does not know that the isosceles triangle is a triangle. But he who knows this proposition (the second) by no means knows the universal, either potentially or in reality (ἐνεργείᾳ). And the universal is an object of the intellect, but the particular terminates in the sensuous perception. (*Analyt. Post.* i. 24.)

(7.) Every proposition belongs either to what is, or to what must be, or to what can be. (*Analyt. Pr.* i. 2.)

(8.) Of all things indeed which exist there are some of such a kind that they can be predicated with truth universally of nothing else, such as Cleon, Callias, and a single thing, and what is an object of sense; but of these things others can be predicated (for each of these persons is both man and animal); and some things are themselves predicated of other things, but of them there is no further predication by other things; and some are both themselves predicated of others, and others of them, for example, 'man' is predicated of 'Callias,' and 'animal' of 'man.' Accordingly that there are somo things which exist which cannot be predicated of anything is manifest. For of sensuous objects nearly every one is such that it can be predicated (κατηγορεῖσθαι) of nothing. (*Anal. Pr.* i. 27.)

The genera are predicated of the species, but not the converse, the species of the genera. (*Categ.* c. 5.)

(9.) It is impossible for the same thing at the same time to belong (ὑπάρχειν) and not to belong to the same thing and in the same manner. This indeed of all principles is the most certain; for it is impossible for any one to conceive that the same thing is and is not. Wherefore all who demonstrate, carry back (their demonstration) to this ultimate notion. (*Metaphys.* iv. 3.)

Every thing which is true must agree with itself in every way: for with truth all which is true is in harmony, but with falsehood the truth is soon at variance. (*Eth. Nic.* i. 8.)

(10.) And since it is possible for what belongs to be enunciated as not belonging, and what does not as belonging, and what belongs as belonging, and what does not belong as not belonging, and with respect to other times than the present in like manner, it is possible to deny both all that a man has affirmed, and to affirm what he has denied. So that it is manifest that to every affirmation a negation is opposed, and to every negation an affirmation; and let the contradiction (ἀντίφασις) be this, affirmations and negations opposed.

And I call opposition (ἀντικεῖσθαι) the contradiction of the same thing about the same thing, but not ὁμωνύμως. (Comp. *Categ.* c. 1; *De Interpr.* c. 6.)

Contradiction is opposition (ἀντίθεσις) in which there is no mean in itself. And as parts of contradiction, there is on one side affirming something of something, and on the other side denying something from (ἀπό) something. (*Analyt. Post.* i. 2.)

In affirmation and negation always, whether it is a thing that exists or does not exist, the one will be false and the other true: for of the two that Socrates is sick and that Socrates is not sick, when Socrates exists it is manifest that one of them is true and the other false, and if he does not exist in the same manner: for that he is sick, when he does not exist, is false, and that he is not sick is true.

Accordingly, to these things alone, which are opposed as affirmation and negation, it will be peculiar for one of them always to be true or false. (*Categ.* c. 10.)

(11.) Things included in the same genus which differ most from one another, are defined to be contrary (ἐνάντια). (*Categ.* c. 6.)

(12.) Therefore I say that affirmation is opposed to negation in the way of contradiction, when the one signifies that a thing is universal and the other signifies that the same is not universal: as for example, every man is white—not every man is white; no man is white—a certain man is white. And I say that the universal affirmation and negation are opposed as contraries: as for example, every man is white - no man is white; every man is just—no man is just. Therefore it is not possible for these to be true at the same time. (*De Interpr.* c. 7.)

(13.) And I say that propositions opposed are in common expression (κατὰ λέξιν) four—namely, all and none, all and not all, some and none, some and not some; but in truth three; for some is opposed to not some merely in expression. And of these three propositions the universal, all and none, are contrary: for example, all knowledge is excellent, no knowledge is excellent; but the other propositions are opposed (as contradictory). (*Analyt. Pr.* ii. 15.)

(14.) And since every proposition is either of being or of necessarily being or of the possibility of being, and of these some are affirmative and some negative in every mode, and again of the affirmative and negative propositions some are universal and some particular and some indefinite, of necessity the proposition which is universally negative can be converted (ἀντιστρέφει) in its terms (ὅροι): for example, if no pleasure is a good thing, neither is any good thing pleasure; but the affirmative proposition must be converted, not indeed universally but particularly; thus if all pleasure is good, some good also is pleasure. And of particular propositions the affirmative proposition must be converted particularly, for if some pleasure is good, some good also is pleasure: but as to the negative, it is not of necessity, for, if 'man' does not belong to (cannot be predicated of) some animal, it does not follow that 'animal' cannot be predicated of 'some man.' (*Analyt. Pr.* i. 2.)

(15.) The things which are sought are equal in number to the things which we know. And we seek four things—the That, the Why, If it is, What it is. For when we seek whether this or that is, referring it to number, for example, whether the sun is eclipsed or not, we seek the That. And there is proof of this; for when we have found out That it is eclipsed we cease inquiring; and if from the beginning we know That it is eclipsed, we do not inquire whether it is. And when we know that it is, we inquire the Why: for example, when we know that the sun is eclipsed and that the earth moves, we inquire Why the sun is eclipsed or Why the earth moves. These things accordingly we inquire after thus; but some things we inquire after in another manner, as for example, Whether there is or is not Centaur or God. I simply mean if there is or is not, but not if he is white or not. And when we know that there is, we inquire What it is, for example, What is God or what is man. (*Analyt. Post.* iii. 1.)

(16.) To know That a thing is and to know Why it is are different; and the knowledge of the Why refers to the first cause. The chiefest of knowledge is to contemplate the Why. (*Analyt. Post.* i. 13, 14.)

(17.) And we think that we know each thing simply when we think that we both know the cause by which the thing is, that it is its cause, and that it cannot be otherwise. (*Analyt. Post.* i. 2.)

(18.) All instruction and all rational learning come from knowledge preceding. And this is manifest to them who contemplate all (sciences); for both those of the sciences which are mathematical by these means exist, and every one of the other arts. (*Analyt. Post.* i. 1.)

(19.) And things are prior and better known in two ways: for it is not the same thing to be prior by nature and prior as regards us, nor yet to be more known by nature and more known by us. And I call those things prior and more known as regards us which are nearer the sense, but I call simply prior and more known those things which are farther from the perception And the farthest off are the most universal, and the nearest are the particular. (*Analyt. Post.* i. 2.)

(20.) We get certainty in all things either by syllogism (συλλογισμός) or by induction (ἐπαγωγή). (*Analyt. Pr.* ii. 23.)

We learn either by induction or demonstration (ἀπόδειξις); and demonstration proceeds from the general, but induction from the particular. (*Analyt. Post.* i. 18.)

(21.) And syllogism is speech, in which when somo things are laid down, something else different from what are laid down results by virtue of their being laid down; and by virtue of their being laid down I mean that it results through them; and I mean by resulting through them, that there is no need of any external term for the necessity to be. (*Analyt. Pr.* i. 1.)

(22.) And I call Term that into which the proposition is resolved, as the predicate and the thing of which it is predicated (subject). (*Analyt. Pr.* i. 1.)

(23.) Whatsoever is affirmed of the predicate, will be affirmed of the subject also. (*Categ.* c. 5.)

(24.) When three terms are so related to one another that the last is in the whole of the middle, and the middle is either in or not in the whole of the first, of necessity there is a perfect syllogism of the extremes. And I call middle that which is both itself in another and another in it, and which also by position becomes middle: And I call extremes both that which is in another, and in which another is. For if A can be predicated of all B, and B of all C, necessarily A can be predicated of all C. And I call a figure (σχῆμα) of such description the first. (*Analyt. Pr.* i. 4.)

(25.) And when the same thing belongs to all of one thing and to none of another, or to all or none of each, such a figure I call the second, and that which is predicated of both I call the middle term in it—And the middle term is placed without the extremes (ἄκρα), but the first in position—And a syllogism will be possible both when the terms are universal and when they are not universal. When they are universal, there will be a syllogism, when the middle is in all of one, and in none of the other, if the negative be in one of the two terms: but otherwise the syllogism cannot be.

For let M be predicated of no part of N, but of all X. Since then the negative proposition can be converted, N will belong to no part of M: but M by the supposition was predicated of all X. Accordingly N will be no part of X: for this has been shown before. Again, if M shall belong to all N, but to no part of X, neither will N belong to any part of X: for if M belongs to no part of X, neither will X belong to any part of M: but M by the supposition belongs to all N. Therefore X will belong to no part of N: for this also has become the first figure. And since the negative proposition is convertible, neither will N belong to any part of X, so that there will be the same syllogism. An affirmative syllogism is not produced by means of this figure, but they are all negative, both the universal syllogisms and the particular syllogisms. (*Analyt.* i. 5.)

(26.) But if one thing belongs to the whole of the same thing and another belongs to no part of it, or both to the whole or to no part, such a figure I call the third; and I call that the middle in it of which both the predications are made, and I call the extremes the predicates:—And the middle is placed without the extremes, and last in position—And a syllogism will be possible both when the terms are universal and when not universal with reference to the middle.

Accordingly if they are universal, when both P and R belong to all S, P will belong to some part of R of necessity: for since the affirmative is convertible, S will belong to some part of R, so that since P belongs to all of S, and S to some part of R, of necessity P belongs to some part of R: for the syllogism is produced by means of the first figure.

To form a syllogism universally by means of this figure is not possible, neither in the negative nor in the affirmative. (*Analyt. Pr.* i. 6.)

(27.) And it is manifest that every demonstration will be by means of three terms and not more. And since this is clear, it is manifest that it consists of two propositions and not more: for the three terms are two propositions. (*Analyt. Pr.* i. 25.)

(28.) It is necessary in all the figures that the middle be in both the propositions. If then the middle term both predicate and be the subject of predication, or itself predicates and anything is denied of it, it will be the first figure: but if it both predicates and is denied of something, it will be the middle figure: and if other things are predicated of it, or one thing is denied and another predicated, it will be the last figure. (*Analyt. Pr.* i. 32.)

(29.) Moreover in all syllogisms one of the terms must be affirmative and it must be universal: for without the universal there will either be no syllogism, or it will not relate to the thing proposed, or the very thing to be proved will be assumed. For let it be proposed to prove that music is an honourable pleasure; if then any one should assume that pleasure is honourable without adding the 'all,' it will not be a syllogism: and if he should assume that some pleasure is excellent, if he means other pleasure, it has nothing to do with the subject proposed, and if he means the very pleasure itself, he assumes the very thing which is to be proved. (*Analyt. Pr.* i. 24.)

(30.) The science of what a thing is, it is possible to investigate by means of this figure alone (the first). For in the middle figure the syllogism is not affirmative, and (the question) what science is, requires the affirmative: and in the last figure there is a syllogism, but not a universal syllogism, and the question what a thing is, belongs to the universal. (*Analyt. Post.* i. 14.)

(31.) All who attempt to syllogize from things less credible than the conclusion, manifestly do not syllogize rightly. (*Top.* viii. 6.)

(32.) From what is true it is not possible to form a false conclusion, but from what is false it is possible to form a true conclusion; not however 'why' but 'that' the thing is. (*Analyt. Pr.* ii. 2.) Accordingly it is manifest that, if the conclusion be false, of necessity those things are false either wholly or partly from which the argumentation (λόγος) is derived; but when the conclusion is true, it is not a matter of necessity for either anything or all to be true, but it is possible when none of the things in the syllogism are true, for the conclusion to be true notwithstanding, but not as a matter of necessity. And the reason is, that, when two things are so related to one another, that when one is, of necessity the other is, when this other is not, neither will the first be, but when it is, it is not a matter of necessity that the first be. (*Analyt Pr.* ii. 4.)

(33.) And a Philosophema is a syllogism demonstrative, and an Epicheirema a syllogism dialectic, and a Sophisma a syllogism contentious, and an Aporema a dialectic syllogism of contradiction. (*Top.* viii. 11.) Demonstration then is, when from true and first things the syllogism comes, or from things of such a kind which by means of some first and true things have received the beginning of the knowledge concerning them; and a Dialectic syllogism is that syllogism which is derived from common notions. (*Top.* i. 1.)

And speech is called false in one manner, when it appears to be conclusive but is not conclusive, which is called a contentious syllogism (ἐριστικὸς συλλογισμός). (*Top.* viii. 12.)

Contentious speech is the syllogizing from notions that appear to be common notions, but are not; or it is merely apparent syllogizing. (*Soph. Elench.* 2.)

The equality of opposite arguments (λογισμοί) would appear to be productive of doubt. (*Top.* vi. 5.)

(34.) Induction (ἐπαγωγή) is the progress from the particular to the universal: thus if a pilot who is skilled is the best, and if a charioteer who is skilled is so, universally also the person who is skilled in each thing is the best. And induction is the more persuasive and more clear, and more intelligible to sense, and in vogue among the many; but the syllogism has more force and is more effective against opponents in argument. (*Top.* i. 12.)

(35.) Induction then and the syllogism from induction, is through one extreme to syllogize the other with the middle term; for example, if B is the middle term of A and C, by means of C to show that A may be predicated of B: for thus we make Inductions.—But C must be considered as composed of all things individually: for induction is made through all. (*Analyt. Pr.* ii. 23.)

(36.) In a manner induction is opposed to syllogism; for the one (syllogism) by means of the middle term proves the first term to be predicated of the third, but the other (induction), by means of the third term, proves the first to be predicated of the middle term. Naturally then the syllogism through the middle term is prior and more familiar; but to us the syllogism through induction is the clearer. (*Analyt. Pr.* ii. 23.)

(37.) Probable (εἰκός) and Sign (σημεῖον) are not the same, but Probable is a proposition conformable to opinion: for what for the most part men know to be produced in a particular way or not produced, or to be or not to be, this is probable; for example, that men hate the envious, or like those who love. And Sign must be considered to be a proposition demonstrative either necessary or conformable to opinion: for if when any thing is, the thing is, or when anything has happened, the thing happens before or after, this is a sign of the thing having happened or being.

Enthymema then (ἐνθύμημα) is a syllogism from probables or signs. (*Analyt. Pr.* ii. 27.)

(38.) And an example is, when the first is shown to belong (ὑπάρχον) to the middle through one like the third. But it must be known that both the middle belongs to the third and the first to the like. For example, let A be bad, and B be to take up war against neighbours; and C, the Athenians, taking up war against the Thebans; and D, the Thebans, taking up war against the Phocians. If then we wish to show that to make war on the Thebans is a bad thing, we must assume that to make war on neighbours is bad. And the evidence of this is from the like things for example, that the war of the Thebans against the Phocians is bad. Since then to make war on neighbours is bad, and since the war against the Thebans is against neighbours, it is manifest that to war against the Thebans is bad. Accordingly it is clear that B belongs to C and to D (for both C and D are to take up war against neighbours), and that A belongs to D (for the war of the Thebans against the Phocians was not good); but that A belongs to B will be shown through D.

And in the same manner also if through more like things, the evidence should exist of the middle belonging to the first. Accordingly it is manifest that the example is neither as a part to the whole, nor as a whole to a part, but as a part to a part, when both are included in the same notion, and the one is known. And it differs from induction, in as much as induction by means of all the particulars shows that the first belongs to the middle, and does not connect the syllogism with the first, but the example both connects it and does not derive its evidence from all the particulars. (*Analyt. Pr.* ii. 24.)

(39.) Both modes of proof, that by syllogisms and that by induction, teach by means of things known before; the one taking its assumptions from the general notions of mankind, and the other showing the universal through the evidence of the particular. And in the same manner rhetorical arguments persuade; for they (the arguments) are either by means of example, which is induction, or by means of enthymemata, which is syllogism. (*Analyt. Post.* i. 1.)

(40.) Refutation (*ἔλεγχος*) is a syllogism of contradiction. (*Analyt. Pr.* ii. 20.)

(41.) And objection (*ἔνστασις*) is a proposition contrary to a proposition. And it differs from the proposition, in as much as it is possible for the objection to be particular, but the proposition either cannot be so at all, or at least not in the universal syllogisms. (*Analyt. Pr.* ii. 26.)

(42.) Since it is the nature of some things through themselves to be known, and of some through other things (for principles (*ἀρχαί*) are known through themselves, but other things subordinate to principles are known through other things), when any one attempts to show through itself a thing not known through itself, then the thing to be proved (*τὸ ἐξ ἀρχῆς*) is assumed. (*Analyt. Pr.* ii. 16.)

And people appear to assume what is to be proved in five ways. Most manifestly and first, if a person should assume that which requires to be proved. And this in itself does not easily escape notice; but in common names (*συνώνυμα*)* and in all those things in which the name and the notion (*λόγος*) have the same meaning, it is more easy to escape detection. And the second way is when a person assumes the universal when it is necessary to prove the particular; for example, if a person attempting to show that of contrary things (*ἐναντία*) there is one science, should universally assume that of opposed things (*ἀντικείμενα*) there is one science; for he appears to assume with many other things that which it was requisite to prove by itself. The third way is, if any one, when the thing proposed is to show the universal should assume the particular; for example, if he had to prove that of all contrary things there is one science, he should assume that there is one science of some particular contrary things; for such a one also appears to assume separately by itself that which it was requisite to prove together with others. Again, if any one should assume the problem (*τὸ προβληθὲν*) by dividing it; for example, if, when it was required to show that the art of medicine concerned both health and sickness, he should assume each separately. Or if any one should assume one of two things which follow one another of necessity; for example, that the side (of a square) has no common measure with the diagonal, when it was required to show that the diagonal has no common measure with the side. (*Top.* viii. 13.)

(43.) The affirmative (demonstration) is prior to the negative, and more easily known, for through the affirmation the negation is known, and the affirmation is prior, as being also is prior to not being. Further, it is nearer to a first principle; for without the positive proof there is no negative proof. (*Analyt. Post.* i. 25.)

(44.) All persons who form a conclusion through that which is impossible, form indeed a false conclusion, but they show what has to be demonstrated by virtue of an hypothesis, when anything impossible results by the assumption of the contradiction (*ἀντίφασις*) (10). (*Analyt. Pr.* i. 23.)

The demonstration which leads to an impossibility is thus:—If it were required to show that A does not belong (*ὑπάρχει*) to B, it must be assumed that it does, and that B belongs to C, so that it follows that A belongs to C. But let this (that A belongs to C) be known and agreed to be impossible. Then it is not possible for A to belong to B. If then it is granted that B belongs to C, it is impossible for A to belong to B. And since the affirmative (*κατηγορική*) demonstrative is better than the negative, it is manifest that it is also better than the demonstrative which leads to impossibility. (*Analyt. Post.* i. 26.)

* See *Categ.* s. 1, definition of *ὁμώνυμα* and *συνώνυμα*.

(45.) The object of science and science differ from the object of opinion and opinion, in as much as science is universal and is of necessity, and the necessary can not be otherwise, but opinion is unsettled. (*Analyt. Post.* i. 33.)

(46.) Induction is not possible when there is no sensuous perception; for sensuous perception belongs to the particular. Nor yet through sense nor through perception is it possible to attain science. For though sensuous perception refers to a thing as being of a certain quality, and not to any definite thing, nevertheless it is necessary to have some one definite thing as the sensuous object, and the where and the when. But what is universal and in all things it is impossible to have sensuous perception of, for it is neither any particular thing nor now; for, if it were, it would not be universal; for we affirm that the always and the everywhere are universal. Wherefore also if we were in the moon and saw the earth intercepting (the light of the sun), we should not know the cause of the eclipse, for we should perceive that it is eclipsed now, but we should not know why at all, for there would be no sensuous perception of the universal. (*Analyt. Post.* i. 18, 31.)

(47.) And I call universal whatever belongs to all both of itself and in itself. It is manifest then that whatever is universal of necessity belongs to the things. And the 'of itself' and 'in itself' are the same; for example, of itself a point belongs to a line inasmuch as it is a line; and to a triangle, inasmuch as it is a triangle, there belong two right angles; for of itself the triangle (as to angles) is equal to two right angles. And the universal then is, when it can be demonstrated of any individual (of the class) and of no class prior to that. (*Analyt. Post.* i. 4.)

(48.) To what thing anything of itself belongs, that very thing is its own cause (*αἴτιον*); and the universal is first, therefore the universal is the cause. (*Analyt. Post.* i. 24.)

(49.) Universally, of all things it is impossible for there to be demonstration; for it would proceed indefinitely, so that thus there would be no demonstration at all. (*Metaph.* iv. 4.) And it is not possible for the thought to go through the infinite. (*Analyt. Post.* i. 22.)

(50.) And those things are true and first which not through other things, but through themselves receive assent; for it is not necessary in scientific first principles for the 'wherefore' to be inquired after, but each of the principles must itself of itself receive assent. (*Top.* i. 1.) And in two ways it is necessary first to know: for as to some things it is necessary first to admit that they are; but as to others it is necessary to understand what the thing spoken of is; and as to others again both; for example, in the proposition that either to affirm or deny every thing is true, we must assume the 'is'; and in the triangle, that it signifies this particular thing; and in the monad both, both what it means and that it is. (*Analyt. Post.* i. 1.)

(51.) But we assert that all science is not demonstrative, but that that of the immediate (*ἄμεσα*) is incapable of demonstration. And that this is a matter of necessity, is clear: for if it is necessary to understand the prior and those things from which the demonstration comes, and the immediate at any time enter into the demonstration, it is a matter of necessity that the immediate are not capable of demonstration. And this then we so affirm, and that there is not only science, but also some first principle (*ἀρχή*) of science by which we know the terms (*ὅροι*). It is necessary not only to know first the first things, either all or some, but also to know them more: for always that through which each thing is, is more (in a higher degree); for example, that through which we love, is more love. So that if we know by the first things and believe, those things also we know and believe more, since by them we know also the things which come after. (*Analyt. Post.* i. 3. 2.)

(52.) And an immediate proposition (*πρότασις ἄμεσος*) is a beginning (*ἀρχή*) of demonstration, and an immediate proposition is that to which there is no prior proposition. (*Analyt. Post.* i. 2.)

(53.) And of an immediate syllogistic beginning I call that the Thesis which need not be demonstrated, and which it is not necessary that he who is going to learn anything should possess; but what he who is going to learn anything must necessarily possess, is an axiom (*ἀξίωμα*). (*Analyt. Post.* i. 2.)

(54.) The first things will be definitions (*ὁρισμοί*) incapable of demonstration. For definition is of what the thing is and of essence: but all demonstrations appear to go by hypothesis and to assume what a thing is, for example, mathematical demonstrations take for granted what a unit is and what odd is, and other kinds of demonstration in like manner.

The definition is a certain notification (γνωρισμός) of essence. (*Analyt Post.* ii. 3.)

(55.) He who defines shows either what a thing is or what the name means. (*Analyt. Post.* ii. 7)

All who in any way by a name give an account of a thing, manifestly do not give the definition of the thing, since every definition is speech (λόγος). (*Top.* i. 3.)

What a triangle means, the geometer assumes; but that it is, he proves. (*Analyt. Post.* ii. 7.)

(56.) And it is necessary to investigate, when considering things which are alike and do not differ, in the first place what they all have in common, then again with respect to other things what things they have which are of the same genus as the former, and are the same as one another in species, but different from the first named. And when in these things it has been found what they all have in common, and in the other things in like manner, we must consider again if there is anything in common in these things which have been taken, until you come to one notion (λόγος): for this will be a definition of the thing. But if a man does not come to one notion, but to two or more, it is manifest that what is sought cannot be one, but more than ono. For example, if we should inquire what magnanimity is, we must consider in the case of some magnanimous persons whom we know, what one thing they all have by which they are such. For example, if Alcibiades is magnanimous, or Achilles, and Ajax, what one thing thoy have all in common? Non-endurance of insult; for the first made war, and the second was enraged, and the third killed himself.

Again in the case of others, such as Lysander or Socrates; if indifference in prosperity and adversity are the things that they have in common, these two things I take and consider what same things are contained in the absence of all feeling (ἀπαθεία) as to fortune, and non-endurance of insult. If they have nothing in common, there must be two species (εἴδη) of magnanimity. (*Analyt. Post.* ii. 13.)

(57.) Of the things indeed which are in the definition each will extend further, but all will not extend further. For of necessity there must be this essence (οὐσία) of the thing: for example, there is number in every Three (τριάς), odd (περιττόν), and the prime in both ways, both so as not to be measured by any number and not to be composed of numbers. This then is Three, number odd, and prime, and prime in this manner: for of each of these things some are in all odd numbers also, but the last is in Two also, but all are in none. (*Analyt. Post.* ii. 13.)

(58.) And it is necessary, when a person is labouring at any whole thing, to divide the genus (γένος) into things indivisible in species, the first; for example, to divide number into Three and Two. (*Analyt. Post.* ii. 13.)

All genus is divided by differences which aro opposed to one another in division, as a living animal by the difference of quadruped and bird and fish. (*Top.* vi. 6.)

That everything should fall under the division, if they be things opposed in which there is no middle, is not an assumption, for it is necessary that everything should be in one of them, if there shall bo a difference (διαφορά) in it (the genus). (*Analyt. Post.* ii. 13.)

It is requisite moreover to divide by privation (στέρησις), and those who cut into two parts divide by privation. And there is no difference in privation, so far as it is privation, for it is impossible that there should be species of a thing which does not exist; for example, of animals without feet or animals without wings, as there is in the case of winged animals and quadrupeds. (*De Partib. Animal.* i. 3.)

(59.) Definition consists of genus and differences. (*Top.* i. 8.)

It is requisite that he who defines well define through genus and differences, and these belong to those things which are plainly clearer than and prior to the species (εἶδος).

And there are three ways in which the definition is not from prior things. The first is, if through what is opposed that which is opposed is defined; for example, if through evil good is defined; for tho opposed exist by nature. But to some the knowledge of each of them appears to be also the same, so that neither is one better known than the other. But it should not escape notice that some things perhaps it is not possible to define otherwise, for example the double without the half, and all those things which of themselves are said in relation to anything (πρός τι): for in all such things to be is the same thing as to be related to something in some manner, so that it is impossible without the one to know the other; wherefore it is necessary in the notion (λόγος) of the one that the other also be included.

Another way is, if a man uses the very thing which is defined. But this escapes notice, when he has not used the name itself of the thing defined; for example, if he defined the sun to be a star which appears in the day time; for he who employs the word day employs the word sun. And it is requisite in order that such errors may be detected to exchange the name (ὄνομα) for the notion (full speech, λόγος), for example, that day is the passage of the sun above the earth: for it is manifest that he who has spoken of the passage of the sun above the earth has spoken of the sun. So that he who has employed the word day has employed the word sun. A third way is, if that which is opposed in division is defined by that which is opposed in division, for example that odd is greater than even by a unit. For things of the same genus opposed in division exist by nature, and odd and even are opposed in division: for both are differences of number. (*Top.* vi. 4.)

(60.) To know what a thing is, is the same as to know why it is. What is an eclipse? Privation of light from the moon through the earth intercepting (the light.) What causes an eclipse? or why is the moon eclipsed? Because the light fails, owing to the interposition of the earth. What is symphony? A proportion (λόγος) of numbers in sounds high or deep (ὀξύ, βαρύ). Why is the high symphonious with the deep? Because the high and deep sounds have a proportion (λόγος) of numbers. (*Analyt. Post.* ii. 2.)

(61.) We seek the cause after we know that a thing is; but sometimes they are manifest at the same time also; but it is not possible to know the cause before we know that the thing exists. (*Analyt. Post.* ii. 8.) For it is impossible to know what a thing is when we are in ignorance whether it exists or not.

And both the notion or expression (λόγος) appears to give evidence to phænomena, and phænomena to the notion. (*De Coel.* i. 3.)

(62.) The cause is the middle (μέσον), and in all things this is sought. (*Analyt. Post.* ii. 2.)

(63.) Not only that a thing 'is' ought the definition (ὁριστικός λόγος) to show, as the most part of definitions declare, but the cause also ought to be in it, and to be clear. But the notions of the definitions are as conclusions: for example, what is quadrature? It is a rectangular equilateral figure being equal to a figure of unequal sides * And such a definition is an expression of the conclusion. But the definition which says that quadrature is invention of a middle, states the cause of the thing. (*De Animal.* ii. 2, § 1.)

(64.) And it appears that not only what a thing is, is useful towards knowing the causes of the accidents of essences (τῶν συμβεβηκότων ταῖς οὐσίαις), as in mathematics what a straight line is and what a curved line is, or what a line and a plane are, is useful towards seeing how many right angles the angles of a triangle are equal to, but conversely also the accidents help in a great degree to perceiving what the thing is: for when we are able by the appearance (φαντασία) to give an account of the accidents either of all or of the greater part, then concerning the essence also we shall be able best to speak: for of all demonstration what a thing is (τὸ τί ἐστιν), is the beginning. So that in all definitions in which it does not happen that we can recognise the accidents, and cannot even form a conjecture of them easily, it is manifest that they are all enunciated dialectically (διαλεκτικῶς) and emptily (κενῶς). (*De Animal.* i. 1, § 8.)

(65.) And of some things some other thing is the cause, and of other things not.

Accordingly it is manifest that of those also which belong to the class of what a thing 'is,' some are immediate (ἄμεσα) and first principles (ἀρχαί), which we must assume (ὑποθέσθαι) both to be, and we must assume what they are, or in some other way make clear, which the arithmetician does: for both what unity is and that it is he assumes. But as to those things which have a middle (μέσον), and of which something else is the cause of the essence, we can, as we have said, show by demonstration. (*Analyt. Post.* ii. 9.)

(66.) And of proposition (putting, placing, θέσις) that which takes for granted either of the parts of the enunciation, for example, that a thing is, or is not, is Hypothesis (ὑπόθεσις); but the proposition without this is Definition: for the defini-

* This is what the 14th Proposition of the Second Book of Euclid shows.

tion is proposition (θέσις); for the arithmetician lays down (puts, places, τίθεται) that the unit is indivisible, as far as quantity is concerned: but it is not hypothesis: for what a unit is and that there is a unit is not the same thing. (*Analyt. Post.* i. 2.)

(67.) All demonstrative science is about three things, two of which are assumed to be; and these two are genus, the affections (παθήματα) of which by themselves it contemplates, and what are called common axioma (ἀξίωματα) from which first principles science demonstrates; and thirdly, the affections (πάθη) of which what each means it takes for granted. (*Analyt. Post.* i. 10.)

(68.) It is clear that it is not possible to demonstrate the peculiar first principles of each thing: for those first principles will be the first principles of all things, and knowledge of those is that which is supreme over all. For he knows more who knows from the higher causes: for he knows from the prior when he knows from causes which depend not on other causes. So that if he knows more and most, that science also will be both more and most. (*Analyt. Post.* i. 9.)

(69.) Accordingly that it is impossible to have science from demonstration, if a man does not know the first principles which admit of no middle (ἀρχαί αἱ ἄμεσαι), has been said before. But as to the knowledge of things which want a middle, a man may be in doubt. All animals have an innate discerning faculty, which men call perception (αἴσθησις). And as they have perception, in some animals there is a permanence (μονή) of the thing perceived (αἴσθημα); and in others there is not. In those animals, then, in which it is not, there is either wholly, or with respect to things of which there is no permanence in them, no knowledge except of what they perceive: but in those animals in which there is, there is the faculty of having the perception in the mind, though they do not then perceive. And many animals being such, there results a difference among them, so that some have reason owing to the permanence of such things, and some have not. Accordingly from perception comes memory (μνήμη), as we call it, and from the frequent remembrance of the same thing comes experience (ἐμπειρία): for many remembrances in number are one experience. And from experience, or from a whole thing remaining tranquil in the mind as one thing apart from the many, whatever thing in all these things is as one and the same thing, is the beginning of art and of science; if about production (γένεσις), of art; if about that which is or being (τὸ ὄν), of science. Neither indeed do the faculties (ἕξεις) exist in the mind separate, nor do they proceed from other faculties which are more intelligent, but they proceed from perception; as in battle when a flight has taken place, when one stops, another stops, and then another, until order is restored: and the mind exists in such a manner as to have the faculty of being so affected. For when one thing of things which are not different stands, it first of all is in the mind as universal (for the mind perceives the individual, but the perception belongs to the universal, for example, it belongs to mankind, but not to a man (*Callias*)): and again it abides in these until the undivided and the universal have abided: for example, such or such an animal abides, until animal generally abides; and in this in like manner. It is manifest then that it is necessary for us to know the first things by induction: for perception also in this manner produces the universal in the mind.

And since of the faculties that concern the understanding (διάνοια), by which we learn the truth, some are always true, and some admit of falsehood, as opinion and reasoning (λογισμός); and since science and intellect (ἐπιστήμη καὶ νοῦς) are always true, and there is no other kind of science more exact than intellect, and since the first principles are clearer than the demonstrations, and since all science is together with reason (λόγος),* there can be no science of the first principles: and since nothing can be truer than science except intellect, intellect must be intellect of first principles: and this appears both from considering these things, and that the beginning of demonstration is not demonstration, so that neither is science the beginning of science. If then we have no kind of truth which exists independent of science, intellect (νοῦς) must be the beginning of science. (*Analyt. Post.* ii. 19.)

ORES, DRESSING, &c. OF. [MINING, P. C., pp. 236, 244, 245; COPPER, P. C., p. 502; TIN, MANUFACTURE OF, P. C., p. 471.]

* The word λόγος is rendered 'ratio' by the Latin translation. Trendelenburg translates the passage thus:—'jede wissenschaft aber mit einem grunde verknüpft ist.' Perhaps λόγος may be understood as in No. 2. Λογισμός should be related to λόγος as ὁρισμός (defining, terming) is to ὅρος (finis, term).

ORI'GANUM (from ὀρίγανον), a genus of plants belonging to the natural order Labiatae. It has an ovate tubular calyx, 10-13 nerved, striated, with nearly 5 equal teeth, the throat villous inside. The corolla has a tube equal in length to the calyx; the upper lip sub-erect, emarginate; the lower spreading, trifid, with nearly equal lobes. There are 4 protruding stamens, distant, somewhat didynamous. The lobes of the style are nearly equal. The species are herbs.

O. vulgare, Marjoram, has stalked ovate obtuse leaves, ovate bracts longer than the calyx, the heads of the flowers roundish, panicled, and crowded. The bracts are usually purple, ovate, obtuse, and at least half as long again as the calyx. It is a native of Great Britain in dry uncultivated places, and of Europe, North of Africa, and of Middle Asia and America. It is an ornamental and aromatic plant, and yields what is sold as oil of thyme in the shops, a common remedy for toothache. It is frequently used mixed with olive oil as a stimulating liniment against baldness, in rheumatic complaints, and against strains and bruises. The dried leaves used instead of tea are very pleasant; they are likewise employed in fomentations. The essential oil is so acrid that it has been used by farmers as a caustic. It is the ὀρίγανον μέλαν of Theophrastus, lib. vi., cap. 2, and the ἀγριορίγανος of Dioscorides, 3. 31.

O. heracleoticum is a very variable species, but is recognised by the bracts being longer than the calyxes, by the loose spikes, and small flowers. The stamens are more or less villous, the leaves pale green, glabrous or pubescent. The flowers are white and one half the size of the preceding species. This, the Winter Sweet Marjoram, seldom ripens seed in this country, and is propagated by slips and cuttings. It requires a dry and sheltered situation. It is a native of the region of the Mediterranean, Greece, and about Odessa on the Black Sea. It has an aromatic sweet flavour, and is much used as a relishing herb in cookery. This is the Culina gallinacea of Pliny, 20, 16; Cato, *De Re Rustica*, c. 127; Seren, v. 909; and the ὀρίγανον ἡρακλεωτικὸν of Dioscorides, 3. 29.

O. creticum, Linnæus, is the ὀρίγανον of Hippocrates, *Morb. Mul.*, 1. 609; the ὀνῖτις of Dioscorides, 3. 30; and the λευκὸν ὀρίγανον of Theophrastus, 6. 2.

O. Majorana of Linnæus is the *Marjorana hortensis* of Moench, and the ἀμάρακον of Theophrastus, *Hist. Plant.* 6, 7; the σάμψυχον of Dioscorides, 3. 41. It has nearly glabrous racemosely panicled branches, petiolate oblong ovate leaves clothed with heavy tomentum on both surfaces, oblong sessile spikelets glomerate on the branchlets. This plant is a tree or shrub in its native country, but an annual in our gardens. It is native of the North of Africa near Mascar, on hills, and of Asia, on the mountains of Kumaon. The bracts and calyxes are complanate, closely imbricate. The corollas small, purplish or white. As the seed seldom ripens in this country, it is generally procured from France. When in blossom, the plant is cut and dried for winter use, as a savoury ingredient in cookery.

O. Dictamnus, the *Amaracus dictamnus* of Bentham; the Δίκταμνος κρητικός of Hippocrates; the δίκταμνον of Theophrastus, *Hist. Plant.* 9. 16; and the δίκταμνος of Dioscorides, 3. 37. It has almost sessile leaves, clothed with dense wool on both surfaces as well as the branches. The leaves are broad, ovate, obtuse, quite entire, rounded at the base; the floral leaves are small, almost glabrous. The corolla purple, without a spur. The heads of the flowers nutant.

O. Smyrnaeum vel *Syriacum* is the ὕσσωπος of Dioscorides, 3. 27, and of Hippocrates, *Morb. Mul.*, 3. 490. The antient plant is usually referred to Hyssopus officinalis, but according to Fraas this plant does not grow in Greece, Asia Minor, or Syria.

O. sipyleum of Linnaeus is the μάρον of Dioscorides, 3. 42.

All the species are of easy cultivation. A sandy soil and dry situation suit them best. The herbaceous species are readily propagated by dividing them at the root, and the shrubby kinds by cuttings or slips, or by separating the rooted shoots.

(Don's *Gardener's Dictionary*; Babington's *Manual of British Botany*; Lindley's *Flora Medica*; Fraas, *Synopsis Plantarum Florae Classicae*.)

ORNI'THOGALUM, a genus of plants belonging to the natural order Liliaceae and the tribe Asphodeleae. It has a perianth of six patent leaves, the stamens inserted upon the receptacle, and adhering only slightly to the perianth. The anthers are incumbent, attached by their backs. The flowers are white or yellow, never blue.

O. umbellatum, Common Star of Bethlehem, has corymbose flowers, the peduncles longer than the linear lanceolate bracts, lanceolate simple filaments, linear glabrous leaves. The flowers are white, with a broad green longitudinal band externally. It is found in meadows and pastures in Great Britain, and is the βολβίνη of Theophrastus, *Hist. Plant.* 7. 13; the ὀρνιθόγαλον of Dioscorides, 2. 173; and the Bolbine alba of Pliny, 29. 5.

O. pyrenaicum, Spiked Star of Bethlehem, has flowers in an elongated raceme; the peduncles at first spreading, afterwards erect; lanceolate acuminate bracts; the filaments dilated below with an elongated point. The flowers are of a greenish white, the segments of the perianth variable in breadth. The leaves wither before the stalk appears; they are rarely contemporaneous. It is extremely common near Bath, and in Sussex and Bedfordshire. This species is the ἐπιμενίδειος σκίλλα of Theophrastus, *Hist. Plant.* 7, 10. 7, 11.

O. nutans has but few leaves in a lax nodding raceme; the peduncles shorter than the bracts; the filaments flat, membranous, and trifid; the lateral points acute, the middle one very short, bearing the anther; the leaves linear lanceolate; the flower large, white, and greenish externally. It is occasionally found in fields and orchards in Great Britain. It is the βολβὸς ἐμετικὸς of Dioscorides, 2, 201.

O. maritimum, Squill, is described under SQUILLA, P. C. and SCILLA, P. C.

(Lindley, *Flora Medica;* Babington, *Manual of British Botany;* Burnett, *Outlines of Botany;* Fraas, *Synopsis*, &c.)

ORNUS. [FRAXINUS, P. C.]

OROBANCHE (from ὄροβος, a kind of vetch, and ἄγχω, to strangle, because its species grow on the roots of vetches, and were supposed to destroy them by strangulation), a genus of plants, the type of the natural order Orobanchaceæ. It has 2 lateral, undivided or cloven permanent sepals; a ringent withering corolla, the upper lip concave, notched, the lower reflexed, in three unequal wavy lobes; a gland under the ovary; the anthers sagittate with the lobes pointed at the base; the filaments almost as long as the tube of the corolla, downy and glandular; the capsule ovate, pointed with 4 parietal parallel placentæ. The species are parasitical, usually simple, rarely branched, scaly erect herbs.

O. major, Greater Broom-Rape, has the sepals 2-nerved equally bifid, nearly as long as the tube of the corolla, the corolla bell-shaped, ventricose at the base, in front arcuate; the lips wavy, obsoletely denticulated (not fringed), upper lip helmet-shaped, scarcely emarginate; sides patent, middle lobe of the lower lip much longer than the lateral lobes; the stamens inserted at the base of the corolla, glabrous below, their upper part and the style glandular pubescent. This plant is a native of Europe, growing parasitic upon broom, furze, and other shrubby leguminous plants, on a barren and dry soil. It is abundant in some parts of Great Britain. This plant is very bitter and is a powerful astringent. It has been used internally in dysentery and other fluxes, and applied externally as a detergent to foul sores.

O. minor, Lesser Broom-Rape, has the sepals many-nerved, the lobes of the lower lip equal, the stigma bi-lobed. The lobes of the stigma are purple, the anthers yellow when dry. It is found in Europe parasitical upon the roots of the *Trifolium pratense*. Although it is sometimes very abundant, it does not appear to injure the crop of clover. It is constantly found in many parts of England with the clover crops.

O. rubra has the corolla glandular, pubescent externally, and the upper lip internally, the lips acutely denticulated, the stamens inserted near the base of the corolla. It is a native of the north of Ireland and of Cornwall in England. It has a sweet scent, and is found parasitical upon the *Thymus serpyllum*, common Thyme.

O. caryophyllea has the corolla tubular, bell-shaped, curved on the back; the stamens inserted above the base; the corolla hairy within. The stigmas are of a dark purple, the anthers at first purple, yellow when dry. It has been found in Siberia and Italy, and on the Himalaya. It has been found also in the county of Kent in England, where it is parasitic on the roots of *Galium Mollugo*.

O. elatior has the corolla curved, tubular, slightly compressed above; the upper lip 2-lobed, toothed; the lobes inflexed; the stigma yellow. It is a native of Europe, and is parasitical on the *Centaurea scabiosa*. It grows in Great Britain, but is a rare plant.

O. barbata has the middle lobe of the lower lip of the corolla longest; the stigma yellow. Found in Europe, parasitical upon ivy (*Hedera Helix*).

Two other British species, *O. caerulea* and *O. ramosa* are described by Babington. These are referred by many systematists to the genus Phelipæa, which is distinguished from Orobanche by the possession of a tubular bibracteate, 4-5-toothed or 4-5-cleft calyx. *P. caerulea* has a calyx of 4 sepals, tubular, with triangular subulate teeth shorter than the tube of the corolla; the corolla tubular, slightly curved in front, the middle of the tube compressed on the back; the throat slightly inflated externally; glandular lobes of the lips obtuse with reflexed margins, lower lip hairy within, suture of the anther hairy. It is a native of Europe, in Austria, Italy, Germany, and the south of France. It has been rarely found in Great Britain in the fields of Hampshire and Norfolk, and in Jersey. The flowers have a bluish colour. It is parasitical upon *Achillæa millefolium*.

P. ramosa has a calyx of 4 sepals, tubular, with triangular ovate acuminate teeth, the anthers glabrous, the stem branched. This plant is a native of Europe, and has been found in Great Britain in Norfolk and Suffolk, where it grows on the roots of hemp, and the *Galeopsis Tetiatut*. There are several other species of Phelipæa, which were formerly described as belonging to the genus Orobanche. All the plants belonging to Orobanchaceæ, have the habits and general character of Orobanche. The genera belonging to this order are distinguished as follows:—

Tribe I.

OROBANCHIEÆ. Parasitical leafless herbs.

1. *Orobanche.* Calyx bractless, somewhat 1-2-parted.
2. *Phelipæa.* Calyx tubular, bibracteate, 4-5-toothed or 4-5-cleft.
3. *Anoplon.* Calyx bractless, 5-cleft, sub-bilabiate.
4. *Boschniakia.* Calyx truncate, unequally 5-toothed.
5. *Canopholis.* Calyx ventricose, 5-parted, bibracteate, corolla incurved; upper lip entire, lower one bifid.
6. *Epiphegus.* Calyx short, 5-toothed, bractless.
7. *Lathræa.* Calyx bibracteate, campanulate, 4-cleft.
8. *Hyobanche.* Calyx tubular, 7-cleft, unequal, bibracteate.
9. *Alectra.* Calyx bilabiate, bractless? upper-lip 2-cleft, lower one bifid.
10. *Æginetia.* Calyx spathaceous, capsule many-celled.
11. *Amblatum.* Calyx campanulate, 4-cleft, both lips of corolla entire.

Tribe II.

OBOLARIEÆ. Terrestrial leafy plants.

12. *Obolaria.* Calyx 5-cleft, bibracteate, corolla campanulate.
13. *Tozzia.* Calyx 5-toothed, bractless (?) corolla ringent, tubular; capsule 1-seeded by abortion (?)

(Don, *Gardener's Dictionary;* Lindley, *Vegetable Kingdom;* Babington, *Manual of British Botany.*)

OROBUS. [VICIEÆ, P. C.]

ORRIS ROOT. [IRIS, P. C. S.]

ORSOVA. [SERVIA, P. C.]

OSMUNDA, a genus of plants belonging to the natural order Filices, and to the sub-order Osmundaceæ. It has clustered thecæ arranged in a branched spike terminating the frond.

O. regalis, the Flowering Fern, has bipinnate fronds, pinnules oblong, nearly entire, dilated, and slightly auricled at the base; the clusters panicled, terminal. This fern is a native of Great Britain in boggy places, and often attains a height of from 1 to 8 feet. It is very common in many parts of England, and especially on the lakes of Killarney in Ireland. It is common throughout Europe, and a plant of the same name is found in the United States.

(Babington, *Manual of British Botany;* Newman, *British Ferns.*)

OSSIFEROUS BRECCIA, OSSIFEROUS CAVERNS. The existence of large fissures and caverns in rocks is a fact known to miners and quarrymen in all parts of the world; that these cavities are frequently filled with stalactical sparry and earthy accumulations, and sometimes with the bones of animals, is another fact on which modern geologists have based a long train of ingenious inferences. Fully to examine these facts and inferences would be to discuss one of the most comprehensive and unsettled problems of geology; it is possible however to present in a small compass the leading considerations which belong to the subject.

Great fissures and caverns, though not absolutely confined to limestone rocks, are yet by far of most frequent occurrence in these deposits. They are not common in all limestones, but have certain determinate relations to their mass and the positions which they occupy. It is peculiarly in *thick masses* of limestone, (whether magnesiferous or purely calcareous) that we find great caverns in England, Ireland, France, Belgium, North Germany, the Tyrol, Carinthia, Italy, Greece, North and South Africa, India, Australia, North and South America. It is sometimes observed that great cavities abound in limestone rocks, not so much at as near to points and lines where the ordinary position of the strata is violently disturbed by great faults, and axes of elevation and depression. Thus the numerous caverns of Derbyshire and Yorkshire, and the Mendip Hills, are situated in or near to situations of violently disrupted strata, and by accumulating observations of this nature we gradually come to perceive, in many cases, a real dependence of the chasms in the rock on the fractures which have broken it.

But there are few caverns or great fissures *all whose features* can be thus explained. The disturbance has not so often produced the caverns as the conditions necessary for their production. On the contrary, in very many cases we perceive, even in caverns now dry, forms of internal surface which mark the decomposing influence of air and moisture and the erosive power of running water. Through many of them water now runs, through more of them it formerly ran, *conducted into these subterranean channels* by the fractured condition of the strata. The great caverns of the Peak at Castleton and Buxton may be quoted as examples. Other caverns occur, nearly or entirely exempt from the direct influence of fractures passing through them. Such a case occurs at Kirkdale in Yorkshire, a cave which has for great lengths an even floor and roof, and is connected, not with faults or axes of movement, but with *great joints* in the limestone. This cave has been traversed by water conducted by these joints. Water dropping, trickling, or running through the fissured limestone rocks dissolves (by the almost constant carbonic impregnation which it derived from the atmosphere and decomposing vegetation) its calcareous channels, and transports away, to the surface of the ground, the materials of petrifying springs, the tufaceous mounds of Matlock, and the travertino of southern Europe. In certain classes of limestone rocks there is reason to conjecture that the caverns have not been occasioned by violent *fractures*, nor yet by the influence of *joints*, but that they are a part of the *original structure* of a coral reef (in which cavities were left by the polypean builders), or have been generated by those chemical processes which we have as yet imperfectly traced and classed as *metamorphic effects*. This may be the case in certain magnesiferous (dolomitic) limestones in Derbyshire, Franconia, &c.

In regard to the filling of these cavities, we must again, in a great majority of instances, appeal to the action of water—an *inverse action*, new circumstances causing water to deposit where once it excavated; or an *indirect action*, occasioning new accidents. Stalactical depositions and many varieties of sparry accumulations, which are now happening in caverns and fissures, exemplify the former case, and as an instance of the latter we may describe what is happening on a part of the Yorkshire coast. Here the chalk is cavernous; the caverns, connected above with small fissures reaching to a mass of diluvial clay, pebbles, &c., are continually enlarged by the waves and spray of the sea, and sometimes their roof, thus weakened, falls in, and the diluvial masses from above pour down into the cave, but are soon removed by the agitation of the tide.

Another instance is of familiar occurrence in the mining districts of the north of England, where limestone, more or less cavernous and fissured, is covered by shales or argillaceous toadstones. Near the edge of these argillaceous beds, many rather regular pits ('Swallow holes') occur, through which the surface drainage reaches the limestone, and carries into its cavities some of the materials which are dislodged in its course.

The geologist, who takes into consideration the possible origin of caverns in limestone from original hollows, the influence of joint fissures, and the effect of violent displacements; and considers further the various degrees and circumstances of their communication to the surface, the various action of water within them, their level in relation to that of the sea, and the nature of the strata or other matter superincumbent on the limestone, will be at no loss to comprehend how various, complicated, and interesting are the sparry and earthy contents of subterranean cavities. These contents have in some cases *fallen* in, so as to constitute confused heaps or masses of *breccia:* in other cases they have been *drifted* by water and arranged into shallow and irregular *beds;* and in addition, certain matters have been *dissolved*, and deposited in crystallized and *stalagmitic* forms.

The occurrence of bones in these breccias, sediments, and stalagmitic incrustations is sometimes to be explained by supposing them to have fallen with the other materials of breccia, or to have been drifted with sediments by water; but in a considerable proportion of the cases which have been examined there is no avoiding the conclusion that animals retired by choice, or through fear, or were dragged by violence into these cavities, and there have left their bones. This conclusion, established by the sagacity of Buckland for the hyæna caves of Kirkdale and Torquay, applies to the numerous bear caverns of the Harz, Franconia, and Westphalia, and to some caves in Brazil and Virginia. It is a conclusion of the highest importance in geology and zoology. It assures us of the *habitat* of many extinct races of quadrupeds, and thus furnishes authentic data for a survey of the geographical distribution of Mammalia in one definite period of high antiquity, under physical and climatal conditions of the globe much different from what we now behold. Thus for instance we find among the perished races of British quadrupeds, the lion, hyæna, and bear; the elephant, rhinoceros, and hippopotamus; the urus and the elk.

To allow of the introduction of these animals to Britain, we must suppose this island joined to the continent: to allow of their long continued existence here (which the phenomena in Kirkdale cave substantiate), we must suppose certain climatal and physical conditions of the country, and certain habits of life among the animals. Migrations may be supposed for the deer and the lion, but settled abodes must be ascribed to the hyæna and perhaps to the pachydermata. The extinction of these animals requires other admissions. It is not a local, but a general phenomenon, extending over a great part of the northern zones of the world, and of such startling magnitude as to have suggested hypotheses of diluvial catastrophes, and glacial periods, to geologists; while zoologists may perhaps regard it as a great example of the law of limited duration and successive predominance, to which, judging from the whole course of palæontological discovery, all the races of the animal creation are made subject. The reader may consult, for the facts and inferences thus briefly noticed, Cuvier, *Ossemens Fossiles;* Buckland, *Reliquiæ Diluvianæ;* Meyer, *Palæologica;* Owen, *On British Fossil Mammalia*, in *Transactions of the British Association;* and a variety of Memoirs by different authors in the *Transactions and Proceedings of the Geological Society of London.*

OSTRA'CION. [SCLERODERMI, P. C. S.]

OTTMER, KARL THEODOR, an architect to whom Brunswick is indebted for what ranks almost among the largest, and certainly among the most elegant palaces in all Europe, was born in that city, January 19th, 1800. He was the son of a physician, who intended him for the same profession; but his father's death leaving him free to follow his own inclination, he made choice of architecture as his future destination, and certainly had no cause to repent of doing so, being eminently favoured even from the commencement of his career by opportunities that fall to the lot of few. While he was completing his studies in his profession, at Berlin, in 1822; he competed for, and was employed to erect the new theatre there, called the 'Königstädter Theater,' which was begun in July 1823, and opened in the August of the following year. This decided success on the part of one so young,—it being in fact his *coup d'essai*,—brought Ottmer forward at once: it should, however, be mentioned that, although it was not known at the time, his designs were corrected by Schinkel. [SCHINKEL, P. C. S.] In his next work of note, the 'Sing-academie' at Berlin (erected 1826-7), his design obtained preference of that of Schinkel, although the latter was in very superior taste, and indeed, one of the happiest ideas of the 'great master,' as may be seen by the published drawings of it in his 'Entwürfe.' Flattering as all this was, it was not without its disadvantages, as by immersing him too early and too completely in matters of mere business, it hindered that calm application to study which is so important to an artist at the outset. There was besides very great danger of his being spoilt by the exaggerated praises bestowed on his first efforts,—praises which, it has been suspected, proceeded partly from a desire to lessen the reputation and keep down the influence of Schinkel. Fortunately, Ottmer felt the necessity for improving himself; and after first studying a short time in Paris, he visited Italy, where he remained nearly two years (1827-9); and where he was so far inspired as to conceive the project and work upon the designs for a palace that should surpass every known edifice of the kind in extent and magnificence.

He was recalled to Germany by an invitation from Dresden, when it was intended to build a new 'Theater,' and he proposed designs accordingly; but the scheme was dropped for several years, and then Semper was the architect employed on the noble structure since erected there. The designs produced for that occasion procured, however, for him while he was at Dresden, a commission from the Duke of Saxe-Meiningen to make others for a theatre and casino for him, and the buildings were forthwith commenced. On his return to Brunswick he published in 1830, the first part of his 'Architektonischen Mittheilungen,' containing plans, &c. of his Theatre at Berlin. At that time his professional occupation consisted of little more than his official duties as Hofbaumeister, nor had he much prospect of ever being called upon to execute any work of importance, when during a popular tumult which took place in September, 1830, the palace at Brunswick was set fire to and destroyed. He was thereupon directed by the new Duke, Wilhelm (the successor of his brother Karl, who was expelled by the revolution), to make designs for rebuilding the palace; and the edifice was begun the following year, and prosecuted with such activity as to be ready for habitation in 1837. The principal mass is 400 feet in extent, by upwards of 200 in depth, and 80 high, and in the centre considerably loftier, though the design has not yet been fully carried out, the open colonnades intended to form a place before the principal façade not being yet erected. Still, should nothing further ever be done, this palace is a most stately and elegant pile as it is; and even now it has been objected to it that it is upon too extravagant and costly a scale. The architect's labour must have been prodigious, for besides that he was obliged to superintend every department of the works personally, from first to last, he designed all the numerous details both of the exterior and interior, which display considerable inventive power as well as refined taste. The principal entablature of the exterior—extending altogether two thousand feet in length—is entirely of cast-iron, and much equally excellent and novel construction is displayed in other parts. The interior is distinguished by many striking pieces—the lower entrance vestibule, a Grecian Doric hall 150 feet in length; the parade staircase; the upper vestibule, a rotunda seventy feet in diameter, and sixty high; gallery; theatre; concert room; banqueting room, &c.

Besides the palace, Ottmer erected at Brunswick several other structures, both public and private, all of them, more or less, of architectural note: viz. the Theater-Intendantur, the Infantry Barracks, in the Florentine style, with a façade of 350 feet; the Iron Bridge, the Villa Bulow, New Richmond, the Schmidtsche-Haus, the Interim Railway-station,' &c. He also made a design for Cavalry Barracks at Brunswick, in similar style to those for the infantry; which design was published in Ronsberg's 'Zeitschrift für praktische Baukunst,' 1842. Other designs which he left behind him will perhaps remain unedited. Naturally of a delicate constitution, Ottmer sank under the barass of business and the multiplicity of his tasks in the prime of life, August 22nd, 1843; but had he lived to the close of the century, hardly would he have had such another opportunity as that afforded him by the Palace of Brunswick.

OVAL, or as the name imports, egg-shaped, is the name given originally to such a form as the section of an egg presents, round, but not circular. In mathematics it has received some extension of meaning. Any curve, or isolated branch of a curve, which returns into itself, would be called an oval: perhaps even a figure of eight would receive the name.

The curve having for its equation

$$y=\sqrt{x(x-a)(x^2-b)}$$

(a and b being positive; and a less than b) has an oval extending from $x=0$ to $x=a$: but there is no curve whatever from $x=a$ to $x=b$, or from $x=-b$ to $x=0$. If a be small, the dimensions of the oval are small: and when $a=0$ the equation becomes

$$y=x\sqrt{(x^2-b^2)}$$

in which the oval has become a point (the origin), and is a *conjugate point* [CURVE, P. C.], an isolated point which is not on any continuous branch.

Some conjugate points have none but imaginary values of $dy{:}dx$, some have one or more finite values. Thus when $y=x\sqrt{(x^2-b^2)}$, there is a conjugate point at the origin, and $dy{:}dx$ is then imaginary: but when $y=x^2\sqrt{(x^2-b^2)}$ there is also a conjugate point at the origin, but $dy{:}dx$ is 0. The meaning seems to be (as far as we can judge from a few instances) that when the oval during its diminution, has axes which preserve a finite ratio to one another, so that its tangents fall in all directions, the ultimate value of $dy{:}dx$ is imaginary. But when one of the axes diminishes without limit as compared with the other, so that, except near the ends of that axis, the tangents tend to assume one direction, there is an ultimate value of $dy{:}dx$ which defines that direction. If our surmise be correct, a double or triple value of $dy{:}dx$ at the conjugate point would indicate the evanescence of a star-shaped oval, or of one which tends to assume that form as it diminishes. But this, with other points relating to the singular values of algebraic functions, has yet to be fully considered.

OWEN, JOHN, DR., was born in 1616, at Stadham in Oxfordshire, of which parish his father, Henry Owen, was for some time minister. At the age of twelve he was admitted a student at Queen's College, Oxford, where he took his first degree in 1632. During the period of his university life he is represented as having so diligently applied himself to study that he never allowed himself more than four hours repose. In the year 1637, when Hampden resisted illegal taxation [HAMPDEN, P. C.], Archbishop Laud, the chancellor of the university, made some new regulations, of which Owen disapproved, and, as he refused to comply with them, he was obliged to leave Oxford. Brought up by his father in the strictest school of Puritanism, he considered the new statutes an attempt to enforce the observance of superstitious rites. On leaving the university he accepted the situation of chaplain to Sir Richard Dormer, of Ascot in Oxfordshire, having been some time previous to his expulsion admitted into holy orders by Bishop Bancroft. He afterwards became chaplain to John, Lord Lovelace, of Hurley in Berkshire, with whom he remained till the outbreak of the civil war, when, as he warmly espoused the cause of the Parliament, he forfeited the protection of his patron. Left to his own resources, Owen retired to London, where he appears to have joined the non-conformists. In 1642 he published his first work, entitled 'A Display of Arminianism,' which soon recommended the author to the notice of the Parliament, and became the foundation of his future advancement. He was shortly afterwards presented by the committee appointed 'to purge the Church of scandalous ministers' to the preferment of Fordham in Essex. He enjoyed this living little more than a year, having been deprived of it by the patron, to whom it had reverted on the death of the sequestered incumbent. The Earl of Warwick then bestowed upon him the living of Coggleshall in the same county. Owen had not been long at Coggleshall before he abandoned the Presbyterian party to join that of the Independents. On the 29th April, 1646, one of the frequent fast days instituted by the Puritans, he was called to preach before the Parliament, and his sermon, on that occasion evinced a larger spirit of religious toleration than was prevalent among his party at that period. He still more strongly manifested his tolerant disposition when he was appointed to the critical task of preaching before the same assembly on the day after the execution of Charles I. In this sermon he solemnly warns his hearers 'against oppression, self-seeking, and persecution.' On the 28th February following, a day set apart for humiliation and prayer on account of the intended expedition to Ireland, he was again appointed to preach before Parliament and the chief officers of the army; on that occasion, Cromwell, who heard him for the first time, received so favourable an impression of his merit, that he named him his chaplain, in which capacity he accompanied the expedition. In 1651 Owen was, by an order of the Parliament, promoted to the dignity of dean of Christ Church, and the following year he became vice-chancellor of the University of Oxford, Cromwell being at that time chancellor. He appears to have discharged the peculiarly difficult duties of this office with much moderation, and his conduct met with the approval of many of the Episcopalian party. After holding it five years, on the death of Cromwell he was deprived of it, as well as of his deanery, to which Dr. Reynolds, a Presbyterian, was appointed.

At the Restoration Owen retired to a small estate which he had purchased in his native place, where he employed himself in preaching as often as an opportunity was afforded him. He was, however, soon obliged to abandon an occupation so congenial to his feelings by the interruption of the Oxford militia, and he determined upon settling in London. It was there that he published a work entitled 'Fiat Lux,' in answer to the writings of a Franciscan Friar, which attracted the attention of Lord Clarendon. This statesman, who was anxious to reconcile the most moderate of the non-conformist party [HYDE, P. C.], offered Owen immediate preferment if he would conform; which proposal, however, was firmly though respectfully declined. He then formed a congregation, among which he assiduously laboured, and in conjunction with Baxter, Bates, and other leading men of his persuasion, instituted the Pinner's Hall Weekly Lecture. In 1677 he contracted a second marriage, by which he was enabled to live in comparative affluence on an estate at Ealing, in Middlesex, where he died on the 24th of August, 1683.

The private character of this divine has been praised equally by those who were united with him by similarity of religious feeling, and by those who differed most widely from him in opinion; they all bear testimony to the temperance of his language and the mildness of his disposition. This character is in a great measure reflected in his works, which, though strongly tinctured by the peculiarities of the Calvinistic system, are remarkable for their devotional spirit and are calculated to encourage practical piety. He certainly belonged to that section of his party whom Lord Clarendon designates as 'the more learned and rational.' (Clarendon 'History of the Rebellion,' vol. v. p. 513; see Warburton's note.) His works are very numerous: among the best known of those not already alluded to may be mentioned, 1, his 'Exposition of the Epistle to the Hebrews;' 2, 'A Discourse on the Holy Spirit,' 1674; 3, 'Vindiciæ Evangelicæ, &c., in answer to T. Biddle,' 1655; 4, 'Θεολογόυμενα, sive de Naturâ, Ortu, Progressu et Studio veræ Theologiæ,' 1661; 5, 'An Exposition of cxxx Psalm,' 1660; 6, 'On the Doctrine of Justification,' 1677; 7, 'The Nature of indwelling Sin,' 1668; 8, A large collection of Sermons and Tracts. His last production was entitled 'Meditations and Discourses on the Glory of Christ,' which it is stated was sent to the press the day he died.

(For further particulars of his life and writings the following works may be consulted: 'Biographia Britannica,' vol. v., London, 1709; 'Memoirs of the Life of Dr. Owen,' prefixed to a Collection of his Sermons, Tracts, &c., London, 1721; and Wood's 'History and Antiquities of Oxford.')

OWNERSHIP. [PROPERTY, P. C.]

O'XALIS (from ὀξύς, sharp, acid; the leaves have an acid taste), a genus of plants belonging to the natural order Oxalideæ or Oxalidaceæ. It has 4 sepals connected below, and 5 petals which are likewise frequently connected below. The stamens are 10 in number, and monadelphous; the 5 outer ones shorter than tho rest. The styles 5, and the capsules oblong and 5-cornered.

O. acetosella, common Wood-Sorrel, is a small perennial plant with a subterranean rootstock consisting of many scaly joints; the leaves are ternate, leaflets obcordate and having the peduncles longer than the leaves, with two scaly bracts at about the middle; the corolla is about 4 times as long as the calyx, and of a white colour beautifully veined with purple. Mr. Curtis remarks that the leaves are often purplish beneath, and that the fruit darts forth its seeds at the smallest touch when ripe. This species of wood-sorrel has a pleasant acid taste, dependent on the presence of oxalic acid, and is frequently used in salads; its flavour approaches near to that of lemons or tartaric acid, with which its medicinal effects also correspond, as it is esteemed a refrigerant antiscorbutic and diuretic. The expressed juice of this species, evaporated and set in a cool place, affords a crystalline salt, which may be used whenever vegetable acids are wanted. It is sold in the shops under the name of Essential Salts of Lemons, and is employed to take iron-moulds and ink-spots out of linen. This salt, which is a binoxalate of potassa, is however seldom to be obtained in a genuine state, cream of tartar and vitriolic acid being frequently substituted for it.

O. corniculata, Horned Wood-Sorrel, has a decumbent stem, branched and rooting; the leaves are ternate with obcordate leaflets; oblong stipules united to the base of the petioles; the peduncles are two-flowered, and shorter than the leaves. It is s native of Europe, particularly in Spain, Italy, and Greece, as well as of Japan, Mexico, North America, and England. The flowers are yellow; those of the North American plant are larger than the European.

O. stricta has an erect leafy stem, umbelliferous peduncles rather shorter than the leaves. It is native of North America, and is naturalized in Cornwall and Devonshiro in England. The flowers are yellow and about the size of those of *O. corniculata*. Browne says, this plant is also a native of Jamaica, and he recommends it as a pleasant cooler and diuretic; formerly it was given in inflammatory cases, but has been superseded by the more agreeable fruit-acids which are now cultivated in the West Indies. Professor Morren of Liege attributes to this species of Oxalis the peculiar properties of a sensitive plant, which are referred to in the article SENSITIVE PLANTS, P. C. He also observed the same movements in *O. acetosella* and *O. corniculata*, and some other species. The *Oxalis sensitiva*, called by De Candolle *Biophytum* on account of its sensitive properties, has long been known to possess this quality. The whole genus of Oxalis is curious and beautiful, and well worthy cultivation. There are above 220 species described, which are distributed in every quarter of the globe. The hardy species require no care. If the roots are planted in a shady border, they will grow and multiply. The greenhouse kinds are mostly bulbous from the Cape of Good Hope. A mixture of sand, loam, and peat is best suited for them; they require no water after they have done flowering until they begin to grow afresh; they are propagated by offshoots from the bulbs or by seed. They may be grown in the frame, but must be protected from frost during the winter.

(Don, *Gardener's Dictionary;* Babington, *Manual of British Botany;* Lindley, *Flora Medica.*)

OXY'RIA, a genus of plants belonging to the natural order Polygoneæ. It has a 4-parted perianth, the 2 interior segments larger; 6 stamens; 2 stigmas; a 1-seeded nut, compressed, with a membranous wing, larger than the persistent segments of the perianth; embryo central.

O. reniformis, Mountain-Sorrel, is the only species. It is found on the highest mountains of Great Britain, and is an inhabitant of Europe. It is the *O. digynia* of many botanists.

(Babington, *Manual of British Botany;* Koch, *Flora Germanica.*)

OZONE (from the Greek ὄζω, to smell) is the name given by Professor Schönbein of Basle to an odour evolved during the progress of certain electro-chemical decompositions. It is also produced by common electric sparks, and by the working of an ordinary electrical machine in the air. This odour attracted no particular notice until M. Schönbein called the attention of the British Association to it in 1840, since which time it has undergone much examination, and various theories have been propounded as to its nature and composition.

Ozone is evolved at the anode, or positive polo of a galvanic battery, at the same time with oxygen, during the electrolization of any of the following bodies, viz. water, dilute sulphuric acid, solutions of phosphoric and nitric acids, potassa, and many oxysalts. Of these dilute sulphuric acid yields it in the greatest quantity. It may also be obtained from atmospheric air, oxygen, nitrogen, hydrogen, carbonic acid, and nitrous oxide, by passing the electrodes through a closely fitting cork into a jar filled with these gases, and frequently making and breaking contact. Under the influence of heat ozone disappears, and it cannot be obtained from heated solutions, or solutions of hydracids, chlorides, bromides, or iodides, the presence of which, even in small quantities, prevents its evolution from solutions otherwise yielding it abundantly. It may be developed by electrolizing a solution of muriate of soda with platinum electrodes, by placing the gas collected at the anode over ammonia and water to absorb the chlorine. Ozone can be preserved for a length of time with the oxygen collected with it in well closed bottles. It possesses the property of bleaching litmus-paper and paper coloured with indigo or a solution of that substance. It is readily absorbed by mercury and the oxidizable metals, forming oxides with them; and when the solutions employed are heated its affinity for metals is so greatly increased that it combines with platinum and gold. Water absorbs it. The inspiration of ozone is very injurious, and the effects similar to those resulting from chlorine and bromine. A mouse is killed with it in five minutes, and M. Schönbein states that he was seriously affected by breathing an atmosphere charged with it.

The electrodes employed in these experiments have a great influence in respect to the evolution of ozone. With water or acid solutions they must be of platinum or gold; for when the more oxidizable metals are used it enters immediately into combination with them. It can be obtained from air or the gases above enumerated when the positive electrode is copper, iron, silver, or platinum, and zinc negative, but not when these arrangements are reversed, or both electrodes are of zinc. With zinc, when either positive or negative, a peculiar scent is produced in nitrogen and hydrogen. On electrolizing a solution of sulphuric acid the following results are obtained:—with platinum electrodes the odour is very powerful; but it is not produced when copper, zinc, or iron electrodes are employed. With boxwood charcoal the gas given off from the positive pole has no smell; but when absorbed by lime-water it turns it milky, proving the gas to be carbonic acid. With gas charcoal, sulphuretted hydrogen is evolved at the negative pole and carbonic acid at the positive; but no odour of ozone is produced. With a solution of muriate of soda the odour is not perceptible until the gas obtained from platinum electrodes at the positive pole is placed over ammonia and water to absorb the chlorine. The residual gas emits the peculiar odour.

There exists much variance in the experimental results with this new substance; and not less in the opinions concerning its nature. Professor Schönbein considers it to be a tritoxide or peroxide of hydrogen. Marignac controverts M. Schönbein's conclusion, that it is to be derived from the decomposition of nitrogen, as he obtained it from water free from this latter gas. Mr. Williamson would prove that it is a compound, and that hydrogen is one of its elements, he having obtained it from a salt of copper, and passing the oxygen with the ozone over metallic copper which had been reduced by carbonic oxide gas, a sensible formation of water resulted. His view of the subject is, that ozone is a higher oxide of hydrogen than water, although not the peroxide of hydrogen of Thénard, which is not volatile like ozone, but inodorous and fixed. Mr. Gann says concerning it, 'I am induced to think that this peculiar odour may be emitted from all metallic bodies in such a manner as to prevent oxidation or combination with other bodies;' and 'that all metals have the power of emitting it, when put into a peculiar electrical state, that is, when the metals are in a state of transition previous to oxidation or combination;' and Mr. Lake, who claims to have demonstrated that the electric fluid is a substance, to which he has given the name of pyrogen [Pyrogen, P. C. S.], considers that it is a compound of this substance with oxygen, that is, an oxide of pyrogen. He says, 'It would seem indeed the necessary inference of Mr. Gann's experiments (the evolution of ozone from oxygen and the other gasses) that oxygen enters into the composition of nitrogen and hydrogen, for ozone is developed, except in these two instances, from oxygen and its compounds, by the combination of oxygen with pyrogen, and hence it would follow that nitrogen and hydrogen contain oxygen.'

The inquiry concerning the substance is of great importance to chemical science, as it involves the question of the nature of oxygen, hydrogen, and nitrogen, from each of which it can be obtained. It is agreed by all that oxygen is one of the elements of ozone. If, therefore, hydrogen is the other, it follows that oxygen is a compound into the composition of which hydrogen enters; that oxygen is an element of hydrogen; and that both oxygen and hydrogen are elements of nitrogen, since ozone can be evolved from each of these gases: and it is to be remarked that this last circumstance agrees with Mr. G. J. Knox's discovery, that nitrogen is a compound of hydrogen and silicon. This also overthrows M. Marignac's opinion, that it cannot be obtained by the decomposition of nitrogen, and confirms M. Schönbein's to the contrary effect.*

Mr. Gann's opinion, in substance and as far as it goes, coincides with Mr. Lake's, for he considers ozone to accrue between the oxidation or combination of the metals with the substances exhibited to them and the time when chemical action commences. According to the views of the latter, ozone must be present and of paramount importance in the processes of acidifaction and oxidation, for he shows that both oxygen and the electric fluid (which he considers the elements of ozone to be) are required to form an acid [Pyrogen, P. C. S.], and of course an oxide. If this view be correct it accounts for the disappearance of ozone where the more oxidizable metals are exhibited to it, and also for the formation of carbonic acid when acid solutions are electrolized with carbon as the positive electrode.

Some singular phenomena connected with ozone were observed by Professor Schönbein, strongly indicative of its electric origin, if not of its electric composition. When perfectly clean and dry plates of gold or platinum are immersed in oxygen containing ozone, they acquire a negatively electric state of polarity. Silver and copper also become thus electric, but in a far less degree than gold or platinum. The plates thus polarized retain their electric powers in air for a considerable time, but rapidly lose them when plunged into hydrogen gas, in which, if retained a sufficient time, they acquire an opposite state, becoming positively polarized.

When a perfectly clean and dry plate of gold or platinum is exposed to an electric brush it becomes positively polarized, the degree of polarity depending on the nature of the point and the time the plate is exposed to the brush issuing from it. This power may be attributed, according to the last of the above theories, to the formation of ozone by the combination of the electric fluid of the brush with the oxygen of the air. If the point from which the electric brush is issuing be moistened with water, the electricity still continues to be given off, but the power of polarizing the plates is lost, which effect is no doubt produced by the water absorbing the ozone. Heat, which destroys, or exposure to hydrogen, which inverts, the electricity of a plate that has been polarized by exposure to oxygen containing ozone, exerts a precisely similar action on plates polarized by the electric brush.

(*Proceedings of London Electrical Society*, 1841-42, p. 160; *Reports of the British Association*, 1840; *Polytechnic Review*, New Series, vol. ii. p. 260; *Athenæum*, 1845, pp. 590, 674, 723; *Chemical Gazette*, September, 1843.)

* According to Professor Schönbein, nitrogen is a combination analogous to hydrochloric acid, and is composed of ozone and hydrogen.

INDEX TO THE LETTER O.

VOLUME II.

P.

PACCHIAROTTO, JACOPO, one of the most distinguished of the old Sienese painters, was born at Siena in the latter part of the fifteenth century; but though he belongs chronologically to the painters of the sixteenth century, he is one of the *quattrocentisti* in style; his works much resemble those of Pietro Perugino; at the same time they are more fully developed in form and of wonderful force of colouring; in expression also many of his heads are admirable.

He lived in Siena until the year 1535, when, owing to his being one of the principals in a conspiracy of the people against the government, he was compelled to fly, and he took refuge in France. Lanzi says that he would certainly have been hanged, had he not been protected by the Osservanti monks who concealed him for some time in a tomb. He succeeded in making his escape, and joined Il Rosso in France, where he in all probability ended his days not very long afterwards, as nothing further is known of him, and he does not appear to have left any works in France.

There are still several excellent paintings, both in oil and in fresco, by Pacchiarotto, in Siena. There is a beautiful altar-piece in San Cristoforo; and some excellent frescoes in Santa Caterina and San Bernardino. Speth takes particular notice of these frescoes in his 'Art in Italy,' and terms Pacchiarotto the second hero of the Sienese school—Razzi, called Sodoma, being the first. They are highly praised also by Lanzi. In Santa Caterina is the visit of St. Catherine of Siena to the body of St. Agnes of Montepulciano, in which are heads and figures worthy of Raphael. According to Speth these works can be justly compared with Raphael's alone, and he adds that designating Pacchiarotto as of the school of Perugino, is only magnifying the injustice he had already undergone in having his works long reported as the works of Perugino. If therefore he were the pupil of Perugino, what Perugino supplied was only the spark, says Speth, which in Pacchiarotto grew into a flame.

Pacchiarotto has suffered the same misfortune that many other excellent masters have undergone, owing to their being omitted by Vasari—their merits have remained long unrecognised. Pacchiarotto is probably the Girolamo di Pac hia who is casually mentioned by Vasari in speaking of Il Sodoma; they painted together in San Bernardino.

There are two beautiful small easel pictures in oil and on wood in the Pinacothek at Munich by Pacchiarotto—San Francesco d' Assisi, with two angels in the background; and the Madonna and Child, with four angels in the background; half-length figures in both. They are two of the best pictures in the collection, in character, colour, and execution, and are among the best specimens of the beauties of the early Italian schools of painting. They were formerly in the church of San Bernardino at Siena, but were purchased about 1818 by the present King of Bavaria, Ludwig I., then crown-prince.

(Lanzi, *Storia Pittorica*, &c.; Speth, *Kunst in Italien*, vol. ii.)

PACHECO, FRANCISCO, was born of a good family at Seville, in 1571, according to his own account, which is nine years earlier than the date given by Palomino. He was nephew of Francisco Pacheco, canon of the cathedral of Seville, a distinguished divine and a celebrated Latin poet.

Pacheco's master was Luis Fernandez, a painter of serges &c. at Seville: he never was in Italy, as Palomino has wrongly inferred from two passages in his treatise on painting; he studied exclusively in Seville. His first works worthy of notice were two large flags or standards for the Spanish fleets of New Spain and Tierrafirma, painted in 1594, in oil on crimson damask, each thirty yards by fifty; the paintings were the royal arms of Spain, and St. Iago on horseback, with rich borders and other decorations. He was one of the principal painters employed on the great decorations of the funeral or catafalque of Philip II. of Spain in the cathedral of Seville in 1598. He was also the first, says Cean Bermudez, in Seville who properly painted and gilded statues—'el primero en encarnar y estofar bien las estatuas'; thin colour was painted over the gold. He was the first likewise who painted the figures and grounds of bassi-rilievi; there are several works of both descriptions by Pacheco in Seville.

In 1600 he was appointed, together with Alonzo Vazquez, to paint a series of large pictures illustrating the life of St. Ramon for the cloister of the convent of the Merced. In 1603 he executed some works in distemper in the palace of Don Fernando Henriquez de Ribera, third duke de Alcala, from the story of Dædalus and Icarus.

It was not till 1611 that he visited Toledo, Madrid and the Escurial, and saw the great works of Titian and other celebrated masters, Spanish and Italian. The sight of the excellent works which he saw on this occasion impressed him forcibly with the varied and incessant application requisite to form a great painter. Accordingly upon his return to Seville he opened a systematic academy of the arts, as well for his own improvement as for the benefit of the rising artists of Seville; and the fact alone that Alonzo Cano and Velazquez were two of his scholars, shows that his system worked with some effect. The improvement he himself acquired by such elementary instruction, and from the true principles of art, is shown by his great picture of the Last Judgment, an altarpiece finished in 1614 for the nuns of the convent of St. Isabel, which he has himself described at great length in his treatise on painting. Soult made a magazine of this convent during his occupation of Andalucia, and the picture was probably removed. It was a large work containing many figures and many incidents, but Pacheco received only 700 ducats for it. On one part of it was inscribed 'Futurum ad Finem Saeculorum Judicium Franciscus Paciccus Romulensis depingebat. Saeculi a judicis natali xvii. anno xl.'

In 1618 Pacheco was appointed by the Inquisition one of the guardians of the public morals, in as far as he was made censor of all the pictures which were exposed for sale in Seville; nakedness was prohibited, and it was Pacheco's business to see that no pictures of the naked human form were sold. It is to such formal morality as this that the Spanish school of painting owes its characteristic ponderous sobriety, and is so directly opposed to Italian painting. There is not probably in the whole art of Spain such a thing as a naked female of the size of life, if of any other size. It reflects the jealous morosity of the Inquisition even in its portraits. Prudery was carried so far in Spain, that in the time of Ferdinand VII. even all the great Italian works which could be reproached with nudities were removed from the galleries, and were condemned to a distinct set of apartments called the Galeria Reservada, and only opened to view to those who could procure especial orders. There is a 'Cabinet des Objets Réservés' at Naples, and though this is separated from the rest of the collection with reason, there is no difficulty whatever in obtaining admission into it; but the Galeria Reservada of Madrid is of a very different nature, and comparatively innocent, and the separation of such works from the general collection is a greater evidence of subjective immorality than of objective indecency. Mr. Ford, in his 'Handbook of Spain,' terms this gallery a sort of Magdalen or penitentiary, into which were banished all peccant pictures whose nudities might corrupt the purity of Madrid; where the Italian and Flemish Ledas, Danaës, and other improper ladies, blushed unseen, lumped together like the naughty epigrams of Martial when collected into one appendix in well-intentioned editions. All these pictures were the works of foreigners. 'Nothing,' says Mr. Ford, p. 116, 'gave the holy tribunal greater uneasiness than how Adam and Eve in Paradise, the blessed souls burning in purgatory, the lady who tempted St. Anthony, or the Last Day of Judgment, were to be painted, circumstances in which small-clothes and long-clothes would be highly misplaced. Both Palomino (ii. 137) and Pacheco (201) handle these delicate subjects very tenderly. Describing the celebrated Last Judgment of Martin de Vos, at Seville, Pacheco relates how a bishop informed him that he had chanced, when only a simple monk, to perform service before this group of nakedness; the mitre had not obliterated the dire recollections; he observed (he had been a sailor in early life) that rather than celebrate mass before it again, he would face a hurricane in the Gulf of Bermuda; the moral effect of the awful Day of Judgment was so much counter-balanced by the immoral deshabille.'

In 1623 Pacheco again visited Madrid, in company with his distinguished scholar and son-in-law Velazquez, and he remained two years in the Spanish capital. Velazquez went to Madrid by the Invitation of the duke de Olivares, who procured him the appointment of painter to the king, Philip IV. It was at this time that Velazquez painted his equestrian portrait of Philip, upon which Pacheco wrote a sonnet, in which Philip was compared with Alexander, and Velazquez with Apelles. (Cean Bermudez, *Diccionario*, v. 161.)

Pacheco, during this visit to Madrid, among many other works, executed one which hardly accords with the present notions of the occupation of a great painter, though it has been the practice of great artists from very early ages to paint their statues: it was common in the time of Plato and of Alexander. [NICIAS, P. C. S.] Pacheco dressed, gilded, and painted (estofó) for the duchess of Olivares, a statue, probably of wood, of the Virgin, by Juan Gomez de Mora, for 2000 reals. The work was much admired, and by none more than Eugenio Caxes, who, says Cean Bermudez, estimated the decoration at 500 ducats. What this process exactly was it is not evident from this mere mention; but the object generally in these painted wooden images appears to have been to obtain an exact imitation in the minutest detail, perpetual facsimiles. The effect of such images, called *Pasos*, must be experienced to be comprehended. The Spaniards dress them as well as paint them. Their churches were crowded with such works; but most have now been removed to museums.

Pacheco returned to Seville, where his house became a chief resort of all men of art, of literature, and of taste, and among his most intimate associates were the Jesuits of Seville, who assisted him in his 'Arte de la Pintura,' and were indeed the authors of that part which is devoted to sacred art; and doubtless to them is due the austere morality which characterises Pacheco's principles of art. He is noticed above as having been the first artist who painted images properly. He published an essay partly on this subject in 1622, complaining of sculptors painting their own statues. But the generality of *Doradores* and *Estofadores* worked so badly, that such sculptors as Juan Martinez Montañes and Alonzo Cano felt compelled to dress and colour their own statues. Pacheco however coloured many statues for Montañes, including the St. Jerome of the monastery of Santiponce. Montañes generally made a contract with his employers, to be allowed to superintend the toilet of his own statues. Mr. Ford gives some curious details about the toilets of these Spanish images. No man is allowed in Spain to undress the *Paso*, or *Sagrada Imagen* of the Virgin; and some images had their mistresses of the robes (*Camerera Mayor*) and a chamber (*Camerin*) where their toilet was made. The duty has, however, now devolved upon old maids; and 'ha quedado para vestir imagines'—she has gone to dress images, has become a term of reproach. Embroidering rich dresses for images of the Virgin is still a great occupation with the rich and pious ladies of Spain. Similar customs prevailed with the antients. But the antients, says Mr. Ford, paid much more attention to the decorum and propriety of costume than the Spanish clergy. In the remote villages and in the mendicant convents the most ridiculous masquerades were exhibited, such as the Saviour in a court dress, with wig and breeches. Some figures have only heads, feet, and arms, the bodies being mere blocks, because destined to be covered with drapery; they are called 'imagines a vestir.' Before the French occupation of Spain there were fifty of these images in Seville alone, which were carried in various processions in the holy week, and on other great occasions.

Pacheco died at Seville in 1654. His works, though not vigorous, are correct in form, effective in light and shade, studied in composition, and simple in attitude; but they have little colour, are dry, and rather feeble or timid in their handling. These defects are more apparent when his pictures are seen together with the works of other Andalucian painters, who have generally made colouring their principal study, and have comparatively neglected purity of form. Besides many religious pictures, he painted or drew in crayons nearly four hundred portraits, the best of which is that of his own wife. One of his sitters also was Miguel Cervantes.

His *Arte de Pintura, su Antigüedad, y Grandezas*, 4to., Seville, 1649, pp. 641, a remarkably scarce book, is considered an indispensable guide by the painters of the school of Seville; it is very elementary, and is said also to be a work of great learning on the subject, and is held throughout Spain to be the best work on painting in the Spanish language: it is in three parts—history, theory, and practice. His works are seldom seen out of Seville; and he is even very inadequately represented in the splendid gallery of the Prado at Madrid. His masterpiece is, or perhaps rather was, the altarpiece of the Archangel Michael expelling Satan from Paradise, which was in the church of San Alberto at Seville; but this church was one of Soult's magazines. There are still at Seville an altarpiece of the Conception at San Lorenzo, two pictures of San Fernando in San Clementi; and a picture in San Alberto. The methodic system of Cean Bermudez to mention the locale of all the most celebrated works of the great Spanish masters, eventually cost Spain the greater portion of these works, for his dictionary was used by the French generals and others as an inventory of what was valuable, and directed them to the places where these works were to be found. Not a moiety of the works of Pacheco described by Bermudez as at Seville is now to be found there. Pacheco's own portrait by himself is in the Spanish museum in the Louvre.

Pacheco collected the poems of his friend Hernando de Herrera, and published them with a portrait, in 1619 His own poems do not appear ever to have been published in a collected form. Bermudez has printed a few in his Dictionary.

PACHYCO'RMUS, a genus of Ganoid fossil fishes, from the lias of England and Wirtemberg. (Agassiz.)

PACHYCE'PHALUS, a genus of fossil fishes from Sheppey. (Agassiz.)

PACHY'ODON, a genus of Dimyarian Conchifera, fossil in the lias and oolites. (Strickland.) This is the genus Cardinia of Agassiz, and includes part of the Unionidæ of Sowerby.

PACHY'PTERIS, a genus of fossil Ferns, from the oolite of Yorkshire. (Brongniart.)

PACKING-PRESS. The hydraulic press invented by Mr. Bramah, besides being used to draw piles, trees, &c. from the ground, or to prove the strength of materials, is frequently employed to pack or compress bales of linen, cotton, and the like goods into small dimensions for the convenience of transport. A description of this machine has been given under HYDRAULICS, P. C.; and it is intended here merely to notice the method employed by Mr. Barlow to determine the thickness which the cylinder should have in order that its strength may be in equilibrio with the strain to which it is subject from the pressure of the fluid within it.

Within any horizontal section of the cylinder the tendency of the contiguous particles of metal to separate from one another in a direction perpendicular to a diameter passing through them, in consequence of the expansion produced by the pressure of the fluid, becomes continually less from the interior to the exterior circumference of the section, and is inversely proportional to the distances of the particles from the axis of the cylinder; and the cohesive power of the particles is, by the laws of elasticity, proportional to their separation, while the strain produced by the pressure of the fluid varies, at any part of the section, with the distance of that part from the axis. It follows that the resistance opposed at such part of a section to the momentum of the pressure is inversely proportional to the square of the distance from the axis.

Therefore r representing the radius of the interior surface of the cylinder, t the whole thickness, and x any variable distance from the interior surface towards the exterior, all in inches; then $\int \frac{r^2\,dx}{(r+x)^2}$, if multiplied by $2\,\pi$, the circumference (rad. $=1$), and by the force of cohesion on a square inch of the metal, will express the resistance produced by an annulus which is one inch deep in a direction parallel to the axis.

That integral, for the whole thickness t, is $\frac{rt}{r+t}$; therefore f (in pounds) denoting the force of cohesion, $\frac{2\pi\,rtf}{r+t}$ expresses the whole resistance.

If f' (in pounds) represent the force on a square inch of the interior surface, by which the pressure of the fluid tends to strain the cylinder, $2\pi rf'$ will denote the whole strain on the same annulus; therefore, equating the strength and strain, there is obtained

$$t=\frac{rf'}{f-f'}$$

This value of t expresses the required thickness.

PACO. [LLAMA, P. C.]

PADDLES, PADDLE-WHEELS. [STEAM-VESSEL, P. C., pp. 493, 495, 508.]

PAEDE'RIA, a genus of plants belonging to the natural order Cinchonaceæ. It has a small 5-toothed permanent calyx, a funnel-shaped corolla, hairy inside, 5-lobed, and with a plaited æstivation. There are 5 stamens, sometimes abortive; the anthers oblong, nearly sessile in the middle of the tube. The style is not protruded, and the stigma bifid. The berry is small, roundish, and globose, tri-celled, with a seed in each cell. The flowers are small, white, and usually unisexual.

P. fœtida has a woody twining stem, round and smooth. The leaves are oblong or lanceolate, cordate at the base and glabrous. The panicles axillary, terminal, opposite, short, and few flowered. The flowers are usually of a deep pink, the bracts ovate, the calyx 5-toothed, the corolla with a long tube somewhat gibbous and woolly inside; the limb narrow and divided into 5-cordate crenulate segments. The berry is dry, compressed, having 5 lines on each side, 1-celled, and 2-seeded. The seeds are smooth, compressed, enlarged with a somewhat membranous ring all round. The leaves have a very fœtid and alliaceous odour when bruised, yet they are used to impregnate baths and are administered in a decoction medicinally in cases of retention of urine and some febrile complaints. According to Roxburgh the root is used by the Hindus as an emetic. It is a native of the East Indies, and of Japan and the Moluccas.

P. ternata has an erect smooth trichotomous stem with triangular branchlets; leaves 3 in a whorl; oblong lanceolate axillary trichotomous corymbs shorter than the leaves; the limb of the calyx campanulate and obscurely 5-toothed. It is a native of the East Indies on the mountains which border on Silhet. The flowers are rather large, funnel shaped, white, on long filiform pedicels, each pedicel having a pair of linear ciliated bracts above the middle. The flowers are said to be fragrant when fresh, but emit a very offensive smell on being steeped in water after they have been dried.

The species of Paederia are free growers and will strike root in any kind of light rich soil under a hand-glass.

PAGA'NI, GREGO'RIO, was born at Florence in 1558: his father, Francesco Pagani, died aged only thirty, when his son was but three years old. Gregorio was an excellent colourist, was first the pupil of Santi Titi, and afterwards of Cigoli, and became one of the first and most able reformers of the Florentine school from the low state to which it had been reduced by the blind followers of the anatomical school of Michael Angelo. [TUSCAN SCHOOL OF PAINTING, P. C.] Barocci and Santi Titi were the leaders of the new school, but Cigoli was its principal representative, and Pagani adhered so closely to the style of his friend and master Cigoli, that he used to be termed the second Cigoli. His masterpiece, however, the Finding of the Cross by St. Helena, in the Carmine, was burnt in the fire which destroyed that building in 1771, and Pagani's reputation has greatly suffered in consequence, though there is a print of it by G. B. Cecchi and B. Eredi. Few of his works still remain; one of the principal is a fresco in Santa Maria Novella: his easel-pictures in oil are also rare. He died at Florence in 1605: Matteo Roselli was his scholar.

(Baldinucci, *Notizie dei Professori del Disegno*, &c.; Lanzi, *Storia Pittorica*, &c.)

PAGANI'NI, NICOLO, whose European fame as a violinist, whether justly acquired or not, entitles him to notice among distinguished characters, was born at Genoa, in 1784. His father, a commission-broker, played on the mandoline, but fully aware of the inferiority of an instrument so limited in power, he put a violin into his son's hands, and initiated him in the principles of music. The child succeeded so well under parental tuition, that at eight years of age he played three times a week in the church, as well as in the public saloons. At the same period he composed a sonata. In his ninth year, he was placed under the instruction of Costa, first violoncellist of Genoa; then had lessons of Rolla, a famous performer and composer; and finally studied counterpoint at Parma under Ghiretti, and the celebrated *maestro* Paer. He now took an engagement at Lucca, where he chiefly associated with persons who at the gaming-table stripped him of his gains as quickly as he acquired them. He there received the appointment of director of orchestra to the court, at which the Princess Elisa Bacciochi, sister of Napoleon, presided, and thither invited, to the full extent of her means, superior talent of every kind. In 1813 he performed at Milan; five years after, at Turin; and subsequently at Florence and Naples. In 1828 he visited Vienna, where a very popular violinist and composer, Mayseder, asked him how he produced such new effects. His reply was characteristic of a selfish mind:—'Chacun a ses secrets.' In that capital he was accused of having murdered his wife. He challenged proofs of his ever having been married, which could not be produced. Then he was charged with having poignarded his mistress. This he also publicly refuted. The fact is that he knew better how to make money than friends wherever his thirst of gold led him. Avarice was his master-passion, and, second to this, gross sensuality in his intercourse with the female sex.

The year 1831 found Paganini in Paris, in which excitable capital he produced a sensation hardly inferior to that created by the visit of a truly great musician, Rossini. Even this renowned composer was carried away by the current of popular opinion. Being asked how he liked the new violinist, he replied, 'I have wept but three times in my life: first, on the failure of my earliest opera; the second time, when in a boat with some friends, a turkey stuffed with truffles (*une dinde aux truffes*), provided for our dinner, tumbled into the water; and, thirdly, on hearing Paganini for the first time.' The public of Brussels, however, were moved in a very different manner. According to M. Fétis, Paganini's performance at a concert given by him in that city, produced only laughter, which continued during the whole of it. He arrived in England in 1831, and immediately announced a concert at the Italian Opera-House, at a price which, if acceded to, would have yielded 3391*l.* per night. He had heard, all over the Continent, of the gullibility of the British public, of the wealth of the aristocratic classes, and of their lavish expenditure on foreign performers; but the attempt was too audacious, even for these, and he was compelled to abate his demands; though he succeeded in drawing audiences fifteen nights in that season at the ordinary high prices of the King's Theatre. He also gave concerts in other parts of London, and performed at benefits, always taking at these a large proportion of the proceeds, and frequently the whole. He visited most of our great towns, where his good fortune still attended him. He was asked to play at the Commemoration Festival at Oxford, in 1834, and demanded 1000 guineas for his assistance at three concerts. Need we add that his terms were scornfully rejected?

Paganini died at Nice in 1840, of a diseased larynx (*phthisie laryngée*). By his will, dated 1837, he gave his two sisters legacies of 60,000 and 70,000 francs; his mother a pension of 1200; the mother of his son Achillino (a Jewess of Milan) a similar pension; and the rest of his fortune, amounting to four millions, devolved on his son. These and other facts before related, we give on the authority of the *Biographie Universelle.*

Paganini certainly was a man of genius and a great performer, but sacrificed his art to his avarice. His mastery over the violin was almost marvellous, though he made an ignoble use of his power by employing it to captivate the mob of pretended amateurs by feats little better than sleight-of-hand. His performance on a single string, and the perfection of his harmonics, were very extraordinary; but why, as was asked at the time, be confined to one string when there are four at command that would answer every musical purpose so much better? His tone was pure though not strong, his strings having been of smaller diameter than usual, to enable him to strain them at pleasure; for he tuned his instrument most capriciously. He could be a very expressive player: we have heard him produce effects deeply pathetic. His arpeggios evinced his knowledge of harmony, and some few of his compositions exhibit many original traits. But money was his object, and he attained it. Were the French, continuing their not uncommon practice, to put the principal incidents of Paganini's life into a dramatic form, 'All for gain, or fair fame well lost,' would make an appropriate title to the piece.

(*Biographie Universelle, Supplement*; *Harmonicon.*)

PAGGI, GIOVANNI BATTISTA, was born of an antient and noble family at Genoa, in 1554. He was the pupil of Luca Cambiaso, and was distinguished chiefly as a painter, but he was also a sculptor and architect. About the year 1580 he was obliged to fly from Genoa in consequence of an unfortunate homicide which the absurd conduct of a friend brought upon him. Paggi went to Florence, and, under the protection of the grand-dukes Francesco I. and Ferdinando, there lived in peace and with reputation, until he was recalled through Archbishop Sinnasio, afterwards cardinal, to Genoa about 1600, where he executed several excellent works, and gave a great impulse, especially in colouring, to the Genoese school of painting, of which he was the best master in his time. His masterpieces are considered two pictures in San Bartolomeo, and the Slaughter of the Innocents belonging to the Doria family, painted in 1606. Paggi died in 1627. In 1607 he published a short treatise on the theory of painting, entitled 'Definizione, o sia Divisione della Pittura:' he wrote it in consequence of his objecting to some of the statements of Lomazzo in his 'Trattato' and his 'Idea del Tempio della Pittura.' Paggi's treatise is extremely scarce.

(Soprani, *Vite de' Pittori, &c. Genovesi;* Lanzi, *Storia Pittorica*, &c.)

PAJOU, AUGUSTIN, a distinguished French sculptor, was born at Paris in 1730, and was the pupil of J. B. Lemoine, likewise a sculptor of eminence. Pajou obtained the grand prize for sculpture in the French Academy, in 1748, and accordingly went as a pensioner of the French government to Rome, where he remained twelve years. Gabet mentions that Pajou was the sculptor of about two hundred works, in bronze, marble, stone, wood, and even in paper or pasteboard; and he gives a list of some of those which he exhibited. In 1768 he exhibited a sketch of the tomb of Stanislaus, King of Poland, and father-in-law of Louis XV.; a statue in lead, of the natural size, for the Duchess of Mazarin, representing Love as ruler of the elements; and four large colossal figures in stone for the garden of the Palais-Royal, representing Mars, Prudence, Liberality, and Apollo. The following are some of his principal works:—Pluto holding Cerberus, chained (for this work he was elected a member of the Academy); Psyche abandoned (in the Luxembourg); statues of Pascal, Turenne, Bossuet, Buffon, and Descartes; the sculptures of the façade of the Palais-Royal, ordered by Louis XVI. He executed also the sculptures of the Salle de l'Opera at Versailles; the ornaments of the Palais Bourbon; and of the Cathedral of Orleans; and also the Naiades of the south and west faces of the Fontaine des Innocens. He died at Paris in 1809. He was made one of the professors of the French Academy of Arts in 1767; and was subsequently a member of the French Institut. His style was natural and manly, and was so far the exponent of his own character. His son Jacques Augustin Pajou was a painter of great merit.

(Gabet, *Dictionnaire des Artistes de l'École Française*, &c.)

PALÆOGRAPHY (from παλαιός, 'old,' and γραφή, 'writing') is a term applied to express the knowledge of the antient styles of writing, or the study of the characters and illuminations of ancient manuscripts. Palæography is a comparatively recent study respecting its ornaments, but it has very lately been the subject of much laborious application in all respects; and the age of a MS. may be now approximated from the form and style of its character, though it cannot be strictly ascertained. The present article is directed particularly to the ornament and general illumination of antient MSS., and their connection with the progress of painting, and not to calligraphy or to the study of MSS. historically, which is treated of in the 'Penny Cyclopædia.' The whole subject is perfectly illustrated, generally, in the splendid work recently published in Paris by Champollion Figeac, and Aimé Champollion, Fils, which contains fac-similes from most of the principal MSS. extant in Europe, admirably executed by Silvestre (*Paléographie Universelle, Collection de Fac-Similes d'Ecritures de tous les Peuples et de tous les Temps*, par M. Silvestre, 1839-42, 4 vols. folio).

The first work which treats of this subject with regard to ornament is Dibdin's *Bibliographical Decameron*, published in 1817, which was followed by the more comprehensive work of D'Agincourt in 1823, *Histoire de l'Art par les Monuments*, but which treats chiefly of Greek and Italian MSS., and the illustrations are uncoloured. D'Agincourt was the first to promulgate the treasures of the Vatican Library in this department of art. A very beautiful work in colours, by Mr. Shaw, on this subject was published in London, in 1833, *Illuminated Ornaments selected from MSS. and early Printed Books, from the Sixth to the Seventeenth Century*, drawn and engraved by Henry Shaw, with descriptions and an introduction by Sir F. Madden, keeper of the MSS. in the British Museum. There are many papers on this subject in the Archæologia; and a series of articles on the 'Progress of the Art of Illuminating Manuscripts,' with illustrative woodcuts, was published in the *Penny Magazine* of 1839.

The illumination of MSS. was in practice among the antient Romans. This is known from passages in antient writers, though there are no MSS. extant of an earlier date than about the third century of the Christian æra. Portraits were sometimes prefixed to the writings of authors: Martial (xiv. 186) mentions one of Virgil which was prefixed to a MS. of his works; and Varro, says Pliny (*Hist. Nat.*, xxxv. 2), inserted the portraits of 700 distinguished men in his writings, and dispersed them over all parts of the world.

The illuminating of MSS. is generally considered as a connecting link between antient and modern painting, but though at the revival of painting MSS. were illuminated by painters, the calligraphists must have been always a distinct class, and even the initial letters and borders were executed by distinct persons from those who wrote the MSS., which is evident from the fact that some MSS. want the initial letters altogether, the spaces being left to be filled in by the proper artist. Though many illuminators of MSS., or *miniatori*, at about the revival of painting became subsequently great painters, it is not likely that painters became the illuminators of MSS. at any time, beyond the execution of the miniatures which were attached to them. There are few even moderately good miniatures as works of art to be found in any MSS., and the best of all are those executed by the celebrated Memling and his nearly contemporary Giulio Clovio, a native of Croatia, who died 1578, aged eighty; executed therefore at the time when painting was at its highest state of perfection, which shows that the influence of the great works with which Flanders and Italy then abounded reached the decoration of MSS. as well as other objects of taste, the less influenced by the greater; but the reverse was probably never the case, and it would be difficult to show that painting was ever in any way improved or even preserved by the illumination of MSS. The *miniatori* (from minium or minio, red lead; Pliny and Vitruvius sometimes mean vermilion by minium) are said to have been the only painters of the middle ages, but this is an incorrect assumption, and that the *miniatori* also were the revivers of painting in the tenth and eleventh centuries is a mere theory founded on assumption. Constantinople always had its painters, and there is a Latin work extant, of as early a date probably as the ninth century, which treats of painting in all its branches, 'De Omni Scientiâ Artis Pingendi,' not omitting painting in oil. There is a MS. of this work now in the British Museum; it is by Theophilus Presbyter, whom Lessing supposes to be the same person as Tutilo or Tuotilo, a monk and painter, 'picturæ artifex,' of the convent of St. Gall in Switzerland. The work is printed in Lessing's *Beiträge zur Geschichte und Litteratur*, No. vi., Brunswick, 1781. [TUTILO, P. C.]

Vasari, in the Life of Don Lorenzo, evidently informs us that the writers of letters were a distinct class after the revival of painting, for he notices Don Jacopo of Florence, a monk of the convent degl' Angeli, of the fourteenth century, as the most celebrated letter-writer, 'scrittore di lettere grosse,' not only in Tuscany but in the whole of Europe. He left his convent sixteen folio choral books with miniature illuminations by another monk of the same convent, Don Silvestro, and their skill was so much venerated by their brother monks, that their right hands were embalmed after their death and preserved in a tabernacle.

It appears that the earliest MSS. extant of Greek and Roman origin are not much ornamented, their embellishment consisting in little more than the occasional use of red ink for titles or commencements of books. No ornaments have been found in the Herculaneum papyri. The Egyptian papyri are written in various colours; they contain mythological figures in red, blue, yellow, green, and white.

The most celebrated collection of Illuminated MSS. is that of the Vatican, already noticed, which, among its 24,000 MSS., contains many interesting works. D'Agincourt notices upwards of fifty valuable MSS. in this collection, and gives specimens of the style of decoration, in design, from most of them. The following are the most remarkable of this collection according to Platner (*Beschreibung der Stadt Rom*, vol. ii. pt. 2, p. 345-363):—Of the Western or Latin MSS. the earliest is probably the Virgil (Vaticana, No. 3225), containing 50 miniatures, 44 of which are from the Aeneid, but they are much damaged, and five are nearly wholly ruined; in D'Agincourt ('Peinture,' vol. v. pl. xx.-xxv.) the damaged parts are restored. P. S. Bartoli published prints from these miniatures, but they are mannered and altered. The designs are supposed to be copied from antient works; the conceptions are better than the execution, which is very coarse; the lights on the draperies, arms, and other accessories are picked out with gold: the date of this MS. is supposed to be not earlier than the fourth centnry. Another celebrated MS. is a Terence (Vaticana, No. 3868), formerly in the possession of Cardinal Bembo. At the commencement of the MS. is a portrait of Terence, and at the beginning of each comedy is a picture of masks: in the text are representations of the scenes with the names of the characters attached. This MS. is supposed to be of the ninth century; and the illustrations are thought to be copies of earlier works, on account of the superiority of the designs to the execution, and the antient costume of the figures; the drawing is very bad. (D'Agincourt, pl. xxxv., xxxvi.) The writer of the MS. was Hrodgarius (Rodgar), from his name apparently a German. There is another Virgil in this collection (Vaticana, No. 3867) of the twelfth or thirteenth century, in which according to Rumohr and Platner the illuminations are also copied from earlier works. It was formerly in the Abbey of St. Denis: it contains sixteen illustrations, with the full-length portrait of Virgil three times, in the same attitude, but the drawing is thoroughly bad in every instance. (D'Agincourt, pl. lxiv.) Vaticana, No. 4922, is an Italian MS. of the year 1125; a eulogistic poem on the celebrated Countess Matilda, by Donizo; the subjects of the illustrations are written against them; they relate to the genealogy and history of the countess: the prints in D'Agincourt (pl. lxvi.) are improved; the originals both in form and colour are poor in the extreme. There is a MS. of the Tragedies of Seneca (No. 355, Biblioteca d'Urbino), with somewhat better illustrations, by an Englishman, with the commentary of an English Dominican, Nicholas Treveth, which is dedicated to Niccolo, Cardinal bishop of Ostia and Velletri, probably Niccolo da Prato, who died at Avignon in 1321 (D'Agincourt, pl. lxxii.). No. 1071 of the Palatina is a treatise of the 13th century, on falconry, by the Emperor Frederick II.; in the illuminations to this work the hawks are well executed, but the horses and the human figures, particularly, are bad. (D'Agincourt, pl. lxxiii.)

The Byzantine MSS., of which there are many in the Vatican, are better illustrated than those of the western empire; their illustrations are strictly in what is called the Byzantine style, but they are often executed with great care, and finished with remarkable detail. No. 405 Vaticana, is a MS. of the book of Joshua, on a roll of parchment 32 feet long, of the seventh or eighth century. Rumohr (*Italienische Forschungen*, i. 167) is of opinion that these illnminations are copies of earlier works, and, though certainly much inferior to their originals, are the best of the early Christian illustrations: in the extremities they have all tho characteristic imperfections of Byzantine art, but in treatment, in costume, and in the military equipments they approach the fine works of antiquity. The Jordan, the cities of Jericho and Ai, and Mount Hebal, are personified, and indicated in writing. (D'Agincourt, pl. xxviii.-xxx.)

Among these MSS. is also the celebrated Menologium (Vaticana, No. 1613), or part of a Greek Calendar, from September to February, with 430 miniatures upon gold grounds, illustrating the life of Christ, and of all the saints whose holidays occur in these months of the year. The miniatures, according to names inscribed upon them, were painted by — Pantaleon, Simeon, Michael Blachernita, Georgius, Menas, Simeon Blachernita, Michael Micros, and Nestor. They are extremely poor in invention, but have considerable merit in the expression of the heads, in the draperies, and detail of execution: the figures in action are the most defective; those in repose are frequently natural. Their martyrdom is generally the subject represented in tho lives of the saints. There are many characteristic Byzantine buildings introduced in the backgronnd. This MS. was executed by the order of the Emperor Basilius II. called Porphyrogennetus (989 – 1025), and is supposed to have been procured from Constantinople by Lodovico Sforza, Duke of Milan. It was presented to Paul V. by Cardinal Sfondrato, and placed in the Vatican Library in 1615. Cardinal Annibale Albani, nephew of Clement XI., published it in 1727, together with a Latin translation, but the engravings of this edition are very inferior to the originals. (D'Agincourt, pl. xxxi.-xxxiii.) The rest of the Calendar was supplied from a MS. in the Library of Grotta Ferrata, in which there are no illustrations.

Platner is of opinion that the best Greek MSS. are those of the period of the Comnene emperors (1056—1204), from Michael VI. to the conquest of Constantinople by the Crusaders; and particularly during the reigns of Alexius I., Johannes II., and Manuel I., and this opinion is borne out by the illustrations of d'Agincourt. Of these MSS. are the Homilies of St. Gregory Nazianzenus (Vaticana, No. 463), finished in 1063, and distinguished for its writing, initial letters, and arabesque marginal decorations; it contains only one miniature—the author writing. A still more important MS. for its illuminations is tho Dogmatica Panoplia, fortifications against heresies (Vaticana, No. 666), executed by order of the Emperor Alexius Comnenus (1081—1118). In this MS. are three large illustrations on gold ground: two, representing one subject, are on the opposite sides of the same leaf—on one the fathers of the Greek church are bringing the materials of the book, and on the other, the emperor is receiving them; above is an apparition of the Saviour, a half figure, with his hand in the act of benediction:—in the third illustration, the emperor is presenting the finished work to the Saviour seated on his throne. The figures of these paintings are perhaps the best extant of this or any preceding period; they are abont nine inches high, are brilliantly coloured, and the heads have much character: the costume of the emperor is on both occasions very complete; it is quite oriental, and bears no resemblance to the antient costume. (D'Agincourt, pl. lviii.) There is also a beautiful MS. of the four gospels, or Evangelium, executed in 1128, in the reign of Johannes Comnenus. The illustrations of this MS. are—Christ seated between Justice and Love, both crowned—the Saviour is blessing with his right hand the emperor, with his left the emperor's son Alexius; the Evangelists writing; the birth of the Saviour; his baptism; the birth of John the Baptist; and the Saviour releasing the souls from purgatory or limbo, the devil lying chained under his feet. The draperies are good, as also are the heads of the emperor, his son, and the Evangelists, which are the best: this MS. is also ornamented. (D'Agincourt, pl. lix.) Another MS. of this period is (Vaticana, No. 394) one of St. Johannes Climacus, which is called the ladder, κλίμαξ, from the work itself, which treats of the virtues as the steps of the ladder to heaven; the vices are also personified accompanied by devils, and causing precipitation from the ladder: the vices are blue, the devils black. The figures are very small, but carefully executed, and the colouring is likewise good. The male are better than the female figures. (D'Agincourt, pl. lii.) Platner remarks that short plump figures are a characteristic defect of the inferior Byzantine MSS.

There are no Latin MSS. of the fourteenth century in the Vatican with illuminations of any value as monuments of art, but there is a commentary on the New Testament, executed in 1358, with illustrations, by Niccolo da Bologna, an artist otherwise unknown. Of the fifteenth century, when the rapidly increasing improvement in painting throughout Italy gradually raised the common standard of mediocrity in all matters of taste, there are some illustrations of a very superior character. Among the most remarkable are those of a Pontificale ('Liber Pontificalis,' Biblioteca Ottoboni, No. 501), generally attributed to Pietro Perugino, but in the opinion of Platner they belong rather to Bartolommeo della Gatta, a celebrated miniature painter of the same time. (D'Agincourt, pl. lxxvi.) With these may be mentioned the illuminations, both miniatures and arabesque and other decorations, of a MS. (Vaticana, No. 2094) of a Latin translation of Aristotle's book on animals; the book is dedicated to Sixtus IV., of whom there is an excellent medallion portrait on the title-page; Aristotle is also represented on the title-page, writing, and surrounded by men, women, and animals, indicating the subject of the treatise: the lights of these illuminations are picked ont with gold and silver. (D'Agincourt, pl. lxxvi.) Another valuable MS. of this century is the Latin Bible of Federigo, duke of Urbino, in two volumes, royal folio, finished by Hugo de Cominellis (Hugues de Comines) in 1478. The ornamental part of this MS. is very elaborate: the miniatures were probably execnted by different artists; they are unequal in their execution, and those in the first volume are inferior to those in the second. (D'Agincourt, pl. lxxviii.) From the Urbino library (No. 112) is also the breviary of Matthias Corvinus, king of Hungary, of which some have supposed the miniatures to be executed by Gherardo of Florence, a celebrated miniature painter, noticed by Vasari as having executed such works for Matthias Corvinus. The MS. was written by the presbyter Martinus Antonius in 1487, but the miniatures were probably not completed until some years afterwards; one is dated 1492, when Corvinus was already dead: every page of the MS. is illuminated. Vante, or Attavante, a celebrated miniature painter, also executed miniatures for Matthias Corvinus, but Vasari adds that all the MSS. belonging to Corvinus, which were in the hands of these artists, were purchased by Lorenzo de' Medici, and afterwards placed in the Laurentiana at Florence. There is only a missal in the Laurentiana which belonged to Corvinus; it was written by tho priest Zanobi Moschino in 1394. Lorenzo de' Medici was probably not the only purchaser of these works. There is an illustrated Dante in this collection, likewise from the Urbino library (No. 365) which was executed for the duko Federigo between the years 1476 and 1482; the last is that of his death, and 1476 is the year in which he was presented with the order of the Garter by Edward IV. The decoration of this order is emblazoned with the arms of the duke on the title-pages of the three parts. (D'Agincourt, pl. lxxvii.) Of the sixteenth century there are, with the exception of Julio Clovio's and Memling's, scarcely any MSS. worthy of the time, and those of Clovio are injured by their excessive finish. Tho miniatures of Clovio have one particular distinction from those of other earlier masters; they are executed in what is at present understood by water-colours, while those of earlier masters are done in body colours, or a species of distemper, a guazzo or a colla: the lights are relieved in white, gold, and silver. The design is in both cases previously put in in fine outline. In Champollion's *Paléographie Universelle* one of the illustrations of a Dante in the Vatican is given as Clovio's; it is extremely highly finished. This painter, according to Vasari, spent nine years in painting the twenty-six miniatures in a breviary of the Virgin (Uffizio della Madonna), executed for the Cardinal Alessandro Farnese, now in the Royal Library at Naples. The works of Clovio, however, are not superior, and in some respects are not even equal to those of his predecessor Memling, which are more masculine in their execution.

The illuminations of Memling and his scholars are in the opinion of Schorn the finest paintings of their class extant: they have all the excellences of his oil paintings; they are painted in body colours, are quite free from the dark outlines of the Greek and Italian MSS., and have no gold but what is put on with the pencil. The most remarkable work of this class by Memling, in which he was assisted by Gerhard of Ghent and Livin of Antwerp, is the celebrated missal of Cardinal Grimani in the Library of St. Mark at Venice (it is described in the Kunstblatt of 1823); Memling died considerably advanced in age in the beginning of the sixteenth century. [MEMLING, P. C. S.] There were also several good miniatori or miniature painters of earlier centuries, who can be mentioned by name. Oderigi of Gubbio, and his pupil Franco Bolognese, who are noticed by Dante, are two of the earliest:—

> Oh, diss' io lui, non se' tu Oderisi,
> L' onor d' Agobbio e l' onor di quell' arte
> Ch' *alluminare* è chiamata in Parisi?
> Frate, diss' egli, più ridon le carte
> Che pennelleggia Franco Bolognese:
> L' onore è tutto or suo, e mio in parte.
> *Purgatorio*, Canto xi.

Oderigi died about 1300, Franco was still living in 1313. Simone Memmi, the painter of Laura, and the friend of Petrarch, was likewise an illuminator of MSS. There is a MS of Virgil with the Commentary of Servius in the Ambrosian Library at Milan, preceded by a miniature of the poet writing with various illustrative accessories, and it is inscribed with the following couplet:—

> Mantua Virgilium qui talia carmina finxit,
> Sena tulit Simonem digito qui talia pinxit.

Memmi died at Avignon in 1342. [MEMMI, SIMONE, P. C. S.] In the fourteenth century Don Lorenzo and Don Silvestro, already mentioned, Florentine monks, were also celebrated illuminators. Some of the choral books of Don Silvestro still exist, and are among the best in Italy. Don Bartolomeo and Gherardo, of Florence, already mentioned, died at about the close of the fifteenth century. Francisco Squarcione, also of Padua, and his school, were celebrated illuminators. Attavante, their contemporary, is the illuminator of some of the most valuable MSS., in respect of their illuminations, now extant. Vasari attributes to him the MS. of Silius Italicus in the library of St. Mark at Venice, but this is disputed by Morelli and others, who are of opinion that its illuminations are superior to other known works by Attavante. It contains many historical figures and a variety of friezes ornamented with birds and children: among the historical figures or portraits are—Silius Italicus himself, Scipio Africanus, Hannibal, Hanno, Hasdrubal, Caelius, Massinissa, L. Salinator, Nero, Sempronius, M. Marcellus, Q. Fabius, the younger Scipio Africanus, Vibius, Mars, Neptune, &c., and Pope Nicholas V. In the library of St. Mark also is a MS. of Marcianus Capella, with illuminations by Attavante; it is signed 'Attavantes Florentinus pinxit.' Tiraboschi praises some illuminations by Attavante in the Este Library, in some MSS. belonging formerly to Matthias Corvinus. In the royal library at Brussels there is a magnificent missal which Attavante illuminated for this king: it is a large folio parchment volume, every page of which is nobly ornamented with arabesques, flowers, and figures. The miniatures of the two first pages and those at the beginning of the canon mass are the most highly praised and are said to be of extraordinary beauty: on the first page is written—'Actavantes de Actavantibus de Florentia hoc opus illuminavit, A. D. MCCCCLXXXV.' and on another is written—'Actum Florentia, A.D. MCCCCLXXXVII.' The Hungarian arms are often repeated, but those of Austria and Spain have been since glued over them: there are gold medallion portraits of Corvinus and his queen Beatrice of Aragon towards the end of the volume. The former regents of Belgium used to take their official oath upon this volume; the first to do so were the archduke Albert and Isabella in 1599; and the prince of Saxen-Teschen, in the name of Joseph II., was the last, in 1781. It was probably brought to Brussels by Maria, sister of Charles V.; she obtained the government of the Netherlands after the death of her husband Ludwig II. of Hungary. It is described by Chevalier in the *Mémoires de l'Académie Royale de Bruxelles*, vol. iv.

Cosimo Tura, or Cosmè da Ferrara, was also a celebrated *miniatore* of this century, but he was not equal to the Florentines. Liberale da Verona and Girolamo da' Libri were, after Clovio, the most eminent *miniatori* in Italy of the sixteenth century.

There was an antient geographer of the name of Agathodaemon, who delineated and illuminated some maps for manuscripts of the Geography of Ptolemy. There is a MS. with these coloured maps at Vienna, and another at Venice. Agathodaemon's time is not known. (Heeren, *Commentatio de Fontibus Geograph. Ptolemaei*, &c.)

The ornamental and initial letter decorations of MSS. are almost infinite, and but very few of the names of these decorators have been preserved. Some of the arabesque and floral decorations are extremely elaborate and beautiful, and there are also many classes of initial letters which display extraordinary ingenuity, skill, and patience. There are many specimens of initial letters in Shaw's *Ornaments*, &c.; Sir F. Madden, keeper of MSS. in the British Museum, in his *Introduction* to that work, enters at some length into a review of the various kinds of letters which prevailed in various times and various countries, and from this the substance of the following remarks is taken. The red ink or minium, cinnabar, was long used very sparingly by the Greeks of the lower empire; it was the sacred *ἔγκαυστον*, and was at one time used only by the emperor or for his name to imperial rescripts, as confirmed by Leo, A.D. 470. This continued until the 13th century. The custom was imitated in the West by Charles the Bald in the ninth century, but was not continued by his successors. Gold and silver letters were common in the earlier centuries, sometimes written on vellum of a purple or rose colour. Julius Capitolinus, in his Life (c. 4) of the Emperor Maximinus the younger, mentions a present to the emperor from his mother, of the poems of Homer written on purple vellum in gold letters; this was at the beginning of the third century. By the end of the fourth century such MSS. of devotional books became common, but in other classes of literature they were still rare. The Codex Argenteus of Ulphilas, in gold and silver letters on purple vellum, of the year 360, is the most antient specimen extant of this magnificent description of calligraphy: other early specimens are the book of Genesis in the library at Vienna; the Psalter of St. Germain des Près; and the fragment of the New Testament in the Cottonian Library in the British Museum (Titus, c. xv.); all of the fifth and sixth centuries. Eddius, the biographer of Wilfrid, archbishop of York, mentions a copy of the Gospels of this description, which that prelate presented to his church: this was in the seventh century. In later times only parts of MSS. were thus richly executed, as the titles. In some Greek MSS. the vellum was burnished with gold on both sides where it was to be written upon, and was then richly ornamented with coloured arabesques or borders: there is such a MS. in the British Museum: see Shaw's *Illuminated Ornaments*, &c., pl. 1-4.

The more beautiful MSS. of the eighth, ninth, and tenth centuries are executed in the gold letter on white vellum. The Harleian copy of the Gospels, No. 2788, and the Bible and Hours of Charles the Bald, at Paris, are among the finest examples of this kind of writing extant. (There are specimens of all the above kinds of MSS. in Silvestre's *Paléographie Universelle.*) The Charter of King Edgar to the new minster, or Hyde Abbey, at Winchester, in the year 966 (*MSS. Cott.*, Vesp. a. viii.), is the only remarkable instance that occurs of gold writing in England: prefixed is a portrait of Edgar between the Virgin and St. Peter. This MS. is much damaged, and the ink has fallen off in many places. In the fourteenth century gold and silver writing became again comparatively common. When MSS. were written altogether in capitals, the initials were in general not larger than the other letters. The large illuminated initials are said to have commenced first among the Greeks about the close of the seventh century. In subsequent centuries large initials were usual, and they gradually became more complicated and elaborate down to the twelfth century, when they attained such a degree of size, ornament, and intricacy, that they have not in these respects been surpassed. These letters are ornamented with all kinds of fanciful figures, composed of men, animals, birds, fish, and flowers. Montfaucon, in his 'Palaeographia,' gives a complete alphabet from MSS. of the ninth and tenth centuries, of what the Benedictines call, from their illustration of the text, *Lettres Historiées;* they occur most frequently in Visi-gothic and Franco-gallic MSS. In this alphabet a T is represented by a fox on its hind legs holding a pole in its mouth horizontally, from the ends of which hang two cocks.

Charlemagne and his grandson Charles the Bald were great patrons of illuminations of MSS. Charlemagne's Bible in the church of St. Paul at Rome is considered by some the best example of ornamental calligraphy extant. There is another very inferiorly ornamented Bible, which is said to have belonged to Charlemagne, now in the British Museum, but which, according to Sir F. Madden, is of the time of Charles the Bald. It is described by Sir F. Madden in the *Gentleman's Magazine* for 1836; see also *Penny Magazine*, vol. viii., p. 52, 1839. It was purchased of M. de Speyer-Passavant, who had spent several years in vain in trying to dispose of it for a large amount, for the comparatively small sum of 750*l.*: he asked the trustees of the Museum originally 12,000*l.* The twelfth century is remarkable, says Sir F. Madden, for profusion of ornament and a graceful but intricate mode of illuminating capital letters, which renders it more easy to recognise MSS. of this period than any other. See specimens in Shaw's *Illuminated Ornaments*, &c., pl. ix.—xvii., where there are many varieties of initial letters. The prevailing colours are red, blue, and green, with gold and silver. In the following century red, blue, and white were most frequently used, and the letters of this time have a very inferior effect: they are mostly German and French. Illuminators were very numerous in the thirteenth century. In the library of Sir Thomas Phillips, Bart., there is a MS. of this century, entitled 'Mappae Clavicula,' which is a manual for illuminators. In French and English MSS. of the fourteenth century, initials in purple, red, and gold are very frequent, which contain figures of men and animals, and terminate in spiral scrolls, which extend along the upper and lower margins of the page, and support small groups or single figures of dogs, hares, apes, &c. much resembling the decorative etchings and woodcuts which have recently appeared in Germany, and also occasionally in England. A Psalter of Lord Braybrooke has beautiful examples of this style of decoration (Shaw's *Illuminated Ornaments*, &c., pl. xxi., xxii.).

English illuminators were in no way behind their continental neighbours. Among the Saxons, at the close of the tenth century, says Sir F. Madden, a peculiar style of ornament prevailed, which, for boldness, correctness of design, and richness, is not surpassed by any works executed on the Continent at the same period. The Benedictional of St. Ethelwold, belonging to the Duke of Devonshire, written and illuminated between 963 and 970, is the most complete example of this art in England. It was executed by a monk of Hyde Abbey (then the most celebrated place in England for such works), named Godeman, for Ethelwold, bishop of Winchester. It is a folio of 119 leaves of vellum, measuring 11¼ inches in height by 8¼ in width, containing thirty large richly coloured drawings; and it is considered the most valuable MS. of the Cavendish collection. See Mr. Gage's 'Dissertation on the St. Ethelwold Benedictional,' in the 'Archaeologia' (vol. xxiv., p. 22), where all these illustrations are engraved. Another curious MS. of this time, now in the British Museum (Cott. MSS., Tib. b. v.), valuable for the pictures it presents of old English habits and costume, is a Saxon calendar, in which the account of each month is headed by a drawing illustrating the agricultural occupations of the respective months of the year. Julius A. vi. is a MS. of a similar class. Cott. MSS. Claudius B. iv. is also a remarkable MS. It contains the first six books of the Bible in Saxon and Latin, with notes by Bede and others, and many drawings illustrating the principal passages; it is of the eleventh century. No. 603 of the Harleian MSS. contains a long series of illustrations of Anglo-Saxon customs, in very curious designs in outline, executed in various coloured inks; and though the execution is ridiculous, the attitudes and proportions are in many of the figures very good. In the Cott. MSS. Cleopatra C. viii. of the same period there is a comparatively very superior drawing of a party at meat drinking together; the poses of the figures are excellent, and the heads and hands are perfectly intelligible and expressive: it is engraved in the *Penny Magazine*, vol. viii., p. 70, 1839, where there are also a few other cuts from some of these MSS. In the thirteenth and fourteenth centuries Saxon MSS. are comparatively rare: the majority of the MSS. of this period are French.

There is a Psalter in the British Museum, supposed to be of English origin, of the latter part of the thirteenth century, or more probably of the early part of the fourteenth (Reg. 2, b. vii.), in which the drawing of the period is much better represented than in MSS. generally: some of the illuminations are in this respect fair specimens of the design of the Italian frescoes of the fourteenth century, but it is very rarely that the illuminations of MSS. at all correspond in design with the highest state of the arts of their time. It is an octavo volume, containing 320 leaves of vellum; on the first sixty-five are illustrations from the Old Testament, in transparent water-colours, in the usual style of such decorations, the designs being drawn in black outline, and the colours lightly washed in. These are followed by drawings of saints in body-colours, which are likewise prepared in black outlines; but in these body-colour drawings the outline is frequently painted over: then follows a Calendar. The greater part of the volume however is taken up by a Psalter, which is profusely ornamented with designs, many illustrating the history and habits of the time. This book was presented to Queen Mary in 1553, by its then possessor, Baldwin Smith. There are some French MSS. of the same period in which the illustrations are equally good, as the 'Life of St. Grael' and 'Les Gestes des Roys de France,' both folio volumes, with numerous illustrations. On the last page of the second is written 'C'est livre est a moy Homfrey Duc de Gloucestre du don des executeurs de Sr. de Fauchere.' There is also a French MS., called the Metrical History of the Life of Richard II., preserved in the British Museum, with many interesting illustrations. It is translated in the 'Archæologia,' vol. xx., by the Rev. John Webb. There are three cuts from these MSS. in the volume of the 'Penny Magazine' already quoted.

One of the most interesting French MSS. of the fifteenth century is the celebrated Bedford Missal, executed for John Duke of Bedford and regent of France, in the reign of Henry VI., now in the possession of Sir John Tobin at Liverpool. It is 11 inches high and 7½ wide, and contains 59 illustrations nearly of the size of the page, and about 1000 very small illustrations, with borders and foliage, &c.: there is a copy of it in the British Museum. In this MS. is the only known portrait of the Duke of Bedford: the portrait of the duke, engraved by Vertue for the translation of Rapin's 'History of England,' was taken from the illustration, in which the duke, in a crimson robe embroidered with gold, is represented kneeling before St. George, who is dressed in a suit of armour, over which is the mantle of the Order of the Garter; behind the saint is his armour-bearer. This MS. was presented by the Duke of Bedford to Henry VI., at his coronation in France: after passing into various hands, it was several times sold by public auction, and was last bought by Sir John Tobin in 1833 for 1100*l.*

There are also in the British Museum many illuminated French romances of the fifteenth century, which are particularly interesting as regards costume. Among the most attractive of these are the celebrated 'Romance of the Rose' (Harl. MSS. 4425), the collection presented by Talbot Earl of Shrewsbury to Margaret of Anjou (Royal MSS., 15 E. vi.), and the poems of Christine of Pisa (Harl. 4431), while the feats of arms and chivalry, by the same authoress, 'Livre des

Fais d'Armes et de Chevalerie,' written in French in London in 1434 (Harl. MSS. 4605), is so inferior in its illustrations, that it presents a great contrast between the states of the art of illuminating in the two countries at this time. The 'Romant de la Rose' is rich in beautiful miniatures; it is supposed to have been executed towards the close of the fifteenth century; it is a folio volume, measuring 15½ inches high by 11½ wide, and contains 183 leaves of vellum, written in double columns, the initial letter of every paragraph being illuminated. This French poem is of the thirteenth century; it is a dream, and was commenced by William de Lorris and finished by John de Meun, and is divided into 100 chapters, and contains 22,000 verses. It has been several times printed, and last at Paris in 1814, in 4 vols. 8vo. The British Museum MS. is considered the most beautiful of the poem extant; the illustrations are probably Flemish. (Dibdin, *Bibliographical Decameron.*)

The Anglo-Saxons were for many centuries among the best illuminators, and the Irish also obtained great celebrity in this art at an early period. This British or Hiberno-Saxon school of illumination shows a distinct character, as seen from the so-called 'Durham book, or St. Cuthbert's Gospel,' of the beginning of the eighth century, now in the British Museum. The initials, observes Sir F. Madden, are characterised by an extreme intricacy of pattern, interlacing of knots, in a diagonal or square form, sometimes interwoven with animals, and terminating in heads of serpents or birds, to which may be added the use of red dotted lines round the edge of the larger letters. The Lombardic and Visi-Gothic letters are tessellated and embroidered. There are no British illuminations later than the reign of Henry VII., and at this time they were much degenerated.

After the establishment of printing and consequent multiplication of books, MSS. became gradually more rare, though they were still occasionally executed as articles of luxury even as late as the eighteenth century; but their immense price, compared with that of printed books, must naturally have so limited the demand, that they can only have been required as works of art and curiosities in calligraphy, not as books. The writing of many MSS. is so beautifully executed, that probably no moveable type has ever equalled the manuscript characters in beauty, and they have perhaps not even been surpassed in equality of execution and finish. See the fac-similes in Sylvestre's *Paléographie Universelle.* Perhaps the latest, says Sir F. Madden, or one of the latest illuminated missals, is the immense folio in the library of Rouen, which is nearly three feet high, and cost the monk of St. Andoen, who illuminated it, thirty years of labour: it was completed in 1682.

PALÆOZA'MIA, a genus of fossil Cycadeous plants, from the oolitic and lias deposits of Yorkshire, Dorsetshire, and Oxfordshire.

PALANQUIN (sometimes written *Palankeen*, *Palanquen*, and *Palkee*), a kind of covered litter carried, by means of poles, upon the shoulders of men, which forms the principal vehicle for personal transport in Hindustan. A very minute description of an ordinary palanquin, together with an amusing account of a *dâk* or *dawk* journey, which is the name given to the mode of travelling long distances by the palanquin, is given in Captain Basil Hall's 'Fragments of Voyages and Travels,' third series, vol. ii., chap. vi., where the palanquin is described as about six feet long by two and a half feet wide, and provided with conveniences which enable it to serve at night-time for a bed, and in the day-time for a parlour. In the front part is usually a broad shelf, with a drawer underneath, and a net stretched above it; and in the hinder part is often a shelf for books, a net for fruit and other loose articles, and hooks for hats, towels, &c. In each side of the palanquin are two doors, or sliding partitions, with Venetian blinds in the upper pannel, and in each end are two small windows. As, owing to the heat of the country, travelling is performed much by night, palanquins are often furnished with a lamp at one corner, so fixed as to throw its light into the interior, but to be trimmed from outside. The bottom, or seat, is made of strips of rattan, like that of a cane-bottomed chair, and is covered with a light elastic mattress stuffed with horse-hair or shavings produced in dressing the bamboo and rattan. Across the palanquin, at about eighteen inches from the hinder end, is hung a flat square cushion for the traveller's back to rest against when sitting up, and towards the other end is a moveable bar against which the feet may be planted as against the stretchers in a boat, which may be shifted nearer to or farther from the end of the palanquin, according to the length of the traveller's legs or his choice of position. In the space behind the back-cushion the bed-clothes and pillow are stowed away during the day; and the shelves, drawers, and nets afford facilities for the conveyance of teapots, canisters, shaving apparatus, scientific instruments, sketching materials, and a sufficient supply of clothing to prevent inconvenience if the traveller be separated for a time from his heavy baggage. Flat articles may be laid beneath the mattress, and bottles and glasses carried in sockets attached to the corners of the palanquin. A cover of waxed cloth is affixed to the top in such a way that it may be rolled up when not wanted, and let down so as completely to envelop the palanquin, in rainy weather or when the night air is cold. A pole is attached to each end of the palanquin, near the top, to carry it by; and to the foremost of these poles is suspended a rattan basket containing a water pitcher, or *goglet*, of porous earthenware; and as the water which exudes through the pores of the goglet is rapidly evaporated by the current of air, its contents are always kept cool in the hottest weather. The action of this apparatus is identical with that of the *alcarrazas* of Spain, described under COOLER, P. C., p. 495. On the hinder pole are carried, in like manner, a kettle, coffee-pot, and wooden wash-hand-basin. As the poles, which rest upon the shoulders of the bearers, are not elastic like those of a sedan-chair, Captain Hall states that a palanquin has not the same unpleasant motion as that vehicle; and Bishop Heber also, who gives an account of dâk travelling in the 'Narrative of a Journey through the Upper Provinces of India,' published after his death, observes that 'the motion is neither violent nor unpleasant,' but that, being incessant, it is impossible to draw in a palanquin, and not very convenient to read, excepting a large print. In the first edition of this work there is also a good representation of dâk travelling. Only four bearers can, in an ordinary palanquin, place their shoulders beneath the poles, two at each end; but in passing over difficult ground two others will occasionally bear part of the weight by thrusting a bamboo under the body of the palanquin. In most cases the bearers follow one another in a straight line; but in some districts it is the custom to proceed obliquely, in which case the sideways motion is said to be exceedingly unpleasant to the traveller. While walking or running with their load, the bearers, who form a peculiar caste among the Hindus, keep up an incessant noise, sometimes like grunting or groaning, and sometimes approaching the character of a song, or of wild vociferation. Captain Hall has some curious remarks on this subject.

In the 'Pictorial Bible,' in illustration of a note on Solomon's Song, iii. 9, are representations of the J'Halledar, or state palanquin of Hindustan, and also of a similar vehicle used by the antient Egyptians; and some further information on conveyances of this character is given in the article 'Litter' in Dr. Kitto's 'Cyclopædia of Biblical Literature.'

PALECHI'NUS, a genus of fossil Echinodermata, from the mountain-limestone of Ireland. (Scouler.)

PALESTRI'NA, GIOVANNI PIERLUIGI, DA, a composer of the greatest renown in the annals of music, was born at Palestrina, near Rome—the antient Præneste—in the year 1524, a date which, though with some hesitation for want of distinct evidence, has been fixed by the Abbé Baini, who devoted thirty years to collecting materials for the Life of Palestrina. Of his family nothing is known, except that his parents were mean in rank, and in circumstances corresponding to their station. The name of the master who is entitled to the credit of having instructed him in an art in which he became so famous was involved in some doubt, but after diligent research the honour seems to have been justly awarded to Claude Goudimel, a native of Besançon, a disciple of the Franco-Belgic school, a Huguenot, and one of the victims of religious bigotry in the massacre of 1572, the Catholics on St. Bartholomew's day having thus resented his heresy in setting to music Clement Marot's and Theodore Beza's metrical version of the Psalms.

Palestrina was appointed Master of the Chapel to Pope Julius III. in 1551, to whom in 1554 he dedicated his first work, consisting of four masses for four voices. Julius, to reward the composer, placed him among the singers of the Pontifical Chapel, who were well paid for their services. The college of chaplain-singers remonstrated, and pleaded the law that no new member could be associated with them unless elected by a majority of themselves. But in vain. The mandate of the infallible tiara was obeyed, though not without a kind of protest. In 1555, however, Cardinal Caraffa succeeded to the papal throne, under the title of Paul IV., who, finding that Palestrina had quitted a state of celibacy, which all the higher appointments in the apostolic chapel enjoined, abruptly dismissed him, and for some time he felt severely his straitened circumstances; then gladly accepted the place of Maestro di Capella of St. John in the Lateran, which he exchanged in 1561 for a more lucrative situation at Santa Maria Maggiore; and in 1571 was restored to his post in the Vatican. Up to the year 1560 he composed many works for the church, among which Baini especially mentions those *Improperij*, 'so remarkable for depth of science and perfect adaptation of music to the sense of the words.' 'To hear them as executed on Good Friday in the Sistine Chapel,' says the abbé, 'the mind is subdued by emotions of tenderness and awe.' But, judging from the *Improperia* published by Dr. Burney, in his collection of music performed in the Capella Pontificia, it seems to us that these much-extolled compositions, consisting of the simplest counterpoint, must owe their effect to place and high-wrought feelings.

During the above period, however, the Council of Trent, among other matters, took the state of ecclesiastical music into serious consideration, and appointed two cardinals whom they charged with its reform, who called to assist them a committee of eight selected from the college of chaplain singers. Much discussion arose out of the case. The cardinals reasonably demanded the abolition of all the secular tunes which had been recklessly foisted into the sacred service, many of them vulgar, some obscene, and required more simplicity in the music. The singers irrationally defended the melodies, and contended for the florid and elaborate. At length it was agreed that Palestrina should write a mass on the principle laid down by their Eminences, and on his success depended the fate, at that time, of music in the Catholic church. In consequence of this determination he produced three masses for six voices. The two first were rather coldly approved, but the third was considered as the perfection of art, and the singers, on whom a ray of common sense had now fallen, could not restrain their expressions of admiration even during its performance. This is known under the title of 'the Mass of Pope Marcellus.' He applied all his powers on the work, and wrought himself up to the most enthusiastic pitch. On his manuscript were found the words 'Domine, illumina oculos meos.' The pope, 'before whom this mass was performed, was enraptured, and compared it to the heavenly melodies which the apostle John heard in his ecstatic trance.' 'By this one great example the question was now for ever set at rest,' says Ranke (in his 'History of the Popes,' acknowledging Baini as his authority); 'a path was opened, in following which the most beautiful, the most touching works, even to those who are not of the church, were produced. ...... This art, which had been perhaps more completely alienated from the spirit and service of the church than any other, now became the most closely connected with it. Nothing could be more important to Catholicism....... Spiritual sentimentality and rapture were the favourite themes of poetry and painting. Music, which speaks a language more direct, more impressive, more adapted to ideal expression than any other art, became the interpreter of these emotions, and thus subjugated all minds to her empire.' (Mrs. Austin's translation of *Ranke*, vol. i.) We here again find the warm expressions of an enthusiast, no doubt; but it must be borne in mind that the writer heard these compositions performed under peculiar circumstances of a very influencing nature—under the roof of the grandest temple in the world, with every advantage that the finest execution, a solemnity unequalled for imposing effect, and the most exciting religious associations could bestow.

On the restoration of Palestrina to his office, his fame spread widely. Cardinal Pacecco announced to him that Philip III. of Spain would receive with satisfaction any work from the composer that he might dedicate to him. To his other appointments was now added that of *Maestro* to the congregation of the Oratory. He also undertook the direction of the school established by Gio. Maria Zannini. Soon after this he was charged by Pope Gregory XIII. with the task of reviving the Roman Gradual and Antiphoner, which, however, he did not live to complete—a duty performed by his son, an only surviving child. Rather late in life his pecuniary circumstances must have been much improved, for on his death-bed, after blessing his son, he added, 'I leave many unpublished works, and thanks to the Abbé de Baume, the Cardinal Aldohrandini, and the Grand Duke of Tuscany, I leave you also the means of publishing them.' In January, 1594, it became evident that his life was rapidly drawing to a close; and on the 2nd of the following month, after receiving the last rites of the church from the hands of his friend (the future Saint) Filippo di Neri, he expired. Of his funeral, Torrigio (*Grotte Vaticano*, ii. 166) says, 'In St. Peter's church, near the altar of St. Simon and St. Jude, was interred, in consequence of his extraordinary abilities, Pierluigi da Palestrina, the great musical composer, and *Maestro di Capella* of this church. His funeral was attended by all the musicians of Rome, and "*Libera me, Domine*," as composed by himself, was sung by five choirs. On his coffin was this inscription:—"Johannes Petrus Aloysius Prænestinus, Musicæ Princeps."'

Palestrina's music is learned and grave, and that written for the church—as well, indeed, as much that proceeded from the same school—when heard in the kind of place for which it is adapted, and attended by pomp and pageantry, is strongly felt by all, and acts with irresistible force on sensitive minds. But in the concert-room or chamber, his compositions, whether sacred or secular, have, with few exceptions, no charms for hearers who have not cultivated a taste for simple, solid, airless harmony, or for the intricacies of fugal points well woven with a skill that owed more to study than genius. His works are exceedingly numerous, chiefly ecclesiastical; but including also many madrigals, now rarely performed, even in societies devoted to this species of music. Clever as these are, their dryness is undeniable, and they are praised by many who derive no pleasure from their performance. Three of his motets are in use in our cathedrals, adapted by the learned and all-accomplished Dean Aldrich to the English version of the 44th, 63rd, and 115th Psalms. Of these the first, 'We have heard with our ears,' and third, 'Not unto us,' are printed in Dr. Arnold's *Collection of Cathedral Music:* the second appears in its original state in Hawkins's History, iii. 175. Of his madrigals but one is found in Yonge's *Musica Transalpina* (1588), a work containing twenty madrigals by Italian masters; and this is the only composition of Palestrina noticed in *La Musa Madrigalesca* (1837); an elegant, interesting volume, comprising the words of 395 compositions, chiefly madrigals, 'of the Elizabethan age,' together with many translations from the Italian, and much curious matter. The Padre Martini, in his *Saggio di Contrappunto*, has given two madrigals, and several extracts, from the works of this celebrated master, all of them evincing his deep knowledge of the art, as understood and practised in his time, but all exclusively confined to that style now distinguished by his cognomen—by the term *alla Palestrina*.

(Baini, *Vita di G. P. da Palestrina;* Burney, iii. 188; *Harmonicon*, x. 71.)

PALI. [SANSCRIT LANGUAGE AND LITERATURE, P. C.]

PALICOU'REA, a genus of plants belonging to the natural order Cinchonaceæ. The limb of the calyx is 5-toothed or 5 lobed, or nearly entire; the corolla tubular and cylindrical, and a little gibbous at the base or curved, 5-cleft, bearded beneath the middle inside. The teeth of the calyx and corolla sometimes rather unequal. The species are American shrubs wholly destitute of pubescence. The leaves often whorled and of considerable size. The flowers are yellow or white in terminal sessile or stalked panicles, thyrses, or cymes.

P. Marcgraavii is a shrub from 5 to 6 feet high, and has smooth quadrangular branches. The leaves are short-stalked, oblong, acuminate, obtuse at the base, smooth; the stipules interpetiolar and trifid. The calyx is 5-toothed and downy; the corolla from 5 to 7 lines long, slightly curved, gibbous at the base, roughly downy yellow-coloured below, purplish above, closely bearded with hairs inside. Sometimes the leaves are downy beneath. It is a poisonous plant, used in Brazil to kill rats and mice. Very little is known of its real properties.

P. crocea has a smooth stem, ovate or oval lanceolate leaves. The stipules are connected by a short ligula, two on each side, linear, acuminate, twice as short as the petiole. The panicle is corymbose, terminal, and saffron-coloured. The corolla is obconical and tubular, the anthers projecting from the tube shorter than the limb. The berry somewhat double. It is a native of Porto Rico, Trinidad, Cuba, and Guadaloupe. According to Von Martius this species is emetic.

P. speciosa has smooth round branches, oblong acuminate leaves acute at the base, membranous, roughish, shining, with smooth stipules. The panicles are stalked, their angular branches and corollas hairy and downy. The leaves have by their yellow colour obtained for the plant the name of Gold-shrub, highly spoken of in Brazil as an antisyphilitic. 'The decoction, which in large doses forms a real poison, acts especially by an increased action of the skin and kidneys, and the digestion is not injured by moderate doses.' (Martius.)

P. officinalis is a shrub clothed with harsh yellow down in every part. The leaves are narrow, elliptical, short-stalked, acute, or rounded at the apex with a mucrone tapering a little at the base. The corymbs are contracted into a panicle. It is native of Brazil, and is reported to be a powerful diuretic, and is used both in human and veterinary medicine.

Other species of this genus are said to have qualities similar to the last. *P. diuretica*, *P. strepens*, *P. sonans*, and *P. longifolia* are amongst those reported to possess medicinal virtues. *P. tinctoria* forms a fine red dye much valued in Peru. There are fifty-five species enumerated, all of which are of easy culture and propagation. They grow best in a mixture of loam, peat, and sand, and will strike root readily under a handglass.

(Don, *Gardener's Dictionary;* Lindley, *Flora Medica;* Burnett, *Elements of Botany.*)

PALIU'RUS (the Greek παλίουρος, and Latin *paliurus*), a genus of plants belonging to the natural order Rhamnaceæ. It has a spreading 5-cleft calyx, 5 obovate convolute petals, 5 protruding stamens, ovate 2-celled anthers, and a flat pentagonal disk. The fruit is dry and indehiscent, expanding into a membrane round the disk, containing a 3-celled nut. The species are shrubs or trees, with alternate simple leaves.

P. aculeatus, Christ's Thorn, is a very common plant in Palestine, and on the borders of the Mediterranean Sea. It has pubescent bractless ovate serrulated leaves, quite smooth, 3-nerved, and with 2 spines at their base—one erect, the other hooked. The flowers are of a greenish-yellow colour. The fruit has a very singular appearance, resembling a head with a broad-brimmed hat on; the French call the tree 'Porte Chapeau.' In the districts where it grows there is a tradition that this is the plant from which the crown of thorns was made which was placed on the head of our Saviour. Hasselquist however is of opinion that it was rather the *Zizyphus spina Christi*. This species of *Paliurus* is one of the most common thorns in the hedges of Asia, and its flexible spiny branches form an impassable kind of fence. The seeds are sold in the herb-shops of Constantinople, and the native doctors prescribe them in many complaints under the name of 'Xalle.' They are also used as a dye. There are two or three other species of this genus, which are handsome shrubs, and well fitted for shrubberies. They will grow in any common soil, and may be propagated either by layers, cuttings, or seed.

(Don, *Gardener's Dictionary;* Burnett, *Outlines of Botany.*)

PALLA'DIUS, a Roman writer on agriculture, whose complete name is Palladius Rutilius Taurus Æmilianus. The place of his birth and his period are uncertain, but it is probable that he lived about the time of Valentinian and Theodosius. He is author of an extant work entitled 'De Re Rustica' in fourteen books. The first book contains general rules about agriculture; the twelve following books are respectively devoted to the agricultural labours of each month; the fourteenth book is in elegiac verse and treats of grafting trees. The work of Palladius appears to be mainly a compilation from previous writers, such as Columella and Martialis Gargilius, whose work on agriculture and garden cultivation is lost. The style is inferior to that of Columella, and indicates a late period. The work of Palladius, probably owing in some degree to the convenience of the division, was much used in the middle ages, and the 'Speculum' of Vincent of Beauvais has borrowed much from it.

Palladius and the other Roman writers on Agriculture are contained in the edition of the 'Scriptores Rei Rusticae' by J. M. Gesner, Leipzig, 1735, and in the improved edition of the same work by Ernesti, 1773. The latest edition and the best is by J. G. Schneider, Leipzig, 1794-7, 4 vols. 8vo.

(Bähr, *Geschichte der Römischen Literatur.*)

PALMA, one of the Canaries, is situated between 28° 29′ and 28° 53′ N. lat., and between 18° 24′ and 18° 43′ W. long. From north to south it extends about 26 miles, and from east to west about 16 miles in the widest part. The average width is about 14 miles. This gives a surface of 364 square miles. Humboldt assigns to it 324 square miles.

The island is one mass of volcanic rocks. The shores are rocky and steep, and generally rise to a considerable elevation from the shore; the country rises in terraces towards the interior, where it attains a great height. Nearly in the middle of the northern portion of the island is an immense crater, the Caldera de Tahuriente, which is seven miles in diameter; the bottom of it is 2406 feet above the sea-level. It is surrounded by steep masses of rocks, which rise 4000 feet above its bottom. In its vicinity are the highest summits of the island, the Pico, the Muchachos, which attains 7712 feet, the Pico de Sta. Cruz, which is 7549 feet, and the Pico del Cedro, which rises to 7252 feet above the sea-level. Farther southward the mountains decrease in elevation. The Paso de Lavanda, situated nearly in the centre of the island, is 4536 feet above the sea. Towards the southern extremity the heights are much lower. These rocky masses are split by deep ravines, called barancas, whose bottoms are frequently 500 feet below the adjacent masses, and the sides very steep. They are most frequent in the high mountains which surround the caldera, around which they are disposed like rays diverging towards the sea; but they have no communication with the crater, with the exception of the Baranca de Angustias, on the west side of the island, which originates in the crater itself, and extends south west to Tazacorte, and in which the only river runs which has water all the year round. It waters the Los Llanos, an uneven plain situated on that side of the island which is the best portion of the whole, and at present contains the only plantations of sugar-cane in the Canaries. The sides of the mountains are very steep, and covered with high forest-trees that yield several kinds of good timber. This is especially the case in the northern districts, where the soil retains the moisture, and in these parts springs are frequent and abundant all the year round. In the southern districts the soil consists partly of lava or of other dry volcanic matter, and there are no springs. The soil, where cultivable and cultivated, exhibits a great degree of fertility; but with the exception of the Llanos, the cultivated tracts occur only on the very shores of the sea, or at a few places on the lower terraces of the mountains.

The climate of Palma is superior to that of the other Canaries in its neighbourhood. This is partly attributed to the extent of the mountains, which for several months are covered with snow, and to the forests, which cover a large portion of its surface. The north-east trade-wind, which blows from spring to autumn with considerable force, diminishes the heat, which otherwise would be insupportable along the coast. The winter, except in the most elevated parts, is so mild that it is compared with the spring in southern Europe. Earthquakes are not rare, and two volcanic eruptions in the southern districts, in 1586 and in 1678, are recorded.

Palma resembles Teneriffe in its productions. Wheat, barley, rye, and potatoes are cultivated to some extent, and also a small quantity of Indian corn, but the crops are far from being sufficient for the consumption. The deficiency is made up by the root of a kind of fern, called *helecho* (*Pteris aquilina*), which grows wild on the small hills in the caldera. It is mixed with flour, or even used alone for making bread, which is as black as rye bread, and is said by Von Buch to constitute the principal article of food for two-thirds of the inhabitants. The cane is still grown in the Llanos, but the cultivation is much diminished, and some years ago only 4000 arobas were annually produced, while at the Havanna one plantation produced 30,000 arobas. It appears that more silk is produced in Palma than on any other of the Canaries. The vineyards are extensive, but no wine is exported: the surplus is converted into brandy, which goes to the Spanish colonies in America. The fruit-trees which are found in the orchards are the same as those mentioned in TENERIFFE, P. C., vol. xxiv. p. 204. Few horses, mules, and asses are kept. Cattle are rather numerous, but neglected; sheep and goats are kept in great number, especially in the vicinity of the caldera. The number of hogs is small.

The population amounted in 1805 to 28,878 individuals, but MacGregor states it in 1830 to have increased to 33,000. The people are descendants of Spaniards, who settled there at the time of the conquest, and of a few Flemish families. The condition of the labouring classes is miserable. They live in straw huts, and subsist for two-thirds of the year on the black bread made of the helecho. But they are very industrious. In the Llanos there are 236 silk-looms, in which stuffs, stockings, and ribbons are made. They make also some coarse cotton and woollen cloth. In two or three places tiles and earthenware are made.

Palma is not visited by foreign vessels. Some vessels from Teneriffe and Lanzerote take away the produce of the island, consisting of sugar, almonds, fruits, deals and timber, pitch, charcoal, raw and manufactured silk, brandy, and orchilla. They import European goods, oil, grain and potatoes, salt-fish and salt.

Palma has several ports: Espindola, Santo Domingo, Tazarotc, Naos, and Santa Cruz. Only the last mentioned, which is on the eastern shores of the island, is visited hy vessels. Tho town of Santa Cruz de la Palma consists of two streets running parallel to the shores from north to sonth, and many isolated houses built on the steep declivities of the rucks. It contains one church and four convents, and a good hospital. The anchorage is good in from 10 to 15 fathoms of water. The population, including that of some hamlets in the neighbourhood, amounts to 6000 individuals.

It is uncertain when Palma was discovered. In tbe thirteenth century it appears to have been visited, like the other Canaries, by the Genoese. It was taken possession of by the Spaniards in 1492, under the command of Don Alonzo Fernandez de Lugo, and has since that time remained in their possession.

PALMA'CEÆ. [PALMS, P. C.]

PALMACI'TES, a genus of fossil plants, from the coal formation. (Sternberg.)

PALMARO'LI, PIETRO, a painter and celebrated picture restorer, who was the first to transfer frescoes from the wall to canvas. The first work so transferred was the Descent from the Cross by Daniele da Volterra, in the church of Trinità do' Monti, in 1811: It is still in this church, but not in the chapel in which it was originally painted. The successful transfer of this picture caused a great sensation at Rome and in other parts of Italy, where such transfers were and still are repeatedly practised with success: the process is described in the article FRESCO, P. C. S. Palmaroli transferred and restored many celebrated works in Rome and in Dresden, and among those in tho latter city the celebrated Madonna di San Sisto by Raphael was restored by him. Palmaroli has done great service as a restorer: he freed in 1816 the celebrated fresco of the Sibyls, painted by Raphael for Agostino Chigi in the church of Santa Maria della Pace, from the destructive *restorations* in oil which were made by order of Alexander VII. Although some restorations were necessary and are evident in tbis work, the lovers of art are bighly indebted to Palmareli; for, before his undertaking, this celebrated fresco was a subject of general disappointment to the admirers of Raphael, and was indeed so dark that the objects were scarcely distinguishable. He died at Rome in 1828.

(Platner, *Beschreibung der Stadt Rom*, vol. iii. pt. 3, p. 385; *Kunstblatt*, 1837; Nagler, *Neues Allgemeines Künstler Lexicon.*)

PANAX (intended to be formed from πᾶν, all, and ἄκος, a remedy), a genus of plants belonging to the natural order Araliaceæ. The flowers are polygamous, the calyx obsolete and 5-toothed. It has 5 petals, 5 stamens inserted with the petals under the edge of the disk, and alternate with them. The fruit is succulent, compressed, orbicular, from 2 to 3 celled; the cells leathery and one-seeded. Tbe species are herbs and shrubs and trees, having the leaves and inflorescence variable.

P. quinquefolium, Five-leaved Panax, or Ginseng, has a fusiform root more or less branched, of a whitish colour, and terminating in fibres. The stem is smooth, round, and green, often with a tinge of red, divided at the top into three petioles with a flower-stalk in their centre. The petioles are round, smooth, and swelling at their base. The leaves ternate, quinate, or septenate. The berries are kidney-shaped, of a bright red colour, and contain 2 semicircular seeds. The flowers are of a yellowish colour. It is a native of Chinese Tartary and North America. In China it has been considered an invaluable drug from time immemorial. In 1709 the Emperor of China commissioned 10,000 Tartars to go in quest of as much of this root as they could find; each one was to give two pounds of the best of it to the emperor, and to sell the rest for its own weight in fine silver. The roots enter into the composition of every Chinese medicine. It is reckoned a stimulant and restorative, and both rich and poor consider it a remedy for every disease. By Europeans and Americans, however, it is comparatively disregarded, and looked upon as a mere succulent, similar in its qualities to liquorice; hence the question arises, is the Chinese plant the same as the North American? For we cannot regard all that the Chinese say and practise as merely imaginary. The common namo of the plant, Gen-seng, Jinchen, or Nindsin, signifies 'wonder of the world,' or the 'dose for immortality;' and the Chinese firmly believe that its powers are almost miraculous. [GINSENG, P. C.]

P. fruticosum is also used in China and Cochin-China as a febrifuge, and as an astringent tonic. It has a shrubby unarmed stem, pinnately decompound leaves; petiolate oval oblong leaflets coarsely and dentately serrated, the ultimate ones deeply trifid, the panicle corymbose, with the branches umbelliferous at the apex. It is a native of the islands of Ternate, Java, and Amboyna.

Tbe hardy species of this genus grow best in peat, and are propagated by dividing at the root. The other species flourish in a mixture of loam and sand, and are propagated by cuttings, which should be planted in sand with a hand-glass over them.

(Don's *Gardener's Dictionary*; Lindley's *Flora Medica*; Burnett's *Outlines of Botany.*)

PANVI'NIO, ONU'FRIO, was born at Verona in 1529. He took at an early age the habit of the order of St. Augustin, and pursued his studies at Rome, whence he was called to Florence in 1554 to fill the chair of theology in that city; but soon afterwards, at his own request, was superseded in the office, and obtained leave from his superiors to visit the chief cities of Italy in order to collect inscriptions. At Venice he became acquainted with Sigonio, who had been appointed professor of belles lettres in that city in 1552, and who was not less enthusiastically attached than Panvinio himself to the study of antiquities. The acquaintance soon ripened into a lasting friendship. At Rome he was patronised by Cardinal Cervini, who in 1555 became Pope Marcellus II., and by him Panvinio was appointed to a situation in the library of the Vatican, with a salary of six gold ducats a month. The pope however died a short time after his election; and Panvinio was then patronised by Cardinal Farnese, who gave him apartments in his palace, admitted him to his table, and treated him in other respects with the greatest liberality. Having accompanied the Cardinal in a voyage to Sicily, he was taken ill at Palermo, and died there April 7, 1568, at the age of thirty-nine.

Panvinio was a man of great learning and indefatigable industry. Niceron, in his 'Mémoires,' mentions twenty-seven of bis works which had been printed; and Maffei, in bis 'Verona Illustrata,' gives a list of his manuscripts in different libraries of Italy and Germany. The most important of his works are the following, some of which were not printed till after his death :—'Epitome Pontificum Romanorum usque ad Paulum IV.,' Venice, fol., 1557; 'Viginti-septem Pontificum Romanorum Elogia et Imagines,' Rome, fol., 1568; 'Fasti et Triumphi Romanorum à Romulo usque ad Carolum V.,' Venice, 1557, of which Mader published another edition in 1662 at Helmstadt; 'In Fastos Consulares Appendix;' 'De Ludis Secularibus et Antiquis Romanorum Nominibus,' Heidelberg, fol., 1588; 'De Baptismate, Paschali Origine, et Ritu consecrandi Agnos Dei,' Rome, 4to., 1560; 'De Sybillis et Carminibus Sybillinis,' Venice, 8vo., 1567; 'De Triumpho Commentarius,' Venice, fol., 1573, and Helmstadt, 1676, 4to., by Mader; 'De Ritu sepeliendi Mortuos apud Veteres Christianos et eorum Cœmeteriis,' Louvain, 8vo., 1572; 'De Republica Romana Libri III.,' Venice, 8vo., 1581; 'De Bibliotheca Pontificis Vaticana,' Tarragona, 4to., 1587; 'De Ludis Circensibus Libri II., et de Triumphis Liber I.,' Venice, fol., 1600; 'Amplissimi Ornatissimique Triumphi, ex Antiquissimis Lapidum Nummorum Monumentis, &c. Descriptio,' Rome, fol., 1618; 'De Antiquitate et Viris Illustribus Veronæ Libri VIII.,' Padua, fol., 1648. The following treatises are contained in the great collection of Graevius, 'Thesaurus Antiquitatum Romanarum :'—'De Civitate Romana,' 'De Imperio Romano,' in vol. i.; 'De Antiquis Romanorum Nominibus,' in vol. ii.; 'Antiquæ Urbis Imago,' in vol. iii.; 'De Ludis Circensibus,' 'De Ludis Saecularibus,' and 'De Triumpho Commentarius, in vol. ix. His great treatise 'De Cærimoniis Curiæ Romanæ,' in 11 vols. folio, is in manuscript in the royal library at Munich.

(Weiss, in *Biographie Universelle*; Tiraboschi, *Storia della Letteratura Italiana*, vol. vii.)

PAPI'LIO, a genus of Lepidopterous insects, established by Linnæus, and divided by subsequent entomologists into many groups and genera. It includes that very natural and beautiful assemblage of insects popularly known as butterflies. The first section of *Lepidoptera*, named *Rhopalocera* (clubhorned) in the arrangement of Boisduval, and *Diurna* in that of Latreille, corresponds with the Linnæan genus *Papilio*. The insects composing it have mostly thin and elongated antennae, terminated by a club. They are all day-fliers. Their larvae, which are variously shaped, have six pectoral, eight abdominal, and two anal feet. The pupae are usually angulated and, with a few exceptions, naked. The perfect insect varies in size from less than an inch across the wings when expanded, to nearly a foot in breadth. Equally variable are their colouring and outlines. They are short-lived. Their powers of flight are very great, and the mode of flight varies in the several species. The males are usually more gaily coloured than the females.

The arrangement according to natural relations of the species of butterflies has been attempted by many naturalists. Even in the time of Linnæus the number and variety of known species was such as to render it necessary to subdivide his great genus *Papilio*. He constituted five principal groups. In the first of these, named *Equites*, he included such butterflies as have the fore wings longer from the posterior angle to the apex than to the base. In the second, the *Heliconii*, the wings are narrow, entire, and often almost naked. The *Danai* had also entire wings. The *Nymphales* have dentated wings; and the group of *Plebeii* was composed of small species, whose larvae are usually short and thick.

Dr. Horsfield has proposed an arrangement of these insects into five groups or stirpes, characterised by the peculiarities of the larvae. He names the first stirps, *Vermiform*, the second *Iuliform*, the third *Scolopendriform*, the fourth *Thysanouriform*, and the fifth *Anopluriform*.

Perhaps the most valuable arrangement of the diurnal *Lepidoptera* is that proposed by M. Boisduval, who divides them into three great sections and fifteen tribes, as follows, founding his classification upon the characters of the larva:—

Section 1. Succincti.

Chrysalis attached by the tail, and also girt.

A. Six feet in both sexes: caterpillars elongated.

Tribe 1. *Papilionides.*
2. *Pierides.*

B. Six feet in both sexes: caterpillars short.

Tribe 3. *Eumenides.*
4. *Lycenides.*

C. The males with four feet, the females with six. Caterpillars short.

Tribe 5. *Erycinides.*

D. Four feet in both sexes: caterpillars elongated.

Tribe 6. *Peridromides.*

Section 2. Suspensi.

Chrysalis suspended by the tail only.

A. Ungues of tarsi simple. Four feet in both sexes.

Tribe 7. *Danaides.*
8. *Helionides.*

B. Ungues of tarsi strongly bifid. Four feet in both sexes.

Tribe 9. *Nymphalides.*
10. *Brassolides.*
11. *Morphides.*
12. *Satyrides.*
13. *Biblides.*

C. The males with four feet, the females with six. Caterpillars elongated.

Tribe 14. *Libythides.*

Section 3. Involuti.

Chrysalis enclosed in a cocoon.

Tribe 15. *Hesperides.*

See Boisduval in the *Suites à Buffon* and his other works; Wood, *Index Entomologicus;* Horsfield, *Catalogue of Lepidoptera in the Museum of the East India Company;* and Westwood's *Modern Classification of Insects*, where an enumeration of the principal treatises on butterflies may be found.

PAPI'RIUS, SEXTUS or PUBLIUS, is the collector or supposed collector of the old Leges Curiatae, or as they are sometimes called, Leges Regiae, which were enacted at Rome during the kingly period. This Papirius is said to have been Pontifex Maximus and to have lived under the last Tarquin. The few and doubtful fragments of this supposed compilation are contained in Hoffmann, *Hist. Juris*, vol. ii. p. i. The collection is mentioned under the name of Jus Papirianum, not because he added anything of his own, but because he arranged the laws in due order (Pomponius, *Dig.* 1, tit 2, s. 2, § 2); and sometimes it is called Lex Papiria. (Servius ad Virg. *Aeneid*, xii. 836.)

PAPI'RIUS, JUSTUS, a Roman jurist, who compiled twenty books of Constitutions, according to the Florentine Index. There are sixteen excerpts from this work in the Digest. In one excerpt (Dig. 2, tit. 14, s. 59) Papirius mentions a rescript of the Emperor Antoninus, addressed to Avidius Cassius. The fact of the rescript being addressed to Cassius shows that Antoninus is the Emperor Marcus Antoninus. Accordingly Papirius was living under Marcus Antoninus; and he also survived him, as appears from his speaking of the Divi Fratres.

A jurist of the name of Papirius Fronto is cited by Callistratus. (Dig. 14, tit. 3, s. 4.)

PAPIST. [Roman Catholics, P. C. S.]

PAPAW. [Carica, P. C.]

PARADOXI'DES, a genus of Trilobites, from the Silurian strata. (Brongniart.)

PARAPET, in Fortification, is generally an embankment of earth which is formed either on the natural ground or on the upper surface of the rampart of a fortress or outwork. In the latter case the parapet rests on that part of the rampart which is nearest to the exterior of the work, the terreplein, or nearly level part on the interior side, being occupied by the artillery or left free for the movements of the defenders. Parapets of brick or stone are sometimes constructed for works which are masked by others in their front, or on heights, or on the sea-coasts; but in other circumstances they would be improper, because the splinters detached from such materials by the enemy's shot are dangerous to the defenders, whereas the shot sinks into earth without doing further mischief.

The height of a parapet above the ground, or above the terreplein of a rampart which it surmounts, is about 7½ feet, in order that it may effectually cover the defenders behind it. In its mass are cut the embrasures through which the guns are fired; and a banquette, or step, about 3 feet high and 4 feet broad is formed, usually of earth, at its foot, on the interior side, in order to enable men, by standing on it, to fire over the upper surface. The form of a transverse section of a rampart, surmounted by a parapet, is represented in *fig.* 2, Bastion, P. C.; the parapet with its banquette being that which occupies, on the right hand side of the figure, rather less than the upper half of the space between the dotted lines.

The exterior face of a parapet of earth is generally formed in a plane making an angle of 45 degrees with the horizon, in order that the earth may stand unsupported; the superior surface, which varies in breadth from 3 feet to 20 feet according to the nature of the shot which it is intended to resist (from musket bullets to the balls discharged from the heaviest ordnance), has its exterior crest or edge lower than the other by about one-sixth of the breadth of that surface. It is recommended that the depression of the slope should not bear a greater proportion to the breadth, lest the upper part of the parapet should by its acuteness be weakened; but the general rule is that the plane of the superior slope should, if produced, meet the counterscarp line of the ditch in front, in order that the enemy, at the time of an assault, and when detained by the obstacles there, may be completely exposed to the fire of musketry from the parapet. The interior face of the parapet is frequently formed in a plane passing through the crest, and, at the terreplein of the banquette, or at the foot of the parapet if there is no banquette, deviating from a vertical plane passing through the same crest about one-third of the height of the slope. By this inclination the earth, when reveted with fascines or sods, and even without any revetment, will support itself for a time, while a man, by leaning a little forward, is enabled without inconvenience to fire over the parapet.

Occasionally parapets of field-works have been formed with the earth obtained by excavating the ground in the interior; and, in this case, the crest of the parapet may be only 3 or 4 feet above the exterior ground. Such a construction is admissible, however, only when the site of the work is several feet higher than the ground which the enemy may occupy, since otherwise the defenders, except when close behind the parapet, would be exposed to his fire. Again, should the ground about the spot to be fortified be higher than that spot, the crest of the parapet must have a greater height than 7½ feet, in order that the defenders may be sufficiently covered by it: but in general the parapets of field-works cannot be raised more than 14 feet above the ground; since a man can scarcely throw earth with a spade to a greater height than 7 feet, and a greater height than 14 feet would require, above ground, more than two rows of shovellers, one row 7 feet above the other, besides one row, or two rows, at an equal interval in the ditch; and it is seldom that the numerical strength of a working party is sufficient to allow such a disposition to be made.

The earth used for forming the parapets should be free from gravel, in order to avoid the accidents which might arise from the dispersion of the stones when shot or shells are fired into the mass; and the slopes, as well as the banquettes, are usually covered with turf.

PARASELENÆ (from παρὰ and σελήνη the moon). This name is given to the ill-defined and faintly luminous disks which occasionally appear in halos surrounding the moon, as the corresponding but brighter spots which are seen in halos about the sun are called parhelia. [Halo, P. C. S.] The phenomena of parhelia and paraselenæ are ascribed to a like cause; that is, a blending of the rays of light reflected from the parallel sides of small triangular plates of ice with those which are refracted through the sides containing one of the angles.

One of the earliest recorded phenomena of this kind is that which was observed by Hevelius at Danzig in 1660: a double halo surrounded the moon, with coloured segments nearly resembling those which are represented in the second figure in the article above referred to; and in the inner circle at each extremity of a horizontal diameter was a false moon: it was faintly tinged with colour and, at intervals, beams of whitish light proceeded from it towards the exterior.

Sir Edward Parry, during his voyage to Melville Island, saw several lunar halos with paraselenæ; and, once, very nearly the like phenomena occurred on two successive nights. Two false moons appeared in the halo at the opposite extremities of a horizontal diameter, and one at the upper extremity of a vertical diameter; while from the real moon proceeded vertical and horizontal brushes of whitish light like the four arms of a cross: on one of the nights a stream of light issued from the eastern moon, like part of a second halo, and at times ascending almost directly towards the zenith. At another time the moon was surrounded by a double halo, and on the circumference of the interior ring were four paraselenæ, at the opposite extremities of a vertical and a horizontal diameter.

PARENT-DUCHÂTELET, ALEXANDRE-JEAN-BAPTISTE, was born at Paris on the 29th of September, 1790. His father held an office under government which had been in the family for upwards of three centuries. At the birth of Alexandre he was possessed of considerable wealth, but the changes that occurred during the Revolution seriously affected his circumstances, and he retired to a house in the country called Châtelet, about a league from Montargis. Here Alexandre, who was the eldest of five, was brought up with little further assistance in his education than could be given by his mother, who was an amiable and accomplished woman. He was, however, fond of study, and early exhibited a taste for natural history by collecting the insects and birds of the neighbourhood.

At the age of seventeen he was sent to Paris, where he commenced the study of medicine. In 1814 he took the degree of doctor of medicine, and commenced practice in Paris. He became early dissatisfied with the practice of medicine, and directed his attention to pathology. One of the earliest works which he published was upon inflammation of the arachnoid membrane. In this work he was assisted by M. Martinet; the title is "Recherches sur l'Inflammation de l'Arachnöide cerébrale et spinale, ou Histoire théorique et pratique de l'Arachnitis,' Paris, 8vo. 1821. This work is a valuable monograph. The mind of the author was however shortly after directed, through the influence of Hallé, to the subject of public health, and from the period that he first thought on this subject to the day of his death, he devoted all the energies of his mind to it. From 1821 to 1836 he published twenty-nine memoirs and papers on various questions relating to public health. One of his first efforts on this subject was a series of researches directed to discover the cause of a disease which had occurred on board a vessel which was conveying *poudrette* across the seas. Parent examined the manufacture of this substance, which consists of animal and vegetable matters which have been collected from the drains and sewers of Paris, and, being exposed to the sun and air, are allowed to dry. In this state it is used as a manure. It was the fermentation of this substance, its conjunction with moisture, that had produced the disease, and Parent recommended that in future plaster of Paris should be mixed with it, which prevented the recurrence of such catastrophes.

His next work was upon the common sewers of Paris, entitled 'Essai sur les Cloaques ou Egouts de la Ville de Paris, envisagés sous le Rapport de l'Hygiène Publique et de la Topographie Médicale de cette Ville,' Paris, 8vo. 1824. Parent-Duchâtelet here displayed the peculiar aptitude of his mind for the investigation of subjects which others regard with natural abhorrence. He not only made inquiries into the state of the health of the workmen employed in cleansing these places, and obtained from them much important information, but he entered with them the places of their noisome occupation, and, from diligent personal inspection and experience, reported on their condition and nature. Shortly after the publication of this work, Parent was appointed on a commission to superintend the emptying of one of these common sewers (*égouts*) which had been blocked up for years, and which threatened to generate fever of the worst kind. Under his direction this place was cleansed without the loss of life to a single workman, and without any evil results.

He subsequently contributed largely to the 'Annales d'Hygiène Publique et de Médicine Légale.' In this work will be found reports and papers by him on the influence on the health of workmen and the public, of tobacco manufactories, of pyroligneous-acid factories, of employments requiring immersion of the feet in cold water; of burying the dead in cities; of putrid emanations from dead animals and vegetables, of dissecting-rooms, &c. He also published a work on the progress of cholera, and a history of its ravages in Paris. His greatest work, and that which most displays the industry and character of the man, is that on prostitution in the city of Paris. It was published after his death, edited by F. Leuret, with the title 'De la Prostitution dans la Ville de Paris considérée sous le Rapport de l'Hygiène Publique, de la Morale, et de l'Administration,' Paris, 2 vols. 8vo. 1836.

Parent-Duchâtelet died of inflammation of the lungs, on the 7th of March, 1836. Few men have led a life of greater usefulness, and his labours have assisted in laying the foundation of those systems of medical police which, when properly conducted, are undoubtedly the most important institutions of a civilized community.

(*British and Foreign Medical Review*, vol. iv.; Leuret, *Notice Historique, sur A. J. B. Parent-Duchâtelet.*

PARE'XUS, a genus of Placoid fossil fishes, from the old red-sandstone of Scotland. (Agassiz.)

PARIETA'RIA, a genus of plants belonging to the natural order Urticaceæ. It has polygamous flowers, surrounded by an involucre, a bell-shaped 4-parted perigone, 4 stamens, and a filiform style.

P. officinalis, Wall Pellitory, has ovate or oblong ovate leaves, without lateral ribs at the base, two axillary bifid cymes, the segments of the involucre ovate obtuse. The leaves are alternate, the flowers small and reddish, the fruit black and shining. It is a British plant, and is found on old walls and rubbish. It is the *P. erecta* of Koch and Reichenbach.

(Babington's *Manual of British Botany*.)

PARIS, a genus of plants belonging to the natural order Asparageæ. It has a patent horizontal perianth, 8-parted to the base, the four inner parts or corolla narrower than the others. There are 8 stamens, the anthers fixed to the middle of a subulate filament. The styles are 4 in number, the berry 4-celled, the cells with from 4 to 8 seeds.

. *P. quadrifolia*, Herb Paris, the only British species, has usually four leaves in a whorl, a stem about a foot high springing from the extremity of a long rhizoma usually with 4, occasionally from 3 to 6 leaves at its summit. The flowers are solitary and terminal, the sepals lanceolate, the petals subulate. It has no root-leaves, and is found in damp woods in England. It is considered to be a narcotico-acrid poison.

P. polyphylla, a native of Nepal, possesses similar properties.

(Babington's *Manual of British Botany*; Burnett, *Outlines of Botany*; Lindley's *Vegetable Kingdom*.)

PARMELIA. [Liverworts, P. C. S.]

PARNASSIA (from the name of Mount Parnassus), a genus of plants belonging to the natural order Droseraceæ. It has a 5-cleft deeply-cut calyx, 5 petals and 5 stamens, with 5 scales fringed with glandular setæ interposed. The stigmas are sessile and 4 in number, the capsules 1-celled with 4 valves. The species are smooth herbs. The leaves ovate, cordate, cauline ones usually clasping the stem or sessile. The flowers are all white striped with green; the tuft of the glands yellow.

P. palustris, Marsh or common Grass of Parnassus, has cordate stalked radical leaves, the stem-leaves amplexicaule, the filaments of the petaloid scales from 9 to 13; the petal has a short claw, and is white and veined; the glands of the scales yellow. It is native throughout Europe, in marshy and damp places, and in Britain in mountainous countries.

P. fimbriata is a very elegant species; the leaves are remarkably hollowed out at the base close to the lateral ribs, which are connected with one another by a common base like the divisions of a pedate leaf. It has palmate glandless appendages, obovate petals fringed at tho base. It is native of the western coast of North America.

The species of this beautiful genus grow best in a peat soil in a damp situation. They may be grown in pots, which should be placed in pans of water. They may be propagated by dividing at the root, or by seeds, which ripen in plenty. Plants must be introduced, as seeds do not vegetate after a voyage.

(Don's *Gardener's Dictionary;* Babington, *Manual of British Botany*.)

PARNY, EVARISTE DE'SIRE' DESFORGES, Chevalier and afterwards Vicomte De Parny, was born in the Isle of Bourbon, on the 6th of February, 1753. At the age of nine he was sent to France and placed at the College of Rennes; but he appears to have shown considerable indifference to the course of studies which were followed there. His imagination, which even at an early age had taken the almost entire guidance of his conduct, impressed him as he grew up with the belief that he was called upon to embrace the ecclesiastical profession, and it is said that he attempted to join the brotherhood of La Trappe. An effort of imprudent zeal, however, on the part of the confessor whom he had chosen as his spiritual guide, produced a rapid change in the mind of the young convert, and he is related to have fallen into an opposite extreme of conduct, and soon after, entering into all the dissipations of youth, finally to have enrolled himself in the military profession. He returned to his native island at the age of twenty, where he became acquainted with a young creole lady, the Eleanor of his verse, which acquaintance his fervent imagination soon converted into the most ardent attachment. Their mutual love inspired his first poetical effusions, which paint with grace and freshness, though perhaps in too vivid colours, the all-absorbing passion of his soul. The affections however of the lady were of an evanescent nature; a marriage of interest, which sho contracted at the desire of her parents, induced Parny to return to France. Distance and time were unable to efface his sad reminiscences, and he there continued to translate into the language of poetry the feelings which appear to have taken a lasting possession of his mind. In 1775 was published his first collection of elegiac poems, which have been so much admired by his countrymen that they have earned for him the titlo of the French Tibullus. On the breaking out of the French Revolution he became deprived of the property which he had inherited from his father, and he was compelled to obtain a livelihood by the cultivation of his talents. A painful and striking change now appears in his writings, which he had the weakness to adapt to the prevalent taste of a corrupt age. The rival of Tibullus became the feeble copyist of Voltaire, and his 'Paradis perdu,' 'Galanteries de la Bible,' and 'Guerre des Dieux,' by their disgusting profaneness and absence of genuine poetical feeling, will only be remembered by posterity as indications of the state of society at a period when 'everything evil was rank and luxuriant.' So strong indeed was the feeling excited against Parny even in France on account of the last mentioned of these three poems, that his name was repeatedly passed over among the candidates for the honours of the Institute. However he was admitted into it in 1803, in the place of Devaines. Most of his other poems are inferior to his early productions; his 'Goddam,' published in 1804, is a spiritless and insipid parody on the invasion of England by the Normans; his 'Isnel and Aslėga,' though possessed of more merit, is but a feeble imitation of the Scandinavian style of poetry; but among his later productions there are two small poems, one on the culture of flowers, and the other entitled 'Journée Champêtre,' which for simple beauty and delicacy of colouring are deserving of being ranked among the finest specimens of lyric poetry. His principal poem, in eighteen cantos, on the loves of the Queens of France, was destroyed by him from fear of its falling into the hands of the suspicious judges of the Revolutionary Tribunal. He died in Paris, after a painful and lingering illness, on 5th December, 1814.

His works have been published in 5 vols. 18mo. by Didot, Paris, 1808, and at Brussels, in 2 vols. 8vo. The best edition, however, is that by Mons. Boissonnade in the 'Collection de Classiques Français,' Lefevre, Paris, 1827. A volume was published in 1826 entitled les 'Poésies inédite de Parny,' with a notice on his life and writings by Mons. Tissot.

PAROCHIAL REGISTRIES. [REGISTRATION OF BIRTHS, &c., P. C. S.]

PARTHE'NIUM. [PYRETHRUM, P. C. S.]

PARTNERSHIP. In 1837 a statute was passed (7 Wm. IV. & 1 Vict. c. 73) authorizing the crown, after a reference of an application to the Board of Trade, to grant a species of incorporation to trading companies by letters patent under the great seal. The patent may limit the responsibility of partners to a certain sum per share. The company obtaining such a privilege must be constituted by deed of partnership, containing its name, its object, the place where its business is to be conducted, the names of the members, and the appointment of two officers in whose name the company may sue and be sued. These matters must also be entered, along with the additions of the members and the shares held by each, in numerical order in a return which must be made within three months after the date of the patent—in England or Ireland, to the Enrollment Office of Chancery; in Scotland, to the General Register House. Notice of transfers of shares must be sent within three months. This registration is the criterion both of benefits and responsibilities: no one is entitled to profits unless as accruing to registered shares, and no one is relieved from responsibility until his name is superseded in the register. The extent to which this statute may have been adopted in practice is not publicly known.

PARTY-WALLS. [BUILDING-ACT, P. C. S.]

PASSA'LODON, a genus of fossil Placoid fishes, from the Bagshot sand. (Buckland.)

PASSENGERS. [SHIPS, P. C.]

PA'SSERI, GIOVA'NNI BATTISTA, a distinguished painter, and author of one of the best collections of biographies of Italian artists, was born at Rome about the year 1610 or earlier. Passeri received a good education, and, according to his own account, did not take up painting until comparatively late; he was first engaged in the capacity of a painter in 1635 by Canini in the Villa Aldobrandini at Frascati, where he contracted an intimate friendship with Domenichino, then returned from Naples. When Domenichino died in Naples in 1641, Passeri was president of the Academy of St. Luke, and he read a funeral oration on him, and painted a portrait of him, which was placed in the academy with other portraits of painters, which are at present in the gallery degli Uffizj at Florence; the portraits now in the academy at Rome are copies. (Platner, *Beschreibung der Stadt Rom.*) At the close of his life Passeri entered into holy orders; and obtained in 1675 a benefice in the college of Santa Maria in Via Lata. He died in 1679.

Passeri is one of the best of the Italian historians of art; his theoretical knowledge was good and his facts are believed to be very correct. The circumstance of his book lying for nearly a century unnoticed, or rather unpublished, was owing to its unfinished state and the severity of many of his remarks, especially on Bernini. It was first published in Rome by an anonymous editor (supposed to be Bottari, editor of the *Lettere Pittoriche*) in 1772, with some omissions, under the title 'Vite de' Pittori, Scultori, ed Architetti che anno lavorato in Roma, morti dal 1641 fino al 1673, di Giambattista Passeri, Pittore e Poeta,' 4to. pp. 492 (Lives of the Painters, Sculptors, and Architects who have practised in Rome, and died between the years 1641 and 1673 inclusive); thus constituting a continuation to the work of Baglione. It contains thirty-six lives, as follow: Domenichino, Baccio Ciarpi, Pieter Laer, called Bamboccio, Guido, Il Fiammingo, Agostino Tassi, Francesco Mocchi, Lanfranco, Camassei, Giambattista Calandra, Vincenzo Armanno, Alessandro Turco, Pietro Testa, A Caroselli, Algardi, G. Rainaldi, Gio. Miele, M. Lunghi, G. U. Abatini, Luigi Gentile, Giuliano Finelli, Ag. Mitelli, Albani, M. Cerquozzi, Catterina Ginnasi, Andrea Sacchi, Romanelli, Giu. Peroni, N. Poussin, F. Baratta, Gio. Ang. Canini, Guercino, F. Boromino, P. F. Mola, Pietro da Cortona, and Salvator Rosa.

There is only one public picture by Passeri in Rome, a crucifixion between two saints, in the church of San Giovanni della Malva. They are not so rare in galleries. He painted sometimes still-life. His nephew Guiseppe Passeri was likewise an eminent painter. He died in 1714, aged sixty.

PASSIGNA'NO, DOME'NICO DA, or DOMENICO CRESTI, Cavaliere, was born at Florence about the middle of the sixteenth century. Some accounts give 1560, but this is probably too late; Baglione says he was eighty years old when he died in 1638, which would place his birth in 1557 or 1558. He was the pupil of Federigo Zucchero, and lived some time in Venice, where he acquired a great preference for the Venetian school of painting, and especially the works of Paolo Veronese. He acquired a great reputation at Rome, where he was employed by the popes Paul V. and Urban VIII.; he painted the Crucifixion of St. Peter for the Capella Clementina in the great church of St. Peter on the Vatican, for which he was created Cavaliere dell' Abito di Cristo. He spent the latter part of his life at Florence, and he was one of the most influential of those painters who contributed towards the reform of the Florentine school by improving the taste for colour and rendering the mannered anatomical school less popular. Passignano was the friend and associate of Cigoli, and is said to have been the master of Lodovico Carracci while in Florence. He died in 1638. He had many scholars, of whom Pietro Sorri of Sienna was the most distinguished.

(Baglione, *Vite de' Pittori*, &c.; Lanzi, *Storia Pittorica*.)

PASTINA'CA (from *pástinum*, the Latin name for a two-pronged fork), a genus of plants belonging to the natural order Umbelliferæ, and the tribe Peucedaneæ. It has a calyx with 5 very small or nearly obsolete teeth; round entire petals, involute, with an acute point. The fruit has a dilated flat margin. The carpels with slender ridges, 3 dorsal equidistant, two lateral distant, near the outer edge of the dilated margin. The interstices with single linear vittæ.

P. sativa, Parsnep, has an angular furrowed stem, pinnate leaves, downy beneath, ovate oblong leaflets, crenate, serrate, often with a lateral lobe at the base. The stem from 2 to 3 feet high. The flowers are yellow. The leaves generally shining above, sometimes downy beneath. It is native of Great Britain and of Europe, even to the Caucasus, on hillocks and dry banks, in a chalky soil. The root is spindle-shaped, white, aromatic, mucilaginous, and has a sweet taste. A variety of this species, *P. edulis*, is the common edible parsnep, and is much cultivated in our gardens. For cultivation and uses of this variety see article PARSNEP, P. C. Another variety, called *P. Coquaine*, has roots from three to four feet long, and upwards of six inches in circumference. It is extensively cultivated in Jersey and Guernsey as fodder for cattle. In the north of Ireland parsneps are used in the composition of a kind of beer brewed with hops. Wine and ardent spirit are likewise made from the roots.

P. Sekakul is another edible species of this genus, and is native of Syria and of Egypt. It has a grey root, a terete downy branched stem, pinnate downy leaves, pinnatifid cut leaflets, blunt and unequally toothed. It is cultivated in the Levant, under the name of Sekakul.

The species are only to be increased by seed, which should be sown in the open border early in the spring.

(Don's *Gardener's Dictionary*; Babington's *Manual of British Botany*; Burnett's *Outlines of Botany*.)

PASTURE, COMMON OF. [COMMONS, P. C.]

PATELLOI'DEA, a genus of Mollusca proposed by MM. Quoy and Gaimard for certain Gasteropoda, which have shells exactly resembling those of limpets, but whose animals are cervico-branchiate. It is synonymous with the genus *Lottia* of J. E. Gray. The *Patella testudinalis* of Otho Fabricius, a shell not uncommon on the northern coasts of Britain, is the type. Numerous species are known, inhabiting all latitudes and living in various depths of water. Their shells are gaily coloured, often tessellated and rayed with purple, orange, or pink. The animals are usually of a uniform tint of white, orange, or pale red.

PATENT. The 7 & 8 Vict. c. 69, § 2, enables a patentee, by petition to the Queen in council, to obtain an extension of the patent term for any time not exceeding fourteen years, 'subject to the same rules as the extension for a term not exceeding seven years, is now granted under the powers of the said act of his late majesty (5 & 6 Wm. IV. c. 83).' This act of Victoria contains also a provision applicable to the extension of time in cases where patentees have wholly or in part assigned their patent right. Sections 5 and 6 contain provisions as to disclaimer and memorandum under 5 & 6 Wm. IV. c. 83, in cases in which a patentee has assigned all or part of his patent right. Section 7 confirms new letters-patent which may have been granted under 5 & 6 Wm. IV. c. 83, to an assignee or assignees, and declares that such new letters-patent shall be as valid as if they had been made after the passing of this act; provided that nothing in this act contained shall give validity to any letters-patent heretofore granted to an assignee or assignees, when any action or proceeding in Scire facias or suit in equity shall have been commenced before the passing of this act, wherein the validity of such letters-patent shall have been or may be questioned.

PATENT. [PARTNERSHIP, P. C. S.]

PATERNITY. [BASTARD, P. C.]

PATERSON, WILLIAM. Of the early history of this man, who originated several celebrated projects, little is known. By some accounts he is said to have been brought up to the clerical profession, to have been sent as a missionary to the West Indies, and to have subsequently become a buccaneer. In the account however of the parish of Tinwald, Dumfries-shire, in the first volume of the old statistical account of Scotland, it is asserted that he was born at Skipmyre in that parish about the year 1660, that he was respectably connected, and that he more than once sat for Dumfries-shire in the parliament of Scotland. Whatever may be his early history, he must have had ample opportunities of making himself acquainted with the commerce and institutions of foreign countries, and he was probably an extensive traveller. His schemes regarding banking and trading projects are said to have been first offered to the mercantile communities in the Low Countries, and to have been coldly received. He subsequently laid his plans before the merchants of London, and it seems to be nowhere doubted that they were the foundation of the project of the Bank of England, incorporated in 1694. [BANK, P. C.] From the rapidity with which the scheme was brought into a working shape, it may be conjectured that very little alteration was made on the original suggestions of Paterson. It does not appear that the inventor was for any length of time practically connected with the working of the institution. It is usually said that the rich capitalists, once possessed of his ideas, quarrelled with him, set him adrift, and managed his project for their own peculiar advantage. It is probable however that Paterson, though so able a schemer, was a bad practical man of business; that his invention was perpetually on the wing, and that he could not settle down to the routine of business with much advantage either to himself or to others. His next project, if it was not conceived at the same time as that of the Bank, was the renowned Darien expedition. Scotland was at that time filled with active and enterprising spirits, who, by the two kingdoms being under one crown, had lost much of that department of foreign service which their ancestors had held in states at war with England. There was an earnest desire to rival England in commerce and manufactures, and in colonies, of which Scotland was not previously possessed. An act of the Scottish parliament was passed on 26th June, 1695, incorporating certain persons by name, of whom Paterson was one, with powers to add to their number, to be called 'The Company of Scotland trading to Africa and the Indies.' Very important privileges, both in connection with foreign trade and with the institutions of the country, were conferred on the members. The company raised a large subscription in England. Its progress roused the English jealousy of trade, and after some representations by the East India Company and other bodies, both houses of parliament presented an address to King William, in which they stated, 'that by reason of the superior advantages granted to the Scottish East India Company, and the duties imposed upon the Indian trade in England, a great part of the stock and shipping of this nation would be carried thither, by which means Scotland would be rendered a free port, and Europe from thence supplied with the products of the East much cheaper than through them, and thus a great article in the balance of foreign commerce would be lost to England, to the prejudice of the national navigation and the royal revenue.' In fact, under the guise of a company having a monopoly, Paterson's plan would have developed itself, had it come into full operation, as a nucleus of free trade; and its opponents rather *felt* how unable they would be to compete with this untrammelled community, than saw in its constitution any general principle of superiority to the restrictive commercial system with which they were connected. 'We do hereby publish and declare,' says the first proclamation of the company, 'that all manner of persons, of what nation or people soever, are and shall from henceforward be equally free, and alike capable of the said properties, privileges, protections, and immunities, and rights of government granted unto us; and the merchants and merchant-ships of all nations may freely come to and trade with us without being liable in their persons and goods to any manner of capture, confiscation, seizure, forfeiture, attachment, arrest, restraint, or prohibition, for or by reason of any embargo, breach of the peace, letter of marque, or reprisals, declaration of war with any foreign prince, potentate, or state, or upon any other account or pretence whatsoever. And we hereby not only grant, concede, and declare a general and equal freedom of government and trade to those of all nations who shall hereafter be of or concerned with us, but also a full and free liberty of conscience in matters of religion.' In contemplation of a company carried on on such principles, the two houses of the English parliament represented that 'the privileges granted their company would render their country the general storehouse for tobacco, sugar, cotton, hides, and timber; the low rates at which they would be enabled to carry on their manufactures would render it impossible for the English to compete with them." King William was induced to discountenance the undertaking, and the projectors were deprived of all aid, not only from England, but from foreign speculators. This only made the scheme a more truly national object, and all the disposable wealth of Scotland was speedily embarked in it. The main scheme of the company was to establish a colony at Darien, when Paterson believed that it would be in the middle of the highway of the world, and form the emporium where the commerce of the East would meet that of the West. With all due respect for the principles on which the commerce was to be conducted, it may be questioned if the place possessed all the peculiar advantages which he attributed to it, especially at a time when regular commercial enterprise had made so comparatively little progress over the globe. The expedition set out on the 26th July, 1698; its disastrous results may be found recorded in the ordinary histories of the period, and particularly in Sir John Dalrymple's Memoirs. Paterson was ambitious, but not mercenary, and in the palmy days of the company he had resigned the profits which those confident of its success had assigned to him. The failure of the expedition preyed deeply on his spirits, and grief and disappointment brought him, during his return home, to the borders of lunacy. He lived subsequently a life of obscurity, and the period of his death is not recorded.

PATRIARCHS. We propose to give a chronological list of the Patriarchs of Alexandria, Antioch, Constantinople, and Jerusalem, arranged systematically with the Roman Popes, for which reason we place the article under ROMISH CHURCH.

PAVONIA (in honour of Don Joseph Pavon, M.D., of Madrid, a traveller in Peru, and one of the authors of 'Flora Peruviana'), a genus of plants belonging to the natural order Malva. It has a 5-cleft persistent calyx, surrounded by an involucel from 5 to 15 leaved. The ovarium has 5, and rarely 4, 1-ovuled cells. It has 10 stigmas, 5 carpels, capsular, 2-valved, and 1-seeded.

P. diuretica has cordate acuminate serrated leaves, velvety on both sides, and full of pellucid dots. The flowers are axillary, solitary, and sulphur-coloured. It is native of Brazil, in the province of Minas Geraes. A decoction of this plant is used in Brazil as a diuretic. This is the only species of Pavonia used in medicine; many others are however worth cultivation for the beauty of their blossoms. They are free-growing plants, for the most part ripening seed in abundance, and cuttings will root freely under a hand-glass.

(Don's *Gardener's Dictionary*; Lindley's *Flora Medica*.)

PAYMENT. If a man owes several sums of money to another on different accounts, and makes a payment of any one of such sums, he may state at the time of payment on which account such sum is paid, and the payment will be considered to be legally appropriated to the debt which he has named. If at the time of payment the debtor makes no appropriation of the payment, the creditor may at the time of payment appropriate it to such debt as he pleases, provided he so appropriates the payment, as he would do, or as it may be presumed that he would do, if he were the debtor. Accordingly the creditor must appropriate the payment to such debt as is the most burdensome to the debtor. If neither party make any appropriation of the debt at the time of payment, the payment will be presumed to be made on account of the more burdensome debt; if there is no difference in the quality of the debts, the payment must be presumed to be made on account of the oldest.

These are the rules of the Roman Law (*Dig.* 46, tit. 3), which perhaps may be considered to be adopted by the English Law, though the decisions are by no means uniform in this matter. (Devaynes *v.* Noble, 1 Mer. 606.) The principles just laid down apply to distinct debts on different accounts (causae). If there are dealings between two persons which are all of one uniform and continuous nature, as for instance between a banker and his customer, there is no question of appropriation of payment. The customer pays money into the bank at different times, and draws it out by drafts at different times. All the sums paid in and all the sums paid out severally make an entire creditor and debtor account, and by striking the balance at any given time it will appear what sum is due at that time from the banker to his customer or from the customer to his banker. It is true that this supposes a kind of appropriation, but not exactly that kind which is meant by the term. It assumes that the sum first paid in is discharged by the sum first paid out, so far as it is sufficient to discharge it; and the same remark applies to all subsequent payments into the bank and sums drawn out. The account therefore must be made out in the order of time, and the balance will show how the account stands at the time when it is made out. (Devaynes *v.* Noble.)

There are various cases in the reports in which the question of appropriation of payments has been discussed. (Boddenham and Purchas, 2 B. and Ald. 39; Simpson and Ingham, 2 B. and Cr. 65; Pemberton and Oakes, 4 Russ. 154; and others.)

PEAR-GAGE. The principle of Smeaton's pear-gage, for measuring the exhaustion of a receiver, differs from that of the other gages, in that the measurement does not take place until after the air has been re-admitted into the receiver. Suppose a wire working through a collar in the top of the receiver and supporting a tube open only at the lower end. Under the tube is a cup of mercury, standing on the floor of the receiver, so that by lowering the wire the open end of the tube may be immersed in the mercury. The exhaustion being made before lowering the wire, the air in the tube will be rarefied equally with that in the rest of the receiver. If the wire be then lowered, and the air re-admitted into the receiver, the mercury will rise in the tube until the elastic force of the recompressed air in the tube, together with the column of mercury, counterbalances the pressure of the external air. A gage attached to the tube shows, by the height of the mercury, what was the original rarefaction.

Now it is plain that while the ordinary gages show the actual amount of elastic force left in the receiver, the pear-gage submits the air, or whatever else there may be, to a process of compression before the measurement is made. If there be nothing but air, all the gages agree; but if, as generally is the case, there be also vapour, the pear-gage shows a much higher degree of apparent exhaustion than the ordinary gage. For further detail see the article 'Pneumatics' in the *Encyclopædia Metropolitana.*

PECO'PTERIS, a genus of fossil Ferns, of which the species occur abundantly, both in the coal-measures and the oolitic strata. (Brongniart.)

PECULIARS, COURT OF, is one of the English ecclesiastical courts. It is the third court of the archbishop of Canterbury, the other two being the Court of Arches, or supreme court of appeal, and the Prerogative or Testamentary Court. The Court of Peculiars takes cognizance of all matters arising in certain deaneries, one of which is in the diocese of London, another in the diocese of Rochester, another in the diocese of Winchester, each comprising several parishes; and some others over which the archbishop exercises ordinary jurisdiction, and which are exempt from and independent of the jurisdiction of the several bishops within whose dioceses they are locally situated.

(*Political Dictionary*, article 'Ecclesiastical Courts.')

PEDICULA'RIS (from the Latin word *pediculus*, a louse, from its supposed quality of making sheep that feed upon it lousy), a genus of plants belonging to the natural order Scrophularineæ. It has an inflated 5-toothed calyx, a ringent corolla, with the upper lip laterally compressed, the lower plane 3-lobed. The capsules are acute, and compressed. The seeds numerous and angular. The species are usually simple herbs. The flowers sessile, disposed in dense terminal interrupted spikes.

P. palustris has a solitary erect stem, branched throughout, pinnatifid leaves, with oblong blunt lobed segments; an ovate pubescent 2-lobed calyx, the lobes incise, dentate, crisped. The upper lip of the corolla has a short truncate beak, with a triangular tooth on each side. The flower is large and crimson, varying to white. It is found in marshes and wet meadows, particularly in the north of England, and is said to be injurious and disagreeable to cattle. This is the *Pedicularis Herba* of Columella, 6. 30, and of Scribonius Largus,

P. sylvatica has a stem branched at the base, erect, the branches long, spreading, and prostrate; the leaves pinnatifid, leaflets ovate and deeply toothed. The upper lip of the corolla as in the last species, the flower large and rose-coloured. It is found on wet, heathy, and rather hilly grounds in Siberia, Europe, and Great Britain. The expressed juice of the herb, or a decoction, has been used with advantage as an injection in serous ulcers. It is injurious to the sheep that feed on it. There are 75 other species of Pedicularis enumerated, none of which are British, or applicable to any useful purpose. They are found chiefly in Europe and Northern Asia. All these herbs are very shy of cultivation. Peat soil and a moist situation suit the generality of them. All foreign species require protection during the winter, and to this end they should be grown in pots. It has been affirmed that these plants breed lice in the animals that feed on them; the truth, however, appears to be that they indicate a very poor pasture, and the want of food may produce an unhealthy state of the animal, and thus cause them to generate vermin.

(Don's *Gardener's Dictionary;* Babington's *Manual of British Botany.*)

PEDRO, DON, Emperor of Brazil and King of Portugal, was the son of John VI., king of Portugal, and was born at the castle of Queluz on the 12th Oct., 1798. From early youth he was the active witness of the long series of political troubles which distracted Portugal, and which are fully detailed in another part of this work. [PORTUGAL, P. C.] At the age of nine he accompanied his father, then regent for the Queen Maria Isabella, in their exile to Brazil. The misfortunes which had befallen his family proved an advantageous school for his political education; they became the means of developing the activity of his mind by depriving him of the hope of depending on other sources than those which should arise from his own talents and energy. He applied himself with considerable success to tho acquisition of various languages, while he devoted the hours usually spent in recreation to the cultivation of poetry and music.

At the general peace of 1815 a marriage was contracted for the young prince of Brazil, the title by which he was then known, with Maria Leopoldina, archduchess of Austria. At that period the colony of Brazil was raised to the rank of a kingdom, and, when, in 1820, John VI. was recalled to Portugal by the Cortes, Don Pedro remained as regent in that country. [BRAZIL, P. C.]

His first position in political life was, as will be seen by reference to the article BRAZIL, P. C., one of peculiar difficulty; to preserve the authority with which he had been intrusted, and to secure the peace and prosperity of the kingdom, required the exercise of diplomatic skill, and a firm resolution of no ordinary kind. The Cortes of Portugal were desirous of reducing Brazil to its antient position as a colony, and to confine its commerce to the mother country; they also designed for it a new system of government by dividing it into provincial administrations. The prince regent, sensible of the impolicy and injustice of this scheme, placed himself at the head of the popular opposition which it excited, and refused obedience to the attempted innovations. The Portugese troops stationed at Pernambuco and Rio Janeiro were sent back to Europe, while, on the other hand, the Portuguese commandant at Bahia retained possession of that town, and expelled from it the militia. Civil war was the necessary consequence of these proceedings, and on the 13th of May Don Pedro was proclaimed protector and perpetual defender of Brazil; and, finally, on the repeated refusal of the Portuguese Cortes to abandon their design, the independence of Brazil was declared; and the prince, yielding to the popular wish, was proclaimed emperor on the 12th of October, 1822, and was crowned on the 1st of December in the same year. The details of the war which followed with Portugal, the constitution which was adopted by the Brazilians, and sanctioned by the emperor, will be found elsewhere. [BRAZIL, P. C.]

Though Don Pedro appears to have satisfied the exigencies of the new state by granting it a constitution based upon liberal principles, partial outbreaks of resistance to his government continued to manifest themselves. The long anarchy which had existed in the provinces rendered the inhabitants indisposed to submit to regular rule, and the instinctive hatred of the Brazilians against the Portuguese diminished the popularity of the ruler. Insurrections broke out at Pernambuco, San Salvador, and Bahia, which were however speedily checked. In 1825 the independence of Brazil was recognised by Portugal. The following year a dispute arose between Brazil and the neighbouring republic of Buenos Ayres [PLATA, LA, P. C.] respecting the possession of a territory named the Banda Oriental, the inhabitants of which were desirous of annexing themselves to the new empire, and a war was the result, which terminated unfavourably to the interests of Brazil. To this cause of discontent another was added by the death of John VI. in March, 1826, and the consequent succession of Don Pedro to the crown of Portugal. This event excited the fears of the Brazilians lest he should prefer the kingdom which descended to him by hereditary right to the empire at whose head he had been placed by the will of the people, and thus Brazil should again become reduced to the position of a dependancy of Portugal. These fears however he endeavoured to dispel by abdicating the crown of Portugal in favour of his daughter Donna Maria da Gloria, reserving to himself the regency, with the title of king, during her minority. The succeeding years of his reign were marked by continual disturbances of a political nature throughout the country. In 1830 the French revolution gave a new impulse to the democratical party, and an affray which took place on the 6th of April, 1831, the details of which are given in the article BRAZIL, P. C., determined Don Pedro upon abdicating the throne in favour of his son, to whom, being under age, he appointed a guardian, and the following day he left the country.

The throne of Portugal, which Don Pedro had resigned in favour of Donna Maria, had been usurped by his brother Don Miguel, whom in 1827 he had appointed regent of the kingdom. [PORTUGAL, P. C.] His object was now to recover the country from the usurper, and to reinstate his daughter in the rights of which she had been deprived. The plan of the enterprise was matured during a somewhat lengthened sojourn in Paris, where ho was joined by the exiled Portuguese who had espoused his cause, at tho head of whom was General Saldanha, and a great number of foreign adventurers. For the details of the civil war which ensued we must again refer to another part of the Cyclopædia. [PORTUGAL, P. C.] On the 26th of May, 1832, Don Miguel was reduced to the necessity of signing a convention, which left the young queen in quiet possession of the throne of Portugal under the regency of Don Pedro.

The acts of his short administration were calculated to secure for him the good will of the more liberal party in his dominions; but many of them, though they may have been expedient, were certainly unjust. He strengthened the external relations of Portugal by a close alliance with England and France, and in order to give an interest to the people in the new revolution he confiscated for the use of the state tho property of the numerous monastic establishments in his kingdom. The anathemas of the Vatican were the natural result of these sweeping measures, and they were soon followed by his own excommunication. In September, 1832, the declining state of his health compelled him to resign the regency, and his daughter, having been declared of age, was placed in full possession of the royal authority. He did not long survive to assist the young queen with his counsels, and the palace where he had been born was the scene of his death on the 24th of September, 1834.

The life of Don Pedro is chiefly interesting as it is connected with the general history of the period; the difficult circumstances in which he was placed deprived him of the opportunity of putting into effect many measures of utility which he had the talent to design, and on a more quiet theatre he might have acted the part of a greater king.

PEEL (or PEELE, as the name is found in most books printed forty years ago), SIR ROBERT, the first baronet, was born 25th April, 1750, at Peel's Cross, near Lancaster, a small property belonging to his father, Mr. Robert Peel, whose third son he was. The family, though not wealthy, appears to have been of some respectability for several generations. It is said to have been lately traced back to the end of the sixteenth century, about or soon after which dato its head was a clergyman of the Established Church; but the common accounts go no higher than to the great-grandfather of the subject of the present notice. He was Robert Peel, and died in 1736. His son is described as William Peel of Oswaltwich, who married Jane, daughter of Laurence Walmesley, of Darwin, Esquire; their son Robert, of Peel's Cross, married Elizabeth, daughter of Edmund Howorth, of Backburn, Gentleman, and had a numerous family of sons.

It is understood that the Peels had been Unitarians for some generations, and that Sir Robert was brought up in that sect. When he conformed we do no know. It is said that he early gave evidence both of remarkable business talents, and of a decided ambition and determination to raise himself in the world. He and most of his brothers were brought up to different branches of the cotton-trade, now fast extending under the effect of the inventions of Arkwright, whose personal success in the acquirement of wealth and station was also of course operating as a powerful example and incentive. The mechanical processes of the trade are said to have early engaged much of Peel's attention, though they were never indebted to him for any improvement, so far as we are aware. He made his fortune by his general ingenuity and sagacity, by his unremitting activity and attention, by his comprehensive boldness of enterprise, and by his admirable conduct of business, alike in its largest scope and in its minutest details.

In 1773 Mr. Robert Peel entered into partnership with Mr. William Yates in an extensive factory at Bury, in Lancashire; and on the 8th of July, 1783, he married Ellen, daughter of Mr. Yates, who had then just completed her seventeenth year. His career from this time was one of great and uninterrupted prosperity. About the time of his marriage he purchased a considerable estate in Lancashire; and in the course of a few years he invested large additional sums of money in land in the counties of Stafford and Warwick.

It has been asserted that Mr. Peel's principles were originally favourable to the French Revolution, or at least to the class of opinions in which that movement originated; but this, we apprehend, must be a mistake. He appears to have first come forward as a politician in 1780 by the publication of a pamphlet entitled 'The National Debt productive of National Prosperity,' a title which may be taken as evidence that his views at that date were the very reverse of revolutionary or disaffected. In 1790 he was returned to parliament as one of the members for Tamworth, in and near which borough he had acquired large property; and it is indisputable that from the moment he entered the House of Commons, in which he sat for the same borough in seven successive parliaments, or to the end of the reign of George III., he was a steady and zealous supporter of the government. We do not see, therefore, to what period of his life we can with any probability assign his imputed republicanism.

In 1797 Messrs. Peel and Yates distinguished themselves by the considerable subscription of 10,000*l.* to what was called the Loyalty Loan. This fact is often stated in such a way as to make it appear that the money was a munificent gift which they made to the public. The truth is, it was merely a purchase of so much stock in the Public Funds, which promised and proved to be an excellent speculation, and was evidence of nothing except the confidence of the subscribers in the stability of the government, and their correct views of their own interest. The entire loan, amounting to 18,000,000*l.*, was all raised in a few hours, and might probably have been doubled in amount if it had been desired; for the only difficulty was to satisfy a mob of applicants whose subscriptions could not be received. The sum subscribed by Messrs. Peel and Yates was far from being the highest; the Duke of Bridgewater, for instance, subscribed 100,000*l.* For each 100*l.* the subscribers received a capital of 112*l.* 10*s.*, bearing an interest of five per cent., with a right to have their stock two years after the conclusion of a peace converted into three per cents. at the rate of 133*l.* 6*s.* 8*d.* for 100*l.* capital.

In 1798 Mr. Peel further showed his loyalty and public spirit by the part which he took in encouraging the volunteer system. Besides assisting in the formation of the Lancashire Fencibles, and the Tamworth Armed Association, he raised, chiefly from among his own workmen, six companies of what were called the Bury Loyal Volunteers, and got himself commissioned as their lieutenant-colonel. On the 14th of February, 1799, he made a speech in the House of Commons in favour of the Union with Ireland, which was soon after printed and extensively circulated in that country. On the 29th of November, 1800, he was created a baronet.

Sir Robert Peel, the number of persons employed by whom is said to have amounted in 1803 to fifteen thousand, lived for ten years after his retirement from parliament in 1820, dying at his seat of Drayton Park, in Staffordshire, on the 3rd of May, 1830. On the 18th of October, 1805, he had married a second wife, Susannah, sister of the Rev. Sir William Henry Clarke, Bart., Rector of the parish of Bury, who was then in her fifty-third year, and who died on the 19th of September, 1824. By his first wife, who died on the 28th of December, 1803, he had six sons and five daughters; the eldest of the former being the present Right Hon. Sir Robert Peel. It may be remarked that, with the exception of two daughters who died in infancy, he saw all his children married before his death. Besides his large landed property, which he entailed upon his eldest son, together with, it is supposed, near half a million in money, he left about 150,000*l.* to each of his younger sons, and above 50,000*l.* to each of his daughters. He had also previously advanced to or settled upon his several children above 240,000*l.*, besides an income of 9000*l.* per annum secured to his eldest son.

(*Gentleman's Magazine* for June, 1830; *Parliamentary History*, and other records of the time.)

PEELE, GEORGE, is supposed to have been a native of Devonshire, and to have been born not later than 1552 or 1553. In 1564 he was a member of Broadgates Hall, now Pembroke College, in Oxford: he took his degree of Bachelor of Arts in 1577, and was made Master of Arts in 1579. In no long time afterwards he appears to have removed to London, and thrown himself upon the world as a literary adventurer. In that age the precariousness always incident to the profession of authorship was so distressingly great, that the pursuit, if entered on by a poor man, was barely compatible with the preservation of personal respectability: and, though the particulars of Peele's career are but very imperfectly known, there is evidence enough to show that it was not only unfortunate but disreputable. His conduct is represented as having been even more irregular than that of Marlowe and Greene, who were his intimate associates and his coadjutors in the improvement of the early English drama. It had been conjectured that he was professionally an actor, and his having been so is now made certain by a document discovered by Mr. Collier. A tract, frequently reprinted, entitled 'The Merrie Conceited Jests of George Peele,' represents him as nothing short of a common swindler. Some of the exploits which it relates are doubtless exaggerated, and others may have been erroneously fathered upon him; but it cannot be doubted that he suffered many pecuniary distresses, and was no way scrupulous in the shifts by which he sought relief. There is extant a begging letter, which, in 1595, labouring under poverty and sickness, he addressed to Lord Burleigh; and it is a characteristic trait of the man, that, relying perhaps on the Lord Treasurer's ignorance of the current literature, he sent with his petition a copy of a poem which, although he evidently wished it to be regarded as new, he had actually published six years before. He was dead in 1598, when Meres, in the second part of his 'Palladis Tamia,' described his death as having been caused by his debaucheries. In the 'Jests' he is spoken of as a married man; and his letter to Lord Burleigh describes the bearer as his eldest daughter.

The earliest of Peele's compositions that is known is a copy of verses prefixed to Watson's 'Εκατομπαθία, which was published in 1581; and his earliest known drama was printed in 1584. In 1828 Mr. Dyce published an excellent edition of 'The Works of George Peele, with some account of his Life and Writings,' 2 vols. post 8vo. A reprint of this edition, with improvements and additions, appeared in 1829; and in 1839 the same editor published a third volume, which probably makes the collection as nearly complete as it will ever be possible to render it. The non-dramatic poems, except a few short miscellaneous pieces and a long piece on the War of Troy, are speeches for pageants (such as 'The Device of the Pageant borne before Woolstone Dixie, Lord Mayor of London, 1585'), or celebrations of public occasions, like the 'Polyhymnia,' which describes a tilting-match held in the queen's presence in 1589, and 'The Honour of the Garter displayed,' which commemorates the installation of the unfortunate Earl of Northumberland in 1593. The dramas in Mr. Dyce's collection are six in number:—1, 'The Arraignment of Paris,' published anonymously in 1584, and assigned to Peele on the authority of his friend Nash; 2, 'The Famous Chronicle of King Edward the First,' printed in 1593 and 1599, and inserted in vol. xi. of the last edition of 'Dodsley's Old Plays,' as also in vol. iv. of the small collection called 'The Old English Drama,' 1830, 12mo.; 3, 'The Old Wives' Tale, a pleasant conceited Comedie,' printed in 1595, and chiefly remarkable as treating, in a coarse and prosaic fashion, a story closely resembling that of Milton's 'Comus;' 4, 'The Love of King David and Fair Bethsabe, with the tragedie of Absolon,' printed in 1599, and reprinted in the second volume of Hawkins's 'Origin of the English Drama,' 1773; 5, 'The Battle of Alcazar,' printed in 1594; 6, 'The Historie of the two valiant Knights, Sir Clyomon and Sir Clamydes,' printed in 1599, with no author's name, but attributed to Peele by Mr. Dyce, on the faith of a MS. marking in a very old hand on the title-page of a copy, to which not a little corroboration is afforded by the play itself. Thomas Campbell, in his 'Specimens,' has spoken of Peele more favourably than any other critic. There is more of justice in the cool estimate of his merits formed by Mr. Dyce and others. 'Those of his dramatic works which have come down to us,' says Mr. Knight, 'afford evidence that he possessed great flexibility and rhetorical power, without much invention, with very little discrimination of character, and with that tendency to extravagance in the management of his incidents, which exhibits small acquaintance with the higher principles of the dramatic art.' His inferiority to Marlowe is great and unquestioned; and perhaps it is only his musical though monotonous versification that entitles him to be compared even with Greene.

PELLERIN, JOSEPH, was born at Marli-le-Roi, near Versailles, April 27, 1684. He studied at Paris, and, besides the Latin and Greek languages, made himself master of the Italian, Spanish, and English. After completing his college studies, he learned Hebrew, Syriac, and Arabic. His knowledge of the three modern languages procured him, in 1706, a situation in the navy-office (bureau de la marine), where he was employed in making translations and extracts in those languages from the foreign correspondence of the minister. Several letters written in cipher having been seized on board a Spanish frigate on her voyage from Barcelona to Genoa, in 1709, Pellerin in a few days deciphered them without the keys. They were found to be important communications, some in French for the court of Turin, and some in Italian for the court of Naples. Torcy, then minister for foreign affairs, had an interview with Pellerin, who was soon afterwards appointed private secretary (sécrétaire de cabinet) to the secretary of state for the navy; and he held the situation when, on the death of Louis XIV., the business of the office was transacted by a council. The Comte de Thoulouse, grand admiral of France, made Pellerin a commissioner of the navy (commissaire de la marine) in 1718, and sent him on service to the great harbours of France, and in 1723 he was destined to make a general inspection of all the harbours, but a change of ministry took place, the council of the navy was suppressed, and other measures were decided on. Pellerin however still continued attached to the department of the minister for the navy, by whom he was appointed commissioner-general, and afterwards was made first clerk of the navy (premier commis de la marine), in which office his activity, probity, and firmness, combined with the suavity of his manners, met with universal approbation. In 1745 bodily infirmities compelled him to retire from the public service. His son, who had served in the navy and in the naval department of the government, succeeded him in his office.

Pellerin, during his long service of about forty years, had used the opportunities which his situations afforded him in the collection of a considerable number of coins and medals, at first from curiosity, but afterwards from a taste for them as monuments of antiquity. To occupy his leisure and alleviate his sufferings, after his retirement, he began to read, explain, classify, and arrange them. His early studies in the oriental languages, as well as in Latin and Greek, were renewed, and became a source of much gratification to him. Such was the origin of that magnificent collection of coins and medals which he formed in the course of the subsequent forty years of his life. He died at Paris, August 30, 1782, in his ninety-ninth year.

In the arrangement and classification of his medals Pellerin adopted a system different from that of any previous collector. Instead of distributing them in drawers according to difference of metals, and arranging them alphabetically without reference to the countries to which they belonged, he placed them according to certain great geographical divisions, preserving however an alphabetical arrangement of the medals of kings, nations, and towns included in each of those divisions. His descriptions of the medals, with his comments and remarks, formed a large Catalogue Raisonné, which he published under the title of 'Recueil de Médailles de Rois, Peuples, et Villes,' &c., 10 vols. 4to., Paris, 1762 to 1778. His delight in his favourite study was such that when upwards of ninety years of age and blind, he composed and wrote with his own hand, by means of an ingenious contrivance, the last volume of the work, which is entitled 'Additions,' &c. A system of arrangement and classification similar to that of Pellerin was adopted by Eckhel, in his 'Doctrina Numorum Veterum.' [ECKHEL, P. C.] Pellerin and Eckhel were probably the two greatest numismatists who have ever lived. Pellerin's collection, which consisted of 32,500 medals, was bought by the King of France, in 1776, for 300,000 francs. The king afterwards allowed Pellerin, as long as he lived, the use of the whole of the royal collection, which then amounted to about 44,000. The most important additions which have since been made to numismatics relate to the coins of the kings of Bactria. [PRINSEP, JAMES, P. C.; AFGHANISTAN, P. C. S.]

(Allier-d'Hauteroche, in *Biographie Universelle.*)

PELLISSON-FONTANIER, PAUL, was born at Béziers in 1624. He was deprived of his father at an early age, and was educated by his mother in the principles of the Reformed church. His family had for a long time been distinguished in the profession of the law, and to that profession he was also destined. He studied successively at Castres, Montauban, and Toulouse, and acquired an intimate knowledge of the best classical writers, and of French, Spanish, and Italian literature. To the study of civil law and jurisprudence he especially devoted himself; the fruits of which shortly afterwards appeared in a paraphrase of the Institutes of Justinian, which was published at Paris in 1645. He commenced his legal career with considerable success at Castres, but it was soon interrupted by a most severe attack of small-pox, which permanently affected his sight and so disfigured him that Mad. de Scuderi, though sincerely attached to him (*Menagiana*, vol. ii. p. 331, Paris, 1715), could not refrain from making him the object of her wit, by remarking that he abused the permission of being ugly.

Compelled by his infirmities to abandon the practice of his profession, he retired into the country and devoted himself to general literature. In 1652 he settled in Paris, where his writings had already made him advantageously known. The French Academy, in acknowledgment of the services he had rendered it by writing its history (the work perhaps by which he is best known), decreed that he should be appointed a member of it on the first vacancy that should occur, and that in the meantime he should be permitted to attend their sittings; to enhance the honour, they further decided that a a similar privilege should on no consideration be granted in future to any man of letters. The same year Pellisson purchased the office of secretary to the king, and the assiduous attention which he applied to the performance of his duties acquired for him a reputation for the management of public affairs. In 1657 he was appointed first clerk to the intendant of finances, Fouquet, of unfortunate celebrity. In an employment where vast sums of money passed through his hands he maintained his reputation for integrity, while his increased means enabled him to render pecuniary services to the distressed men of letters in the capital. Several traits of his generosity are recorded and their value is increased by the delicate concealment which accompanied them. (*Menagiana*, vol. ii. p. 16.) His services were rewarded by Fouquet with the appointment, in 1660, to the office of state counsellor. The following year he partook of the disgrace of his patron, and, as being the principal sharer in his fortunes and the supposed confidant of his secrets, was imprisoned in the Bastille. He remained upwards of four years in captivity, and constantly resisted every attempt which was made to induce him to divulge anything prejudicial to the interests of his benefactor. During this imprisonment he composed three Memoirs in behalf of Fouquet, which have been reckoned the finest models of that species of writing in the French language; the author of 'Le Siècle de Louis XIV.' considers them the nearest approach to the Ciceronian style that French literature possesses; they are indeed alike honourable to his talents as a writer and his feelings as a friend. They became however the plea for additional severity towards Pellisson. In order to increase the rigour of his confinement he was deprived of the use of ink and paper, the want of which compelled him to have recourse to divers ingenious expedients, such as writing on the margin of his books with the lead of the casements. He found some alleviation to his sufferings in the grateful sympathy of his friends, one of whom, Tannegui le Fevre, did not fear to incur the risk of royal displeasure by dedicating to the imprisoned advocate of a persecuted minister his edition of Lucretius and a translation of Plutarch's Treatise on Superstition. The persevering influence of his friends was at length successful in restoring him to liberty; and he was even received into favour by a king whose characteristic was seldom to forgive any opposition to his despotic will. The sufferings he had undergone at the Bastille were compensated for by a pension and the appointment of historiographer to the king. In 1670 he abjured Protestantism for the Roman Catholic faith. This change, followed soon after by his entrance into holy orders, enabled Louis XIV. to bestow upon him the abbacy of Gimont and the priory of St. Orens, a benefice of considerable value in the diocese of Auch. However, he is favourably distinguished from most proselytes by the lenient and tolerant disposition which he evinced towards those who disagreed with him in opinion, and, when high in royal favour, he publicly disapproved and opposed by his influence and writings the violent measures which were employed by the king's command [Nantes, P. C.] to bring his Protestant subjects within the pale of the Roman church. In 1671, on the occasion of the reception of the archbishop of Paris as member of the Academy, he delivered a panegyric on Louis XIV., which was translated into the Latin, English, Spanish, Portuguese, Italian, and even Arabic languages. In 1673, having incurred the displeasure of Madame de Montespan, he was deprived of his office of royal historiographer, but, at the special request of Louis, he continued to write the Life of the King, and for that purpose accompanied him in several of his campaigns. Nearly every succeeding year of Pellisson's life was marked by some instance of royal favour. His death took place at Versailles, in February, 1693. The fact of his not receiving the Sacrament in his last moments has been explained by the Roman Catholic writers to be owing to the suddenness of his death, by Protestants to his unwillingness to sanction a conversion, which they allege to be insincere, by a solemn act of hypocrisy. The arguments on both sides will be found impartially stated by Bayle (art. 'Pellisson').

The principal works of this writer, who enjoyed a greater reputation in his life-time than has been accorded to him since his death, are—1, 'Histoire de l'Académie Française,' which was first published at Paris, in 1653; the best edition is that by l'Abbé d'Olivet, by whom it has been continued, Paris, 1730. The fault of this work is generally considered to be its diffuseness; the style however is commended by Bishop Sprat, in his 'Hist. of the Royal Society of London' (part i., sect. 19). 2, 'Histoire de Louis XIV.,' which extends from the death of Mazarin, in 1661, to the peace of Nimeguen in 1678; this history has the faults to be expected in the work of a professed courtier; the best edition is that of Paris, 3 vols. in 12mo., 1749. 3, 'Abrégé de la Vie d'Anne d'Autriche,' 1666, in 4to.; a panegyric rather than a history. 4, 'Histoire de la Conquête de la Franche Comté,' in the 5th vol. of 'Les Mémoires du Père Desmolets;' this work has been greatly praised by Voltaire. 5, 'Lettres Historiques et Œuvres diverses,' 3 vols. in 12mo., 1749; the letters, 273 in number, are a journal of the king's journeys and encampments in the above-mentioned campaign. 6, 'Recueil des Pièces Galantes,' 5 vols., 1695, being a correspondence in prose and verse between him and the Comtesse de la Suze; his verse partakes of the elegance of his style in prose, but it is deficient in imagination. 7, 'Réflexions sur les Différends de la Religion,' 4 vols. 12mo., an answer to the arguments of Jurieu on religious toleration; on this treatise Bayle has made several valuable remarks in his notes on the article 'Pellisson.' 8, 'Traité de l'Eucharistie,' a work he left unfinished. The Prologue in verse of the comedy 'Les Facheux' of Molière is stated in the 'Menagiana' (vol. i. p. 90) to be by Pellisson. An edition of his select works has been published by Desessarts, Paris, 1805, 2 vols. 12mo.

(Bayle, *Dict. Historique; Biographie Universelle Classique;* Baillet, *Jugemens des Savans*, vol. ii.; *Menagiana*, vol. ii., p. 16, 89, 207, 331; vol. iii. p. 131.)

PENSTOCK, a kind of small sluice or floodgate, employed to retain or let go at pleasure the water of a mill or other pond. A cut of a simple form of penstock sluice is given under Irrigation, P. C., p. 42. See also Sluice, P. C., p. 142.

PENTZ, PENCZ, or PENS, GEORG, a celebrated German painter and engraver, was born at Nürnberg about 1500. He was first the pupil of Albrecht Dürer, and he afterwards studied the works of Raphael at Rome, probably after the death of Raphael, but before his school was dispersed in 1527. If however Pentz were born in 1510, as some accounts give, it must have been after the dispersion of the school of Raphael that he was in Rome. He died, according to Doppelmayr, in 1550, at Breslau.

Pentz was one of the most correct in design of the early German masters, perhaps the most correct. His prints are numerous, but his pictures are scarce; there are some at Nürnberg, and a few in the galleries of Berlin, Munich, and Schleissheim. Bartsch enumerates and describes 126 engravings by Pentz, of which the best are seven of the history of Tobias. He was the pupil of Marcantonio, and assisted him in some of his prints after Raphael.

(Sandrart, *Deutsche Academie*, &c.; Doppelmayr, *Historische Nachricht von den Nürnbergischen Künstlern*, &c. Bartsch, *Peintre-Graveur*.)

PEPPER-CORN RENT. [Rent, P. C.]

PERAMBULATION. A perambulation is a walking through or over ground for the purpose of settling boundaries. A perambulation of a forest is a walking over the boundaries of a forest by justices or others to fix and preserve its bounds. A perambulation of a parish is made by the minister, churchwardens, and parishioners once a year, in or about Ascension-week, for the purpose of preserving the boundaries. Usage will justify the parishioners in following the boundary over any man's land. Manors and lordships also are or may be perambulated: and there is a writ De Perambulation facienda, which ought to be sued with the assent of both parties when they are in doubt about the bounds of their lordships or manors. The writ is addressed to the sheriff, who is to execute it and make his return to the justices at Westminster on a certain day; or to the justices of assize, under his seal and the seals of those who make the perambulation with him. The king may direct the writ to other persons to make the perambulation, as well as to the sheriff. This perambulation made by assent binds the parties and their heirs. But unless both parties who assent to the perambulation are tenants in fee-simple, it seems that the perambulation shall not bind him who is in reversion.

Questions of boundaries are now generally determined by actions of trespass or ejectment.

It was an old Roman practice at the time of the Terminalia, in the month of February, to perambulate the boundaries of a district or community. The old original boundaries of the territory of Rome, which extended six miles from the city, were perambulated at the Terminalia; the boundaries between private properties were also perambulated at the Terminalia, and the usual religious offerings were made. This antient and simple mode of preserving boundaries probably fell into disuse as the land-surveyors became more skilful, and the records of boundaries were better kept. It is stated that the practice fell into disuse with the establishment of Christianity. But this is not probable. The religious ceremonies might be changed or dropped: but the fact of perambulations being still kept up in this country in the case of parishes, leads to the conjecture that the practice extended from Rome to other countries which the Romans occupied, and was retained in some form among the Christianized people in the provinces.

(Fitz-Herbert, *The New Natura Brevium*, p. 296; Rudorff, in the *Zeitschrift für Geschicht. Rechtswiss.* x. 436.)

PERCIER, CHARLES, an architect of celebrity, whose name is so intimately associated with that of his friend and professional colleague, Pierre François Louis Fontaine, that the reputation of the one is inseparable from that of the other, for both their buildings and their publications were the productions of their joint talent. Percier, whose father was a colonel of dragoons, was born at Paris, August 22, 1764; and had for his first instructor in art one Poirson, who was no more than a mere water-colour draftsman. In 1783 he entered the school of Peyre, and afterwards studied under the elder Gisors, another architect of considerable repute; and having obtained the prize for a project for a Jardin des Plantes, in 1786, he went to Rome, where he was at first quite overwhelmed and perplexed by the multiplicity of buildings and other objects of art that all at once solicited his study. It was at Rome that his friendship and connexion with Fontaine commenced, and there he also became acquainted with Flaxman, Canova, and other artists, who afterwards rose to eminence. During their residence in that city, Percier and Fontaine made the drawings which form the subjects of their first publication, viz. 'Palais, Maisons, et autres Édifices modernes, dessinés à Rome,' Paris, 1798, a folio with 100 plates, beautifully delineated and engraved in outline. In the interim, and for a while after their return, they had to contend with necessities and difficulties for a subsistence: the agitated state of public affairs was most unpropitious to their profession, more especially to beginners in it; they were therefore fain to provide for their actual subsistence by making designs for various articles of ornamental manufacture and furniture. The careful study and superior taste displayed by them, rescued them from the obscurity to which they seemed doomed, by bringing their talents in some degree before the public. Various decorations, executed by them at Malmaison for the First Consul and Madame Bonaparte, secured for them the powerful patronage of the Emperor Napoleon; and almost immediately after the commencement of his reign they were employed to restore, complete, and embellish the two palaces of the Tuileries and the Louvre, of which latter more especially the very extensive, numerous, and complicated works fully occupied them for a series of years extending to some time after the restoration of the Bourbons. This accounts for their having, with all their high reputation, been employed on so few buildings; and flattering and favourable as it was, it was not wholly without drawback, because they could not lay claim to those edifices as their own architectural creations, and their fame in them merged in the renown of their original authors. One distinct work of theirs is the arch (1806) in the Place du Carrousel, before the east front of the Tuileries; and such also are the ground staircase and other separate portions of the interior of the Louvre. The chief other monument by them is the Chapelle Expiatoire erected after the Restoration, in memory of Louis XVI. The line of houses called the Rue Rivoli adds nothing to their professional fame, it being no more than a handsome and regular piece of street architecture.

For the general celebrity attached to their names, Percier and his colleague are perhaps, after all, mainly indebted to their publications, and not least of all to that entitled 'Recueil de Decorations Interieures, contenant tout ce qui a rapport à l'Ameublement,' folio, Paris, 1812, a collection of designs for rooms and various articles of furniture in the ultra-classic style of embellishment that was affected in France at the beginning of the century, but which was so entirely matter of mere fashion, that Percier lived to see it pass away. Another publication brought out by them about the some time, was the 'Choix des plus belles Maisons de Plaisance de Rome et ses Environs,' a series not of strictly architectural studies, but pictorial views of Roman villas and their gardens. To these may be added two magnificent graphic works, one of them recording the ceremonies and pomps at Napoleon's coronation; the other, those which took place on his marriage with Marie Louise. Besides these, there is another work attributed to Percier, but which does not appear to have got into public circulation, 'Parallèle entre plusieurs Residences de Souverains de France, d'Allemagne, de Suède, do Russie, et d'Italie,' Paris, 1833, with thirty-eight plates.

Percier died September 5th, 1838.

PERCOIDEÆ (or *Percidæ*), a family of Acanthopterygious osseous fishes, of which the perch is the type. The *Percoideæ* have bodies covered with rough scales, ciliated at the margin. The edge of the opercle or preopercle is denticulated or spiny. The vomer, both jaws, and usually the palatine bones, are armed with teeth. *Perca*, *Trachinus*, and *Mullus* are British genera of this family. *Beryx* is an intertropical percoid genus, containing two or three species remarkable for bright-red colours, tinged with golden hues. *Holocentrum* is an allied genus, including very beautiful fishes, mostly tropical species. *Myripristis* differs from *Holocentrum* in the absence of opercular spines. *Trachichthys* is also a genus of this family.

PERIDI'NIUM, a genus of infusorial fossils, which occurs in flint. (Ehrenberg.)

PERIECHO'CRINUS, a genus of fossil Crinoid echinodermata, found in the Silurian strata. (Austin.)

PERI'ODUS, a fossil fish from Sheppey. (Agassiz.)

PERRY, JAMES, was born in Aberdeenshire on the 30th of October, 1756. He received the rudiments of his education at the rural parish school of Chapel of Garioch, studied Latin at the grammar-school of Aberdeen, and in the year 1771 was entered a student of Marischal College. He seems to have been destined for the profession of the law, and was for some time employed in the office of one of the attorneys, or, as they are by local usage termed, advocates, of Aberdeen. There are some local traditions of his having been found an inefficient clerk, and having stolen so much time from the unscientific details of the country practitioner's office, to be devoted to higher studies, that his master losing all patience dismissed him as incorrigible, and blighted all his prospects of becoming a prosperous country attorney. Perry was master of that ordinary Scottish education which fits its owner for many of the progressive and less-established departments of business or literature. He first proceeded to Edinburgh, where he in vain attempted to procure the means of livelihood. He went afterwards to Manchester, and was rather more fortunate, obtaining employment as clerk to a manufacturer. He had all along occupied his hours of involuntary leisure in cultivating his mind, and fitting himself for those higher walks of industry which he felt an innate capacity to occupy. He had shown intelligence and ability as a member of a debating society in Manchester, and went thence in 1771 with introductions to people of some influence in London. Among the friends who had made him general promises of assistance in procuring a situation was Mr. Urquhart the bookseller. Perry had in the mean time dropped some anonymous contributions into the letter-box of the 'General Advertiser,' which duly appeared in its columns. In one of his unsuccessful visits to Urquhart, that gentleman, who had been highly pleased with the last subject of his reading, pointed to an article in the Advertiser, and told Perry that if he could write *like that* he would at once procure an engagement. The delighted aspirant claimed the article as his own, and produced from his pocket the next contribution, which he was about to drop into the letter-box. He was immediately engaged as a stipendiary contributor, both to the 'General Advertiser' and the 'Evening Post.' During the trials of Keppel and Palliser, he surprised the London world by the rapidity and completeness of the reports of the proceedings. Becoming subsequently editor of the 'Gazetteer,' he systematised the method of rapid reporting, by establishing the employment of relays of reporters, which has made so marked a change in the nature of the daily press. He became afterwards joint proprietor and editor of the 'Morning Chronicle,' to which he communicated a decided Whig spirit, which it has ever since retained. From his marked position he was the first selected to be the victim of Sir Vicary Gibbs's attempt to crush the independent press. On the 24th February, 1810, his case came on for trial before Lord Elleuborough and a special jury, on an *ex officio* information for libel. The substance of the charge was a reprint in the Chronicle of a paper in the 'Examiner' descriptive of the blessings which might be anticipated from a new reign commencing with a change of system. This was interpreted as an insinuation that the existence of George III. was a barrier to improvement. Perry defended himself, maintaining his right to inculcate the necessity of improvement, and to look with hopeful anticipations towards any quarter whence it might come. He said that the doctrine maintained in the paragraph—the necessity of a change—had not been said in one solitary instance, but was the doctrine he had ever promulgated since he had risen to manhood. The jury pronounced a verdict of Not guilty, and the other official informations were dropped. Mr. Perry died at Brighton on the 6th December, 1821. He was the author of some pamphlets and poetical pieces, the reputation of which was temporary.

PERSPIRATION. [SKIN, P. C.]

PESNE or PENE, JEAN, a French painter and engraver, distinguished chiefly for his excellent prints after N. Poussin. He was born at Rouen in 1623, and died at Paris in 1700. The chief merit of his prints after Poussin is the preservation of the peculiar style of that painter: they are generally of a large size, and are valued by collectors. He engraved also many prints, chiefly landscapes, after Annibal Carracci.

(Watelet et Levesque, *Dictionnaire des Beaux Acts*; Huber, *Manuel des Amateurs*, &c.)

PETASITES. [TUSSILAGO, P. C.]

PETECHIAL FEVER. [PETECHIÆ, P. C.]

PETIT SERJEANTY. [SERJEANT, P. C.]

PETIVE'RIA (in honour of Mr. James Petiver of London) a genus of plants belonging to the natural order Petiveriaceæ. It has 6, 7, or 8 stamens; 4 permanent styles, at length becoming spiny and reflexed; the point is armed with spines at the apex. The species are West Indian herbs, and in pastures are troublesome weeds, giving an unpleasant flavour to the milk of cows which feed upon them.

P. alliacea, Guinea-hen Weed, is a small bush with a disagreeable odour. It bears an erect downy stem, not branched, and of a deep green colour. The leaves are oblong-obovate or oblong-lanceolate, acute and scabrous at the edge, glandular near the petiole, which is both glandular and downy; the stipules are small and spiny. The spikes are long, slender, and drooping at the upper end. The flowers are white, and placed close to the rachis, which is angular; the calyx 4-parted with linear spreading segments, which afterwards become erect, leafy, and cover the fruit. The juices of this plant are excessively acrid, and if a small portion of it be chewed it will render the tongue as dry, rough, and black as in cases of malignant fever.

The negroes consider it a sudorific, and say that fumigations or vapour-baths of it will restore motion to paralysed limbs. The roots are used in the West Indies as a cure for toothache; the negresses also employ it to procure abortion. The plant is rejected by most animals as food. Pintados alone seem fond of it; hence its common name *Guinea-hen weed*.

Martius says *P. tetandra*, another species, is employed in Brazil, under the name of *Raiy de Pipi*, in warm baths and lotions for defective contractility of the muscles or in paralysis of the limbs.

(Lindley's *Flora Medica;* Burnett's *Outlines of Botany.*)

PETROSELI'NUM (πετροσέλινον, which means 'rock parsley,' rock being the habitat of the species,) a genus of the plants belonging to the natural order Umbelliferae. It has an obsolete calyx; roundish entire incurved petals, scarcely emarginate, contracted into an inflexed lobe. Tho disk is short and somewhat annulate. The fruit ovate and contracted at the side. The species are smooth-hranched herbs. The leaves decompound, with wedge-shaped segments. The involucels many-leaved; the flowers are white or greenish, uniform; those of the disk often sterile. The stamens longer than the corolla.

P. sativum, common Parsley, is described under PARSLEY, P. C.

P. segetum, Corn Honewort, has pinnate lower leaves: nearly sessile leaflets, ovate and serrated, the upper leaves entire or trifid. The umbels are very irregular, the general involucre having from 1 to 2 leaves. The flowers are whitish, the stem erect, roundish, nearly leafless above from a foot and a half high. It is found on damp fields in a calcareous soil in Great Britain, France, and Switzerland. Goodyer has given an accurate account of this herb, and says that the origin of its name was from the fact of its having cured a swelling in the cheek called a hone.

The species are easily cultivated and can be raised only from seed.

(Don's *Gardener's Dictionary;* Babington's *Man. of Brit. Bot.;* Lindley's *Flora Medica;* Burnett's *Outlines of Botany.*)

PEUCE, a fossil Coniferous tree, of which the species occur in the oolitic strata. (Witham.)

PEUCE'DANUM (the πευκέδανον of Theophrastus and Dioscorides, from πεύκη a pine, on account of the resinous smell of the plant), a genus of plants belonging to the natural order Umbelliferæ and the tribe Peucedaneæ. It has a calyx of 5 teeth, obovate petals, contracted into an inflexed segment, emarginate or nearly entire. The fruit has a dilated thin flat margin, the carpels with equidistant ridges, 3 dorsal filaments, 2 lateral close to the base of the dilated margin obsolete. The interstices have single linear vittæ. The species are perennials, generally smooth. The leavea are pinnated, more or less compound. The flowers are white, yellow, or yellowish green.

P. officinale, Sulphur-wort, or Hog's-fennel, is a smooth herb 3 or 4 feet high, with a resinous juice and a strong sulphureous smell. The leaves are four or even five times ternate, with linear lanceolate acuminate flaccid segments. The involucre 3-leaved and deciduous; the pedicels much shorter than the fruit. The fruit of a pale brown colour, the vittæ of a deep chocolate; the primary ridges much depressed and paler. The commissure a light fawn-colour with two crimson vittæ very evident upon it. It is native in marshy and shady places throughout Europe and in Great Britain. The juice of the root of this plant is resinous and has a peculiarly strong smell. Many stimulating qualities have been attributed to it, and it is reputed anti-spasmodic and diuretic, but it seems to be rather a dangerous internal remedy.

P. oreoselinum has a taper striated stem. Triternate leaves with tho petioles hroken back, the leaflets remote, ovate, deeply pinnatifid and shining. The fruit is roundish oval. The flowers white with a tinge of blue. The leaves and stem are bitter and aromatic, as is the fruit in a higher degree. They were formerly used as stimulants, and are still esteemed in some countries.

P. montanum is a native of the north and middle of Europe, and has a tapering simple root with many long fibres. The stem is erect from 4 to 5 feet high, hollow, deeply furrowed, smooth branched, and corymbose at the top, and of a bright purple colour at the base. There are about 5 or 6 leaves on a stem, which are alternate, remote, and with hipinnate divisions; the leaflets are opposite, deeply pinnatifid, dark green and smooth; the petioles striated, smooth, with a reddish membranous margin. The flowers are white and numerous; the fruit a very light straw-colour, shining and obovate. The root is said to supply the place of ginger in Russia. The whole plant abounds in a white bitter fetid juice which soon hardens into a hrown acrid resin. It is a famous remedy in Courland in epilepsy.

P. palustre has 3-pinnate leaves pinnatifid with linear lanceolate acuminate segments, the general involucre of many persistent lanceolate deflexed leaves. The stem is furrowed and from 3 to 5 feet high. The flowers are white. It is found in Great Britain, but rarely. Any common garden soil will suit the species of Peucedanum, and they are easily raised from seed.

(Don's *Gardener's Dictionary;* Babington's *Man. of Brit Bot.;* Lindley's *Flora Medica;* Burnett's *Outlines of Botany;* Lindley's *Vegetable Kingdom.*)

PEVENSEY. [SUSSEX, P. C.]

PEZI'ZA. [HYMENOMYCETES, P. C. S.]

PHACOPS, a genus of Trilobites, found in the Silurian strata. (Emmerich.)

PHALÆNA, one of the three Linnæan genera of Lepidopterous insects. It corresponded to the division *Nocturna* in the arrangement of Latreille. It included the Night-moths. The *Phalænæ* are now distributed among many genera, all of which form part of the division *Heterocera* in M. Boisduval's arrangement of *Lepidoptera.*

PHALLUS. [GASTEROMYCETES, P. C. S.]

PHANEROTI'NUS, a genus of fossil Gasteropoda, from the mountain-limestone of England and Ireland. (Sowerby.)

PHANTASMAGO'RIA. [MAGIC LANTERN, P. C. S.]

PHARBI'TIS, a genus of plants belonging to the natural order Convolvulaceæ. It has 5 sepals, a campanulate funnel-shaped corolla, one style, a capitate granular stigma, a 3-celled rarely 4-celled ovary, and 2-seeded cells. The species of this genus are easily distinguished from others of the same order: they are mostly climbing American herbs, usually beset with retrograde hairs.

P. Nil has twining annual round hairy branches and stem stalked, 3-lobed, downy leaves, axillary peduncles from 2- to 3-flowered, the flowers large, of a beautiful light bright blue colour. The capsulo is much shorter than the calyx, smooth, 3-celled, with two seeds in each cell. The seeds are sold in apothecaries' shops of Calcutta under the name of 'Kala dana' and are said to act as a purgative and an effectual speedy cathartic. They are roasted like coffee, powdered, and administered in doses of from 30 to 40 grains. It is native of the tropics in every part, and in tho South Sea Islands.

There are about fifteen species of this genus, but the one described is the only one of use in medicine. They are however showy plants, and should be reared in a hotbed and then planted out in a warm sheltered situation. A light rich soil or a mixture of loam and decayed leaves suits them best.

(Don's *Gardener's Dictionary;* Lindley's *Flora Medica.*)

PHASCOCHŒRUS. [SUIDÆ, P. C.]

PHILLIPS, THOMAS, R.A., one of the most distinguished English portrait painters, was born at Dudley, in Warwickshire, October 18, 1770. He was placed very early with Mr. Edgington at Birmingham to learn to paint on glass; and he came to London in 1790 with a letter of introduction to West, who employed him at Windsor on the glass paintings in St. George's Chapel. In 1792 Phillips exhibited a view of Windsor Castle from the north-east; and in the following year he exhibited two historical pictures—the Death of Talbot, earl of Shrewsbury, at the Battle of Cassillon, and Ruth and her Mother-in-law. He exhibited likewise two pictures of similar classes in 1794—Cupid disarmed by Euphrosyne, and Elijah returning the recovered Child to the Widow. He seems in the year 1796 to have already turned his attention to portrait painting, for from that year he appears chiefly in the Exhibition notices as a portrait painter, though he occasionally painted some historical pieces. It is as a portrait painter however that he acquired his reputation, and as such he will be known; for nearly half a century he was a favourite exhibitor, and for a great portion of the timo the encouragement he met with was not limited to applause, as is often the case, but he was substantially patronised, and fully occupied, notwithstanding the rivalry of Hoppner, Owen, Jackson, Lawrence, and others of nearly equal reputation; few however of the nobility sat to him.

In 1804 he removed into No. 8, George-street, Hanover-square, where he remained until his death. In 1808 he was made a member of the Royal Academy, to which he presented a picture of Venus and Adonis as his diploma piece: there is a large picture of this subject hy him in Stafford House. In 1824 he succeeded Fuseli in the professorship of painting, an office which he held until 1832; and he delivered in all ten lectures, which he published together in one volume 8vo. in 1833, dedicated to the Earl of Egremont, under the title 'Lectures on the History and Principles of Painting:' the first four lectures are on the History of Painting; the fifth is on Invention; the sixth on Design; the seventh on Composition; the eighth on Colouring; the ninth on Chiaroscuro; and the tenth on the Application of the Principles of Painting. These lectures are clear and simple in their style, and instructive in substance and arrangement, especially in some of the author's expositions of his views of the principles of art. The author made a tour in Italy in company with Hilton, in 1824, after his appointment to the professorship, and before the delivery of any lectures, in order to be able to discharge the duties of his office more efficiently. He died April 20, 1845. He was one of the trustees of the Royal Academy. The following are some of Phillips' principal portraits:—A portrait of Lord Thurlow, painted in 1802; one of Napoleon, of the same year, but which was painted chiefly from memory, Napoleon did not sit to Phillips; the Prince of Wales, in 1806; Blake the painter, in 1807; Sir Joseph Banks as president of the Royal Society, in 1809; two of Lord Byron, in 1814, one in an Albanian dress; Hetman Count Platoff, the Cossack general, on his charger, in 1816, the horse was painted by J. Ward, R.A.; Sir F. Chantrey, in 1818; the poet Crabbe, for Mr. Murray, in 1819; Earl Grey and Lord Brougham, in 1820; the Duke of York, for the town-hall of Liverpool, in 1823; Major Denham, the African traveller, the best of his portraits according to Lawrence, in 1826; Lord Stowell, Sir E. Parry, and Sir J. Brunell, in 1827; Wilkie, in 1829; Mrs. Somerville and Sir Francis Burdett, in 1834; Mr. Justice Littledale and Lord Lyndhurst, in 1836; W. Currie, Esq., first mayor of Liverpool under the Municipal Reform Bill, painted for the town-hall of Liverpool, and Lord William Bentinck, in 1838; Rev. Dr. Arnold, and the late Earl of Egremont, a posthumous portrait, in 1839; the Duke of Sussex in the chair of the Royal Society, and Sir Nicholas C. Tindal, late Lord Chief Justice of the Common Pleas, in 1840; Dr. Shuttleworth, late Bishop of Chichester, and George Green, Esq., for the town-hall, Poplar, in 1842; and others in 1843 and 1844. He painted also portraits of Lord Byron and some other poets and writers for the late Mr. Murray, of Albemarle-street, comprising those of Sir Walter Scott, Camphell, Southey, Coleridge, Crabbe, and others. He painted very few pictures besides portraits after the establishment of his name as a portrait-painter. He exhibited a piece called Field Sports in 1832; Rebecca, in 1833; a Nymph Reposing, in 1837; and in 1839 a picture of Flora MacIvor having received the letter sent to her by her brother Fergus on the morning of his execution at Carlisle. His last picture of this class is said to be the Expulsion from Paradise, at Petworth. He was the author of several articles on painting in Rees's 'Cyclopædia.'

(*Athenæum*, 1845; *Catalogues of the Exhibitions of the Royal Academy;* and the Artist's *Lectures*.)

PHILLIPSIA, a genus of Trilobites, found in the mountain-limestone strata of England and Ireland. (Portlock.)

PHILOSOPHY OF THE HUMAN MIND. [METAPHYSICS, P. C.]

PHILOSOPHY, POSITIVE. The distinction of philosophy as positive and negative, is chiefly to be found in the German school. Thus Kant's 'Kritik der Reinen Vernunft,' his 'Prolegomena zu einer jeden Künftigen Metaphysik,' and his 'Kritik der Urtheilskraft,' are regarded as forming a sort of Prima Philosophia, preparatory to a positive or formal and detailed system of metaphysics. For though the philosophies which have successively arisen in Germany since Kant's day, such as the Scientific-doctrine of Fichte, the Transcendental Idealism of Schelling, the Phenomenology and Logic of Hegel, or the Metaphysic of Herbart, are all genealogically descended from Kant's Critical review (the review which reason was made by him to engage in, of the faculties of the soul), yet Kant himself, in his Kritik, did not profess to do more than pave the way for a system or dogmatik of speculative philosophy. Hence Rixner observes:—'Billig haben alle die sein Lehrgebäude nicht selbst für ächte Philosophie im positiven Sinne, sondern nur für Philosophie im negativen Sinne, d. h. für universalen Protestantismus gegen alle philosophische Anmassungen des seine eigne Grenzen misskennenden Verstandes erkannt und gehalten. Denn überall verfährt Kant nur kritisirend, nicht construirend' (*Geschichte der Philosoph.* Bd. iii. § 129). 'Those are right who have regarded Kant's doctrine not as genuine philosophy in the *positive* sense, but as philosophy in the *negative* sense—that is, as a universal protest against all the philosophical pretensions of an understanding which does not know its own limits. For Kant proceeds throughout, only in the way of criticism, not constructing a system.' We have quoted the words of Rixner to exemplify the use of the term *positive*, as distinguished from that of the term negative, in this school of philosophy. Kant's main question proposed for solution in the criticism of reason was, 'are metaphysics possible?' or, are synthetic judgments *à priori* possible?—judgments, or propositions, that is—the truth of which is not learned from experience, and which also are not merely analytical, or judgments in which the predicate barely unfolds the subject. Thus 'all body is extended,' is an analytical judgment: 'all men are mortal,' is synthetical indeed, but then it is *à posteriori*, being founded on experience: but, 'every change must have a cause,' is synthetical *à priori*, being universal and necessary, and founded in nothing but 'pure understanding and reason.' Now all such axioms, conceptions, and principles as are *à priori*, being enumerated, are regarded by those who make a distinction between positive and negative philosophy, as forming a negative philosophy, or as drawing the ground for a positive constructive system. Kant held out the expectation of such a system, as a superstructure to be erected by himself on the basis of the 'Kritik:' such a system of pure speculative reason I hope 'to furnish myself, under the title, Metaphysic of Nature; which shall have far richer matter than this Kritik, though the latter was necessary, first, to exhibit the sources and conditions of its possibility, and to cleanse and level a soil altogether overgrown with weeds' (*Kritik: Vorrede*). Such a system would have been, in the German phrase, a positive philosophy: but the Transcendental Criticism professes only to examine and secure the foundation on which, the author says, 'every future metaphysic' must be built, and is, relatively to such supposed system, merely negative.

PHLEBO'PTERIS, a genus of fossil Ferns, from the oolite of Yorkshire. (Brongniart.)

PHLIA'SIA was a small territory bounded by Sicyonia and Corinthia on the north and Arcadia on the west. The chief town, Phlius, is mentioned in Homer under the name of Aræthyrea. The old Phliasians were Argeii, but the population became Dorian in consequence of the invasion of the Heraclidae (Pausanias, ii. 12) and the settlement of some Dorians in the territory. This little state sent a contingent of 200 men to oppose the Persians at Thermopylae, B.C. 480, and in the following year it sent 1000 men to oppose them at Plataea. (Herod. vii. 202; ix. 28.) In the Peloponnesian war the Phliasians were on the side of the Spartans, as was natural, inasmuch as they were a Dorian state. Its position and comparative feebleness exposed it to hostile invasions from the Athenians, when they were leagued with Sparta, and from Sparta when a cause of quarrel arose with that more powerful state. When Phlius was reduced by Agesilaus, B.C. 379, it had above 5000 citizens. (Xenophon, *Hellen.* v. 3, 11.) At the time of the formation of the Achæan league, Phlius was under a tyrant, Cleonymus, who abdicated his power and induced the people to join the confederation.

Phlius is placed by Pausanias at the distance of 40 stadia from Titane, and he adds that the road to Phlius from Sicyon was straight. The site of the old town is supposed to be at Agios Giorgios (St. George), and there are said to be traces of several temples on the height above the river Asopus. Pausanias mentions two temples on the acropolis, a temple of Aesculapius on the right below the fort of the acropolis, and a theatre near it. Celeae, a small place, was four stadia from Phlius.

(Pausanias, ii. 12, &c.; Strabo, p. 382, ed. Casaubon; Cramer's *Greece*, iii. 288.)

PHLIUS. [PHLIASIA.]

PHOLIDO'PHORUS, a genus of fossil fishes, from the lias of England. (Agassiz.)

PHOSPHORESCENCE IN PLANTS AND ANIMALS. Organic bodies under certain circumstances become luminous, and upon the supposition that this appearance depends on the combustion of phosphorus at a low temperature, the phenomenon has been called phosphorescence. This luminosity is very constantly developed under the same circumstances in both animals and plants. It is observed both during the decomposition of the bodies of plants and animals as well as whilst they are still living. The oldest observations on this subject were made on the wood of trees whilst in a state of decay. This however takes place only under peculiar circumstances. It generally occurs when the wood of trees is buried in the earth whilst they are in a green state, and does not take place when wood is allowed to decompose in the usual way and in free contact with the air. It is also found that the phosphorescence does not take place when the wood is allowed to decompose in a damp place. Wood exhibiting this property will retain it for a long period when kept in a dry place. Albrecht observed luminosity in a tree during the night at a spot where one of its branches had been torn off. Decaying fungi have been often observed to emit this light. Travellers in tropical climates have observed that when plants containing a milky juice are wounded, the juice frequently becomes luminous, whilst it is descending the sides of the tree. The cause of this phenomenon in decaying plants is probably owing to a slow decomposition of the tissues attended with a union of oxygen gas, but what determines the development of light under these more than other circumstances is still unknown.

In living plants luminosity has been frequently observed. It is most constant amongst some forms of fungi, especially of the genus Rhizomorphæ. In the coal-mines in the vicinity of Dresden the species of Rhizomorphæ are so numerous as to 'dazzle the eye by the brilliant light they afford.' [BYSSACEÆ, P. C. S.] The light from decaying wood, as also from the living Rhizomorphæ, continues although they are immersed in irrespirable gases, linseed oil, phosphoric acid gas, oxygen, &c. The phenomenon in both the living and the dead plants is probably due to the same cause.

Another class of plants in which light has been observed is the Mosses. Several species of the genus Schistostega, which grow in caverns and other damp places, have been observed to give out light. Mr. Babington and other botanists have observed it in this country in the *S. pennata*; whilst Funk, Brandenburg, Nees von Esenbeck, Hornschuche, Struve, Unger, Bridel-Briderei and Agardh, have observed it on the continent of Europe. The two latter attributed this light to a small alga, which Bridel-Briderei called Catoptridium smaragdinum, and Agardh called Protococcus smaragdinus, which they supposed was parasitic on the moss. Unger however has examined the moss accurately, and finds that at certain seasons the utricles of this moss assume a globular form, and being partly transparent, the light is refracted and reflected in such a way as to present a luminosity on the surface of the vesicles.

Another class of these phenomena is that which is exhibited by the flowers of some plants. The first observation on this subject was recorded by Linnæus, and made by his daughter Christina Linnè. She was walking in the garden one hot summer's evening, when she observed the flowers of Tropæolum majus to give forth a stream of light. This was attributed by many to an optical illusion, but the fact has since been repeatedly observed on this as well as other plants. We are not perhaps in a position to say this was not an optical illusion; but if it was, one would expect that it should be more constant. It has also been seen by several observers at the same time in different positions, and when one has seen it, the others have seen it also. A correspondent of the 'Gardener's Chronicle,' October, 1843, says 'I have frequently observed the luminous appearance of garden plants, and have looked for it in each succeeding summer on the double marygold, and more especially on the Papaver pilosum, the hairy red poppy, in my garden at Worcestershire. In the evening after a hot dry day, the flashes of light have afforded much amusement to myself and others.' It is to this phenomenon that Coleridge alludes in the following lines:—

'Tis said on summer's evening hour
Flashes the golden-colour'd flower
A fair electric flame.

Decaying animal bodies frequently emit a luminous appearance, which has generally been attributed to the presence of phosphate of lime in their skeletons, which become decomposed and yield phosphorus when exposed to the action of organic compounds in a state of decomposition. It is to this cause that the luminosity of putrefying fish is attributed. Light has also been observed on the bodies of those dying of spontaneous combustion. [COMBUSTION, SPONTANEOUS, P. C. S.] But the emission of light is a very constant phenomenon of many of the invertebrate animals under peculiar circumstances. Thus during warm weather, when a vessel passes through the ocean, the waves frequently exhibit a diffused lustre with here and there streaks and stars of a brighter light. This occurs in our own climate, but the phosphorescence is much more brilliant in tropical seas. Poeppig, in his 'Reise in Chili, Peru, und auf dem Amazonstrome,' describes this phenomenon in an equatorial sea. 'Whilst one side of the vessel is still illuminated by the last fading rays of the evening sun and the opposite side darkened by the shade of the sails, the sea in this direction already becomes brilliant. One spot after another begins to be illuminated, indistinct stripes of light commence glimmering from greater depths, till at last, with the approach of night, a new creation seems to be called into existence. These illuminated beings move in various directions, sometimes appearing like sparks, sometimes like a radiating ball of fire, at others darting through the dark surface of the water like a rapid flash of lightning. A great number of these beings are undoubtedly true night animals which conceal themselves during daylight in the dark depths of the ocean.'

These lights in the sea are principally produced by various species of the family Acalephæ, or jelly-fishes. The light emitted by these animals seems to be due to the secretions on the surface of their bodies, for when this secretion is removed it retains for some hours its luminous character, and will even impart it to milk or water. But this property is not confined to the Acalephæ; many species of Polypifera, some of the Echinodermata, and the lower forms of Mollusca, also exhibit this appearance. Some few of the Crustacea and even fishes have been observed to possess the same property.

Amongst insects this phenomenon is not uncommon. Those which possess the greatest luminous power belong to the Coleoptera, the beetle tribe, and of these the two families represented by the fire-fly—the Elateridæ, and the glow-worm—the Lampyridæ, are the most distinguished. [ELATERIDÆ, P. C.; LAMPYRIDÆ, P. C.] Some of the species of the tribes of Myriapoda and Annelida give out light occasionally, as the centipede and the common earth-worm.

(Meyen, *Pflanzen-Physiologie*, Band ii.; Carpenter, *Animal Physiology*; Lankester, *Gardener's Chronicle*, 1843.)

PHOSPHORUS, BOLOGNIAN, is one of the most powerful of the solar phosphoric substances, and was the accidental discovery of Vincenzio Cascariolo, a shoemaker of Bologna, who about the year 1630, being engaged in some alchemical experiments, had occasion to calcine a quantity of native sulphate of barytes, found near Bologna, at Monte Paterno. He observed that whenever this mineral had been sufficiently heated, it acquired the property of shining in the dark after having been exposed to the sun's rays, and that it would even continue thus to emit light for some hours.

The best mode of preparing this phosphorus became a subject of no small pecuniary importance, and a family of the name of Zagoni appear to have been the most successful preparers of it; their process however is not exactly known; but if sulphate of barytes, obtained from any source, be powdered, made into cakes with gum tragacanth, and calcined carefully, they will be found to answer the purpose.

PHOTOGRAPHY. In the brief notice of this art given under PHOTOGENIC DRAWINGS, P. C., p. 113, very slight reference is made to any other processes than that of M. Daguerre, in which the images produced by the action of light in a camera-obscura are, by chemical agency, permanently impressed upon prepared metallic plates; although it is intimated that similar effects had been, though less perfectly, produced upon paper. Since the date of that article (1840), many curious facts have been discovered respecting the chemical action of light, and the various means of rendering the results of such action both permanent and visible to the eye in a pictorial form, although even yet the art of photography, or light-drawing, remains in an experimental state. We shall therefore merely notice a few general points, referring the more curious to the scientific journals of the last few years, and especially to the numerous papers published in the 'Athenæum' and the 'Art-Union,' for further information as to the processes employed, the discoveries made, and the theories proposed, by the numerous individuals, in this and other countries, whose ingenuity has been called into exercise by this new and curious art. One of these individuals, Mr. Robert Hunt, secretary to the Royal Cornwall Geological Society, published in 1844, in an octavo volume, a valuable contribution to the history of photography, under the title of 'Researches on Light,' professing to contain 'an examination of all the phenomena connected with the chemical and molecular changes produced by the influence of the solar rays; embracing all the known photographic processes, and new discoveries in the art.'

Though not absolutely the earliest as regards the date of its discovery, the Daguerréotype claims notice before any other branch of the art of photography, from the circumstance of its having been the first to attract general attention, and being also that which appears to have made the nearest approach to practical perfection. The peculiarities of Daguerréotype pictures being already described under PHOTOGENIC DRAWINGS, P. C., it is only necessary here to refer to some of the more important recent improvements, in consequence of which the practice of the art is steadily gaining ground, it being already extensively employed for the production of miniature-portraits, views of buildings, &c. A pretty full account, illustrated with engravings of the apparatus employed, of the Daguerréotype process, both as originally practised in this country under Daguerre's patent, and as modified by the subsequent patents of Mr. Richard Beard and M. A. J. F. Claudet (both of whom had purchased licences of M. Daguerre), is given in the 'Supplement' to Dr. Ure's 'Dictionary of Arts,' &c., art. 'Daguerrotype;' and in the fifty-fifth volume of the 'Transactions' of the Society of Arts (pp. 89-110), is a paper presented to the Society, in December, 1843, by M. Claudet, on 'The Progress and present State of the Daguerréotype Art,' in which much valuable information is conveyed. In addition to such improvements as could only be satisfactorily explained in connection with a minute account of the process, these sources of information show that much has been done in rendering Daguerréotype portraits more correct and more pleasing by the improved management of light, and by placing behind the sitters painted screens, to relieve the head, and to form artificial backgrounds. One of the greatest difficulties in the original process arose from the circumstance, that, as the image produced in the camera-obscura was totally invisible until brought out by a subsequent exposure to the vapour of mercury, it was impossible to tell precisely at what moment the action of the light should be stopped, to avoid, on the one hand, an image imperfectly developed, and, on the other, the misty, indefinite appearance occasioned by the unavoidable motion of the object to be copied (whenever it is an animate object), and the discoloured or burnt appearance of an image which has been exposed too long to the chemical action of light. This inconvenience is remedied by M. Claudet's method of applying the mercurial vapour in the camera-obscura simultaneously with the action of light, and providing means to enable the operator to watch the progressive development of the image. One important class of improvements has reference to the means of fixing and securing from injury by the subsequent action of light or other means, the Daguerréotype image. M. Claudet, in the paper above referred to, after alluding to some inventions for this purpose, observes, that 'it was left to Mr. Fizeau to discover what has proved one of the greatest improvements in the Daguerréotype process, and which consists in fixing the delicate image by means of a transparent coating of gold, applied by boiling upon the plate a solution of chloride of gold, which not only renders the image more durable, but has the advantage of increasing the tint, so that a picture fixed by Mr. Fizeau's process is rendered more forcible, and the mirror-like effect is almost destroyed. In the 'Athenæum' for 1843, pp. 92, 93, is an account of experiments, by M. Ulex, of Hamburg, to test the durability of Daguerréotype impressions, from which it would appear that they may be rendered insensible to the action of light, and of some more trying chemical agencies; and that even when rubbed away with leather and rotten-stone, they may be reproduced by the action of heat. On p. 292 of the same volume is an announcement of a method of Daguerréotyping in colours, by Professor Böttiger, of Frankfort-on-the-Main, by which, however, it is observed that 'as yet he has only succeeded in bringing out three colours, of which the flesh-colour is the most perfect.' In the absence, however, of any further and fuller account of this invention, we are led, from the results obtained by other experimentalists, to suspect that in this, as in the other cases about to be mentioned, the colouring was not simply the result of the action of variously coloured rays. In the ordinary coloured Daguerréotypes, some of which make a tolerably near approach to the effect which might be expected if colours could be fixed in the camera-obscura, the tinting is produced by the application of finely-powdered colours to the surface of the photographic impression, which is previously coated with an alcoholic solution of copal, and nearly dried; so that the colouring, which is so delicately performed as not to impair the distinctness of the impression, is not in any degree the result of the action of light. Since this mode of colouring photographic drawings has been in use, a new and ingenious process has been invented by C. G. Page, professor of chemistry in Columbia College, U. S., for producing a similar effect by forming coloured oxides of copper upon the surface of the Daguerréotype plates, in lieu of the deposit of gold invented by Fizeau. An account of this process, reprinted from 'Silliman's Journal,' appeared in the 'Athenæum' for 1845, p. 277. Mr. Fizeau, the inventor of the mode of fixing Daguerréotypes by a golden deposit, has also devised a process, of which an account was presented by Mr. Goadby to tho British Association in 1846, for *etching* or biting in the photographic impression by the aid of an acid menstruum; by which means the Daguerréotype is converted into a perfect, though very faintly-engraved, plate, capable of yielding impressions. Though too delicate for use under ordinary circumstances, such plates may be finished by an engraver, and it is anticipated that the process may be advantageously applied to minute anatomical illustrations, and similar purposes in which the utmost fidelity and delicacy are required. M. Claudet, in the paper above quoted, mentions the names of M. Donné, of Paris, Dr. Berrès, of Vienna, and Professor Grove, in England, as having, concurrently with Mr. Fizeau, attempted to accomplish this object. Before turning to other branches of the art of photography we may quote from the conclusion of M. Claudet's paper the remark that, notwithstanding the very recent origin of the Daguerréotype, it already ranks as one of the most prominent inventions of the present day, leaving scarcely anything to look for in the way of improvement. 'It is true,' he adds, 'that it remains to find the means of reproducing the natural colours of objects; but, although there seems no dream too marvellous in the progress of discovery, still the idea of fixing the colours of the object in the camera-obscura is so little in accordance with the present state of science, and with the properties of the known elements, that we must be satisfied with the process as it is.'

The process invented by Mr. H. Fox Talbot, and known most commonly by the name of *Calotype*, but recently called, in commemoration of its inventor, *Talbotype*, is a photographic process widely different from that of M. Daguerre, and one which, though not brought to so great perfection as regards the representation of minute details, claims some important advantages in point of cheapness and convenience. Mr. Talbot's experiments were suggested by an unsatisfactory attempt to use the camera-lucida for the purpose of sketching, in October, 1833; but although his photographic researches date from that time, his invention of the Calotype process was not completed until September, 1840, since which time some minor improvements have been made. Both the original invention and its subsequent modifications are secured by patent. In a description of the process communicated shortly after its invention to the Royal Society, and published in the 'Athenæum' for 1841, pp. 540, 541, Mr. Talbot gives directions, from which the following are abridged, for the preparation of the photographic paper which, in this branch of photography, is used instead of the silvered plate, of M. Daguerre.

The paper, which should be of the best kind of writing paper, smooth, of a close and even texture, and without water-marks, is in the first instance to be washed on one side with a solution of 100 grains of crystallized nitrate of silver in six ounces of distilled water; the solution being applied with a soft brush, and the surface either dried cautiously at a distant fire, or spontaneously in a dark room. In performing this operation the prepared side should be marked, as the paper is not visibly changed by it. When dry, or nearly so, it is dipped in a solution consisting of 500 grains of iodide of potassium dissolved in a pint of water, and left in that solution for two or three minutes, after which it is dipped into pure water, partially dried with blotting-paper, and then finished drying either spontaneously or by a fire, which will not now injure it. These processes, which it is best to perform by candle-light, produce what Mr. Talbot calls *iodized paper*, which is coated with a pale yellow iodide of silver. Though not very sensitive to light, it should be kept shut up in a portfolio or drawer until wanted for use; and if so protected from the light, it may be kept for any length of time. When required for use, but not until then, the iodized paper is to be washed with a solution which the inventor calls gallo-nitrate of silver, which is thus prepared:—In one vessel dissolve 100 grains of crystallized nitrate of silver in two ounces of distilled water, and add to the solution one-sixth of its volume of strong acetic acid. In another vessel make a saturated solution of crystallized gallic acid (of which very little will dissolve) in cold distilled water. Keep these two solutions separate, but mix them in equal volumes as required, and wash the prepared or marked side of the paper with the mixture, applied with a soft brush, observing that the operation must be performed by candle-light. After a pause of half a minute the paper should be dipped into pure water, then blotted dry, and finally dried at a considerable distance from a fire. It is then ready for use, and if kept in a press, secluded from light, it will sometimes remain good for three months; but as this is not to be depended upon, Mr. Talbot recommends the final preparation of the paper only a few hours before using it. It is so sensitive, that a momentary exposure to light, even on a clouded winter day, is sufficient to produce an impression; but the impression so produced is latent and invisible. In this state the paper is subjected to the action of light in a camera-obscura, after which the image is brought out by washing it again with the gallo-nitrate of silver, and warming it before a fire. In some cases, however, a strong impression will become visible in a minute or two after applying the gallo-nitrate of silver, without the aid of heat. The image thus brought out is subsequently fixed or rendered permanent by washing with water, lightly drying with blotting-paper, and then washing with a solution of bromide of potassium containing 100 grains to eight or ten ounces of water. A minute or two after the application of this solution the paper is again dipped in water, and finally dried. The picture thus produced is what is termed a *negative* one, in which all the light parts of tho object represented are shown of a dark colour, and *vice versâ*, and the representation is also the reverse of the original in position. It is, however, according to Mr. Talbot's second patent, rendered transparent by the application of wax, and by laying it face downwards upon another sheet of photographic paper, and exposing both to the light, a copy is produced in which the objects are brought into their true position, and the right effect of light and shade is obtained; the copy, or secondary impression thus produced, having very much the appearance of a sepia drawing. By this arrangement one original negative Calotype may be employed to produce a great number of secondary positive copies; and although it sometimes grows faint after frequent repetition of the process, its strength may be renewed by washing by candle-light with gallo-nitrate of silver, and subsequent warming. The positive Calotypes, it should be observed, may be taken upon paper prepared as above described for the negative or original impressions; but Mr. Talbot prefers using for them a paper prepared by washing first with a weak solution of common salt, and then with a solution of nitrate of silver; as such paper, though requiring more time for the perfect action of the light, affords an image with tints more harmonious and pleasing to the eye than the more sensitive paper above described. In obtaining the secondary impressions the original and the sheet of photographic paper are laid upon a board and covered with a piece of glass, which is pressed down to keep them in close contact with each other. The images are subsequently fixed in the same way as the original. The sharpness and delicacy of Calotype, or Talbotype, pictures is somewhat impaired by the mode of production; so faithful is the action of the light that even the texture of the paper on which the negative picture is taken is imitated in the positive Calotype, by which circumstance a certain objectionable woolliness of texture is given. Notwithstanding these defects, which will doubtless be greatly reduced, if not entirely dono away with, some very pleasing representations of buildings and other objects have been produced by the Talbotype process, many of which are published by Mr. Talbot in a work appropriately called 'The Pencil of Nature,' the illustrations of which are not prints, but actual photographic or sun pictures. By this process, also, a perfect fac-simile of the recent Chinese treaty has been obtained, which copy is deposited among the State Papers.

The Daguerréotype and Talbotype processes, though they may be regarded as the types of two great branches of the photographic art, are but two out of many processes which have been devised for producing pictures or images by the agency of light. On this point we cannot do better than quote the following observations from the 'Athenæum' for 1845, p. 203, premising that in the pages of that journal may be found pretty full details respecting all the processes referred to, and of some others also. 'It is a startling fact,' observes the writer of the article quoted, 'that all substances, from the delicately sensitive film which is formed on the silver plate in the Daguerréotype process, to all the salts of the metals, and even to the metals themselves, or plates of glass or stone, have been found capable of receiving light-impressed pictures. A shadow cannot fall upon any solid body without leaving evidence behind it, in the disturbed and undisturbed condition of its molecular arrangement in the parts in light and shade.' 'It is evident, then,' he proceeds, 'that all bodies are capable of photographic disturbance, and might be used for the production of pictures, did we know of easy methods by which the pictures might be developed; and we are not without hope that these means may be discovered. It must be remembered that in all the best photographic processes, the images are invisible at first. In the Calotype they are developed by the agency of gallic acid. In the Daguerréotype, the picture is brought out by mercurial vapour. In the Chromatype, nitrate of silver is the active material for the same purpose; and it may be used to bring out pictures formed on paper with any of the salts of copper. In the Chrysotype, a beautiful process discovered by Sir John Herschel, a dormant picture is brought into view as a powerful negative one, by washing tho paper with chloride of gold. In the Cyanotype, the same phenomenon is seen under the influence of the ferro-prussiate of potash. The Amphitype, and some other processes, the result of the researches of the same investigator, Sir J. Herschel, are of a remarkable character – the pictures remaining dormant as long as the paper is kept dry, whilst the simple process of breathing over it discloses the hidden picture with wonderful intensity. Lastly, the Energiatype, or, as the discoverer now names the process, the Ferrotype, enables us to keep the pictures invisible on the paper for any length of time, yet bring them out in full force in an instant, by washing with a solution of an iron salt. These are but a few of the curious phenomena which have resulted from the discoveries of Niepce, Daguerre, and Talbot. Arago said, with prophetic truth, when speaking on the subject of Daguerre's pension, 'In this instance, it is upon the unforeseen that we are especially to reckon.'

That we are as yet only beginning to understand this curious and important subject is evident from the uncertainty which yet prevails as to the precise nature of the agency by which photographic impressions are produced. Several phenomena have been observed which lead to the supposition that the remarkable chemical changes by which such impressions are produced are not due to the simple action of light itself, but of 'some power associated with it, which,' according to the writer from whom we have just quoted, 'does not affect the eye or produce colour.' 'It would appear,' he adds, 'from experiments described by Mr. Hunt, that we can separate, to a certain extent, these influences one from the other by coloured media.' 'We are therefore,' he subsequently observes, 'led to inquire, Is this a new element, distinct from light, heat, and electricity, or is it a modification of one of these?' Further researches only can settle this point. Sir John Herschel proposed the epithet of *Actino-Chemistry* for this new branch of physico-chemical science, and it has been suggested that *Actinism* would be an appropriate term to distinguish this chemical power from the light and heat with which it is associated. As having some connection with this subject we may refer to the circumstance mentioned by M. Claudet in his paper already referred to, that the operation of the Daguerréotype has been found to be much slower, with the same brilliancy of light, in an alpine region than elsewhere; and to the evidently different effects produced in the Talbotype process by different coloured rays, a circumstance which renders the foliage of some landscapes thus produced very defective. In a review of 'The Pencil of Nature,' in the 'Athenæum' for 1845, p. 593, it is observed that perhaps this defect might be remedied by some alteration in the paper, and we are informed that paper prepared with bromide of silver, if exposed to the prismatic spectrum, will be found to be equally sensitive to all the rays. In this paper is an important correction of an erroneous notion which appears to have been commonly received, that the light of the moon would not act photographically, it being supposed that the chemical principle, or *actinism*, of the rays of solar light was absorbed by the moon's surface. In answer to this we are informed that photographic impressions have been obtained by moon-light both upon Daguerréotype plates and upon paper; thereby showing that the moon's beams are of the same character as, though of less intensity than, the rays received direct from the sun. Both kinds of photography have also been performed by the artificial light emitted from lime ignited by the oxyhydrogen flame.

Of an art so new it would be premature to attempt to enumerate the advantages. Among the more obvious may be mentioned the procuring of accurate representations of the most complicated scenery, to be used in aid of an artist's memoranda for the production of landscapes, architectural representations, and even, under certain circumstances, pictures of great historical interest. On one such occasion, at least, the Daguerréotype has been employed to depict an illustrious assemblage at the opening of a continental railway; a momentary quiescence being produced, by signal, for the purpose. For producing faithful transcripts, upon a reduced scale, of works of art, and for obtaining accurate representations of machinery, for the use of the engraver, it may be rendered available; and it will doubtless be extensively employed as a means of transferring to pattern-books indisputable representations of various articles of manufacture. Still, as Arago well observed, 'it is upon the unforeseen that we are especially to reckon' in forming an estimate of the future value of photography as a handmaid to art and science.

PHY'LLODOCE, a genus of plants belonging to the natural order Ericaceae. It has a 5-parted calyx, an ovate corolla with a contracted 5-toothed mouth, 10 stamens enclosed, slender glabrous filaments longer than the anthers, short truncate cells opening by pores at the apex. The seeds are compressed and shining. The species are small evergreen shrubs, natives of the north of Europe, Asia, and North America.

P. coerulea has linear leaves with denticulated margins, glandular hairy peduncles; calycine lanceolate-acute segments; anthers three times shorter than the glabrous filaments. The stem is from 4 to 5 inches high, determinately branched, naked below, densely hairy above. The flower is large, pale bluish red; the peduncles terminal, aggregate, and simple. The plant is native of Perthshire and the north of England. There are three other species of *Phyllodoce*, which are natives of North America. They thrive only in a peat soil, and are propagated by layers. They are a genus of elegant, small, heathlike plants.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

PHY'LLODUS, a genus of fossil fishes from Sheppey. (Agassiz.)

PHY'SALIS (from φῦσα, a bladder, in reference to the inflated calyx), a genus of plants belonging to the natural order Solanaceae. It has a 5-toothed calyx, a campanulate rotate 5-lobed corolla, converging anthers opening longitudinally, a capitate stigma, smooth 2-celled berry, covered with the angular membranous inflated calyx. The species are annual or perennial herbs, rarely shrubs.

P. somnifera has several shrubby branched stems, round and downy. The leaves are in lateral pairs, short stalked, ovate, downy, and from 2 to 4 inches long. The flowers are axillary, subsessile, small, crowded, and of a greenish yellow or white. The berry is red and smooth, and about the size of a pea. This plant is the στρύχνος ὑπνωτικός of Theophrastus, *Hist. Plant.*, 9, 12; and the στρύχνον ἁλικάκαβον of Dioscorides, 4, 72. It is a native of rocky places in the south of Europe and the East Indies. It is reputed to be narcotic, diuretic, and alexipharmic. The leaves steeped in oil are in India applied to inflammatory tumours, and they are used in a similar way in Egypt. Kunth recognised this plant in Egyptian mummies.

P. Alkekengi, the Winter Cherry, is an herbaceous downy plant, with a perennial creeping root; ovate deltoid leaves; spotless flowers, ovate coloured calyx, and subulate segments. It is a native of Europe on exposed hills, and of Japan. The corolla is a dirty white; the calyx reddish yellow, enclosing a red berry. The fruit of this plant was well known to the antients, and is described by Dioscorides. In this country, however, the fruit is seldom eaten, and the plant is cultivated chiefly on account of its appearance. In Arabia and Armenia, Spain and Germany, however, the berries frequently supply the place of other eatable fruits. They have a subacrid and not unpleasant flavour, but the persistent calyx with which they are invested is very bitter. Ray speaks of these berries as a preventive of gout, and others have extolled them as diuretics, and recommended them in the treatment of dropsy.

P. pubescens, Downy Winter Cherry, is a native of North America and the East Indies. The whole plant is densely clothed with down. The corolla is yellow, marked with five roundish brownish violet spots at the throat. The berries are yellowish when ripe; they are called gooseberries, and are used as a substitute for them in many parts, and when preserved with sugar make an excellent sweetmeat. It is the *Camara* of Brazil. All the species of Physalis thrive best in a light rich soil, and are easily propagated by seed, and cuttings will take root under a hand-glass.

PHYSONE'MUS, a genus of fossil fishes from the mountain-limestone of Ireland. (Agassiz.)

PHYSOSPERMUM (from φῦσα, a bladder, and σπέρμα, a seed, in reference to the tegument not adhering to the seed when young), a genus of plants belonging to the natural order Umbelliferæ. It has a 5-toothed calyx, obovate petals, with an inflexed point; the fruit laterally compressed; the carpels reniform, globose, didymous, with five filiform slender equal ridges, the lateral within the margin. The interstices with single vitæ. The species are perennial herbs, the flowers white.

P. Cornubiense has triternate radical leaves, wedge-shaped leaflets deeply toothed, the stem-leaves ternate, lanceolate, and entire; the stem from one to three feet high, erect, round, striated, minutely scabrous, bearing a few small ternate leaves with linear lanceolate segments; the umbels are terminal; the carpels longer than broad; the coat loose. It is native only of Cornwall, in bushes and hedges; in great plenty in the neighbourhood of Bodmin. Cattle are so fond of this plant that they will eat it down to the ground. The root contains a yellow resinous juice. There are but few species of this genus. Any common soil will suit them, and they may be divided at the root or raised from seed.

(Don's *Gardener's Dictionary*; Babington's *Manual of British Botany*.)

PHYTE'LEPHAS. [Vegetable Ivory, P. C.]

PHYTEUMA (a name adopted by Dioscorides), a genus of plants belonging to the natural order Campanulaceae; it has a 5-parted calyx, a rotate corolla with 5 long linear segments; free anthers, and filaments dilated at the base.

P. orbiculare, Round-headed Rampion, has the heads of its flowers globose, those of the fruit oblong, the leaves crenate-serrate, the lower ones cordate-ovate, stalked, the upper ones linear, lanceolate, sessile. It is native of the mountains of Europe and of England in chalky soil. The flowers are of a deep blue colour.

P. spicatum, Spiked Rampion, is distinguished by having the heads of its flowers oblong, those of the fruit elongated, cylindrical; the lower leaves cordate-ovate, the upper ones linear lanceolate, sessile; the flowers are white, cream-coloured, or blue. It is native of the temperate parts of Europe, and in Sussex, in England. All the species are hardy and well fitted for garden borders or rockwork. They will grow in any common garden soil, and may be divided or raised from seed. *Campanula Rapunculus* is likewise known as the *Rampion*. [Rampion, P. C.]

(Don's *Gardener's Dictionary*; Babington's *Manual of British Botany*.)

PIAZZE'TTA, GIOVA'NNI BATTISTA, one of the most celebrated of the later Venetian painters, was born at Venice in 1682 or 1683, and was first instructed in design by his father, Jacopo Piazzetta, a carver in wood. He was taught painting by Molinari, but he acquired his style in Bologna from the works of Spagnoletto and Guercino. Piazzetta is one of the *Naturalist* school of painting, and he is one of the darkest of those who are sometimes called *Tenebrosi*: they generally painted on dark grounds. He died at Venice in 1754.

Piazzetta's pictures are doubtless much darkened through time: they are distinguished by their strong contrasts of light and shade. His masterpiece is considered the Beheading of John the Baptist, at Padua. He excelled in caricature. Many of his works have been engraved.

(Zanetti, *Della Pittura Veneziana*, &c.; Lanzi, *Storia Pittorica*, &c.)

PICART, ETIENNE (called Le Romain, the Roman), a celebrated French engraver, was born at Paris in 1631, and died at Amsterdam in 1721. His prints, chiefly portraits and history, are very numerous: they are firmly executed, but want harmony. He worked with the graver and the etching-needle, much in the style of Poilly. He is supposed to have been called Le Romain from his long sojourn in Rome, or he assumed the name that he might not be confounded with another engraver of the name of Picart. He was engraver to the king, and a member of the French Academy of Painting, &c.

Bernard Picart, the son of Etienne Picart, born at Paris in 1663, was a designer and also a distinguished engraver, and superior to his father. He was the pupil of Le Clerc; his best works are those executed in France; in Amsterdam, to which place he accompanied his father in 1710, he worked exclusively for the booksellers, and became mannered, metallic, and merely ornamental. A great many of his prints are from his own designs, in which he imitated the style of composition of Antoine Coypel. He had a facility in imitating the styles of other earlier engravers, and he published many prints of this class which are said to have deceived collectors; Picart used to call them *Impostures innocentes*, and they were published under this title, to the number of 78, with a list of his works, at Amsterdam, in 1738, after his death. His prints altogether amount to about 1300; and one of the best of them is a Slaughter of the Innocents, after a design of his own: there are various impressions of it. Darius opening the Tomb of Nitocris, after Le Sueur, is also one of his best prints; it is much in the style of Girard Andran. He died at Amsterdam in 1733.

(Watelet et Levesque, *Dictionnaire des Arts*, &c.; Huber, *Manuel des Amateurs*, &c.)

PICO is one of the Azores, or Western Islands, so called from the remarkable volcano which it contains, and which is called 'the Peak' (Pico). This island lies between 28° 3′ and 28° 42′ W. long., and between 38° 15 and 38° 33′ N. lat. It extends from west-north-west to east-south-east about forty-five miles, and is about eight wide towards its western extremity, where it is widest, whence it gradually grows narrower as it proceeds farther east, until it terminates in a forked rock hardly a mile in width. The average width is about five miles. This gives an area of 225 square miles; which is about equal to the Isle of Man.

The coast-line is bordered by rugged rocks, which form no port nor allow an anchorage; at Lagens, on the south coast, is a small cove, in which small craft find shelter. The western districts present the most rocky surface. The country rises from the shores towards the peak, which occupies the centre of this part of the island, and is more than 8000 feet above the sea. The soil is composed of lava, which in many places is entirely naked, and in others covered with a thin layer of earth, formed by the decomposition of volcanic matter. The country round the volcano and even the lower parts of its sides are richly cultivated, principally with vineyards; there are also gardens and orange-groves wherever there is any soil. From the cultivated grounds to within a third of the distance from the summit, it is thickly covered with splendid cedars, the myrica faya, the white yew, immense junipers, myrtles, and tree-ferns, beyond which point vegetation begins to decline, and on approaching the top of the peak nothing is seen but moss and lichens. From the eastern base of the volcano a high ground runs eastward to Cape Calhagrossa, the eastern extremity of the island. It occupies the middle of the island, and descends with a very broken surface towards the northern and southern shores. Though this part of the island also consists of lava-rocks, it contains a much larger portion of cultivable land, but is not so well cultivated as the country round the volcano. The southern declivities are much better cultivated than those which slope towards the northern shores, which are less covered with soil.

The chief article of produce is wine. Until lately there were annually exported nearly 25,000 casks. It is considered better than any kind grown in the Azores, and goes by the name of Fayal wine, because it is brought to foreign countries from Horta, the capital of the island of Fayal. Great quantities of fruit are also sent to Fayal. Grain and pulse are grown sufficient for the consumption of the population; the onions of Pico are much valued, and large quantities of them are disposed of to the Americans and other traders who frequent Fayal. Among the forest-trees, the cedar and white yew are greatly prized for furniture, nearly as much as mahogany. Pasture-grounds abound on the higher part of the ridge, where a large number of sheep are bred for the wool, which is worked by the natives into clothing for home consumption; goats are still more numerous. Cattle abound, and are of a fine breed. In many places orchilla is collected.

The climate is mild, neither the cold of the winter nor the heat of the summer being intense, but it is very irregular. No decidedly settled weather can be calculated on except between the summer solstice and the autumnal equinox. Showers of rain are frequent throughout the year, and in the winter so violent as to cause constant changes in the face of the country, washing away enormous masses of pumice from the mountains, throwing down projections of soft volcanic materials, and leaving the surface of the rocks and heights in many places destitute of soil. This island, like the other Azores, is subject to incessant gales, which render the approach to it dangerous to vessels. Earthquakes are frequent, and four eruptions of the volcano are on record. Three of them occurred in the sixteenth century, and the last in 1718, which burst from the western side of the peak and overwhelmed a large portion of the best vineyards.

The population, which is stated at 30,000, consists of the descendants of the Portuguese who settled in the Azores in the fifteenth century. They are an industrious race, and are settled on the shores of the island, where they live in neat white cottages, with bright, cane-reed thatched, conical roofs.

The capital is Lagens, a small place built round a small cove. In the strait which divides Pico from Fayal, but at a short distance from Pico, are two immense masses of red volcanic rock, called the Isles of Magdelena, and between them and Pico is an anchorage in six to eight fathoms. Opposite to them is the town of Magdelena Criaçaovelha, whence the produce of Pico (wine, brandy, fruits) is shipped to Fayal, and where the rich inhabitants of Horta have villas.

It is not ascertained when Pico was first settled, but probably many years after 1466, when Fayal was occupied by a colony of Flemings, who were soon afterwards followed by the Portuguese. It was not till the best portion of this island had been settled, that the inhabitants passed over to Pico, which is so difficult of access. It has always remained in the hands of the Portuguese.

(Ashe's *History of the Azores*; Boid's *Description of the Azores*; Von Buch's *Physikalische Beschreibung der Canarischen Inseln*.)

PICRIS, a genus of plants belonging to the natural order Compositae, and the suborder Cichoraceae. It has an involucre of one row of equal scales, with unequal linear, often spreading, scales at the base; the receptacle is dotted; the fruit terete, transversely striated, constricted, or slightly beaked above; the pappus in two rows, feathery, external row subpilose. *P. hieracioides*, the only British species, has rough leaves, with forked and hooked bristles, lanceolate leaves, dentate or sinuated, the upper leaves somewhat clasping, the head solitary, terminating the stem and branches, the outer involucral scales lax, oblong, bristly on the keel, glabrous on the margin. The fruit constricted just below the pappus. The flowers are a bright yellow colour. This species is found on dry banks in Great Britain.

(Babington's *Manual of British Botany*.)

PIERMARI'NI, GIUSEPPE, an architect who occupies a foremost place among those of Italy during the latter half of the eighteenth and at the beginning of the present century, was born at Foligno, July 18th, 1734. His father (Pietro) was a merchant, and intended that Giuseppe should apply himself also to business, where he had only to pursue the course opened and prepared for him, in order to prosper. Nor does he seem to have at all rebelled against paternal wishes, except that his bent of mind led him to give his attention more willingly to mechanics and scientific pursuits. Having constructed for himself a geographical globe, 20 Roman palms (about 14½ English feet) in diameter, it attracted many visitors, and among others the celebrated mathematician Boscovich, who recommended, or rather, enjoined his father to send him to Rome to pursue his studies systematically under proper instructors.

He was nearly twenty years of age when he went to Rome, and, eager to make up for lost time, he applied himself with ardour to mathematics and architecture, which last he studied first under Poggi, and next under Vanvitelli [VANVITELLI, P. C.], who conceived a particular regard for him. The master was sincerely desirous of bringing his pupil forward, and afforded him every opportunity of gaining practical instruction, the means for which were abundantly supplied by Vanvitelli's numerous engagements. On Vanvitelli's going to Naples to erect the palace of Caserta, he took Piermarini with him as his principal assistant in that extensive work. Again, when Vanvitelli was afterwards invited to Milan, by the Austrian government, for the purpose of altering and embellishing the palace there, or that now called the Palazzo Imperiale, for the Archduke Ferdinand, Piermarini accompanied him; and for Piermarini this proved a singularly important event. Meeting with obstacles and having other engagements that demanded his attention, Vanvitelli contented himself with making some general designs and explaining his ideas, and recommended his pupil as fully competent to supply his place. The work was accordingly transferred to Piermarini (1769), who thus unexpectedly found himself established at Milan, the city destined to become the chief theatre of his professional labours, with the title of architect to the archduke, and inspector-general of buildings. Afterwards on the Academy of Fine Arts at the Brera being established, he was appointed to the professorship of architecture. For thirty years Piermarini was constantly employed at Milan, which is indebted to him not only for most of the principal structures erected at that period, but also for the more correct taste which he introduced both by his example and his precepts. Had he executed nothing of any note besides the theatre *Della Scala* [THEATRE, (Table), P. C., vol. xxiv. p. 298], that edifice alone would have secured his professional fame; but he erected, or else altered and improved, so many buildings as greatly to enhance the architectural character of the city. Among the private palaces or mansions by him are the palazzi Greppi, Moriggia, Lasnedi, Sannazari, Litta, Cusani, and the magnificent and extensive façado of the Palazzo Belgiöioso; also one of the fronts of the archbishop's palace. Among his public buildings are the Monte di Pietà, the Monte Napoleone, the Luoghi Pii, the Teatro della Canobbiana, and the Porta Orientale, his designs for which were adopted in preference to Cagnola's. [CAGNOLA, P. C. S.] He likewise conducted many general public improvements, such as several new streets, the Piazza del Tagliamento, and almost the whole of the new quarter called the Contrada di S. Redegonda; to which may be added the Public Gardens and their buildings. Nor were his labours confined to Milan itself, for he was the architect of the elegant imperial villa at Monza; also of the Villa d'Adda in Casano, and of the Villa Cusani at Desio, at which last place he improved and completed the church.

Some years before his death, political changes and the state of public affairs induced him to withdraw altogether from Milan, and retire to his native town Foligno, where he occupied himself with his favourite studies, and formed a valuable collection of books, especially rich in works upon art. There he died, February 18th, 1808. The Academy of the Brera, at Milan, honoured his memory with a monument in the portico of their building.

(P. E. Visconti, in Tipaldo, *Biografia*, &c.)

PIG. [HOG, P. C.; SUIDÆ, P. C.]

PIG-NUT. [BUNIUM, P. C. S.]

PIGALLE, JEAN BAPTISTE, a celebrated French sculptor, was the son of a carpenter, and was born at Paris in 1714. He was the pupil of Robert le Lorrain and the elder Lemoyne, and studied three years in Rome. On his return to Paris he attracted great notice and obtained a permanent reputation for a statue of Mercury. The king (Louis XV.) purchased the statue, and the Royal Academy of Painting and Sculpture elected Pigalle a member. Louis XV. ordered the sculptor to make a Venus as a companion to this Mercury, which, however, was considered unequal to it, and the king presented them both to Frederick the Great of Prussia: they are still at Sans Souci. Another celebrated work by Pigalle is the statue of Louis XV. at Rheims; but his masterpiece is the great allegorical monument of the Maréchal de Saxe, or Moritz von Sachsen, who commanded the French at Fontenoy, in the church of St. Thomas at Strassburg, commenced, by the order of Louis XV., in 1765, and finished in 1776. It is a group of five figures against a pyramid, which proclaims the glories of the marshal: the idea is singular—the marshal is represented in his own costume, and crowned with laurel, entering a tomb; on one side is Death, as a skeleton; on the other, Hercules mourning; an impersonation of France is endeavouring to restrain the marshal and avert death; a weeping Genius is also in attendance, with an inverted torch: many military trophies are introduced as accessaries. The marshal is most elaborately modelled. It has been several times engraved.

Pigalle was much employed by Madame Pompadour, and his great success is said to be originally owing to her patronage. There is no great work by Pigalle in Paris: the tomb of the Comte d'Harcourt, in Notre Dame, is the principal. Among his smaller works, a figure of a child holding a cage from which a bird has escaped, obtained him great applause. He is considered one of the best sculptors of the eighteenth century, though his taste cannot be called classical. He died in 1785, as Chancellor of the antient Academy of Painting and Sculpture. The bronze equestrian statue of Louis XV., by Bouchardon, which was in the Place Louis XV., and was destroyed by the populace in 1792, was finished and put up by Pigalle.

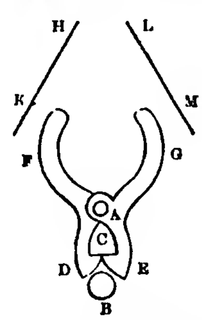
(D'Argenville, *Vies des fameux Architectes et Sculpteurs*; W. Füssli, *Kunstwerke am Rhein*.)

PILE-ENGINE is a machine by which a heavy mass of iron is raised to a considerable height in the air; the mass being then allowed to fall by gravity on the head of a pile, the momentum acquired by the descent forces the pile into the ground.

Such an engine is employed in driving piles for the support of the sleepers or horizontal timbers on which are built the piers of bridges, the revetments of the ramparts of fortresses, or any other heavy mass of brick or stone work when the soil is not sufficiently firm to carry the structure. Piles are also thus driven in order to form coffer-dams in rivers, preparatory to the construction of piers or the faces of quays, basins, &c.

A pile-engine generally consists of two pieces of timber, from 20 to 30 feet long, which are braced together and retained in upright positions by means of props; at their lower extremities they are inserted in a horizontal frame constructed with four pieces of timber crossing one another at right angles and resting immediately on the ground, or upon the sides of a barge when the piles are to be driven into the bed of a river. The two nearest sides of the upright timbers are covered with sheet-iron in order that while the *ram*, or driving mass of iron (two of whose opposite sides are grooved or cut to fit the sides of the timbers), may move freely up and down, the shock arising from its impact on the head of the pile may not force it out of its place.

The ram is raised up by means of a rope or chain attached at one end to the barrel of a *crab* whose supports are bolted to the horizontal frame constituting the base of the machine: the rope or chain passes from thence over a pulley at the top of the two upright timbers; and, descending between them, it is made fast to an apparatus called a *monkey*, which, by means of forceps or tongs, remains in connection with the ram during the ascent of the latter. The monkey is a block of wood having two opposite sides grooved like those of the ram, so that it may slide freely between the two upright timbers without quitting them; and in front of it is a frame carrying the forceps, whose form is indicated in the figure: the two curved arms F D, G E, of which it consists, turn freely on a strong pin at A, and, in the descent, their lower



extremities D, E, coming in contact with the top B of a staple which is fixed in the top of the ram, open by pressure, far enough to allow that top to enter into the space C; when the weight of the upper parts F, G, cause D, E, to close together under B. Thus, on turning the barrel of the crab, the monkey and the forceps are raised and the ram is drawn up with them.

At the top of the machine are formed two inclined planes, between the surfaces of which, at K H and L M, enter the arms F, G, of the forceps; these closing up in the contracted space near H and L, the extremities D and E open and allow the top B of the staple to escape, by which means the ram, being no longer retained, falls directly on the head of the pile. The weight of the monkey and forceps is sufficient to cause them afterwards to descend, the men ceasing to act at the winch of the crab; and the lower part of the forceps falling on the staple of the ram, the latter becomes engaged with the monkey, when it may be raised up and, subsequently, suffered to fall as before.

In order that the pile may penetrate more easily into the ground, or the bed of the river, its lower part is pointed and shod with iron; and, to prevent the top from splitting by the action of the ram, it is surrounded by an iron hoop. The weight of the ram employed, in large engines, is generally about half a ton.

An ingenious machine for driving piles was invented by M. Vauloue, and is described by Desaguliers. The power of horses was employed to give motion to a horizontal cylinder, about which was wound the rope for raising the weight; and, while the weight was being raised, the cylinder was

PISA'NO is the surname of several distinguished artists of Pisa in the thirteenth century, namely, Giunta, Niccola, Giovanni, and Andrea Pisano. Of two of these artists, Niccola and Giovanni, some account is given in the Penny Cyclopædia, but chiefly as architects. [NICCOLA DI PISA.] Vasari commences his 'Lives of Artists' with Cimabue, but there were several Tuscan artists anterior to Cimabue, especially at Siena and Pisa. [TUSCAN SCHOOL OF PAINTING, P. C.]

GIUNTA PISANO was one of the principal of these artists, and is the earliest known Tuscan painter; Niccola was a sculptor, and Giunta appears to have preceded him for a time, though he was eventually much surpassed by him in design: and as they were contemporaries, the name of Niccola accordingly takes the lead in the list of celebrated Tuscan artists. Giunta may have been born about 1180 or 1190. He is said to have learned painting about 1210, from some Greek artists, who were then engaged probably at Pisa, a tradition which is disputed by some Italian historians of art, who suppose that Pisa had at that period its native artists. The arts were very active at Pisa, owing to the construction of the cathedral there, which was commenced in 1063. The notice of Giunta in question occurs in an old history of the Basilica of Assisi, by Pater Angioll, who says, 'Juncta Pisanus ruditer a Graecis instructus primus ex Italis artem apprehendit circa an. sal. 1210.'

Giunta appears to have attained considerable reputation, for Frat' Elia of Cortona, general of the Minorites, invited him about 1235, or sooner, to Assisi, to execute some works there in the upper church of San Francesco. There are still some remains of the paintings of Giunta in this church, around the window behind the altar. He painted also a Crucifixion in 1236, in which he introduced the portrait of Frat' Elia. The painters of this time were acquainted with some excellent water-colour medium, for another Crucifixion at Assisi, with other figures, painted upon a wooden cross in the church of Santa Maria degli Angeli, by Giunta, is remarkably solid in impasto and unaffected by water; it was painted probably about 1236, and has the following inscription upon it, according to the restoration suggested by Lanzi:—'*Junta* Pisanus *Juntini* me *fecit*.' Lanzi assumes Giunta di Giustino to be the name, from the occurrence of this name in an old MS. mentioned by Morrona in his 'Pisa Illustrata.' Other existing works ascribed to Giunta are—a Crucifixion in San Ranieri at Pisa, a picture (a panel) of Saints in the chapel of the Campo Santo, and a Martyrdom of St. Peter in the church of San Francesco at Assisi (it is engraved by Lasinio in the 'Etruria Pittri' of Lastrici). The Campo Santo was built or commenced by Giovanni Pisano in 1278. (*Archæologica*, vol. xxiii. pt. 1.) Giunta was contemporary with Guido of Siena and Bonaventura Berlingieri of Lucca; and all belong to the Byzantine school in style—brown carnations, positive colour in the draperies, emaciated faces, drawn in coarse outlines with hatchings for the shadows, and elongated extremities, even with occasional short thick figures; but their forms are generally attenuated and emaciated. This meagreness of form however, often had an historical and illustrative signification; as sorrow, resignation, or bodily suffering are almost exclusively the sentiments expressed in early paintings; as we also generally find to be the case in MSS. These peculiarities of style were not much improved until the time of Giotto, and not wholly corrected until Masaccio, two centuries later than Giunta. They were, says Lanzi, faults of the times rather than of the men. Mr. W. Y. Ottley possessed an old Italian distemper picture of the Crucifixion, which he supposed was a work by Giunta. Vasari has omitted the Life of this painter. There is no notice of him later than 1236, but he may have lived some time beyond this date.

ANDREA PISANO was another early artist of Pisa, but nearly a century later than Giunta and Niccola Pisani. He was born in 1280, was distinguished as architect and sculptor, and particularly as a metal-founder, in which art he was the first of his age. He is said by Vasari to have imitated the design of Giotto in the Campo Santo. He was invited early to Florence, where he executed several celebrated works. The first were statues of Pope Boniface VIII. and St. Peter and St. Paul, from designs by Giotto, for the façade of Santa Maria del Fiore; they are now, with other works by Andrea, in the Stiozzi garden al Valfonda; the pope is engraved in Cicognara's *Storia della Scultura*. Vasari attributes to Andrea the colossal Madonna and Child, and the two accompanying angels, in marble, in the chapel della Misericordia of the Piazza San Giovanni at Florence, but this was the work of Alberto di Arnoldo in 1364; the error was detected by Vincenzio Follini: the documents are given by Cicognara and Rumohr. The half-figure of the Madonna above a side door of the Misericordia, on the wall of the Cialdonai, is the work of Andrea, and was a celebrated work, because, says Vasari, contrary to his usual custom, he imitated the antique. Andrea's great work in sculpture, however, was the bronze gate for the Baptistery of St. John, which he undertook to make from a design by Giotto, who was in the time of Clement residing at Avignon. He had a few years previously sent Pope Clement V. (1305-1314), through Giotto, a bronze crucifix as a present, and the excellence of this work led to the important commission to model and cast two of the bronze gates of the Baptistery, which, after the lapse of twenty-two years, says Vasari (Baldinucci says eight years), in 1339, with the assistance of his son Nino, he successfully accomplished; not that he was all this time exclusively occupied on this work, for he executed many others in the meanwhile. The sculptures are from the life of John the Baptist, and were gilded, and the gates were fixed up in the central entrance to the Baptistery; but upon the completion of the much more excellent gates of Ghiberti, they were removed to one of the side entrances, and those of Ghiberti were put in their place. The year 1339 in Vasari appears to be a misprint; for, according to most good authorities, the gates bear the following inscription: Andreas Ugolini Nini de Pisis me fecit anno dominin. MCCCXXX. (Cicognara, *Storia della Scultura*, iii. 396; and Lasinio, *Le tre Porte del Battisterio di Firenze*, Florence, 1823, in which all the gates (six) are well engraved.) But this date, according to Giovanni Villani, one of the superintendents of the work, is the year in which they were commenced; if therefore they occupied twenty-two years from this time, they were not finished until 1352, seven years after Andrea's death, and accordingly by Nino, Andrea's son; but this is impossible, as Villani, who died in 1348, saw the completion of the work—the date therefore, 1330, is apparently the year of the commencement of the casting in metal, which was done by Venetian artists, the model only being finished in that year; they may therefore have occupied twenty-two years from the commencement of the model to the completion of the cast. Twenty-two years from 1339 give 1317, one year after Giotto's return from Avignon, as the date of the commencement of the work, which is quite probable. As an architect, Andrea designed the Castello di Scarperia in Mugello at the foot of the Alps; and Vasari says, according to report, the Arsenal of Venice, where he spent a year; he raised part of the walls of Florence eight ells in 1316; he designed the church of San Giovanni at Pistoja, commenced in 1337, and he executed many works for Gualtieri, duke of Athens and tyrant of Florence, until the duke was expelled from Florence in 1343.

Andrea was made a citizen of Florence, and had other honours conferred upon him. He died in 1345, and was buried in Santa Maria del Fiore, where his son Nino raised a monument and placed the following inscription to his memory:—

Ingenti Andrea jacet hic Pisanus in urna,
Marmore qui potuit spirantes ducere vultus,
Et simulacra Deum mediis imponere templis
Ex aere, ex auro candenti et pulchro elephanto.

Nino completed the unfinished works of his father, and executed many original works of merit. Tommaso Pisano, another pupil of Andrea, is supposed also to have been his son.

(Vasari, *Vite de' Pittori*, &c., and the notes to the German translation by Schorn; Lanzi, *Storia Pittorica*, &c.; Cicognara, *Storia della Scultura*; Köhler, *Kunstblatt*, 1827; Rumohr, in the *Kunstblatt*, 1821, and *Italienische Forschungen* D'Agincourt, *Histoire de l'Art par les Monumens*.)

PISCARY. [FISHERIES, P. C.]

PISCI'DIA (from piscis, a fish, and cædo, to kill or destroy), a genus of plants belonging to the natural order Leguminosæ. It has a campanulate 5-cleft calyx, an obtuse keel, and a papilionaceous corolla. The stamens are monadelphous, with the tenth one free at the base. The style is filiform and smooth, the legume pedicellate linear, furnished with four membranous wings, the seeds separated by a spongy substance. The species are West Indian trees, with broad unequally pinnate leaves and terminal panicles of white and red flowers mixed.

P. erythrina (Dogwood) is a tree about twenty feet high. The leaflets are in pairs, from 3 to 4 together; they are oblong or obovate, rounded at the base, downy on both sides when young, but smooth when old. The racemes are compound, axillary, staminal. The flowers whitish tinged with purple. This plant possesses the peculiar property of intoxicating fish; the bark of the root is the part used. Dr. Hamilton, in a paper read before the Medico-Botanical Society of London, gives a lengthened account of this process and of the properties and uses of this plant. He says that a preparation of the root is infused into the water containing the fish, which soon rise to the top. They float perfectly insensible along, and are easily taken by the hand; they recover on being thrown into pure sea-water, and neither their flavour nor wholesomeness is in any degree impaired. The same gentleman made a series of experiments on himself as to the effect of a tincture of this plant. Labouring under an attack of severe toothache, he took a powerful dose of the tincture, which was succeeded by a profound sleep and entire relief from pain on awakening. As a topical application to carious teeth he found it equally successful, and came to the conclusion that the tincture of the dogwood is more powerful than that of opium. The root-juice is used to poison the arrows with which birds are shot in the Antilles. It is said to be an effectual remedy for mange in dogs: it is also reputed to possess tanning qualities. It is one of the best timber-trees in Jamaica; the wood is coarse, heavy, resinous, and almost imperishable, lasting equally well in or out of water; hence it makes excellent piles for docks and wharfs.

P. Carthaginensis is a native of Jamaica, Guadaloupe, and Carthagena, on the mountains. It closely resembles the former species, and is scarcely distinguishable from it. These trees grow best in sandy loam; cuttings of them may be rooted in sand under a hand-glass in heat.

PITUS, a genus of fossil plants from the Carboniferous strata of Tweeddale. (Witham.)

PLANE, PLANING MACHINERY. Of the planes commonly used by carpenters and cabinet-makers for levelling and smoothing the surface of wood, an account is given under JOINERY, P. C. S., p. 123, where the use of what is termed a *double-iron* is briefly alluded to. This improvement, which has been in common use for many years, is not found sufficient, in all cases, to meet the difficulties which arise in planing hard and coarse woods. To remedy this defect Mr. C. W. Williamson contrived, and submitted to the Society of Arts in 1825, what he terms a double-bevelled plane, in which a single iron is used, but it is made thicker than those of ordinary planes, and its edge is produced by two bevels instead of one. By this arrangement is produced a cutting edge which is 'much stronger, will retain its keenness much longer, and will cut much smoother' than any other plane known to its inventor. This modification of form has the further advantage of allowing the use of the finest cast-steel for making the plane-iron; whereas the comparative weakness of plane-irons of the ordinary make had presented serious difficulties in the way of applying that material, although it is known to be preferable to any other for cutting-instruments. A fuller account of this invention, coupled with a testimony as to the superiority of the improved plane for use in smoothing box-wood for the use of engravers, is given in the Society's 'Transactions,' vol. xlviii., pp. 86-88. In the preceding volume of the same work (pp. 83-85) is a description of an ingenious contrivance rewarded by the Society in 1824, 'to make one plane answer the purposes of the jack-plane, the pannel-plane, the smoothing-plane, and the moulding-plane,' by having the bottom, or *sole*, of the plane moveable, and attached to the body of the stock by means of a dove-tailed groove. By this contrivance a workman may have several different irons or blades, and any number of different soles, made either flat like those of an ordinary plane, convex or concave in different degrees, either longitudinally or transversely, for planing curved surfaces, or adapted to the form of an ogee or other moulding, all fitted to one stock, thereby effecting a great saving both in expense and portability. This contrivance is the invention of Mr. G. Gladwell, who, like the author of the double-bevelled plane, is described as a working carpenter.

The first attempt to economize labour by means of planing-machinery was made, according to Nicholson's 'Architectural Dictionary,' by General Bentham, who obtained a patent in 1791 for a contrivance by which large planes, wide enough to take the whole width of a plank at one stroke, and supplied with apparatus for directing their course, regulating the depth to which they could cut, and, generally speaking, for superseding the necessity of skill and judgment on the part of the operator, might be worked either by mechanical power or by manual labour. The machine was used for a time, worked by hand, but did not succeed well. A patent was obtained in 1803, by a person named Bevans, for a similar apparatus for planing, or, to use a technical term, *sticking*, mouldings, rebates, grooves, &c. The improved principle, now generally adopted, of moving the wood to the tool, instead of, or in combination with, the moving of the tool to the wood, was introduced in Bramah's patent of 1802. In a beautiful machine of this character constructed by Bramah for the Woolwich Arsenal the wood is placed upon a carriage and drawn, by hydraulic power, under the lower surface of a rapidly revolving disk or wheel, to the face of which a series of planes or cutting instruments are attached, which, acting upon the wood in quick succession, bring it to a very smooth and even surface. A remarkable feature in this machine is that the vertical spindle which carries the revolving wheel or cutter-frame is supported, by hydrostatic pressure, upon a column of oil, its lower end forming, as it were, the piston of a hydrostatic press in which oil, instead of water, is the fluid employed. This arrangement not only saves much friction and wear, but also affords the means of adjusting and varying at pleasure, with the greatest accuracy, the height of the spindle, and consequently the level of the cutter-frame carried by it. Of both this and General Bentham's machinery very full details are given by Nicholson, and also in Barlow's 'Treatise on Machinery and Manufactures,' in the 'Encyclopedia Metropolitana.' Machines for planing flooring-boards are mentioned under HOUSE, P. C. S., p. 54; and under SAW-MILL, P. C., p. 479, is noticed a contrivance for partially planing the surface of boards as they are cut in a saw-mill.

Immense saving of labour, accompanied with a corresponding improvement in accuracy, has been effected by the application of planing-machinery to the levelling of iron and other metals, in lieu of the cold chisel and the file, worked by hand. In some instances this has been done on the principle of Bramah's machine, above referred to; but more generally the planing of iron is effected by a stationary cutter, the iron being brought under it by a rectilinear motion. For this purpose it is not usual to employ wide cutting-instruments, as for wood; but a narrow tool, cutting a mere line of the surface at once, is brought into contact with all parts of the surface to be levelled in succession; the action of the machine being more like that of a lathe and slide-rest than that of wood-planing machinery, and still more widely different from the action of a hand-plane, in which the accuracy of the surface is in a great measure dependent upon the width and extended face of the stock. In some machines the cutter is raised a little during the return of the carriage after a stroke; but others are so contrived that at the end of each stroke the cutter is turned round and again applied to the iron, so as to cut in both directions. A minute account, illustrated with plates, of the admirable metal-planing machinery of Mr. Joseph Clement, of Newington Butts, is given in the forty-ninth volume of the 'Transactions' of the Society of Arts, part i., pp. 157—185.

PLANTA'GO, a genus of plants, the type of the natural order Plantagineæ. It has a 4-cleft calyx, a corolla with an ovate tube and a 4-parted reflexed limb. The capsules burst transversely; they are from 2 to 4 celled and have from 2 to 4 seeds.

P. Coronopus, Buck's-horn Plantain, has linear pinnatifid leaves, with a slender spike; the bracts are subulate from an ovate base, erect; the midrib of the lateral sepals with a ciliated membranous wing; the placenta 4-winged, with one seed in each sell. This species is found in gravelly and sandy places, both near the sea and inland. It is native of Great Britain. It has been eaten as a salad, but it is too bitter and astringent to be palatable, and these qualities have given it some reputation as an expectorant and vulnerary. Strange accounts are given of its efficacy in medicine, and some very improbable cures attributed to its use.

P. maritima has linear grooved fleshy leaves, convex on the back; the sepals not winged, the capsules 2-seeded, the tube of the corolla pubescent, the spike cylindrical, the bracts ovate acuminate. It is found on the sea-coast and on high mountains in Great Britain.

P. lanceolata is distinguished by its leaves being lanceolate, attenuated at both ends, and 5-nerved; the scape furrowed, the spike ovate or oblong; cylindrical bracts, ovate-acute or cuspidate; the capsules 2-celled, the cells 1-seeded, the tube of the corolla glabrous. The root produces long fibres; the neck is clothed with dense wool, and the scape and leaves with silky hairs. This species was once cultivated as an agricultural plant, but was found to be unprofitable, and has long ceased to be sown.

P. media is known by its ovate leaves, with short broad pubescent stalks; the sepals are not keeled; the capsules 2-celled, and each cell contains one seed. It is found in meadows and pastures in England. The leaves and root have been used in decoction as an astringent lotion.

P. major, Great Plantain, has broadly ovate leaves on a long channelled stalk, terete scapes, an elongated spike, ovate obtuse keeled bracts, the sepals with a prominent dorsal nerve, the capsules 2-celled, each cell containing many seeds. It is found in Great Britain, and has been called 'Way-bred,' from its prevalence on the way side. This plant has a peculiar tendency to grow in the neighbourhood of the abodes of men, and seems as though it followed the migrations of the human species. Thus, although not intentionally conveyed, it has accompanied our colonists to every part of the world, and is known in some of our settlements to the natives under the name of 'The Englishman's foot;' for with a strange certainty, wherever our countrymen have trod, there it is to be found. Small birds are almost universally fond of the seeds of these plants, which are covered with mucus. According to De Candolle the seeds of *Plantago arenaria* are exported in considerable quantities from Nismes and Montpellier to the north of Europe, and are supposed to be consumed in the completion of the manufacture of muslins. The seeds of *P. Ispaghula* are of a very cooling nature, and with boiling water form a rich mucilage, which is much used in India in catarrh, gonorrhœa, and nephritic affections. Soda is obtained in Egypt from the ashes of *P. squarrosa*.

PLANTAIN. [PLANTAGINACEÆ, P. C.; PLANTAGO, P. C. S.]

PLANTIN, CHRISTOPHE, was born in 1514, at Mont-Louis, in the French province of Touraine, of poor parents. He went to Paris in his youth, and worked there some time in a bookbinder's shop, but afterwards went to Caen, in Normandy, where he learned the art of printing. After working in several of the printing-offices of France, and especially at Lyon, he returned to Paris, but the religious disturbances, which commenced about that time, induced him to remove to Flanders, and he is known to have been a master printer at Antwerp in 1555. The beauty as well as the correctness of the works which issued from his presses, extended his reputation rapidly, and he soon acquired a considerable fortune. He employed as correctors of the press several men distinguished for their learning, among whom were Corneille Kilian, who was fifty years in his establishment, Pulman (Poelmann), Giselin, and Raphelengius (Ravlenghien). Plantin's house was resorted to by learned men from all countries. He died July 1, 1589, and was buried in the cathedral at Antwerp. Besides his printing-establishment at Antwerp, he had one at Paris, and another at Leyden. Plantin had three daughters. The eldest was married to Raphelengius, and he inherited the printing-office at Leydon; the second daughter was married to Jean Moretus, and he carried on the business at Antwerp, in conjunction with his mother-in-law: the youngest daughter was married to Gilles Béys, who succeeded to the printing-office at Paris.

The work which has given most celebrity to Plantin's printing establishment at Antwerp, is the edition which he printed of the great Polyglott Bible, which had previously been printed at Alcala, in Spain, under the direction of Cardinal Ximenes. [CISNEROS, P. C.] Plantin was engaged to perform the work by Philip II. of Spain, who sent Arius Montanus to superintend it, and he was employed four years (1568 to 1572) in this occupation. [ARIUS MONTANUS, P. C.] Guillaume Lebé was sent for from Paris to engrave the punches and superintend the casting of the type. The work, in addition to the contents of the Alcala Polyglott, gave a Chaldaic paraphrase and a Syriac version of the New Testament in Hebrew and Syriac characters. The proofs of the Antwerp Polyglott were all revised by Raphelengius, and the work was published in 8 large folio volumes, 1568 to 1572. Plantin was not so learned as the Aldi of Venice or the Estiennes of Paris, but his Latin prefaces to several of the works which he printed seem sufficiently to establish that he had acquired considerable scholarship.

(Weiss, in *Biographie Universelle*; Maittaire, *Annales Typographici*.)

PLANTS, FOSSIL. The progress of knowledge concerning the vegetation which in antient geological periods covered the surface of our planet has been, until within a few years, neither rapid nor sure. No small amount of time and patience was required to establish the conviction that organization, not crystallization, was indicated by the wood, leaves, and fruits which abound in the stratification of Europe. Much profound investigation of the *natural orders* of plants was an indispensable preliminary to the reference of even perfect specimens of fossil plants to their living congeners, and microscopic scrutiny of the minutest tissues could alone determine in fragments of petrified wood the essential characters of primæval trees.

These investigations have been so far advanced by eminent living botanists, that a very great proportion of fossil plants has been satisfactorily referred to the proper classes and great natural orders, and in some instances to the true families and genera. On this basis, furnished by physiological botany, geologists have erected very important inferences and very remarkable speculations—inferences concerning the succession of vegetable life, and the varying distribution of land and sea; and speculations concerning the antient temperature of the surface of the globe, and the antient chemical constitution of the atmosphere.

Passing over, but not without approbation, the earlier labours of Steinhauer, Parkinson, and Artis, in England; of Schlottheim, Sternberg, Rhode, and Martius, in Germany; of Nilson and Agardh, in Sweden, we may safely attribute to M. Adolphe Brongniart the advanced position among the natural sciences which is conceded to fossil botany. Guided by views of botanical classification at once profound and practically applicable to the subject before him, this zealous naturalist, by personal observations over great part of Europe (1825 and following years) and by communications from many distant parts of the world, gathered and methodised that body of information which is the basis of his two great works, viz.: the 'Prodrome d'une Histoire des Végétaux Fossiles,' 1828; and the 'Histoire des Vegetaux Fossiles,' which occupied many subsequent years.

A somewhat parallel but less extensive inquiry has since been undertaken in England by Dr. Lindley and Mr. Hutton (*Fossil Flora of Great Britain*, 1831-36); Göppert (*Systema Filicum Fossilium*, 1836), has revised the numerous tribes of fossil ferns; Mr. Bowerbank has collected extensive information concerning the fossil fruits of the London clay, and we are indebted to Dr. Brown, Mr. Witham, Mr. Bowman, Mr. King, and some other writers for a variety of notices on particular tribes of fossil plants. Mr. Morris has combined in his catalogue a summary of the results for the British Islands.

Previous to the year 1828 there can hardly be said to have been specifically known so many as one hundred fossil plants. In the Prodrome of M. Brongniart appeared (p. 219) 501 fossil plants, while the recent tribes were estimated at 50,350. In 1845 Mr. Göppert estimated the known fossil plants at 1792, and the recent species at 80,000. (*Reports of the British Association.*) Following the classification of M. Brongniart, we find his 501 plants thus divided and compared with living tribes:—

	Fossil.	Recent.
Agamia	27	7,000
Cryptogamia cellulosa	2	1,500
Cryptogamia vasculosa	266	1,700
Phanerogamia gymnospermia	67	150
Phanerogamia monocotyledonea	49	8,000
Phanerogamia dicotyledonea	100	32,000

It thus appears that the vascular Cryptogamia numerically constituted above half the fossil flora known in 1828, while among living plants they count only as 1 in 30; and the dicotyledonous group, which includes more than half the recent plants, is represented in the stratification of the globe by one-fifth. These results, though modified by later discoveries, are still firmly established. Are we to conclude from this statement, that the vegetation of the antient world was entirely different in the numerical *proportions* of its constituent classes from the actual flora? Do the plants which we collect in the strata truly represent the entirety of the antient flora; or only such part of it as remained after decay and the transforming agencies of nature had destroyed another and perhaps larger proportion? M. Brongniart (though not without some limiting expressions and corrections) generally assumes the fossil flora preserved in the strata as proportionate to the flora that was in existence before those strata were deposited; and arranging the 501 species of fossil plants in periods of geological succession, as well as in groups of natural affinity, arrives at results which appear in the following table. (We have altered the *form* of the original, and added the general terms Palæozoic, Mesozoic, &c., in conformity with the views advocated in this work.)

	Agamia.	Cryptog. cellulosa.	Cryptog. vasculosa.	Phanerog. gymnosper.	Phanerog. monocotyled.	Phanerog. dicotyled.	
Actual period	7000	1500	1700	150	8000	32,000	Cainozoic
Fourth period	13*	2	7	17	25*	100*	
Third period	3	0	31	35*	3	0	Mesozoic
Second period	7	0	8	5	5	0	
First period	4	0	220*	0	16	0	Palæozoic

Hence it would appear that vascular Cryptogamia had their greatest predominance in the first (Palæozoic) period: that gymnospermous Phanerogamia acquired their greatest development in the third (Mesozoic) period, while true Monocotyledonous and Dicotyledonous plants became most numerous in the fourth (Cainozoic) period, and in it approximated to the proportions now actually observed between them in living nature.

But it is thought by Dr. Lindley (*Fossil Flora*, vol. iii. p. 3) that the proportions among the several classes and families of plants preserved in the strata may be very different from those which obtained between the plants when living, because only part of the whole living creation of plants could be expected to resist long immersion in water and the many destructive agencies which are at work on vegetable substances, so as to be preserved in the earth. And this view is to a certain extent confirmed by experiments made by Dr. Lindley, for the purpose of ascertaining the relative conservability of plants belonging to different natural families.

For this purpose, on the 21st of March, 1833, he immersed in a large iron tank full of water, 177 specimens of various plants, belonging to all the more remarkable natural orders, taking care, in particular, to include representatives of all those which are either constantly present in the coal-measures or as universally absent. The vessel was left uncovered in the open air, and filled with water as it evaporated, till the 22nd April, 1835. The result of the experiment was then registered in respect of each plant: of the 177 tried, 56 only remained recognizable in the water; 121 were not to be traced. The numbers were thus proportioned in several natural groups:—

	Tried.	Recognizable.	Lost.
Acotyledones	22	10	12
Dicotyledones apetalæ	38	26	12
Dicotyledones polypetalæ	45	2	43
Dicotyledones monopetalæ . . .	41	6	35
Monocotyledones	31	12	19

Among the Acotyledones the recognizable families were mostly Filices, and Lycopodiaceæ, these being frequent in a fossil state. Among the Dicotyledones apetalæ the recognizable plants were numerous, especially in the Coniferæ, and these abound in a fossil state. 'With these exceptions, the Dicotyledonous plants tried were, in general, unable to remain for two years in water without being totally decomposed.' 'The Monocotyledonous plants were found more capable of resisting the action of water, especially Palms and Scitamineous plants, which occur as fossils; ferns exhibited a great power of resisting water, if gathered in a green state, but immersion in water caused their fructification to rot away.'

If we were completely assured by observation that the circumstances under which the fossil plants were buried in the sediments now hardened around them, were similar to those under which the above-narrated experiments were made, the inferences from the experiments might be relied on for modifying and perfecting a general view of the antient vegetation of the globe. But this is not the case; we have no such assurance. On the contrary, in very many cases there is little room for doubt that the plants were speedily enveloped in mud, and not for a long time scattered in water. They appear in fact to be a fair sample of the vegetation which actually prevailed on or near to the spots where they are found buried, and were subject to be drifted for that distance by water transporting mud and sand. Sometimes drifted in a fresh state, sometimes in a decomposed state, according to the degree in which they had withstood *atmospheric* rather than *watery* agencies, these plants should perhaps rather be compared to the weeds which cover the surface of some rivers in flood, than to the rotten vegetation at the bottom of stagnant pools. This comparison has, we believe, not yet been made under favourable circumstances, but certainly the flood-transported plants on English rivers are by no means to be taken as a sample of our upland flora, if even they do tolerably represent the vegetation of the river-banks.

Another important question affecting the general inferences to be derived from the study of fossil plants remains to be asked. Did these plants grow in or near to the situations where now they remain buried? The answer must be affirmative in some cases, doubtful in many, and negative in the remainder. It must be affirmative in respect of many cases of Stigmaria, if we admit the stems of this plant, with their articulated leaf-like processes, to be really the roots of trees analogous to Stigmaria and Lepidodendron; and to this, now a prevalent opinion, M. Adolphe Brongniart has assented. It must be affirmative in respect of the Cycadeoid plants of the Isle of Purbeck, which remain yet rooted as in their period of life, with the bed of soil in which they grew.

In the case of the great proportion of fern-leaves, and scattered branches and fragments of stems of Lepidodendra, which abound in the roof of many coal-beds, we cannot doubt that these have been subject to drifting, though it is not easy to determine from what distance or in what direction; as however the leaves retain almost universally their figure, expansion, and veins, and are represented by so much of a carbonaceous pellicle as may correspond to their whole mass, and have sometimes preserved their fructification, we need not suppose them to have been drifted from far, nor to have been long immersed in water.

Many other cases of fossil plants occur, which require us to admit at least the possibility of their having been drifted from great distances. The large broken stem of coniferous wood found in the sandstone of Craigleith, and described by Mr. Witham, may be taken as an example. It suggests, concerning many other cases of coniferous fossil wood found in the lias, oolites, Wealden and London clay, the idea of a great muddy river flowing through a woody region, and depositing in marshy plains, in æstuaries, or in the bed of the open sea, the spoils collected in its course. In this latter case we frequently observe the wood to be perforated by Teredines (London clay).

From the above observations we collect that the *large accumulations* of fossil plants which belong to certain stratified deposits, represent approximately, though not completely nor exactly, the flora of the period of their deposition at and near the places where they are found; but that single plants or scattered small collections of them may have been derived from remote situations.

Can we, from the catalogues of fossil plants, determine what was the climate in which they flourished during primæval periods? Confining our attention to the British Isles, we remark three great accumulations of fossil plants, in three successive periods. The land vegetation of Palæozoic periods is well represented by the plants of our coal-measures; that of the Mesozoic periods by the plants of the oolitic shales of the Yorkshire coast; and that of Cainozoic ages is known to us in some particulars by the deposits of Sheppey, rich in seed-vessels.

The most numerous group of fossil plants, in the two former great periods, is certainly the tribe of Ferns, which, with the other vascular Cryptogamia, are known to be most numerous, in comparison of the other races of plants, in countries where the climate is warm and the atmosphere damp. Some of these are Tree-ferns, which remarkably characterize warm though not necessarily very hot climates. With these are associated in great abundance large stems, like Cacteaceæ; others like gigantic Equisetaceæ; others like monstrous hybrids of Lycopodiaceæ and Coniferæ, and a few Palms; all confirming, by their structural analogies, the conclusion that the climate of the carboniferous period in the northern zones of Great Britain was warm. Now this conclusion applies with equal force to the whole of the European and North

American coal-fields; and thus we find reason to admit a prevalent warm climate in the northern zones of the globe. With these conclusions from the examination of the carboniferous flora, the inferences from the oolitic flora agree sufficiently. Substituting cycadeoid plants, which abound in these, for the lycopodioid and cactoid forms in those, we have a parallel series of results. And warmth of climate appears still to be indicated by the seed-vessels of Piperaceæ, &c., which occur in the London clay. In harmony with the data which are here generalized, into the inference of a warm climate prevailing in the northern zones of the world, even into the Cainozoic periods, is a parallel series of data and inferences derived from the contemplation of the perished races of animals.

Granted, then, a certain high probability that the great masses of fossil plants—those of the coal-formation in particular—grew in an atmosphere warm and damp, in a climate analogous to the shores and islands of the tropics, we shall not wonder if these vegetable accumulations are of *considerable* extent. But they are of *enormous* extent; for coal, itself nothing else than plants accumulated, compressed, and transmuted, is of such thickness, even in some of many workable beds, as to have absorbed the growth of plants on an equal area for hundreds of centuries, if that growth was after the rate now to be witnessed in temperate or even the most favourable tropical regions. In every natural effect time and force are reciprocally involved: if we suppose the antient growth of plants to have been more rapid than the modern, the *time* above alluded to may be conceived to be reduced. M. Brongniart does so suppose the force of vegetation to have varied and to have diminished towards our days, and he speculates on a cause for this, viz. a change of the constitution of the atmosphere by the gradual diminution of the proportion of its contained carbonic acid. That such a diminution of the carbonic acid of the air may have happened, nothing in physical science forbids: that it is not improbable, the late development of air-breathing animals (in the succession of life on the globe), seems to indicate; and, finally, that it really did happen to some extent at least, after the great period of carboniferous vegetation, may be maintained in a very simple argument. Calculate the quantity of carbonic-acid gas proportioned to the carbon in a given weight of coal: that quantity of the gas, *at least*, existed in the atmosphere before the fixation of the carbon in the plants which yielded that coal. The whole quantity of coal actually buried in the earth is of course not known, but *that which is known*, submitted to this calculation, is enough to leave no doubt that previous to the Carboniferous period the atmosphere must have been *loaded with* carbonic-acid gas, unless compensating processes, of which we have now no example, were contemporaneously in action. The compensating process now in action is chiefly animal respiration; but we have little or no evidence of the existence of air-breathing terrestrial animals previous to the carboniferous æra.

In Morris's Catalogue of British Fossils (published in 1843), occur the names of 524 species of fossil plants, distributed in 107 genera or families. We propose to enumerate these genera and show their geological distribution so far as relates to the British Islands, according to the classification developed in the Cyclopædia [PALÆOZOIC SERIES, P. C.; SALIFEROUS SYSTEM, P. C.] and exemplified in the article on FISHES, FOSSIL, P. C. S.

General Distribution of Fossil Plants.

Tab. I. In British Strata:—

	Total.
Cainozoic strata	121
Mesozoic strata	125
Palæozoic strata	279
	525

For comparison we add M. Göppert's statement of the numbers of plants in corresponding strata obtained from all parts of the globe:—

Cainozoic strata	454
Mesozoic strata	398
Palæozoic strata	929

In both estimates the Palæozoic Plants are more than equal in number to those of all the other strata. They are chiefly obtained from the coal-measures.

Selecting particular groups for consideration, we find some characteristic circumstances of distribution (as in Tab. II.).

Tab. II. Geological distribution of Ferns, Cycadeæ, Coniferæ, and Fucoids in British Strata:—

	Ferns.	Cycadeæ.	Coniferæ.	Fucoids.
Cainozoic	0	0	Few.	2
Mesozoic	51	27	12	6
Palæozoic	105	0	10	0

Tab. III. Geological distribution of certain genera of plants:—

	Pecopteris.	Neuropteris.	Sphenopteris.	Sigillaria.	Lepidodendron.	Leguminosites.
Cainozoic	0	0	0	0	0	18
Mesozoic	13	0	11	0	0	[illegible]
Palæozoic	21	22	31	19	20	[illegible]

General series of the genera of British fossil plants:—

Cainozoic Strata.

Names of Plants.	Number of Species.	Names of Plants.	Number of Species.
Amentaceæ	1	Leguminosites	18
Carpolithes	2	Lycopodites	1
Ceratophyllum	1	Mimosites	1
Chara	6	Nipadites	13
Cucumites	1	Petrophiloides	7

PLASTERING is the art of applying plastic adhesive compositions or cements to walls, ceilings, and such other parts of a building as may require a smooth and even surface, to conceal the roughness of brickwork or masonry, or the timber framing of partitions, floors, roofs, and staircases, in such a manner as to admit of colouring, painting, and other modes of decoration. The business of the plasterer also embraces the formation and fixing of ornamental cornices, centre-pieces, and other ceiling and similar ornaments. 'No art in the economy of building,' observes Mr. Hosking, in his treatise on 'Building,' in the seventh edition of the 'Encyclopædia Britannica,' 'contributes more to produce internal neatness and elegance, and no one is less absolutely important, as far as the use and stability of a structure are concerned, than that of the plasterer;' and he further remarks that its general application is of comparatively late date, 'for wainscoted walls, and boarded or boarded and canvassed ceilings, or naked joists alone, are frequently found in houses of less than a century old, both in this country and on the Continent.'

In the application of plaster or stucco [STUCCO, P. C., p. 166] to a brick wall, the first thing to be observed is to secure a rough and porous surface to which the composition may adhere readily. If the walls be new, and built with the intention of receiving stucco or plaster, the joints are, as mentioned under BUILDING, P. C. S, p. 248, left rough and prominent, instead of being *drawn* with the trowel, as is done for exposed brickwork; but if they be old, and have had the joints drawn, the mortar must be removed to a small depth, as for repointing, and the surface of the brickwork must be *stabbed* or picked over to make it rough, and to expose portions of new and porous surface. In applying the plaster, the surface must first be brushed free from dust, then wetted with water, and covered with a first coat of fluid stucco, applied with a coarse bristle-brush, after which, before it is quite dry, the first coat of coarse mortar-like composition is applied. In plastering upon quarter-partitions [CARPENTRY, P. C. S., p. 292], or upon the under surface of timber floors [HOUSE, P. C. S., p. 52], to form ceilings, a very different process is adopted. In both of these cases a surface is formed to receive the first coat of plaster by nailing to the timber quarterings, or to the joists in the case of a floor, narrow slips of wood called *laths*. These slips of wood, which are generally of fir, though oak is occasionally used, are about an inch wide, from three to five feet long, and either one quarter, three-eighths, or half an inch thick; these several thicknesses being designated respectively single, lath and a half, or double. They are, to ensure greater strength and elasticity, formed by splitting, or *rending*, so that they are not perfectly straight, and their surfaces are comparatively rough. They are laid transversely across the joists or other timbers to which they are applied, and nailed to them, frequently with cast-iron nails, in such a manner as to leave a narrow slit or opening between every two adjacent laths. As explained under HOUSE, P. C. S., it is frequently necessary to level the under surface of the joists or floor-timbers, by attaching slips of wood, technically called *furrings* or *firrings*, before nailing on the laths, in order that a perfect level may be obtained for the laths; and a similar precaution is sometimes required in timber or quarter partitions. In lathing it is important, especially in ceilings, to select laths of uniform thickness, and also to break or vary the joints produced by the abutting ends of two laths, which must be made to meet upon a joist or quartering, as much as possible. This done, the first coat of plaster, consisting of what is called *coarse stuff*, which is a mortar of lime and sand mixed with ox or horse hair, to give it consistency, is applied with a peculiar kind of trowel, in such a way as to force the mortar through the narrow openings between the laths, behind which, in consequence of its soft and wet state, it swells in such a way that, as it sets or hardens, it becomes firmly *keyed* to the laths, so that it could only be broken away in little bits, and by the application of considerable violence. As the security of the plaster depends upon this keying between and over or behind the laths, and not upon simple adhesion to their surface, it is evident that the hold must be in some degree interrupted wherever the laths lie in close contact with the joists, quarterings, or battens to which they are nailed, and hence the importance, alluded to under HOUSE, P. C. S., of keeping these timbers narrow, or, where that cannot be conveniently done, of producing a similar effect by interposing narrow fillets between them and the laths. Projections and pannelled compartments in a plastered surface are provided for by bracketing or cradling down the laths to as nearly as may be the required form.

The first coat of plaster being thus laid, the subsequent operations vary considerably according to the nature of the work, and the number of coats it is intended to apply. If it be intended to use only two coats, which, when upon laths, is technically called *laid and set*, the first coat, or the laying, is levelled with the trowel, and when sufficiently dry, its surface is scratched up or roughed with a birch-broom, and a thin coat, or *set*, of finer plaster is laid on and smoothed with the trowel, assisted by a wet bristle-brush to moisten such parts as are inclined to dry too suddenly. In applying this second coat, the first will occasionally need sprinkling with water to facilitate their perfect union. In better work, where three coats are used, the first coat is laid very roughly, and, while moist, scored over with lines about three or four inches apart, as deeply and roughly as can be done without laying the laths bare in any place, to make the second coat adhere the better. This first coat may project a quarter or three-eighths of an inch from the laths, and it is, in this case, called the *pricking-up*. When it is so far dry as to be thoroughly firm, ledges or margins of plaster, called *screeds*, are formed at the angles, and at intervals of a few feet across the surface, these being very carefully adjusted to nearly the degree of projection or level which the finished surface should have, in order that they may form gauges for the rest of the work. When these screeds, which are about six or eight inches wide, are set, the intervening spaces or bays are filled up flush with them, the plaster being very carefully adjusted to the required surface, by means of flat wooden instruments called *floats*, made with one or two handles (the latter being called *Derby floats*), and *straight-edges*, or long pieces of wood, carefully planed to a perfectly straight edge, which are moved backwards and forwards over the work in various directions, to test its accuracy. When this second coat is nearly dry, it is swept over, and a third very thin coat of fine stuff, or superior plaster made with very fine white lime, is applied as above described, the hand-float being sometimes employed to perfectly flatten and condense it, and, by the aid of occasional sprinkling with water, to rub or grind it to a smooth hard surface. In performing the like operations upon a brick or stone wall there are some trifling variations, and the first rough coat is called *rendering* instead of *laying*. For minute details in this and other departments of the art of plastering we must, however, refer the reader to the articles on the subject in Nicholson's 'Architectural Dictionary,' and to that department of the article 'Building' in the 'Encyclopædia Britannica' which treats on the duties of the plasterer. Ceilings or fine surfaces that have to be whitened or coloured are finished with putty, which is a fine plaster made of the finest powdered lime, macerated so completely as to be held in solution by the water, and forming a delicate paste, which is allowed to evaporate until of the proper consistency for working; but surfaces which are to be papered are finished with a somewhat less delicate variety of fine stuff, with the admixture of a little hair. Surfaces intended for painting are finished, or *set*, with *bastard stucco*, which is composed of two-thirds ordinary fine stuff, without hair, and one-third very fine clean sand, and these are finished with the trowel, without the use of the float upon the last coat.

The various modes of finishing stuccoed or cemented surfaces on the exterior of buildings may be passed over with the remark that they are often spoiled by the presence of muddy earth, and decayed animal and vegetable matter, in the sand which is mixed with the lime and cement, to which causes of failure may be added the occasional presence of argillaceous matter with the lime, and defects in the cements themselves. 'These things might,' Mr. Hosking observes, 'remain quiescent for a long time, if the work were well protected from access of moisture, which is the grand exciting cause.' 'The paint, or distemper wash on the surface,' he adds, 'is generally sufficient to prevent tho rain which may beat against a vertical face from penetrating, especially if the work have been well hand-floated and trowelled, to make it close and compact; but the evil arises from exposure above, and from the numberless horizontal unfloated surfaces which are constantly presented,' which receive and detain the water until the work becomes saturated, when either frost seizes and bursts it, or warmth calls the vegetative power of its impurities into action, so that it becomes covered with minute vegetation. Hence he insists on the importance of excluding road-drift, (unless it be thoroughly cleansed from animal and vegetable matter), and all mud and clay, from the composition of both plastering mortars and mortars for building, although such materials are often used in mixing what the plasterer terms coarse stuff, under the impression that, so long as it is unctuous and tenacious, its composition is unimportant. He also recommends that care be takon to guard against the effects of wet, not only by providing sufficient shelter, and by frequent painting or distempering, but also by carefully hand-floating and trowelling the upper horizontal surfaces of all projections. *Rough-cast* is a cheap mode of stuccoing adopted in inferior buildings, when there are good projecting eaves to keep the walls dry, consisting of two coats of coarse lime and hair, covered, as soon as a piece of two or three yards is completed, with a semi-fluid mixture of fine clear gravel and strong lime, and washed immediately with an ochreous colour.

Mouldings and cornices are formed upon a core or foundation, either of brackets and laths, or in some cases in external work, of projecting bricks and tiles. Very trifling projections may sometimes be supported sufficiently hy a few projecting nails. If large, a layer of comparatively coarse stuff is applied to the foundation, and to this, when dry, is applied the finer composition of which the moulding is to be formed, as nearly as possible in tho required shape. The precise form is then given by *running* or sliding along the cornice, with the aid of guides attached to the wall or ceiling, or both, a mould formed of a thin board, one edge of which is cut so as to be a perfect counterpart of the profile of the moulding. The quirks or small angles, and in some cases the whole of the acting edges of these moulds, are formed of metal. The composition used for in-door cornices and mouldings is called *gauge-stuff*, and consists of three-fourths of the *putty* used in setting ceilings, to one-fourth of calcined gypsum, or plaster of Paris. As the addition of the gypsum causes it to set very quickly, only a small quantity of gauge-stuff must be mixed at once, and the moulding must be frequently sprinkled to keep its surface soft until the shape of the mould is perfectly transferred to it. The mixture of plaster of Paris with stucco for external mouldings should not be permitted, as it will not bear exposure to the weather, although it enables the workman to produce a sharper and better looking moulding. Such ornaments as cannot be formed by *running* are cast separately in plaster of Paris, being run in moulds in the ordinary way, and are secured in their places in the ceiling or cornice, either with plaster or some other cement, or when too heavy for such a mode of fixing, by screwing them to wooden cradling fixed to receive them. Mouldings and cornices are nsually formed before the final or setting coat is given to the walls aud ceilings. Ornaments of papier-maché and some other substances, both lighter and less liable to injury than plaster or any plaster-like composition, have been extensively introduced of late years fo internal decoration, and especially for ceilings.

Plasterer's work is measured in feet and inches, and charged by the superficial yard of nine square feet, under separate heads according to the description of the work; with special charges, according to certain established rules, for arrises or external angles, quirks, mouldings, and other enrichments, and curved work.

Plaster being, in a great measnre, incombustible, it is to be regretted that its use is not generally so modified as to render it a more important protection to buildings against fire than it commonly is. Under FIRE-PROOF BUILDINGS, P. C. S., p. 577, is a notice of one of several attempts that have been made for the attainment of this desirable object.

PLATFORM, for guns, mortars, &c., is a floor of timber or a pavement of stone of a rectangular form which is laid on the ground for the support of a piece of ordnance, and to prevent the wheels of its carriage from sinking.

A gun platform has one of its extremities at the foot of the interior slope of the parapet; it is generally 14 or 15 feet long and 10½ or 11 feet broad, and is laid either in a horizontal position, or with a slope of about 6 inches, from the rear down towards the parapet, in order to diminish the recoil of the gun. It consists of five joists or sleepers, each 6 inches square, which are sunk in the ground, and covered with planks each one foot broad and two inches thick; the planks are sometimes fastened to the sleepers hy nails or screws; but in siege batteries, they are kept in their places by means of a ribband or piece of timber lying across their ends on each side of the platform, and confined to them by short ropes called rack-lashings, each of which passed under a sleeper and over a ribband. By this contrivance the platform may be laid, even in the dark, quickly, and without noise; and the timbers not being injured by nails or screws, may be removed and re-laid elsewhere as often as it may be necessary to change the position of the battery. Four men accustomed to the service can take up a platform in three minutes, and lay one in an hour.

A mortar platform is 7½ feet long and 6½ feet wide; the planks are three inches thick and rest on sleepers. This platform is placed at such a distance from the foot of the parapet towards the rear of the battery, that the shell, when discharged at the required elevation, may pass above the crest.

Along the head of every gun-plstform is laid a piece of timber called *heurtoir* or *hurter*, which, in general, serves to prevent the wheels of the gun-carriage from damaging the interior of the parapet. When the line of aim is oblique to the capital of the embrazure the hurter, which is in contact with the wheels of the carriage, in their front, serves to keep the gun in its position.

When a gun is directed against a particular object, as in breaching, the platform sometimes consists merely of four planks each six feet long, ten inches broad, and three inches thick; two of these serve as sleepers, and the other two, being placed across them, serve to support the wheels of the carriage; all the planks are kept in their places by pickets driven in the ground.

PLATING; PLATED MANUFACTURES. [SILVER, P. C., p. 25; GILDING, P. C., p. 218; ELECTRO-METALLURGY, P. C. S., p. 518; CHASING OF METALS, P. C. S., p. 332; SPOON, P. C., p. 377; SOLDERING, P. C., p. 202.]

PLECTRANTHUS (from πλῆκτρον, a cock's spur, and ἄνθος, a flower, in reference to the corolla being spurred or gibbous above the base), a genus of plants belonging to the natural order Labiatæ. It has a campanulate 5-toothed calyx in the floriferous state; the teeth equal or the upper one largest. The corolla with an exserted tube; the upper lip from 3- to 4-cleft, the lower one entire, usually longer and concave. Thero are 4 stamens, declinate, didynamous, the lower ones longest; free toothless filaments, ovate uniform anthers. The species are herbs, subshrubs, and shrubs. There are 45 species of this genus described, which are of easy culture and propagation. Any light rich soil will suit them. The shrubby and perennial species are increased by cuttings. The seeds of the annuals should be raised on a hot-bed before planting in the open ground. *P. crassifolius* is esteemed in India both as a perfume and a spice, being equally valued in the toilet and the kitchen. The Patchouly, so inimical to vermin and so efficacious in preserving clothes from moths, is said to be the leaves of P. *graveolens*, which have a very powerful odour, but the comminuted state in which it is imported renders this uncertain.

(Don, *Gardener's Dictionary*; Burnett, *Outlines of Botany*.)

PLENARTY. [QUARE IMPEDIT, P. C.]

PLINUS. [SERRICORNES, P. C. S.]

PLOOS VAN AMSTEL, CORNELIS, a celebrated Dutch amateur engraver and designer, was born at Amsterdam, in 1726. He is chiefly distinguished for his imitations of the drawings of old masters, of which he possessed one of the best collections known, amounting to 5000 drawings by celebrated Italian, German, French, Flemish, and Dutch masters, from Giotto to his own time. Born of a good and wealthy family, he had every opportunity suitable for improving his taste and advancing his pursuits: he is said to have had a mature judgment in matters of art in his fourteenth year; and being acquainted with all the principal collectors of Amsterdam, he commenced making his own valuable collection at a very early age. He had likewise a very valuable collection of prints and etchings, especially of the works of Lucas van Leyden, Albert Dürer, Golzius, Cornelis and Jan Visser, N. Berchem, and especially Rembrandt.

Ploos van Amstel's own works consist chiefly of imitations of drawings of old masters, in chalk, washed, and coloured; the coloured imitations were accomplished by printing with several plates. In 1765 he published a collection of forty-six such imitations in various styles, after drawings by Zaftleven, A. Vandevelde, Rembrandt, Ostade, Van Campen, Vandyck, Van Goyen, Gerard Dow, Backhuyzen, Metzu, Berchem, A. Bloemart, Golzius, C. Visser, Wouvermann, P. Saenredam, Van Mander, Flink, Brouwer, Mieris, Terburg, J. Steen, De Bray, and others.

There are altogether upwards of one hundred imitations of drawings by Ploos van Amstel, and many of these are published in various stages of progress, but very few impressions were taken of any. They are enumerated and described by Weigel in the 'Kunst Katalog,' and in Nagler's 'Künstler Lexicon.' A collection of one hundred of Van Amstel's and some additional similar imitations, with a portrait of Van Amstel, was published by C. Josi, in London, in 1821, royal folio; but only one hundred copies were printed, and at the enormous price of forty guineas per copy.

Ploos van Amstel died at Amsterdam, December 20, 1798, and on March 3rd, 1800, his valuable collection, with the exception of the etchings of Rembrandt, was sold by auction, and realized the large sum of 109,406 florins.

When Van Amstel's coloured prints first appeared, his countrymen disbelieved that they were produced solely by using various plates, and he accordingly drew off some impressions in the presence of a deputation of the Dutch Academy of the Sciences at Haarlem in 1768, which decided the question satisfactorily.

(Van Eynden en Vander Willigen, *Geschiedenis der Vaterlandsche Schilderkunst sedert de helft der XVIII. Eeuw*, 1816-42.)

POA (the Greek πόα, 'grass'), a genus of Grasses belonging to the tribe Festucineæ. This tribe is characterized by very short styles, protruded stigmas, and the glumes shorter than the lowest flower. The genus Poa has its glumes rather unequal; the outer palea with 3 or 5 nerves, membranous below, scarious at the tip, compressed, keeled, unarmed; the styles terminal. The species of this genus are very numerous, constituting the commonest weeds that follow the migrations of man, and generally containing a sufficient quantity of nutritive matter to render them fodder for various animals. Thirteen species of this genus are described by Babington as natives of the British Islands. Of these the most common are the *P. annua* and *P. pratensis*. The former is perhaps the commonest of British plants, springing up on every neglected spot around the habitations of man. The latter is known by the name of the smooth-stalked meadow-grass, and is found in most pasture lands. *P. nemoralis*, the wood meadow-grass, is also a common grass in shady places. Many of the recent genera of Grasses were formerly referred to the genus Poa.

POILLY, FRANÇOIS, a distinguished French engraver, was born at Abbeville, in 1622. He was the pupil of P. Daret, and studied some time in Rome. He adopted the somewhat hard style of engraving of Bloemart in direct cross-lines, in which he was completely successful: his drawing also, which is quite correct, adds much to the value of his finely executed engravings. Though Poilly's style is very laborious, there are about 400 prints which bear his name, in which however he was of course assisted by his pupils. His master-piece is the print from Mignard's celebrated picture, now lost, of San Carlo Borromeo administering the Sacrament to the Milanese attacked with the Plague. A catalogue of his prints was published by R. Hecquet in 1752; it comprises several after Raphael, including the Vierge au Berceau, La Vierge au Linge, the large Holy Family in the Louvre, and other Holy Families by Raphael. Poilly died at Paris in 1693. His brother Nicolas and nephew Jean Baptiste Poilly were likewise distinguished engravers.

(Watelet et Levesque, *Dictionnaire des Arts*, &c.; Huber, *Manuel des Amateurs*, &c.)

POINDING, in the law of Scotland, is a process for enforcing payment of a debt, against the property of the debtor. It is divided into 'personal poinding,' and 'poinding of the ground.' The former is the method by which any ordinary creditor attaches the moveables of his debtor; the latter is peculiar to the holders of real rights over estates belonging to others—as to superiors entitled to feu duties or the holders of real securities entitled to payment of the interest—who can by this process attach the rents or other proceeds of the estate, and pay themselves. Personal poinding is the most usual form—it is of very frequent occurrence, and is a rapid and effective process. The procedure was simplified and regulated, and was brought within the authority of the sheriff's local court, by 1 & 2 Vict. c. 114.

POISONING, SECRET. When the knowledge of the nature of mineral, vegetable, and animal compounds was less known than at present, it was not uncommon for individuals to become acquainted with the poisonous properties of bodies, and to keep this a secret for the purpose of exercising a control over the lives of their fellow creatures. The entire ignorance that existed of the means of ascertaining the presence of poisons, or of the symptoms of poisoning as distinguished from other diseases, gave to persons who had accidentally discovered a poison a great power, and offered a temptation to crime. In antient history many instances are recorded of persons who died under suspicious circumstances and who were supposed to have been secretly poisoned. Beck in his 'Medical Jurisprudence,' says that 'Theophrastus speaks of a poison prepared from aconite which could be moderated in such a manner as to have effect in two or three years, or at the end of a year or two years; and he also relates that Thrasyas had discovered a method of preparing from other plants a poison which, given in small doses, occasioned an easy but certain death without any pain, and which might be kept back for a long time without causing weakness or corruption. This last poison was much used at Rome about two hundred years before the Christian era.' During the reigns of Caligula, Claudius, and Nero, a woman named Locusta seems to have been frequently employed for the purpose of administering poisons whose powers were known to herself alone. Locusta was employed by the second Agrippina, to poison her husband the emperor Claudius, and also by Nero to poison Britannicus, the son of Claudius and Messalina. (Tacitus, *Annal.* xii. 66; xiii. 15.)

The poisons used by the Greeks and Romans seem to have chiefly belonged to the vegetable kingdom, and were chiefly obtained, it is supposed, from the aconite, hemlock, and poppy. One of their animal poisons is said to have been the acrid juice secreted by a species of Tectibranchiate mollusca, called the sea-hare, the Aplysia depilans of Linnæus. They did not seem to be acquainted with mineral poisons.

In modern times secret poisoning has often been carried on to a great extent; although the relation of many of the incidents has been so connected with superstition, and a belief in supernatural powers, that it is sometimes difficult to distinguish between the true and fictitious. The aid of poisons appear sometimes to have been resorted to to obtain credence for the powers of the witch and the wizard. A singular combination of poisoners was discovered at Rome during the pontificate of Alexander VII. in 1659. It was observed that many young married women became widows, and that many husbands died who were known to have become disagreeable to their wives. Great exertions were used to detect the poisoners, when at length suspicion fell upon a society of young wives whose president was an old woman who pretended to foretell future events, and who had often predicted very accurately the death of many persons. At length the society was detected, arrested, and every member put to the torture, and the old president, by name Spara, with four others were publicly hanged. It appeared that Spara was a pupil of Tofania, an infamous woman who lived at Palermo and afterwards at Naples. The poison used by Tofania went by the name of Aqua Tofana [AQUA TOFANA, P. C.], but its composition was never accurately made known.

The practice of secret poisoning was carried to a great extent in France about the year 1670. One of the most distinguished agents in this business was Margaret d'Aubray, wife of the Marquess de Brinvilliers. She formed an improper intimacy with a villain named Sainte Croix, who taught her the art of poisoning, which she put in practice in order to better her circumstances. For the purpose of ascertaining the strength and action of her poisons, she assumed the dress of a nun, and distributed food to the poor, nursed the sick in the Hotel Dieu, and administered to them her poisons. She poisoned her father and brother, but was at last discovered. She was publicly beheaded in Paris on the 16th of July, 1676. She left behind her a complete catalogue of all her crimes. The principal poison used by herself and accomplices was the corrosive sublimate. The practice at this time had extended so widely in France that the government thought it necessary in 1679 to institute a court under the title of Chambre de Poison, or Chambre Ardente. The powers of this court however were abused, and very shortly after its institution it was suppressed.

Wherever evidence has been left sufficiently positive to admit of an inquiry into the nature of these secret poisons, it has been found that they contain ingredients well-known at the present day. It is only where the sciences of chemistry and medicine are not sufficiently known, or where they are neglected in the inquiry that secret poisoning can take place. In this country we have recently seen an instance at Happisburgh in Norfolk, where, from the neglect of inquiry, a man succeeded in poisoning at different times his wife, two grandchildren, and other members of his family, and several neighbours, amounting in all to 16 or 18 people, and eventually poisoned himself without discovery till after his death. Secret poisoning is at the present day practised in Turkey. Mr. Madden says, that whilst residing in that country he witnessed eight cases, in most of which death ensued within twelve hours, and in all within forty-eight hours. It is not uncommon amongst uncivilized nations. Dr. James, in his account of Major Long's Expedition, says that 'The celebrated chief, Black Bird, of the Omahaws, gained great reputation as a medicine man; his adversaries fell rapidly before his potent spells. His medicine was arsenic, furnished him for this purpose by the villany of the traders.'

(Beckmann, *History of Inventions*; Beck, *Medical Jurisprudence*; Adams, *Edinburgh Medical and Surgical Journal*, vol. xxxiii.)

POISSON, SIMEON DENIS. We regret that we are unable, from want of materials, to give any account of the private life of this very eminent mathematician. He was born June 21st, 1781, in an humble station, and was admitted in 1798 a pupil of the Ecole Polytechnique. M. Fourcy, in his history of this school, records the manner in which the young student, at the age of eighteen, attracted the notice of Lagrange by an improvement in the method of demonstrating the binomial theorem, which the latter read publicly to the class, and announced his intention of abiding by it for the future.

Poisson never held any political situation, or took public share in anything but education. In 1828 he was baron, officer of the legion of honour, repetiteur-adjoint and permanent examiner of the Polytechnic School, member of the Council of Public Instruction, and of the Academy of Sciences. He died April 25th, 1840.

As far as so few words can go, it may be said that the labours of Poisson were directed to the introduction of the use of definite integrals into all branches of mathematical physics, and the extension of the various branches by their means. There is nothing out of which to make a popular reputation; the successes of Poisson are all purely mathematical, and none but the mathematician can as much as understand the description of them.

The greater part of the writings of Poisson are contained in various periodicals, particularly the Memoirs of the Institute, the Journal of the Polytechnic School, the *Annales des Mathématiques*, the *Connaissance des Tems*, &c., &c. There is hardly any subject on which they do not treat, and almost always with decided success; electricity, magnetism, heat, gases, capillary attraction, gravitation, the pendulum, &c. &c., are titles each of which suggests to the well-informed mathematician of our time the memory of some ably-written paper by Poisson. His object was to leave no branch of physics unexplored by aid of the new and powerful methods of investigation which a school yet more modern than that of Lagrange and Laplace had added to the pure mathematics. Towards the end of his life he began to collect his scattered memoirs into separate works, with the additions which his subsequent researches had given.

Poisson's separate works are—1, 'Traité de Mécanique,' Paris, 1811, 2 vols. 8vo.; second edition, Paris, 1833, 2 vols. 8vo. Perhaps this is the best elementary work on a branch of mathematical physics which exists, considered as an introduction to the use of modern analysis. An English student should read with it some of our own writers, who abound in examples. 2, 'Nouvelle Théorie de l'Action Capillaire,' Paris, 1831, 4to. The principal distinction between this theory and that of Laplace, physically speaking, is the consideration of the variation of density which takes place at the end of the capillary column of fluid. 3, 'Théorie Mathématique de la Chaleur,' Paris 1835, 4to. The data from which Poisson starts are derived from the experiments on the nature of heat, made subsequently to the time of Fourier, his great predecessor in this branch of the subject. 4, 'Recherches sur la Probabilité des Jugemens en Matière Criminelle et en Matière Civile,' Paris, 1837, 4to. This is, in fact, a treatise on the theory of probabilities, with especial reference to its application to matters of evidence, particularly of the judicial kind. With the exception of some partial substitution of definite integrals for series, there is little advance, mathematically speaking, upon Laplace; but the application is much more extensively treated, and in new points of view. Accordingly, Poisson has, with great judgment, made the application the heading of the whole work, though it occupies only the quarter of its space. It is said that Poisson left another work nearly finished; but it has not yet been published.

POLANI'SIA (from πολ, many, and ἄνισος, unequal; stamens numerous and unequal), a genus of plants belonging to the natural order Capparideæ. It has 4 spreading sepals, 4 petals, a small torus; silique sessile within the calyx or hardly stipitate, terminated by a distinct style.

P. icosandra has a stem covered with viscid glandular hairs, 3 to 5 foliolate leaves, the leaflets obovate, cuneate, or oblong pubescent, scarcely longer than the petiole. The stamens are about 10 in number. The silique terete striated, rough with glandular horns, sessile and acuminated. It is native of the East Indies, and is used in Cochin China as a counter-irritant in the same way as sinapisms in Europe, and as a vesicant. The root is used as a vermifuge in the United States of America.

P. graveolens is a plant beset with glandular hairs; it has trifoliate leaves, elliptical oblong leaflets, from 8 to 12 stamens, oblong siliques narrowed at the base, glandularly muricated and pubescent. It is native of North America, and is employed as a vermifuge.

The species of this genus are all annual plants from tropical countries: the seeds require to be sown in a hotbed frame, and when the plants are of sufficient size they should be planted out in the open border in a sheltered situation, but this should not be done before the middle of May. A plant of each should be kept in pots and placed in the greenhouse during the summer in order to secure seeds for next year's sowing, in case the summer should prove unfavourable for ripening in the open border.

POLARIZATION. [CIRCULAR POLARIZATION, P. C. S.; ELLIPTIC POLARIZATION, P. C. S.]

POLARIZATION, MOVEABLE, is the name given by Biot to a supposed oscillatory movement of the molecules of polarized light in passing through a plate of doubly refracting crystal; and the hypothesis was proposed in order to account for certain variations of tint observed in the coloured images produced by the *ordinary* and *extraordinary* pencils of light.

This philosopher assumed that, in permanently polarized light which has been transmitted through a doubly refracting medium, the molecules composing the ordinary pencil or ray have their axes at right angles to those of the molecules which compose the extraordinary pencil; and M. Arago having observed that the tints of the two images formed after the transmission of a pencil of polarized light through a plate of sulphate of lime varied with the thickness and position of the plate—that at certain angles of incidence the red rays entered wholly into one image and the green or violet rays into the other, while at other angles of incidence the contrary phenomena occurred,—he was led to imagine that the polarized pencil, after having entered the plate, does not assume the character of permanently polarized light till it has penetrated to a certain depth, depending on the degree of attractive or repulsive power to which the particles are subject in the medium; and he conceived that, previously to being in that state, the axes of the molecules assume, in a series of alternations, first one and then the other of two particular planes of polarization.

Considering then that the phenomena of the colour seen in polarized light are analogous to those of Newton's rings, the ordinary and extraordinary rays giving rise to colours corresponding to those of the rings seen after transmission and reflexion respectively, M. Biot infers that, as these transmissions and reflexions take place alternately at intervals between the plates which, for homogeneous light of any colour, are comprehended between the terms in the series of distances 0, e, $2e$, $3e$, &c., so, in the passage of light through the plate of sulphate of lime, the alternate polarizations take place at intervals equal to those between the terms in a corresponding progression, these intervals being, however, much greater than the others. Thus, till the polarized light has penetrated to a depth represented by e' in the crystal, the molecules are conceived to be polarized in the original plane of polarization; between the depths represented by e' and $2e'$ they are supposed to be polarized in a plane making with the origina plane of polarization an angle equal to that which the two axes of the biaxal crystal make with each other; within the next depth, that is between $2e'$ and $3e'$, they appear to be again polarized in the first plane, and so on.

In the same kind of crystal the values of e' are supposed to differ for the different kinds of light, but the limits of the oscillation are the same for all particles whose motions are in the same direction; and the oscillatory motion is supposed to cease when the luminous particles quit the posterior surface of the plate and pass into the air, or enter into any other medium which has not the property of double refraction.

The phenomena presented by mica, beryl, rock-crystal, Iceland spar, and many other crystals, are the same as those presented by sulphate of lime, except with respect to the thicknesses at which the periodical variations of the tints take place; and they are equally capable of being explained by the hypothesis of a moveable polarization: the oscillations, however, do not take place on each side of a line bisecting the angle between the two axes of the biaxal crystal, but on each side of the plane towards which the axes of the particles in the pencil ordinarily refracted by the plate would be turned if those particles had acquired a permanent polarization.

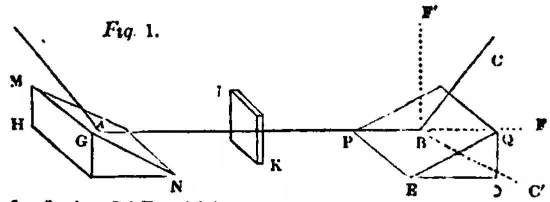
Though Biot's hypothesis of moveable polarization has been found capable of explaining most of the phenomena of polarized light, both that in which the incident pencil consists of parallel rays and that in which, the rays being convergent, coloured rings [POLARIZED RINGS, P. C. S.] are produced, yet it is known to be, in many respects, defective. The displacement of the plane of polarization in plates of crystal may be satisfactorily explained on the principles of the undulatory theory: thus, suppose a polarized ray to be incident perpendicularly on a crystallized plate having its principal section inclined to the plane of primitive polarization in a certain angle; that ray will then be resolved into two, the vibrations of the ætherial molecules in which are respectively performed in the principal section and perpendicularly to it. Now, if the thickness of the plate be such as to render the difference between the lengths of the paths of the rays within the crystal equal to an exact number of vibrations, the rays will emerge from the plate in exact accordance: in this case the ordinary and extraordinary rays being polarized in opposite planes, they will not destroy each other, and it will be found that the resultant ray, at emergence, is, in respect of intensity and polarization, similar to the incident ray. But if the difference between the lengths of the paths within the crystal be an exact odd multiple of half an undulation, the waves at their egress will be in discordance, and the resultant ray, at emergence, will become polarized in a plane making an angle with the plane of the incident ray equal to twice that at which the principal section of the plate is inclined to the plane of primitive polarization.

POLARIZED RINGS. Between the year 1812 and 1816 several important properties of polarized light were discovered by philosophers in England, France, and Germany, and of these the formation of the coloured rings which are seen when polarized light is transmitted through plates of a doubly refracting crystal, are the most remarkable.

As early as 1811 MM. Arago and Biot had observed the variations in the colours of images, which take place when polarized light is transmitted through plates of mica: and in 1812 Dr. (Sir David) Brewster had made similar observations with agate, mica, and topaz. But the British philosopher vastly extended this branch of optics by his discovery of the systems of rings, which may be seen both in bi-axal and uni-axal crystals when conical pencils of polarized light are transmitted through them; and his experiments, with those of Young, Wollaston, and Sir John Herschel, in England, have afforded ample materials for determining the laws of the phenomena. In 1813 Brewster observed circular rings in ruby, emerald, and beryl; in the following year the like were witnessed by Dr. Wollaston in Iceland spar and in 1815 they were seen by M. Biot in France and by Dr. Sebeck at Nürnberg.

In order to understand the manner in which the phenomena may be observed, it will be convenient to imagine that the light is polarized by reflexion: thus let MN be the upper surface of a plate of glass either parallel or inclined to the horizon; (a plate of obsidian or a pile of glass plates placed one on another may be employed) its posterior surface being blackened; and let PQ be the surface of a second plate of glass having its posterior surface also blackened. The former is called the polarizing and the latter the analyzing plano. Let SA be the axis of a slender pencil of light from the clouds or from a lamp surrounded by unpolished glass, and let it fall on MN at an angle of incidence equal to 56° 47′, the reflected pencil, of which let AB be the axis, will then be polarized in the plane

Fig. 1.

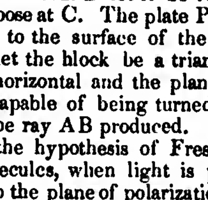


of reflexion SAB, which may be called the plane of primitive polarization; and in this state let it fall on PQ at an equal angle of incidence: from B let it be reflected to the eye of the observer, suppose at C. The plate PQ should be attached, as in the figure, to the surface of the block PQED; and, for convenience, let the block be a triangular prism of which the plane PD is horizontal and the plane EDQ vertical: the block should be capable of being turned on an axis as BF in the direction of the ray AB produced.

Agreeably to the hypothesis of Fresnel the vibrations of the ætherial molecules, when light is polarized, take place perpendicularly to the plane of polarization; therefore, if the plates MN and PQ are disposed as in the figure, so that the course SABC of the ray is in one plane (suppose vertical) and no object is placed in the direction of the pencil AB, the vibrations will take place after reflexion from PQ, exactly in the same manner as they take place between the mirrors, and the spectator will have a strong perception of the reflected light. But if PQ be turned on the axis ABF, the perception of the reflected light diminishes; and when the base PD is perpendicular to its first position, in which case the planes SAB and ABC are at right angles to one another, the vibrations are destroyed in consequence of a polarization with respect to the plane ABC′, so that the eye at C′ has no perception of reflected light.

Now, let a thin plate of Iceland spar, ruby, emerald, or other uni-axal crystal cut with parallel surfaces, each perpendicular to the axis of the primitive crystal, be placed as at I K in the direction of the polarized pencil AB, the former state of the pencil BC will be partially restored; and an eye at C′ receiving the pencil through a small aperture, there will be

Fig. 2.



seen in the field of view a number of concentric circular rings of different colours, traversed by a black cross consisting of branches at right angles to one another. When the phenomenon is observed with common white light polarized as above said, the centre of the field is occupied by a black spot surrounded by a deep blue colour, which gradually declines to whiteness; and, proceeding from the centre outwards, the colour becomes successively a pale yellow, orange and deep red, similar to the first series of Newton's rings. [COLOURS OF PLATES, P. C. S.] The colours in the succeeding rings are arranged in the like order till the rings cease to be perceptible, the cross remaining black.

The phenomena may be observed with equal or greater facility by placing the plate of Iceland spar or other crystal between two plates of tourmaline parallel to each other and to the plate of spar, and observing the lights directly through them: the plate of tourmaline which is farthest from the eye polarizes the light transmitted through it as the plate MN (*Fig.* 1) polarized it by reflexion; and the plate nearest to the eye, having its axis perpendicular to that of the former plate, performs the same office as the analyzing plate PQ, when the surface of the latter is perpendicular to MN. The plates of tourmaline should be cut with their surfaces in planes passing through, or parallel to, the axis of the natural prism; and what is called the axis of the plate is any line drawn on either of its surfaces parallel to the axis of the prism.

In 1813 Dr. Brewster observed that certain crystals, when polarized light was transmitted through them, exhibited two distinct systems of rings; and his first observations were made on blue topaz: a plate of this mineral being placed, as at IK (*Fig.* 1), and the analyzing plate PQ being turned round on BF till PD was in a vertical position, that is, till the plane ABC was at right angles to SAB, there appeared a system of rings, apparently elliptical with a rectilinear band quite dark in the direction of the major axis: the colours of the rings apparently corresponding to those of Newton's rings when seen by reflexion. By turning the plate PQ on BF as an axis 90° further, or 180° from the position in the figure, the series of rings appeared with colours seemingly complementary to those of the former series, or, apparently similar to those of Newton's rings seen by transmission. But, turning the plate PQ on an axis BF′ perpendicular to BF in the plane SAB of primitive polarization, there was found a position in which, by the reflected ray BC, there was seen a system of oval rings similar to the first. Dr. Brewster observed the like phenomena with plates of mica, nitre, sulphate of lime, &c.; and this led to the discovery that, in such crystals, there are two axes along which there is no double refraction. These are the *optic axes* of the crystal, or, as they were called by Brewster, axes of no polarization. In different crystals these axes have different inclinations to one another; in mica they make with each other an angle of 45°, in nitre much less; and a plate of crystal cut for the purpose of exhibiting the double system of rings should have its faces cut perpendicularly to a line bisecting the angle formed by the optic axes.

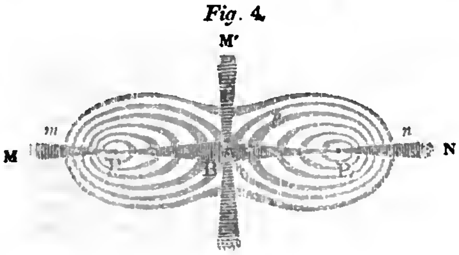
Now, if a plate of any bi-axal crystal, as mica, nitre, &c., be placed as at IK in the direction of the polarized ray, and be turned so that one of the optic axes is coincident with that ray; the analyzing plate PQ (*Fig.* 1) being also turned so that the reflected ray BC may be in a plane at right angles to SAB, there will be seen, about a dark point P (*Fig.* 3), representing that in which the axis intersects the field of view, a series of oval rings brightly coloured and divided

Fig. 3

unequally by a dark band MN. A like series of rings about a point corresponding to P, with a dark band like MN passing through that point, will be seen if the plate of crystal be turned so that the other optical axis is in the direction of the polarized ray AB. And when the angle which the optical axes make with one another, or with a perpendicular to the surface of the crystal, is small, as in nitre, both series of rings with their bands may be seen at the same time.

When a plane passing through AB (*Fig.* 1), and the two optic axes of the crystal is made, by turning the plate of crystal on the ray AB, to coincide with the plane SAB of primitive polarization, the dark curves passing through the two polar points P and P′ (*Fig.* 4) become one straight line MN; the coloured rings come together as in the figure and

Fig. 4.



are crossed by another dark line as M′N′ passing through B the centre at right angles to the former. This appearance takes place at every quarter revolution of the crystal plate IK (*Fig.* 1), on the axis AB; and by actual admeasurement the coloured rings are found to have the form of lemniscates, whose principal property is that the product of two lines drawn from the points P and P′ to any point in each curve is constant.

The general equation of Bernoulli's lemniscate is

$$(x^2+y^2)^2-p^2(x^2-y^2)=0$$

in which p is equal to half the axis mn of the particular curve, x and y are rectangular co-ordinates of any point as p in the curve, B the centre being the origin. If BP or BP′ be represented by a, and p be made equal to $a\sqrt{2}$, the product of two lines as Pp, P′p (not drawn in the figure) will be equal to a^2. But, in order to allow B P to be constant for all the different curves, the equation may be put in the form

$$(x^2+y^2)^2+a^2(a^2-b^2)-2a^2(x^2-y^2)=0,$$

in which b may be of any magnitude whatever from zero to infinity; and from this equation the value of the rectangle Pp, P′p for any one curve is the product ab.

In explaining the phenomena of polarized rings on the undulatory hypothesis, it is assumed that a pencil of polarized light, in its passage along the axis, or along one of the axes of a doubly refracting crystal, ceases to have its ordinary and extraordinary ray polarized in planes exactly at right angles to one another, in consequence of the different degrees of retardation which the waves in the two kinds of rays experience in passing through the crystal, so that they emerge from it in different phases: hence, instead of the dark spot which, on looking into the plate PQ (*Fig.* 1), when the planes SAB and ABC are at right angles to one another, would present itself to the eye, the light partially depolarized gives rise, on entering the eye, to the perception of the coloured rings.

The crystal being uni-axal, let v be the velocity of light before it is incident on the crystal, λ the length of a wave, and a^2 the expression for the intensity of the impression of light when the vibration is a maximum: also within the crystal, let $a \sin. \frac{2\pi}{\lambda} vt$ be the extent of a vibration of polarized light (perpendicularly to the primitive plane of polarization) in the ordinary ray; and, representing the excess of the retardation of the extraordinary ray above that of the other by R, the vibration of a particle perpendicular to the plane of primitive polarization, in the most retarded ray will be represented by $a \sin. \frac{2\pi}{\lambda}(vt+\mathrm{R})$.

By two successive resolutions of forces, the vibrations perpendicular to the plane of primitive polarization reduced first to directions perpendicular and parallel to a plane passing through the optic axes of the crystal (the angle between these planes being represented by θ), and then to directions perpendicular to the plane of polarization at the analyzing plate, (those vibrations alone producing a perception of light in the eye, which are perpendicular to the plane of polarization) the angle between that plane of polarization and the plane of primitive polarization being represented by α; a resolved vibration, for the ordinary pencil produced by the double refraction of the crystal becomes

$$a \cos. \theta \cos. (\theta+\alpha) \sin. \frac{2\pi}{\lambda} vt \quad ,$$

and, for the extraordinary pencil,

$$a \sin. \theta \sin. (\theta+\alpha) \sin. \frac{2\pi}{\lambda}(vt+\mathrm{R}).$$

Developing $\sin. \frac{2\pi}{\lambda}(vt+\mathrm{R})$ and then adding together the squares of the coefficients of $\sin. \frac{2\pi}{\lambda} vt$ and $\cos. \frac{2\pi}{\lambda} vt$ the sum

$$a^2\left\{\cos.^2 \alpha - \sin. 2\theta \sin. (2\theta+2\alpha) \sin.^2 \frac{\pi}{\lambda} \mathrm{R}\right\}$$

is, by the undulatory theory, an expression for the intensity of light in the image, at a point where the apparent field of view is intersected by a ray whose inclination to the axis AB (*Fig.* 1) enters into the expression for R; the plane passing through such ray and the axis AB making with the plane of analyzation a variable angle equal to $\theta+\alpha$.

Putting ψ for $\theta+\alpha$ the above expression has the form

$$a^2\left\{\cos.^2 \alpha - \sin. (2\psi-2\alpha) \sin. 2\psi \sin.^2 \frac{\pi}{\lambda} \mathrm{R}\right\} ; \qquad (a)$$

and, when $\alpha=90°$, or the planes of polarization for the rays AB and BC are perpendicular to one another, the last expression becomes

$$a^2 \sin.^2 2\psi \sin.^2 \frac{\pi}{\lambda} \mathrm{R} \quad : \qquad (b)$$

the length λ of a wave differs for the different kinds of light, but the conclusion arrived at being independent of any particular value of λ, it follows that all the light vanishes when $\psi=0$, 90°, 180° and 270°; consequently there are at the same time two lines or bands traversing the coloured field of view at right angles to one another, in which the light vanishes; and thus there is produced the appearance of a dark cross, the point of intersection being in the centre of the field, or where the latter is traversed by the ray AB.

When $\alpha=0$, or the planes of polarization in AB and BC are coincident, the expression (a) becomes

$$a^2 \left(1-\sin.^2 2\psi \sin.^2 \frac{\pi}{\lambda} R\right) \qquad (c)$$

which when $\psi=0$, $90°$, $180°$, and $270°$ becomes a^2, a maximum: hence the coloured field of view will be traversed by a white cross whose arms are at right angles to one another.
