SUPPLEMENT

TO

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

[The abbreviations P. C. and P. C. S. signify the Penny Cyclopædia and Penny Cyclopædia Supplement.]

HABENA'RIA, a genus of plants belonging to the natural order Orchideæ. The tribe has a ringent hooded perianth, a 3-lobed entire spurred lip. There are three species natives of Great Britain.

Habenaria viridis, the Frog Orchis, has a very short 2-lobed spur, linear flat 3-pointed lip, the middle point the shortest. The flower is green, and the lip of a brownish colour. It is the Peristylus of Lindley, and the Himantoglossum of Reichenbach. It grows in pastures.

H. bifolia, the Lesser Butterfly Orchis, is distinguished by the lip being linear and entire, and the pollen masses parallel. The flowers are white. It is found in heathy places.

H. chlorantha, the Great Butterfly Orchis, has the same general characters as the preceding species; but the flowers are larger and the plant is taller and stouter. The pollen masses ascend obliquely and converge upwards. It grows in moist woods and thickets.

(Babington, *Manual of British Botany*.)

HABINGTON, WILLIAM, was the son of Thomas Habington, a Roman Catholic gentleman of family and fortune in Worcestershire. His mother, the daughter of Lord Morley, has been supposed to have been the writer of the famous letter which revealed the Gunpowder Plot [FAWKES, GUY, P. C.]; and her husband (who had been long imprisoned as implicated in Babington's conspiracy) gave shelter to some of the accomplices of Fawkes, and was sentenced to die, but received a pardon through the intercession of his wife's brother, on condition of retiring to his manor of Hindlip. Their son had been born there upon the very day now marked as the date of the plot, the 5th of November, 1605. He was educated in the Jesuit college of St. Omer, and afterwards at Paris; and endeavours were used, but in vain, to induce him to enter the society. He returned to England, and lived in retirement with his father, who long survived him, and who directed and co-operated with him in historical and other studies. William Habington married Lucy, daughter of William Herbert, the first Lord Powis; and the whole of his subsequent life appears to have been spent in literary and rural quiet. It is said by Anthony Wood that he 'did run with the times, and was not unknown to Oliver the Usurper,' a charge which may either be untrue or involve nothing discreditable. He died at Hindlip on the 13th of November, 1645, when he had but just completed his fortieth year. His published writings were the following:—1, 'Castara,' a collection of poems, first printed together in 1635, and again more fully and correctly in 1640. They were included in Chalmers's English Poets in 1810, were reprinted separately in 1812, and are given wholly in Southey's 'Select Works of the British Poets.' The name at the head of them is the poetical one he gave to the lady whom he married. They are in three parts: the first containing sonnets and other small pieces, chiefly addressed to his mistress before marriage; the second part containing similar poems, chiefly addressed to her as his wife; and the pieces in the third being mainly religious and contemplative. 2, 'The Queen of Arragon, a Tragi-Comedie,' acted both at court and at the Blackfriars theatre against the author's will, printed in 1640, folio, brought again upon the stage in 1666, with a prologue and epilogue by the author of Hudibras, and reprinted in all the three editions of Dodsley's 'Old Plays.' 3, 'The History of Edward IV.,' 1640, folio, said to have been partly written by his father. 4, 'Observations upon History,' 1641, 8vo.

Habington's poems, although infected by the tendency to puerile and abstruse conceit which prevailed in his time, are yet in most parts exceedingly delightful. Their fancy is sweet, especially in rural description; their feeling is refined and ideal; the language is correct and tasteful; and the tone of moral sentiment is everywhere pure and elevated. The romantic and chivalrous cast of thought and sentiment gives much interest to his play, although the story is meagre, and the characters are not vigorously depicted.

HABZE'LIA, a genus of plants belonging to the natural order Anonaceæ. It has a 3-lobed calyx; 6 petals, the inner ones smallest; the stamens very numerous; the torus convex, the carpels distinct, indefinite in number, long, cylindrical, obsoletely ventricose or torulose, smooth, striated lengthwise, becoming many-celled by the pericarp growing together; many-seeded, the seeds elliptical, arillate, somewhat erect, numerous, shining, one in each of the cells of the fruit; tho acillus formed of 2 white unequal obcordate membranes.

H. Æthiopica has ovate-acute leaves, 3 inches long, 12 to 14 lines broad, smooth on the upper surface, and downy beneath; the carpels are pod-shaped, 1-2 inches long, knotted, striated, quite smooth, with the taste of pepper. The fruit has a pungent aromatic taste, and is often substituted for other spices. It is the *Piper Æthiopicum* of the shops, and the Nuona Æthiopica of Duval and other botanists. It is a native of Sierra Leone. *H. aromatica* is another species, yielding a pungent aromatic fruit. It grows in the forests of Guyana, and the fruit is used by the negroes as a condiment.

(Lindley, *Flora Medica*.)

HACKERT, PHILIPP, a celebrated German landscape painter, was born at Prenzlau in Prussia, in 1737. His father was a portrait painter and a native of Berlin, where Hackert spent some time with an uncle who was a decorative painter. He acquired his chief knowledge of painting, however, by copying good pictures; and he derived great benefit also from the acquaintance of Le Sueur, the director of the Berlin Academy, and of Sulzer. In 1765 he visited Paris, and in 1768 he went, with his brother Johann, to Italy. They spent some time in Rome sketching and painting the scenery about Albano and Tivoli: many of their works were purchased by Lord Exeter. Philipp's first works of importance however were the six large pictures of the Russian naval victory of Tschesme, and the burning of the Turkish fleet, by Count Orlow, in 1770, painted for the empress Catherine II. of Russia, and for which he was paid 2950 zecchini, about 16,000 florins, or 1350*l.* sterling. Count Orlow, to whom the works were sent at Leghorn, was upon the whole highly gratified by their successful accomplishment, but he was dissatisfied with the representation of the explosion of a ship, in the picture of the burning of the fleet; and in order to give the artist a proper impression of such a catastrophe, he ordered, with a spirit worthy of an autocrat, one of the frigates of his fleet, an old vessel, to be blown up in the presence of Hackert, in the roads of Leghorn, and he was well satisfied with the results of his experiment, for Hackert greatly improved the picture. These works, with six other similar subjects, are now at St. Petersburg. In 1772, the year in which the first-mentioned pictures were completed, Johann Hackert died at Bath, aged only twenty-nine; he came to England with some pictures which had been ordered by English travellers in Rome. In the meanwhile two other brothers, Wilhelm and Karl, joined Philipp in Rome, but Wilhelm went shortly afterwards to St. Petersburg, and died there in 1780, aged only thirty-two, and Karl settled in Switzerland. Philipp accordingly in 1778 sent for his youngest brother Georg, who was an engraver at Berlin, and they lived together from that time until the death of Georg at Florence in 1805.

Hackert was highly patronised in Rome both by Italians and foreigners; Pius VI. was delighted with his works, and his reputation as a landscape painter was unrivalled by any of his contemporaries, though he was a very inferior painter to Wilson, who was neither appreciated nor known at that time: Wilson left Rome in 1755. In 1777 Hackert made a tuur in Sicily with Richard Payne Knight and Charles Gore; and in 1778 a tour in the north of Italy with Charles Gore and his family. In 1782 he went to Naples and was presented to the king, Ferdinand IV., by the Russian ambassador, Count Rasumowsky. The king took great pleasure in the works of Hackert, and treated him with great kindness and familiarity; he used to style him Don Filippo. In 1786, after the departure of Count Rasumowsky, he appointed Hackert his principal painter, who settled with his brother from that time in Naples. They had apartments in the Palazzo Francavilla on the Chiaja, which they occupied until they were dispossessed by General Rey, the French commandant of Naples in 1799, who took possession of them himself; he however treated the Hackerts with great kindness, gave them passports, and suffered them to depart with all their goods and chattels, with which they arrived safely at Leghorn. Hackert's salary was 100 ducats per month, with his apartments free, both in Naples and at Caserta. In 1787 Hackert painted a large picture of the Launch of the Parthenope, 64, the first ship of war which was built at Castel-a-Mare; it was engraved by his brother Georg; he painted five other large pictures of Neapolitan seaports, which were all enlivened by some historical scene of interest: they are in the palace at Caserta. In 1788 the king sent him to Apulia to make drawings of all the seaports of that coast, which he painted, from Manfredonia to Taranto. In 1790 he visited on a similar mission the coasts of Calabria and Sicily: the king equipped for him a small felucca called a scappavia, manned with twelve men well armed, for the express purpose; he was out about five months, from April to August inclusive.

Hackert lived, after his departure from Naples in 1799, a short time in Leghorn, whence he removed to Florence, where he resided in a villa which he purchased in 1803, until his death in April, 1807.

Hackert's works are not remarkable for any particular quality of art: they are simple portraits or prospects in ordinary light and shade, and their beauty accordingly depends upon the local beauty of the scene. The detail is careful, without being minute, and where a memento of any particular scene is the chief object of desire, his works are calculated to give perhaps complete satisfaction, except in the case of some fastidious connoisseur who might require a bolder and more artistic foreground than those which characterise his works generally. His drawings are extremely numerous, and his paintings are not rare; many of them have been engraved. He painted in oil, in encaustic, and in body water-colours or à guazzo, a species of distemper. He also etched several plates.

Goethe has written a eulogistic Life of Hackert, whose close imitation of nature delighted the German critic, and he has extolled him beyond his merits; while he compares Flaxman with Sabatelli, and damns his noble designs with the faint praise that they have some pretty ideas in them; he condemns them for their want of detail in execution.

(Goethe, *Werke—Philipp Hackert;* and *Winckelmann und sein Jahrhundert.*)

HACKNEY-COACH. The derivation of the word Hackney, as applied to a class of public conveyances, has occasioned much speculation. Bailey, in his Dictionary, adopts what appears to have become a popular notion, that the name is derived from the suburb of London so called; for which supposition however we find no plausible ground; but he adds, 'unless you would rather have it from the French *Hacquenée*,' which is a word of similar meaning. Many curious conjectures on the subject are given in Todd's 'Johnson's Dictionary,' and in the lexicographical division of the 'Encyclopædia Metropolitana.' From these it is evident that a similar word is found in most European languages. Menage traces the French form from the Latin *equus*, a horse, thus:—*equus, akus, akinus, akineus, akinea, haquenée.* Another conjecture derives it from an Anglo-Saxon word meaning to *neigh*, on the supposition that a lively horse, given to neighing, would be the most likely to be lent for hire. Perhaps the most probable derivation is from *haque*, an old French word for a gelding, which would be fitter than a more spirited *neighing* horse for hiring for public use. However this may be, it is sufficiently evident that the term *hackney* was first applied to horses let for hire, and then, by a very natural transition, extended to coaches, and subsequently to sedan-chairs, employed in a similar way.

By the act 1 & 2 Wm. IV. c. 22, by which the laws relating to hackney-carriages in London were consolidated and amended, it is declared that every carriage with two or more wheels, used for plying for hire in any public street at any place within five miles from the General Post-office in London, of whatever form or construction, or whatever may be the number of persons which it shall be calculated to convey, or the number of horses by which it shall be drawn, shall be deemed a *hackney-carriage;* and the distinction between hackney-carriages and *stage-carriages* is further implied, rather than distinctly expressed, by the provision that nothing in the act shall extend or apply to any stage-coach used for plying for passengers to be carried for hire *at separate fares.* A hackney-carriage is one which may be hired at certain regulated fares, calculated either by time or distance, and being the same whether it is hired by one person or by the full number which it is licensed to carry, to run in any required direction, and at any required time, under certain regulations provided by law; while a stage-carriage is one which performs a certain specified journey, at a specified time, carrying passengers only in the line of its specified route, at a certain fare (which is not regulated by act of parliament), for each individual passenger, the amount of such fare being usually, though not invariably, dependent upon distance.

So far as can be gathered from such notices as the writer has met with, this class of public vehicles appears to have originated in London. The rise and progress of their use in London may be pretty distinctly traced from notices in Macpherson's 'Annals of Commerce,' and in Anderson's 'History of Commerce,' of which work the early volumes of Macpherson are a reprint with but few alterations. Under the year 1625 Macpherson, or rather Anderson, observes that 'Our historiographers of the city of London relate that it was in this year that hackney-coaches first began to ply in London streets, or rather at the inns, to be called for as they were wanted; and they were at this time only twenty in number.' In 1634 sedan-chairs appear, for the first time, to have entered into competition with hackney-coaches, the sole privilege being granted in that year to Sir Sanders Duncomb to 'use, let, and hire' a number of 'covered chairs,' such as he represented to be in use in many places beyond sea, for a period of fourteen years; the avowed reason for their introduction being the inconvenience occasioned in the streets of the metropolis by 'the unnecessary multitude of coaches.' In the following year an attempt was made to check the increasing annoyance occasioned by the 'general and promiscuous use of coaches' by a proclamation from the king (Charles I.) that no hackney or hired coach should be used in London, Westminster, or the suburbs, unless it were engaged to travel at least three miles out of the same, and that every hackney-coach owner should constantly maintain four able horses for the royal service when required. Finding it impossible to prevent the use of so great a convenience, a commission was issued to the master of the horse in 1637 to grant licences to fifty hackney-coachmen in and about London and Westminster, and as many others as might be needful in other places in England, each coachman being allowed to keep not more than twelve horses. In 1652 the number of hackney-coaches daily plying in the streets was limited to 200; in 1654 it was increased to 300, allowing however only 600 horses; in 1661 to 400; and in 1694 to 700. By an act of the 9th year of Anne (c. 23) the number was to be increased to 800 on the expiration, in 1715, of the licences then in force, and 200 hackney-chairs were also licensed. The number of chairs was shortly increased to 300, and by the act 12 Geo. I. c. 12, to 400. In 1771 the number of coaches was further increased to 1000.

Notwithstanding this steady increase in the use of hackney-coaches, they were long assailed as public nuisances in a way which it is amusing to look back upon. Some curious details on this subject are given in Knight's 'London,' vol. i. p. 27, &c., from which it appears, by a quotation from a letter of Garrard, that the first hackney-coach *stand* was established in 1634, by one Captain Baily, at the May-pole in the Strand. Even so late as 1660 Charles II. issued a proclamation against hackney-coaches standing in the streets to be hired; but on the very day it was to come into force, Pepys records that he got one to carry him home. The monopoly long enjoyed by the London hackney-coachmen produced great indifference to the increasing wants of the community; and down to the year 1823, while that monopoly was undisturbed, hackney-coaches appear to have sunk lower and lower in the scale of efficiency. 'For some two hundred years,' observes Mr. Knight, in the work above referred to, 'those who rode in hired carriages had seen the hackney-coach passing through all its phases of dirt and discomfort; the springs growing weaker, the 'iron ladder' by which we ascended into its rickety capaciousness more steep and more fragile, the straw filthier, the cushions more redolent of dismal smells, the glasses less air-tight.' So slow, also, were their movements, that it was almost hopeless to think of gaining time by riding in them.

While this was the state of things in London, a lighter kind of vehicle, drawn by one horse, had been brought into extensive use in Paris. In the year 1813, according to a paper on the 'Vehicular Statistics of London,' in No. 78, new series, of 'Chambers's Edinburgh Journal' (to which we are indebted for many of the following particulars), there were no less than 1150 of these vehicles, which were called *cabriolets de place*. Efforts were made to introduce similar vehicles into this country, but, owing to a regard for the 'vested rights' of the hackney-coach owners, it was long found impossible to get licences for them. With great difficulty Messrs. Bradshaw and Rotch (the latter a member of parliament) obtained licences for eight cabriolets in 1823, and started them at fares one-third lower than those of hackney-coaches. The new vehicles were hooded chaises, drawn by one horse, and carrying only one passenger besides the driver, who sat in the cabriolet (or, as more commonly called for brevity, the *cab*), with his fare. An improved build was soon introduced, by which room was provided for a second passenger, and the driver was separated from the fare; and with the rapid extension of this lighter class of vehicles, numerous varieties of construction have been introduced, in most of which the original model is completely lost sight of, but in which comfortable and safe accommodation, with complete shelter from the weather and separation from the driver, is provided for two, three, or, in a few cases, four persons. The name 'cab' is still commonly applied to all hackney-carriages drawn by one horse, whether on two or four wheels. During the first few years of the employment of such carriages their number was restricted to sixty-five, while the number of coach-licences was increased to twelve hundred; but in 1832 all restriction as to the number of hackney carriages was removed, and in the paper above referred to it is stated, on the authority of information received from the registrar of hackney-carriage licences, that the number of hackney-carriages licensed for use during the year ending January 4, 1845, was 2450, all of which, with the exception of less than 200, were cabs, or one-horse vehicles. The number of drivers licensed during the year ending May, 1844, was 4627, besides 371 'watermen,' or attendants upon the 130 regular metropolitan coach-stands.

While the changes above noticed have greatly benefited the public, there is reason to fear that the great increase of accommodation has not been accompanied by any elevation of moral character in the large class of men engaged in this business. Since the year 1822 hackney-carriage drivers have been required to deposit any articles which may be accidentally left in their vehicles with the registrar of licences, to whom the owners of the lost property may apply for its restoration, upon paying for the driver's time and trouble; and, incredible as it may appear, the estimated value of the property thus taken to the office in the first four years and a half after the introduction of this rule is estimated at 45,000*l.*, while very few applications were made for property which was not thus restored. Of late years however the case has been very different, for while from fifteen to sixteen hundred 'strays,' or lost articles, have been taken to the office in twelve months, they are all of small value; and the applications made for lost property are at least fourteen times that number. To lessen the risk in reference to one very important department of hackney carriage business, the great railway companies which have termini in London enter into arrangements by which a limited number of carriages, driven only by men of well attested respectability, are allowed to stand within their stations, to convey passengers arriving by the trains to their respective destinations, under a system of supervision so strict, that any case of misconduct or overcharge is almost certain to be brought home to the guilty party; and it is gratifying to know that this measure has proved productive of the best results in promoting honesty and civility among a most useful class of men. Further than this, much good has been effected by the strictness of the licensing system, and by the various efforts made, especially by the agents of the London City Mission, for their education and religious welfare. The generally low standard of moral character among cab-drivers leads to the (we believe universal) adoption of a system of remuneration which is not calculated to promote honesty and good feeling. 'It appears,' observes the writer of the paper we have quoted above, 'that the masters would have no chance of being honestly dealt with, if they were to pay wages to their servants.' 'They therefore,' he adds, 'lend out the vehicles and horses at a fixed sum per day; or rather, the men are expected to bring home the stipulated amount. Sometimes, in the dull season, they beg off for less, but it was remarked to us by the manager of the largest establishment of cabs in London, that, let the town be ever so full, or the season ever so prosperous, they never produce *more* than the stipulated amount, to make up for former deficiencies.' The experiment of paying liberal wages, and trusting to the honour of the men, is said to have been tried and found utterly impracticable. 'The average produce of each hackney-carriage to the proprietor,' according to our authority, 'may be about ten shillings and sixpence a day, to which, if about three-and-sixpence be added for cash appropriated by the drivers in lieu of wages, the amount (of earnings or receipts) per diem is raised to fourteen shillings.' 'Hence,' he adds, 'we may conclude that there is spent daily by the London public for coach and cab hire 1715*l.*, and yearly almost 800,000*l.*'

Hackney-coaches were, according to Beckmann (*History of Inventions*, English edition of 1814, vol. i. p. 134), first established in Edinburgh in 1673; and on the same authority (p. 131) it appears they were first used at Paris in 1650, although, if this date be correct, he is wrong in stating that the use of hackney-coaches originated there. He attributes their introduction to Nicholas Sauvage, from whose residence, the Hôtel S. Fiacre, such carriages took their common French name of *fiacres*. About 1669 a small kind of hackney carriage, resembling a sedan-chair on wheels, called a *brouette* or *roulette*, or sometimes, by way of derision, a *vinaigrette*, and drawn by men, was brought into use. Cabriolets, as above stated, appear to have originated in Paris.

For an abstract of the law relating to hackney and stage carriages, duties, licences, &c., see METROPOLITAN STAGE CARRIAGE, P. C. S.

HADRAMAUT. [ARABIA, P. C. and P. C. S.]

HÆMANTHUS. [AMARYLLIDEÆ, P. C.]

HÆMATOCOCCUS (from αἷμα, blood, and κόκκος, a grain), a genus of plants belonging to the natural order of Algæ. It is characterised by being composed of spherical or oval cells of various sizes, each cell being invested with one or more concentric vesicles or membranes, multiplied either by division or by granules formed within the parent cells. Several species of this genus have been described. One of the first observed was the *H. sanguineus*, which, like the red-snow plant (*Protococcus nivalis*), has its cells coloured red; hence the generic name. Several of the species however are of a green colour, and Kutzing and others on this account have proposed the name Microcystis for this genus of plants.

The species are found upon moist rocks, on the walls of caverns, and in damp places. Mr. Hassall has recently described several new species of this genus; they belong however to a class of plants in which it is most difficult to discover permanent specific characters. [RED SNOW, P. C.]

(Hassall, *British Freshwater Algæ*.)

HÆRETICO COMBURENDO, WRIT DE. [HERESY, P. C. S.]

HAGUE, ALLIANCE OF THE. As the general war which was terminated by the Peace of Ryswick in 1697 [P. C., xx. 287] was preceded by what is called the First Grand Alliance, concluded at Vienna betwixt the Emperor and the United Provinces, 12th May, 1689, and joined by Great Britain 9th December following, so the next general war, which broke out in 1702, was preceded by the Second Grand Alliance, or Alliance of the Hague, concluded at that town between the Emperor, Great Britain, and the United Provinces, 7th September, 1701, and subsequently joined by Portugal and other European powers. Its object was to resist the seizure of the Spanish crown by the French king Louis XIV. for his grandson the Duke of Anjou, who nevertheless eventually became King of Spain, by the title of Charles III. The Alliance of the Hague was the last political combination arranged by William III. of England, who died 8th March, 1702; and war was declared against France by Queen Anne 4th May following. [PARTITION TREATIES, P. C., xvii. 292.]

HAHNEMANN, SAMUEL, founder of the system of medicine called Homœopathy, was born at Meissen, in Upper Saxony, on the 10th April, 1755. His father, Gottfried Hahnemann, who was an artist of considerable merit, was employed in the painting of china in the celebrated porcelain manufactory of Meissen. He was a clever well-educated man, and to him his son owed the first rudiments of his education. He was afterwards placed at an elementary school, the director of which, Dr. Müller, remarking talents that only required cultivation to raise the boy to eminence, persuaded his father to place him at the High School of Meissen, into which they obtained him a free admission. Hahnemann gladly availed himself of these increased facilities; he made himself master of Latin, Greek, and Hebrew, and evinced a decided bias for the study of the physical sciences, natural history, and medicine. Botany was also a favourite pursuit, and his hours of leisure were devoted to the collection of plants and their systematic arrangement. His intense application and amiable disposition won the goodwill of the head master and teachers, who vied with each other in affording him every facility in the prosecution of his studies; and his progress was so rapid, that in a short time he was appointed an assistant teacher.

Having chosen medicine for his profession, at the commencement of 1775 he left the high school of Meissen, and, assisted by the friendship of his former teachers, he entered the University of Leipzig, having, as a candidate, written a Latin thesis on the construction of the human hand.

Being wholly dependent upon his own exertions for subsistence, he supported himself during his residence at Leipzig by giving lessons in German to foreign students and by the translation of English and French medical authors. The professors of the University, in admiration of his ardent zeal for knowledge and great acquirements, invited him to attend their lectures gratuitously. Having passed two years in the study of the theory of medicine, and saved a small sum of money, he departed for Vienna, there being no clinical lecturer in the University of Leipzig and entered himself at the Hospital of Charitable Brothers, with a view to the completion of his studies and to acquiring a practical knowledge of his profession.

His moderate pecuniary resources were almost exhausted, when his talents and marked attention to his duties gained for him a firm friend in Dr. Quarin, physician to the Emperor of Austria and chief physician to the Hospital, through whose recommendation, although he had not yet graduated, Hahnemann obtained the situation of family medical attendant and librarian to Baron von Brückenthal, Governor of Siebenbürgen, then residing at Hermannstadt. He remained here for two years, and being allowed to attend private practice he saved a small sum of money; with this he removed to Erlangen, where, on the 10th of August, 1779, he took his degree of M.D., and produced his thesis 'Conspectus Adfectuum Spasmodicorum Etiologicus et Therapeuticus.'

In the year 1781 he was appointed district physician at Gomern, near Magdeburg, where he married the daughter of an apothecary named Köhler. Previous to this he had resided some time at Hettstadt and Dessau, diligently pursuing, in addition to his professional labours, the studies of chemistry and mineralogy.

In the year 1784 he removed to Dresden, where he gained a high reputation in the hospitals as a judicious and skilful practitioner, but, struck with the absence of a guiding principle in therapeutics, and the great uncertainty of the healing art, he gradually withdrew himself as much as possible from practice, and endeavoured to support his family by his old resource of translations of English and French medical authors, pursuing at the same time his favourite study of chemistry.

His feelings at this period are best explained in his own words in a letter to the celebrated Hufeland, written many years after he had founded the system with which his name is now so intimately connected. 'Eighteen years have elapsed since I quitted the beaten path in medicine. It was agony to me to walk in darkness, with no other light than could be derived from books, when I had to heal the sick, and to prescribe, according to such or such an hypothesis concerning disease, substances which owe their place in the Materia Medica to an arbitrary decision. I could not conscientiously treat the unknown morbid conditions of my suffering brethren by these unknown medicines, which being very active substances, may, unless applied with the most rigorous exactness (which the physician cannot exercise, because their peculiar effects have not yet been examined) so easily cause death, or produce new affections or chronic maladies often more difficult to remove than the original disease. That I might no longer incur the risk of doing injury, I engaged exclusively in chemistry and in literary occupations.'

About this time he published his pamphlets on Mercurius Solubilis; on the mode of detecting Adulteration in Wine; on Calcarea Sulphurata; and on the Detection of Arsenic in cases of Poisoning: he also contributed many able papers to Crell's 'Chemical Annals,' and gave to the world a number of minor medical works, which have since been collected by Dr. Stapf and published under the title of 'Kleine Schriften,' Dresden and Leipzig, 1829.

In the year 1790, while engaged upon the translation of the 'Materia Medica' of Cullen, he was struck with the different explanations given of the mode of operation of Peruvian Bark, in intermittent fever: and dissatisfied with them, he determined to try its effects upon himself. Finding that powerful doses of this substance produced symptoms strikingly analogous to those of that form of intermittent fever for which it was an acknowledged specific, he determined to try further experiments with other medicinal substances upon himself and upon some medical friends. He obtained similar results: that is, he produced by these agents factitious or medicinal disorders resembling the diseases of which they were esteemed curative; and thus, the first dawn of the law of *Similia Similibus* gleamed upon him. In a work ascribed to Hippocrates (Ed. Basil. ap. Froben., 1538, p. 72) a similar doctrine was enunciated, and the same doctrine has since found advocates in many eminent medical writers; but Hahnemann was the first who assumed it to be *the* guiding principle in Therapeutics, and supported his position by a series of experiments. Confident that he had discovered the long sought for *law*, he assiduously pursued his proving of medicines, and adopted the new principle in the treatment of his patients with (according to his own testimony and that of his disciples) a success fully commensurate with the limited means then at his disposal. Thus encouraged, he ventured, in 1796, to address a paper to Hufeland's 'Journal,' in which he announced his new discovery to the medical world, pointed out the defects of the 'Materia Medica' as then constituted, and the necessity of its reconstruction upon the basis of pure experiment; at the same time he earnestly invited the co-operation of his medical brethren. The attention of the German physicians was then deeply engaged in the investigation of the Brunonian theory, and Hahnemann's suggestions were coldly received.

In 1801 he published a short treatise on the efficacy of Belladonna in the prevention and cure of scarlet fever, and affirmed that its curative properties were based upon the homœopathic law. In 1805 he published the results of a number of experiments in a work in two volumes, entitled 'Fragmenta de Viribus Medicamentorum positivis sive obviis in Corpore Sano;' and in the same year his 'Medicine of Experience,' in which he still more strongly expresses his objection to the old system of medicine. In 1810 he brought out his great work the 'Organon of the Healing Art,' in which he developed his new system of treating disease; and for the first time gave it the name of 'Homœopathy,' by which it has since been distinguished. [HOMŒOPATHY, P. C. S.] In 1811 the first part of the 'Materia Medica Pura' was published, six volumes of which appeared in succession till it was completed in the year 1821, since which time five editions have been published.

In the year 1812 he returned to Leipzig, where he was appointed Magister Legens. To prove his qualifications for this chair, he wrote an excellent treatise on the hellebore of the antients, 'Dissertatio historico-medica de Helleborismo Veterum.' At Leipzig he had an extensive practice, and was assisted by a great number of friends and pupils in the proving of his medicines. The apothecaries of that city, however, rose against him, and appealing to an old law long dormant, that forbade a physician to dispense his own prescriptions, they eventually, after some litigation, succeeded in 1820 in obtaining a decision in their favour. Hahnemann, unwilling to risk his own reputation and that of his system upon medicines prepared and dispensed by individuals avowedly hostile to his medical tenets, had determined to retire from practice, when the Duke of Anhalt Cöthen offered him an asylum in his dominions, with the enjoyment of those privileges of which he had been deprived at Leipzig. It was during his sojourn at Cöthen, in the year 1828, that he published in four volumes his work on 'Chronic Diseases, their Peculiar Nature, and Homœopathic Cure.' In the year 1829 the disciples and admirers of Hahnemann caused a bronze medal to be struck to mark their attachment to the new system and their esteem for its founder. It bore on the face the head of Hahnemann, with the inscription, 'Ssmuel Hahnemsnn natus Misenæ D.X Aprilis MDCCLV. Doctor creat. Erlangæ D.X Augusti MDCCLXXIX.' On the reverse, in the centre, 'Similia Similibus;' the inscription, 'Medicinæ Homœopathicæ Auctori, Discipuli, et Amici, D.X Augusti MDCCCXXIX.' His adherents had at this period greatly increased, and he enjoyed a very extensive practice among his own countrymen and foreignors.

Having been a widower for some years, he married in 1835 a French lady, Melanie de Herville, who had visited Cöthen for the benefit of his advice, and at her desire he removed to Paris. In commemoration of his arrival in the French capital, an admirably executed medal by David was struck, in bronze, silver, and gold, bearing on its face the head of Hahnemann, with the inscription 'Ssmuel Hahnemann.' On tho reverse, in the centre 'Similia Similibus curantur,' encircled by a snake; the inscription, 'Les Homœopathistes Français à leur Maître. Né à Meissen le 10th Avril, 1755, venu en France le 25 Juin, 1835.' He remained at Paris in the active exercise of his profession, and surrounded by numerous followers of his system, of all nations, till the time of his decease, which took place on the 2nd July, 1843, in tho eighty-ninth year of his age.

HAIL. [SNOW, P. C., p. 166, col. 2.]

HAIL-STORMS. [SNOW, P. C., p. 166.] The principle of insurance has been recently applied to indemnify persons for the very heavy losses sometimes occasioned by these meteorological phenomena, both by the Royal Farmers' and General Insurance Institution and by a society connected with the Norwich Union Insurance Company. The uncertainty which exists in reference to tho occurrence of these frequently calamitous storms in any particular locality, and the circumstance that, while no human sagacity can foresee or prevent them, it is utterly impossible to produce them by fraud, appear to render such casualties peculiarly fit, so soon as observation and experience shall have established accurately the average risk, for the application of a principle which has long been applied to casualties of a nature less uncertain, more easily provided against, and which afford greater opportunities for deceit and imposition. The Hail-storm Insurance societies have published chronological lists of the most remarkable hail-storms in this country during the present century, which present an array of destructive calamities far exceeding what might have been expected from their rarity. It is curious also to observe that they appear to have increased in frequency of late years. In one case, which we select solely from the more circumstantial way in which the details are given, many farms of corn were (on the 14th of July, 1824) literally destroyed in Hertfordshire, Middlesex, and Essex; the damage done upon a space of 3487 acres in the last-mentioned county alono was estimated at 14,574*l.*, or about 4*l.* 3*s.* 7*d.* per acre, upon an average. It is stated that this was the third time within a period of thirty years that the crops in the north-western part of that county had been destroyed in like way. During the great hail-storms in the months of July and August, 1843, by which immense damage was done in Cambridgeshire, Norfolk, Suffolk, Essex, Hertfordshire, Berkshire, Kent, Oxfordshiro, Bedfordshire, Gloucestershire, and Yorkshire, several cases of individual loss amounted to upwards of 2000*l.* The breakage of glass in windows and skylights, and more especially in conservatories and hothouses, is one of the most frequent injuries inflicted by hail-storms, the masses of ice which fall being sometimes sufficient to demolish the wooden framework also. Such extraordinary cases of devastation will be fully accounted for if it be considered that, as it is stated in a paper issued by the Farmers' Insurance Institution, on the authority of 'Leslie's Elements,' 'hailstones having a diameter of two inches,' a size which has been exceeded in several well-authenticated cases, 'will fall with a velocity of 113½ feet in a second, or more than 1¼ mile in a minute.' On the 19th of May, 1809, it is estimated that 200,000 panes of glass were broken in London alone, besides great damage being done in fields and gardens, and the foliage and branches of trees being cut off. An equal number of panes is supposed to have been broken in the northern suburbs of the metropolis on the 30th of July, 1826. Hailstones of from six to eight or nine inches in circumferenco are frequently mentioned as having fallen in this country, in the lists referred to, which are compiled from contemporary publications; and on the 3rd of August, 1824, when the eastern part of Suffolk was visited by a violent hail-storm, by which fowls and game, as well as glass and crops, were extensively destroyed, the ice accumulated in some places to a surprising depth. In many cases a considerable extent of ground has been covered to the thickness of several inches. It is worthy of remark how very large a proportion of the destructive storms recorded have occurred in the months of June and July. Without noticing the cases in which two or more storms which occurred about the same time are alluded to as one, which would render this proportion yet more remarkable, the cases recorded in the above-mentioned lists occurred as follows. We have, of course, taken care to count but once those storms of which two separate accounts aro given:—

In the article 'Hail,' in Brande's 'Dictionary of Literature, Science, and Art,' are some curious facts collected from various authorities, from which it appears that hailstones have been found weighing from five to twelve or thirteen ounces, and of all sizes up to about fourteen inches in circumference; the largest being frequently of very rugged and irregular form, resembling portions of a great sheet of ice broken to pieces rather than balls of ice. 'Hail,' according to this authority, 'usually precedes storms of rain, sometimes accompanies, but never or very rarely follows them, especially if the rain is of any duration. The time of its continuance is always very short, generally only a few minutes, and very seldom so long as a quarter of an hour.' The writer of the article referred to further remarks, that 'the clouds from which hail is precipitated appear to be of very considerablo extent and depth, inasmuch as they produce a great obscurity. It has been remarked,' he adds, 'that they have a peculiar grey or reddish colour, and that their lower surfaces present enormous protuberances, while their edges exhibit deep and numerous indentations.' Hail is said to be always accompanied with electrical phenomena, and it is generally believed that such are the causo of its formation. The copious list of hail-storms published by the Farmers' Insurance Institution, which gives references to authorities, and in many cases minute details of the damage done, appeared in the advertising sheet of the 'Farmer's Almanac' for 1845.

HAINES is the name given to a river lately discovered in the eastern parts of Africa, in those countries which are comprehended on our maps under the name of Zanguebar. The eastern coast of Africa, from the equator northward to Cape Guardafui, has been considered nearly as a complete wilderness; its aspect from the sea is very unpromising, the coast south of Magadoxo presenting only an uninterrupted series of sand-hills, whilst that north of Magadoxo is formed by rocky masses of moderate elevation. But Lieutenant Christopher, in 1843, discovered, that at the back of the sand-hills there is a considerable river, which waters an extensive valley, filled with alluvial soil and exhibiting a great degree of fertility: this river is the Haines, which probably originates in the high countries which surround the most southern affluents of the Abaï, or eastern branch of the Nile; but as the intervening countries have never been visited by Europeans, we are unable to determine whether any of the rivers rise in these countries and which of them sends its waters to the Haines. Lieutenant Christopher was informed that north of 4° N. latitude the river is already considerable. He visited it at Girédi, a town situated twenty-two miles north-west of Magadoxo, inhabited by more than 7000 individuals, and surrounded by extensive fields, on which Indian corn and millet yield such abundant crops that large quantities are exported to Hadramaut and Oman. The river was here about 200 feet wide, and too deep to be forded in the dry season. From this place the Haines runs nearly parallel to the coast, at a distance varying between twenty and four miles, and numerous villages are found on its banks, surrounded by extensive fields irrigated from the river. The volume of water carried down decreases considerably by this irrigation, and is less at the most southern point where it was seen by Lieutenant Christopher, which was due north of the town of Brava, where it was only from 70 to 150 feet broad, but from 10 to 15 feet deep. From this place the river continues in a south-western direction, and terminates, according to the statement of the natives, in an extensive lake said to be unfathomable. This lake is about sixty miles from the eastern banks of the river Jubb or Gavind, and perhaps not much more than twenty miles from the sea. The inhabitants of the broad alluvial tract traversed by the Haines River are a mixture of Somaulis, Galla, and negroes, among which a small number of Arabs are settled. It appears that the greater part of them are Mohammedans. The chiefs of the country are Somaulis, but their power is limited, as it appears, by a kind of aristocracy.

(Christopher, 'On the East Coast of Africa,' in *London Geograph. Journal*, vol. xiv.)

HAL. [HALLE, P. C. S.]

HALE'SIA (named in honour of Stephen Hales, D.D., author of 'Vegetable Statics,' &c.), a genus of plants belonging to the natural order Styraceæ. It has a monopetalous corolla ventricosely campanulate, with a 4-lobed erect border; the stamens 12 to 16; filaments combined into a tube at the base, and adnate to the corolla; the anthers oblong, erect, 2-celled, dehiscing lengthwise; the ovary inferior; the style single; the stigma simple; the fruit a drupe, which is dry, oblong, with 2-4 winged angles, terminated by the permanent style; the cells 1-seeded, with the seeds at the bottom of the cells. The species are trees with alternate serrated leaves, and lateral fascicles of pedicellate drooping white flowers. This genus has been made the type of an order Halesiaceæ by D. Don, who is followed by Link and others.

H. tetraptera, common Snowdrop-tree, has ovate, lanceolate, acuminated, sharply serrated leaves; the fruit with four wings. This plant is a tree, growing from 15 to 20 feet high, and is a native of South Carolina. It has fine white flowers, from 9 to 10 in a fascicle, drooping and resembling those of a snowdrop. The wood is hard and veined. It is one of the hardest and also one of the handsomest of the American deciduous trees. The rate of growth for the first five or six years is from 12 to 18 inches a-year. It ripens its seeds freely in this country, and it may be propagated from these or imported seeds. There is another species, *G. diptera*, which is also an American plant, but does not attain so great a height as the last, and has much larger species. *H. parviflora* is a native of Florida, and is supposed by some botanists to be merely a small flowered variety of the first. They will grow in any common garden soil, and may be propagated by slips from the root, as well as from seeds.

(Don, *Gardener's Dictionary*; Loudon, *Encyclopædia of Trees and Shrubs*.)

HALFORD, SIR HENRY, was born on the 2nd of October, 1766, and was the son of Dr. James Vaughan, physician to the Infirmary at Leicester, and author of 'Observations on Hydrophobia, on the Cæsarean Section, and on the Effects of Cantharides in Paralytic Affections.' Sir Henry received his early education at Rugby, and was afterwards admitted at Christ Church, Oxford; he graduated in medicine at Oxford in 1794, and was elected a fellow of the College of Physicians in the same year. Having been well introduced into London society, and being distinguished for the elegance of his manners, and having early married a daughter of Lord St. John, it was not long before his practice became considerable. He was appointed by George III. one of his physicians, and in 1809 he became possessed of a large fortune by the death of his mother's cousin, Sir Charles Halford, and changed his name from Vaughan to Halford. He was made a baronet in the same year. Sir Henry continued to hold the office of physician to George III. till the king's death, and subsequently held the same appointment under George IV., William IV., and Victoria I. He was appointed president of the College of Physicians in 1824, and delivered the oration on the occasion of that body removing from their old building in the City to the new one in Pall Mall.

During his professional career Sir Henry was too much occupied with the kind of practice to which his early connexions in life introduced him, to contribute much valuable information to the literature of his profession. His publications consist of essays and orations: the latter were delivered before the college, and are written in Latin, and exhibit a purity of style beyond the average of such productions at the present day. His essays are as follows: 1, 'On the Climacteric Disease.' 2, 'On the Necessity of Caution in the Estimation of Symptoms in the last Stages of some Diseases.' 3, 'On the Tic Douloureux.' 4, 'On Shakspere's Test of Insanity.' 5, 'On the Influence of some Diseases of the Body on the Mind.' 6, 'On the Καυσος of Aretæus.' 7, 'On the Treatment of Gout.' 8, 'On Phlegmasia Dolens.' 9, 'On the Treatment of Insanity.' 10, 'On the Death of some Illustrious Persons of Antiquity.' 11, 'On the Education of a Physician.' 12, 'On the Effects of Cold.' These essays and papers display the elegant scholar and observant physician, and are mostly written in an easy graceful style. In 1813 Sir Henry Halford descended with the Prince Regent into the royal vaults of St. George's Chapel, Windsor, where, amongst other curiosities, they discovered the head of Charles I. Of this visit and discovery Sir Henry has given an account, which is deposited in the British Museum, and is authenticated by the signature of the Prince Regent. He died on the 9th of March, 1844. He had been for more than twenty years president of the College of Physicians, and was mainly instrumental in establishing the evening meetings of that body. His urbanity of manners and devotion to the interests of the college have left behind them a grateful recollection amongst the members of that corporation.

(Pettigrew, *Portraits and Memoirs of Medical Men*; *Transactions of Medical and Surgical Association*, vol. i.)

HALIFAX, GEORGE MONTAGU, EARL OF, was the fourth son of George Montagu, Esq., of Horton in Northamptonshire, who was the fifth son (the eldest by his third wife) of Henry, first Earl of Manchester. He was born at Horton, 16th April, 1661. His education was begun in the country, but he was eventually sent to Westminster School, where he was chosen a king's scholar in 1677, and whence in 1682 he was removed to Trinity College, Cambridge. He had distinguished himself, while a pupil of Busby's at Westminster, by his extemporaneous epigrams; and the same liveliness of talent showed itself in a way to attract wider attention in an effusion of English verse which he produced on the Death of Charles II., in February, 1685, beginning (not at all in jest or satire)—

> Farewell, great Charles, monarch of blest renown,
> The best good man that ever filled a throne;

and proceeding in the same strain till at last the poet exclaims—

> In Charles, so good a man and king, we see
> A double image of the Deity.

This performance, we are told, so charmed the Earl of Dorset that he induced the young poet to come up to town, where he was introduced by his lordship to all the wits of his acquaintance. In 1687 he and Prior brought out in conjunction their burlesque upon Dryden's 'Hind and Panther,' entitled 'The Hind and the Panther transversed to the Story of the Country

Mouse and the City Mouse.' It is for the greater part a dialogue in prose, apparently in imitation of the Duke of Buckingham's 'Rehearsal,' with the parody in verse of portions of Dryden's poem interspersed. The best parts of it are said to be Prior's, as may very well be believed; it is not, however, printed in the common collections of his poetry; but it is preserved in the 'Supplement to the Works of the Minor Poets' (1750), vol. i. pp. 47-82, under the head of 'Additions to the Works of the Earl of Halifax.'

Montagu appears to have some time before this entered upon his career as a politician. Johnson, in his 'Lives of the Poets,' merely says that 'he signed the invitation to the Prince of Orange, and sat in the convention;' but his signing the invitation to the Prince would seem to imply that he had occupied some public post, and he is, therefore, we suppose, the Charles Montagu who is set down as one of the members for the city of Durham in James II.'s parliament which assembled 19th May, 1685. In the convention parliament he sat for Malden; and he was returned for the same place to the next parliament, which met in March, 1690. It is stated to have been about the time of the Revolution that he married the Countess Dowager of Manchester: she was Anne, widow of Robert, third Earl of Manchester, and daughter of Sir Christopher Yelverton, Bart.

According to Johnson, it was his intention when he formed this connexion to take orders; but afterwards altering his purpose he purchased for 1500*l.* the place of one of the clerks of the council. He was also fortunate in his next poetical performance, 'An Epistle to Charles, Earl of Dorset, occasioned by His Majesty's Victory in Ireland,' being a celebration of the battle of the Boyne; for which King William, to whom he was introduced upon the occasion by Dorset, is said to have bestowed upon him a pension of 500*l.* A repartee of his majesty's, who when Dorset presented the poet as a mouse is said to have replied that he would make a man of him, is upon good grounds discredited by Johnson. His Epistle on the Victory of the Boyne, which extends to above two hundred lines, is Montagu's greatest effort in verse.

The rest of his history is that of a political character, and only a patron of poets. Johnson relates a well known anecdote of a speech he made in one of the debates on the Trials for Treason bill, in 1691, in the midst of which he is said to have fallen into confusion, and then, when he recovered himself, to have ingeniously turned the circumstance into an argument for what he was urging, the allowance of counsel to the prisoner. There is no notice of this speech in the Parliamentary History. He had already, however, raised himself by his speaking to great distinction; and on the 21st of March in this year he was taken into office as one of the lords of the Treasury. Burnet first notices him as making a great figure in the House under date of the year 1693. 'He had,' he says, 'great vivacity and clearness, both of thought and expression. His spirit was at first turned to wit and poetry, which he continued still to encourage in others when he applied himself to more important business. He came to have great notions with relation to all the concerns of the treasury and of the public funds, and brought those matters into new and better methods: he showed the error of giving money upon remote funds, at a vast discount, and with great premiums, to raise loans upon them; which occasioned a great outcry at the sums that were given, at the same time that they were much shrunk before they produced the money that was expected from them. So he pressed the king to insist on this as a maxim, to have all the money for the service of a year to be raised within that year.' But part of this applies to what was done by Montagu after he became chancellor of the Exchequer, to which office he was appointed on the 1st of November, 1695, and to which on the 1st of May, 1697, he conjoined that of first lord of the Treasury. In 1695 and 1696 he obtained great credit by his management of the operation of the general recoinage of the silver money. It was in the latter of these years that, to supply a temporary circulating medium, he contrived what are called Exchequer Bills, the convenience of which species of paper, both for the government and the public, has kept it in use ever since. Many of Montagu's Exchequer bills, however, were for sums much lower than any for which such bills are now issued. After he became first lord of the Treasury he was appointed one of the lords justices on the king going abroad, both in July, 1698, and again in May, 1699. 'In the House of Commons,' says Burnet under the year 1698, 'Mr. Montagu had gained such a visible ascendant over all that were zealous for the king's service, that he gave the law to the rest, which he did always with great spirit, but sometimes with too assuming an air;' 'which,' subjoins Mr. Speaker Onslow, in a note, 'did him infinite hurt, and lowered at last his credit very much in the House of Commons.' Lord Hardwicke, in a note on the same passage, affirms, that for two sessions together Montagu did not exert himself in the House (for what reason Hardwicke does not know); but suffered Mr. Harley and his friends to take the lead, even while he continued in the king's service. He is also asserted to have lost some credit about this time, and to have been thought to have behaved meanly, by stating in the House, in one of the debates on the Irish grants, some information which had been communicated to him in confidence. On the modification of the ministry in November, 1699, Montagu was removed to the auditorship of the Exchequer, and his places of first lord and chancellor were given, the former to Lord Tankerville, the latter to Mr. John Smith. In the end of the following year, on the acquisition of the complete ascendency by the Tories, he was removed from the House of Commons by being created Baron Halifax (with remainder, failing his own issue male, to George Montagu, son and heir of his eldest brother Edward Montagu). This, it seems, was insisted upon by Harley, the new manager of the House of Commons. The title of Marquis of Halifax had just become extinct by the death of the son of the first marquis [SAVILE, GEORGE, P. C.]; and according to Lord Dartmouth, in a note on Burnet ('Own Times,' ii. 108), Montagu took his title in grateful remembrance, as he pretended, of the old marquis, who, Dartmouth says, had first brought him into business by recommending him to be a clerk of the council; 'but,' he adds, 'generally thought more out of vanity (of which he had a sufficient share), in hopes of raising it to as high a degree as his benefactor had done.'

Lord Halifax was impeached by the new House of Commons in April, 1701, along with Lord Somers [P. C., xxii. 217] and the Earls of Portland and Orford. The question was carried in the House by a vote of 186 against 163; but the impeachment was not prosecuted, and on the 24th of June the charges were dismissed by the Lords. (See the proceedings in the 5th volume of the 'Parliamentary History,' and in the 14th volume of Howell's 'State Trials.') The articles exhibited against Halifax were six in number:—1, That he had directed a grant to the value of 13,000*l.* to pass to Thomas Railton, Esq., in trust for himself, out of the forfeited estates in Ireland; 2, That he had received to his own use 1000*l.* a year out of tho said grant; 3, That, while chancellor of the Exchequer, he had obtained and accepted of several other beneficial grants to or in trust for himself; 4, That in 1697 he had procured a grant to Henry Segur, gent., in trust for himself, of wood from the Forest of Dean, to the value of 14,000*l.*; 5, That while he was chancellor of the Exchequer he had obtained for his brother Christopher the office of auditor, in trust, as to the profits thereof, for himself; 6, That he had advised his majesty to enter into the two Partition treaties. [P. C., xvii. 293.] In his answer Halifax maintained that the grants from the Irish estates and the Forest of Dean were legal, and were also not of the value charged; that there was nothing wrong in procuring the auditorship of the Exchequer for his brother, to be held by him till he should himself be ready to step into the office; and that, as to the Partition treaties, he was rather opposed to than in favour of them.

In 1703, after the accession of Queen Anne, Halifax was again attacked by the Commons on the charge of having been guilty of breach of trust in the management of the public accounts while he was chancellor of the Exchequer; and an address was voted to the queen requesting that she would be pleased to give directions to the attorney-general to prosecute him. But he was again protected by the Lords; and after some altercation between the two houses the matter was dropped. The proceedings are given in the 'Parliamentary History,' vi. 127, &c. Though out of office during this reign, he continued to take an active part in the debates of the House of Lords, especially distinguishing himself in 1707 in the defence of the union with Scotland. Lord Dartmouth, however, complains (note on Burnet, 'Own Times,' ii. 431) that he and Lord Wharton brought up a familiar style with them from the House of Commons, 'that has,' says his lordship, 'been too much practised in the House of Lords ever since, where everything formerly was managed with great decency and good manners.' To Halifax also belongs the credit of having first moved, and taken the most active part, in the project for the purchase of the Cotton manuscripts and the establishment of a public library, out of which eventually came the British Museum. (Burnet, 'Own Times,' ii. 440.)

Having always kept up a connexion with the Hanoverian family, Lord Halifax was found, on the death of Queen Anne, to be one of the nineteen persons appointed by the new king to hold the government along with the seven great officers of state till his majesty should come over. On the 14th of October, 1714, he was raised to the dignities of Earl of Halifax and Viscount Sunbury, and was restored at the same time to his former post of first lord of the Treasury, his office of auditor of the Exchequer being given to his nephew. But he died of an inflammation of the lungs on the 19th of May in the following year. He left no issue, so that his earldom and viscounty became extinct; but he was succeeded in his barony according to the limitation by his nephew George Montagu, who a few weeks after was made Earl of Halifax and Viscount Sunbury by a new creation. The son of the second Earl of Halifax died without issue in 1772, when all the honours became extinct.

Halifax was one of the most consistent of the Whig party to whom we are indebted for the Revolution, the Hanoverian Succession, and the Union with Scotland. It is evident also, from the detail that has been given, that he was a person of great general ability. But he was much more a man of action than of any remarkable powers of thought; and what he has written, whether in verse or prose, is of very little value. A list of his pieces is given by Walpole in his 'Royal and Noble Authors.' His character as a patron of literature has been drawn with some severe satiric touches, under the name of 'Full-blown Bufo,' by Pope, in his 'Prologue to the Satires.'

HALL, REVEREND ROBERT, was born the 2nd of May, 1764, at Arnsby in Leicestershire, where his father, of the same names, had been settled since 1753 as pastor of a congregation of Particular Baptists. He had come from Northumberland, where his forefathers belonged to the class of yeomanry; and he is stated to have been a man, though not of much learning, of considerable native power of mind. He is the author of several short religious publications: one of which, entitled 'A Help to Zion's Travellers,' was several times printed.

The subject of this notice was the youngest of fourteen children. It is related that he was two years old before he learned to speak: but after this, the progress he made in all branches of his education was very rapid. Though the circumstance is absurd, it is an evidence of the impression he had made by his precocity—that when he was only eleven years old, a fellow-clergyman of his father's (Mr. Beeby Wallis, of Kettering), to whom he had been taken on a visit, seriously set him to preach to a select auditory assembled in his house. His gift of ready expression had, it would appear, already strongly developed itself. He used to attribute much of his early intellectual excitement to the conversation of a metaphysical tailor in his native village, a member of his father's congregation.

He lost his mother in 1776, and it appears to have been after this that he was sent to board at a Baptist school in Northampton, kept by the Rev. Dr. John Ryland. Here he remained for a year and a half, after which he was placed, in October, 1778, at the Bristol Academy, with the view to his becoming a Baptist clergyman. It is the practice, it seems, for such students to commence preaching before they have finished their education; and Hall was, as it is expressed, set apart as a preacher by his father's congregation in August, 1780. In the autumn of 1781 he was selected by the authorities of the Bristol Academy to be sent to King's College, Aberdeen, on what is called Dr. Ward's exhibition; and here he studied for the usual period of four winter sessions; preaching, at least occasionally, in the intervening summers. It was at Aberdeen that Hall and the late Sir James Mackintosh, then also a student at King's College, became acquainted. They bore a close resemblance in intellectual character, in their powers of mind as well as in their tastes, and the intimacy which now sprung up between them led to an affectionate friendship, which lasted while they both lived.

Hall did not finally leave Aberdeen till May, 1785; but he had already, during the preceding summer, officiated as one of the regular pastors of the Baptist congregation at Broadmead, Bristol, in association with Dr. Caleb Evans; and in August, 1785, he was also appointed classical tutor in the Bristol Academy. His father died in 1791, and the same year a difference with Dr. Evans led to his removing from Bristol and accepting an invitation to become pastor of the Baptist congregation at Cambridge on the departure of the Rev. Robert Robinson to be successor to Dr. Priestley at Birmingham.

He had already acquired considerable celebrity as a preacher, but it was not till now that he appeared as an author; and the impulse that sent him to the press was rather political than theological. His first publication (unless we are to reckon some anonymous contributions to a Bristol newspaper in 1786-7) was a pamphlet entitled 'Christianity consistent with a Love of Freedom, being an Answer to a Sermon by the Rev. John Clayton,' 8vo., 1791. Like most of the ardent minds of that day, he had been strongly excited and carried away by the hopes and promises of the French Revolution, and he appears to have retained his first faith without much alteration for some years. In 1793 he published another liberal pamphlet, entitled 'An Apology for the Freedom of the Press, and for general Liberty, with Remarks on Bishop Horsley's Sermon preached 31st January, 1793.' This was largely diffused, and brought him much reputation. The impression that had been made upon him, however, by the irreligious character of the French revolutionary movement was indicated in his next publication, 'Modern Infidelity considered with respect to its Influence on Society, a Sermon,' 8vo., 1800. It was the publication of this able and eloquent sermon which first brought Hall into general notice. From this time whatever he produced attracted immediate attention. The Sermon on Modern Infidelity was followed in 1802 by another on the Peace, which also brought him great reputation.

In November, 1804, Hall was visited by an attack of insanity, the violence of which did not last long, but from which he did not entirely recover for some years. His state of health made it necessary for him to resign his charge at Cambridge; but, apparently about 1807, he became minister of the Baptist chapel in Harvey-lane, Leicester, and this situation he held for nearly twenty years. He married in March, 1808. At last, in 1826, he removed to the pastoral care of his old congregation at Broadmead, Bristol; and here he remained till his death, which took place at Bristol, on the 21st of February, 1831.

Besides occasional contributions to various dissenting periodical publications, Hall published various tracts and sermons in the last twenty years of his life, which, along with those already mentioned, have since his death been collected and reprinted under the title of 'The Works of Robert Hall, A.M., with a brief Memoir of his Life by Dr. Gregory, and Observations on his Character as a Preacher by John Foster; published under the superintendence of Olinthus Gregory, LL.D., professor of mathematics in the Royal Military Academy,' 6 vols. 8vo., London, 1831-2. It was intended that the Life should have been written by Sir James Mackintosh, but he died (in May, 1832) before beginning it. Dr. Gregory's Sketch, from which we have abstracted the materials of this article, is contained in the last of the six volumes. The first contains sermons, charges, and circular letters (or addresses in the name of the governing body of the Baptist church); the second, a tract entitled 'On Terms of Communion,' in two parts, 1815; and another entitled 'The Essential Difference between Christian Baptism and the Baptism of John' (a defence of what is called the practice of free communion), in two parts, 1816 and 1818; the third, political and miscellaneous tracts, extending from 1791 to 1826, and also the Bristol newspaper contributions of 1786-7; the fourth reviews and miscellaneous pieces; the fifth, notes of sermons, and letters. The sixth, besides Dr. Gregory's memoir, contains Mr. Foster's observations, and notes taken down by friends of twenty-one sermons.

Hall was a man of many virtues, and of intellectual powers which placed him in the first class of mere men of talent. His acquirements were very considerable, and he appears to have kept up the habits of a studious man to the end of his life. But the great temporary impression that he made as a preacher and as a writer is to be attributed chiefly to general force and fervour of mind, and not much to any higher or rarer faculty. He was more of an orator or of a rhetorician than of a thinker. His greatness lay in expression and exposition, not in invention; and even his eloquence was rather flowing and decorative than either imaginative or impassioned. His mind was not in any sense an original or creative nor even a subtle or a far-seeing one. It may be predicted, therefore, that the six volumes of his writings, with all their general finish and elegance, and occasional brilliancy, although they may preserve his name from being forgotten, will not greatly interest posterity. They do not contribute anything to the world's stock of thought or even of knowledge; and are therefore nothing more than a record or memorial of what their author was.

HALL, BASIL, CAPTAIN, R.N., was born at Edinburgh in 1788. His father Sir James Hall, Bart., of Dunglass, was President of the Royal Society of Edinburgh. He was the author of an 'Essay on the Origin, Principles, and History of Gothic Architecture,' published in 1813, and a frequent contributor of scientific papers, chiefly on geological subjects, to the Royal Society of Edinburgh. Sir James Hall was married to Helen, a daughter of the fourth Earl of Douglas.

Basil Hall entered the Royal Navy in 1802; in 1808 received his first commission as lieutenant; in 1814 was promoted to the rank of commander; and in 1817 he was made a post-captain. The opportunities which the naval profession affords both for scientific pursuits and the study of men and manners in various climes happened in Captain Hall's case to lead him into scenes of more than usual interest; or perhaps it would be more correct to state that his eager and indefatigable pursuit of knowledge induced him to seek every means of extending the sphere of his observations. In 1813, when acting commander of the Theban on the East India station, he accompanied Sir Samuel Hood, the admiral, in a journey over the greater part of the island of Java. Soon after his return to England, he was appointed to the command of the Lyra, a small gun-brig, in which he accompanied the expedition which took out Lord Amherst as ambassador to China. While the ambassador was pursuing his journey inland to Pekin, Captain Hall in the Lyra visited the places of greatest interest in the adjacent seas, and on his return to England in 1817 he published 'A Voyage of Discovery to the Western Coast of Corea, and the Great Loo Choo Island in the Japan Sea.' There is an appendix to the work, which contains charts and various hydrographical and scientific notices. A second edition was published in 1820, in which the scientific details are omitted; and in 1827 the work appeared in a still more popular form as the first volume of 'Constable's Miscellany.' In this edition there is an interesting account of Captain Hall's interview at St. Helena with the ex-Emperor Napoleon. Sir James Hall (Captain Hall's father) had been the emperor's fellow-student at Brienne, and was the first native of Great Britain whom the Emperor recollected to have seen. Captain Hall was next employed on the South American station in command of the Conway. The period was one of great interest to the Spanish colonies of South America.

Having returned to England early in 1823, Captain Hall published 'Extracts from a Journal written on the Coasts of Chili, Peru, and Mexico, in the years 1820, 1821, and 1822,' with an appendix containing a memoir on the Navigation of the South American station. There are also appendices which contain various scientific notices; and a paper by Captain Hall 'On the Duties of Naval Commanders-in-chief on the South American Station before the appointment of Consuls.' In 1825 he married Margaret, youngest daughter of the late Sir John Hunter, Consul-general for Spain; and in April, 1827, he and his wife and child sailed from Liverpool for the United States, where they remained above a year, during which Captain Hall travelled nearly nine thousand miles by land and water conveyances. In 1829 he published his 'Travels in North America,' 3 vols. 8vo. He next published 'Fragments of Voyages and Travels.' They form three series, each of three volumes, 12mo. In 1834 he met at Rome with a sister of Mrs. Dugald Stewart, who having married Count Purgstall, an Austrian nobleman, had resided many years at her schloss or castle of Heinfeld, near Gratz, in Styria. He accepted an invitation to visit the countess, and his book 'Schloss Heinfeld, or a Winter in Lower Styria' was the result of his notes during his residence there. Captain Hall supposes that Die Vernon, in Sir Walter Scott's novel of 'Rob Roy,' was sketched from Miss Craunston, which was the maiden name of the countess. Captain Hall's last work was published at the end of the year 1841, in three volumes, under the title of 'Patchwork.' It consists of detached papers, which embrace recollections of foreign travel, incidents worked into short tales, and a few essays.

Captain Hall was a Fellow of the Royal Societies of London and Edinburgh, and a member of the Astronomical Society of London. The following is a list of some of his scientific papers:—An Account of the Geology of the Table Mountain; Details of Experiments made with an invariable Pendulum in South America and other places for determining the Figure of the Earth; Observations made on a Comet at Valparaiso. The above three papers are published in the Transactions of the Royal Society. A Sketch of the Professional and Scientific Objects which might be aimed at in a Voyage of Research. A Letter on the Trade Winds, in the Appendix to Daniell's Meteorology; with scientific papers in Brewster's Journal, Jamieson's Journal, and the Encyclopædia Britannica.

Captain Basil Hall having been unfortunately seized with mental alienation, was placed in the Royal Hospital, Haslar, Portsmouth, where he died on the 11th of September, 1844.

HALLE, a flourishing town with a population of above 5000 inhabitants, is situated on the river Senne, in the province of South Brabant, in the kingdom of Belgium, ten miles south-west of Brussels. The town has several breweries, distilleries, tanneries, saltworks, and a paper-mill. It is celebrated for the manufacture of beautiful articles of wood, of which considerable quantities are exported.

(Hassel, *Handbuch*; Cannabich, *Lehrbuch*; Stein, *Handbuch*, by Hörschelmann.)

HALLER, JOHANN, a distinguished German sculptor, was born at Innsbruck in 1792. He studied in the academy of Munich, and in his third year obtained the prize in sculpture, for a statue of Theseus raising the Rock to discover the Sandals of his Father. He executed many works in Munich for the present king of Bavaria, both as prince and king; the principal of which are the models of the sculptures for the pediment of the Glyptothek, representing Pallas Ergane (Ἐργάνη, the 'worker'), from a design by Wagner; the six colossal statues of the niches in the front of the same building, namely Hephæstus, Prometheus, Dædalus, Phidias, Pericles, and Hadrian; and the Caryatides of the royal box of the great theatre at Munich; besides a basso-rilievo in the interior of the Glyptothek after a design by Cornelius, representing the Fall of the Giants; and many busts of eminent men, some of a colossal size. He executed the bust of William III. of England for the Walhalla. He died in 1826, aged only thirty-three. He studied some time in Rome.

(Nagler, *Allgemeines Künstler-Lexicon*.)

HALO is a circular band of faintly coloured light which is occasionally seen surrounding the disk of the sun or moon at a distance from it equal to 22 or 23 degrees, measured on a great circle passing through the luminary. The colours of the solar halo are such as are observed in the rainbow, but they are less bright, and they do not always, in the halo, follow the same order as in the bow. Generally the red is nearest to the sun, the exterior of the band being a pale indigo or violet, and sometimes white; but occasionally the interior edge appears to be white, and beyond this, in succession, are green, yellow, and a pale red. The lunar halo in general appears to be white, but it is at times tinted with pale green or red. Often about either luminary the halo is double, consisting of two concentric circular bands, the exterior one being broader than the other, but its colours paler, and its distance from the luminary being twice as great as that of the interior band. Between either halo and the luminary the sky is frequently grey, on account of a thin veil of clouds which covers it, but sometimes its colour is a deep blue.

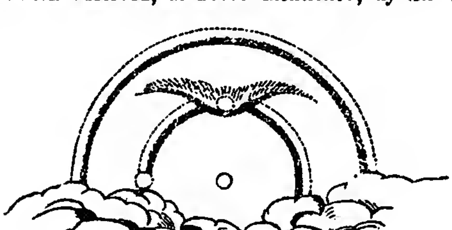
When a mist or a thin cloud is between the sun or moon and a spectator, there is frequently observed an ill-defined circle of coloured light immediately surrounding the disk of the luminary: this is called a corona; it sometimes appears when a halo is also seen, but it is more commonly observed without such accompaniment. The solar corona generally consists of three concentric bands variously coloured; and in one which was seen by Newton the colours of the three bands were successively, proceeding from the sun outwards, blue, white, and red; purple, blue, green, and pale red; pale blue and pale red. The semi-diameter of the exterior circumference was about six degrees. The coronæ are supposed to be produced by the refractions of light in the globules of water which are suspended in the atmosphere between the spectator and the luminary.

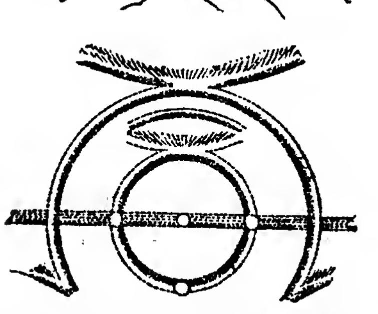
It may be observed in this place that images of the sun have been occasionally seen as if by reflexion from some cloud, the sun being near the horizon: these are called anthelia; and Mr. Swinton, from the top of a hill near Oxford, saw one which was for a short time as bright as the true sun and equal to it in magnitude. The cause of these phenomena is yet uncertain; but such an image may be produced when in the lower part of the atmosphere there exist innumerable prisms of ice with their axes in vertical positions and so situated that the rays of light falling on one side of each prism may enter the eye of the spectator after two refractions with one intermediate reflexion; or after two refractions with two intermediate reflexions. The index of refraction in ice being 1·31, and the prisms equilateral; it may be proved that, in the first case, the false sun will appear to be at a distance from the true sun equal to 142 degrees, and in the latter case at a distance equal to 82 degrees.

Halos are frequently accompanied by a horizontal ring or band of whiteish light passing through the sun or moon, appearing to ascend as the luminary rises, and having its apparent semi-diameter equal to the zenith distance of the latter; and at times a similar band appears in the direction of a diameter perpendicular to the horizon. At the intersections of these bands with the halo (but in a few instances a little beyond such intersections) are sometimes seen images of the sun or moon, which are ill defined and less bright than the true disc of the celestial body: these, when the halo is formed about the sun, are called parhelia; and when about the moon, paraselenæ. Occasionally also segments of circles, or branches of curves of contrary flexure, proceed from these images of the sun or moon so as to assume the appearance of wings or tails.

Many remarkable phenomena of this kind have at various times been observed: in the History of England, by Matthew Paris, there is a description of a halo which is stated to have been seen in the year 1233, on the borders of Herefordshire and Worcestershire: it is related that on each side of the halo was a semicircle which intersected the halo in two places; and that at the four intersections were as many false suns. In 1586 Rothman observed at Cassel, soon after sun-rise, a false sun above, and one below the true sun, all being in one vertical line; and in 1629 Scheiner observed a remarkable halo at Rome. In 1660 Hevelius, at Danzig, observed a single halo, and in 1661 a double halo; the former was accompanied by two false suns at the extremities of a horizontal diameter; and another at the upper extremity of a vertical diameter; the two horizontal suns had tails tending away from the true sun: the latter halo was accompanied by three false suns like the other, and by several segmental bands of light, two of which had false suns at their places of intersection. In the last-mentioned year Hevelius observed also a halo with two paraselenæ and a double corona about the body of the moon. Dr. Halley observed a halo with parhelia in 1702; and a very remarkable one was seen by Sir Henry Englefield at Richmond, in 1802 (*Journal of the Royal Institution*, vol. ii). Besides these, many such phenomena have been observed in Europe, in the United States, and in Canada; and Captain (Sir Edward) Parry observed and measured several during his voyages to the arctic regions.

The first of the subjoined figures is a representation of the phenomenon observed, as above mentioned, by Sir Henry





Englefield. The sun being about 14 degrees above the horizon, portions of two halos were seen, one at 24 degrees, and the other at 48 degrees from it; the interior portion was of a pale yellow, and a degree broad; and the other, which was about 1½ degree broad, was tinted with prismatic colours, the red being nearest to the sun. On the left hand side of the interior ring, and in a line imagined to be parallel to the horizon, was a faint parhelion; and vertically above the sun, in the same ring, was a very remarkable parhelion rather brighter than the true sun: it had a pearly appearance, was ill defined, and about two degrees broad. From each side of this image proceeded a bright curve of contrary flexure, being first convex and then concave towards the sun. It extended nearly to the outer circle, and its lower side was tolerably defined; but the upper side melted, with streaks of light, into the sky: the parhelion with its curved prolongations is said to have had very much the appearance of a vast bird hovering over the sun.

The second figure is a representation of a great double halo which was observed by Captain Parry: in this, a horizontal circle of light, at the intersections of which with the interior halo were parhelia, passed through the true sun; and there were segments of circles both at the upper extremities of the two halos and at the lower extremities of the exterior one, the latter being incomplete. The altitude of the true sun was about 23 degrees; and the radii of the two circles were, respectively, 22½ degrees and 45 degrees. The lowest parhelion was very bright, but had no colours, while all the segments were strongly tinted with colour. Above the sun, at about 26 degrees from it, and between the two halos, was a small portion of a third halo, which appeared to be elliptical; and the space between the two segments was extremely brilliant, in consequence of strong reflexions of the sun's rays from the snow which floated in the atmosphere.

In the tropical regions coloured halos are frequent and brilliant; and, near the equator, Humboldt has observed small ones surrounding the planet Venus.

The explanation which has been given of the halo by Mariotte and Dr. Young, is nearly as follows:—Between the spectator and the sun innumerable crystals of snow or ice, having the form of equilateral prisms, may exist in the air, in all possible positions: of these probably one half will be so situated as to be incapable of transmitting any refracted light to the eye, but vast numbers may have their transverse sections in planes nearly passing through the sun and spectator; and it will follow (the index of refraction in ice being about 1·31 and assuming the angles of incidence to be such that the incident and emergent rays may make equal angles with the surfaces) that the deviation of the refracted from the incident ray, at the eye of the observer, is about twenty-two degrees. Hence, the incident rays being considered as parallel to one another, there must appear to be formed a circle of light about the sun at a distance from the latter equal to that number of degrees. The semidiameter of the common halo is rather greater than this quantity; but the index of refraction in ice or snow is uncertain, and the angles of the prisms may, from partial meltings, be rather greater than sixty degrees.

Dr. Young supposes that the rays refracted from prisms so situated may fall on other prisms similarly situated, and may thus suffer two additional refractions at their surfaces; by which means the rays entering the eye of a spectator would form angles of twice the above quantity, or nearly forty-four degrees with the direct rays from the sun; and this may account for the exterior halo. Mr. Cavendish, however, suggested that the latter may be produced by the two refractions which a ray would undergo in passing through a face and one end of a prism; that is, through two surfaces which are at right angles to one another. Such refractions would cause the incident and emergent rays to make with one another an angle of about 45° 44′; and this is, nearly, the distance of the exterior halo from the sun. The red rays of light, being those which suffer the least refraction, come to the eye from the interior edges of the rings; and hence those edges generally appear of a red colour: the exterior parts should be blue, and they frequently are so; but it may be readily imagined that, with such prisms, considerable irregularities in the order of the colours must take place.

Immense numbers of very short prisms, or thin triangular plates, of ice will assume, in the air, vertical positions by the action of gravity; and Dr. Young conceives that horizontal rays from the sun falling on their flat surfaces may be reflected from thence to the eye of the observer, so as to produce the appearance of the horizontal circle, or band, of light which so frequently accompanies the halo. Plates of ice disposed so as to reflect the sun's light in a vertical plane may be the cause of the column which is sometimes seen to form a vertical diameter of a halo; and a similar explanation may be given of the bands forming oblique diameters such as, on one occasion, were observed by Captain Parry, when the halo had the appearance of a great wheel in the heavens, the sun being in its centre. The blending of the reflected rays above mentioned with the rays refracted from the sides of the prisms, at the places where the horizontal and vertical bands of light intersect the halo, is, apparently, the cause of the parhelia which are very generally observed in those parts of the halo; and, when the transverse sections of the refracting prisms deviate from a plane passing through the observer, towards the right or left, the axes being horizontal, there will be produced a curvilinear band of light, like a wing, inclining upwards on either side of a parhelion.

HALO'NIA, a genus of fossil plants, allied to Lepidodendron, and occurring in the coal formation.

HAMILTON, DAVID, a Scotch architect, to whom Glasgow is indebted for its chief modern edifice (the Exchange) and some other buildings, was born in that city, May 11, 1768. Of his professional education and earlier studies little is known. We must therefore content ourselves with enumerating some of his principal works, which alone will show that he was extensively employed. At Glasgow, besides the Exchange, he erected the Theatre (1804), the Western Club House, the Glasgow, the British, and some other banks; and in the West of Scotland several private mansions of a very superior class, viz. Hamilton Palace, the princely seat of the Duke of Hamilton; Toward Castle, that of the late Kirkman Finlay, Esq.; Dunlop House, Ayrshire, for Sir John Dunlop; and Lennox Castle, for John Kincaid, Esq. of Kincaid, which last is considered one of his best works. Among the structures above named, the one by which he will be most generally known is the Glasgow Exchange (erected about 1837-40), an insulated edifice (200 by 76 feet) standing in the centre of a regular *emplacement* or area of 300 by 200 feet. That end of the building which faces Queen Street is entirely occupied by an octastyle Corinthian portico, which besides being diprostyle has two inner columns behind the second and the seventh of those in front, consequently although there is exactly the same number of columns (twelve) as in the portico of the Royal Exchange, London, there is considerable difference of plan as regards the interior. Still more does the Exchange itself differ from the London one, since instead of being an open cortile like the latter, it is covered over, and forms a spacious room of about 100 by 65 feet, divided into three spaces on its plan by a range of seven columns on each side.

Hamilton was one of the few architects at a distance who entered into the competition for the New Houses of Parliament, on which occasion he so distinguished himself that one of the four 500*l.* premiums was awarded to him for his designs. On another occasion (the completion of the Exchange) he was complimented, in July, 1840, by a public dinner, and the present of a service of plate, and gold box, &c., from the citizens of Glasgow. He was in fact universally respected no less for his probity and excellence of character than for his abilities.

He died at Glasgow, December 5, 1843, in his seventy-sixth year, leaving a son in the same profession whom we conjecture to be the present Mr. Thomas Hamilton of Edinburgh, architect of two of the most tasteful structures in that city; the High School, a happy application of Grecian Doric; and the new Physicians' Hall just completed (1845), which though a small façade, exhibits some freshness of design, and is remarkable for the novel and effective manner in which the two statues are introduced.

HAMPTON COURT PICTURE GALLERY. This historically highly interesting collection, which occupies the state apartments of Hampton Court Palace [MIDDLESEX, P. C., p. 195], is open to the public gratuitously on every day of the week except Friday, when it is closed for the purpose of being cleaned. It is open from ten in the morning until six in the evening, from April 1 to October 1; and from ten until four for the remainder of the year.

The present collection, which has been lately re-arranged, has been chiefly formed within the last few years from the royal collections at Kensington Palace, Buckingham House, and Windsor Castle. It contains, besides tapestries and other mural decorations, 1025 pictures and drawings of various descriptions, by 256 different masters; but the good works are numerically a small proportion of the whole, notwithstanding the great names inscribed upon the frames, which are distributed with a recklessness certainly unparalleled in any other collection. The arrangement of the whole collection, also, though much improved of late, is extremely bad; several distinct and highly interesting galleries might be formed by judicious selection and arrangement out of the present incongruous mass: there is material for an excellent historical portrait gallery in the many interesting works which are at present scattered about in the thirty-one apartments which compose the gallery. In their present scattered condition, their pictorial value is the chief attraction of these portraits, and this, in most cases, is of a very low degree; but were they arranged according to their ages and characters, they would obviously have a great historical interest for multitudes who would scarcely glance at them as mere paintings.

The old royal collection of Hampton Court was a comparatively small collection; but it contained a large proportion of interesting works, including many that were in the collections of Charles I. and James II., of which some still remain; but the best were removed by George IV. to Windsor Castle, when that palace was repaired and enlarged by Sir Jeffrey Wyatville in 1828. The original collection of Charles I. consisted of 332 pictures, which were valued at 4675*l.* 10*s.* by the appraisers of the Council of State previous to the sale of Charles's effects. Charles possessed altogether 1387 pictures and 399 pieces of sculpture, which were valued by the same party at 31,913*l.* 12*s.* and 17,989*l.* 10*s.* 6*d.* respectively. (*A Catalogue and Description of King Charles the First's capital Collection of Pictures, &c.*, London, 1757.)

The following are the principal works of the present collection at Hampton Court:—

1. *The Guard Chamber*, containing numbers 1 to 17 inclusive: Zucchero's portrait of Queen Elizabeth's giant porter who was seven feet six inches high. 2. *The King's first Presence Chamber*, 18-61, contains Queen Mary's Beauties, by Kneller, known as the Hampton Court Beauties; a wooden Equestrian portrait of William III., by Kneller; an excellent portrait of the first Marquis of Hamilton by Mytens; an extravagant allegory of Calumny, by Zucchero, which, though founded upon the story of Lucian [ANTIPHILUS, P. C. S.], is not painted from his description of the picture of Apelles of Ephesus; a portrait by Dobson, and one by Riley; an Italian lawyer by Bordone, and a portrait by Titian, both good pictures; a well-painted picture of the painter De Bray and his family, by himself; and a copy of a Venus by Titian, in the Pitti Palace, attributed to Titian; there are also several inferior portraits and others in this room which are attributed to great masters, particularly a Man showing a Trick, attributed to Da Vinci, which is evidently not by that master. 3. *The second Presence Chamber*, 62-106, contains an admirably painted picture described in the catalogue as 'The Sculptor Baccio Bandinelli, by Correggio;' but the head is not like the authentic portrait of Bandinelli, and the painting, though in the style of Correggio, is more probably a later imitation; a finely-painted head of Alessandro de' Medici, by Titian; a copy of the large picture at Windsor of Charles I. on horseback, by Vandyck; a copy by Sir J. Reynolds of Guido's St. Michael; a Dutch gentleman, by Vanderhelst; Christian IV., King of Denmark, by Vansomer; and Philip IV. and his queen, two portraits by Velazquez. 4. *The Audience Chamber*, 107-149, contains five Scripture pieces by Sebastian Ricci, which are elevated in sentiment and beautiful in colour; Ignatius Loyola, by Titian, a very sinister-looking countenance; a portrait of the Queen of Bohemia, the daughter James I., by G. Honthorst; and several bad pictures attributed to great masters, especially a Venus and Cupid said to be copied by Rubens after Titian. 5. *The King's Drawing-room*, 150-172, contains the Cornaro Family, by Old Stone, after the original by Titian in Northumberland House; Joseph and Potiphar's wife, by Gentileschi; and the family of Pordenone, by himself, an extremely bad composition. 6. *King William III.'s Bed-room*, 173-206. In this room are the beauties of the court of Charles II., or the Windsor Beauties, painted chiefly by Lely: as pictures, they are dry, cold, monotonous and formal, and as portraits, so much alike that it is difficult to believe in a resemblance to the originals: the Duchess of Portsmouth, by Gasker, has a very different physiognomy from those by Lely, which are absolutely void of individuality; of Lely's the best in the room is the Princess Mary as Diana. 8. *The King's Writing-Closet*, 225-246, contains a good drawing, by Gibson the dwarf, of the queen of Charles I. 10. *Her Majesty's Gallery*, 272-448, contains many old portraits, some of which are among the historically most interesting works in the collection—Henry VIII., Queen Elizabeth, &c., by Holbein and others, though all the pictures attributed to Holbein in this gallery are certainly not by that master: the best works of this room are the children of Henry VII., by Mabuse, painted in 1495; and the portraits of Fro-

benius the printer and two of Erasmus, by Holbein. 12. *The Queen's Drawing-room*, 490-504, all by West, among them a duplicate of the death of Wolfe. 13. *The Queen's Audience Chamber*, 505-541, contains two excellent paintings, in their style, of James IV. of Scotland, with his brother Alexander and St. Andrew; and his queen, the daughter of Henry VII., with St. George, by Mabuse, attributed by Passavant to Hugo Vander Goes, but certainly erroneously [GOES, HUGO VANDER, P. C. S.]: in this room also are the three curious large pictures of the Battle of Spurs, the Embarkation of Henry VIII. at Dover, and the Field of the Cloth of Gold, attributed to Holbein, for the reason probably that Holbein was painter to Henry VIII.; but there is not in all three pictures the slightest evidence of the hand or style of Holbein; the execution is minute, but it is at the same time coarse and dirty. 15. *The Prince of Wales's Presence Chamber*, 546-589, contains Adam and Eve, by Mabuse; Walker's portrait, by himself; and two drawings by Isaac Oliver. 20. *The private Dining-room*, 668-690. In this room is a richly-coloured portrait of Fisher the composer, by Gainsborough. 26. *The Cartoon Gallery*, 769-775. This gallery is occupied entirely by the seven cartoons of Raphael [CARTOONS, P. C.], for which it was expressly built by Sir Christopher Wren, and perhaps there never was a building so ill adapted to its purpose; it is too narrow, the cartoons are placed much too high, and the light is wholly bad; the windows are actually below the pictures which they are intended to light. 27. *The Ante-room*, 776-797. In this room is an admirable drawing in chalk upon paper of Raphael's Transfiguration, from the original in the Vatican at Rome: it was drawn by Giambattista Casanova for Lord Baltimore, who presented it to George III.: this drawing and the cartoons together show Raphael to full advantage. 28. *The Portrait Gallery*, 798-855. This apartment, though styled the portrait gallery, is chiefly occupied by the nine large distemper paintings of the Triumph of Julius Cæsar, painted on canvas by Mantegna for the Marchese Ludovico Gonzaga of Mantua, about 1490, after Mantegna's return from Rome: there are some well-known woodcuts of them by Andrea Andreani. These works are Mantegna's masterpiece, and are among the greatest works of the fifteenth century: they are unfortunately in a very bad condition, and what is still more to be regretted, William III. had them restored by Laguerre in 1690: they were purchased by Charles I., with the collection of the Duke of Mantua, for about 20,000*l.*, and were sold at the state sale for 1000*l.*, while the cartoons of Raphael were sold for 300*l.* only. In this room is also a portrait of William of Nassau, Prince of Orange; Dobson and his wife, by Dobson; and a picture of the dwarf Sir Jeffrey Hudson, by Mytens. 29. *The Queen's Guard Chamber*, 857-928. This room contains several portraits of painters; Henry IV. and Mary de' Medici, by Pourbus; an excellent copy by Romanelli of Guido's triumph of Bacchus; and a Samson and Delilah, attributed to Vandyck, which is a copy of the original picture at Munich. 30. *The Ante-room*, and, 31, *the Queen's Presence Chamber*, 929-1025, are devoted to naval battles, marine views, and shipping generally, including several pieces by Vandevelde, and many beautifully painted hulls of ships of war, by Marshall, and three large pictures of the Battle of Trafalgar by Huggins.

The great hall is decorated with tapestries of the story of Abraham, said to be made from designs by Bernard van Orlay, a Fleming who studied under Raphael at Rome. They are certainly of the style of the sixteenth century, but are charged in manner; many of the heads however are full of character, and the composition is in many parts natural and effective. The colours are much faded, but as tapestries they are of a very superior class: Evelyn says of them in his Diary—'I believe the world can show nothing nobler of the kind than the stories of Abraham and Tobit.' They were estimated in the parliamentary inventory at 8200*l.*; but they were reserved by Cromwell for the state: the whole history is told in ten compartments, eight of which are in the hall, and two in *the public dining-room* (14), where there is also a tapestry of Tobias, with the angel, taking leave of his father Tobit, and his mother grieving for his departure. In the large apartment next to the hall, called *the Withdrawing-room*, are some much older tapestries, in a barbarous style of composition; their subjects are allegorical, but the colours are so faded that they are almost obliterated. Above the tapestries are some freely executed and beautiful drawings by Cignani: they are the cartoons of some frescoes painted by him in the ducal palace at Parma.

Every facility is afforded for students desirous of copying in the gallery; but permission must first be procured of the Chief Commissioner of her Majesty's Woods and Forests, or of the Deputy Surveyor; for without permission no person is allowed to make even the slightest sketch in a pocket-book, or in any way to make a *graphic* note of what he has seen—an injurious and extremely absurd regulation; for if an artist should wish to sketch a Tudor ruff, or a Stewart tie, or any thing else of as much importance, he must first forward a petition to her Majesty's Chief Commissioner of Woods and Forests.

Hampton Court is a very favourite resort in the summer; there have frequently been as many as 5000 visitors in a single day. Guides and catalogues may be had at the palace; there are catalogues also in Mrs. Jameson's 'Hand-Book to the Public Galleries of Art in and about London;' and in 'The Environs of London,' by John Fisher Murray.

HANDWRITING, PROOF OF. [EVIDENCE, P. C.]

HAREBELL. [CAMPANULA, P. C. S.]

HARLOW, GEORGE HENRY, was born in London in 1787. He was the only son of his parents; his father, who was a merchant, died while he was an infant, and he was brought up by his mother, who watched with interest and anxiety the early development of her son's talent for drawing. He was educated for a few years at Westminster school; but when about sixteen he was placed with a Flemish landscape painter of the name of De Cort, whom he left for the late Mr. Drummond, A.R.A., the portrait-painter; and he was finally placed in the studio of Sir Thomas (then Mr.) Lawrence, in Greek Street, with the privilege of copying pictures there, from nine until four o'clock, but with an especial proviso that he should receive 'no instruction of any kind:' for this privilege he paid one hundred guineas per annum. At the expiration however of a year and a half, the master and pupil quarrelled. Lawrence used to employ Harlow to dead-colour, and Harlow had so far a share in painting a much admired dog in a portrait of Mrs. Angerstein, which, at the Angerstein's, he had the imprudence to claim as his own. This came of course to the ears of Lawrence, who in consequence said to his pupil, 'As the animal you claim is among the best things I ever painted, of course you have no need of further instruction from me. You must leave my house immediately.' Harlow has the credit of having revenged Lawrence's resentment by painting a caricature of his style, upon a sign-board at Epsom, in one corner of which he wrote, 'T. L., Greek Street, Soho.'

Harlow, however, had little need of any man's assistance or instruction; he possessed a fine feeling for colour, a tolerably correct eye for form, and great facility of execution, especially in portraiture in small, whether in pencil, crayons, or oil-colours; and he was the rival of Lawrence at the age of twenty-two. He never studied at the Royal Academy: he professed to consider study in schools and academies as so much time spent in the destruction of originality. His first picture of note was Hubert and Prince Arthur; but he painted few historical pieces; the most celebrated of them is the Trial of Queen Catherine, of which the principal characters were portraits of the Kemble family; Mrs. Siddons as Queen Catherine. Harlow painted many portraits, of which the best is certainly that of Fuseli, painted for Mr. Knowles, Fuseli's biographer; it is a work of the highest merit in every respect. The portraits of Northcote and Nollekens are also among his best works.

Having already obtained a considerable reputation and some means, Harlow set out, in June, 1818, upon a visit to Rome, where he attracted great notice and excited some wonderment by completing an effective copy of the Transfiguration, by Raphael, in eighteen days. Canova was much pleased with it, and told Harlow that it looked like the work of eighteen weeks; he exhibited one of Harlow's pictures at his house, and it procured him his election as a member of the Academy of St. Luke, where it was also exhibited. The only English artists that had been elected members of St. Luke's besides himself were West, Flaxman, Fuseli, and Lawrence. Harlow, before he left London, was a candidate for the degree of associate in the Royal Academy, but he had only one vote, that of Fuseli. He wrote a most sanguine letter from Rome on November 23, 1818, full of hopes and plans for the future; but in less than ten weeks from that date his body was borne to its final abode; he died in London of a virulent attack of cynanche parotidea (mumps), on the 4th of February, 1819, in the thirty-second year of his age, and shortly after his return from Italy. He was elected a mem ber of the academy of Florence on his passage home through that city. His biographers describe him as having been frivolous in character and prodigal in his habits; he was, however, little more than a youth when he died. As a painter he had great merit: Lawrence said of him, 'He was the most promising of all our painters.'

(Smith, *Nollekens and his Times*; Cunningham, *Lives of British Painters*, &c.)

HARPES, a genus of fossil Crustacea (Trilobites), from the Devonian strata.

HARRIS. [MALMESBURY, EARL OF, P. C. S.]

HARRISON, THOMAS, generally called 'Harrison of Chester,' although he was not a native of that city, for he was born at Wakefield in Yorkshire, in 1744. While yet little more than a mere lad, he was sent to Italy, then considered almost the only efficient school for architectural study; and during his stay at Rome, where he remained for several years, he made designs for improving and embellishing the Piazza del Popolo, which obtained for him both a gold and silver medal from Pope Ganganelli; and he was also complimented by being elected a member of the Academy of St. Luke. On his return, one of his first works was a bridge of five arches over the Lune, at Lancaster, at which place he was subsequently employed upon various alterations and improvements in the castle. At Chester, he erected the gaol, and the county courts, which last was considered at the time a very fine and correct specimen of the Grecian Doric style, and the portico certainly does produce more effect than ordinary in regard to columniation, for though only hexastyle, it has twelve columns, there being a second row of six columns behind those in front. He executed several works at both Liverpool and Manchester; in the former place the Athenæum, and the tower of St. Nicholas' church; in the latter, the Exchange buildings (since greatly enlarged and altered), the theatre (burnt down in 1843, and now succeeded by the new structure by Messrs. Irwin and Chester, opened September 29, 1845); and the library and reading-room called the portico. The Hill column at Shrewsbury, the triumphal arch at Holyhead, and the jubilee tower erected on Moel Famma in commemoration of the fiftieth year of the reign of George III. are all by Harrison. He also built for the Earl of Elgin his new mansion of Broome Hall, in Scotland, in the Grecian Doric style, which seems to have been equally the favourite one of his noble employer and himself. Cumberland in his 'Observer' has complimented Harrison in very high terms for the pure classicality of his taste.

Harrison died at Chester, March 29, 1829.

HARRISON, WILLIAM HENRY, late President of the United States, was born in Virginia, 9th February, 1773. His father was Benjamin Harrison, who was a member of the first Congress which met at Philadelphia in 1774, was one of those who signed the Declaration of Independence, and was afterwards governor of Virginia, his native state. He died in 1791. William Henry was educated at Hampden Sydney College, in Virginia, for the medical profession; but soon after the death of his father he joined a force which was raised to defend the Ohio territory against the Indians; and the next six years of his life were spent in military service. In 1791 he received a commission as ensign in the United States' artillery; he was soon after raised to the rank of lieutenant, and in that capacity he was present and distinguished himself at what is called the battle of the Miami, in which a signal victory was obtained over the Indians. After this he was placed in command of Fort Washington, one of the most important defences of the western frontier. In 1797, this war having been brought to an end, he resigned his commission, and was appointed secretary and *ex officio* lieutenant-governor of the north-western territory, then comprehending all the country to the north-west of the river Ohio. In 1799, when the north-western territory was admitted to what is called the second grade of territorial governments, entitling it to a legistive body composed of representatives chosen by the people, he was elected a member of the territorial congress. In 1801, when Indiana was erected into a territorial government, Harrison was appointed governor, and this situation he appears to have held till the erection of Indiana into a state in 1816. He greatly distinguished himself both in the war with the Indians under Tecumseh in 1811, and in that with the English in 1812 and 1813. In both these wars he held the rank of a general. In 1816 he was returned to the House of Representatives as one of the members for Ohio. In 1828 he was sent as minister from the United States to Columbia. By all these military and civil services General Harrison had acquired great popularity; and in 1840 he was elected president; but he died, at the official residence in Washington, on the 4th of April, 1841, being the first president who had died in office. Harrison was a valuable public servant and an able man; but he did not belong to the same class of minds with his predecessors Washington, Adams, Jefferson, and Madison. In his Essay on the Aborigines of the Ohio valley, which was published in the 'Transactions of the Historical and Philosophical Society of Ohio,' vol. i. 1839, he has made some interesting remarks on antient Indian mounds and on the original state of the forests of America. (See Lyell's 'Travels in North America,' vol. ii. p. 34.)

(*Gentleman's Magazine* for June, 1841.)

HARTSHORN, SPIRIT OF. [AMMONIA, P. C. S.]

HARTSOEKER, NICOLAS, a Dutch natural philosopher, was born at Gouda in 1656: his father, who was a minister of the Reformed religion, intended that he should enter the church as a profession; but a taste for the sciences, which the youth early evinced, prevented this intention from being carried into effect.

From the money which was allowed him by his father, young Hartsoeker saved enough to pay the fees of a teacher of mathematics; and he passed the greater part of each night in studying the subjects connected with the instruction which he received by day.

An accidental circumstance is said to have directed his attention to the construction of optical instruments: having presented a filament of glass to the flame of a candle, he was surprised to observe that the extremity, when melted, assumed a spherical form; and he immediately conceived the idea of using such spheres as object glasses for microscopes. In an account, which he published in 1678, of the instruments thus formed, he asserts that he discovered the animalcules which exist in animal fluids [LEEUWENHOECK, P. C.]; and, with the like instruments, Latorre is said to have, first, perceived the red globules in blood.

In 1674 Hartsoeker was sent to pursue his theological studies at Leyden; and, in that city, he became known to Huyghens, who encouraged him in the prosecution of his microscopical observations: the two philosophers subsequently went together to Paris, where Hartsoeker was introduced to Cassini, who recommended him to exercise his ingenuity in the formation of object-glasses for telescopes; and it appears that, after several fruitless essays, he succeeded in obtaining some which were superior to any that had been before executed. These were of about 600 feet focal length; and in order that they might have truly spherical forms, he first, by means of sand, made a very shallow excavation in a plate of glass; then giving, by the like means, a slight convexity to one side of the plate of which the intended object-glass was to be formed, he placed the convex side of the latter in the concavity of the other, and, by friction, brought the contiguous surfaces of both plates to equal and consequently spherical figures. In 1694 he published his 'Essai de Dioptrique;' (Paris, 4to.) in which, besides treating of the science, he attempted to give a general theory of the laws of nature respecting the hardness, elasticity, transparency, &c. of bodies. These subjects were, afterwards, explained in detail in his 'Principes de Physique,' which he published in 1696. The work was criticised by a writer in the 'Journal des Savans,' in the same year; and Hartsoeker seems to have revenged himself by making a violent attack on the 'Mémoires de l'Académie des Sciences.' The attack, however, remained unnoticed. It appears to have been the character of Hartsoeker to seek occasions of entering into discussions with his friends; and he, at length, lost the good opinion of the patient Leuwenhoeck by urging captious objections to the results of some of his experiments.

Having become embarrassed in his circumstances, Hartsoeker was obliged, in 1696, to quit Paris: he retired to Rotterdam, where he published the work above mentioned; and he afterwards removed to Amsterdam. At this time he was introduced to the Czar Peter, then travelling incognito, and he was appointed to give the monarch lessons in mathematics: his conversation was so agreeable to the Czar that the latter invited him to Russia. Hartsoeker however declined leaving Amsterdam, and the magistrates of the city built for him an observatory in one of the bastions.

The Elector Palatine having repeatedly offered Hartsoeker the place of professor of mathematics and philosophy at Düsseldorf, he at length accepted it; and, in the year 1704, he went to reside in that city: while he held this post he made several journeys to different parts of Germany in order to visit the learned men of the country; and at Hanover he was presented to the elector by the celebrated Leibnitz. On his return to Düsseldorf he caused three burning-lenses similar to those of Tschirnhausen to be executed. On the death of the Elector Palatine, Hartsoeker, declining the solicitation of the Landgrave of Hesse-Cassel that he would reside in that city, retired to Utrecht, where he died, in 1725. He had been admitted a foreign associate of the Académie des Sciences of Paris in 1699; and he was also a member of the Academy of Berlin.

Hartsoeker is said to have entertained, at one time, an opinion that there existed in every animal a plastic soul which was charged with the preservation and development of the individual: he is said to have maintained also, and the opinion was probably founded on a more refined idea expressed by Plato in the Timæus, that, from the divinity descended a succession of intelligent beings, the lower orders of which directed and preserved the universe; he had moreover some wild notions respecting an empire which he imagined to exist in the interior of the moon.

In 1722 Hartsoeker published a work entitled 'Recueil de plusieurs Pièces de Physique, où l'on fait principalement voir l'Invalidité du Système de Newton:' he also caused a letter to be printed in the 'Journal des Savans,' containing some absurd remarks on the hypothesis of the English philosopher. He treated Leibnitz no better, attacking with great violence his system of 'monads' and of a 'pre-established harmony.' He would never admit the advantages of the 'Infinitesimal Calculus,' and persisted in considering it as an unintelligible jargon by the aid of which certain learned men sought to increase their reputation. He is characterized by J. Bernoulli as a superficial and an arrogant man; but his violence is supposed to be less owing to envy than to a morbid taste for dispute.

HARTZ. [Germany, P. C., p. 186.]

HASSELQUISTIA, a genus of plants named by Linnæus in honour of Fred. Hasselquist, M.D., his pupil, who travelled in the Holy Land. It belongs to the natural order Umbelliferæ, and to the tribe Tordylineæ. The species closely resemble those of Tordylium, and are regarded by some botanists as monstrous forms of this genus.

HAUGHTON, WILLIAM, a dramatic writer, was probably somewhat the junior of Shakspere. In Henslowe's Diary, under the date of November, 1597, he is called 'Young Haughton:' and his name occurs frequently in that curious record, till the end of the year 1600, but not later. In March, 1599, Henslowe lent him ten shillings to pay a debt, for which he then lay in the Clink prison; and constant advances of small sums, in earnest of the price of dramas which he was writing for the old manager, show him to have been as poor or improvident as most of his fellow-playwrights. He wrote several plays unassisted; in others his coadjutors were Chettle, Day, and still more frequently Dekker, with whom indeed he seems to have stood in particularly close relations. In 1600 there was licensed a tragedy of his, not preserved, called 'Ferrex and Porrex;' and Mr. Collier has conjectured that Haughton's 'Devil and his Dam,' described as in progress about the same time, may have been an alteration of 'Grim, the Collier of Croydon.' The same critic is more confident in believing that 'The Spanish Moor's Tragedy,' for which, in February, 1600, Henslowe made to Dekker, Haughton, and Day a payment of three pounds to account, was the wild tragedy called 'Lust's Dominion,' which was printed for the first time in 1657, and has been inserted (without reason) in the recent edition of Marlowe's works. But the only extant plays in which Haughton was certainly concerned are two. 1, He was sole author of the lively comedy called 'Englishmen for My Money; or, a Woman will have her Will,' which (under the latter title) appears in Henslowe's book in 1598. It was printed in 1616, 1626, and 1631, and has been reprinted in a small collection called 'The Old English Drama,' 1830, 4 vols. 12mo. 2, Dekker, Haughton, and Chettle were jointly the authors of 'The Pleasant Comodie of Patient Grissill,' entered at Stationers' Hall in March, 1600, printed in 1603, and reprinted from a very rare copy by the Shakespeare Society in 1841.

HAUTEFEUILLE, JEAN DE, a French mechanician, was born at Orleans, March 20, 1647. His father, who was a baker, being accustomed to supply with bread the master of the house at which the duchess of Bouillon then resided, prevailed on this person to recommend the youth to the notice of that lady. The duchess having consented to see him, an interview took place, when the lady was so well satisfied with the young man that she engaged to pay the expense of his education; and, on his entering into the ecclesiastical state, she retained him in her service. He never afterwards quitted his benefactress, who conferred upon him several benefices, and at her death she bequeathed to him a pension.

The Abbé Hautefeuille, such was his designation, devoted himself to the study of subjects connected with physical science, and to the construction or improvement of instruments; but he is distinguished chiefly by the claims which he advanced in 1675 to the honour of having invented a spring-balance for watches. This contrivance consisted of a straight spring of steel which he applied so that it served to regulate the movements. About the same time Huyghens invented, for the like purpose, a spring, which he made of a spiral form: it happened however that Hautefeuille had communicated his invention to the Académie des Sciences of Paris in the preceding year; therefore when Huyghens applied to the French Government to be allowed the exclusive privilege of using it, he was opposed by Hautefeuille, and he subsequently withdrew his application. It is remarkable that Dr. Hooke had, about the year 1658, invented a balance-spring for watches, but he spent several years in improving his escapement, and his watches were not made public till about the same year that the inventions of Hautefeuille and Huyghens were in use in Paris.

The other inventions, or rather the projects, of Hautefeuille are numerous, but few of them appear to have been brought to perfection. He published in 1692, at Paris, a work entitled 'Recueil des Ouvrages de M. de Hautefeuille,' which contains an explanation of the effects of speaking-trumpets; an account of a pendulum clock in which the weight was to be raised by the action of the atmosphere; a method of raising water by means of fired gunpowder; and an account of some improvements in telescopes in which the field of view was to be increased by means of a concave mirror; also some observations on machines for raising water; a description of a pump which was to act without friction; and an account of a contrivance for mounting telescopes of great length.

Hautefeuille published a method of finding the declination of a magnetic needle (1683); an account of a magnetic balance (1702); with accounts of a micrometrical microscope, and of an instrument for observing the altitudes of celestial bodies. He also published, in 1719, a work entitled 'Nouveau Système du Flux et Reflux de la Mer,' in which the phenomena of the tides are made to depend upon a particular motion which he ascribes to the earth; but the best of his works is his 'Dissertation sur la Cause de l'Echo,' which had been read before the Academy of Bordeaux in 1718, and was published in that city in 1741.

Hautefeuille appears to have been in haste to publish his ideas as soon as they arose in his mind, without waiting to put them to the test of experiment; and consequently most of his projects are crude conceptions which have not led to any object of practical utility. The opinion entertained of him by his countrymen is manifest from the fact that he was never admitted a member of the Académie des Sciences though he ardently desired that honour. He died October 18, 1724, being then seventy-seven years of age.

(*Biographie Universelle.*)

HAWKER. [Pedlar, P. C.]

HAYMAN, FRANCIS, R. A., the best historical painter in England before the arrival of Cipriani, was born at Exeter about the commencement of the eighteenth century. He was the scholar of Robert Brown, and was in early life much employed by Fleetwood, the proprietor of Drury Lane old theatre, and by Tiers, the proprietor of Vauxhall. He also made many designs for booksellers, the best of which are the illustrations to Sir Thomas Hanmer's 'Shakspere.' He was the first librarian to the Royal Academy: he died in 1776. (Edwards, *Anecdotes of Painters*, &c.; *Somerset House Gazette*, 1824.)

HEADBOROUGH. [Constable, P. C.]

HEALTH, PUBLIC. [Public Health, P. C. S.]

HEARSAY. [Evidence, P. C.]

HEAT. [Abstraction and Absorption of Heat, P. C. S.; Conductors of Heat, P. C. S.]

HEAT, ANIMAL. The conversion of the food of man and the higher animals into nutriment for the body is attended with changes which produce an evolution of heat which constantly maintains the temperature of an animal at a point above or below, according to circumstances, the temperature of the medium in which it exists. The degree of heat possessed by animals not gifted with the power of locomotion is very small above that of surrounding media, and in this respect resembles the heat given off by plants. [TEMPERATURE OF PLANTS, P. C.] In proportion as animals possess the power of locomotion they evolve heat from their bodies. This arises from the fact that where the muscular system is most exercised there is greatest demand made upon the nutritionary processes going on in the system. We should therefore expect to find that the quantity of heat developed in the invertebrate animals was less than that in the vertebrate class. Infusoria are for a time capable of resisting cold; for when the water in which they are contained is frozen, the animalcule is observed to live for a time in a little uncongealed space which the caloric from its body prevents freezing. John Hunter found that various forms of Annelida, as leeches and worms, and several of the Mollusca, exhibited temperatures higher than the surrounding media. As might have been anticipated from their activity, the insects of all the invertebrate animals exhibit the highest temperature. They have been lately the subject of experiment by Mr. Newport. He found that they possessed a temperature above that of the medium in which they lived, varying from 2° to 9°. With respect to the temperature of the different tribes, Mr. Newport observes, 'Our previous observations lead us to anticipate the fact, that the volant insects, in their perfect state, have the highest temperature, while, on pursuing the inquiry, it is found that those species which have the lowest temperature are located on the earth. Among the volant insects, those hymenopterous and lepidopterous species have the highest temperature which pass nearly the whole of their active condition on the wing in the open atmosphere, either busily engaged in the face of day despoiling the blossoms of their honied treasures, or flitting wantonly from flower to flower, and breathing the largest amount of atmospheric influence. Of these the hive-bee, with its long train of near and distant affinities, and the elegant and sportive butterflies, have the highest. Next to these are probably their predatory enemies the hornets and wasps, and others of the same order; and, lastly, a tribe of insects which have always attracted attention, and in general are located on the ground, but sometimes enjoy the volant condition—the ants, the temperature of whose dwelling has been found to be considerably above that of the atmosphere. Next below the diurnal insects are the crepuscular, the highest of which are the sphinges and moths; and almost equal with them are the Melolonthæ.' In insects which live in societies the temperature is still greater. Mr. Newport found that a bee's-nest in a chalk bank had a temperature 14° to 16° above that of the atmosphere, and 17° to 19° above that of the bank.

Amongst the vertebrate animals, fishes and reptiles have the lowest temperature. Dr. Davy, John Hunter, and others, have found that fishes have a temperature of from ·7° to 2·7° above the surrounding medium.

In man the temperature of the accessible parts of the body, as the mouth, axilla, &c., is usually between 97·7° and 98·6°. The human blood is found to have a temperature in health varying from 100·6° to 101·75°; in disease it rises to 106° or 109°. In healthy persons the temperature is said to attain its maximum during the day, and to fall from 1·8° to 2·7° during sleep. Dr. Davy has also found that the temperature of the interior of the body is 2·7° to 3·6° higher in tropical than in temperate climates. Most of the Mammalia have a higher temperature than man, and birds develop a greater quantity of heat than any other class of animals. This arises from the nutritionary changes going on in the bird in order to support the enormous muscular power which it is compelled to exert during flight. The following is a table of temperatures, as given by Rudolphi and Tiedemann, for several birds and Mammalia:—

Birds.

	Degrees.
Great Titmouse	111·25
Swallow	111·25
Fringilla, different species	111·25 to 107
Anas, different species	111 to 106
Common Hen	109·94 to 102·99
Falco, different species	109·74 to 104·5
Pigeon	109·58 to 106·7
Raven	109·23 to 105·99
Vulture	107·49
Common Cock	103·78 to 102·99
White Game	102
Gull	100

Mammalia.

	Degrees.
Bat (Vespertilio pipistrellus)	106 to 105
Squirrel	105
Sheep	104 to 100·4
Ox	104 to 99
Rabbit	104 to 99·46
Ape	103·86
Cat	103·6 to 98·6
Bat (Vespertilio noctula)	102
Dog	101·3 to 99·3
Guinea Pig	100·4 to 96·37
Hare	100
Elephant	99·25
Horse	98·24 to 97

There is now no question that the cause of animal heat is the chemical changes which are going on in the nutrient fluid of the body. During the act of respiration a large quantity of oxygen gas is taken into the lungs, which is absorbed by the blood. In this fluid it meets the various compounds of carbon which have been taken in with the food; and the consequence is a union of the oxygen with the carbon, and the formation of carbonic acid gas, which gas is given out when the blood again reaches the lungs during expiration. When carbon and oxygen unite out of the body, heat is the result, and the same thing occurs when they unite in the body; and it is through the medium of this change that the bodies of animals are raised to a given temperature by the circulation of the blood through the system. It has been calculated that there is more oxygen absorbed than is given out of the system in the form of carbonic acid gas: it is probable that this enters into combination with hydrogen and compounds of hydrogen, nitrogen, and carbon, and thus contributes to the raising of the animal heat.

This theory of animal heat explains many well-known phenomena; as for instance, the slight independent warmth of the fœtus, and of those young animals which are born in an imperfectly developed condition. The low temperature of persons with *morbus caeruleus*, where the blood is only imperfectly oxygenated, and the cold experienced by aged and debilitated persons in whom a small quantity of blood circulates slowly; as also the increased temperature observed in persons labouring under attacks of inflammatory disease where the blood circulates rapidly, are also confirmatory facts. The phenomena also exhibited by the *hybernation* of animals are explained by this theory. During the period of hybernation, when the blood is circulating only slowly and respiration is almost suspended, and the oxygenation of the blood is feebly performed, the temperature of the animal is low. The observations of Pallas and others show that hybernation is prevented by a temperature of from 50° to 80°, whilst it is induced in those animals which exhibit it even in summer by the application of artificial cold.

The production of heat is also dependent on the mass of the globules of the blood and the rapidity with which they circulate. When there are few blood-globules the necessity for the absorption of oxygen is diminished in the same ratio, and the circulation becomes slower, and the consequence is that there is less heat developed. On the other hand, blood containing an excess of globules, but which is circulated less slowly, develops less heat than blood which contains a smaller proportion of globules but which is more rapidly circulated, for more oxygen may be consumed in the latter than in the former case.

'The metamorphosis of the blood and the general change of matter lead to still another secondary source of heat. It has been shown by Pouillet that all solid bodies, organic and inorganic, undergo an elevation of temperature when moistened with different fluids. In organic substances it may amount to from 11° to 18°. Since the act of metamorphosis is always effected through humid membranes, this source of heat must be regarded as of great importance, even if it be not actually identical with the catalytic metamorphosis of the cells themselves.' (Simon.)

(Carpenter, *General and Comparative Physiology*; Simon, *Medical Chemistry*, by Day.)

HEBER, REGINALD, second Bishop of Calcutta, was born April 21, 1783, at Malpas, Cheshire, of which place his father was for many years co-rector. The family was of considerable antiquity in the county of York, and on the death of an elder brother without heirs-male, the father of Reginald Heber succeeded him as lord of the manor of Marton, Yorkshire, and patron of the rectories there, and to estates at Hodnet, Shropshire, which had come into the possession of the family by intermarriage. By his first marriage, with Mary, co-heiress of the Rev. Martin Baylie, rector of Wrentham, Suffolk, he had one child, Richard, who for some time was representative in Parliament of the University of Oxford, and is known as a great collector of books; and by his second marriage, with Mary, daughter of Cuthbert Allanson, D.D., he had three children—Reginald, the subject of the present notice, Thomas Cuthbert, and Mary.

At a very early period of his childhood Reginald Heber was remarkable for his piety and for his eager thirst for knowledge. An excellent memory enabled him to recollect through life whatever he read with almost verbal accuracy. He gave early indications of his poetical talents, and at seven years old he had translated Phædrus into English verse. At eight he was sent to the grammar-school of Hawkhurst under Dr. Kent, and in his thirteenth year he was placed in the school of a clergyman near London. He remained here about three years, and in November, 1800, was entered at Brasenose College, Oxford. In his first year at the University he gained the prize for Latin verse, the subject of his poem being on the commencement of the new century. In the spring of 1803 he wrote his prize poem, 'Palestine,' which has obtained a permanent place in English literature. His career at Oxford was one continued course of success. From the winning modesty of his manners, his gentleness of disposition, and the charm of his conversation, his society was courted by persons of all ages. In his studies he evinced no taste for the exact sciences, but the antient languages he studied with larger views than is usual with most young men at the universities. In 1804 he became a Fellow of All Souls. The year after he had taken his degree he gained the Bachelors' prize for an English prose essay on the 'Sense of Honour.' About the middle of 1805, in company with his friend Mr. John Thornton, son of the member for Surrey, he set out on a continental tour. They proceeded through Russia, the Crimea, Hungary, Austria, and Prussia, and returned to England in October, 1806. In 1807, before he had obtained his degree of M.A., he took orders, and was instituted by his brother Richard to the family living at Hodnet. Here, as he himself described, he was in 'a half-way situation between a parson and a squire.' Never however were the duties of a parochial clergyman discharged with more exemplary zeal and benevolence; and Heber's conduct n his parish has often been pointed at as displaying in the greatest perfection all the best characteristics of a Church of England priest. In April, 1809, he married Amelia, youngest daughter of Dr. Shipley, Dean of St. Asaph. While discharging the dnties of his parish with so much earnestness he was ardently attached to the pursuits of literature. He was a frequent contributor to the 'Quarterly Review' from its commencement. In 1812 he commenced the preparation of a 'Dictionary of the Bible,' on which he laboured with much delight, bnt other duties compelled him to suspend this work, and no part of it was ever published. In the same year he published a small volume of 'Poems and Translations for Weekly Church Service.' The composition of his 'Hymns,' with a view of improving the psalmody and devotional poetry used in churches, was also a favourite recreation. He was an elegant versifier, and continued to indulge his poetical talents even while engaged in visiting his diocese in India. He had a great distaste for controversial theology, and only once was engaged in a discussion of this kind, in reply to what he conceived were the unwarrantable imputations of a writer in the 'British Critic.' His life was diversified by an occasional visit to his friends in other parts of England, or to his father-in-law in Wales, and by correspondence with a few friends. His political views were those of the High Church and Tory party, but devoid of all bitterness. He was well content with things as they were, and apparently had no perception of those abuses which have been swept away within the last thirty years. In 1815 he was appointed Bampton lecturer, and the subject he selected was 'The Personality and Office of the Christian Comforter.' In 1817, Dr. Luxmore, the Bishop of St. Asaph, appointed Heber to a stall in that cathedral, at the request of his father-in-law, tho Dean. In 1819 he edited the works of Bishop Jeremy Taylor. His other works consist of 'Parish Sermons' preached at Hodnet; and Sermons preached in India. In April, 1822, he was elected preacher of Lincoln's Inn, for which he had formerly been an unsuccessful candidate. On the 2nd of December, in the same year, his friend and connection, the Right Honourable Charles W. Williams Wynn, who was at the time President of the Board of Control, consulted him confidentially respecting the appointment to the vacant see of Calcutta, but did not offer him the appointment. There was every probability in fact that in the course of a few years Heber would obtain a mitre at home. But in another communication the vacant see was offered to him, and, without pressing him to accept it, Mr. Wynn expressed the opinion that in no position would Heber's talents find so ample a field or be so beneficial as in India. Twice the offer was declined, on account of his wife and child, but immediately after the second refusal he wrote (12th Jan. 1823) stating his willingness to go to India. He congratulated himself upon the fact that no worldly motives led him to this decision. The prospects of usefulness in so grand a field as India overbore all pecuniary considerations, and they had no influence in determining his conduct when the proposition of going to that country was first made to him. Besides, he had often expressed his liking for such a sphere of action, and he had 'a lurking fondness for all which belongs to India or Asia.' On the 22nd of April he saw Hodnet for the last time, and after having been consecrated, he embarked for his diocese, June 16, 1823. The diocese of Calcutta extended at this time over the whole of India, and embraced Ceylon, the Mauritius, and Australasia. In India the field of the bishop's labours was three times larger than Great Britain and Ireland. The number of chaplains who constituted his staff in Bengal was fixed at twenty-eight, but this number was never completed, and of the number who were appointed several were on furlough. The Bishop had no council to assist him, was required to act on his own responsibility, and to write almost every official document with his own hand. On the 15th of June, 1824, Bishop Heber began the visitation of his vast diocese. He visited nearly every station of importance in the upper provinces of Bengal and north of Bombay, and after an absence from Calcutta of about eleven months, during which he had seldom slept out of his cabin or tent, he arrived at Bombay. The Journal which he kept during his visitation, and which has been published in three octavo volumes, shows the extent of his observations on general subjects and the graphic power which he possessed of describing the novel scenes in which he was placed. From April to August he remained at Bombay to investigate and superintend the interests of the western portion of his diocese. Ou the 15th of August he sailed for Ceylon, and after remaining there some time he proceeded to Calcutta, which he reached on the 21st of October. If it had been possible to have educated his children in India, he was now prepared, he states, to end his days amongst the objects of his solicitude. In February, 1826, he left Calcutta for Madras to visit the southern provinces. On the 1st of April he arrived at Trichinopoli, and on the 3rd, after investigating the state of the mission and confirming fifteen natives, on whom he bestowed the episcopal benediction in the Tamul language, he retired to use a cold bath, in which he was found dead about half an hour afterwards. Within less than three weeks he would have completed his forty-third year. The candour, modesty, and simplicity of his manners, his unwearied earnestness and his mild and steady zeal, combined with his talents and attainments, had inspired veneration and respect not only amongst the European but the native population of India. It was said by those who were capable of judging, that few persons, civil or military, had undergone so much labour, traversed as much country, seen and regulated so much in so short a time. On the announcement of his death the most eminent men at each of the three Presidencies and in Ceylon united in showing their regret at the loss which they had sustained. At Calcutta it was agreed to erect in the cathedral a monument to his memory, which was afterwards executed by Chantrey. A monument, also by Chantrey, was erected in St. George's Church, Madras, in testimony of the public regret. At Bombay it was resolved to establish, in Bishop's College, Calcutta, one or more scholarships under the title of 'Bishop Heber's Bombay Scholarship.' Mural tablets were erected in the churches of Trichinopoli and at Colombo in Ceylon. His friends in England placed a monument in St. Paul's Cathedral; and in Hodnet church there is a tablet to his memory, the inscription on which was written by Southey.

(*Life of Reginald Heber*, by his Widow, 2 vols. 4to., London, 1830. This work contains Selections from his Correspondence, Unpublished Poems, and Private Papers; the Journal of his Tour in Russia, &c., and a History of the Cossaks. *Last Days of Bishop Heber*, by the Archbishop of Madras.)

HECTOR (Ἕκτωρ), the greatest of the Trojan heroes who figure in our accounts of the Trojan war. He was the son of Priam and Hecuba, and married to Andromache. The poet of the 'Iliad' describes him not only as a bold and gallant warrior whom Achilles himself dreaded to approach, but as a hero ennobled by all the more tender and humane virtues, so that it almost seems as if the poet had developed his character with more care than that of any other hero, not even excepting Achilles. Hector is the favourite of his parents, and himself a happy husband and father. The reader need only be reminded of the beautiful passages in the 'Iliad' (vi. 369, &c.), where Hector, before going to battle, takes leave of his wife and child, and where (xxii.), amid the lamentations of his parents, he prepares himself for the contest with Achilles. Wherever the battle is fiercest, Hector is foremost, and, protected by the gods Ares (Mars) and Apollo, he fights victoriously against the bravest of the Greeks, such as Ajax, Nestor, Diomedes, and Teucrus. He was foremost among those who stormed the Greek camp, and advanced as far as the place where their ships were stationed. Patroclus then came forward and drove the Trojans back to their city, but was slain by Hector. This calamity roused Achilles from his inactivity, and, thirsting to avenge the death of his friend, he sought Hector, who, though implored by his parents to save himself, resolved to engage with his enemy. Achilles thrice chased him round the walls of Troy, and finally pierced him with his spear. Hector's body was tied to the conqueror's chariot and dragged to the camp of the Greeks; at the funeral solemnities of Patroclus, it was dragged thrice around his tomb, and then thrown away to be devoured by the dogs; but at length Achilles gave up the body to Priam, who appeared as a suppliant before him and begged for it. The remains of Hector were buried at Troy, where funeral sacrifices were offered to Hector as a hero; at a later time, however, his remains are said to have been conveyed to Thebes, in pursuance of an oracle. (Pausanias, iii. 18. 9; ix. 18. 4.)

HEDJAZ. [ARABIA, P. C. and P. C. S.]

HEDY'SARUM (from ἡδύσαρον, the Greek name of the *Coronilla securidaca*), a genus of plants belonging to the natural order Leguminosæ. It has a 5-cleft calyx, with the segments linear-subulate and nearly equal; the corolla with a large vexillum, and obliquely truncate; keel much longer than the wings; the stamens diadelphous; the legume of numerous flat orbicular or lenticular regular 1-seeded joints, which are connected together in the middle, and therefore the sutures are convex on both sides. The species are herbs or under-shrubs, with unequally pinnate leaves, axillary, with simple peduncles, and bearing racemose spikes of large purple, white, or cream-coloured flowers. The old genus Hedysarum has been subdivided into many smaller genera. The Saintfoin [SAINTFOIN, P. C.], *H. onobrychis* of older writers, now forms the genus *Onobrychis*, which differs from *Hedysarum* in the legumes consisting of many joints, not of one joint, as in that genus.

H. coronarium, French honeysuckle, has diffuse stems, the leaves with 3-5 pairs of elliptic or roundish leaflets, which are pubescent beneath and on the margins; the spikes or racemes of flowers are ovate crowded; the wings of the flower twice the length of the calyx; the legumes glabrous, with 25 orbicular prickly joints. It is a native of Spain and Italy. It has deep red or white flowers. In Calabria this plant grows wild in great abundance, and horses and mules are fed with it. It grows well in our gardens, but probably would not make a good field crop.

H. fruticosum has an erect shrubby stem, the leaves with 5-7 pairs of alternate elliptic obtuse leaflets, which are clothed with pubescence on both surfaces; the flowers few, disposed in spikes; the wings hardly longer than the calyx; the vexillum the length of the keel; the joints of the legume wrinkled; the nerves slightly echinate. It is a native of Siberia in sandy places. It has a pale purple flower, and is a very handsome plant. Horses eat it with avidity, and it may be made useful in fixing sand, in which it grows readily.

H. Mackenzii has recumbent stems; the leaflets oblong, clothed on both surfaces with canescent pili; the stipules sheathing; the joints of the legume transversely wrinkled and pilose. It is a native of arctic America and about the Saskatchewan, on the Eagle and Red-deer hills. The flowers are large and of a red colour. This was described as a liquorice plant by Sir A. Mackenzie, and named after him. The whole plant has a sweet taste.

H. lineare is used in Cochin China as a stomachic, and *H. alpinum* is used in Siberia for the same purpose. The *H. sennoides* of Willdenow, now *Ormocarpum sennoides*, has a root which is used in India as a tonic and stimulant. The *H. alhagi* of Linnæus is the *Alhagi maurorum* of recent writers. It is a spiny shrub, and from its branches exudes a sweet substance like manna. *H. tuberosum* of Roxburgh, *Pueraria tuberosa* of De Candolle, grows in the Circar mountains. The roots are used by the natives as poultices for swellings of the joints.

All the species of the genus Hedysarum may be cultivated. They thrive in a light rich soil; the perennial sorts may be increased by dividing the roots; and the seeds of the annual species should be sown in an open border.

(Lindley, *Flora Medica*; Don, *Gardener's Dictionary*; Burnett, *Outlines of Botany*.)

HEEM, JAN DAVITZE DE, one of the most distinguished of the Dutch fruit and flower painters, was born at Utrecht about 1600, and died at Antwerp in 1674.

His son, Kornelis, or Cornelius, was likewise an excellent painter in the same department.

(Houbraken, *Groote Schouburg*, &c.)

HEEMSKERK, MARTEN, a celebrated Dutch painter, who was born at Heemskerk, near Haarlem, in 1498: he was the son of a peasant farmer, Jacob Willemsze Van Veen, but he is known only by the name of his birth-place. Marten was employed by his father in common farm labour, which was particularly distasteful to him. He had given evidence of a talent for the art of design, and his mother was favourable to his plan of becoming a painter. As he was returning home one evening with a pail full of milk upon his head, lost in a reverie about his future prospects, he came unconsciously in contact with a tree; the milk was lost, and to Marten's dismay he saw his father hastening up to him with a stick in his hand. His mind was instantly made up; he fled to Delft, obtained admission into the house of a painter of the name of Jan Lucas, and he too became a painter. He studied afterwards with Jan Schoorel, at Haarlem, and his earliest works of distinction were painted in the style of that master. After painting for some years at Haarlem with great success, he set out, in 1532, for Rome, but before he left he presented the Painters' Company at Haarlem with a picture of St. Luke painting the Virgin Mary, a picture which is much praised by Van Mander, and it was long preserved with great care at Haarlem. In Rome, Marten, known as Martin Tedesco, distinguished himself as an imitator of Michel Angelo; the jealousy of the Italians, however, forced him to return to his own country, after a stay of three years in Italy. When he arrived at Dordrecht, he had a narrow escape of his life, for he put up, by recommendation from Rome, at an inn, which turned out to be a den of murderers, in which many travellers had perished: the story is told by Van Mander.

Heemskerk's early admirers were not at all pleased with the new style which he imported from Italy; he however found many new admirers, and he executed numerous works in this new style. In his earlier paintings he belonged to the school of the Van Eycks: his style was simple, earnest, and in character natural; in his later paintings he imitated in a manner the antique and the cinquecento style of Italy, but he caricatured the antique, and caught only the defects of the modern. There are scarcely any works by Heemskerk now at Haarlem; some were carried to Spain during the Spanish war, and many were destroyed by the iconoclasts in the riots of 1566. There is a Last Judgment by him at Hampton Court; and there are several of his earlier works in the Pinakothek, at Münich, which, however, show that he was not one of the best of the Van Eyck school. He died very rich, and, though twice married, childless, at Haarlem, in 1574. The engravings after his works, by various masters, amount to many hundreds.

(Van Mander, *Het Leven der Schilders, &c.*; Schopenhauer, *Johann Van Eyck und seine Nachfolger*.)

HEERE, LUCAS DE, a distinguished painter and poet, was born at Ghent in 1534. His father, Jan de Heere, was a good sculptor, and his mother excelled in miniature painting. Lucas was placed with Frans Floris, after he had made sufficient progress with his father to benefit by the instruction of Floris.

De Heere painted in France; and he was in England in the reign of Queen Elizabeth, whom he painted several times. There is a flattering allegory of her by him at Hampton Court: it represents Elizabeth as queen, attended by two maids of honour, coming into the presence of Juno, Minerva, and Venus; the first is put to flight, the second is astonished, and the last blushes; this is partly ascertained by the follow ing Latin verses, probably by De Heere himself, written on the frame:—

Juno potens sceptris, et mentis acumine Pallas,
Et roseo Veneris fulget in ore decor;
Adfuit Elizabeth; Juno perculsa refugit;
Obstupuit Pallas, erubuitque Venus.

In 1570 Lucas was employed to paint a gallery for Edward earl of Lincoln, lord high admiral, in which he was to represent the costumes of different nations. For England, says Van Mander, he painted a naked man surrounded by all sorts of woollen and silk stuffs, with a pair of scissors and a piece of chalk; and when the admiral asked him to explain it, Lucas said that he could not paint the Englishman in any particular costume, as he changed it daily; he therefore painted him naked, gave him stuff and shears, and left him to make his own clothes. This however, as Walpole has pointed out, was not an original device; it is prefixed by Andrew Borde, or Andrea Perforatus as he called himself, to his 'Introduction to Knowledge,' with the following lines:—

I am an Englishman, and naked I stand here,
Musing in my mind what raiment I shall wear.

The principal of Lucas's poetical works was the Garden of Poetry, 'Boomgaard der Poësijë;' he commenced also in verse the 'Lives of the Painters,' but this is lost. He died at Ghent in 1584: he used for a monogram an H and E joined, and he used also sometimes the following moral anagram of his own name, 'Schade leer u' (injuries teach you). De Heere was the master of Van Mander.

(Van Mander, *Het Leven der Schilders*, &c.; Walpole, *Anecdotes of Painting*, &c.)

HEEREN, ARNOLD HERMANN LUDWIG, was born at Arbergen, a village near Bremen, on the 25th of October, 1760. His father, who was pastor at Arbergen, and a man of extensive knowledge, gave him his first instruction in religion, Latin, and mathematics. His further education, until his sixteenth year, was intrusted to private tutors; but in 1776 his father was appointed preacher at the cathedral of Bremen, and young Heeren entered the domschule or gymnasium of Bremen to prepare himself for the university. He states that the exercises in Latin disputations at school and the intercourse with the wealthy merchants of Bremen exercised a great influence upon the development of his mind and upon the manner in which he afterwards viewed and described the phenomena of history and of human life. In the autumn of 1779 he went to the university of Göttingen with the intention of devoting himself to the study of theology, but the influence of Heyne, one of whose lectures he attended, wrought a complete change, and Heeren was soon engaged exclusively in philological pursuits. However he soon felt that philology, in the narrower sense of the term, was not his vocation, for the things about which he read in the antients interested him more than the languages themselves. Heyne did all he could to win Heeren for philology, and for a short time he succeeded. In 1784 Heeren took his degree of doctor in philosophy, and on that occasion wrote a dissertation 'De Chori Graecorum tragici natura et indole, ratione argumenti habita.' In the year following he published a new edition of the rhetorician Menander, and formed the plan of a new edition of the 'Eclogae' of Stobaeus. The preparations that he had to make for this work convinced him more and more that verbal criticism was not congenial to his mind. He had commenced giving lectures at Göttingen as privatdocent, but the opposition between his actual pursuits and what he felt to be his vocation became more and more painfully felt; his spirits began to fail, and his health also began to sink. It was fortunate for him that he possessed ample means, for otherwise he would perhaps have fallen a victim to his melancholy, the result of an ill-chosen career of life. He resolved to visit Italy, and principally Rome. One of the main objects of this journey was to collate the various MSS. of Stobaeus, but this did not prevent his paying attention to a variety of other subjects, which had more interest for him. His stay in many of the principal towns of Germany, France, and Italy was of great advantage to him; the future historian became acquainted with the world at large; he saw with his own eyes some of the countries to whose history a great part of his future life was to be devoted, and formed friendships with men of the highest eminence, such as Zoëga, Filangieri, and Cardinal Borgia, in the intercourse with whom his mind became expanded and enriched with new ideas. On his return to Göttingen in 1787, he was appointed professor extraordinary in the philosophical faculty, and henceforth his life flowed undisturbed by any changes of fortune; being possessed of wealth, he was enabled to continue his philological and historical studies without anxious cares; he enjoyed the favour and friendship of the highest in rank and literature, and in 1796 he married a daughter of Heyne, who remained his devoted and sympathizing companion throughout his life. All his energies were divided between his professional studies and duties, and the production of those works which will ever secure him a place among the best historians. His lectures had from the first an historical tendency, and if it had not been for the edition of Stobaeus, which he had undertaken, he would have confined himself exclusively to lecture on history. At length in 1799 he was appointed ordinary professor of history, as the successor of Gatterer. His reputation as a scholar and historian was already established, for the first two volumes of his Stobaeus had appeared in 1792 and 1794 (the third and last was published in 1801); in 1793 and 1796 he had published the first two volumes of his 'Ideen über die Politik, den Verkehr und den Handel der vornehmsten Völker der alten Welt' (the third and fourth volumes appeared in 1812 and 1815), which is his principal work, and the one on the completion of which he looked as the main object of his life; a fifth edition in 5 vols. appeared in 1824, &c. In 1799 he published the first edition of his manual of antient history ('Handbuch der Geschichte der Staaten des Alterthums'). A fifth appeared in 1826. It must be remembered that in addition to these works, which followed one another in rapid succession, and of which each has its own merits, he had for some years been editing, conjointly with his friend Tychsen, a journal on antient literature and art ('Bibliothek der alten Literatur und Kunst'), and had written a great variety of essays for other periodicals, and for the 'Transactions of the Royal Society of Göttingen.' His activity was astonishing, and, in addition to all this, he began about the year 1800 to study the history of the middle ages and of modern times, and also lectured upon these subjects with as much applause as he had before obtained by his lectures on antient history. It is further worth mentioning that Heeren's activity as an author was always in the closest connection with that of a lecturer, and before he wrote a work on any subject he had at least once or twice lectured on it in the university. Hence he always appears a master of his subject, and was enabled to give to his productions that finish and perfection which makes them popular in the best sense of the term, and which is certainly a rare characteristic of German writers. A great work relating to the history of modern times, and which is thought by some to be the best of his productions, bears the title 'Handbuch der Geschichte des Europaeischen Staatensystems und seiner Kolonien,' Göttingen, 1809; a fourth edition appeared in 1822. A work on the influence of the Crusades ('Sur l'Influence des Croisades,' Paris, 1808) was crowned by the Academy of Inscriptions. A collection of his minor historical works, in 3 vols. ('Kleine historische Schriften'), appeared from 1803 to 1808, and another embracing all his historical works, in 15 vols., from 1821 to 1826. Most of his works have been translated into English and Dutch, and some of them are still regarded as standard works of their kind. On the death of Eichhorn, in 1827, he undertook the editorship of the 'Göttingische Gelehrten Anzeigen,' which, together with his professional duties, took up so much of his time that he was unable to complete his great work on the politics and commerce of the states of antiquity, although considerable preparations had already been made for it.

Heeren's merits were universally acknowledged. The academies of St. Petersburg, Berlin, Munich, Stockholm, Dublin, and Copenhagen showed him their respect by electing him a member. He was also a member of the Asiatic societies of London and Calcutta. In 1827 or 1828 Heeren, in conjunction with Ukert, formed the plan of editing a series of works, containing the histories of the states of Europe. The best historians of Germany were induced to write histories for the series. The whole is not yet completed, but among these works there are some of the highest eminence, such as Lappenberg's 'History of England,' and Geijer's 'History of Sweden.' Heeren died at Göttingen, on the 6th of March, 1842.

The great merits of Heeren's works, especially of those relating to antiquity, are these: they are usually the result of a diligent study of the antient writers themselves, and represent the nations in their political and commercial relations in a very lively manner. His works are written in a clear style, so as to be intelligible to any person of moderate education, and the influence which they have exercised is, for this very reason, very considerable. His works are not indeed without their defects, and many of them no longer satisfy the demands of our age; but it must not be forgotten that Heeren was the first historian, at least in Germany, who breathed life into the history of antiquity, saw in it something more than a mere succession of battles and defeats, and made his readers familiar with the more peaceful pursuits of the antients and their principles of government. In his private life he is said to have been a man of the most gentle and benevolent disposition.

(For further particulars respecting his life, see Heeren's Letter to a friend in the first volume of his historical works, and Karl Hoeck, *A. H. L. Heeren, eine Gedächtnissrede*, Göttingen, 1843, 4to. A complete list of his works may be found in Pütter, Saalfeld, and Oesterley's *Geschichte der Universität Göttingen*, vol. ii. p. 194; vol. iii. p. 344; and vol. iv. p. 442.)

HEGE'SIAS (Ἡγησίας), a Greek rhetorician and historian, was a native of Magnesia, and lived about the time of the historian Timæus, that is, about B.C. 250. Respecting his life no particulars are known, but as an author he appears to have been of some importance in antiquity, though more for his bad than for his good qualities. Strabo (xiv. p. 648) calls him the founder of that florid and inflated style of oratory which was afterwards designated by the name of the Asiatic; and this testimony is borne out by Cicero (*Brut.* 83; *Orat.* 67, 69) and others. Hegesias himself pretended to imitate the Attic orators, especially Lysias. He seems to have been destitute of all the qualities required of an orator, and to have taken a great delight in childish conceits and a pretty way of expressing them. This we must conclude both from the opinions of antient critics as well as from the few specimens of his oratory which have come down to us, and are preserved in Dionysius (*De Compos. Verb.*, 4, 18) and Photius (*Biblioth. Cod.*, 250). As an historian he appears not to have been much better than as an orator. The subject which he chose was the history of Alexander the Great, but that he had no notion of the dignity of history is evident from the specimens given by Dionysius, Photius, and Plutarch (*Alex.* 3); and A. Gellius (ix. 4) does not appear to be much mistaken in classing him among those who, unconcerned about historical truth, filled their books with marvellous occurrences and incredible stories. (Compare Strabo, ix. p. 396; Longinus, *De Sublim.*, 3; Theon, *Progymnasm.*, 2; St. Croix, *Examen critique des Historiens d'Alexandre*, p. 47, &c.)

From this Hegesias we must distinguish HEGESIAS *the Cyrenaic philosopher*, who lived somewhat earlier, in the reign of Ptolemæus Philadelphus, and was a disciple of Paraebates. His doctrines, however, differed in several points from those of other Cyrenaics, and so much so that his followers were regarded as a distinct school, and are called as such Hegesiaci (Ἡγησιακοί). In the main points they agreed with Aristippus, the founder of the Cyrenaic school, who maintained that pleasure was the great object of man's life; but Hegesias and his school went further; they denied that kindness, friendship, and benevolence had any independent existence, but that they arise and disappear with our feeling of the want of them. Happiness, they said, is a thing impossible to attain, for our body is subject to many sufferings, and the soul suffers with it. Life and death are equally desirable; nothing is by nature either agreeable or disagreeable, but becomes so through the circumstances in which a man lives. A wise person therefore looks upon life with indifference, and regards nothing and nobody so much as himself, reducing everything to his own convenience. This miserable view of human life was somewhat softened down and improved by Anniceris, the disciple of Hegesias. Hegesias wrote a work entitled Ἀποκαρτερῶν, in which he introduced a person resolved to starve himself, and explaining to his friends why death was more desirable than life. He seems to have taught philosophy at Alexandria, but as in consequence of his doctrines many persons destroyed themselves, King Ptolemy Philadelphus is said to have forbidden him to teach any more. (Diogenes Laert., ii. 86, 93-96; Cicero, *Tuscul.*, i. 34.)

HEINRICH, CARL FRIEDRICH, a distinguished German scholar, was born on the 8th of February, 1774, at Moschleben in the duchy of Saxe-Gotha, where his father was pastor. He received his first education at the Klosterschule of Dondorf, and afterwards at the Gymnasium of Gotha, where he enjoyed the instruction of Döring, Manso, Jacobs, and other eminent scholars. Heinrich had read the principal Greek writers, even before he entered the Gymnasium, and his intimate acquaintance with them caused him to be looked upon as a wonderful boy. In 1791 he went to Göttingen, where he became the favourite pupil of Heyne, who made him the tutor of his son. In 1795 Heinrich was appointed teacher at the Gymnasium of Breslau, and in 1801 he obtained the title of professor. Böttiger, the eminent archaeologist, persuaded him to take an interest in the theatre at Breslau, and Heinrich not only exerted himself to raise its character, but wrote several dramas himself, and in the end became one of the managers of the theatre. In 1804 Heyne procured him the professorship of eloquence and of Greek in the university of Kiel. Philological studies had been greatly neglected there, and Heinrich at first lectured to empty benches, but he soon attracted a great concourse of students. In 1819 he was invited to a professorship in the newly-established university of Bonn. He accepted the offer, and henceforth continued to lecture there until his death on the 20th of February, 1838.

Heinrich was a very excellent Latin scholar, though his lectures on Latin authors were very unequal. The best were those on the Satires of Horace, Juvenal, and Persius, for he himself had great satirical talent; his explanations always excited a most lively interest, being seasoned with his own wit and sarcastic allusions. The philological seminary of Bonn was much indebted to his exertions; but his personal character was anything but amiable: he was whimsical, inconstant, and not unfrequently malicious. He published few works, but all of them have great merit; the following is a list of them:—1. 'Epimenides aus Creta, eine kritisch-historische Zusammenstellung aus Bruchstücken; nebst Zwei kleinern antiquarischen Versuchen,' Leipzig, 1801, 8vo., an excellent critical essay on the life of Epimenides and the works attributed to him. 2. 'Lycurgi Oratio in Leocratem,' Bonn, 1821, 8vo. 3. An edition of Cicero's treatise 'De Re Publica,' Bonn, 1828, 8vo., with an extensive critical commentary. He further wrote critical essays in several periodical works, and was one of the editors of Köppen's German Commentary on Homer, in 6 vols., Hanover, 1794-1823. In the year after Heinrich's death his edition of Juvenal, for which all preparations were made before, was published by his son, Bonn, 1839, 2 vols. 8vo., which is the best edition of Juvenal that we have. (See Long, in the *Classical Museum*, vol. i. p. 369, &c.) An edition of Persius, for which Heinrich had likewise left the MS. ready, was published by Otto Jahn.

HELIA'NTHEMUM, a genus of plants named from ἥλιος, 'the sun,' and ἄνθος, 'a flower,' because the flowers open with the rising of the sun, and fall with the setting of the sun in the evening. This genus belongs to the natural order Cistineæ or Cistaceæ, and the species were at one time included under the genus Cistus, but they differ materially in their characters. There are about 150 species enumerated, which are distributed in various parts of the world; they are chiefly found in the south of Europe, the north of Africa, and a few species in America. The calyx consists of 5 sepals, the 2 exterior ones smaller or wanting, 5 deciduous petals, numerous stamens, and 3-valved capsules. The flowers are yellow, red, or white, and are very elegant; none of the species possess any available property in the arts or medicine, but they are extensively cultivated on account of their very beautiful and ornamental appearance.

H. guttatum is an erect herbaceous plant with oblong lanceolate or linear leaves, the racemes without bracts, and the stigma subsessile. The flowers are yellow, with a deep red spot at the base of each petal. It is a native of France, Italy, Spain, Portugal, and Turkey, and is found in Anglesey and Jersey in Great Britain, but is a very rare plant.

H. canum, the Hoary Sun-rose, is distinguished by its shrubby appearance, without stipules, and having terminal bracteated racemes. The flowers are yellow and small. It is a native of the south of France and Germany, and is rarely found in Great Britain.

H. vulgare, the common Rock-rose, is a procumbent shrub, with stipules, bracteated racemes, the style larger than the ovarium, and bent at the base. The flowers are yellow, and bloom from May to September. It is a native of Europe, and is found in Britain in dry hilly pastures.

There is a very beautiful variety with double pale yellow flowers, which is much cultivated by florists. The stamens, if touched in the sunshine, spread slowly, and lie down upon the petals.

Almost all the species of Helianthemum are elegant plants, of hardy growth, and easily cultivated. They grow best in a light sandy soil, and should be protected during the winter in a frame.

(Don, *Gardener's Dictionary;* Babington, *Manual of British Botany;* Loudon, *Encyclopædia of Trees and Shrubs.*)

HELIOTRO'PIUM (from ἥλιος, the sun, and τροπή, a turning), a genus of plants belonging to the natural order Ehretiaceæ. It has a salver-shaped corolla, with the throat usually naked, but in some species bearded; the segments of the limb furnished with a single fold or a tooth between each; the stigma sub-conical; the carpels 4, 1-celled, combined, closed at the base, without any manifest receptacle. The species are annual or shrubby plants, with alternate leaves, and circinate spikes of small blue or white flowers.

H. Peruvianum, Peruvian Heliotrope or Turnsole, has a shrubby stem, petiolate oblong-lanceolate wrinkled leaves, terminal branched spikes; the tube of the corolla hardly the length of the calyx. The mouth of the corolla is intersected with five plicatures of a purple-lilac colour with a greenish throat. It is a shrub, growing one or two feet high, and is much cultivated on account of the scent of its flowers, which resembles very much the smell of the vanilla. It is a native of Peru.

H. Europæum, the European Turnsole or Heliotrope, has an herbaceous erect stem, with ovate flat-lined finely tomentose leaves, the lateral spikes solitary, the terminal ones conjugate, the calyx spreading in the fruit-bearing state. It is a native of the south of Europe and the regions of the Caucasus. The flowers are sweet-scented.

H. villosum has an herbaceous erect very villous stem, with ovate, flat, villous leaves, the spikes lateral, terminal, solitary, and conjugate; the corollas large; the calyx spreading in the fruit-bearing state. It is a native of Greece and of the islands of the Archipelago. It has large white corollas with a yellow throat. This appears to be the ἡλιοτρόπιον μέγα of Dioscorides (iv. 190) and the *H. supinum*, the ἡλιοτρόπιον μικρόν.

Upwards of eighty species of this genus have been enumerated. They are natives of the warmer parts of Europe, Asia, Africa, and America, and are found in New Holland. They do not possess any active properties.

Many other species besides those here described have sweet-scented flowers, and are cultivated on that account. Some of them are consumed in large quantities by perfumers for the sake of their volatile oil. They are astringent and also mucilaginous, and poultices made of the leaves have been applied to cancerous and scrofulous sores. It is supposed that the plant used for the cure of warts, and called 'Verrucaria,' belonged to this genus. In their cultivation the shrubby and perennial kinds will be found to thrive in any kind of rich light soil, and cuttings will root readily in sand under a hand-glass. The European annual species may be propagated from seed sown in an open border, whilst the tropical annual species must be sown upon a hot-bed before being planted out.

(Don, *Gardener's Dictionary;* Burnett, *Outlines of Botany;* Fraas, *Synopsis Plant. Floræ Classicæ.*)

HELL, MAXIMILIAN, a distinguished astronomer and member of the order of Jesuits, was born May 15, 1720, at Schemnitz in Hungary, and manifested, at an early age, a decided taste for the study of natural philosophy and astronomy. At twenty-five years of age he was employed as an assistant in an observatory belonging to the Jesuits at Vienna, and he was at the same time keeper of the museum of experimental philosophy which had just then been formed in that city. In 1746 he was made rector of an academy at Leutschau in Hungary; but this post he held only one year, when he returned to Vienna. Here he completed his theological studies, and received a small number of pupils, whom he instructed in mathematics. He took orders in 1751, and after three years he obtained the rank of doctor, with an appointment to the professorship of mathematics at Clausenburg in Transylvania. Having continued in this situation four years, he again returned to Vienna, where he was established in an observatory which had been built in conformity to his own directions; and he held the appointment during the remainder of his life. Besides the duty of making celestial observations, he was charged with that of giving lessons in mechanics; as, in England, about eighty years earlier, the first astronomer royal was required to teach the use of nautical instruments to two boys from Christ's Hospital: the German astronomer, however, gave the lessons only during one year, his time afterwards being fully occupied in performing services more important to science.

Through the mediation of Count Bachoff, who was sent from Copenhagen for the purpose of making the proposal, he accepted an invitation from the court of Denmark to undertake a journey to Wardhuys in Lapland, in order to observe there the transit of Venus over the sun's disc. Accordingly he set out from Vienna in 1768; and, after staying a short time at Copenhagen, he proceeded to the place of his destination: he was absent about two years and a half on that mission, when, having fully succeeded in its object, he returned to Vienna. Besides observing the transit, Hell took advantage of his residence in Lapland to study the geography, the natural history, and the climate of the country; the history, language, and religion of the people, with the state of the arts among them: he made also numerous observations on terrestrial magnetism, on the phenomena of the tides and winds, and on the variations of the barometrical column; and he measured the heights of the principal mountains. After his return he prepared a work containing a full account of his researches, which was to have been published in three volumes, 4to., but it never appeared.

Hell was very fortunate in the sky being favourable, on the day (June 3, 1769) that the transit took place, so that he was enabled to observe the interior contact at the commencement, and both the interior and exterior contacts at the termination of the phenomenon; and it is a proof of the accuracy of his observations that the value of the sun's parallax, which he deduced by comparing them with the corresponding observations at certain other places, agreed, within one-fifth of a second, with the value afterwards determined from comparisons with all the best observations which were made.

On accepting the engagement, Hell was enjoined by the Danish ministry to abstain from publishing any account of his observations till his return to Copenhagen, and till he had made all the requisite computations. The delay which, in consequence of this injunction, took place in making Hell's observations public, gave offence to Lalande, who had, by letters addressed to the different governments of Europe, greatly promoted the measure of observing the phenomenon at different places on the earth's surface; the two astronomers were however soon reconciled, and they continued to correspond with each other as before. Hell drew up a memoir relating to the transit, which was read before the Academy of Sciences of Copenhagen, November 24, 1769.

The principal work published by this astronomer was a series of Ephemerides in thirty-five volumes, 8vo., the collection being entitled 'Ephemerides Anni 1757—1791 ad Meridianum Vindobonensem Calculis definitæ.' With the exception of two volumes, these contain appendixes on astronomical subjects by himself or other scientific men, chiefly by Pilgram and Triesnecker; the former of whom edited the work during the absence of Hell in Lapland. The rest of his publications on astronomical subjects are as follow:—'Tabulæ Solares Nicol. Ludov. de la Caille cum Supplemento Reliquarum Tabularum,' 1763; 'Tabulæ Lunares Toh. Mayer cum Supplemento, etc.,' 1763; 'De Satellite Veneris,' 1765; 'De Transitu Veneris ante Discum Solis die 3 Jun., 1769, Wardoehusii observato,' 1770; 'De Parallaxi Solis ex Observationibus Transitûs Veneris, anni 1769,' 1773; and 'Methodus Astronomica sine Usu Quadrantis, etc.,' 1775. He also edited a collection, which had been made by Hallerstein, of the astronomical observations made by the Jesuits at Pekin from 1717 to 1752; this was published at Vienna, in 2 vols. 4to., in 1768.

Besides these works he published 'Elementa Algebræ J. Crivellii,' 8vo., 1745; 'Adjumentum Memoriæ Manuale Chronologico-Genealogico Historicum,' 16mo. 1750; 'Elementa Arithmeticæ Numericæ et Literalis,' 8vo. 1763; also a tract on the true magnitudes of the sun and moon when seen by the naked eye, 1775; and one on a New Theory of the Aurora Borealis, 1776.

All his works were published at Vienna; and he died in that city, April 14, 1792, being seventy-two years of age. A brother of Hell was a distinguished mechanician at Schemnitz, and the inventor of a sort of siphon for draining mines: this is described in the 'Mémoires de l'Académie des Sciences de Paris' for the year 1760.

HELM WINDS. [WIND, P. C.]

HELMINTHOCORTON. [SEA-WEEDS, P. C.]

HE'LODUS. [FISHES, FOSSIL, P. C. S.]

HELOSCIA'DIUM, a genus of plants belonging to the natural order Umbelliferæ and to the tribe Ammineæ. It has a calyx of 5 teeth or obsolete; the petals ovate, entire, with a straight or encurved apiculus; the fruit ovate or oblong; the carpels with 5 filiform prominent equal ridges; the interstices with single vittæ, the carpophore entire. There are three British species of this genus.

H. nodiflorum, with the leaflets obtusely serrate; *H. repens*, with the leaflets roundish, ovate, unequally and acutely inciso-serrate; and *H. inundatum*, with the leaflets of the lower leaves divided into capillary segments. The first is a native of brooks and ditches, and is frequently mistaken for the water-cress. [SIUM, P. C.] The second is a rare plant in Great Britain. The last species is found in ponds.

(Babington, *Manual of British Botany*.)

HELSTON, a market town and parliamentary and municipal borough, in the hundred of Kerrier or Kirrier, in the county of Cornwall, 296 miles west-south-west of the General Post Office, London: viz., 197 to Exeter by railway, and from thence 99 miles by coach road through Oakhampton, Launceston, Bodmin, and Truro. Helston was made a borough by King John (A. D. 1201). According to Lysons, the townsmen paid him forty marks of silver and a palfrey that their town might be made a free borough. King Edward I. made it one of the coinage towns; and it sent members to Parliament from his reign. There was a castle here in which Edmund, Earl of Cornwall, cousin of Edward I. resided at one time, but it was afterwards so neglected that it was in ruins in the time of Edward IV.; and the town itself was in the reign of Henry VIII. one of tho decayed towns for the repair of which an act of parliament was passed.

The town stands on the left or eastern bank of a small stream, the Lo or Low or Loo which forms about a mile below the town a wide expanse of water called Lo-pool. The river Hel or Heyl, distinguished from another stream of the same name in the county, as the Heyl in Kirrier, and sometimes called the Helford, flows about two miles east of the town, or rather less. The streets are irregularly laid out; but are paved and lighted with gas, and the town presents a neat and clean appearance. The market-house and town-hall are near the centre of the town, and the antient coinage-hall stands at the end of a street to which it gives name. There are no remains of the castle. The Church dedicated to St. Michael is a modern building of 'white moorstone' (granite), erected by the Earl of Godolphin in A. D. 1763. There are a baptist meeting-house and a Wesleyan chapel. Tho population of the old borough and chapelry which has an area of 130 acres was in 1841, 3584; the number of houses was 763, viz., 682 inhabited, 66 uninhabited, and 15 building. The number of houses in 1831 was only 616, viz. 581 inhabited, 23 uninhabited, and 12 building; the population was 3293, so that the increase of population in the ten years 1831-41 was 291; and the increase in the number of inhabited houses, 101. The town is the centre of an important agricultural and mining district: it has two markets, on Wednesday and Saturday; and there are several fairs or great markets in the year. A great number of shoes are made in the town, and are sold at the markets and fairs; or are sent to Redruth. The borough, which previous to the Reform Act returned two members, now returns only one; the old borough was, for parliamentary purposes, enlarged by the addition of the adjoining parish of Sithney and of a considerable part of the parish of Wendron. The population of Sithney parish in 1841 was 3362, of Wendron 5576, which, united with the population of the old borough, makes a total of 12,522; but what deduction is to be made for that part of Wendron parish which is not in the parliamentary borough, we have no means of ascertaining. The number of electors on the register in 1835-6 was 356, in 1839-40 it was 406, showing an increase in four years of 50 voters. The town is a polling station for the western division of the county of Cornwall. By the Municipal Corporations Reform Act, the borough has 4 aldermen and 12 councillors, but was not to have a commission of the peace except on petition and grant. The old municipal boundaries have not been altered. The living is a perpetual curacy united with the vicarage of Wendron, of which parish the chapelry of Helston is a dependency; the clear yearly value of the united benefice is 876*l*., with a glebe-house: it is in the rural deanery of Kerrier, in the archdeaconry of Cornwall and the diocese of Exeter. There were in the chapelry of Helston in 1833 two national schools with 100 boys and 70 girls partly supported by subscription; and five other day or boarding schools with 123 boys, 66 girls and 40 children of sex not stated, giving a total number of 399 children, or about one in eight of the population (according to the then recent census of 1831) under daily instruction. There were at the same time two Sunday-schools, with 260 children, viz., 127 boys and 133 girls connected with the two dissenting congregations.

(Lysons, *Magna Britannia (Cornwall)*; *Municipal Corporations Commissioners' Reports*, *Population Returns* and other *Parliamentary Papers*.)

HELVELLA. [HYMENOMYCETES, P. C. S.]

HEMANS, FELICIA DOROTHEA, was born September 25, 1794, at Liverpool, where her father, whose name was Browne, was engaged in mercantile pursuits. He was a native of Ireland; her mother was an Englishwoman, but was descended from a Venetian family, through her father, who was commercial agent at Liverpool for the Venetian government. Felicia Dorothea Browne was the fourth child of a family of three sons and three daughters. About the year 1800 Mr. Browne, in consequence of the failure of a mercantile concern in which he was engaged, removed his family from Liverpool to an old mansion, spacious and solitary, called Grwych, not far from Abergele, in Denbighshire, North Wales. Mr. Browne died not long afterwards. Felicia Browne began to write poetry before she was nine years of age, and her mother, a woman of education and taste, was her first confidant and encourager.

Miss Browne's first volume of poems was published in 1808, and contains some verses written by her as early as 1803 or 1804. A harsh review of this little volume affected her so much that she was confined to her bed for several days. Her second volume, 'The Domestic Affections,' was published in 1812.

In 1812 Miss Browne became the wife of Captain Hemans, of the fourth regiment. His constitution had suffered so severely in the retreat upon Corunna, and subsequently by fever caught in the disastrous Walcheren expedition, that he felt it necessary, a few years after their marriage, to exchange his native climate for that of Italy. This at least is the motive assigned for his leaving his wife; but their union, it is said, was not happy, and this separation, which took place just before the birth of her fifth son, closed it for ever. Mrs. Hemans, with her five sons, went to reside with her mother, then living at Bronwylfa, near St. Asaph, in North Wales.

Mrs. Hemans now resumed her literary and poetical pursuits with increased ardour. She studied the Latin, Italian, Spanish, Portuguese, and German languages. She made some translations from Horace, Herrera, and Camoens, and contributed a series of papers on Foreign Literature to the 'Edinburgh Magazine.' 'The Restoration of the Works of Art to Italy' was published in 1815; 'Tales and Historic Scenes,' in 1819; and, about the same time, 'The Sceptic,' a didactic poem, in heroic rhyme; and 'Modern Greece,' in ten-line stanzas. Her poem of 'Dartmoor' obtained the prize from the Royal Society of Literature in 1821.

When about twenty-five years of age, Mrs. Hemans became acquainted with the Rev. Reginald Heber, afterwards Bishop of Calcutta, who passed a part of every year at Bodryddan, near St. Asaph, and their acquaintance soon ripened into friendship. At his suggestion she wrote her first dramatic work, the tragedy of 'The Vespers of Palermo,' which was represented at Covent Garden Theatre, London, in 1823. It was unsuccessful there, but was afterwards better received at Edinburgh, when Walter Scott wrote an epilogue for it. 'The Siege of Valencia, the Last Constantine, and other Poems' was published in 1823.

In 1825 Mrs. Hemans removed, with her mother, her sister, and her own sons, to Rhyllon, near St. Asaph. Her sister had returned, in 1821, from Germany, where one of her brothers was attached to the Vienna embassy, bringing with her a fresh supply of German books, and Mrs. Hemans's delight in German literature may be dated from that time. Her 'Lays of many Lands,' most of which appeared in the 'New Monthly Magazine,' then edited by Thomas Campbell, were suggested by Herder's 'Stimmen der Völker in Liedern,' and, preceded by 'The Forest Sanctuary,' formed her next volume, published in 1827, which was followed, in 1828, by the 'Records of Woman.' Most of these poems were written at Rhyllon, and many of those in the last volume are tinged by the melancholy occasioned by the recent death of her mother, for whom her affection was always exceedingly strong.

In the autumn of 1828, on the marriage of her sister, and the removal of her brother, who was in the army, to Ireland, Mrs. Hemans established herself at the village of Wavertree, near Liverpool, in the expectation of obtaining good schools for her children and pleasant society for herself. She had little success in either of these objects. The schools were not such as she wished for; her house was inconveniently small; she was besieged by visitors, pressed to attend fashionable parties, and complains with some bitterness of 'this weary celebrity.'

In the early part of the summer of 1829 Mrs. Hemans paid a visit to Scotland. After staying a few days in Edinburgh, she proceeded to Chiefswood, in Roxburghshire, the residence of the author of 'Cyril Thornton,' and was there introduced to Sir Walter Scott, with whom she afterwards spent several days at Abbotsford. She returned to Edinburgh in August, and thence proceeded home to Wavertree.

In 1830 she published another volume of poetry, 'The Songs of the Affections,' and in the summer of the same year paid a visit to the lakes of Cumberland and Westmoreland. She remained a fortnight with Wordsworth at Rydal Mount, and then took up her residence at Dove-Nest Cottage, near Ambleside. After remaining some weeks, she was induced to make a second visit to Scotland, on which occasion she spent the greater part of the time at Milburn Tower, the seat of Sir Robert Liston. During this visit she formed a friendship in consequence of which she was induced to visit Dublin before she returned to Wavertree, and ultimately decided on leaving England, and fixing her abode at Dublin.

In the spring of 1831 Mrs. Hemans left England for Dublin, where she took lodgings. Her health, from the time of her leaving England, became rapidly worse, to which the advancing age of the sons remaining under her care was an additional cause of anxiety. 'My position,' she writes, 'obliged as I am "to breast a stormy world alone," precludes me from a calm still meditative life, which I would desire.' In November, 1831, after a visit to her brother in Kilkenny, she writes thus to a friend in England:—'On my return to Dublin I became a sufferer from the longest and severest attack of heart-palpitation I have ever experienced. It was accompanied by almost daily fainting fits, and a languor quite indescribable.' And not long afterwards, in another letter, she says:—'The constant necessity of providing sums of money to meet the exigencies of the boys' education has obliged me to waste my mind in what I consider mere desultory effusions,

"Pouring myself away,
As a wild bird amid the foliage turns
That which within him thrills and beats and burns
Into a fleeting lay."'

The latter months of 1833 were busily spent by Mrs. Hemans in arranging and preparing for publication the three collections of her poems which were published in the spring and summer of 1844: 'Hymns for Childhood;' 'National Lyrics and Songs for Music;' and 'Scenes and Hymns of Life.'

In August, 1834, Mrs. Hemans took the scarlet fever, and when imperfectly recovered, caught a cold; ague was superinduced, and never left her till it was subdued by her last fatal malady, dropsy, which before the end of 1834 had assumed an unequivocally dangerous aspect. The summer residence of the Archbishop of Dublin was placed at her disposal; change of scene and the kind attentions of the archbishop and his wife afforded some relief, but no permanent benefit; and in order to be near to her physicians, she was taken back to Dublin.

On the 26th of April, 1835, Mrs. Hemans dictated her last poetical effort, the 'Sabbath Sonnet.' She continued to sink gradually till May 12, 1835, when, after a long and quiet sleep, she died without a sigh or movement. She was buried in St. Anne's Church, Dawson Street, Dublin, which is close to the house in which she died. A tablet was erected by her brothers in the cathedral of St. Asaph, 'in memory of Felicia Hemans, whose character is best pourtrayed in her writings.' A volume of 'Poetical Remains' was published after her death.

Mrs. Hemans could hardly be called a beautiful woman, but her personal appearance was very pleasing. In early youth she was greatly admired for the brilliance of her complexion and her glossy golden hair; her complexion retained its clearness in her maturer years; her hair darkened into auburn, of a silk-like softness, and very long and abundant. In her aspect and movements there was something more than usually delicate and feminine. She was unassuming, and went seldom and reluctantly into general society. Her family, a few friends, her music, her books, and her poetical pursuits, were her chief sources of enjoyment. She played on the harp and piano-forte, and about the time when she went to reside at Wavertree, discovered in herself a faculty which gave her much gratification—that of composing melodies; she would sometimes make a musical air, and then write words for it, and sometimes set to music a song or lyrical piece already written. Among her friends she was distinguished by much vivacity and a very delicate wit. She was kind and affectionate; and was free from the slightest taint of jealousy towards the other female writers of her day, with most of whom she was on terms of friendship, either personal or by correspondence—with Joanna Baillie, Miss Mitford, Miss Landon, Miss Jewsbury, Mary Howitt, and others.

Mrs. Hemans's love of the art to which she had devoted herself was intense, and her appreciation of it was serious and high, as a means to purify and elevate the mind. In her later years her religious impressions became stronger, and her poetry became more tinctured with religious thoughts and feelings. Her knowledge was extensive, but it was not philosophical or scientific knowledge. Poetry was the object of all her studies, and she sought for its materials in history, voyages and travels, and the fine arts; but her especial delight was to contemplate the scenes of nature in all their aspects of beauty, and to muse upon the associations and sympathies connected with them. Her thoughts are unborrowed, are never vague or indistinct, and always seem to flow naturally from the scene or circumstance present to her mind. She is most successful when the subject is native, something which she has seen, or something which by its associations calls up the sympathies which are familiar to her. In foreign subjects she is less effective. Her poetry is thus peculiarly and strikingly the representation of her own character, of the thoughts and feelings of the woman; it is essentially lyrical and descriptive, filled with imagery, sometimes overflowing with it. She has no dramatic power; she cannot enter into the thoughts and feelings of others; she can only exhibit her own. Her tragedy was deservedly condemned. The actions and sentiments of the characters are above nature or out of it, and the diction is not dramatic, but poetical, and monotonously uniform from prince to peasant. Her versification has three distinct styles. Her 'Domestic Affections,' and other early poems, are obviously modelled on 'The Pleasures of Hope,' of Campbell; her 'Tales and Historic Scenes,' and other poems of the middle period, are in the manner of Byron, less flowing than her early style, but more vigorous. Her last style is her own, and whether in blank verse, in couplet rhymes, in stanzas, in sonnets, or in the varied measures of lyric poetry, exhibits in its free and continuous flow a perfection of rhythmical melody which in sweetness and fullness of sound has never been surpassed. In uninterrupted reading, however, it has an effect of cloying uniformity. Her great defect is the similarity of tone and treatment which pervades all her works. Many of her lyrical pieces are exceedingly beautiful.

(Chorley, *Memoirs of Mrs. Hemans;* Mrs. Hemans's *Poems.*)

HEMERO'BIUS, a genus of insects of the order *Neuroptera* and section *Planipennes.* The genus, as established by Linnæus, has been dismembered by subsequent entomologists, and is now equivalent to a family distinguished by the filiform antennae and by the number (four) of the palpi of the insects included in it. They have soft slender bodies, much exceeded in length by the large reticulated wings, which, when the animal is at rest, are deflexed. Their eyes are globular and vividly metallic. The larvæ are ferocious in habit, and prey upon plant lice, seizing them with their powerful jaws and sucking their prey to death. When full grown, they spin and envelop themselves in a silken cocoon. The eggs of Hemerobii are deposited on plants, and are pedunculated, so as to resemble fungi, for which they have sometimes been mistaken. These insects range from Europe to Australia, and there are many species natives of the British isles.

HEMICI'DARIS, a genus of fossil Echinodermata, from the oolite.

HEMIPNE'USTES, a genus of fossil Echinodermata, from the chalk marl.

HEMI'TRYPA, a genus of fossil Polypiaria, in the limestone of Devonshire, allied to Fenestella. (Phillips.)

HEMLING, HANS. [MEMLING, HANS, P. C. S.]

HENDERSON, THOMAS, was the son of a respectable tradesman at Dundee, where he was born December 28, 1798. After an education such as his native town could afford, he was apprenticed to a writer (or attorney) for six years. At the end of this term be was sent to Edinburgh, at the age of twenty-one, to complete his legal instruction. He was then successively secretary to the celebrated judge John Clerk of Eldin, the Earl of Lauderdale, and the Lord Advocate Jeffrey, and in these employments he continued till 1831.

During his residence at Dundee he acquired a taste for practical astronomy, as well as for the history and literature of that science. At Edinburgh he frequented the observatory, then a very small establishment, but sufficiently well equipped to give valuable opportunities to a learner. Weak bealth and a tendency to disorder in the eyes are very poor aids to an astronomer, but they did not hinder Mr. Henderson from bringing himself into notice, though his scientific pursuits could only be the relaxations of a life of business. In 1824 he began to communicate with Dr. Thomas Young, then superintendent of the Nautical Almanac, whom be assisted both by methods and calculations. The consequence was, that at Young's death it was found that he had placed in the hands of Professor Rigaud a memorandum desiring that the Admiralty might be immediately informed, as soon as his death sbould take place, that be knew of no one more competent than Mr. Henderson to be appointed his successor. The government, however, confided the trust to Mr. Pond, the astronomer royal, who immediately offered Mr. Henderson, on terms of remuneration, employment for a great part of his time. This offer was not accepted: but on the death of Mr. Fallows the Admiralty proposed to Mr. Henderson to succeed him in the charge of the observatory at the Cape of Good Hope. This offer was accepted; and from April, 1832, the date of his arrival at the Cape, be must be considered as a professional astronomer.

After vigorous application to bis duties for little more than a year, he found his health and spirits give way. His isolated position and separation from his family, accompanied by the knowledge that he was subject to a disorder of the heart, which might at any time, and which finally did, prove fatal, made him wish to return to Scotland. He came back accordingly in 1833, with a rich store of observations, the reduction of which he imposed upon himself as a voluntary duty. In 1834, by an agreement between the government and the Astronomical Institution of Edinburgh, the latter gave up their observatory to the University, the former agreeing to appoint and provide for an astronomer, who was also to hold the professorship of practical astronomy in the University. On the recommendation of the Astronomical Society of London, to whom Lord Melbourne applied for advice, Mr. Henderson was appointed the first astronomer royal for Scotland. Here, in the midst of his friends, and in the position which, of all that could have been imagined, he would have chosen for himself, he pursued his observations and researches till his death, which took place suddenly, November 23, 1844.

A very full account of Mr. Henderson's astronomical writings will be found in the annual report of the Astronomical Society for 1845, with a list of his writings, which consist of upwards of seventy communications, of different degrees of magnitude and importance, to different scientific publications, independently of the volumes of observations which issued from the Edinburgh Observatory. We might particularise what he did on occultations, on the solar and lunar parallaxes, &c.; but it will better suit our limits and the nature of the subjects, to refer the reader to the memoir just cited, and to confine ourselves to a mention of the manner in which his name is connected with the discovery of the parallax of the fixed stars. [PARALLAX, P. C.] Mr. Henderson, when at the Cape, repeated the attempt in which Brinkley had failed, namely, the detection of the effect of parallax upon the meridian observations. The stars chosen were α^1 and α^2 Centauri; and the results derived from the former star show discordances, both in right ascension and declination, very much resembling those which parallax would cause. Mr. Main, in his elaborate Investigation of the modern claims upon this subject (*Mem. Astron. Soc.* vol. xii.), says that in the event of a parallax at all comparable to that assigned by Mr. Henderson being ultimately found to belong to the star, he will deserve the merit of the first discovery. Mr. Maclear, Mr. Henderson's successor, made a new series of observations on the same stars, with a different instrument, from which Mr. Henderson produced results very nearly agreeing with bis own.

The private character and social qualities of Mr. Henderson are among the pleasant recollections of those who knew him. In his astronomical career be resembled his friend Mr. Baily in bringing to his subject the most methodical habits of business. He was well acquainted with astronomical literature, and with other branches of science; and at different times supplied the places of the professors of mathematics and of natural philosophy in the University of Edinburgh. He formed a great attachment to the methods of the German astronomers, and his models were MM. Bessel and Struve. His determination to be well acquainted with all that was doing abroad made him collect an astronomical library which, for a man of his very limited means, was of extraordinary extent and goodness; and those who knew him remember the ready manner in which he could produce the results of his reading. Of bis writings we may say, briefly, that, in addition to their valuable masses of observations, they abound in all that distinguishes the astronomer, properly so called, from the noter of phenomena.

HENRI'CO CATERI'NO DA'VILA, born at Pieve di Sacco near Padua, was the son of Antonio Davila, who was great constable of Cyprus when that island was taken by the Turks from the Venetians in 1571. Antonio emigrated to Spain, where he had relations, and afterwards to France, where he won the favour of Catherine de Medicis, and of her son King Henri III. Lastly he went to reside in the Venetian States, where a son was born to him in 1576, to whom he gave the names of Henrico Caterino, in homage to bis royal French patrons. When Henrico was seven years old his father took him to France for his education. At the age of eighteen he entered the army of Henri IV., in which he served four years, and was severely wounded at the siege of Honfleur. In 1599 be was recalled to Pieve di Sacco by his father, who soon after, in a fit of temporary insanity, put an end to his life by throwing himself out of a window. Not long afterwards Henrico entered the military service of Venice, and was employed successively in Candia, Friuli, Dalmatia, and other stations. In 1631 he was sent to take the command of the garrison of Crema, with orders from the senate to the postmasters on the road to supply him with every conveyance required for the service. On arriving at the stage of S. Michelo, near Verona, the postmaster refused to furnish the necessary accommodations. High words ensued, and the postmaster fired a pistol, and shot Davila dead in sight of bis wife and children. One of Davila's sons attacked the murderer, and killed him on the spot; others were wounded in the affray, and the chaplain of Davila was also slain.

Davila is known to the world through his History of the Civil Wars in France, 'Storia delle Guerre Civili di Francia,' from the death of Henri II. to the peace of Vervins in 1598, a period of forty years most eventful in the history of that country. He treads, therefore, upon the same ground as De Thou in his 'Historia sui Temporis.' Some critics have noticed that Davila evinces a partiality for the French court, and especially for Catherine de Medicis, who had been his father's benefactress. The facts, however, stated by Davila are acknowledged to be true, and he was well acquainted with them through his own and his father's connexion with France. He was familiar with the politics of his age, and with the leading contemporary characters. He was also well acquainted with the topography of the places in which most of the events which he narrates occurred. His style is graphic and animated, especially when he describes a popular insurrection, a combat, or the storming of a town. His account of the massacre of St. Bartholomew may be quoted as a specimen. Apostolo Zeno, comparing Davila with Guicciardini, observes, that whilst the prolixity of Guicciardini in dwelling minutely upon minor matters becomes wearisome to the reader, the course of Davila's narrative runs on uninterrupted, adverting briefly to circumstances of subordinate importance, and dwelling chiefly upon those which have materially affected the interests either of religion or the state. By common consent Davila is numbered among the best historical writers of Italy. His work has gone through many editions, and has been translated into several languages. Apostolo Zeno published a splendid edition of it in 2 vols. fol. Venice, 1733, to which he has prefixed a life of the author.

(Tiraboschi, *Storia della Letteratura Italiana;* Corniani, *I Secoli della Letteratura Italiana.*)

HENRYSON, ROBERT, a Scottish poet of much merit, lived in the latter part of the fifteenth century. Of his life hardly anything is known. He is supposed to have been the

Robert Henryson whose signature as notary-public is attached to a charter granted in 1478 by the abbot of Dunfermline, in Fifeshire; and he is elsewhere said to have been a schoolmaster in that town. It has been inferred that he must have been an ecclesiastic; and it has been conjectured that he may have been a Benedictine monk. In a poem of Dunbar, printed in 1508, he is spoken of as dead: and in one of his poems he had described himself as a 'man of age.' His tale of 'Orpheus Kyng, and how he yeid to hewyn and to hel to seik his quene,' was printed at Edinburgh, in 1508: and in 1593 there was printed his 'Testament of Faire Creseide,' which had been suggested by the 'Troilus and Creseide' of Chaucer, and is found in the common editions of that poet's works. His beautiful pastoral of 'Robin and Makyne' is known to most readers from Percy's 'Reliques.' Other specimens of Henryson's poems are in Sibbald's 'Chronicle of Scottish Poetry,' in Dr. Irving's 'Lives of the Scottish Poets,' and in Ellis's 'Specimens.' The fullest collections of them, however, are in Lord Hailes's 'Ancient Scottish Poems,' 1770, and in a volume containing his thirteen poems, called 'Fables,' edited by Dr. Irving in 1832, for the Bannatyne club. For that club, in 1824, Mr. George Chalmers had edited the 'Testament of Creseide,' and 'Robin and Makyne.' Henryson writes with much greater purity and correctness than most Scotsmen of his time: his versification is good, and his poetical fancy rich and lively.

HEPATI'TIS. [Liver, Diseases of, P. C.]

HERACLE'UM, a genus of plants belonging to the natural order Umbelliferæ and the tribe Peucedaneæ. The calyx consists of 5 minute teeth, the petals abcordate with an inflexed point, the outer ones radiant. There are 34 species noticed, but only one of these is found in Great Britain, and few are applied to any useful purpose.

H. Sphondylium, Cow Parsnip, has ternate pinnate leaves, the leaflets lobed or pinnatifid, cut, and serrated. The stem is about four feet high, the lower leaves very large, and the flowers white or reddish. It is a native of Europe, and probably of Siberia, and is found plentifully in the meadows and hedges of Great Britain. The whole plant affords wholesome and nourishing food for cattle, and is collected in Sussex for fattening hogs; hence it is sometimes called hog-weed. Cows and rabbits are also fond of it, and horses will sometimes eat it, but it does not appear to be so agreeable to them. The Kamtchatdales and Russians are in the habit of using the shoots and leaf-stalks as food, after the rind, which is bitter, has been taken off. They collect large bundles of tho plants, and during the process of drying the stalks become covered with a saccharine efflorescence which is esteemed a great delicacy. The Russians distil an ardent spirit from the stalks thus prepared by first fermenting them in water with bilberries. The seeds of the plant are diuretic and stomachic, and exhale a powerful odour.

H. pubescens has ternate leaves, somewhat pubescent beneath; the leaflets toothed and pinnatifid; the umbels of many rays; involucre from 1 to 2 leaves; the fruit elliptic, having the disk rather villous. It is a native of Taurida in shady places, and of the Caucasus in alpine places. The young shoots are filled with a sweet aromatic juice which is eaten by the natives of the Caucasus in a crude state.

H. Pyrenaicum has large leaves, tomentose beneath; the leaflets lanceolate, toothed, or ternate; the involucre of few leaves; the young fruit covered with long hairs; the matured ones glabrous and nearly orbicular. It is a nativo of the Eastern and Central Pyrenees, and of Italy. D. Don thinks that this plant is identical with the *H. gummiferum* of Willdenow, which was supposed to yield the gum ammoniacum of commerce. Don has however identified the plant which yields this gum, and has placed it in a new genus. [Dorema, P. C. S.]

All the species of Heracleum grow well in any soil, and are easily propagated by seeds or by dividing the root.

(Don, *Gardener's Dictionary*; Burnett, *Outlines of Botany*; Babington, *Manual of British Botany*.)

HERA'CLIUS, Roman emperor from A.D. 610 to 641. Since the publication of the volume of the 'Penny Cyclopædia' containing the life of this great emperor, the importance of Asia Minor and the adjacent countries as regards Europe has been much increased, and accordingly it appears useful to give a more circumstantial description of his campaigns against the Persians, which are of equal interest for the historian, the geographer, and the soldier.

The destitute condition of the empire at the accession of Heraclius compelled him to be an almost inactive spectator of the ruinous invasions of tho Avars in Europe and the Persians in Asia. By submitting to an annual tribute of one thousand talents (pounds?) of gold, as many talents of silver, one thousand silk robes, and one thousand slave girls, he induced the Persian king Chosroes or Khosrew to discontinue his invasions of Asia Minor and to be satisfied with the conquests he had made from the Greek empire, which comprehended Egypt and the whole of the Asiatic provinces east and south of a line drawn from the northern frontiers of Syria to the eastern extremity of the province of Pontus. Heraclius made a less humiliating peace with the Avars. Having got rid of his enemies, he employed vigorous means to fill his treasury, not sparing the property of the churches; and he was thus enabled to raise an army strong enough to stop all further designs of the Persian king. The plan of attacking that powerful foe was bold and well designed, and it was executed with so much boldness and prudence, and such a startling combination of offence and defence, as to equal the strategical operations of the greatest generals.

A powerful Persian army was stationed in the valley of the Upper Euphrates ready to descend through the passes of the Anti-Taurus into the high plains of Cappadocia, and to push on towards Constantinople as they had done in A.D. 616. The army of Heraclius, consisting chiefly of raw levies, was quartered in the environs of Constantinople, and afterwards in those of Chalcedon on the Asiatic shore of the Bosporus, and a whole year was required to prepare his men for a campaign. But Heraclius was master of tho sea, and his numerous fleet enabled him to choose his base of operation. Early in the spring of 622 he embarked his troops, and from the Bosporus sailed to the eastern corner of Cilicia, which lies round tho bay of Iskénderún (Alexandria), and is protected on the north and east by the Taurus and on the south by Mount Amanus. There on the plain of Issus he continued accustoming his troops to actual warfare by making them manœuvre in the same way as modern troops do, and he occupied tho Cilician and Syrian gates and other passes that lead through the surrounding ranges. A Persian army approaching in full confidence of making the Romans prisoners of war, or of forcing them to re-embark, was turned, routed, and driven into the mountains of Armenia. Having thus cleared his way and secured his rear, Heraclius marched through tho Cilician gates northward in the direction of Mount Argæus (Arjísh) and the Upper Halys (Kizil Irmák), where, as it seems, a portion of his troops remained during the winter as a body of observation. The emperor with the main body advanced upon Trebizond, and quartered his troops in the province of Pontus. Trebizond now became the centre of his operations. He left it, however, soon after his arrival, sailed to Constantinople, and in the following spring of 623 returned with a fleet and a chosen body of 5000 men. It is important to ascertain his motives for conveying his army by sea to the south-eastern extremity of Asia Minor, and thence fighting his way through inaccessible mountains right across Asia Minor to the Euxine, if he intended to make Trebizond the basis of his operations; for it seems that he could have gone there directly from Constantinople without incurring the risk of losing half his army, or perhaps the whole of it, in the defiles of tho Taurus and Anti-Taurus. Our sources say nothing of his motives, and generally we know few details of his first campaign. However, if we take the state of the empire into due consideration, and draw conclusions from his subsequent campaigns as to his first, we cannot hesitate to believe that Heraclius intended to attack Persia from two points, each of them equally well situated for an attack and affording equal security in case of a forced or voluntary retreat. And it becomes no less probable that he chose the bay of Iskénderún for his place of disembarkation, and thence marched towards the Euxine, because he wanted to relieve, through his presence at tho head of an army, the minds of those of his subjects who were most exposed to the inroads of the Persians, and to occupy as many mountain-passes as possible in order to prevent the Persians from breaking through the defiles between Cappadocia and the Upper Euphrates. In this, however, he did not succeed. The plan of his campaign further shows a fact corroborated by many subsequent wars, namely, that the inland tract between Trebizond and Issus is unfit for operations on a large scale, and that the only points from which Armenia, Mesopotamia, and Syria may be successfully invaded by an army coming from Asia Minor are the eastern angles of Pontus and Cilicia, whence it is evident that a power which is master of the sea, especially the Mediterranean, and lands sufficient forces at either of those points, will effect or prevent the conquest of all Asia Minor and the adjoining eastern countries with less force and in a shorter time than any power which is only a land force, however strong it may be. In preferring Trebizond to Cilicia as his principal basis of operation, and attacking Persia from the north, Heraclius further intended to compel his rival to withdraw his advanced troops from Syria and the other western provinces for the defence of his hereditary dominions, and thus to relieve his subjects and increase his means.

From Trebizond Heraclius carried the war, in the spring of 623, into the heart of Persia. The nations in the Caucasus were his allies, and he had entered into negotiations with the khazars beyond the Caucasus. These were the causes of his first advancing north-east into the Caucasian provinces, and only after having shown himself there and increased his army through the contingents of his allies, he marched south upon Charsa (Kars) and thence in a direction parallel with the Araxes as far as the great bend of that river, where, after a south-eastern and eastern course, it turns north-east. Thence he marched right upon Gazaca or Gandzaca, which is the still common Armenian name of Tabriz, and this city fell into his hands with all its wealth, Chosroes, who was in the neighbourhood with 40,000 men, not daring to offer battle for the relief of his northern capital. According to an absurd tradition Crœsus, King of Lydia, had saved his treasures in Gandzaca, where they were kept till they became a prey of Heraclius. From Gandzaca Heraclius marched south, turned the Persian army and fell upon their rear, took and destroyed Theabarma, now Urúmíyeh, near the western shore of the large lake of Urúmíyeh, which is said to be the birth-place of Zoroaster, and many other cities which have not yet been identified, and at last wheeled round and took up his winter-quarters in the flat country between the Lower Araxes and the Caspian, which is now known as the plain of Mogan. We may suppose that he chose that tract, which is renowned for its vast pasturages, for the support of his numerous cavalry, and for the purpose of having an easy communication with the khazars, who used to pass through Daghestán and the Iron Gate, near Derbent, whenever they invaded Persia.

In the following year, 624, Heraclius penetrated into the heart of Media, took Casbin, and probably also Aspahan (Isfahán), defeated Chosroes in a pitched battle, and, after having carried the Roman arms farther into Persia than any of his predecessors, returned to his former winter quarters at the foot of the Caucasus.

Our knowledge of the campaign of 624 is very imperfect; the accounts in the sources are vague and scanty, and the whole is so obscure that D'Anville gave up the idea of investigating it critically.

During this time Chosroes had withdrawn his troops from Egypt and Syria, and thought himself strong enough to act on the offensive. In the spring of 625 he ordered his lieutenant Sarbar, or Sarbaraza, to menace Asia Minor, while he endeavoured to keep the Roman emperor at check in the Caucasus. Sarbar was in Northern Mesopotamia; however, he did not take his way through the inland tract, which he could have done either in the direction from Diyárbekr, Málátiyeh, Síwás, and Amasia, through the province of Sophene and the north-eastern part of Cappadocia, or in the direction of Marásh and Kaisáríyeh through the centre of Cappadocia; but he marched south-west and fell upon the eastern angle of Cilicia. His intention was apparently to take the easiest way for penetrating into Asia Minor, to cut off the communication between the Romans in the fortresses of the Anti-Taurus and the Taurus with the Mediterranean, and to destroy the magazines of the Romans in Cilicia. Informed of this diversion, Heraclius moved on; but while he appeared to threaten the main body of the Persians under Chosroes, he suddenly passed by, left the defence of Armenia to his Caucasian allies, and followed Sarbar through Mesopotamia, either by his track or on a parallel road. They met in Cilicia on the banks of the Sarus, now Sihún, at a moment when Sarbar was in a very critical position, for although we do not know whether he entered Cilicia through the Syrian gates, or through the valley of the Pyramus or Jihún, it is evident that either one or both of those passes were already stormed by Heraclius before the Persians had even entered the defiles of the Cilician passes, which were defended by Roman troops. Theophanes says, that Heraclius approached from Germanicia (Marásh) passed by Adána, and arrived in Cilicia before Sarbar; and as, when the battle began, the Romans were on the right and the Persians on the left bank of the Sarus, we may suppose that Sarbar came through the Syrian passes and found himself in presence of the main army of the Romans, just when he was going to attack the Cilician passes. In the ensuing battle Heraclius astonished both his own and his enemy's troops by his heroic deeds. At the head of a few veterans he stormed the stone bridge over the Sarus (below Adána), which the Persians had occupied and fortified, and slew with his own hand a gigantic Persian whom nobody dared to fight. After a bloody conflict the Persians were routed; and Sarbar escaped, through the Syrian passes, with the scattered remnants of his army to Persia. Heraclius did not pursue him, but marched through the Cilician passes upon Sebaste (Síwás), and took up his winter-quarters in Pontus.

The next campaign of 626 equals the most splendid military operations in antient or modern time. In its grand outlines it may be compared to the operations of Hannibal and Scipio in B. C. 204, and to Napoleon's campaign in France in 1814: Hannibal was still in sight of Rome when Scipio boldly sailed to Africa; and the allies were fast advancing upon Paris, when Napoleon turned them and marched towards Germany: under similar circumstances Heraclius was more fortunate than either Hannibal or Napoleon, and it is only just to say, that his fortune was not accidental, but the effect of his superior genius. Early in 626 Chosroes opened the campaign with two armies against Heraclius, and a third under Sarbar, who was commissioned to attempt a second invasion of Asia Minor. Sarbar was successful, traversed the whole peninsula, and reached the walls of Chalcedon, opposite Constantinople; and, at the same time, a host of more than a hundred thousand Avars and other barbarians, the allies of Chosroes, invaded Thrace, laid siege to Constantinople, and twelve times assailed its walls. Chosroes hoped to induce Heraclius to hasten to the succour of his capital, but the emperor stood firm at the foot of the Caucasus, dispatching however, by sea, twelve thousand armed horsemen, who arrived safely at Constantinople. He knew that, however great the danger was for Constantinople, the Persians and Avars had no ships to effect a union, and that the inhabitants of the capital would fight to the last before they surrendered to an enemy whom it was more dangerous to encounter in the open field than in their assaults upon walls and towers. A Slavonian fleet having entered the Bosporus, destined to convey the Persians over to the European shore, the Greek galleys left the Golden Horn, and, in sight of the besiegers, destroyed the ships of the barbarians or took them and carried them off into the harbour of Constantinople. Shortly after this event the Avars withdrew and Constantinople was free, although Sarbar continued to amuse himself with the siege of Chalcedon.

While this took place in the west, Theodore, the brother of Heraclius, defeated the Persian general Said, in Armenia, and the emperor defended with success the Caucasian provinces against the desperate attack of Chosroes, who took the field against him with a select army of 50,000 men called the Golden Spears. A still greater advantage the emperor derived from effecting an alliance with Ziebel, the khan of the Khazars, who came through the Iron Gate with a numerous host, and joined the Romans at Tifilis (Tiflis). Another army of Khazars invaded Persia on the side of Turkistán. The united Romans and Khazars were 70,000 men, or perhaps more, since the Khazars alone were 50,000 strong, and Heraclius led them forthwith into the province of Atropatene, where he took up his winter quarters. He crowned the success of his arms by a stratagem which proved more advantageous than the winning of three pitched battles. After the junction of the Romans and the Khazars Chosroes sent a dispatch to Sarbar, with an order to give up all further designs against Constantinople, and to join him without delay in Persia. The messenger having fallen into the hands of the Romans, Heraclius altered the dispatch, enjoining him to hold out as long as possible, and the letter was forwarded through another courier. Sarbar continued the siege, but his protracted absence irritated the king so much that he dispatched a second messenger to the first lieutenant of Sarbar with an order to kill his general as a traitor. This dispatch having been delivered to Sarbar instead of his lieutenant, he added the names of four hundred of the principal officers as being all destined to be sacrificed to the anger of their master, whereupon he showed them the order, and declared the only way to save themselves was to break their allegiance to Chosroes and to make peace with the emperor on their own account. The officers gave their consent, they persuaded the army to follow their example, and Heraclius having granted them favourable conditions, they laid down their arms, and abandoned Chosroes at a moment when he stood most in need of them. There is something strange in this story, and it would seem as if Heraclius had not so much a hand in it as Siroes, the son of Chosroes, who rebelled against his father, and put him to death in 626.

In spite of this loss Chosroes had still a numerous army, the amount of which is however exaggerated when it is stated at 500,000 men, to oppose Heraclius in the campaign of 627. But his efforts were in vain. With irresistible power the Roman emperor moved on upon Assyria, and although his progress was slow, he was successful in every siege and engagement. He came from the province of Atropatene, passed the Zabas (Great Záb) in its upper part, and marched towards Niniveh (opposite Mósul), where he encountered a Persian army commanded by Rhazater, who had followed the emperor for some time, but gained some marches over him, and had taken a position near the ruins of Niniveh with the intention of preventing the Romans from occupying the valley of the Tigris and marching upon Ctesiphon. After an obstinate resistance from daybreak till night Rhazater was routed and killed, and Heraclius, who had again signalized himself as a general and a warrior, pursued the fugitive enemy, and occupied the bridges over the Great and the Little Záb, which the Persians had no time to secure. The battle at Niniveh was fought on the 12th of December, 627. On his way to Dastagerd or Artemita, Heraclius took, plundered, and destroyed the royal palaces of Rusa, Beglali, and others, and immense treasures fell into his hands. Soon afterwards he took Dastagerd, the favourite residence of Chosroes, and its treasures, of which Theophanes gives a fabulous description; and many thousands of captive Romans, chiefly inhabitants of Edessa and Alexandria, as also three hundred standards and other trophies taken from the Romans in former campaigns, were recovered by the victors. Chosroes fled from Dastagerd to Ctesiphon (El-Modain), and thence into the interior of Persia. Heraclius was already in sight of Ctesiphon, when he suddenly retreated north-east upon Siazura (Sherzúr) and Gandzaca, crossing the Assyrian mountains in the midst of winter without loss. The motives of his retreat were either the fear of being unable to take the well fortified city of Ctesiphon in the winter, the want of provisions in Assyria, which had been ravaged, being already very sensibly felt, or perhaps the rebellion of Siroes against his father Chosroes, whom he treacherously seized and put to death with eighteen of his sons, the brothers of Siroes. (February 28th, 628.) In the month of March following peace was concluded between Siroes and Heraclius. Siroes ceded Syria, Egypt, Mesopotamia, and Armenia, and gave back the Holy Cross taken by his father at the conquest of Jerusalem; and Heraclius gave up many thousand Persian captives, and allowed the Persian troops who still occupied the principal towns of Egypt, Syria, and Mesopotamia to return to their native country: they were treated with great humanity on their march through the Roman provinces. In the same year Heraclius had his triumphal entrance in Constantinople. Theophanes, so vague and obscure in his accounts of the first campaigns of Heraclius, gives a detailed and accurate description of the campaign of 627. It is not in the plan of this article to relate the particulars of the latter part of the reign of Heraclius, during which he lost all his conquests, which fell into the hands of the Arabs. A colossal statue of Heraclius existed at Barletta in Puglia so late as the end of the fifteenth century.

(Theophanes, p. 250, &c.; Nicephorus, p. 4, &c.; Cedrenus, p. 407, &c.; Zonaras, vol. ii. p. 82, &c.; Glycas, p. 270, &c., in the Paris editions; Georgius Pisida, *De Expeditione Heraclii; Bellum Avaricum; Heraclius:* the author of these short historical poems, which however are very valuable, accompanied Heraclius on his campaigns against the Persians; Gibbon, *Decline and Fall;* Lebeau, *Histoire du Bas Empire;* D'Anville, *Recherches Géographiques concernant l'Expédition de l'Empereur Héraclius en Perse,* in the xxxii. vol. of *Mémoires de l'Académie des Inscriptions et Belles Lettres.* The map of Asia Minor and part of Persia, in Kinneir's 'Journey through Asia Minor, Armenia, and Kurdistán,' indicates the routes taken by Heraclius in his campaigns, but they are not correct. We want a complete critical commentary on the expeditions of Heraclius, which would offer less difficulties now than it did to D'Anville, since our knowledge of the country is more exact than it was a hundred years ago.)

HERBART, JOHANN FRIEDRICH, a distinguished German philosopher, was born in 1776, at Oldenburg, where his father at the time held an office connected with the administration of justice. Receiving his religious instruction from a man well acquainted with the philosophical systems of Leibnitz and Kant, Herbart, at the age of about twelve, was led to speculate upon such subjects as God, freedom, and immortality. In his eighteenth year he went to the University of Jena, where he studied under Fichte, and formed an intimate acquaintance with him, and he entertained the highest opinion of his master until Schelling's work, 'Vom Ich,' fell into his hands, which was admired by Fichte, while Herbart opposed its tendency with the greatest zeal. This caused a breach between Fichte and Herbart, who gladly accepted a place of private tutor which was offered to him at Bern in Switzerland. He had already conceived the idea of a system of psychology based upon mathematics, and the more clearly Fichte explained his views upon psychology in his 'Sittenlehre' (Leipzig and Jena, 1798), the more Herbart became convinced that the speculations of Fichte must be abandoned if any permanent basis was to be gained for his science. About the same time he devoted himself with great zeal to the study of the history of antient philosophy, which led him to form an intimate acquaintance with the systems of Plato and the Eleatics. However he continued his own researches which he had commenced under Fichte, and from 1802 to 1805 he delivered philosophical lectures in the University of Göttingen, where he developed his peculiar method of thinking, which was subsequently much extended, but remained essentially the same as it had been from the beginning. His tendency was pre-eminently practical, and it was partly owing to this circumstance, and partly to his personal acquaintance with Pestalozzi, that his first works treated on education. In 1809 he was appointed professor of philosophy at Königsberg, and was at the same time entrusted with the superintendence of the higher educational establishments in the eastern parts of Prussia, in the organization of which he did great service. In 1833 he was invited to the chair of philosophy in the University of Göttingen, where his lectures attracted great attention on account of the clearness and precision with which he explained his views. He remained at Göttingen until his death, on the 14th of August, 1841.

Herbart is the founder of a particular system of philosophy, which is interesting on account of his peculiar method rather than his originality of thought, for in reality his system is of a syncretic kind, and Fichte's influence upon it cannot be mistaken. Although Herbart occasionally professes to be a follower of Kant, still he is of opinion that Kant's 'Criticism of Pure Reason' is almost without any objective value, and that its method must be entirely abandoned if metaphysics are to be founded on a secure and permanent basis. Herbart's realistic tendency further reminds us of the monades of Leibnitz. Philosophy, according to Herbart, has not, like ordinary sciences, any particular set of subjects which are its province, but it consists in the manner and method in which any subject whatsoever is treated. The subjects themselves are supposed to be known, and are called by him 'notions' (Begriffe), so that philosophy is the methodical treatment and working out of those 'notions.' The different methods of treatment constitute the main departments of philosophy. The first of them is logic, which considers the nature and clearness of notions and their combinations. But the contemplation of the world and of ourselves brings before us notions which cause a discord in our thoughts. This circumstance renders it necessary for us to modify or change those notions according to the particular nature of each. By the process of modification or change something new is added, which Herbart calls the supplement or complement (Ergänzung). Now the second main department of philosophy is metaphysics, which Herbart defines to be the science of the supplementary notions. The method of discovering the supplementary notions which are necessary in order to render given facts which contain contradictory notions, intelligible, is, according to him, the method of relations, and it is by this method alone that the other notions of the world and of ourselves can be properly defined. Hence arises what he calls practical metaphysics, which is subdivided into psychology, the philosophy of nature, and natural theology. A third class of notions, lastly, add something to our conceptions, which produces either pleasure or displeasure, and the science of these notions is aesthetics, which, when applied to given things, forms a series of theories of art, which may be termed practical sciences. They are founded upon certain modal notions, such as the ideas of perfection, benevolence, malevolence, justice, compensation, equity, and the like. In his metaphysics Herbart points out three problems containing contradictions, viz. things with several attributes, change, and our own subjectivity (das Ich). In order to solve these contradictions, and to make the external and internal world agree and harmonize so as to become conceivable, he assumes that the quality of everything existing (des Seienden) is absolutely simple. Things therefore which exist have no attributes referring to space and time, but they stand in relation to a something, which is the essence of things. Wherever this essence consists of a plurality of attributes, there must also be a plurality of things or beings, and these many simple things or beings are the principles of all things in nature, and the latter, consequently, are nothing but aggregates of simple things. They exist by themselves in space so far as it is conceived by our intellect, but not in physical space, which contains only bodies. We do not know the real simple essence of things, but we may acquire a certain amount of knowledge concerning internal and external relations. When they accidentally meet in space they disturb one another, but at the same time strive to preserve themselves; and in this manner they manifest themselves as powers, although they neither are powers nor have powers. By means of these principles Herbart endeavours to reform the whole system of psychology which he found established by his predecessors; for, according to him, the soul too is a simple being, and as such it is and remains unknown to us; and it is neither a subject for speculation nor for experimental psychology. It never and nowhere has any plurality of attributes, nor has it any power or faculty of receiving or producing anything; and the various faculties usually mentioned by psychologists, such as imagination, reason, &c., which sometimes are at war and sometimes in concord with each other, are, according to Herbart, mere fictions of philosophers. In like manner he denies that it possesses certain forms of thought or laws regulating our desires and actions. The soul as a simple being, and in its accidental association with others, is like the latter subject to disturbance and exerts itself for its own preservation. The latter point is the principal question in Herbart's psychology, and he endeavours to deduce and calculate the whole life of the soul, with the aid of mathematics, from those mutual disturbances, checks, and from its reactions against them. Hence he is obliged to deny man's moral or transcendental freedom, although he allows him a certain free character. He maintains the immortality of the soul, because the simple principles of all things are eternal; but he denies the possibility of acquiring any knowledge whatever of the deity.

These theories, which betray a tendency to subtleties and over-refinement, are explained more fully in his works, of which the principal are contained in the following list:—1, 'Pestalozzi's Ideo eines A. B. C. der Anschauung, untersucht und wissenschaftlich entwickelt,' Göttingen, 1802, 8vo. 2, 'Allgemeine Paedagogik,' Göttingen, 1806, 8vo. 3, 'Allgemeine Practische Philosophie,' Göttingen, 1808, 8vo. 4, 'Hauptpunkte der Metaphysik,' Göttingen, 1808, 8vo. 5, 'Einleitung in die Philosophie,' 1813, an improved edition appeared in 1816. 6, 'Kleines Lehrbuch der Psychologie,' Göttingen, 1815, 8vo. This work called forth great opposition, to which he replied in 7, 'Ueber meinen Streit mit der Modephilosophie dieser Zeit,' Königsberg, 1814. His great psychological work, however, is 8, 'Psychologie als Wissenschaft, neu gegründet auf Erfahrung, Metaphysik, und Mathematik,' Königsberg, 2 vols. 8vo., 1824-25. 9, 'Allgemeine Metaphysik, nebst den Anfängen der Philosophischen Naturlehre,' Königsberg, 1828-29, 2 vols. 8vo. 10, 'Kurze Encyclopaedie der Philosophie, aus practischen Gesichtspunkten entworfen,' Königsberg, 1831, 8vo. His smaller essays appeared in three volumes, Leipzig, 1842-43, 8vo.; the first volume contains a good Life of Herbart.

(*Neuer Nekrolog der Deutschen*; Brockhaus, *Conversations-Lexikon*.)

HEREDITAMENT. [CHATTELS, P. C.; DESCENT, P. C.; ESTATE, P. C.]

HERESY. This word is the English form of the Greek Haeresis (αἵρεσις). It signifies literally 'a choice,' and hence it came to denote an opinion on any subject; and it was used to express a sect in philosophy. The word occurs in the New Testament, sometimes simply to denote a religious body, and sometimes as a term of reproach applied to the religious opinions of persons which differed from the opinion of him who used the term. When ecclesiastical councils determined what was the orthodox or Catholic faith, then Christians who would not acknowledge the decisions of such councils were called Heretics, and their guilt was expressed by the term Heresy: those who reject Christianity altogether are infidels and unbelievers.

The fifth title of the first book of the Code of Justinian contains penalties against Heretics, Manichæans, and Samaritans, which, in some cases, extended to death. Heretical books were ordered to be burnt. Before the Reformation in England heresy was the holding of opinions contrary to the Catholic faith and the determination of Holy Church: at least this is the definition of heresy in the statute 2 Hen. IV. c. 15. The court in which a man could be convicted of heresy, according to the common law, was that of the archbishop in a provincial synod. After conviction the criminal was delivered up to the king to do what he pleased with him. If the criminal had abjured his heresy and then relapsed, the king in council, upon a second conviction, might issue the writ De Haeretico comburendo, upon which the criminal was burnt alive. One Sawtre, it is said, was the first man burnt alive for heresy in England, and the writ De Haeretico comburendo was formed in his case. But the statute 2 Hen. IV. c. 15, empowered the diocesan alone, without a synod, to commit a man for heretical opinions, and to imprison him as long as he chose, or fine him; or if he refused to abjure, or after abjuration relapsed, the sheriff, mayor, or other officer, who should be present, if required, with the ordinary or his commissary, when the sentence was pronounced, was to take the convict and burn him openly, without waiting for the king's writ.

It is unnecessary to mention the statutes of Henry VIII. relating to heresy. The Reformation was not fully established till the reign of Elizabeth, and the statute 1 Elizabeth, c. 1, declares that the persons to whom the queen or her successors shall give authority to judge of heresies shall not declare any matters to be heresies except 'such as heretofore hath been adjudged heresy by the authority of the canonical Scriptures, or by the first four general councils, or any of them, or by any other general council wherein the same was declared heresy by the express and plain words of the canonical Scriptures, or such as shall hereafter be adjudged heresy by parliament with consent of the clergy in convocation.' But there is no statute that determines what heresy is. After this statute of Elizabeth the proceedings in cases of heresy remained as they were at common law; for this statute repealed all former statutes about heresy, which was accordingly punished, after the Reformation was fully established, by ecclesiastical censures, and by burning alive a criminal who had been convicted, in the manner above described, in a provincial synod. The writ for burning the heretic could not be demanded as a matter of right, but was left to the discretion of the crown; and both Elizabeth and James the First, in their discretion, thought proper to grant the writ. Elizabeth, it is said, burnt alive two Anabaptists, and James burnt alive two Arians.

The statute of 29 Charles II. c. 9, abolished the writ De Haeretico comburendo. Heresy is now left entirely to the ecclesiastical courts; and the punishment of death in consequence of any ecclesiastical censure was by that act abolished in England. As Elizabeth and James practically showed their approbation of burning heretics alive, so Lord Coke (3 *Instit.* c. 5) approves of the punishment.

At present the ecclesiastical courts punish for heresy, when they do punish, *pro salute animae*, as it is termed—that is, solely out of regard to the soul of the offender. But it is difficult to say at present what can be called heresy; and perhaps it is difficult to say what is exactly the punishment for it. It is remarked in the Report of the Criminal Law Commissioners on Penalties and Disabilities in regard to Religious Opinions, 1845 (p. 22), that 'the jurisdiction, as it may affect the laity, and clergy not of the established church, or indeed as administered *pro salute animae*, appears to militate with the principles contained in modern acts of toleration, that are inconsistent with the infliction of punishments for mere opinions with respect to particular articles of faith or modes of worship.' Indeed there seems no risk in asserting that much of the jurisdiction of the ecclesiastical courts in respect to heresy, whether it shows itself in speaking, writing, or preaching, has been destroyed by the various Toleration Acts. The Criminal Law Commissioners see no reason for retaining the jurisdiction of the ecclesiastical courts in matters of heresy, 'except, so far as it may be directed, to prevent ministers of the Established Church from preaching in opposition to the Articles and doctrine of the establishment of which they receive their emoluments.' So far as this, there is certainly no objection. There ought to be some speedy mode of depriving a man of these emoluments, which he accepts upon certain terms. He who will receive alms [Frankalmoigne, P. C. S.], and yet preach against the doctrines which he is paid for teaching, deserves the reprobation of all mankind; and those who dislike ecclesiastical authority most could not be better pleased than to see such an offender handed over to his brethren to be dealt with in any way that the rule of the church provides, to which the offender has solemnly submitted himself.

In the year 1845 proceedings were commenced in the Arches' Court of Canterbury against the Rev. Mr. Oakley for writing, publishing, and maintaining doctrines contrary to the Articles of Religion.

The history of Heresy in England is instructive. The change from burning alive to the free expression of opinion on religious matters is one of the steps in the social progress of England. For some other matters connected with the subject, see Blasphemy, P. C.

HERMES, GEORG, the founder of a philosophical school of Roman Catholic theology, was born on the 22nd of April, 1775, at Dreyerwalde, near Münster in Westphalia, where he received his first education from the priest of the place. He subsequently became a pupil of the gymnasium at Rheina, and there gave the first proofs, especially in his mathematical lessons, of his strong mental powers. After the year 1792, when he entered the theological faculty at Münster, he devoted himself with great zeal to the study of the philosophy of Kant, and thus arrived at the conviction that no one can establish a perfect system of theology unless he has previously fathomed the first principles on which all human knowledge is based. In 1798 he was appointed teacher at the gymnasium of Münster, and all his exertions henceforth were directed towards restoring, on a firm basis, that which had been demolished by Kant's 'Criticism of pure Reason.' But as a teacher at the gymnasium, he had no opportunity of making known the results of his philosophical studies. This opportunity however was offered to him in 1807, when he was appointed professor of theology at Münster. His great talent as a lecturer, and his kind and benevolent manners, attracted great numbers of students. On one occasion, when he had to give his opinion on some ecclesiastical question, he greatly offended Droste-Vischering, afterwards Archbishop of Cologne, and the ill feeling thus created had probably some influence in the subsequent proceedings against the doctrines and followers of Hermes. In 1819 Hermes was appointed professor of theology in the newly established University of Bonn. His lectures again attracted students not only from all parts of Catholic Germany, but the King of the Netherlands sent a large number of young men to Bonn for the special purpose of studying under Hermes. In the enjoyment of the highest esteem both of his colleagues and pupils, he died at Bonn on the 26th of May, 1831.

The only work that Hermes published bears the title 'Einleitung in die Christ-Katholische Theologie,' Münster, 1819, 8vo.; a second edition appeared in 1831. So long as the Archbishop Spiegel zum Desenberg was alive, Hermes and his views were not attacked by the see of Rome; but soon after the elevation of Droste-Vischering to the archbishopric of Cologne, reports were made to Rome about the infidel tendency of Hermes's work, which still continued to be the chief theological manual at Bonn and other German universities, where the chairs were filled by the disciples of Hermes. There is no doubt that the denunciation against Hermes was in the first instance made by some German who was hostile to him, but it was taken up very eagerly at Rome by Perronne, who made his report to the pope. The objectionable point in Hermes's work was his principle, that reason or philosophy must in the first place prove the reality of a divine revelation, and in the second, the truth of the Roman Catholic system. These points being ascertained, Hermes demanded absolute submission to revelation. He does not attempt philosophically to prove the truth of every particular dogma, but only to show that the Church has a right to establish her dogmas, and to demand submission to them. Hermes thus did not attack a single dogma of the Church, and his orthodoxy can scarcely be disputed; but if we consider that the whole method of Hermes claimed for every theologian the right of exercising his private judgment, and at the same time remember that the Roman hierarchy had reason to dread every philosophical inquiry into its system, since, although Hermes remained orthodox, it was by no means certain that future theologians might not be led astray by their application of philosophy to theology, it will not be surprising to find that, on the 26th of September, 1835, the pope issued a brief against the work of Hermes. The severity with which Archbishop Droste-Vischering carried the brief into execution produced a rupture between the courts of Berlin and Rome. The disciples of Hermes made all possible efforts to defend their master, and two of them, Professors Braun and Elvenich, went to Rome to point out to his holiness that Perronne had misrepresented the views of Hermes. But their exertions were of no avail. The pope, as late as the year 1844, severely censured the Prince-bishop of Breslau for not being zealous enough in preventing the circulation of the doctrines of Hermes. In the same year the professors Braun and Achterfeld of Bonn, who refused to recant their Hermesian opinions, were forbidden to lecture in the university by order of the archiepiscopal coadjutor, Von Geissel, at Cologne. The number of pamphlets that have been written for and against Hermes is prodigious, and has probably contributed not a little towards the religious movement now going on among the Roman Catholics of Germany. The best exposition of the whole controversy may be found in Elvenich's 'Der Hermesianismus und sein Römischer Gegner Perronne,' Breslau, 1844, 8vo.

(Brockhaus, *Conversations-Lexikon*, ninth edition.)

HERMIT, more properly *Eremite*, from the Greek ἐρημίτης, signifying an inhabitant of a desert, is the name given to such religious persons as retired from society without becoming members of any monastic community. The distinction between hermits and monks, and the origin of both, are explained in P. C. under the term Monachism (xv. 312). See also Anchoret (i. 507) and Ascetic (ii. 437).

HERMO'GENES, a heretic of the early church, against whom Tertullian has written a treatise, was most probably a native of Africa, and flourished, according to Basnage and Le Clerc, A.D. 168. The chief information we possess respecting him is contained in Tertullian and Theodoret. It appears from the former of these writers that Hermogenes, though professedly a Christian, had throughout his life evinced a strong tendency to the doctrines of the Heathen philosophers, and especially to those of the Stoics. He is accused of having taught that God made the world out of matter that was coeternal with him. The chief design of Tertullian's treatise is to confute that notion: his principal argument against him is, that if matter be eternal, there must necessarily be two Gods, which however Hermogenes did not allow, but expressly asserted the existence of one supreme governor of the universe. The following, in a few words, appears to have been the system of this heretic: he did not introduce any con or any creator different from the one God, the Father; but he asserted the eternity of matter, and that God created the universe out of it. This matter had a confused and turbulent motion, and to it he ascribed all the evils which exist in the creation. It was out of this confused matter that God brought order and perfection. He however believed in a future judgment, and, probably, most of the other great doctrines of religion, as he is not charged by either Tertullian or Theodoret with any other heresy than that to which we have alluded. We have no account of any of his writings, though it may be inferred from the arguments of his opponents that he was an author. We are ignorant of the year of his death. For a fuller detail of his opinions see Lardner, *Hist. of Heretics*, ch. xviii.; Tillemont, *Hist. Eccl.*; and Cave.

HERNANDIA'CEÆ, a natural order of incomplete Exogenous plants. It has monœcious or hermaphrodite flowers, with an involucellum in the pistiliferous and hermaphrodite flowers: a petaloid calyx, tubular, 4-8-parted, deciduous; definite stamens inserted into the calyx in two rows, of which the outer is often sterile, with the anthers bursting longitudinally; the ovary superior, 6-celled, with a pendulous ovule and peltate stigma; a drupaceous fruit with one seed, which is pendulous; the embryo is inverted, without albumen; the cotyledons somewhat lobed, shrivelled, and oily. The species are trees with alternate entire leaves, and flowers arranged in axillary or terminal spikes or corymbs.

This order has been constituted by Blume. It contains only two genera, Hernandia and Inocarpus. These were sometimes referred to Myristiceæ, from which they differ in the absence of albumen from their seeds. Their longitudinal anthers distinguish them from the Lauraceæ, in which order they have also been placed. Their affinity is undoubtedly with Thymeleaceæ, from which they differ only in their drubaceous fruit, lobed cotyledons, and the involucel to some of the flowers.

Hernandia, the typical genus of this order, was named after Hernandez, a naturalist sent out to Mexico by Philip II. of Spain; and it is said to have been given to these plants, which have large leaves and little flowers, in allusion to the great opportunities afforded to this naturalist and the little use he made of them. The characters of this genus are the same as the order.

H. sonora is a tall erect tree, with cordate peltate leaves, yellowish panicled flowers, a large inflated succulent calyx, with a small roundish entire mouth. It is a native of the various parts of the East and West Indies, and has obtained its name *sonora* from the noise made by the wind in whistling through its persistent involucels. The bark, the seed, and the young leaves of this tree are slightly cathartic. Rumphius says that the fibrous roots chewed and applied to wounds produced by the Macassar poison, act as an effectual cure. The juice of the leaves is employed as a depilatory. It destroys the hair wherever it is applied, and this without producing pain. The wood of this species is very light, and Anblet says that the wood of H. Guianensis takes fire readily from a flint and steel, and may be used as tinder. Several species of Hernandia are mildly purgative.

(Lindley, *Natural System*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany*.)

HE'SPERIS (from 'Hesperus,' the evening), a genus of plants belonging to the natural order Cruciferæ, and the tribe Sisymbreæ. The flowers emit a sweet fragrance during the night, and hence the genus derives its name. The pods are quadrangular, or sub-compressed, the valves keeled and somewhat swerved, the seeds in a single row. There are only three species enumerated, and none of these are made use of by man but as ornamental and sweet-scented plants.

H. Matronalis, Dame's Violet, is the only British species; it has an erect branched stem, ovate lanceolate leaves, and large handsome lilac fragrant flowers. The ladies of Germany have pots of this plant placed in their apartments; hence it has been called Dame's Violet. Parkinson calls it Queen's Gilliflower; and Gerard, Damask Violet.

All the species thrive best in a light rich soil, and require the same treatment as most other tardy garden-plants.

(Don, *Gardener's Dictionary*; Babington, *Manual*.)

HETERO'CERUS, a genus of pentamerous coleopterous insects established by Bosc. Latreille places it in his second section of his family *Clavicornes*, and forms of it a tribe under the name of *Acanthopoda*, on account of the flattened broad limbs armed with spines. These beetles have small oval depressed bodies, and eleven jointed antennæ, the last six articulations forming a cylindrical club. They live in sand or mud, by streams or among marshes, burrowing in the ground by means of their spinous tibiæ. When disturbed or alarmed they come out of their holes. The larvæ live in the same situations with the perfect insects. Several species are found in Britain.

HETERO'MERA, the second section of coleopterous insects in the arrangement of Latreille, including such as have five articulations in the first four tarsi, and four in the two posterior. They are all vegetable feeders. Latreille divided the *Heteromera* into four groups: 1st, the *Melasoma*, dusky or black insects, for the most part apterous and having hard elytra, which are often anchylosed. Their jaws are furnished with a hook, their claws are simple, and their eyes are oblong and depressed, a character which indicates nocturnal habits. They live in sand, or under stones, and often in cellars and vaults. They are very tenacious of life, living many months after being transfixed by a pin and placed in the cabinet. Doubtless this is owing to the quantity of fat in their bodies, which much exceeds that found in allied insects, and enables them to subsist for a long period without food. They are found in all parts of the world. The genera *Pimelia*, *Blaps*, and *Tenebrio* are types of as many tribes among the *Melasoma*. The *Blaps mortisaga* and the meal-worm, *Tenebrio molitor*, are familiar British examples.

2nd. The *Taxicornes*, insects without hooked jaws, with more or less square bodies, hard elytra, wings, short antennæ, and feet adapted for running, furnished with simple claws. They live under the bark of trees, or in the fungi parasitical on their trunks. A few live on the ground under stones. The genera *Diaperis* and *Coryphus* are types of tribes in this division.

3rd. The *Stenelytra*, which differ from the preceding in the structure of the antennæ, those organs being perfoliate or clavate in the Taxicornes, but simple among the insects of the present section. In other respects they are similar. The genera *Hylops*, *Cistela*, *Dircaea*, *Oedemera*, and *Myctera*, are types of tribes. They mostly inhabit wood. The *Oedemeræ* are found on flowers: they fly well.

4th. The *Trachelides*, beetles having triangular or heart-shaped heads, remarkable for being pedunculated. The neck is not retractile. Their bodies are soft, and furnished with wings, protected by flexible elytra. The jaws are not furnished with hooks, and the claws are bifid. *Lagria*, *Pyrochroa*, *Mordella*, *Anthecus*, *Horia*, and *Meloe*, are types of tribes in this division. In the tribe of *Cantharidea*, of which *Meloe* is the type, are found the blistering beetles, which were probably the insects known to the ancients under the name of *Buprestis*, and regarded as poison to cattle and even to man.

HEUCHE'RA, a genus of plants named in honour of John Henry de Heucher, professor of botany at Wittemberg, and author of the Hortus Wittenbergensis. This genus belongs to the natural order Saxifragaceæ, and consists of about sixteen species. It has a permanent 5-cleft calyx with an imbricated æstivation; undivided somewhat unequal petals; 5 stamens; 2 styles, very long, distinct, the length of the stamens, eventually diverging; the capsule crowned by the withered flower, at the lower part united to the calyx, 1-celled, dehiscing between the styles. The species are herbs with leafless stems, radical leaves, and racemose or panicled flowers.

H. Americana, Alum root, has rough scapes and leaves, and the whole plant pubescent; the leaves on long petioles, somewhat 5-7-lobed, toothed; the inflorescence elongated, panicled; the lobes of the calyx short, obtuse; the petals lanceolate the length of the calyx; the stamens much exserted. This plant is a native of North America, where it has obtained, on account of its astringent properties, the name of *Alum Root*. It contains tannin, and it is to this principle that its astringent character is to be ascribed. The other species contain tannin, but are not used for any purpose in the arts or medicine.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

HEXAPLA, the plural of ἑξαπλοῦς, which means 'six fold,' was an edition of the Scriptures of the Old Testament prepared by Origen, which exhibited, in addition to the original Hebrew text, six Greek versions in as many parallel columns; namely, the Septuagint, that of Aquila, that of Symmachus, that of Theodotion, one found at Jericho, and one found at Nicopolis in Epirus. It also comprehended a seventh version of the Psalms. The Hebrew text was besides given both in Hebrew and in Greek characters: so that properly speaking there were eight columns in all, whence the work is sometimes called Origen's Octapla. And he also prepared a less extensive work, containing only the versions of the Seventy, of Aquila, of Symmachus, and of Theodotion, which he entitled Tetrapla. Only some fragments of Origen's Hexapla remain, which have been collected and published by Montfaucon under the title of 'Origenis Hexaplorum quae supersunt,' 2 vols. fol., Paris, 1713. There is also a later edition, which however is held in far less estimation, by C. F. Bahrdt, 2 vols. 8vo., Leipzig and Lübeck, 1769-70. Before Montfaucon published his edition, which is now of great rarity, many fragments of the Hexapla had been collected by Petrus Morinus Parisinus, and inserted by Flaminius Nobilius in his Greek Bible printed at Rome in 1587; and all that had then been recovered were given by Joannes Drusius in his 'Veterum Interpretum Graecorum Fragmenta,' Arnheim, 1622.

(See P. C. AQUILA, ii. 206; BIBLE, iv. 372; SEPTUAGINT, xxi. 257; SYMMACHUS, xxiii. 445; THEODOTION, xxi. 326.)

HEYWOOD, JOHN, one of our earliest dramatic writers, lived in the first half of the sixteenth century. He was probably a native of London, was educated at Oxford, and possessed lands at North Mims, in Berks, where he is supposed to have made the acquaintance of his neighbour Sir Thomas More. This lover of wit introduced him at the court of Henry VIII., where his musical skill as a player on the virginals, and his liveliness, both in society and in his writings, gained him high favour. To Queen Mary he was further recommended by his zealous attachment to the Romish Church. In the reign of Edward VI. he was accused of plotting against the government, and is said to have with difficulty escaped the halter. He retired to the continent, and died about 1565, at Mechlin, in Brabant. Heywood's dramatic pieces stand between the miracle-plays and moral-plays on the one hand, and the elaborated dramas on the other. 'They may properly and strictly,' says Mr. Collier, in his 'History of Dramatic Poetry,' 'be called Interludes—a species of writing of which he has a claim to be considered the inventor.' The earliest of them, 'A mery Play between the Pardoner and the Frere, the Curate and Neybour Pratte,' was not printed till 1533, but must have been written before 1521. In Dodsley's Old Plays will be found his 'Play called the Foure P. P., a new and a very mery Enterlude of a Palmer, a Pardoner, a Potycary, a Pedlar,' which is a fair specimen of his undramatic arrangements and of the grotesque coarseness of his humour. Among the other productions bearing his name was a posthumous volume of 'Woorkes,' 1576, 4to., which contains proverbs in verse, and six hundred epigrams, by which in his own time he was probably best known. In respect of them, and to distinguish him from a later play-writer [Heywood, Thomas, P. C.], he is not unfrequently called 'The Epigrammatist.'

HIERA'CIUM, a genus of plants belonging to the natural order Compositæ. The heads are many-flowered, the involucre imbricated with many oblong scales. Fruit terete, angular, and furrowed, with a very short crenulated margin. There are nineteen British species of this genus, but none of them are valuable on account of the properties they possess.

H. Pilosella has a leafless single-headed stem; elliptic-lanceolate or lanceolate leaves, hairy above, glabrous beneath. The flowers are of a pale lemon colour with a red stripe on the back. It is found on dry banks and elevated places.

H. alpinum has lanceolate leaves narrowed into a footstalk, entire or toothed; the involucre is covered with long silky hairs, and the florets externally hairy and of a bright yellow colour. It is found on rocks in Great Britain.

(Babington, *Manual of British Botany*.)

HIERO'CHLOE, a genus of grasses belonging to the Phalacideæ. It has two glumes nearly equal, membranous, 3-nerved, about as long as the flowers; three flowers, the lower with three stamens, the upper palea with two keels, the upper flowers with both stamens and pistils, the stamens two, the upper palea with 1 keel. One species of this genus, the *H. borealis*, has been found in Great Britain: it has an erect panicle, glabrous pedicels, and flowers without awns. The stem is about a foot high. It has only been found in Scotland.

(Babington, *Manual of British Botany*.)

HIGH COMMISSION COURT, a tribunal established by Queen Elizabeth under the authority of a clause in the Supremacy Act (1 Eliz. c. 1), which exercised arbitrary power in matters of faith and in ecclesiastical concerns as the Star Chamber did in civil affairs. The commissioners were forty-four in number, of whom twelve were ecclesiastics, and three commissioners constituted a quorum. Their jurisdiction extended over the whole of the kingdom, and was not confined to the clergy, but included all classes. They were directed to visit, reform, redress, order, correct, and amend all errors, heresies, schisms, abuses, offences, contempts, and enormities whatsoever which by any ecclesiastical authority whatever might be lawfully ordered or corrected. The commissioners, or any three of them, judged at their own discretion of any speech or writing which tended to heresy or schism. All appeals from the inferior ecclesiastical courts were carried before the Court of High Commission. The court was empowered to punish incests, adulteries, fornications, and to inquire into matters relating to matrimonial offences. Other ecclesiastical courts had been subject since the Reformation to inhibitions from the supreme courts of law, but this court was exempt. It exercised its powers therefore without control, and was authorised to conduct its proceedings, not only by the ordinary legal processes, by juries and witnesses, but to use 'all other means and ways which they could devise.' This empowered them to resort to the rack, to torture, inquisition, and imprisonment, and to proceed, not upon information, but at their own discretion upon rumour and suspicion. The court could bring before it a suspected person, and by administering to him an oath, compel him to answer any question, and thereby criminate himself or his friends. Refusal to take this oath was punishable by imprisonment. Fines were levied which often ruined the offender, and he might be imprisoned for any length of time at the discretion of the court. The great object for which the court was established was more especially to punish any departure from the Act of Uniformity in matters of religion or in the services and ceremonies of the Established Church. Elizabeth, in a letter to the Archbishop of Canterbury, said she was resolved 'that no man should be suffered to decline, either on the left hand or on the right hand, from the drawn line limited by authority and by her laws and injunctions.' The Commons remonstrated feebly against the tyranny of the Court of High Commission, and by way of answer she granted towards the close of her reign a new patent in which the powers of the court were in some respects extended.

In the reign of James I. the sentences of the Court of High Commission were most generally confined to deprivation; but when the Commons remonstrated on account of its proceedings he refused to interfere. In 1610, by virtue of the royal prerogative, he established a Court of High Commission in Scotland, the authority of which was readily acknowledged by the bishops and some of the clergy.

In 1641, the Court of High Commission and the Star Chamber were both abolished, and a clause was introduced into the act which prohibited the revival of the former court or any other of a like nature. James II., however, issued a new commission, and appointed seven commissioners to exercise full and unlimited authority over the Church of England, and with the full powers of the former courts. Sancroft, archbishop of Canterbury, refused to be a member. Four of the commissioners were bishops, and the three laymen were the Earl of Rochester, Chancellor Jeffries, and Lord Chief Justice Herbert. The Revolution swept away this arbitrary institution.

HIGH CONSTABLE. [Constable, P. C., p. 466.]

HIGH STEWARD. [Steward, Lord High, P. C.]

HIGH TREASON. [Treason, P. C.; Law, Criminal, P. C. S.]

HIGHMORE, JOSEPH, a portrait and historical painter of some reputation in his day, was born in London in 1692. He was the nephew of Highmore, Serjeant-painter to William III., and was originally bred to the law, but having a decided disposition for painting, he gave up the law and became the pupil of Sir Godfrey Kneller, in whose style he painted. The City was the first field of his labours, whence he removed to Lincoln's Inn Fields, where he painted a set of portraits of the Knights of the order of the Bath, which has been engraved by John Pine. Highmore was a man of much general information; he had a good knowledge of anatomy and was thoroughly acquainted with perspective. He used to attend Cheselden's lectures, and he made the drawings for his treatise on anatomy: we owe to him also one of the best practical books on perspective:—'The Practice of Perspective, on the principles of Dr. Brook Taylor; in a series of Examples, from the most simple and easy to the most complicated and difficult cases,' London, 1763. He published also a critical examination of the ceiling painted by Rubens, in the Banqueting-House at Whitehall; it represents the apotheosis of James I. Highmore painted many portraits of royalty, nobility, and gentry, one of the best of which is that of Young, the poet, at all Souls' College, Oxford. His historical pieces are of only average merit: one of the best, Hagar and Ishmael, was presented by him to the Foundling Hospital, where it still remains; there is also in the same institution a portrait of Mr. Emerson by him. He painted several pictures from the works of Richardson the novelist, but his chief works are taken from the Scriptures. He died at Canterbury in 1780, in the house of his daughter, who was married to one of the prebendaries of that city, and he was buried in the cathedral.

(*Gentleman's Magazine*, April, 1780.)

HIGHTEA, a genus of fossil plants from the Isle of Sheppey. (Bowerbank.)

HILLIARD, NICHOLAS, limner, jeweller, and goldsmith to Queen Elizabeth and to James I., was born at Exeter in 1547; his father, Richard Hilliard, was high sheriff of Exeter and Devonshire in 1560.

Hilliard, a jeweller by education, acquired painting by studying the works of Holbein, and he obtained great celebrity as a miniature painter. Dr. Donne, in a poem on a storm in which the Earl of Essex was surprised, returning from the island voyage, says—

> a hand or eye
> By Hilliard drawn, is worth a history
> By a worse painter made.

There are many miniatures, especially of ladies, by Hilliard extant. He painted Mary Queen of Scots, Elizabeth several times, James I., and Prince Henry. He had for twelve years the exclusive privilege of painting and engraving the portraits of James I. and the royal family. Charles I. possessed several of his works, among them a view of the Spanish Armada, 'and a curious jewel containing the portraits of Henry VII., Henry VIII., Edward VI., and Queen Mary; on the top was an enamelled representation of the battle of Bosworth, and on the reverse the red and white roses.'

Hilliard was the master of Isaac Oliver: he died in 1619, and was buried in St. Martin's-in-the-Fields.

(Walpole, *Anecdotes of Painting*, &c.)

HILTON, WILLIAM, R.A., was born at Lincoln on the 3rd of June, 1786. His father, who was a portrait painter and a native of Newark, died in 1822. Hilton was placed with J. R. Smith, the engraver, in London, in 1800; he obtained about the same time admission into the Royal Academy as a student, and in 1803 he exhibited at the Academy-exhibition a picture of banditti, in a good style, and of extraordinary merit for so young a man. In 1804 he exhibited Hector re-inspired by Apollo; and in 1806 Cephalus and Procris. These early works were followed by a series of noble compositions, in a superior stylo of execution and treatment, which greatly distinguished him from the majority of his brother labourers. However, neither his subjects nor his style were popular, and he had the mortification to witness the success of very inferior artists, while his own works remained on his hands.

In 1814 he exhibited Miranda and Ferdinand bearing a Log; and he was elected an Associate of the Academy in the same year. He was elected a member in 1820, when he exhibited his picture of Ganymede, which he presented to the Academy as his diploma piece. In 1825 he exhibited his Christ crowned with Thorns. Two years afterwards he succeeded Fuseli as keeper of the Academy, a post which he held until his death on the 30th of December, 1839, in his fifty-fourth year.

Hilton died in possession of his best pictures—The Angel releasing St. Peter from Prison; Serena rescued by Sir Calepine; Comus; the Murder of the Innocents, exhibited in 1838, the last work exhibited by Hilton; Amphitrite; Una with the Lion entering Corceca's cave; and Rizpah watching the dead bodies of Saul's Sons (unfinished). Sir Calepine rescuing Serena, exhibited in 1831, was purchased by subscription from Hilton's executors, for 500 guineas, and was presented to the National Gallery, where it now hangs, and it is one of the most attractive English pictures in the collection, though far from being the best of Hilton's works. Una entering the cave of Corceca, exhibited in 1832, was purchased by R. Elison, Esq., and was engraved by W. H. Watt for the Art Union of London, and distributed among the subscribers of 1842. St. Peter delivered out of Prison by the Angel, of which the figures are of the size of life, also exhibited in 1831, was purchased by William Bishop of Plymouth. Mr. Robert Vernon, who possesses the best collection of recent English paintings extant, has two capital works by Hilton—Rebecca with Abraham's servant at the Well, exhibited in 1829; and Edith and the Monks searching for the body of Harold, exhibited in 1834. The following also are among Hilton's best works:—Nature blowing Bubbles, in the possession of Sir John Swinburne, Bart.; Jacob parting from Benjamin, in the possession of W. Wells, Esq.; the Graces teaching Cupid to play on the Lyre, the property of Sir George Phillips, Bart.; Cupid sailing on his Quiver, belonging to W. Smith, Esq.; Cupid and a Nymph, the property of J. H. Turner, Esq.; the Rape of Europa, painted for the late Earl of Egremont, of which there is a print by Charles Heath; and the Infant Warrior—

——'This Hotspur Mars in swathing clothes;
This infant warrior.'——Shakspere.

exhibited in 1836.

The greater part of the above-mentioned works were exhibited with the works of old masters at the British Institution in 1840.

Hilton must ever rank very high among the painters of his own country, up to his own age; but his glory will diminish as the sphere of comparison is extended. He was not a great painter; his energy was not extraordinary, nor was his invention exuberant, but his colouring is harmonious and rich, and his taste in composition and design was refined and manly. The figure of Sir Calepine, in the National Gallery, is not a very good specimen of his style; it is exaggerated, and is not upon its feet. This is a peculiarity which occurs more than once in Hilton's works; his figures appear sometimes to want their specific gravity. Those who knew him describe him as a man of much intelligence and great amiability. 'His manners were mild and graceful; his voice was at all times low, and his demeanour peculiarly quiet: like all men of genius he was modest, retiring, and unassuming.' He died a widower, and childless.

(*Art Union*, 1840; *Catalogues of the Exhibitions of the Royal Academy*.)

HINCMAR was born in France in 806. He was of a noble family, and nearly related to Bernard, Count of Toulouse. At a very early age he was placed under the care of Hilduin, abbot of St. Denis, in which monastery he soon acquired a high reputation for learning and strict observation of monastic discipline. His talents and high birth brought him under the notice of the Emperor Lewis the Meek, at whose court he became a frequent attendant. It was there that, conjointly with the emperor and Hilduin, he formed a plan, which was sanctioned by the council of Paris in 829, of reforming the rules of the monastery of St. Denis, into which many abuses had been gradually introduced. Hilduin, having fallen under the displeasure of his royal master, was banished from the court, and retired to Saxony, whither he was accompanied by Hincmar. On the death of Hilduin, his successor Lewis, an illegitimate grandson of Charlemagne, again introduced him to the court of the emperor, who presented him with the government of the abbeys of Notre Dame at Compiègne and St. Germer. On this occasion he evinced his respect for the observance of the canon law, which at that period was often set aside, in requesting the sanction of the bishop of the diocese, and that of his own abbot, previous to accepting that preferment. In the year 845 was assembled the first council of Beauvais, consisting of ten bishops of the provinces of Rheims and Sens. In that council the deposition of Ebbonius, archbishop of Rheims, was confirmed, and Hincmar was elected by the clergy and people to succeed him. During the session of the council of Beauvais, eight articles of convention between the emperor and Hincmar were drawn up, defining the extent of their separate jurisdictions in matters spiritual and temporal. During the same year a council was likewise held at Meaux, presided by Hincmar and the primates of Sens and Bourges, in which the powers of the metropolitan bishops were more clearly defined and extended.

About this period Godeschalcus, a native of Germany, and monk of Orbais in France, attracted popular notice by a new exposition of the doctrines of St. Augustine on predestination. His peculiar views on this abstruse subject were prominently brought forward during a pilgrimage which he made to Rome, and drew upon him the displeasure of the principal theologians of the day. A council was convened at Mayence by Raban Maurus, archbishop of that city, in which the opinions of Godeschalcus were combated and condemned, the arguments against him being chiefly deduced from the writings of St. Augustine himself. It was there resolved to transmit his case, and to leave the judgment to be pronounced upon him to Hincmar, in whose province was situated the monastery of Orbais. The peculiar opinions of this imprudent monk, magnified by the hostile interpretation of them which Raban sent to Hincmar, brought upon him a severe chastisement from one who had already begun to rule the church with an iron hand. Hincmar caused him to be accused before thirteen bishops at the council of Quiercy, where he was declared an incorrigible heretic, and deposed from the order of priesthood, into which, it appears, he had been irregularly admitted. This punishment, however, was not sufficient to appease the rancour of his judges; tho bold enunciation of his tenets was construed into contumacy, and, as such, punishable, according to the rule of St. Benedict, by corporal chastisement. He was condemned to a public flagellation, and to commit his writings to the flames, which sentence was executed with all the cruelty so characteristic of that barbarous period. He was afterwards confined in the monastery of Hautvilliers, where, twenty years afterwards, he ended his miserable existence.

In the year 852 Hincmar embellished and enlarged the church of St. Remy at Rheims, and caused a magnificent vault to be constructed, in which he deposited the relics of its patron saint. The following year he assisted at the council of Soissons, in which all the ministerial acts of his predecessor Ebbonius were declared to be void, the administration of baptism alone excepted. In 857 he composed his first great work on Predestination, the preface of which is the only part extant: in his zeal to combat in it the doctrines of Godeschalcus, he is accused of having fallen into the opposite error of Semi-Pelagianism. About this time also he wrote several letters to Charles the Bald, in which he complains of the frequent pillage of the churches and monasteries, and appears to intimate that the depredators were emboldened, if not by the countenance of the king, at least by the knowledge that the offence would go unpunished. These letters present a singularly interesting picture of the lawless manners of the age. A few years after he wrote a second treatise on the subject of Predestination, which has been preserved. The arguments in it are chiefly directed against the opinions of the learned John Scotus Erigena, whom he accuses of error respecting the doctrine of the Trinity in Unity, and the real presence in the eucharist. Among other curious accusations brought against Scotus, he charges him with believing that the soul of man is not lodged in the body, and that the punishment of hell solely consists in remorse of conscience caused by the remembrance of sins.

In the year 862 we find Hincmar engaged in controversy with the pope, Nicholas I., one of the most learned ecclesiastics of the age. The occasion of it was as follows:— Rothadius, bishop of Soissons, had incurred the displeasure of his metropolitan, Hincmar, on account of the deposition of a priest of his church, whom Hincmar wished to restore to office. Rothadius, refusing to re-admit this priest, was condemned in two councils held at Soissons, excommunicated, and afterwards deposed and imprisoned. On an appeal of Rothadius to Rome, the pope issued a peremptory order to Hincmar to restore this bishop to his see within thirty days, or to appear at Rome, either in person or by legate, to answer the charge which had been made against him. In the year following Hincmar commissioned Odo, bishop of Beauvais, to proceed to Rome, and to request a confirmation of the decrees of the council of Soissons. Nicholas, irritated at the opposition of Hincmar, rescinded the decisions of that council, and demanded the liberation of Rothadius, in order that he might plead in person at Rome the cause of his appeal. This demand was at first resisted by Hincmar, but, through the interference of the king, Rothadius was released, and deputies were finally sent by Hincmar to the pope to state the reasons of his conduct. This triumph of Nicholas was soon succeeded by one more important; Rothadius was restored to the episcopal dignity, and he returned to his diocese accompanied by a legate of the pope. The pretensions of Rome in this affair were founded on 'The Decretals of the Ancient Pontiffs,' a work probably composed by Isidore Mercator, but claiming much greater antiquity. Hincmar, though the most learned canonist of the age, does not appear to have doubted the authenticity of these Decretals.

The interference of the Pope in temporal matters was however more successfully resisted. On the death of Lothaire, king of Lorraine, Adrian II. was desirous of excluding Charles the Bald from the succession of his states, and to bestow them upon the Emperor Lewis. To this effect he addressed two letters, one to the nobles of Lorraine, and the other to the subjects of Charles, threatening excommunication should they disobey his injunctions to favour the cause of Lewis. Hincmar, in the name of his fellow subjects, replied to the pretensions of the Pope. In his letter he remarks that Adrian should bear in mind that 'he is not at the same time king and bishop, and that his predecessors had regulated the church, which was their concern, not the state, which is the heritage of kings.' The opposition was successful, and Charles, with the aid of Hincmar and other prelates, took possession of the throne of Lorraine, of which all the subsequent efforts of the disappointed pontiff were unable to deprive him.

In the year 871 Hincmar presided at the Council of Douzi, composed of twenty bishops assembled by the order of Charles the Bald, for the purpose of inquiring into the conduct of Hincmar, bishop of Laon, nephew of the archbishop of Rheims. He was accused of spoliation of church revenues, of usurpation of powers not properly belonging to a bishop [Interdict, P.C.], and of revolt against his sovereign. His uncle appears to have conducted the trial with severe impartiality, and, on conviction, sentenced him to be degraded from his ecclesiastical office.

About ten years after these events Hincmar exercised the same firmness in defending the rights of the church against the encroachments of regal authority that he had shown in opposing the claims of the Roman pontiff. Lewis III. wished to bestow the bishopric of Beauvais upon Odacer, a favourite courtier, who had been rejected as unworthy of the office by the Council of Vienne, and he endeavoured, both by supplication and menace, to obtain the acquiescence of Hincmar to his nomination. This prelate, however, boldly defended the liberty of canonical elections, and the independence of the church. In a letter addressed to Lewis, he fearlessly reminds him of the sanctity of the oath he had taken to respect the privilege which the church possesses to refuse induction to unworthy candidates, and warns him against arrogating to himself a power which had been denied to the most eminent of his predecessors. 'I trust,' he observes in it, 'ever to preserve inviolate my fidelity and devotedness to your service, indeed I have not a little contributed to your own election; return not therefore evil for good, by endeavouring to persuade me in my old age to depart from the holy rules of the church, which, thanks be rendered to God, have ever been my pride during six and thirty years of my episcopacy.' (Hinc. *Op.* tom. ii. p. 188.) He proceeds to advise him to assemble a council, in order that his nomination may be ratified by the clergy and people of Beauvais. In a second letter he uses still stronger language, and terminates it with these ominous words: 'It is your lot soon to depart from this earth, but the church with its pastors, under J. C. their chief, has, according to his promise, an eternal existence.'—'This threat,' says Fleury, 'appeared a prophecy, when the king, while yet in the strength of his youth, died the following year.' (Fleury, b. liii. c. 31.)

Hincmar did not however long survive his royal master; about this period the Normans extended their predatory incursions as far as his province, the principal towns of which they pillaged and destroyed. They were advancing towards Rheims, when notice of their approach was given to Hincmar, who was obliged to leave the city by night, having previously taken the precaution to secure the treasures of the church, and the relics of St. Remy. The aged prelate arrived at Epernay, worn down by fatigue and anxiety. Severe illness compelled him to remain in that town, where, on the 21st of December 882, he ended his eventful life. The name of Hincmar, though associated with the darkest period of ecclesiastical history, will ever be conspicuous as that of one of the most zealous defenders of the liberties of the church. His great object was to produce that unity among its members which could alone present an effectual barrier against the encroachments of regal and papal authority. The memorable words which he uttered when he heard that the Pope was about to visit France, and threatened the excommunication of its bishops, are a sufficient index of his fearless spirit. 'Si excommunicaturus venit, excommunicatus abibit,' 'if he comes to excomminicate, he will return excommunicated.'

The principal works not alluded to in this article, are 1st, 'A Treatise on the Duties of a King,' addressed to Charles the Bald. 2nd, 'On the Ordeal by Water,' which practice he attempts to authorize by quotations from Scripture, and which unfortunately proves that he was not superior to the superstitions of the age. 3rd, 'On the Rights of Metropolitan Bishops.' 4th, 'On the Translation of Bishops and on their Duties.' 5th, 'On the Council of Nice;' and 6th, 'On the Nature and Sanctity of Oaths;' besides several letters and 'Capitularia.' His works have been collected in two volumes folio by the learned Sirmond, Paris, 1645, and another volume was added to this collection by Cellot, in 1658.

The following are the principal authorities which have been consulted, and may be referred to for a fuller detail of his life. Fleury, Mosheim, and Waddington's *Eccles. Hist.*; Longueval, *Histoire de l'Eglise Gallicane*, tom. vi.; Mézerai, *Hist. de France*, tom. ii.; Michelet, *Hist. de France*, l. ii. c. 3; and Guizot's *Sixth Lecture on Modern Civilization.*

HINDOO ARCHITECTURE. [Hindustan, P. C., p. 235.]

HINGE, a kind of joint, usually made of iron or brass, upon which doors, gates, shutters, box-covers, &c., are made to turn in the act of opening and shutting. Hinges are constructed in a great variety of forms; but in most of the commoner kinds the action is that of a hollow cylinder working round a fixed central pin. Without pretending to describe contrivances so familiar to every one, we may briefly notice a few of the more important deviations from the ordinary form, referring to Hebert's 'Engineer's and Mechanic's Encyclopædia' for fuller details. In Collinge's patent hinges, which are peculiarly adapted for hanging large heavy doors and gates, the principal rubbing action is between a hollow cap and an accurately turned sphere, formed, as it were, upon the end of the pin; a cavity being provided for the reception of a supply of oil to lubricate the rubbing surfaces. Mr. Redmund, another celebrated manufacturer, who has displayed his ingenuity especially in designing hinges for unusual and apparently impracticable situations, in rendering them ornamental where, if of the ordinary form, they would be a disfigurement, and for contriving invisible hinges for situations in which it is desirable to conceal the hinges altogether, is the inventor of the *rising hinges* so frequently used for hanging room-doors in houses of superior character.

In ordinary door-hinges the hollow cylinder which works round the axis or central pin is divided transversely into two, three, or more portions: one or more of such portions being attached to and forming part of that leaf or half of the hinge which is screwed to the door, while the other portion or portions form part of that half of the hinge which is screwed to the door-post. In the rising hinges a similar arrangement is followed; but instead of the hollow cylinders being divided transversely *at right angles*, they are divided by spiral or rather helical lines. The result of this contrivance is, that when the door is opened it is lifted up a little from the floor by the sliding upon one another of the inclined helical surfaces; so that although the door may shut very close to the floor, it rises, when opened, to a sufficient height above the floor to allow its lower edge to clear the carpet. Another advantage of this kind of hinge is, that the weight of the door acting upon the inclined rubbing surfaces of the hinges, causes it gently to close itself so soon as the hand is removed from it; but as this might in some cases prove inconvenient, it is usual to cut a portion of the helical curves away, so as to form two horizontal planes which come opposite to each other when the door is opened to about an angle of 90°, or so as to form a right angle with its position when shut. By this arrangement the door retains its disposition to close whenever it is not opened more than 50° or 60°, which is as much movement as is usual upon a person entering or leaving the room, but will stand open if opened to or beyond 90°, although even then a very slight push is sufficient to cause it to close steadily and quietly. In some cases a small spring is attached to hinges of this description, to aid the closing of the door when it has been opened but a little way. Hinges supplied with much more powerful springs are often used for the doors of public offices, where it is desired to render the closing of the door both certain and quick. For such doors, hinges which will open in either direction and cause the door to spring back to its original position are often used. In connection with such spring hinges, we may notice Hebert's contrivance of a hinge for external shutters, in which a spring catch or detent is employed to hold the shutter open, the pressure of the finger being needful to release the catch before the shutter can be closed.

One of the most curious contrivances of the hinge kind is that which Hebert describes as Whitechurch's patent hinge, the details of which are too complicated to be explained without several illustrations. We can only state that it is an apparatus by which doors or windows may be opened at pleasure either on the right or left hand, or by which, in other words, either edge of the door may be made, at pleasure, the opening edge. A handle is fixed near to each side of the door or window, by turning which the required positions of the apparatus are varied at pleasure: the action of this handle being to disconnect or release the door from the style or post near to which it is placed, and at the same moment to complete its hinge-like connection with the opposite style. Notwithstanding the singularity of this action, the door is stated to be even more securely hung and better supported, and capable of turning upon its hinges with greater facility than one hung in the common way; and it cannot be unhung more readily, both requiring the aid of a turnscrew. Such a mode of hanging doors is recommended for cabins in ships and steam-vessels, and for other situations in which space is very limited and great convenience is required.

Another contrivance worthy of notice, which is also described and represented by Hebert, is Nettlefold's hinge for the doors of book-cases, by which two adjacent doors opening in contrary directions may be hung without an intervening style: the two doors being connected together by a hinge resembling that by which ordinary doors are hung, and the axis of this hinge being connected with the edge of a thin partition in the book-case by metal brackets above and below the hinge, the space occupied by which is notched or cut out of the edges of the doors. Doors hung in this way fold completely back, and the hinges do not offer the slightest impediment to the removal of the volumes which happen to stand next to the partition, and which, were the doors hung in the usual way, could only be removed by first taking out those which stand adjacent to them.

HIPPO (Ἵππων), a Greek philosopher, who is called by some a native of Samos and a follower of Pythagoras, and by others a native of Rhegium, in southern Italy. With regard to his age, some writers have made him a contemporary of Thales, or have placed him even before the age of Thales; but he evidently belongs to a much later time, and was perhaps a contemporary of the comic poet Cratinus (about B. C. 450), who ridiculed him in one of his last comedies; further, Hippo mentions the four elements of the physical philosophy of Empedocles in such a manner that we must infer that he was acquainted with the theory of Empedocles. Aristotle (*Metaphys.* i. 3) does not appear to attach any great value to the philosophical system of Hippo, which in fact was that of Thales, with sundry additions and modifications. He thus went back to the materialism of the early Ionic school; and as Thales had taken water, so Hippo took moisture to be the principle of all things. (Aristot. *De Anima*, i. 2; Plutarch, *De Placit. Philos.* 5.) He explained his views in a work which seems to have been called φυσικὰ δόγματα, which, however, owing to its insignificance, appears to have fallen into oblivion at a very early period, and scarcely any fragments of it have come down to us. Clemens of Alexandria (*Cohortat. ad Gent.* vol. i. p. 48, ed. Potter) has preserved an epigram of Hippo, which is also printed in the editions of the Greek Anthology. (Iamblichus, *De Vita Pythag.* 36; Sextus Empir. *Pyrrhon. Hyp.* iii. 30, *adv. Mathem.* ix. 361; Scholiast. *ad Aristoph. Nub.* 97; compare Brandis, *Geschichte der Griech. Römischen Philosophie*, vol. i. p. 121, &c.; Bakhuizen van den Brink, *Variae Lectiones ex Historia Philosophiae Antiquae*, pp. 36-59.)

HIPPOBRO'MA (from ἵππος, a horse, and βρῶμα, food), a genus of plants belonging to the natural order Lobeliaceæ. It has the limb of the calyx 5-parted with linear segments; the tube of the corolla long, straight, entire, with the limb 5-parted nearly equal; the stamen-tube projecting, completely monadelphous and syngenesious; the stigma sloped, the capsule 2-celled, 2-valved, many-seeded.

H. longiflora is the only species. It is an herbaceous plant, with short axillary pedicels, mucronate or coarsely toothed leaves, with long slender white flowers. It is a native of Jamaica, St. Domingo, Cuba, and Martinique, in damp places and by the side of streams. This is one of the most poisonous of plants. If the juice only accidentslly touches the lips or eyes it produces a burning inflammation. Horses are violently purged after eating it.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica.*)

HIPPOCRE'PIS (from ἵππος a horse, and κρηπὶς a shoe, on account of the curved shape of its pods), a genus of plants belonging to the natural order Leguminosæ, the tribe Hedysareæ. It has diadelphous stamens, a piliform acute style; the legume curved, with numerous 1-seeded joints; the seeds cylindrical or compressed, oblong, curved, fixed to the middle part of the joint, and therefore the umbilicus is in the middle of the curve. The species are herbs, or under-shrubs, with unequally pinnate leaves and yellow flowers, which are sometimes solitary and axillary, sometimes sessile, but usually disposed in umbels on the tops of the axillary peduncles.

H. Balearica, Minorca Horse-shoe Vetch, is a shrubby erect plant, with the peduncles longer than the leaves, bearing an umbel of flowers at the apex, the legumes glabrous, a little arched. It is a native of the island of Minorca. It is a pretty plant, worthy of cultivation, but requires the greenhouse in winter. It grows well in a soil composed of loam and peat; and cuttings strike readily under a hand-glass.

H. comosa, common Horse-shoe Vetch, has the pods umbellate, their joints rough, curved, neither dilated nor bordered, glabrous; the peduncles longer than the leaves. It is a native of Europe, and is found on dry chalky banks in Great Britain. It is also found in the north of Africa.

There are seven or eight more species of Horse-shoe Vetch. They are all worth cultivation on account of their beauty. The perennial species are adapted for rockwork and banks, and may be propagated by dividing the roots. The annual species should be grown from seeds, which may be sown early in spring.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany.*)

HIPPO'PHAË, a genus of plants belonging to the natural order Elæagneæ. It has diœcious flowers with ovate scaly bracts. The staminiferous flowers have a perianth of two leaves adhering by their points; the stamens have four very short filaments; the pistilliferous flowers have the perigone tubular and cloven at the summit; the style is short, the stigma elongated; the nut 1-seeded, clothed with the large coloured berry-like perigone.

The only species of this genus is the ***H. rhamnoides***, which is a small shrub found on the east and south-east coasts of Great Britain, and other parts of Europe. The acid berries yielded by this plant are often eaten as a salad both in this country and in France. This plant also yields a colouring matter, which is used for dyeing yellow. Although in this country the berries are innocuous, they seem to exert a deleterious influence, or are supposed to do so, in some of the countries of the south of Europe. They are said to be a favourite food with the Tartars, and the fishermen of the Gulf of Bothnia eat them with their fish.

(Babington, *Manual of Brit. Bot.*; Burnett, *Outlines of Botany.*)

HIPPU'RIS (from ἵππος, a horse, and οὐρα, tail, from the resemblance of the stem to a horse's tail), a genus of plants belonging to the natural order Halorageæ. It has the calyx-limb very minute, obsoletely 2-lobed; no petals; one stamen; a filiform style lying in a channel of the anther; the stigma simple, acute; the fruit nucumentaceous, 1-celled. Three species of this genus have been described. Of these, *H. vulgaris*, the common mare's-tail, is found abundantly throughout Europe and North America. It has linear leaves, 6-12 in a whorl, and callous at the point. It is found in ditches and lakes. In deep water the submersed leaves are flaccid and pellucid, and not callous at the points. This plant is very common in Great Britain in stagnant waters and slow streams.

(Babington, *Manual of British Botany.*)

HIRCIC ACID. This substance was obtained by Chevreul from the fat of the goat.

To prepare it, the aqueous product of the distillation of the liquid acid separated from the soap of goat's fat, is saturated with barytes. After having evaporated the solution, the dry salt is decomposed by dilute sulphuric acid; the hircic acid then floats on the surface of the liquid in the form of an oil.

This acid remains fluid at 32°: it is lighter than water, smells of the goat, is insoluble in water, and forms soluble salts with potash and barytes. It has not been analyzed.

HIRING OF SERVANTS. [SERVANT, P. C.]

HIRT, ALOYSIUS, was born at Bela near Donaueschingen in Baden, June 27, 1759. In early life he visited Italy and studied the remains of classic art there, and on his return settled at Berlin, having been appointed preceptor to Prince Henry of Prussia. In 1796 he became professor of architecture and the fine arts at the academy of Berlin, and was subsequently made professor of archæology at the University of Berlin. Among his numerous publications are several special disquisitions on particular structures, such as the Temple of Solomon, the Temple of Diana at Ephesus, and the Pyramids of Egypt; but those by which he will be most generally and longest known are his 'Baukunst nach den Grundsätzen der Alten,' 1809, and his 'Geschichte der Baukunst bey den Alten.' 1821-7, 3 vols. 4to., with a folio atlas of plates. This last not only gives a history of antient architecture, that of Egypt included, down to the time of Constantine, but also a full account of all the various classes of buildings. Latterly he was much occupied in arranging the collections in the Berlin Museum, which brought him into a literary dispute with his former pupil and protégé, Dr. Waagen, since well known here by his visit to England and remarks on English art. Hirt died at Berlin June 29, 1837, just two days after entering his seventy-eighth year.

HOADLEY, BENJAMIN, M.D., eldest son of Bishop Hoadley [HOADLEY, BENJAMIN, P. C.], was born February 10, 1705, in London. He was admitted of Corpus Christi College, Cambridge, April 8, 1722, and received his degree of M.D. in 1729. In June, 1742, he was appointed physician to his Majesty's household, and in January, 1746, was appointed physician to the household of Frederic, Prince of Wales, and he held both offices at the same time. He was the author of 'Three Letters on the Organs of Respiration,' read at the Royal College of Physicians, London, 1737, being the Gulstonian Lectures for that year; 'Oratio Anniversaria in Theatro Col. Medicor. ex Harveii instituta, habita die 18mo Oct. 1742;' 'Observations on a Series of Electrical Experimenta,' 1756, 4to. Dr Hoadley is now known chiefly as the author of 'The Suspicious Husband,' 1747, a bustling comedy, full of incidents of intrigue, in which Garrick was distinguished for his performance of the character of Ranger, as Elliston was also in more recent times. Dr. Hoadley died August 10, 1757, in his house at Chelsea. His brother, the Rev. JOHN HOADLEY, LL.D., born October 8, 1711, died March 16, 1776, was the bishop's youngest son. He was the author of several poems in Dodsley's Collection, and of five dramatic pieces, which are now forgotten. He published an edition of Bishop Hoadley's Works, London, 1773, 3 vols. folio

HOANG-HAI, or WHANG-HAI, *The Yellow Sea*, is a large mediterranean sea, which runs into the eastern coast of Asia, being enclosed on the west and north by China Proper, and on the east by the Peninsula of Corea; on the south it is open and united to the Pacific Ocean. It lies in the parallels of the Mediterranean, which divides Europe from Africa, between 34° and 41° N. lat., and extends from 117° 40′ to 127° E. long.

The northern portion extends in length from west to east somewhat more than eight hundred miles from the shores of the Gulf of Petcheli, near the mouth of the river Peiho, to the coast of Corea, at the back of James Hall's Island; and it comprehends two basins, being divided nearly in the middle by a widely projecting peninsula, which juts out on the northern coast, and may be called the Peninsula of Leao-tong, as it forms a part of the province of that name. The strait which lies between the most southern point of this peninsula and the northern shores of the Province of Shan-tong is about fifty miles wide, and it contains numerous small rocky islands, so that it would appear that at some remote period the Peninsula of Leao-tong was united to that of Shan-tong. Between these islands are passages which lead to the most western basin, which consists of two gulfs, that of Petcheli and that of Leao-tong.

The Gulf of Petcheli washes the north-western shores of Shan-tong and the eastern of Petcheli. These shores are low, and can only be seen from the deck of a vessel at the distance of about nine miles. The uniformity of the soundings along these shores is unusual. At the distance of ten miles from the beach they vary only between four and a half and six fathoms, and at twelve miles between six and eight fathoms. Large vessels cannot approach the shores, and must remain at anchor from four to six miles off. This part of the Hoang-hai is only navigated by flat-bottomed vessels, which find shelter in the embouchures of some small rivers. Where the gulf approaches the above-mentioned strait between Leao-tong and Shan-tong, the shores rise higher, and are well defined. Here a range of mountains stretches from south-west to north-east at the distance of ten or twelve miles from the sea, and between them and the shore is a lower belt of elevated ground in a state of high cultivation, covered with many towns and villages, and interspersed with scattered trees and several extensive woods. Along this coast the soundings are somewhat deeper than on the other, but not so deep as might be expected from the bold outline of the land; and there appear to be some harbours for larger vessels.

The northern portion of the western basin, or the Gulf of Leao-tong, is imperfectly known, for no European vessel has sailed up to its most remote recess. The shores are rocky and high, and they increase in elevation and steepness as they proceed farther north. But in spite of the rocky nature of the adjacent countries the soundings are rather regular and of moderate depth. Some good harbours for large vessels are known to exist, and it is supposed that several others may be found when this portion of the Hoang-hai is better known. The upper part of the mountains which enclose this gulf are barren and nearly destitute of trees, but between them and the shores there are many fertile and well-cultivated tracts.

The water in the western basin of the Hoang-hai is of a dirty yellow or green, which colour seems to be derived from that of the mud, which constitutes its bottom. There are a few small islands in this part of the sea, but the group of three islands, called the Moatao Islands, which lie partly in the strait between the western and eastern basin, are of moderate extent and well cultivated and populous.

The eastern basin of the northern portion is very little known. Only the most southern part of it, that which washes the north-eastern shores of the Peninsula of Shan-tong, has been navigated by Europeans, and in these parts the navigation is safe, and there are only a few rocky islands. The soundings are regular and moderate, and there are some tolerable harbours for small vessels. The northern unknown part is represented on the Chinese maps as containing several extensive groups of islands, especially along the shores of the Peninsula of Leao-tong.

The most southern part of the Yellow Sea, or that which lies south of a line drawn from the most north-eastern cape of the Peninsula of Shan-tong to the coast of Corea at the back of James Hall's Islands, is at its southern extremity between the mouth of the river Hoang-ho and the south-west cape of Corea nearly seven hundred miles wide, but grows narrower as it proceeds north, being near its northern boundary hardly more than two hundred miles across The shores of this part of the Hoang-hai are high and rocky, with the exception of a tract of about sixty miles contiguous to the mouth of the Hoang-ho on the north, where the country consists of alluvium. Farther north on the Peninsula of Shan-tong several ranges of high ground advance to the coast, and in this part some harbours of considerable extent are said to exist, but they have not yet been visited by Europeans. The navigation along this country is not dangerous, though farther south between the mouths of the Hoang-ho and Yang-tse-kiang the sea is full of shoals and sandbanks. On the opposite side, along the coasts of Corea, the sea to the distance of fifty or sixty miles from the continent is literally dotted with islands and rocks, which are generally small. Though the number of islands renders the navigation dangerous, and requires great caution on the part of seamen, they contain numerous excellent harbours. The straits which separate the islands are generally from one mile to two or three or even four miles across, and are all close harbours, capable of containing in security all the navies of the world. They form, in fact, an almost endless chain of harbours communicating with each other. They appear to be all inhabited, and therefore must possess fresh water.

Though the Yellow Sea is not visited by European vessels, navigation is very active, as it washes those parts of China Proper which are most populous and best cultivated, and where the manufacturing industry is carried to the highest point. Accordingly the number of junks which are met with along this coast, or are seen in the harbours, is very great, and sometimes excites the surprise of European navigators; but along the coast of Corea these vessels are rarely met with.

(Staunton, *Account of an Embassy to the Emperor of China;* Mac Leod, *Narrative of the Alceste's Voyage to the Yellow Sea;* and Basil Hall, *Account of a Voyage of Discovery to the West Coast of Corea*, &c.)

HOANG-HO. [Yellow River, P. C.]

HOARE, WILLIAM, R.A., an historical and portrait painter, born at Bath about the year 1706. He studied at Rome nine years, where he was the fellow pupil of Pompeo Batoni, under Francesco Fernandi, called D'Imperiali. Upon his return to England he established himself at his native place, where he acquired a great reputation as a portrait painter in oils and crayons; he painted also some historical pieces. There is an altar-piece by Hoare, of Christ bearing the Cross, in the church of St. Michael at Bath; and another of the Lame Man healed at the Pool of Bethesda, in the Octagon Chapel, for which he received 100*l.* and a pew in the chapel. He was one of the original members of the Royal Academy, and sent several works to its early exhibitions. He died at Bath in 1792.

HOARE, PRINCE, who succeeded Boswell as foreign secretary to the Royal Academy, was the eldest son of William Hoare: he was professionally a painter, and is known as the author of about twenty dramatic pieces, among which are—'No Song no Supper;' 'Lock and Key;' 'My Grandmother,' and other lively farces; and he published in 1806, 'An Inquiry into the requisite cultivation and present state of the Arts of Design in England,' 8vo. p. 270.

Prince Hoare presented the so-called 'Slaughter of the Innocents,' by Raphael, to the Foundling Hospital, which institution has lent it to the National Gallery; it is however only a part of a composition, and has been so completely painted and varnished over, that if originally by Raphael, now at least nothing whatever of Raphael remains but the composition, which is brutal and without expression. Prince Hoare died at Brighton in 1834, aged eighty.

(Edwards, *Anecdotes of Painting*, &c.; *Literary Gazette.*)

HOARE, SIR RICHARD COLT, Baronet, the historian of Wiltshire, and an eminent biographer and antiquary, was born the 9th of December, 1758, and died the 19th of May, 1838. His father, the first baronet, was married to Anne, second daughter of Henry Hoare, Esq., and of Susanna, daughter and heiress of Stephen Colt, Esq. In a very pleasing autobiography which Sir R. Colt Hoare drew up in his old age, he says:—'In my youth I was initiated in the business of our family bank (Messrs. Hoare's bank, Fleet-street, London), till my grandfather removed me from it, and gave up to me during his life-time all his landed property. An early habit of application to business induced me to have recourse to the pen and pencil: for, without some amusement, life ultimately must produce tedium and *ennui*; and, thanks to Providence, I used in my advanced age to feel the benefits of the early habits of application.' In 1783 he married the eldest daughter of Lord Lyttleton, who died in 1785, leaving one child, Henry. In 1787 he succeeded to the baronetcy. After the death of his wife he made an extensive tour on the continent, which occupied him nearly two years; and in 1788 he again left England on a continental tour, and did not return until August, 1791. He devoted ample time to the examination of interesting objects, and filled his portfolio with valuable drawings. For the gratification of his family and friends he printed an account of his travels in four volumes. They were subsequently condensed, and published in 1818 in two volumes, 8vo., under the title of 'A Classical Tour through Italy and Sicily; tending to illustrate some districts which have not been described by Mr. Eustace in his Classical Tour.' When the greater part of the Continent had become closed in consequence of the war, Sir Richard travelled through his own country, and he began with Wales; 'but, as travelling without a pursuit becomes tedious, I resolved,' he says, 'to take Giraldus as my guide.' In 1806 he published a translation of Giraldus, with views, annotations, and a life of Giraldus, in two splendid quarto volumes. He furnished the drawings for the description of Monmouthshire by Archdeacon Coxe. In 1807 he visited Ireland, and published a short account of his excursion. But it is as the historian of Wiltshire, his native county, that Sir R. Colt Hoare's fame as a topographer and antiquarian is best established. The first volume of South Wiltshire is confined to British antiquities, and includes Stonehenge. The second volume commences with North Wiltshire, and Part I. is devoted to the British Period, and contains the account of Avebury. Part II. comprises the Roman Period. These two elaborate volumes were followed in 1821 by the History of Modern Wiltshire. In the description of several of the hundreds he had a coadjutor for each; but the difficulty of obtaining aid of this kind at length compelled him to confine his attention to South Wiltshire. A catalogue of works printed for private circulation by Sir R. Colt Hoare is given in the 'Gentleman's Magazine' for July, 1838, which also contains a list of his communications to the Royal Society of Antiquaries.

HODGES, WILLIAM, R.A., was born in London about the year 1744; his father was a blacksmith, and kept a shop in St. James's Market. He attended Shipley's drawing school when very young, and became afterwards the pupil of Wilson the landscape painter. He painted decorations for theatres, landscapes, and architectural views; among the latter, a view of the interior of the Pantheon, Oxford Street, which was burnt down on January 14, 1792.

In 1772 Hodges accompanied Captain Cook as draftsman on his second voyage to the South Seas; and his drawings were published in Cook's narrative. After the completion of this work he went to India, where, under the patronage of Warren Hastings, he realized a considerable fortune, and returned to London in 1784. About 1790 he made a tour on the Continent of Europe, visiting Russia; and he exhibited a view of St. Petersburg at the Royal Academy in 1793. In 1795, finding that his Indian fortune was diminishing instead of increasing, he established a bank at Dartmouth in Devonshire, which however broke two years afterwards in consequence of the devastations of the French in Newfoundland. The shock brought on the death of Hodges, on the 6th of March; and his wife, his third, died a few months afterwards. He was elected a member of the Royal Academy in 1787.

Hodges was not a painter of great ability; in style he imitated Wilson, but with little success; his best works are—a view of Windsor from the great park, and three or four views painted in India. He painted also two or three historical pieces for Boydell's Shakspere. His last works were two ordinary landscapes illustrating the effects of peace and war, which he exhibited with twenty-three others, one of which was a large view of Falconet's equestrian statue of Peter the Great at St. Petersburg, in Old Bond Street; one was a seaport in prosperity, the other was the same view devastated by fire and sword. He closed the exhibition in disgust at the little attention which it attracted; sold his pictures by auction, gave up painting, and, as already mentioned, turned banker. These two pictures, which have been engraved, are now in Sir John Soane's museum. Several of the works of Hodges have been engraved; he himself executed a set of Indian views in aquatinta which he dedicated to the East India Company. He published also an account of his Travels in India, with plates.

(Edwards, *Anecdotes of Painting*, &c.)

HOENE, referred to in P. C., from Brahe, p. 327, is a misprint for Hveen, the name of the island on which Brahe's observatory was built. [Uranienburg, P. C.]

HOERBERG, PEHR, a distinguished Swedish painter, was born in a village of Småland, in 1746; his father was a private soldier and extremely poor. Hoerberg's youth was spent in begging, watching sheep, and other peasant's labour; and like Giotto's, his first efforts were made with sticks or chalk in the woods when performing his pastoral duties. When only fourteen years of age he entered the service of a painter of Wexiö, but he remained with him for a very short period. However, by the time be was two and twenty years of age, he contrived to learn so much from one painter and another in his own district, that he was enabled to maintain himself by his paintings, and he even ventured to take a wife. In 1784, in his thirty-eighth year, he became a student in the Royal Academy of Arts at Stockholm, in which he obtained two prizes, and made rapid progress. In 1790 he established himself at Olstorp in East Götaland, where he obtained a great reputation, and in 1797 be was elected a member of the Swedish academy, and was appointed historical painter to the king. He died in 1816.

There are eighty-seven altar-pieces by Hoerberg in Sweden, five of which are copies; his paintings altogether amount to about 700, mostly religious pieces; his drawings are likewise numerous, and he executed many engravings.

His execution is unfinished, but his compositions are vigorous and perspicuous: and his figures are more distinguished for character than for beauty.

His autobiography was published at Upsala in 1817; it has been translated into German and Danish; the original MS. is in the library of tbe Gymnasium of Linköping.

(*Kunstblatt*, 1822; Nagler, *Allgemeines Künstler Lexicon.*)

HOLA'STER, a genus of fossil Echinodermata, from the chalk and greensand deposits.

HOLCUS, a genus of grasses belonging to the tribe Sesloriceæ. It has 2-flowered glumes, the lower perfectly awnless, the upper usually staminiferous, with a dorsal awn; the paleæ hardening on the fruit. There are two British species of this genus. *H. lanatus* has the upper glume obtuse, apiculate; the awn smooth, except for a short distance from the tip. It grows in meadows and pastures. *H. mollis* has the upper glume acute, and the awn rough throughout its whole extent. It grows in thickets or open places on a light soil. The *H. cernuus* of Willdenow, and the *H. sorghum* of Linnæus are now referred to tbe genus Sorghum. [SORGHUM, P. C.] Fraas refers the μέλινη of Theophrastus (*Hist. Plant.* viii., 1, 3, 7, 10) to these grasses, and not to the *Setaria Italica*, as had been done by previous authors.

(Babington, *Manual of British Botany*; Fraas, *Synopsis Plant. Floræ Classicæ.*)

HOLL, ELIAS, a distinguished German architect, was born at Augsburg in 1573. His father, Johann Holl, was likewise an architect, and was much employed by the celebrated graf Fugger of Augsburg. Elias was taken when young to Venice, by a rich merchant of the name of Garb; and he there studied the Italian architecture, which style he adopted in his future works at Augsburg, though much simplified in parts and in decorations. Augsburg owes to Holl a great portion of its public buildings, but his masterpiece is the Rathhaus, or town-hall, built 1615-20, which, though not among the largest, is still one of the handsomest in Europe. The façade is 147 feet wide, its depth is 110 feet, and in the centre 152 feet high; there is a print of it by Solomon Kleiner. Holl built also several churches, and the castle or palace of Schönfeld, and the palace of Wilibadsberg at Eichstädt. He died in 1636, aged sixty-three.

(Von Stetten, *Erläuterungen der in Kupfer gestochenen Vorstellungen aus der Geschichte der Reichstadt Augsburg*, &c.; Lipowsky, *Baierishes Künstler Lexicon.*)

HOLLAND, SIR NATHANIEL, historical, landscape, and portrait painter, was the third son of Dance, the architect of the Mansion House, who died in 1768, and the younger brother of George Dance, R.A., the architect of Newgate.

Nathaniel Dance was the pupil of Hayman, and he studied also a few years at Rome. He was one of the original thirty-six members of the Royal Academy, founded in 1768, though he cannot have been at that time more than twenty-five years of age. He contributed many works to the academy exhibitions as Sir Nathaniel Holland, as well as Nathaniel Dance. He changed his name to Holland upon his acquisition of a baronetcy in 1800, having previously married Mrs. Dummer, who was connected with several noble families. This lady was possessed of entailed estates, chiefly in Hampshire, including Netley Abbey on the Southampton river, to the value of 18,000*l.* per annum. Upon his acquisition of his title, Sir Nathaniel Holland appears to have resigned his academical diploma, for from that time he exhibited as an honorary exhibiter. He represented for some time the borough of East Grinstead: he resided at Cranbury House, near Winchester, and he died suddenly in that city on October 15, 1811, aged about sixty-eight. Lady Holland survived until 1825, when she died, leaving personal property to the amount of half a million, the greater portion of which came to her nephew the late Earl of Cardigan, who was her sole executor and residuary legatee. A story was circulated about Sir Nathaniel Holland, that when he became possessed of his great fortune, he was ashamed of his profession, and that he spent thousands in the repurchase of his own works, for the purpose of destroying them to obliterate the recollection of his ever having been an artist. This story, however, independent of the warm contradiction it met with from some of his friends, is contradicted also by the facts of his continuing to paint and exhibit, and of his presenting pictures to his friends; it is also absurd to suppose that people of rank would part with the portraits of their relations for a pecuniary consideration to the painter, to enable him to destroy them. The report was no doubt magnified from the fact that he destroyed some of his own works in his own possession, because he thought that they were not calculated to add to his reputation. All his best works however still exist, but chiefly in private collections. The Marquis Camden and Sir W. W. Wynne contributed three to the exhibition of the works of deceased British artists at the British Institution in 1817—Orpheus, and Garrick as Richard III.; two of his very best works; and Charles, Earl Camden, Lord Chancellor. The following are also among his best works:—Timon of Athens, of which there is a fine print by J. Hall; Virginia, scraped in mezzotint by J. G. Haid; and the death of Mark Antony, engraved by T. Watson. Dance painted many portraits, including both royal personages and bishops, and latterly also some landscapes; the last work which he exhibited was 'A View in the New Forest.'

It has been also reported that Sir Nathaniel saved 200,000*l.* out of his wife's income and bequeathed it to his relatives: but this report is also untrue; he distributed only 30,000*l.* among his relations, the residue was bequeathed to his widow. These reports have been here noticed, more particularly because they have been carelessly repeated and with considerable asperity by the writer of the article on GEORGE DANCE in this work. [P. C. S.] They appeared in the 'Gentleman's Magazine' for 1811, and in part, in 1825, but have been contradicted in subsequent editions of Pilkington; and upon their insertion in 1824 in the 'Somerset House Gazette,' they were immediately afterwards contradicted in that same work, and an apology was made for their appearance. The statements of the 'Gentleman's Magazine' were apparently not seen by any of Sir Nathaniel's friends, or that work would have certainly contradicted them also.

(*Somerset House Gazette*, 1824; *Gentleman's Magazine*, 1811, 1825; *An Account of all the Pictures exhibited in the Rooms of the British Institution, from* 1813 *to* 1823.)

HOLLAND, HENRY, holds a high rank among the architects of his own time, and was greatly patronised by George IV. when Prince of Wales. But we have no information as to his personal history; and his finest work, the portico of Carlton House, has passed away. It was one of unusual grandeur, especially when we consider the period of its erection (about 1784), and was a fine specimen not merely of the Corinthian order, but of the Roman Corinthian style, in its full and uniform luxuriance, every part of it being highly finished up, and not only was the frieze of entablature enriched with sculpture throughout—with one exception, and that by Holland himself, the only instance of such classical decoration among the whole of our modern classical porticoes—but even the very bases of the columns were enriched with carving, a species of adornment by no means thrown away since, being so near the eye, it challenged direct and minute observation. Being only hexastyle—and there was not at that time any instance of an octastyle in the metropolis—it did not make that display in regard to columniation in front which some later examples do: yet it excelled all before or since in its bold projection from the building, which rendered it of *triprostyle* proportions in that respect, although unfortunately, as regarded architectural character, a column was omitted on each flank, in order to obtain an intercolumn sufficiently wide to admit carriages. The depth and consequently the effect of the portico was still further increased by its being also recessed within the building, by which it was rendered very nearly a square in plan, the depth being almost equal to the breadth. The Ionic colonnade screen in front of Carlton House was censured at the time, not for its real deficiencies, but as an architectural absurdity in itself. It was objected as a conclusive argument against it, that the columns supported nothing, whereas at any rate they were essential for the support of their entablature, and the entablature was requisite for connecting together the two gateways; therefore had there not been such open colonnade, there must have been a wall, shutting out a view of the portico from the street.

While Carlton House and its fine portico have disappeared without being recorded by any engravings intended as adequate architectural studies of them (those in the 'Illustrations of the Public Buildings of London' being both too few and upon much too small a scale to serve such purpose), another work of Holland's, for the same royal patron, and which has also disappeared, though in a different manner—namely, the Pavilion at Brighton, as it existed previously to its being transformed into its present shape by Nash—has, unluckily for the credit both of the architect and his princely employer, been preserved in Richardson's 'New Vitruvius Britannicus.' As a residence for the Duke of York, Holland altered Featherstonehaugh House, Whitehall (built by Paine), adding to it the elliptical entrance-hall, on what was originally the court-yard, and the screen façade towards Whitehall. This, which was afterwards called Melbourne House and is now Dover House, would have been in every respect a far worthier and more interesting subject for the 'Vitruvius' than the preceding one; nevertheless, not only is it omitted there, but has never been edited in any elevation of it, though in such separate form the composition and design would show themselves in some respect more advantageously than in the building itself, it being too low and upon too diminutive a scale for a piece of street architecture, and for its actual situation.

Holland erected old Drury-Lane Theatre, that is, the structure which was begun in 1791, and burnt down in February, 1809; and which was considerably larger than the present one, their respective dimensions being 320×155 and 240×135 feet; yet, except for its extent and loftiness of mass, the edifice made scarcely any pretensions to architecture externally. He was also the architect of another building in the metropolis, of considerable architectural distinction, the India House, Leadenhall Street, the credit of which has, rather strangely, been generally given to Richard Jupp, who was only the Company's surveyor, and the conductor of the works, the design, and consequently the architecture, belonging to Holland. And the design is in some respects unusually florid in character, the frieze of the portico (a recessed Ionic hexastyle loggia) being highly enriched, like that of Carlton House, the pediment filled in with sculpture, and its acroteria surmounted by colossal emblematical statues. All the rest of the façade however is by much too plain and undignified to accord with such degree of embellishment confined to the centre of it, and the rustication of the ground-floor, showing merely horizontal joints, will bear no comparison with that classical mode of such decoration which was exhibited by him in the façades of Carlton House and Dover House. The entablature of the portico is suppressed elsewhere, the cornice alone being continued along the rest of the front, for which there is some reason, since otherwise the cornices of the windows would have joined the architrave. Holland also made some alterations in the mansion built by Brown [Brown, P. C. S.] at Claremont, and added the colonnade screen wings to the Assembly Rooms at Glasgow.

He died at his house in Hans Place, Sloane Street, Chelsea, June 17, 1806, aged about sixty; he therefore did not live to witness the destruction of his Drury-Lane by fire and that of Carlton House, his finest work, by demolition.

HOLLAND, HENRY RICHARD VASSAL FOX, LORD, was the only son of Stephen, second Lord Holland. His mother was Mary, daughter of John Fitzpatrick, first Earl of Upper Ossory.

Sir Stephen Fox, Knight, distinguished for his magnificence and public spirit, as well as for his great wealth, having, in 1703, at the age of seventy-six, married a second wife, Christian, daughter of the Rev. Charles Hope of Naseby in Lincolnshire, had by her, besides a daughter, two sons, Stephen and Henry, and died in 1715 at the age of eighty-nine. Stephen became Earl of Ilchester; and Henry, who figures in our political history as the rival of the first Pitt, was, in 1763, raised to the peerage as Baron Holland, of Foxley, in the county of Wilts, his lady having the year before been made Baroness Holland, of Holland, in the county of Lincoln. Both baronies passed to their descendants. The eldest son of the first Lord Holland was Stephen, the second lord; his second son was the Right Hon. Charles James Fox, the celebrated orator and statesman.

The subject of the present notice was born at Winterslow House, in Wilts, 21st November, 1773. On the 9th of January, 1774, that mansion, a splendid building, was destroyed by fire, and the infant was with difficulty saved from the flames, his mother, who rescued him at the risk of her own life, having however, in so doing, taken probably the only direction by which she could have made her escape. On the 1st of July the boy lost his grandfather, the first Lord Holland; on the 24th of the same month, his grandmother Lady Holland; and on the 26th of December in the same year, his father, the second Lord Holland; on which he succeeded to the peerage, when he was little more than a twelvemonth old.

His mother died in 1778, and then the care of the child's education devolved on her brother, the Earl of Upper Ossory. After having been for some time at a school in the country, he was sent to Eton, where he spent eight or nine years, and where George Canning, Mr. Frere, the present Lord Carlisle, and other persons who subsequently rose to distinction, were among his contemporaries and associates. In October, 1790, he was entered as a nobleman at Christ's Church, Oxford; but all that is told of his academical career is that he took the honorary degree of master of arts, in right of his rank, in June, 1792.

It appears to have been before leaving the university that he made his first visit to the Continent, in the course of which he saw Copenhagen, Paris, and a part of Switzerland. He is stated to have been present when Louis XVI. accepted the constitution (as revised), after being brought back from Varennes, which was on the 13th of September, 1791. In March, 1793, he went abroad a second time, and, France being now closed, directed his course to Spain, over a great part of which country he travelled, studying the language and literature, and making himself acquainted with the character and manners of the people. From Spain he proceeded to Italy; and there, at Florence, in the beginning of the year 1795, first met Lady Webster, the wife of Sir Godfrey Webster, with whom he returned to England in June, 1796, and whom he married the next year, after she had been divorced from her first husband, who obtained 6000*l.* damages in an action against Lord Holland. (See the particulars in the *Annual Register* for 1797, pp. 10, 11.) After his marriage with Lady Webster, Lord Holland assumed, by sign manual, her family name of Vassal, which however has been laid aside by his children.

He now took his place in the House of Lords. His first speech was made on the 9th of January, 1798, on the motion for committing the bill for trebling the assessed taxes. He addressed the House both early in the debate, and again at the close, in what is described as having been a very animated and successful reply to Lord Grenville, who, while he complimented the young peer on the ability with which he had spoken, had noticed some of his remarks in a way that was considered to be personal. On the division, nevertheless, Lord Holland found himself one of a minority of six against seventy-three; so that he had early and emphatic experience of the position in which he was to pass the greater part of his political life. He began also on this occasion a system which he probably carried to a greater extent than any other peer ever did, by entering a long protest against the bill on the Journals of the House. This first of Lord Holland's long series of protests, many of them very able papers, and valuable for the constitutional information they contain, was signed only by himself and Lord Oxford (the present peer).

From this date Lord Holland took a frequent part in the debates for the next four years, being all this time one of the steadiest opponents of the administration, and seconding in the Upper House the principal efforts of his uncle Charles James Fox in the Commons. Among other measures which met with his opposition was the Union with Ireland, which he contended (8th May, 1800) would both impoverish that country and endanger the constitution of England. A few days before this (on the 30th of April) he had moved that the penal laws against the Roman Catholics should be taken into consideration by a committee of the whole House. This motion, the first of the kind that had been made in the Lords, was got rid of by the previous question without a vote.

Meanwhile, in 1800 before the war was suspended, he had paid a visit to Germany, and returned from Dresden by Cologne and Brussels, having obtained a French passport from Talleyrand, and liberty to make use of it from Lord Grenville, then foreign secretary. In the summer of 1802, after the conclusion of the peace of Amiens, he repaired, with Lady Holland, to Paris, and was there soon after joined by Mr. Fox, along with whom he was introduced to the first consul. From Paris, Lord and Lady Holland proceeded through France to Spain, and they remained in that country till after the breaking out of the war with England in January, 1805, returning home through Portugal by means of passports obtained through the Prince of the Peace.

He now resumed his attendance in the House of Lords; and his name, as before, appears frequently in the reported debates. He was not admitted to office during the ministry of Mr. Fox and Lord Grenville (January—September, 1806); but on the 28th of August he and Lord Auckland were appointed joint-commissioners and plenipotentiaries for arranging and settling the several matters in discussion between this country and the United States, with Mr. Munro and Mr. Pinckney, the United States commissioners; and on the 27th of the same month he was sworn of the privy council. An arrangement of the differences with America was effected after a long negociation (with the omission however of the impressment question); but Mr. Jefferson refused his ratification, and it came to nothing. On the 15th of October, after the death of Mr. Fox, Lord Holland was appointed lord privy seal; and he held that office for the six months longer that the Grenville ministry lasted.

In 1806, Lord Holland became an author by the publication of 'Some Account of the Life and Writings of Lope Felix de Vega Carpio,' in an octavo volume. This work, which was republished in 1817, when it was extended to two volumes by the addition of an account of Guillen de Castro and other matter, was creditable to his lordship's taste and familiarity with the more popular parts of Spanish literature, without being very learned or profound. It had the merit, or luck, of leading the way in the revival of that interest in the literature of Spain which has since prevailed to some extent in this country, though it spread more rapidly at first than it has done of late years—a difference to be attributed partly to the allurement of novelty and the promise held out by an unexplored field, but more perhaps to the political circumstances and events which for a time drew so much attention to every thing Spanish. Lord Holland followed up his Life of Lope de Vega the next year by another octavo volume entitled 'Three Comedies from the Spanish;' and in 1808 he edited and introduced by a preface of some length Mr. Fox's fragment entitled 'A History of the early part of the Reign of James the Second.'

On the breaking out of the Spanish insurrection in this last-mentioned year, he hastened once more to visit the peninsula; and he remained there till the latter part of the year 1809. The rest of his public life for many years was a continuation of the same course of opposition to the policy of the government with which he had set out on his entrance into parliament. He took a leading part in most of the great questions that came before the House of Lords, and particularly distinguished himself by his support of Sir Samuel Romilly's law amendments, by his advocacy of Catholic emancipation, and his opposition to the orders in council, the cession of Norway, and the detention of Bonaparte at St. Helena. However opinion may differ as to the positive wisdom of his politics, the praise at least of consistency cannot be refused to him. He was one of the steadiest Whigs of the school of Mr. Fox. But in those days the boundaries of party were much more clearly marked than they are now; and almost the only sort of inconsistency that was possible was going over openly from the one camp to the other, changing from Whig to Tory or from Tory to Whig. These two great parliamentary divisions were then quite distinct, and did not shade off into one another as they do now.

When the unsuccessful attempt was made through the Marquess Wellesley to effect a union of parties in January 1811, it was proposed that in the new ministry to be formed upon that principle Lord Holland should occupy the post of First Lord of the Admiralty. Like the majority of his party he supported without joining the ministry of Mr. Canning in 1827. In 1828, he made what has been described as his best speech in introducing the Bill for the repeal of the Test and Corporation Acts to the House of Lords. At last, on the accession of the Whigs to power in November 1830, he became once more a cabinet minister as Chancellor of the Duchy of Lancaster; and this office he held (with the exception of the ministerial interregnum of a fortnight in May 1832, and Sir Robert Peel's four months' tenure of power from December 1834 to April 1835) till his death at Holland House on the 22nd of October 1840. He was succeeded by his son, the present Lord Holland.

The only performances which Lord Holland sent to the press besides those already mentioned were 'A Letter to the Rev. Dr. Shuttleworth in favour of the Catholic Claims,' 8vo., Lon., 1827, and 'A Letter from a Neapolitan to an Englishman,' which is stated to have been privately printed in 1818, and to have been written to clear up some misconception by Murat of a conversation which his lordship had had with him. He is also the author of a translation of Ariosto's Seventh Satire, which Mr. Stuart Rose has printed in an Appendix to the Fifth Volume of his translation of the Orlando Furioso (1827), together with a version of the 25th Canto of that poem, which is stated by Mr. Rose to be the performance of an old schoolfellow, who may perhaps be Lord Holland. As a speaker Lord Holland was more animated than graceful; when he began, in particular, he was usually for some time extremely impeded and embarrassed; and he never rose from this hesitation into any thing like the free and impetuous torrent of argument or the impassioned declamation by which his relative Mr. Fox, after a similar unpromising outset, used to carry every thing before him. But his speaking had always the great charm of honesty and earnestness; and it commonly also indicated, with however little of what could be called brilliancy, a well-informed and full mind. Lord Holland was much beloved by as extensive and varied a circle of friends as perhaps any man ever possessed; and his house at Kensington, interesting from its earlier history, was during all his lifetime the resort of the most distinguished persons both in the world of politics and in that of literature.

(*Gentleman's Magazine* for December, 1840.)

HOLO'STEUM (from ὅλος, 'all,' and ὀστέον, 'a bone,' an antiphrasis applied to this plant because it is soft and unlike bone), a genus of plants belonging to the natural order Caryophylleæ, and the sub-order Alsineæ. It has 5 sepals; 5 petals, toothed at the end; 3, 4, or 5 stamens; 3 styles; a subcylindrical many-seeded capsule, opening at the end, with 6 teeth. The species of this genus are herbs with nothing to recommend them for use or cultivation. One species, *H. umbellatum*, is British. It has umbellate flowers, pubescent viscid peduncles, the pedicels reflexed after flowering, the leaves acute, elliptical, or elongate. It is not a common plant, but has been found on old walls and dry places at Norwich, Bury St. Edmunds, Eye, and Yarmouth.

(Babington, *Manual of British Botany*.)

HOLY ORDERS. [ORDINATION, P. C.]

HOLZER, JOHANN, a distinguished German fresco painter of the early part of the eighteenth century, was born at Burgeis, near Marienberg in Vintschgau, in the Tyrol, in 1709. His father was miller to the Benedictine Convent of Marienberg, and Holzer was first instructed by N. Auer at Meran in the Tyrol. He made here such extraordinary progress, that at the early age of eighteen his reputation spread far into Germany, and he was invited by the painter J. A. Merz, to Straubing in Bavaria, to assist him in some frescoes in the convent church of Oberalteich. From Straubing Holzer went to Augsburg, where he lived six years in the house of the painter J. G. Bergmiller, from whom he learnt much in the mechanical department of painting, both in fresco and in oil, for Bergmiller was the principal painter in Augsburg at that time, and was much employed. Holzer painted many excellent frescoes upon the exteriors of houses in Augsburg, but few, if any, now remain; there is however a collection of twenty-eight prints after them by J. E. Nilson, entitled Picturæ a Fresco in Ædibus Augustæ Vind., a J. Holzer, &c. Among these frescoes, a peasant dance, upon the façade of a beer shop, was a very popular work; and it is spoken of in the highest terms in the letters of J. L. Bianconi and Count Algarotti. The neighbouring peasant girls at that time wore extremely short petticoats; in the dance the movements and forms of their legs were accordingly fully displayed; and Bianconi speaks with enthusiasm of the beauty and life of the young peasant girls in this painting; the figures were above the size of life. Holzer's greatest works however are the frescoes of the convent church of Schwarzach near Würzburg; he obtained the commission to execute them by competition; and they were painted in 1737, when he was only twenty-nine years of age. They are the best works that were executed at that time in Germany; and Holzer is by some considered the founder of the new era of German fresco painting. They are however now in a most dilapidated condition; the church is in a ruinous state, and the convent is a paper mill. Dr. Waagen does not notice the Benedictine Convent of Schwarzach in his account of the works of art in Franken, though it contains many works besides the frescoes of Holzer; there are frescoes by Piazzetta and Tiepolo, but they are said to be inferior to those by Holzer. Holzer painted the cupola and ceiling of the church; the subjects represented are—the Glorification of St. Benedict; the Transfiguration of Christ; the Martyrdom of St. Sebastian; St. Felicita and her Seven Sons; the Foundation of the Convent; and the Papal Confirmation of the Foundation. The martyrdom of St. Sebastian is described as the most successful composition.

After the completion of these works, Holzer was invited by the prince bishop of Würzburg to paint his palace, for which he made the designs, but they were not quite satisfactory to the bishop. He was in the meanwhile invited by the Elector Clement of Cologne to paint the newly established capuchin convent at Clemenswerth, and he accordingly immediately prepared himself for this work. He however did not live to commence it; he died of a fever at Clemenswerth, a few days after his arrival, in July, 1740, at the age of thirty.

Holzer's works are described as successful in every department of art, in invention, form, character, light and shade, and colour. He engraved a few plates. Several accounts of him have been published in Germany; the first in 1765, at Augsburg, and the last in the Tyrol in 1834. In the latest accounts he is called Johann Evangelist Holzer; see Nagler, *Künstler Lexicon*.

(Zapf, 'Leben Johann Holzers,' printed in Meusel's *Miscellaneen Artistischen Inhalts*, 1781.)

HOMŒOPATHY, the art of curing founded on resemblances, expressed in the Latin expression 'similia similibus curantur.' It is derived from the two Greek words 'ὅμοιος,' 'similar,' and 'πάθος,' 'feeling' or sensation, and hence a condition of body, such as that of disease. According to this law, disease is cured by remedies which produce upon a healthy person effects *similar* to the symptoms of the complaint under which the patient suffers.

This system of medicine stands in direct contradistinction to that founded upon the principle of treating diseases by their opposites, 'contraria contrariis curantur,' which has served more or less as a guiding law since the time of Galen. To this last method the disciples of the new school have given the name of Allopathy, from the two Greek words 'ἄλλος,' 'other,' and 'πάθος,' 'condition.' This distinctive nomenclature will be adopted in this article as a matter of convenience, and to avoid circumlocution. The arguments adduced in support of the truth of the homœopathic law seem principally drawn from three sources, namely, from popular experience, from observations upon the effects of medicinal agents recorded in the works of eminent medical men of different schools and various epochs, and from experiments upon healthy individuals made by the founder of the system and his disciples upon themselves.

1st. Popular experience has proved that the safest manner of restoring the circulation of a frozen limb is to rub it with snow (similia similibus); warm applications, according to the evidences of the same experience, would cause the destruction of the part affected (contraria contrariis).

Again, severe burns are most quickly cured by the use of heated spirits of wine or oil of turpentine, which excite a very similar sensation, although in a greatly modified degree (similia similibus). Cold applications, although they give temporary relief, are, as is well known, generally followed by increased inflammation and severe after-suffering (contraria contrariis), as corroborated by the evidence of John Hunter, Kentish, Sydenham, and other medical names of high repute.

The homœopathists also insist that the acknowledged efficacy of Jenner's great discovery is a powerful argument of the truth of the homœopathic law, since by producing a similar disease an almost perfect immunity from attacks of the small-pox is obtained.

2ndly. They endeavour to show by a number of observations collected from the works of different medical allopathic authors, that many drugs recorded by them as curative in different forms of disease were observed by others, also allopathists, to produce effects closely resembling the symptoms of those very forms of disease, or in other words, that they acted upon the principle, similia similibus: an instance or two will be sufficient illustration. The English sweating sickness, which committed such ravages in the year 1485, and for some time baffled the physicians, yielded, according to Willis, to sudorifics; and it is upon record that after the adoption of this mode of treatment very few died of it. Opium in general causes extreme drowsiness, heavy and deep sleep; and it has, according to the testimony of many allopathic physicians, proved curative in diseases characterised by similar symptoms. Moreover, it is asserted by the homœopathists that all the remedies acknowledged as specifics by the medical profession, of whatever school, act upon this law; for instance, they maintain that Peruvian bark produces medicinal symptoms closely analogous to those of marsh fever, and that the well-known efficacy of mercury in syphilitic complaints, and of sulphur in various forms of cutaneous disease, is attributable to the same power (similia similibus), and as above stated, that the action of vaccine matter, as a prophylactic or preventive medicine against small-pox, depends upon the same law.

Assuming, therefore, that the position of the homœopathists is supported by the arguments which they adduce, and that the law upon which specifics act have been clearly ascertained, it would seem to be incumbent upon those who have dedicated themselves to the advancement of the healing art to endeavour, by personal experiment and careful observations upon the effects of medicines upon the human body in health, to add to the numbers of this class of remedies, and in this manner materially to improve the treatment of disease. This view of the subject appears strengthened by the opinion of Sydenham and other great names in medicine. Dr. Alison, professor of the University of Edinburgh, observes, 'The increasing efficacy and usefulness of our art must depend on the progress which may be expected in the discovery of specifics which may counteract the different diseased actions of which the body is susceptible as effectually as the cinchona counteracts intermittent fever, citric acid the scurvy, or vaccination the small-pox.'

3rdly. Dr. Samuel Hahnemann, the founder of this system of medicine, being struck, as noticed in his life [HAHNEMANN, P.C.S.], with the close analogy between the symptoms produced by Peruvian bark and those of the forms of disease for which it was considered a specific, and having obtained similar results from other medicines tried upon his own person, was led to the discovery of the homœopathic law; and he, believing that the mode of operation of all remedial agents was in perfect harmony with this principle, by repeated experiments upon himself and some medical friends, converted to his opinions, first determined their direct action and then employed them in disease. The practical results obtained by himself and the physicians of his school are appealed to by them as a further confirmation of the truth of their fundamental law.

The extremely minute quantities in which the remedies are administered seem to form a marked difference between the homœopathic and all other schools of medicine. The homœopathists however assert that this is merely a point of practice to be determined by the physician at the bedside of his patient, and that in the application of the homœopathic principle to the treatment of disease, it was soon found that remedial agents given in the doses usually employed acted too energetically upon a frame already predisposed to their influence by the affinity existing between their medicinal effects and the morbid signs of the disease; and hence a gradual diminution was made in the quantity of the medicine exhibited, in order to approximate to that amount which might exert its full curative power without aggravating the sufferings of the patient by an excess of medicinal action. The result has been, the general adoption among homœopathists of the minute doses at present in use, which perhaps more than any other cause, from its discrepancy with generally received opinions, has prevented any impartial investigation into the principles of the new system by the profession at large.

Homœopathy numbers in its ranks many medical men who had obtained high repute and professional eminence in the other systems before they embraced the principles of homœopathy, and seems to be more or less diffused in all parts of the world, if we may form any opinion from its literature, which comprises medical works in German, Italian, English, French, Swedish, Russian, Spanish, Latin, and Portuguese. The system has also adherents in North and South America and Asia. The great bulk however of the medical profession are more or less opposed to its adoption.

HOMICIDE. [MURDER, P. C.]

HONE, WILLIAM, was born in 1779 at Bath, where his father is stated to have been an occasional preacher among the dissenters. He is said to have been so rigid in his religious notions that he would not suffer his son to be taught to read out of any other book than the Bible. William was placed at the age of ten in an attorney's office in London; but after some time his father, finding that he had attached himself to some reforming society and begun to take part in what he seems to have thought very objectionable politics, removed him to another master at Chatham, with whom he remained between two and three years. He then returned to London, and was engaged for some time as clerk to an attorney of Gray's Inn; but at last he quitted the law, and, having married, set up in July 1800 as a bookseller, with a circulating library, in Lambeth Walk. From this locality he removed to what was then called St. Martin's Churchyard, in the neighbourhood of Charing Cross; and here he appears to have remained stationary for several years, although it is stated that he was once burnt out, and also underwent many vicissitudes in business. He had always been fond of literature, and in 1806 he brought out his first publication, an edition of Shaw's 'Gardener.' After this he devoted much of his time to an attempt which he made in conjunction with a friend to establish a savings bank in Blackfriars Road, which, however, failed. He then entered into partnership as a bookseller with this friend, Mr. John Bone; but the speculation ended in bankruptcy. When he got upon his feet again he established himself in a shop in May's Buildings, whence he removed to High Street, Bloomsbury; and here he appears to have remained till 1811, when on the retirement of Mr. John Walker he was selected by the booksellers to be what is called the Trade Auctioneer, and placed in a counting-house in Ivy Lane. Before this he had been employed to compile the Index to the new edition of Lord Berners's Translation of Froissart. But he had no genius for business, and, having now taken to the investigation of the abuses in lunatic asylums, he soon became bankrupt again. The date is not given in the account from which our abstract is derived; but it is stated that he had now seven children, whom he took to a humble lodging in the Old Bailey, and endeavoured for a time to support by contributing to periodical publications, especially the 'Critical Review' and the 'British Lady's Magazine.' At length, however, he found means to set up once more as a bookseller in a small shop in Fleet Street. Here he was again unfortunate in having his premises twice broken into and plundered, much of the stock that was carried off having been borrowed; but he seems to have weathered these disasters; and in 1815, it is stated, he became publisher of the 'Traveller' newspaper. In that year he exerted himself with most praiseworthy humanity and spirit in the investigation of the case of the unhappy Elizabeth Fenning, executed on a charge of poisoning of which there can scarcely be a doubt that she was innocent; and he published a very striking account of the case, modestly, however, withholding his own name from the title-page (except as the publisher), and giving the literary credit to a Dr. John Watkins, who only contributed three letters, forming the least interesting part of the publication. The volume, an octavo of 240 pages, professes to be 'printed for William Hone, 55, Fleet Street.' In 1816 he commenced a weekly paper called 'The Reformists' Register;' but it does not seem to have gone on long. The next year, however, he brought himself into great notoriety by a series of political satires, published as separate pamphlets, which had immense success, the effect partly of their literary merit, partly also of the wood-cut embellishments from the clever and humorous designs of Mr. George Cruickshank, whom they first made generally known to the public. One of them, 'The Political House that Jack Built,' went through fifty editions, besides producing a host of inferior imitations. Another, entitled 'A Slap at Slop,' was a scourging attack upon the since defunct daily morning paper called 'The New Times,' its editor Dr. (afterwards Sir John) Stoddart, and the Constitutional Association, or 'Bridge Street Gang,' as Hone designated it. But those of the series that turned out the most productive for the author were three composed in the manner of parodies upon various parts of the Book of Common Prayer. For the printing and publishing of these parodies Hone was brought to trial on three several indictments in the Court of King's Bench, on the 18th, 19th, and 20th of December, 1817; the first day before Mr. Justice Abbot (afterwards Lord Tenterden), the second and third days before Lord Ellenborough. He defended himself on all the three trials (which were before special juries); and, notwithstanding the best exertions of the bench to procure a conviction, was acquitted on each indictment. His address to the jury on the third day, especially, which lasted seven hours and a half, when, although fatigued by his previous exertions, he was inspirited by success, was remarkably effective. The feeling of the public was that the alleged libels were really prosecuted for their political tendency, and that if they had been on the other side of the question, written in defence of the ministry instead of in ridicule of it, they never would have been questioned. There is also, we believe, no reason to think, however objectionable their form may have been, that Hone had any design to bring religion into contempt. His acquittal, besides the reputation which it brought him, was followed by the subscription of a considerable sum of money for his use, which enabled him to remove from Fleet Street to a large house on Ludgate Hill. But when he attempted to resume the business of a book auctioneer, he was, we are told, even less successful than before. How long he continued in business is not stated. In 1823 he published the results of researches to which he had been originally directed with a view to his defence, in an octavo volume entitled 'Ancient Mysteries described, especially the English Miracle Plays founded on the Apocryphal New Testament Story, extant among the unpublished MSS. in the British Museum.' This is a curious work, not at all addressed to the multitude, or chargeable with any irreverence of design or manner, but treating an interesting antiquarian subject in the dispassionate style of a studious inquirer. It has now been nearly superseded by more elaborate works that have since appeared; but when it was produced it was by far the fullest account of our old miracle plays that had been given to the public. In 1826 Hone began the publication, in weekly numbers, of his 'Every Day Book.' The sale was large, but his family had now increased to ten children, and he again got into difficulties; the end of which was that he was arrested by a creditor and thrown into the King's Bench prison. Here he remained for about three years, during which time he finished his 'Every Day Book,' in two volumes, and began and finished his 'Table Book,' in one volume, and also his 'Year Book,' in one volume. These three works, which may be considered as forming properly so many series of the same undertaking, are full of curious information, and will probably preserve the name of their compiler after everything else he did shall be forgotten.

The rest of Hone's life was a continuation of vicissitudes such as those to which he had been all his days accustomed. Some time after he got out of prison a number of his friends attempted once more to establish him in the world as landlord of the Grasshopper Coffee-house in Gracechurch Street; but after a few years this speculation also failed. He then fell into the hands of some new acquaintances of the Independent connexion, who persuaded him to try his talents as a preacher; and he appeared frequently in the pulpit of the Weigh House Chapel in East Cheap. He had had an attack of apoplexy so long ago as in 1815; in 1835 he was struck by paralysis at this chapel; in 1837 he was again similarly attacked at the office of the 'Patriot' newspaper, of which he was then sub-editor; soon after he suffered another attack, from which he never recovered; and he died at Tottenham on the 6th of November, 1842. We have mentioned his principal works, but he was the author of a good many more. His last publication was, we believe, an edition of Strutt's 'Sports and Pastimes of the English,' in one volume octavo, which appeared in 1838. We have not seen a work which has appeared since his death, entitled 'Early Life and Conversion of William Hone, a narrative written by himself, edited by his son, William Hone,' 8vo., London, 1841. Hone was a warm-hearted but mild-tempered man, much misconceived by those to whom he was known only through his parodies, which he probably produced in mere thoughtlessness and innocence of heart. It is evident from the above sketch of his history that the unworldliness of his nature was such as is rarely met with.

(*Memoir in Gentleman's Magazine for January*, 1843.)

HONG KONG, one of the group of rocky islands situated at the mouth of the Canton river, about thirty-seven miles from Macao, and one hundred from Canton. It is said to be between 22° 9′ and 22° 21′ N. lat.; but this probably includes some small dependent islands: only one meridian of longitude has been given, 114° 18′ east. The island is separated from the mainland of China by a narrow strait, which varies in width from less than a mile to four or five miles; but one account states that the breadth of the channel is in one part little more than a quarter of a mile. The length of the island from east to west is stated to be about eight miles; but its breadth is very irregular, and varies from about six miles to two miles. The coast-line forms a succession of small bays and headlands. There is excellent anchorage in Hong Kong Roads and Victoria Harbour, both opposite the town of Victoria. There is deep water for a man-of-war within a cable's length of the shore. The harbour lies between the mountains of Hong Kong and those of the mainland; but it is notwithstanding exposed to the violence of typhoons. The northern side of the island is traversed by a ridge of mountains which vary in height from 500 to upwards of 1000 feet. They present a steep declivity towards the coast, and their base approaches nearly to the edge of the sea. In the map of Hong Kong which accompanies Bernard's 'Voyages of the Nemesis' (London, 1844), Mount Victoria is said to be 1827 feet high, and Mount Gough, 1575 feet. These two mountains immediately overlook the town and harbour of Victoria. The elevation of Mount Parker, at the other or eastern end of the island, is said to be 1711 feet. The mountains furnish a supply of excellent granite for building; and there are numerous quarries which are skilfully worked by Chinese labourers. The southern side of the island is much less rugged, and consists of an undulating surface with occasional portions of flat land. The total quantity of land suitable for cultivation is small, and the greater part of it is in one valley. Deep ravines extend from the interior towards the sea, and furnish a constant supply of good water. The words Hong Kong are in fact a corruption of Hoong Keang, 'the red torrent,' so called from the colour of the soil through which flows a stream that tumbles over a cascade adjacent to the harbour. The mean temperature of Hong Kong in July, 1843, was 88°. 'On one occasion the thermometer rose to 92° during the middle of the day, and once only fell to 84° during the night.' (Bernard.) In October, November, and December the variations of the temperature are often from 10° to 20° in the course of twenty-four hours, and the feeling of cold is greater than in many northern countries in the same months. The northern side of the island is fully exposed to the north-western monsoon during the winter season; but it has the serious disadvantage of being deprived by the mountains of the south-western monsoon in the hot season. At that time of the year the rain falls in torrents, and this is succeeded by a hot unclouded sun, which acts upon the undrained parts of the surface and creates malaria. The healthiness of the island may doubtless be improved by attention to drainage and the formation of channels for carrying off the superabundant moisture. In the cold season, when sudden variations of temperature occur, the practice of the natives should be followed, who prudently increase the warmth of their clothing at the proper time. The south side of the island enjoys the benefits of the south-western monsoon, and is healthier than the northern side; but it is destitute of a harbour of sufficient extent. The merchants of Victoria might, it is thought, have their residences on this side, and at the same time proceed daily to their business.

Hong Kong was taken possession of by the British during the war with China. The cession of the island formed one of the conditions of the treaty of peace negotiated by Captain Elliot and Keshen, which the emperor disavowed; but the British continued to hold the island, and by the Treaty of Nankin, signed Aug. 30, 1842, they gave up the island of Chusan, and Hong Kong was ceded in perpetuity to Great Britain. The wisdom of this selection has since been doubted. [CHUSAN, P. C. S.] On the 26th of June, 1843, Hong Kong was regularly constituted a British colony. It is what is called a crown colony, that is, it has no legislative assembly, but is governed by orders from the Colonial Office at home. There is a legislative and executive council to aid the governor with their assistance and advice. The governor, as superintendent of trade, is head of the consular establishments at the five ports opened in pursuance of the Treaty of Nankin. The offices of the government are at Victoria. There is a chief justice and attorney-general, with other law-officers, and the usual departments of a colonial administration. All grave offences committed by British subjects must be tried at Hong Kong. There are four newspapers published at Victoria. At the time when the British first occupied Hong Kong the number of Chinese inhabitants was supposed to amount to about five thousand, exclusive of the boat-people and migratory labourers from the mainland. The resident population consisted chiefly of fishermen and smugglers, who were distributed in about fourteen or fifteen villages. Since the island became a British colony there has been a great increase of Chinese, and their numbers are now estimated at upwards of 30,000. They make themselves generally useful as domestic servants, labourers, tailors, shoemakers, builders, carpenters, &c., and they become tenants of the little shops in the Chinese bazaar. There is a small body of Chinese police. The command of cheap labour to any extent has been one great cause of the rapid progress of the town of Victoria. In June, 1841, when the British forces assembled in the Bay of Hong Kong, on their return from Canton, there was not a house on the island fit for the residence of Europeans, and Sir H. Pottinger, the plenipotentiary, lived, when on shore, in a tent. During the two months that the fleet remained here, a few mat sheds and temporary huts were erected; but in the month of August, 1841, the site of Victoria was still covered with brushwood. Within a year after the first house was completed, there had been constructed regular streets and bazaars for the Chinese, numerous large storehouses, substantial wharfs and jetties, two European hotels and billiard-rooms, and various public buildings. The government had begun the formation of an excellent road along the front of the harbour at the foot of the hills, which was carried to a distance of four miles; and it has since been extended, and other roads have also been made, and bridges erected. In consequence of the limited space between the beach and the base of the mountains, the town necessarily stretches in a line, which is about three miles in front of the harbour. The distance fom one end of the town to the other is already an inconvenience, and a second town in some other situation is thought desirable. In July, 1844, a liberal arrangement was made with a body of Chinese shopkeepers who had been allowed to settle in a district which after the ratification of the Treaty of Nankin became the centre of the European town, and they were removed to another part of Victoria, where a large number of their countrymen were already settled. The government does not grant land in perpetuity, but assigns it on leases for seventy-five years; and there is a clause under which it is to be given up at a valuation assessed by twelve jurors, on oath, if required for public purposes. In 1844 the government derived an income of 9530*l.* from ground-rents; and its revenue from this source was rapidly augmenting.

Early in 1845 the governor of Hong Kong legalized the opium trade. In March the privilege of retailing the drug was farmed by a mercantile house at 720 Spanish dollars a month. All the houses in which opium is sold must adjoin the street, and they may be open from day-light till ten in the evening, except on Sundays, when they are to be closed. No person is to be admitted into these houses with any kind of weapon or edged tool. There is a tax on salt, and a duty of 2½ per cent. on sales by auction. Victoria is a free port, and, like Singapore, its prosperity must depend upon its commerce being freed from all restrictions which can properly be dispensed with. In May, 1845, the currency was regulated by a proclamation which had previously been sanctioned at home by the privy council. The gold mohur, coined since September, 1835, is to be equivalent to 29*s.* 2*d.*; the East India Company's rupee, coined since September, 1845, to 1*s.* 10*d.*; Spanish and Mexican dollars 4*s.* 2*d.*; and 228 cash are declared to be equivalent to 1*s.*

HONTHORST, or HUNDHORST, GERHARD, called by the Italians Gherardo dalle Notti, from his night and candle pieces, was born at Utrecht in 1592. He was the pupil of A. Bloemart, studied some time in Rome, and was engaged for six months by Charles I., in England. He painted Charles's sister, the Queen of Bohemia; the portrait is now at Hampton Court. There are also at Hampton Court—James II., when young; the Duke of Buckingham and family; and a large painting on the queen's staircase, of Charles I. and his queen, as Apollo and Diana, sitting in the clouds, and the Duke of Buckingham below as Mercury, introducing the Arts and Sciences to them, while several genii are driving away Envy and Malice. For these paintings Honthorst received 3000 florins, a service of plate complete for twelve persons, and a beautiful horse. Honthorst was the favourite painter of the Queen of Bohemia, and he was the court painter to the Prince of Orange. He died at the Hague in 1660. He had a remarkable number of scholars, especially among the highest classes. Sandrart also was one of his pupils. His style of execution is much like that of Guercino; his pictures occur frequently in European galleries.

(Sandrart, *Teutsche Academie*, &c.; Walpole, *Anecdotes of Painting*, &c.)

HOOD, THOMAS, was born in 1798, in the Poultry, London, where his father was a bookseller, of the firm of Vernor and Hood. Thomas Hood was sent to a school in Tokenhouse Yard, in the city, as a day-boarder. The two maiden sisters who kept the school, and with whom Hood took his dinner, had the odd name of Hogsflesh, and they had a sensitive brother, who was always addressed as 'Mr. H.,' and who subsequently became the prototype of Charles Lamb's unsuccessful farce called 'Mr. H.' Hood was afterwards sent to a preparatory school, and in due course was transferred to a finishing school in the neighbourhood of London, but derived little benefit from either.

In 1811 Hood's father died, and soon afterwards his elder brother died also. Thomas Hood being then the only remaining son of the widow, she was anxious to have him near her, and recalled him home. In 1812 she sent him to a day-school. His account of this school and its master is so characteristic as to be worth extracting from his 'Literary Reminiscences' ('Hood's Own,' p 292):—'In a house, formerly a suburban seat of the unfortunate Earl of Essex, over a grocer's shop, up two pair of stairs, there was a very select day-school, kept by a decayed Dominie, as he would have been called in his native land. In his better days, when my brother was his pupil, he had been master of one of those wholesale concerns in which so many ignorant men have made fortunes, by favour of high terms, low ushers, gullible parents, and victimized little boys. As our worthy Dominie, on the contrary, had failed to realize even a competence, it may be inferred, logically, that he had done better by his pupils than by himself; and my own experience went to prove that he attended to the interests of his scholars, however he might have neglected his own. Indeed he less resembled, even in externals, the modern worldly trading schoolmaster than the good honest earnest olden pedagogue—a pedant perchance, but a learned one, with whom teaching was a labour of love, who had a proper sense of the dignity and importance of his calling, and was content to find a main portion of his reward in the honourable proficiency of his disciples. Small as was our college, its Principal maintained his state, and walked gowned and covered. His cap was of faded velvet, of black or blue or purple or sad green, or, as it seemed, of all together, with a *nuance* of brown; his robe of crimson damask, lined with the national tartan. A quaint carved highbacked elbowed article, looking like an *émigré* from a set that had been at home in an aristocratical drawing-room under the *ancien régime*, was his professorial chair, which, with his desk, was appropriately elevated on a dais some inches above the common floor. From this moral and material eminence he cast a vigilant yet kindly eye over some dozen of youngsters; for adversity, sharpened by habits of authority, had not soured him, or mingled a single tinge of bile with the peculiar red-streak complexion so common to the healthier natives of the north.' 'In a few months my education progressed infinitely farther than it had done in as many years under the listless superintendence of B.A. and LL.D. and assistants. I picked up *some* Latin, was a tolerable grammarian, and so good a French scholar that I earned a few guineas—my first literary fee—by revising a new edition of "Paul et Virginie" for the press. Moreover, as an accountant, I could work a *summum bonum*, that is, a good sum.'

From this school he was removed to the counting-house of Messrs. Bell and Co., Russia merchants, Warnford Court, City, but his health soon began to fail, and he was sent in a Scotch smack to Dundee, and consigned to a female relation, who however refused to take charge of him, and even reshipped his luggage, and would have sent him back to London, if Hood had not played her an evasive trick, and frustrated her intentions. He immediately took lodgings for himself in Dundee. He was then fifteen years of age, and seems to have been left entirely at his own disposal. Fortunately he was not idle, and had no taste for dissipation, but took great delight in reading, as well as in rambling, fishing, and boating. His health gradually improved, and, after remaining two years at Dundee, he returned to London. He engaged himself to Mr. Robert Sands, an engraver, who was his uncle, in order to learn his art, and was afterwards with Le Keux for the same purpose.

In 1821, Mr. John Scott, then editor of the 'London Magazine,' was killed in a duel; the Magazine passed to other proprietors, who happened to be Hood's friends, and he was offered the situation of sub-editor. He had published some trifles in the Dundee Advertiser and Dundee Magazine, while he remained at that place, which were favourably received, but he had not been stimulated to any further appearance in print. 'My vanity,' says he, 'did not rashly plunge me into authorship, but no sooner was there a legitimate opening than I jumped at it, à la Grimaldi, head foremost, and was speedily behind the scenes.'

Hood, while in this situation, became acquainted with several persons who have distinguished themselves in English literature, and who were then contributors to the 'London Magazine,' with Lamb, Carey, Procter, Cunningham, Bowring, Barton, Hazlitt, Elton, Hartley Coleridge, Talfourd, Soane, Horace Smith, Reynolds, Poole, Clare, Benyon, and others. With Lamb especially Hood afterwards became on terms of great intimacy, which continued till Lamb's death.

Hood's first publication in a separate form was 'Odes and Addresses to Great People,' in which he was assisted by his brother-in-law, J. H. Reynolds, and which was brought out anonymously. 'Whims and Oddities,' published in 1826, in small 8vo., consisted chiefly of his contributions to the 'London Magazine,' with some additions. His next work was in prose, 'National Tales,' sm. 8vo., which was followed by 'The Plea of the Midsummer Fairies, Hero and Leander, Lycus the Centaur, and other Poems,' sm. 8vo., 1827, a volume of serious poetry which obtained praise from the critics, but little favour from the public. His experience of the unpleasant truth that

'Those who live to please must please to live,'

induced him to have recourse again to his lively vein. He published a second series of his 'Whims and Oddities,' and a third series in 1828. He commenced the 'Comic Annual' in 1829, and it was continued nine years. In the same year his comic poem of 'The Epping Hunt' came out, and excited much mirth at the expense of the Cockney sportsmen. He was for one year editor of 'The Gem,' and wrote for it his poem called 'Eugene Aram's Dream.'

In the spring of 1831 Hood became the occupier of a house called Lake House, belonging to the proprietor of Wanstead, in Essex, near which it was situated. While residing here he wrote his novel of 'Tylney Hall.' Pecuniary difficulties compelled him to leave his pleasant residence. The dedication of 'Tylney Hall' is dated Lake House, Oct. 20, 1834. He left it in 1835.

The 'Comic Annual' having terminated in 1837, Hood commenced the publication of 'Hood's Own,' in a series of monthly numbers, in 8vo., 1838. It consisted chiefly of selections from the prose and poetry which he had published in the series of the 'Comic Annual,' with several additions. A portrait of himself, for which he sat at the request of the publisher, is attached to the work, and is, as he says himself, a faithful likeness.

Hood went to the continent for the benefit of his health, but while in Holland the unwholesome air of the marshes produced an accession of illness, which proved of so dangerous a nature that he was compelled to remain abroad much longer than he intended. He went up the Rhine, and was altogether three years in Germany and three years in Belgium. He was in Belgium when he published his 'Up the Rhine;' in the preface of which, dated December 1, 1839, he states that he constructed it on the groundwork of 'Humphrey Clinker.' The work consists of a series of imaginary letters from a hypochondriacal old bachelor, his widowed sister, his nephew, and a servant-maid, who form the imaginary travelling party. Each individual writes to a friend in England, and describes the scenes, manners, and circumstances, in a manner suitable to the assumed character. The nephew's remarks seem to embody the opinions and observations of Hood himself. The book is illustrated with whimsical cuts in Hood's usual rough but effective style, and abounds in good sense as well as humour.

Hood afterwards became editor of the 'New Monthly Magazine;' after his retirement from which, in 1843, he collected his contributions to that work, and, with additions of prose and poetry, published them under the title of 'Whimsicalities.' He still continued to suffer from ill health; and when the secretary of the Manchester Athenæum requested permission to place his name in the list of patrons to a bazaar, he replied in a letter of kindly feeling as well as humour, dated 'From my Bed, 17, Elm Tree Road, St. John's Wood, July 18, 1843.'

In 1844 Hood started his last periodical, 'Hood's Magazine,' and continued to supply the best of its contributions till within about a month before his death. Those who have read the work, and have a taste for wit, humour, and character, will not readily forget his 'Schoolmistress Abroad,' 'Mrs

Gardener,' and his novel of 'Our Family,' which was interrupted by his last illness and death: the last chapters were in fact written by him when he was propped up by pillows in bed. He had the consolation, a short time before his death, of having a government pension of 100*l.* a-year, which was offered to him by Sir Robert Peel, transferred at his own request to his wife. After a lethargy, which continued four days, he died, May 3, 1845. He was buried on the 10th of May in Kensall Green Cemetery.

Hood left two children, a girl and a boy, of whom the girl is the eldest, and is now (1845) about fourteen years of age. Soon after his death a subscription was commenced in order to raise a fund for the benefit of the widow and children. The amount already realized (Nov. 1845) is between 1400*l.* and 1500*l.*

Hood was undoubtedly a man of genius. His mind was stored with a vast collection of materials drawn from a great variety of sources, but especially his own observations; and he possessed the power of working up those materials into combinations of wit and humour and pathos of the most original and varied kinds. His vigilance of observation must have been extraordinary. The appearances of nature, the forms and usages of society, great diversity of characters, all arts, professions, and trades lie ready in his mind to supply the demands of his rapid subtle and versatile imagination. He has wit of the highest quality, as original and as abundant as Butler's or Cowley's, drawn from as extensive an observation of nature and life, if not from so wide a reach of learning, and combined with a richness of humour of which Butler had little and Cowley none. His humour is frequently as extravagantly broad as that of Rabelais, but he has sometimes the delicate touches of Addison. As a punster he stands alone. His puns do not consist merely of double meanings of words, a low kind of punning of which minds of a low order are capable, and with which his imitators have deluged English comedy and comic literature, but of double meanings of words combined with double meanings of sense in such a manner as to produce the most extraordinary effects of surprise and admiration. His power of exciting laughter is wonderful, his drollery indescribable, inimitable. His pathetic power is not equal to his comic, but it is very great. In some of his 'National Tales,' as well as in his singular poem of 'Eugene Aram's Dream,' he produces an effect upon the feelings which is sometimes little less than sublime. 'His Song of the Shirt,' which he wrote a short time before his death, was a burst of poetry and indignant passion by which he produced tears almost as irrepressibly as in other cases he produces laughter.* In his 'Plea of the Midsummer Fairies, Hero and Leander, Lycus the Centaur, and other Poems,' he supports a poetic character quite different from those in which he usually appeared. Without a trace of anything that can be called wit or humour or punning, he displays a gracefulness and delicacy of fancy, a tenderness and sweetness of feeling, a choice of diction, and beauty of versification, which render these serious poems exceedingly delightful; but the poetry is not poetry for the many, though, from its elaborate structure, it may be inferred that it cost him much labour, if not much time. In extenuation of the neglect of the public, it may however be observed that such poems can never be popular. The subjects of the three longest poems are allegorical and mythological, and entirely out of the limits of actual existence. As a novelist Hood has considerable faults. His pages overflow with the exuberance of his imagination to such a degree as to interrupt the course of the narrative, and, by diverting the reader's attention, to weaken his interest in the story. Some of the characters, too, are injured by what may be called the intrusiveness of his wit, by which both the thoughts and language are often rendered less appropriate to the characters than they would have been without it. These objections however are much less applicable to 'Our Family' than they are to 'Tylney Hall.' They are defective as novels, but they are mines of wit and humour.

The rude but graphic and humorous sketches by which many of his comic works are illustrated, are for the most part very slightly connected with the pieces to which they are annexed, and seem to be introduced merely for the sake of the whim, as some pun or odd fancy occurred to him.

* In the course of the year 1843 public feeling had been much excited by cases of distress and destitution which came before the London police magistrates, arising from the excessively low rate of wages paid by dealers in ready-made linen to their workwomen. Taking advantage of a market overstocked with labourers, these tradesmen got their work done for a rate of payment so small that fourteen or fifteen hours' labour were frequently required in order to obtain sixpence. Hood's sympathy was excited, and the 'Song of the Shirt' was the result.

The moral tendency of Hood's works is excellent. In the indulgence of his spirit of fun he is anything but strait-laced as regards the introduction of images and phrases which a fastidious person might call vulgar or coarse; but an indecent description, or even allusion, will not easily be found. He is liberal-minded, a warm eulogist as well as a glowing depictor of the good feelings of our nature and the generous actions which those feelings prompt, and he is an unsparing satirist of vice, pretension, and cant, in all their forms.

Hood, in his person, was thin, pale, and delicate. In his temper he was kind and cheerful; he seems to have imbibed the social and benevolent feeling of his friend Lamb, and he was no less than Lamb a favourite among his friends. His long-continued sufferings only stimulated him to amuse himself and others by the exercise of his extraordinary imagination, and when at last he could no longer bear up under his bodily pains, his complaint was simple, but it indicated a terrible degree of suffering—'I cannot die, I cannot die.'

(*Literary Reminiscences* in *Hood's Own*; *Athenæum*; *Gentleman's Magazine*; and other periodical works.)

HOOK, THEODORE EDWARD, was born September 22nd, 1788, in Charlotte-street, Bedford-Square, London. He was the son of James Hook, a musical composer of some celebrity in his day, by his first wife (Miss Madden), a beautiful, accomplished, and excellent woman. There was only one other child by that marriage, Dr. James Hook, dean of Worcester, who was born in 1773, and died February 5th, 1828. Dr. Hook married a daughter of Sir James Farquhar, physician, in 1797; and wrote two musical pieces, 'Jack of Newbury,' 1795, and 'Diamond cut Diamond,' 1797, which were never printed; and two clever novels, 'Pen Owen,' and 'Percy Mallory,' which have been lately republished. Theodore Hook's mother died in 1802, while he was yet a schoolboy at Harrow: his father did not send him again to school after the funeral; and not long afterwards he married again.

Theodore Hook was a handsome boy and remarkably clever. He had a fine ear, was an expert performer on the pianoforte, had a sweet and powerful voice, and sang a pathetic song well, and a comic song delightfully. His father was employed at Vauxhall and the theatres, and Theodore wrote songs for him, and sometimes composed the airs. The stripling soon received a free admission before the curtain and behind it, and had his share of his father's profits. His brother, who had taken his degrees at St. Mary Hall, Oxford, and was then advancing in the church, seeing the danger to which the young man's character was exposed in this career of dissipation, persuaded his father to send him to the University, and the future dean went with him to be entered at Oxford. But, in order to go through a prescribed course of reading, he was not to commence his residence at the University till after the expiration of a couple of terms, and he returned with his brother to London. He immediately set about writing an operatic farce, 'The Soldier's Return,' 1805, which was very successful, and he gave up all thoughts of the University. He afterwards wrote several other successful operatic pieces and farces:—'Catch him who can,' 1806; 'The Invisible Girl,' 1806; 'Tekeli,' 1806; 'The Fortress,' 1807; 'Music Mad,' 1808; 'Siege of St. Quintin,' 1808; 'Killing no Murder,' 1809; 'Safe and Sound,' 1809; 'Ass-ass-ination,' 1810; 'The Will, or the Widow,' 1810; 'Trial by Jury,' 1811; 'Darkness Visible,' 1811. In 1809 (he was then only twenty) he made his first essay as a novelist by the publication of 'The Man of Sorrow,' under the assumed name of Alfred Allandale, Esq. It was a very flimsy work, and had no success. His life at this time was a series of riotous buffooneries. In 1809 he played off one of the most audacious and reckless hoaxes on record, which is known as the 'Berners-street Hoax.' Not only Berners-street, but all the streets connected with it were rendered almost impassable by vehicles of all descriptions laden with goods of all kinds, from the heaviest to the lightest; and persons of all ranks and professions, including the Commander-in-Chief, the Archbishop of Canterbury, and the Lord Mayor, received invitations, and most of them attended.

Hook was even at this period distinguished for his conversational powers, but his talent as an *improvisatore* is described as marvellous. He was the companion of Charles Matthews; and Mrs. Matthews, in her Memoirs of her husband, relates numerous instances, not only of Hook's displays of improvisation, but of the feats of mimicry which they played off separately and conjointly. Hook was invited to perform before the Prince Regent, who was so much delighted, that after some similar exhibitions at Lady Hertford's and elsewhere, the Regent declared that 'something must be done for Hook;' and late in 1812 something was done for him:—he was appointed Accomptant-General and Treasurer of the Colony of the Mauritius, with a salary and allowances amounting to nearly 2000*l.* a-year. He reached his destination on the 9th of October, 1813, being then only twenty-five years of age. The climate, the society, the amusements, everything delighted him, and he indulged in the most lavish expenditure. Towards the close of 1817, General Farquhar, the governor, sailed for England, and Major-General Hall was sworn in as deputy-governor during his absence. An examination of the accounts and state of the treasury took place, and the report of the examiners declared that everything was correct. Soon afterwards, however, a man of the name of Allan, who was in the treasury department, made a declaration that he knew and had long known that there was a deficiency of 37,000 dollars. Further examinations took place, more deficiencies were discovered, and the result was that Hook was arrested on the 9th of March, 1818; all his property was seized, and he was sent back to England in custody. The ship reached Portsmouth in January, 1819, and the documents were submitted to the law-officers of the crown. The attorney-general's report was, that though Hook might be liable to a civil prosecution for debt, there was no apparent ground for a criminal prosecution, and he was set at liberty with only two gold mohurs in his pocket. He took a small cottage in Somers Town, and formed connections with newspapers and magazines, by which he was enabled to supply himself with the present means of subsistence. He lived in obscurity, and was known only to a few of his old associates, such as Matthews, Terry, and Tom Hill.

In 1820 Sir Walter Scott was in London, and, dining one day with his old friend Terry, met there Matthews, and, for the first time, Hook. The inquiry into Hook's defalcation was still before the audit-board, and the proceedings were represented to Scott as a cruel persecution; he was much pleased with Hook's conversational powers; they were both staunch Tories; and Scott having soon afterwards been applied to by a nobleman of influence to recommend an editor for a provincial newspaper, he named Hook. Hook, however, was not destined for provincial celebrity. The 'John Bull' newspaper was established, with Hook for its editor. The career of the 'John Bull' is well known; its attacks upon Queen Caroline and her supporters, its virulence, its personalities, and the talent which raised its circulation to so great a height. Hook, in its prosperous state, received full 2000*l.* a year from it; and though its circulation gradually diminished, he derived a considerable profit from it up to the time of his death. Meantime the Whigs took care that the inquiry before the audit-board should not be dropped; and the result was, that at first the balance found against him was 20,000*l.*, which on further investigation was reduced to 15,000*l.*, and at last the extent was issued for 12,000*l.* Hook admitted at an early date that the deficiency was 9000*l.*, but afterwards asserted that a strict scrutiny would have struck off 3000*l.* from that sum. There is no proof of actual peculation on the part of Hook; but there is proof that he himself and his officers kept the treasury books with the most culpable and scandalous carelessness, and that the keys of the treasure-chest were frequently left with underlings while he was absent on pleasure excursions. In August, 1823, he was arrested under a writ of Exchequer, his property was sold, and realized about forty pounds, and he was taken to a spunging-house in Shire-lane, Fleet-street, where he remained till April, 1824, whence he was transferred to the Rules of the King's Bench, and he remained there till May, 1825, when he was released from custody, but with an intimation that the crown abandoned nothing of its claim for the debt. He then took a cottage at Putney.

Hook published his first series of 'Sayings and Doings' in Feb. 1824, while confined in the spunging-house, and his diary records the profit to have been 2000*l.*, and he realized sums almost as large by the novels and other works which he published in rapid succession afterwards. The following is a list of the whole of them:—'Sayings and Doings,' First Series, 3 vols., 1824; Second Series, 3 vols., 1825; Third Series, 3 vols., 1828; 'Maxwell,' 3 vols., 1830; 'Life of Sir David Baird,' 2 vols. 8vo., 1832; 'Parson's Daughter,' 3 vols., 1833; 'Love and Pride,' 3 vols., 1833; 'Gilbert Gurney,' 3 vols., 1835; 'Jack Brag,' 3 vols., 1837; 'Births, Deaths, and Marriages,' 3 vols., 1839; 'Gurney Married,' 3 vols., 1839; 'Precepts and Practice,' 3 vols., 1840; 'Fathers and Sons,' 3 vols., 1840; 'Peregrine Bunce,' 3 vols., 1841, some months after his death. In 1836 he became editor of the 'New Monthly Magazine,' and 'Gilbert Gurney,' 'Gurney Married,' 'Precepts and Practice,' and 'Fathers and Sons,' were originally published in periodical portions in that work. He also wrote 'Kelly's Reminiscences,' from Kelly's notes, in 1836, without remuneration, and merely out of kindness to his old friend.

While residing at Putney he gradually mixed more and more freely in society; and in 1827 took a house in Cleveland Row, St. James's, which has since been the residence of a wealthy nobleman; he became a member of divers first-rate clubs, received invitations from persons of the highest distinction, in town and country, and ran himself rapidly and deeply into debt, notwithstanding the large sums which he obtained by his literary labours. By his ambitious and criminal extravagance, which he supplied at a ruinous expense of labour of mind and body, his constitution, excellent as it was originally, was completely broken up. In July, 1841, when dining at Brompton, he was observed to be unwell, and as he stood with the coffee in his hand, turned suddenly to the mirror, and said, 'Ay, I see I look as I am; done up in purse, in mind, and in body too at last.'

From that time he was confined to his house. About the middle of August he requested the Rev. Mr. Gleig, chaplain of Chelsea Hospital, who was an old acquaintance, but had never been at his house, to pay him a visit. He did so, and being known to the servant as a clergyman, was admitted without announcement. Hook was somewhat confused at being caught in dishabille, but after a moment's pause, observed, 'Well, you see me as I am at last—all the bucklings, and paddings, and washings, and brushings, dropt for ever—a poor old grey-headed man, with my belly about my knees.' He had latterly been much *made-up.* He died Aug. 24, 1841, in the fifty-third year of his age. His novel of 'Gilbert Gurney' contains a sort of autobiography of himself.

While living at Somers Town he had become acquainted with a young woman, and by her he had six children: she was respectable, and he always behaved well to her, but he had not the moral courage to marry her, though, according to his diary, he had sometimes thoughts of doing so. A few hundred pounds were subscribed for her and the children after Hook's death. He was a good-natured man, and willing to do acts of kindness, but he had no moral principle sufficiently strong to restrain the impulses of the moment.

Hook's conversational power was greater than his power as a writer. He was an admirable narrator, abounded in smart sayings, which, if not of the highest quality of wit and humour, were so said as to appear the best things ever uttered, and could intermix serious remarks full of good sense and derived from a wide observation of life. His novels are not of the highest order; they contain indeed excellent descriptions of the various forms of life with which he had been conversant, rapid but striking sketches of character, and laughable extravagances, conveyed in a clear, fluent, and often picturesque style. He was well calculated for a popular writer, but is not likely to continue popular long. His novels will shortly share the fate of his dramatic pieces, and be forgotten. His satirical poems are little better than doggrel, and the points, now that the circumstances which gave rise to them have passed away, seem very blunt indeed: his power in these poems was generally in the coarseness of his invectives, not in satirical wit, of which indeed he had little, and that of inferior quality. There are many songs written by him which have never been published, and it is doubtful if they are worth publication.

(*Quarterly Review*, May, 1842, an entertaining and instructive article, written in a fair spirit, by one who knew Hook well; *Gent.'s Mag.*, Oct. 1841, a bad article, written in a spirit of absurd encomium.)

HOOLE. [Tasso, P. C.]

HOPE, THOMAS. Descended from the wealthy family of the 'Hopes' of Amsterdam, and possessing with more than ordinary taste far more than ordinary means of cultivating and gratifying it, this gentleman established for himself a reputation in art, exceeding that of a mere patron of it, or of a mere amateur and collector, since he did much in behalf of art, both with his pencil and his pen.

Mr. Hope, who was born about the year 1770, gave very precocious indications of his decided attachment to that branch of art which seems more than any other to depend upon acquired rather than natural and instinctive taste. 'From an infant,' as he himself tells us, 'architecture was always my favourite amusement. I was scarcely able to hold a pencil, when, instead of flowers, landscapes, and all those other familia· objects of which the imitation chiefly delights the generality of such children as show a turn for design, I already began dealing in those straight lines which seem so little attractive to the greatest number even of good draughtsmen of a more advanced age. No sooner did I become master of myself, which unfortunately happened at the early age of eighteen, than disdaining any longer to ride my favourite hobby only in the confinement of a closet, I hastened in quest of food for it in all the different countries where any could be expected.' This valuable little scrap of autobiography amply indemnifies us for the absence of more matter-of-fact account of his youth and education. At the age of eighteen or nineteen, then, he went abroad, and remained there several years, occupied all the while very differently from most young men of fortune who visit other countries, for his passion for architecture induced him to explore regions that were then considered almost beyond the track of civilization—to study the monuments of Egypt on the banks of the Nile; those of Ionia, Northern Greece, the Peloponnesus, and Sicily; those of the Tartar and Persian styles in Turkey and Syria; of the Moorish and Arabian on the coasts of Africa and in Spain; those of the Etruscan, Lombardic styles, &c. in Italy; and finally, those of the Gothic, in France, Germany, Spain, Portugal, and afterwards here at home.

Eight years, he tells us, were thus occupied by him with a persevering application that would have daunted most professional students, more especially as his researches were attended with many fatigues and privations, and frequently with great risks.

Soon after his return to England he began to apply his studies practically by remodelling and enlarging his mansion in Duchess Street, Portland Place, extending the plan of the original house very considerably by galleries carried round three sides of the court-yard. Of these rooms, which are in continuation of the apartments on the principal floor, the largest one (about 100 feet by 24) is on the north side, and the others, consisting respectively of a suite of small cabinets filled with Etruscan or Greek fictile vases, on the east side, and the statue gallery on the west. And in addition to these, Mr. Hope added several years afterwards (1820) the Flemish Gallery, so called from being entirely occupied by productions of that school. He thus rendered his house one of the largest private mansions in the metropolis; and though he did not bestow on it the slightest beauty of exterior or even any regard at all to appearance, he fitted up and furnished the interior in a style of refined classical taste that was then a decided novelty in this country. His first and memorable publication on 'Household Furniture,' in 1805 (a splendid folio volume with sixty plates exquisitely engraved in outline, and representing together with views of the rooms the furniture and decorations of his own mansion), created a revolution in taste. But it also drew down upon him the merciless ridicule of the 'Edinburgh Review,' which could not resist sneering at the gentleman-upholsterer. Yet, unless it be perfectly indifferent whether good or bad taste be shown in such matters, the reform in furniture of which Mr. Hope set the example, and further promoted by that publication, was assuredly a desirable one, and though there was a good deal of absurdity and caricature in the *ultra-classical* affectations of vulgar and parodying imitators, a very improved style of furniture—one marked by greater simplicity and intrinsic beauty of form has taken place and still prevails, where it has not been superseded by the tawdry frivolity of the *Louis Quatorze* and other fashions.

In 1809 appeared his 'Costume of the Ancients,' which had also great influence in promoting a taste for classical design and study; and in the same year he contributed to a periodical (by J. Landseer) entitled 'Review of Publications of Art,' an essay on the 'Architecture of Theatres.' Mr. Hope had been the first to discern and patronize the talent of Thorwaldsen, whom he commissioned to execute his Jason for him in marble, now in the gallery in Duchess Street. But he was not always so fortunate as to select worthy objects of patronage, for in one instance he bestowed it where it was altogether unmerited. Some dispute arising between him and a French artist named Dubost, the latter painted and made a public exhibition of a libellous icture professing to be the portraits of Mr. and Mrs. Hope, and announced under the title of 'Beauty and the Beast.' As may be supposed, the affair, which occurred in 1810, made a very great noise at the time, but the exhibition was soon brought to a close in a very summary manner by Mrs. Hope's brother, who mutilated the picture by thrusting his stick through the canvas. Dubost brought his action for the injury, but did not succeed in obtaining damages.

With the exception of a minor work entitled 'Modern Costumes,' in 1812, Mr. Hope did not publish anything further till 1819, when appeared his 'Anastasius, or Memoirs of a Modern Greek at the close of the Eighteenth Century,' but as his name was not attached to it, he was so far from being known or even suspected to be the author, that it was at first confidently attributed by many to Lord Byron, as the only person capable of having produced it; and certainly Mr. Hope's previous pursuits and publications were by no means of a kind to point him out as likely to be the author of so powerful a work of fiction. Of his two last works, both of them published posthumously, one of them was even still more remote from what may be supposed to have been the constant tenour of his studies, for that 'On the Origin and Prospects of Man' was almost the very last subject that would have been expected from his pen: from furniture to cosmogony the distance is immeasurable. Abstruse in its speculations, it was also considered unorthodox in some of its opinions, on which account it was afterwards withdrawn from publication, while his 'Historical Essay on Architecture,' first published in 1835, has, on the contrary, become a popular and standard work, having reached a third edition in about eight years. Still it is nothing more than a mere Essay,—which touches indeed upon a good deal that is passed over in other treatises on the subject, yet very slightly; and towards the end it becomes very little more than a series of hasty fragmentary notes. In fact it seems to have been left by the author in an unfinished state, and not to have been prepared by publication by any one else. Probably the plates showing specimens of Lombardic and other styles scarcely ever before represented in English publications, contributed not a little to the popularity of the 'Essay,' but the information they afford is of a very imperfect kind, as they consist of little more than outline elevations of the façades alone of the respective buildings, without even so much as a scale to enable us to judge of their dimensions, nor does the text supply any information as to the plates. Besides being sadly disfigured by typographical errors and other mistakes, the first edition was brought out with so little regard to convenience as a book of study and reference, that there was not even an index to it; wherefore Mr. E. Cressy published, the following year, an 'Analytical Index,' but it ought to have been accompanied by an alphabetical one also.

Besides the above works, Mr. Hope was author of several minor productions and pieces of criticism, one of them being a 'Letter to James Wyatt,' relative to his designs for Downing College, Cambridge, upon which he animadverted very freely and apparently very justly. Another work—if so it may be called—of his, was his villa of Deepdene, in Surrey, which, if he did not entirely build, he very greatly enlarged, and greatly embellished both the house and the grounds, which contain a handsome family mausoleum.

Mr. Hope died February 3, 1831.

HOPPNER, JOHN, R. A., was born in London in 1759. 'There is a mystery,' says Cunningham, 'about his birth, which no one has ventured to explain: all that is known with certainty is, that his mother was one of the German attendants at the Royal Palace.'

When young he was one of the choristers in the Chapel Royal. He studied afterwards in the Royal Academy of Arts; and before he was thirty years of age he had, owing to the active patronage of the Prince of Wales, painted more royal and noble portraits than usually falls to the lot of distinguished portrait painters during the whole of a long life. Hoppner soon distanced Opie and Owen in fashionable favour, and for eighteen years Lawrence was his only rival: Lawrence was patronized by the king, while the prince and his party patronized Hoppner. Hoppner's style is easy and effective, but gaudy; his heads have frequently much character, and are well modelled, though perhaps the opposite case occurs more frequently, especially in his male heads: he had also great skill in landscape painting. He died of dropsy in 1810. His son was for some years British consul at Venice.

At the exhibition of works of 'deceased British artists,' at the British Institution in 1817, there were seven portraits by Hoppner, including his own, a very spirited work, which he presented to the Royal Academy in 1809, upon his election as a member of that body. His portrait of Nelson was in the exhibition at the same institution, in 1820, of 'Portraits representing distinguished persons in the history and literature of the United Kingdom:' it is, however, a less manly head than the one painted by Lemuel Abbot, which was engraved by J. Heath in 1801.

(Cunningham, *Lives of British Painters*, &c.; *An Account of all the Pictures exhibited in the rooms of the British Institution, from* 1813 *to* 1823.)

HORN. Mr. Arthur Aikin, in a paper on the manufacture of horn, tortoiseshell, and whalebone, read before the Society of Arts in 1832, and published in the fifty-second volume of their 'Transactions' (part ii., pp. 334-349), observes that 'in the English language we have only one word to express two quite different substances, namely, the branched bony horns of the stag genus, and the simple laminated horns of the ox genus, and other kindred genera.' Of the former kind, which are, with few exceptions, confined to the male sex, and which are reproduced annually, an account is given under DEER, P. C., p. 349. The uses to which they are applied are the same as those of bone and ivory, and the manufacture presents no point which requires notice. The other kind of horn, to which the French appropriate the name *corne* (while they apply the name *bois* to bony horns), is found in the ox, the antelope, and the goat and sheep kinds. Such horns, with the exception of those of the prongbuck [ANTELOPE, P. C., p. 71], which are not referred to by Aikin, are, he observes, 'never branched or palmated, but are always of a simple conical figure, more or less curved, and, in some of the antelopes, spirally twisted; they are found in both sexes, but, in the goats and sheep, are much larger in the male than in the female.' 'In all these animals,' he adds, 'a bony core, of a loose texture and conical figure, rises from the bone of the forehead, covered by a permanent vascular membrane, from the surface of which are produced or secreted thin layers of horn in constant succession.' 'It is supposed that one layer, or rather one set of layers, is produced every year; but, as the former layer remains closely adherent to the new one, such horns are permanent, lamellar in texture, and exfoliate only very slowly from the outside by exposure to weather and friction.' The structure of such horns may therefore be described as a number of conical sheaths inserted into one another, the innermost of which lies upon the vascular membrane which covers the bony core. The tip, or that portion of the point of the horn which projects beyond the core, is very dense, and the several layers of which it is composed are scarcely distinguishable; while towards the base the layers may be readily distinguished, owing to their successive terminations forming prominent rings. The horn proper is quite insensible, so that the tip may be cut off without giving pain to the animal; but if the core be cut into, bleeding ensues, and it becomes evident that pain is inflicted. Horn appears to consist of coagulated albumen; and Aikin traces the connection between the substance of horns, nails, claws, hoofs, the scales of animals of the armadillo and tortoise kind, of lizards, serpents, and fishes, hair, feathers, and even skin. In the case of tortoiseshell and the armour, or covering shell, of the pangolin and armadillo, the identity of the substance in appearance as well as in chemical character is sufficiently obvious; and the horns of the rhinoceros appear to form a link with the hairy covering of land mammalia generally, the bristles of the boar tribe, and the spines of the hedgehog and porcupine. These horns are not formed upon a bony core, but are described as merely an aggregation of flattened hairs or bristles adhering by their sides, and presenting longitudinal pores or interstices of considerable magnitude at the base of the horn, and which become smaller towards the point, these interstices being, in the living animal, filled with a pulpy matter. Whalebone, also [WHALES, P. C., pp. 294, 295], is another substance illustrating the transition from horn to hair; but its uses in the arts differ much from those of horn. It is softened by boiling in water for some hours, and then cut into suitable lengths for the various purposes to which it is applied, its longitudinal division being effected by splitting, or separating its fibres. It is usually of a dark colour, but that which appears jet black is dyed. It is much used in the manufacture of umbrellas and parasols, in stiffening stays and other articles of female dress, in whip-making, and in various other ways. White whalebone is also manufactured into very elegant bonnets, and occasionally into artificial flowers of great delicacy and beauty, which may be dyed by the usual processes.

The principal kinds of horn employed in manufacturing operations are those of oxen, to which the hoofs of the same animals may be added. The horns of bulls and cows are preferred, those of bullocks being thin and of a coarse texture: a circumstance which seems to indicate some connection between the sexual functions and the development of the horns, similar to that mentioned under DEER, P. C., p. 350. Our domestic supply being unequal to the demand, great quantities of horns are imported from Russia, the Cape of Good Hope, and South America. The horns of goats and sheep, according to Dr. Ure (*Dictionary of Arts*, &c. art. 'Horn'), are to be preferred as whiter and more transparent than those of any other animals.

The first process in the manufacture of horn is to remove the bony core or pith, which is accomplished by steeping the horns in water for a month or six weeks, according to Aikin's account, or for about fifteen days in summer or a month in winter, according to Dr. Ure, by which operation the membrane which lies between the core and the horny sheath is so destroyed or softened by putrefaction that the cores may be easily extracted. These, Aikin observes, are not thrown away, but are burnt to ashes, in which state they form the best material for the small tests or cupella employed by assayers of gold and silver. In some cases, according to Babbage (*Economy of Machinery and Manufactures*, sec. 270), instead of being thus used, the cores are boiled down in water, by which a quantity of fat is extracted, which, rising to the surface, is skimmed off and sold to the makers of yellow soap; while the liquid itself is used as a kind of glue, and is purchased by cloth-dressers for stiffening; and the remaining insoluble substance is crushed in a bone-mill for manure. The solid tip of the horn is sawn off with a frame-saw, and is employed for making knife-handles, umbrella-handles, the tops of whips, buttons, and various other articles. The remainder of the horn, which is employed for purposes for which thin laminæ are required, may either be left entire, or sawn into two or more lengths, according to the use to which it is to be applied. When divided, the lower part, or that next the root of the horn, is frequently employed for making combs, while the portion which has formed the middle of the horn is used for lanterns and similar purposes. To prepare the horn for use, it is immersed in boiling water for about half an hour, by which it is softened; and, while hot from this operation, it is usually held in the flame of a coal or wood fire, until it acquires about the temperature of melting lead, and becomes so soft as to be semi-fluid. If the horn be from an old animal, care must be taken to expose the inside as well as the outside to the action of the flame. Mr. James, of Lambeth, a worker in horn, was rewarded by the Society of Arts in 1827 for a machine for accomplishing this object much better than in the usual way. His apparatus, which is described in the forty-fifth volume of the Society's 'Transactions,' p. 164, consists simply of a block of cast iron pierced with a conical hole, and a conical plug of the same metal, about one-eighth of an inch less in diameter than the hole. These are heated in a stove or common fire to about the temperature of melting lead. The block is then taken out and placed on a firm support. A piece of horn, which, if intended to be spread out flat, should be previously slit longitudinally, is then put into the hole, and the heated plug is dropped into the cavity of the horn. As the horn becomes softened by the heat, the plug is carefully driven in with a mallet; and by its pressure any original crookedness of the horn is removed. After remaining about a minute in this state the block is turned on one side, the plug is driven out, and the horn, which is sufficiently soft to be opened out flat, is removed. This apparatus is said to effect considerable saving of time, in addition to avoiding all risk of overheating the horn. In the more ordinary process, as described by Aikin, the heat is applied before the horn is slit; the slitting is performed while it is in the semi-fluid state, by a strong pointed knife resembling a pruning-knife; and, by the application of two pairs of pincers, one to each edge of the slit, the cylinder or cone of horn is opened until it is nearly flat. Several such pieces are then exposed to pressure between alternate plates of iron, previously heated and greased, to prevent the horn adhering to them, either in a press, or by placing them vertically in a strong iron trough, and compressing them by means of wedges. The degree of pressure applied depends on the intended use of the horn; if it be intended to form very thin leaves for making lanterns (or *lanthorns*, as the word was formerly written, apparently with reference to the use of this material), the pressure should be sufficiently strong to break the grain, or cause the laminæ of the horn to separate a little, so that the edge of a round-pointed knife may be inserted between them to complete the splitting or separation. The thin sheets of horn are then scraped with a blunt or wire-edged draw-knife, upon a board covered with bull's hide, and when thus smoothed and brought to the required thickness, they are polished by a woollen rag dipped in charcoal dust, a little water being added from time to time. They are afterwards rubbed with rotten-stone, and finally with horn shavings. Dr. Ure states that the polish is advantageously completed by rubbing with sub-nitrate of bismuth, applied with the palm of the hand. The painted toys known under the name of Chinese sensitive leaves, which possess the curious property of curling up is if they were alive when laid upon a warm hand, or near a fire, are made of the best of the thin films removed by the draw-knife. When the horn is to be converted into combs, the pressure applied in flattening must be as slight as possible, lest, by the breaking of the grain, the teeth of the comb become liable to split at the points. If a comb or any other article be required of greater size than can be made out of a single plate of horn, two or more may be united by the dexterous application of a degree of heat sufficient to melt but not to decompose the horn, assisted by pressure. When this is well managed, the junction cannot be perceived. 'The Chinese,' Aikin observes, 'are remarkably skilful in this kind of work, as may be seen in the large globular lantern in the museum at the East India House, about four feet in diameter, composed entirely of small plates of coloured and painted horn.'

Combs are roughly cut by a hatchet or saw to the required shape, and then finished by rasps and scrapers. The mode of cutting the teeth is described under COMB, P. C. S., p. 398. If required to be of a curved shape, they are first made flat, and after the teeth are cut they are softened in boiling water, and pressed until cold in a die of hard wood. Horn combs ornamented with openwork are not, according to Aikin, made in this country, because the expense of cutting them in the way practised upon tortoiseshell would be greater than the selling price of the article would repay. Such are, however, extensively imported from France, where they are produced by pressure in steel dies, which are made in London for the French manufacturers. From an examination of such combs, it appears that the horn, when put into the die, must have been in a soft state, approaching to fusion. Aikin states that, according to French authorities, 'horn steeped for a week in a liquor, the active ingredient of which is caustic fixed alkali, becomes so soft that it may be easily moulded into any required shape.' 'Horn shavings subjected to the same process become semi-gelatinous, and may be pressed in a mould into the form of snuff-boxes and other articles;' but he adds that horn so treated becomes hard and brittle, probably in consequence of its laminated texture being obliterated by the joint action of the alkali and strong pressure.

Drinking-horns, respecting which some curious notices are quoted under BISON, P. C., pp. 461, 462, are now made by sawing the horn to the required length, scalding and roasting it over the fire, as above described, but, instead of slitting and opening it, placing it while hot in a conical wooden mould, and driving a wooden plug firmly into the interior, to bring it to accurate shape. When cold and hard, it is fixed on a lathe, and turned and polished both inside and outside, and a groove, or *chime*, is cut with a gage-tool within the smaller end, for receiving the bottom. The horn is then softened before a fire, and the bottom, which is a round flat piece of horn cut out of a plate with a crown-saw, is dropped in at the larger end, and forced down until it reaches the chime. By the subsequent contraction of the horn in cooling, the bottom becomes so firmly fixed as to be perfectly water-tight.

In the manufacture of all articles made of fragments of horn compressed into a solid mass, great care is necessary to avoid the presence of grease, which would prevent perfect union. The masses of horn should be moved with wooden instruments while at the fire, and in carrying them to the moulds. Bell-pulls, the handles of table-knives and forks, knobs for drawers, and many other useful articles, are thus formed, care being taken, whenever the article is put into the mould in two or more pieces, to fit them together so that they may dovetail into one another.

Horn is easily dyed of various colours; but in this country it is usually coloured of a rich reddish brown, and spotted to imitate tortoiseshell, by a mixture of pearl-ash, quicklime, and litharge, or red lead, with water and a little pounded dragon's blood. These are boiled together for half an hour, and applied hot to the parts of the horn which it is desired to colour. For a deeper colour the mixture may be applied twice, and for a blacker brown the dragon's blood may be omitted. This process,' Aikin observes, 'is nearly the same as that employed for giving a brown or black colour to white hair; and depends on the combination of the sulphur, which is an essential ingredient in albumen, with the lead dissolved in the alkali, and thus introduced into the substance of the horn.' Some other dyes are mentioned by Dr. Ure.

No part of the refuse of the horn manufacture is without its value. When exposed to a decomposing heat in close vessels, horn produces a large quantity of the gaseous compound which forms the base of prussic acid, on which account hoofs and horn cuttings are in great request among the manufacturers of Prussian blue, and of the beautiful yellow prussiate of potash. The clippings of the comb-maker are also used as manure. 'In the first year after they are spread over the soil,' observes Babbage in the work above quoted, 'they have comparatively little effect, but during the next four or five their efficiency is considerable.' The shavings of the lantern-maker, from their extremely thin and divided form, produce their full effect on the first crop.

Among the various uses to which horn has been applied, Aikin alludes to bows, both antient and modern, made either entirely or partly of this material, and to armour. He had seen a complete suit of scale armour, which was said to have come from Arabia, made entirely of horn. The employment of this substance for glazing windows has long been superseded by the use of glass.

Hebert (*Engineer's and Mechanic's Encyclopædia*, vol. i. p. 683) alludes to a kind of artificial horn, the manufacture of which is said to have been established in France. It consists of gelatine, usually obtained from bones by treating them with muriatic acid, converted into a horny substance by tanning. Upon becoming hard and dry it resembles horn or tortoiseshell, both in appearance and in the facility with which it may be softened, by boiling in water with potash, and moulded to any required form. By inlaying with gold and silver, and staining with various colours, it may be rendered highly ornamental.

HORNER, FRANCIS, was born, Aug. 12, 1778, in the city of Edinburgh, where his father was a merchant. He was educated at the High School of Edinburgh; in 1792 he matriculated at the University of Edinburgh, where he pursued his studies till the summer of 1795. He was then seventeen years of age, and being disposed to select the law as his profession, his father sent him to England, and placed him under the care of the Rev. John Hewlett, of Shacklewell, in Middlesex, in order that he might get rid of his Scottish dialect, and gain some experience among strangers, as he had hitherto constantly lived at home. He returned to Edinburgh in Nov. 1797, and, having fixed upon the Scottish bar as his profession, at the age of twenty he laid down for himself a scheme of study which included almost every branch of science and literature. He studied Scotch law with his friend Henry Brougham, and with another friend, Lord Webb Seymour, he studied metaphysics and political economy.

In 1802 Horner began to have thoughts of exchanging the Scottish for the English bar, and in April of that year he came to London in order to observe the proceedings in the courts of law, and fix his determination. His friendships and political opinions had associated him with the rising Whigs in Edinburgh; he was now received with alacrity by men of congenial opinions in London, by Mr. Abercromby, Sir James Mackintosh, Sir Samuel Romilly, and others. He resolved to attach himself to the English bar, and in the spring of 1803 he took up his permanent residence in London. It was an eventful and a stirring time. The French war was again breaking out, the King's sanity was doubtful, and the Addington administration was giving way before the cross-firing of Pitt and Fox. Horner was not allowed to remain an unengaged spectator. As his abilities became more known, his connections with the leading Whigs were extended. On the death of Mr. Pitt in 1806 the government was placed in the hands of Lord Grenville and Mr. Fox. Horner accepted a seat at the Board of Commissioners established by the East India Company for settling the Nabob of Arcot's debts, an unsalaried office, which however was to be remunerated at the close of the investigation. On the 23rd of June, 1806, Lord Henry Petty made him an offer, through the intervention of Lord Kinnaird, of a ministerial seat in the House of Commons, which, after consultation with his friends, was accepted, and in Nov. 1806, he was returned for St. Ives. Fox had died in September, and the old Whig party, which he had held together, immediately fell to pieces. A new parliament was summoned, and met on the 15th of December. This parliament was very short-lived. A change of ministers took place on the 24th of March, 1807; parliament was prorogued on the 27th of April, and was immediately afterwards dissolved. Horner did not obtain a seat at the general election, but in the following July was elected for the borough of Wendover through the interest of Lord Carrington. He spoke little at first, on matters of business only, and briefly. By degrees he began to take a part in great questions. He entirely coincided with the Whig party in their condemnation of the seizure of the Danish fleet; he differed from them in their shrinking policy on the question of the Spanish war. In May, 1809, he resigned his seat at the Board of Commissioners for investigating the debts of the Nabob of Arcot, in consequence of finding its duties interfere too much with the pursuit of his profession. On the 1st of February, 1810, Horner made a motion for an inquiry into an alleged depreciation of bank notes. The subject was one which he had studied extensively, and he made a very decided impression on the House. He was appointed a member of the Bullion Committee, and by the part which he took in it, by his share in drawing up the report, and by his speeches on the question in the House, he acquired a solid reputation and a position and influence there which he afterwards rather augmented than diminished. On the Regency question he spoke on the side of his friends with great power and effect. In the negotiations for the formation of a ministry by Lord Grenville in 1811, Horner was offered the situation of one of the Secretaries of the Treasury, but he declined the offer. In the general election in 1812 he was not returned as a member, but by the intervention of Lord Grenville he was elected for St. Mawes, through the interest of the Marquess of Buckingham. In the sessions of 1813 and 1814 he took a prominent part in the debates, and became one of the acknowledged leaders of his party. He took advantage of the opening of the continent, in 1814, and made the tour of Geneva and the north of Italy. In the great crisis arising from the return of Bonaparte from Elba, when Lord Grenville urged the necessity of a war and Lord Grey deprecated the haste with which the country seemed disposed to enter upon it, Mr. Horner supported Lord Grey, and the difference of opinion seemed to be so irreconcilable that he offered to surrender his seat, but the Marquess of Buckingham declined to accept his resignation. On the 25th of June, 1816, he made his last speech in parliament, in favour of the Catholic claims, and against the intolerant and harsh treatment which Ireland had experienced from the government of this country. Symptoms of a pulmonary disease had already begun to show themselves in his constitution, and he was advised by his physicians to spend the winter in the south of Europe. Accompanied by his brother, Mr. Leonard Horner, he set out on his journey, and arrived at Pisa in the latter part of November. His disease grew rapidly worse, but he had no suspicion that it was dangerous, and he continued to lay down for himself plans for future studies of the most comprehensive extent. On the 6th of February his difficulty of breathing came on with increased severity. He died on the 8th of February, 1817. His body was opened, and his complaint was found to be, not consumption, but induration of the substance of the lungs and enlargement of the air-cells to an extraordinary extent. He was buried in the Protestant cemetery at Leghorn, where a marble table-tomb was erected to his memory by his father. At one of the ends of the monument is a likeness of him in relief, of the size of life, by Chantrey. A marble statue of him, also by Chantrey, is placed in the north transept of Westminster Abbey, the cost of which was defrayed by subscription among his personal and political friends. It is one of Chantrey's best works, and indeed one of the finest portrait-statues in the Abbey.

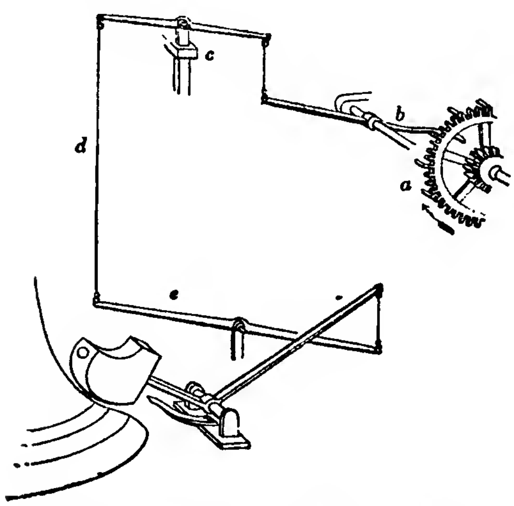
The character of Horner's understanding was that of vigorous reasoning in pursuit of important and often difficult truth. He had no wit, and made no pretence to any. His knowledge was extensive, and his judgment accurate, not only in the various branches of political economy, but in a great many other departments of literature. He was one of the projectors of the Edinburgh Review, and wrote many articles for it. As a public man his independence was unquestionable; his integrity, sincerity, and moderation were acknowledged by all parties. He was modest, free from pretension, and equally free from any kind of affectation or any trace of rancour. As a public speaker he was grave and forcible, without imagery or any of the accessories of oratory, but with an earnestness and evident sincerity of manner which produced an effect greater than he could have done by any appeals to the imagination or the passions.

(*Memoirs and Correspondence of Francis Horner, M.P.*, edited by his brother, Leonard Horner, Esq., F.R.S.; *Quarterly Review*, May, 1843.)

HOROLOGY. A general notice of the history and of the chief peculiarities in the construction of the principal kinds of machines for measuring time is given under this head in P. C. p. 297; and under CHRONOMETER, P. C. p. 134; JEWELLING OF WATCHES, P. C. p. 117; PENDULUM, P. C. p. 402; and WATCH, REPEATING, P. C., p. 107, are further details respecting some branches of the science of horology. The principal object of this article is to supply information respecting some important modern improvements in the construction of the large clocks used in church towers and public buildings, which, from their most usual position, are generally known by the name of church or turret clocks.

Turret-clocks differ from other machines employed for measuring time, not only in their greatly superior size, but also in the arrangement of their parts, and in the circumstance that they are usually made to strike the hours, and often the quarters also, upon large bells, and are occasionally connected with machinery for chiming whole tunes at certain intervals upon a set of bells which, when mounted in a church-tower, are so hung, that by disconnecting the hammers of the chimes and striking apparatus, they may also be rung in the ordinary manner by means of ropes. A popular description of the mechanism of such a clock is given in a paper in the 'Penny Magazine' for 1842 (No. 641), describing a visit to a church-clock factory and bell-foundry, which is illustrated by a representation of the clock of St. Anne's Church, Limehouse. One of the most curious peculiarities of a turret-clock consists in the circumstance that it is frequently required to indicate the time upon as many as four different dials, on the four external faces of the tower in which it is mounted. This apparently difficult matter is accomplished in a simple and beautiful manner, by placing the clock in or near the centre of an apartment either on a level with the external faces, or above or below them, and causing the motion of the axis which under ordinary circumstances would carry the minute-hand (which revolves once in an hour), to be transmitted by bevil-gear to a vertical rod, the opposite end of which carries a horizontal bevil-wheel nearly on a level with, and situated centrically with reference to, the four external dials. The motion of this central wheel is communicated, by four vertical bevil-wheels of the same size and number of teeth, ranged round its circumference, to four horizontal rods, the opposite ends of which, passing through the several dials, carry the four minute-hands. At the back of each dial is a series of wheels and pinions, technically called the *motion-work*, precisely resembling that described in the account of a vertical watch under HOROLOGY, P. C., p. 302, by which motion is imparted to the hour-hand, which revolves once in twelve hours. As in the case of the eight-days' spring clock, described under HOROLOGY, P. C., the movement of the hands and that of the striking apparatus are provided for by separate trains of wheel-work, each of which is impelled by its own moving power. In a turret-clock, the moving power is supplied by the descent of a weight, regulated in the case of the movement, or going-train, by the oscillations of a large pendulum, and in that of the striking-train by the resistance of the air to the rapid revolutions of a fly or fan set in motion by the wheelwork. In the arrangement of these trains, and in their connection with each other, there is nothing which requires special notice here, as these matters may be readily understood from the account of a spring-clock above referred to. Owing to the necessity for using a very heavy hammer to strike the hours in a church-clock, the power required for working the striking-train considerably exceeds that of the going-train. In the Limehouse clock above referred to, the going weight is about sixty pounds, while that of the striking-train is about five hundred pounds. These weights are wound up (in most cases, weekly) by means of winch handles and toothed wheels connected with the massive drums round which their ropes are coiled; and, for convenience, they do not descend immediately from the drums or barrels, but in the angles of the tower, or any convenient situation, the course of their ropes being directed by guide-pulleys. In this clock the pendulum-rod, which, as is usual in large clocks, is made of wood, is about thirteen or fourteen feet long, its bob, or weight, being a mass of cast iron shaped like a double convex lens, about thirty inches in diameter, and weighing two hundred pounds. Each of the four clock-faces is thirteen feet in diameter, and each pair of hands weighs about sixty pounds; but as the hands are very nicely balanced by weights attached to the extremity opposite to the pointed end, the power required for moving them is much less than might be supposed. In some turret-clocks, indeed, the small size of the going-train and of the apparatus by which motion is communicated to the hands appears strangely disproportionate to the magnitude of the dials. In the Limehouse clock, the head of the hammer by which the hours are struck weighs fifty-six pounds, and it is set in motion by the apparatus represented in *Fig.* 1., which may serve as an example of the striking mechanism of turret-clocks in general, although the details of course vary according to the relative situation of the clock and the bell, which, in some cases, is the reverse of that here represented: the bell being above, instead of beneath the level of the clock itself.

Fig. 1.



In this cut *a* represents the pin-wheel, corresponding to the wheel *f* in the striking-train of the clock represented in HOROLOGY, P. C., p. 300, *Fig.* 1, by the action of the projecting pins of which upon the end of the lever *b*, communicated through the levers *c* and *e*, the tail *f* of the hammer is depressed, and the hammer-head is consequently raised ready for a stroke. By the continued revolution of *a*, the end of the lever *b*, after being raised to a considerable height, is suddenly released, by which the hammer falls upon the rim of the bell, and the connecting apparatus resumes its original position ready for the next stroke. It must be borne in mind that the rod or wire *d* by which the levers *c* and *e* are connected, is here represented much too short. In ordinary cases, it is of sufficient length to reach from one story of the tower to another.

Musical chimes, which form a pleasing though not very common addition to the mechanism of turret-clocks, require the addition of another train of mechanism, somewhat like to that which constitutes the striking-train, inasmuch as, like it, it is perfectly at rest for considerable periods of time, and is brought into action only at certain predetermined intervals by the action of the going-train of the clock upon a detent. The mechanism of the chimes very nearly resembles, on a large scale, that of a musical snuff-box; levers connected with hammers which strike upon a series of bells, being substituted for the springs which in the musical snuff-box are caused to vibrate by the projecting pins on the revolving barrel. Beautiful machinery has been introduced to facilitate the accurate *pricking* of the barrel, or insertion in their proper places of the pins which project from its surface; but the principle by which the operation is regulated may be sufficiently explained by an account of the old method of performing it. A sheet of paper exactly equal in size to the surface of the barrel, and which, therefore, would completely cover it if wrapped round its circumference, was ruled in a direction perpendicular to, or at right angles with, the axis of the barrel, with as many parallel and equidistant lines as there are different notes in the tune to be performed, each of these lines indicating the position of one of the series of levers worked by the barrel, and on each of these lines was marked the name of the note represented by it. This series of lines was then crossed by another series lying parallel with the axis of the barrel, which divided the circumference of the barrel into as many equal parts as there are bars or equal divisions of time in the tune. These spaces being then subdivided by other lines, according to the number of minims, crotchets, or quavers in each bar, the notes of the required tune were marked by ink dots upon the paper on their respective lines and in the order of time in which they should be produced, as regulated by the bar-lines and by the subdivisions of the bar. This done, the paper was pasted upon the barrel, and the pins were inserted at the points indicated by the marks on the paper. This comparatively rude process, though inefficient for cases in which one barrel is made, by shifting a little longitudinally upon its axis, to perform several tunes, indicates the principle common to the pricked barrels of chimes, musical snuff-boxes, and barrel-organs.

Owing to the very limited demand for turret-clocks, and their great durability when well made and carefully preserved, the business of making them is confined to very few establishments, and has hardly been systematised into a manufacture, in the more definite sense of that term. Every clock being, in ordinary cases, made individually, and with comparatively little aid from machinery, turret-clocks have been very expensive, and in many cases inferior in accuracy of workmanship to many far simpler cheaper and more common machines, in the manufacture of which more extensive use is made of the lathe, slide-rest, planing-machine, and other contrivances for abridging labour and attaining a higher degree of perfection than could be secured by hand-labour. Mr. Dent, who had previously succeeded, in the face of much prejudice and opposition, in remedying a similar defect in the manufacture of chronometers, determined, when engaged by the Gresham Committee to make a turret-clock of unprecedented perfection for the new Royal Exchange, under the superintendence of Mr. Airy, the astronomer royal, to meet this deficiency by establishing a clock-factory supplied with all the aids and appliances of modern ingenuity, in which the several parts of a turret-clock should be produced as far as possible in the same way as the component parts of a power-loom or other machine manufactured upon an extensive scale. By such a judicious outlay of capital it becomes easy, having once made the required models, to produce as many clocks as may be desired, the component parts of which are perfectly alike, and which, while finished in a very superior manner, can be supplied at a cost greatly below that of what may be termed hand-made clocks. In the manufacture of smaller clocks and other horological machines, for which there is a more extensive demand, the application of manufacturing principles is even more important; and we may express a hope that the prejudices which have hitherto stood in the way of such improvements, and restrained the application of capital to this branch of ingenuity, are giving way. When the gentleman referred to above first introduced the use of the slide-rest in the manufacture of turret-clocks, his machines were found to be, in consequence of the jealousy of the clockmakers employed to use them, so continually out of order that he was compelled to call in the assistance of engineers to repair and work them; but now the clockmakers and engineers work together in the most cordial manner, and with the most satisfactory result.

One of the first points which would strike an observer in the Exchange clock, and in other turret clocks made on the same principle, is the use of a simple but strong cast-iron framing, in which every strain is so completely self-contained that the operation of fixing the clock in its destined position is one requiring but little skill; scarcely any adjustment being required beyond the fixing of the frame on a firm and level base. Another, and a more unusual feature, which Mr. Dent has introduced into the turret-clock manufacture, although it is not adopted in the Exchange clock, is the use of cast iron wheels for the striking train, which is considerably larger than the going train. This peculiarity, which will be of great advantage, not only on account of the superior durability of the metal, but also as tending greatly to reduce the cost of the clock, is not claimed as an invention by Mr. Dent, such wheels having been, according to information with which he has favoured the writer, used in France for forty years past. In some old English clocks, we may state on the same authority, wheels of wrought iron were used, but the teeth of these had to be cut in the same manner as those of the ordinary gun-metal wheels used for the same purpose, while those of the cast-iron wheels are formed by the casting operation alone, from an accurate model. The wheels of the going train, which are not only smaller but require greater accuracy from the circumstance that any irregularity in their action would impair the correctness of the clock, which is not the case with the striking train, are best made of hammered brass, which is a material more to be depended upon than gun-metal. The wheels of both trains are formed with teeth of a peculiar shape, on the subject of which Mr. Dent presented a paper to the British Association in September, 1844, in which he states that the geometrical form of the wheel-teeth in chronometers, watches, and clocks is seldom attended to by the persons who either cut the wheels or make the pinions; which he thinks may be explained from the circumstance of these operations being separated into two distinct trades. 'The system pursued by workmen to insure what they suppose to be the proper form of the wheel-teeth is,' he observes, 'that it should, as nearly as possible, resemble *the shape of a bay-leaf;* while the terms geometrical circles or pitch-lines are not understood.' Mr. Dent then proceeds to show that 'as the wheels of a clock move in one direction, an opportunity is afforded of the teeth being so shaped that the contact, or commencement of the force, may take place at the line of centres, and, if possible, it should not take place before. 'After cutting many experimental segments of wheels and pinions,' he adds, 'adopting various proportions in each case beyond the geometrical circles, I came to the conclusion to use for the wheel-teeth (the driver) the epicycloidal curve, and for the pinion (the driven) the hypocycloidal curve, putting nearly the whole of the curve on the wheel-teeth, increasing the circumference beyond the geometrical circle, by the addition of three teeth and spaces, allowing only 0·5 of the pitch of the tooth for the increased circumference of the pinion, just to remove the possibility of any sharp edge. In every case the epicycloidal curve has been described by rolling the semi-diameter of the driven on the geometrical circle of the driver. It is very necessary that segments of the teeth should be cut for the purpose of ascertaining the breadth that the wheel-teeth should be in excess above those of the pinion-leaves; for as the breadth of the wheel-teeth is increased, and the leaves of the pinion narrowed, the effect of driving before and after the line of centres is varied.' Mr. Dent has also applied this theory to the lifting of the hammers, both for the striking apparatus and the chimes, by using projections of an epicycloidal shape instead of the ordinary round pins in the pin-wheel.

Among the other important features of the Royal Exchange clock, which are applicable to all others of similar character, whether constructed with its peculiar contrivances for insuring perfect accuracy or not, we may mention the use of hollow iron drums instead of wooden cylinders for the driving barrels, and the use of wire instead of hempen ropes for suspending the weights. The first-mentioned of these improvements renders permanent accuracy of form more attainable, while the latter obviates, in consequence of the much smaller size of the cord, the necessity for overlaying it, since a sufficient length of rope may be coiled in a single layer upon the barrel without increasing its length or diameter in an inconvenient degree. The result is that the weight continually exerts the same force to turn the barrel, while with a thicker rope, covering the barrel in two or three layers, its effective force is of necessity greater at the commencement of its descent, when it acts upon the circumference of the barrel *plus* the thickness of the first or innermost layer of rope, than at the latter part of its descent, when it acts on the circumference of the barrel alone. Another important arrangement, which, though formerly in use, had been departed from, and is revived in this clock, is the driving of the hands of the clock, and the raising of the hammers of the striking apparatus directly from the axis of the driving-barrel, without the intervention of any wheels and pinions.

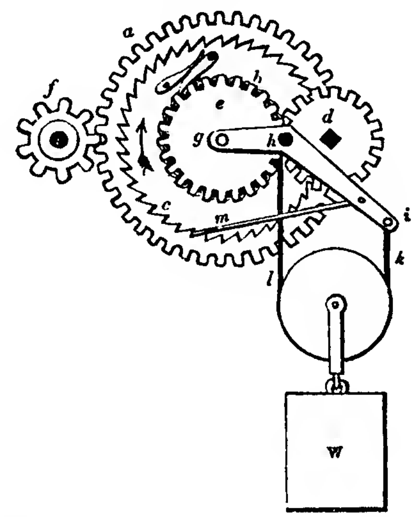
In their determination to secure a public clock of unexampled accuracy, the Gresham Committee required that the Exchange clock should have a compensation-pendulum, and that it should be so constructed as not only to show perfectly correct time upon the dials, but also to tell it with accuracy by making the first stroke of the hour upon the bell true *to a second*. This degree of precision is unattainable with the ordinary striking-apparatus, as the effect of variations in the state of the atmosphere upon the motion of the fly by which its action is regulated, and of various circumstances affecting the inertia of the machinery to be brought into motion, together with the uncertainty as to the precise moment when the tail of the lever by which the hammer is moved will become disengaged from the pin or tooth of the pin-wheel by which it is raised or depressed, render it impossible to adjust the mechanism with certainty to produce such a result. In the Exchange clock this difficulty is provided for by an arrangement for moving the lever and hammer to nearly the utmost degree required before the time of striking, and causing the end of the lever, which is formed in a peculiar manner for the purpose, to remain poised delicately upon the rounded point of the projecting tooth of the pin-wheel until the moment of striking, when it is instantaneously released, and thus the stroke is produced without being affected by the preliminary operation of raising the hammer.

The principles upon which pendulums are provided with compensations for changes of temperature are explained under PENDULUM, P. C., pp. 402, 403. That of the Exchange clock is of a comparatively simple construction, which appears well adapted for large clocks. The centre rod of the pendulum is of steel, and is sufficiently long to pass completely through the bob or weight, which, however, is not immediately attached to it. Upon the bottom of this rod is fixed a nut, by turning which the length of the pendulum may be nicely adjusted, and upon which stands a hollow or tubular column of zinc, through which the steel rod passes freely. On the top of the zinc column is a metal cap, from projecting portions of which descend two slender steel rods, to the lower ends of which the weight, which is a hollow cylinder of iron, capable of sliding freely upon the zinc column, is suspended. Thus, while both the central steel rod and the two smaller steel rods by which the weight is suspended, expand *downwards* upon any increase of heat, the position of the weight in reference to the point of suspension of the pendulum remains nearly the same, because the zinc column, though shorter than the central steel rod, expands, owing to the different nature of the metal, to an equal extent *upwards*, and consequently raises the weight just as much as it is depressed by the lengthening of the steel rod. As the pendulum of the clock we are describing weighs nearly four cwt., the operation of 'setting' it to the required nicety, that its beats might be correct to within a *fraction of a second*, was a matter of extreme difficulty. This was met by a contrivance suggested by Mr. Airy: the clock being started at a very small losing rate, a slender spring so mounted as to touch the pendulum slightly, and to cause a gain in the going of the clock, was brought in contact with the pendulum-bob nearly at the centre of percussion by means of a line in the clock-room. By this means the beats of a large turret-clock may be brought to coincide perfectly with those of a chronometer by which it is set. The regulating screw by which the length of the pendulum is adjusted is not moved for the correction of small errors in the rate of going, such being provided for by the use of small supplementary weights laid upon each side of the top of the pendulum-bob, which weights may be applied or removed without stopping the clock.

While on the subject of compensation-pendulums we may notice a paper presented by Mr. Dent to the British Association in 1838, in which, among other matters, he explains an improvement which he had introduced in the construction of the mercurial pendulum, which is that generally adopted for the very perfect kind of time-keeper known as an Astronomical Clock. The ordinary construction of this admirable pendulum, which is described and illustrated under PENDULUM, P. C., has the mercury in a glass jar, the fragility of which not only exposes it to the risk of fracture, but also renders it unsafe to boil the mercury after filling it, to drive off the air which it always contains. Further than this, while it is possible to give, externally, a mathematically correct form to a glass jar, the interior cannot be made of a perfect figure, and consequently the column of mercury which it contains cannot be a perfectly regular cylinder. 'This condition,' Mr. Dent observes, 'combined with the irregularity of expansion which glass is peculiarly liable to from its compound nature, renders measurement and calculation, with regard to the column, so vague and deceptive that they are never employed.' These defects he has removed by substituting a jar or cistern of cast iron, with which mercury is as little disposed to amalgamate as it is with glass, for the ordinary glass jar. This material may be wrought with the utmost accuracy into the required form, and although, from the effects of expansion and contraction, the figure of the vessel is not perfectly permanent and unchangeable, its changes are of a nature which is well understood, and may be calculated upon with accuracy. In such a cistern, again, the mercury may be boiled at any time. 'The clock-maker may do it himself on the first putting of the machine together,—may adjust the column,—may then hermetically seal it, and dispatch the pendulum to the most distant countries with the adjustment so perfect that it may be instantly attached to the wheel-work by any workman capable of setting the clock upon its supports;' and 'if at any subsequent period, minute portions of air have, from any cause, again mingled with the mercury, and rendered the pendulum susceptible of barometric changes, the air may again be driven off with the greatest facility by repeating the process of boiling, without removing the mercury from the cistern.' In connection with this improvement Mr. Dent has introduced some other alterations in the construction of the mercurial pendulum, among which is the attachment of the cistern directly to the pendulum-rod, and consequent removal of the metal stirrup or frame formerly used to carry it, and the prolongation of the rod so as to plunge its lower end into the mercury, nearly to the bottom of the cistern, an arrangement favourable to uniformity of temperature in the rod and mercury; and since the date of the paper we have quoted, he has, with a view to obtaining additional precision in the performance of the astronomical clock, taken out a patent for giving impulse to the pendulum at, as nearly as can be determined, the centre of percussion. In this arrangement, the pendulum, instead of being suspended below the clock, is suspended from a fixed point at the top of the clock-case, while the clock itself is at the bottom, the only connection between the two being effected by momentary contact, at the extremities of the range of the pendulum's vibration, with two slender pieces attached to the escapement. 'In the old arrangement,' the inventor observes in his published 'Abstract from Two Lectures on the Construction and Management of Chronometers, Watches, and Clocks, delivered before the members of the United Service Institution, May, 1841,' 'the pendulum never vibrates independently of the mechanism of the clock; besides which, the impulse is given under very disadvantageous circumstances, as the greater part of the force communicated by the escapement is lost at the point of suspension.' In his patent astronomical clock, with the detached pendulum, these defects are in a great measure remedied, for he states that 'if the pendulum vibrates two degrees from the perpendicular, one degree and forty-five minutes will be entirely detached from the mechanism, and the irregularities occasioned by friction and other disturbing causes are avoided.'

Returning to the turret-clock at the Royal Exchange, in which the connection of the pendulum with the wheel-work is of the more ordinary nature, the escapement is the next point which claims notice, though it is too complicated to be fully described without several figures. Its chief peculiarity is that it is of the *remontoire* kind, a circumstance in which it resembles some of the best public clocks in France; among others, that of the Bourse at Paris. To explain this it may be sufficient to state that the impulses imparted to the pendulum are not given immediately from the large going-train of the clock, which is exposed to variations of force and resistance from varying friction, from changes in the state of the oil used to lubricate the mechanism (the use of which, however, is limited to the least possible degree), and from the effect of the wind upon the large hands of the four external dials, which in this case are nine feet in diameter; but these impulses are given by a small secondary train, set in motion by the descent of a ball or weight, which is itself raised at intervals of twenty seconds by the mechanism of the going-train. The action is therefore very similar to that of a *remontoire-spring*, which, as used in some horological machines, is a small spring employed only to set the escapement in motion, it being itself wound up at very short intervals by the going-train, which receives its impulse from the prime mover. Such a contrivance favours accuracy of performance by detaching the escapement, by which the velocity of the machine is determined, or, in other words, by which the measurement of time is effected, from the power, necessarily subject to some irregularities, by which the greater part of the machinery is kept in motion, whether that power be supplied by a weight or a spring. The escapement of the Exchange clock is Graham's dead-beat escapement, and has the pallet jewelled with large sapphires; but in his ordinary turret-clocks Mr. Dent uses a modification of Lepaute's escapement, over a single pin. In this clock has been introduced a beautiful contrivance for maintaining the motion of the wheels during the time of winding up, which was invented a few years since by Mr. Airy for the clock-work of the great Northumberland telescope at the university of Cambridge, and of which he published a description in the 'Transactions of the Cambridge Philosophical Society,' vol. vii. part ii. p. 217. Harrison's beautiful contrivance of the *going-fusee*, of which a description is given under HOROLOGY, P. C., p. 301, is not sufficiently powerful for application to large clocks, in which the strain of very heavy weights has to be provided for; but Mr. Airy's contrivance, which he describes as 'a new construction of the going-fusee,' supplies the deficiency. Its action will be understood from the annexed diagram, *Fig.* 2, which represents

Fig. 2.



one of several forms of the apparatus shown in the illustrations of Mr. Airy's paper. In this diagram *a* represents the first wheel of the clock, which is mounted, as usual, upon the axis of the rope-barrel *b*, with a ratchet and click so arranged that the two must turn together whenever the rope-barrel is turned, by the action of the weight W, through the line *l*, in the direction indicated by the arrow; while, when the rope-barrel is turned in the opposite direction, to wind up the weight, by the action of a windlass on the axis of the wheel *d*, which engages the toothed wheel *e* on the axis of the barrel, the wheel *a* will not turn back with the barrel. *f* is the pinion which is turned immediately by connection with the first wheel *a*; and both this and the winding-wheel, or pinion, *d*, have their axes mounted in the plates of the clock-frame. The axis of the barrel and first wheel *a*, instead of being thus mounted, is attached to what may be termed a lever-frame, one side of which is seen in the cut at *g*, *h*, *i*, which is itself pivoted to the clock-plates at *h*, and to the end *i* of which the end of the line *k*, *l*, is attached, after passing under a running pulley attached to the weight W. *c* is an internal ratchet on the first wheel *a*, acted upon by the long click *m*, which has its opposite end attached to the lever-frame near its extremity *i*. While the clock is going in the ordinary way the descent of W causes that part of the line marked *l* to turn the barrel in the direction of the arrow, carrying with it the first wheel *a*, the internal ratchet of which slips under, without being affected by, the click *m*. Under these circumstances the action of the weight W (through the line *l*), and the resistance of the pinion *f*, produce a certain pressure on the lever-frame at *g*, which causes the end *i* to assume a determinate position, in which it remains without motion so long as the weight continues to descend, and consequently to draw down the line *l*; but so soon as, by the operation of winding up the clock, the pressure upon *l* ceases to operate, the stress of the weight upon the portion of the line marked *k* causes the end *i* of the lever-frame to be depressed, and the click *m*, which is connected with it, to be thrust against the internal ratchet *c* with sufficient force to maintain the action of the first-wheel *a*, which turns as it were in one piece with the lever-frame round the axis *h*, thereby producing a pressure upon the pinion *f* exactly corresponding, if the axis *h* corresponds with the point at which the strain of the line *l* is applied to the rope-barrel, to the pressure which is exerted during the ordinary action of the machine.

The machinery connected with the Exchange clock for chiming tunes upon a set of large bells in the turret has been constructed by the same gentleman as the mechanism of the clock itself; but, owing to difficulties in the tuning of the bells, it is not yet (Nov. 1845) brought into action. These chimes will be the first constructed in this country to play tunes in harmony, two or more notes being struck simultaneously upon different bells, whereas in most cases the melody is produced in single notes, without the introduction of chords, which not only requires the machinery to be more complex, but renders it necessary to bring the bells into more perfect tune than is necessary for ordinary chimes.

HORSE-RADISH. [COCHLEARIA ARMORACIA, P. C. S.]

HORSE-SHOE. [HORSE, P. C.]

HOSIERY. [WEAVING, P. C.]

HOSPITALLERS. [TEMPLARS, P. C.]

HOTTO'NIA, a genus of plants belonging to the natural order Primulaceæ. It has a 5-parted calyx, divided almost to its base; the seeds, with the hilum, close to one end; the stamens, 5, inserted and included in the tube of the corolla; the capsules many-seeded and 5-valved, with 10 teeth. *H. palustris* has the flowers whorled, stalked, and seated upon a long solitary cylindrical common peduncle, the corolla longer than the calyx, the leaves pectinated. It is a native of Great Britain in ponds and ditches, and is called the Water-Violet. The leaves are submerged and crowded; the flowers rising above the water are of a purple and yellow colour. It is a pretty plant, but possesses no useful available properties.

(Babington, *Manual of British Botany.*)

HOUBRAKEN, the name of two distinguished Dutch artists, father and son—

ARNOLD HOUBRAKEN, the father, was born of a good family at Dort, in 1660, and was the pupil of Samuel van Hoogstraten. He painted history and portrait, and executed many designs for booksellers. He lived chiefly at Amsterdam; and he visited this country and remained here eight or nine months, for the purpose of making drawings of some portraits by Vandyck, which were engraved by Van Gunst. Houbraken is, however, chiefly known for his account of the lives of Dutch painters, with portraits engraved by his son, in continuation of Van Mander—'Groote Schouburg der Nederlantsche Konstschilders en Skilderessen,' in three parts. The first and second parts were published at Amsterdam in 1718 and 1719, for the author; the third part was published in 1721 for his widow: Houbraken died in 1719.

JACOB HOUBRAKEN was an admirable engraver; in execution he has never been surpassed, and perhaps seldom equalled. He was born at Dort in 1698, and accompanied his father when very young to Amsterdam. The excellent etched portraits of painters in his father's 'Groote Schouburg' are among his earliest works, yet they are certainly some of the finest etchings in existence. The most beautiful specimens, however, of Houbraken's engravings are some of 'The Heads of Illustrious Persons of Great Britain,' published in London by the Knaptons in 1748: the excellence of some of these heads must be seen to be comprehended. Vertue was a good engraver, and executed a few of the heads in this collection; but his inferiority to Houbraken was so apparent that the Knaptons ceased to employ him on that work. Some of the heads, however, which were engraved by Houbraken, though of the highest excellence as works of art, want authenticity as portraits, as, for instance, those of Carr, Earl of Somerset, and Secretary Thurloe, which Walpole says are spurious. [VERTUE, GEORGE, P. C.] The collection is notwithstanding of great historical interest. Houbraken engraved also a great number of portraits of distinguished Dutch characters. He died in 1780.

(Van Gool, *Nieuwe Schouburg der Nederlantsche Kunstschilders*, &c.; Watelet, *Dictionnaire des Arts*, &c.; Huber, *Manuel des Amateurs*, &c.)

HOUSE. [HOUSE, P. C.] A general outline of the principal features in the construction of houses being given under BUILDING, P. C. S., and in the various articles in P. C. and P. C. S. which are referred to under that head, the sole object of this article is to supply one of the articles of the series there pointed out, which, in consequence of an accident, was unavoidably omitted under its proper title, FLOOR.

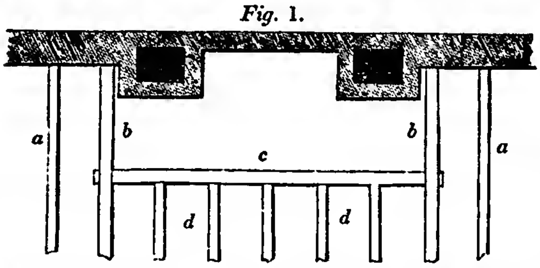
In an extended sense, the name floor is sometimes applied, collectively, to all the apartments and passages in a house upon one and the same level, in which sense it is almost synonymous with story. In a more literal sense however the floor is the level platform which forms the lower horizontal side of such apartments, and the under surface of which either constitutes or supports the upper horizontal side, or ceiling, of the apartments of the story immediately beneath it. While the external walls of a house usually afford the principal support of the floors, the internal or partition walls should be made to bear their share of the weight and strain; and where, as in the case of shops, warehouses, and public buildings, partition walls cannot be allowed, the support of the upper floors, supposing the span to be too great for being sustained by the external walls alone, may be assisted by means of brick piers or iron columns. Where, owing to the subdivision of the upper stories into smaller rooms than the lower stories, quarter partitions are fixed without any support from beneath, they may, as explained under CARPENTRY, P. C. S., p. 293, not only be so constructed as not to throw any weight upon the floor, but, if necessary, so as to assist in supporting it.

An ordinary wooden floor may be considered as consisting of two distinct parts: the actual flooring, or platform of boards upon which we tread; and the framework of timbers, commonly called the *naked* or *carcass flooring*, upon which the boards are laid, and which may be constructed in various ways, according to the strength required, and the span or width of the area to be covered. The simplest, and, under ordinary circumstances, the strongest kind of carcass flooring, or, as it is sometimes called, *floor of joists*, is that known among carpenters as a single framed floor, or, according to some writers, single flooring, which consists of a single row or horizontal tier of timbers called *joists*, or, more specifically, *floor* or *flooring joists*, which, in order to dispose their strength in the most efficient manner, are made much deeper than they are wide, the ends of which are supported upon the walls, or in some cases, where the walls are too far apart, upon stout beams called girders, which may be strengthened by trussing. To the upper edges of these joists the flooring-boards, which lie across them at right angles, are secured, while their lower edges support the laths upon which the ceiling of the room beneath is formed. The ends of the joists rest upon timbers let into the wall, called *wall-plates* [BUILDING, P. C. S., p. 248], by which the weight of the floor is equally distributed along the wall; the connection between the joists and the wall-plates being formed by cogging or cocking, or, as it is sometimes termed, *corking* or *caulking*, as illustrated under ROOF, P. C., p. 148, *Fig.* 25. Sometimes, in inferior buildings, the ends of the joists are laid immediately upon the brickwork, without the intervention of wall-plates; but such a practice is highly reprehensible, as it not only causes the stress of each joist to press on the bricks immediately beneath it, to the exclusion of those on each side, but also prevents that evenness and solidity of bearing which is necessary to keep the joists to a true level, that the pressure of the flooring-boards upon them may be uniform. Joists for a single framed floor should never be less than about two inches thick or wide, because of their liability to splitting with the operation of nailing down the boards, nor should they be much more, because, as will be better understood from PLASTERING, P. C. S., any increase in the width of their under edges interferes with the key or hold of the plaster, which arises from its passing up between, and swelling over, the laths. To remedy this inconvenience, where thick joists are used, narrow fillets may be nailed along their lower edges to receive the laths, instead of nailing the laths immediately to the joists. Such fillets are called *furrings*, and their application, either for the above-mentioned purpose, or for the purpose of rendering the ceiling perfectly flat, which a floor of joists never is, especially upon its under surface, owing to the roughness and warping of the timbers, is termed *furring-down*. *Furring-up* is the contrary operation of laying slips on the upper edges of such joists as may happen to be below the proper level, in order to produce a perfectly horizontal bed for the flooring-boards. The depth of the joists, and their distance apart, may be varied according to circumstances, the former ranging from about nine inches to fifteen, and the latter being usually twelve inches, though a distance of twelve inches from centre to centre, leaving an interval of about ten inches, is to be preferred. The strength of such a floor may be increased to any degree by increasing the depth of the joists and diminishing the intervals between them.

The buckling or twisting of the joists, by which the strength of the floor would be greatly impaired, is guarded against by the introduction between them of small diagonal struts or braces, as represented in the cut *Fig.* 2, in a subsequent column; these struts being introduced in lines or rows extending completely across the width of the floor, at right angles with the direction of the joists, and at intervals of not more than five or six feet. These struts are not commonly notched into, but simply skew-nailed to the joists, but their effect would be increased by either notching the joists to give them a proper bearing, or, without cutting into the joists, by nailing triangular fillets to them to afford abutments for the struts. In some cases solid pieces of wood cut to fit the intervals between the joists are used instead of diagonal, or, as it is sometimes called, *herring-bone* strutting; and, whatever be the form of strutting employed, it is advisable in cases where the floor will have to bear great weight to make the struts approximate very slightly to the wedge-shaped form of the voussoirs of an arch, in which case the floor may, by the addition of iron tie-rods passing through the joists, rather below the middle of their depth, be forced up into a convex form, whereby its strength will be enormously increased.

When a timber floor is carried near to a chimney or fire-place it is necessary to cut off the joists at some distance from the brickwork, to prevent the risk of fire. In such a situation the carpenter has recourse to what is termed *trimming*, which may be understood from the subjoined ground-plan of part of a floor of joists, abutting against a wall in which is a fire-place with chimney-flues in the jambs. In this cut *a*, *a* are two of the ordinary joists, the ends of which are supported in the

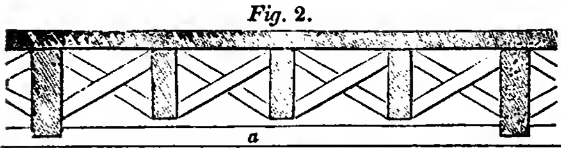
Fig. 1.



usual way upon wall-plates; *b*, *b* are two joists made somewhat thicker than the rest, on account of the extra strain thrown upon them, and called *trimming-joists*; *c* is a piece of timber called a *trimmer* or *trimmer-joist*, the ends of which are formed into tusk-tenons, which pass completely through the trimming-joists, and are secured by keying or wedging in such a way as to prevent them from separating; and *d*, *d* are the *trimmed joists*, or those which, being cut off short of the wall, have their ends supported by being framed into the trimmer. The stone slab in front of the fire-place is supported over the vacant space between the trimmer and trimming-joists by a flat brick arch, sometimes called a *brick trimmer*, turned between the wall on the one side, and a piece of wood called a *springing-piece*, which answers the purpose of what engineers term a skew-back, attached to the trimmer, on the other side. When the direction of the joists is parallel to that of the wall in which the chimney is formed, the arrangement is of course somewhat different; one strong trimming-joist then takes the place of the trimmer *c*, and two short trimmers are put in the place of *b*, *b*.

The chief objections to the use of single flooring are, that the construction offers little obstruction to the transmission of sound from one story to another, and that, for the sake of the ceiling, the joists must be made thin. Both of these defects may be in some measure overcome by the arrangement shown in *Fig.* 2, in which every third or fourth joist is made an inch

Fig. 2.



or an inch and a half deeper than the rest, and a series of slight bars called *ceiling-joists*, one of which is shown in the cut at *a*, is nailed, or notched and nailed, to these deeper joists, so as not to touch the intermediate joists, and to these the ceiling laths are nailed. By this arrangement the joists may be made of any required thickness, and the ceiling is in a great degree relieved from the injurious vibration of the floor: and the effect of the shrinkage of the joists, which would cause the ceiling to crack.

In a *double*, or more properly a *double-framed floor*, three sets or tiers of joists are used, of which the middle set, called *binding-joists*, or simply *binders*, form the real support. These reach from wall to wall, or from one primary point of support to another, at intervals which may vary according to circumstances, but are usually about six feet; and they are surmounted, at right angles with their own direction, by a series of smaller joists, called *bridging-joists*, which may, if it be important to save depth, be notched on to them, and upon which the flooring-boards are laid. Beneath the binding-joists is a set of yet smaller *ceiling-joists*, similar to those in the construction illustrated by *Fig.* 2. If it be necessary to save depth in fixing these also, care must be taken to notch only the ceiling-joists themselves, because, as should always be remembered, the fibres at the lower edge of the binding-joists (or of the flooring-joists in a single floor) are always in a state of tension, and therefore cannot be cut through without materially impairing the strength of the joist, while those towards the upper edge are in the opposite state of compression, and may consequently be cut without danger, provided that the notches made in them are filled with an incompressible substance. As, however, timber, even when well seasoned, is more compressible laterally than longitudinally, or across than along the grain, it is obviously better to avoid cutting into even the upper edge of the binders, because the bridging-joist, though it may fit the notch in the binder very tightly, will inevitably be more liable to compression than the portion of the binder which is cut away to receive it. Sometimes the ceiling-joists, instead of being fixed underneath the binders, are cut into short lengths and fixed between them, with only a sufficient degree of projection below them to keep the ceiling clear of the binders. Some builders, in such a case, mortice the ceiling-joists into the binders, employing a chase mortice at one end to allow the ceiling-joist to be slipped laterally into its place after the binders are fixed; but as the mortices cannot fail to weaken the binders, it is far better to nail projecting slips within the lower edges of the binders, and to notch the ends of the ceiling-joists so as to fit on to, and be supported by them. In either plan it is necessary to nail small pieces of wood beneath the binders to connect the ends of the short ceiling-joists, in order that the hold for the laths may not be interrupted. Bridging-joists must be distinguished from the short pieces of timber called *bridgings* which are fitted between the joists when a quarter partition is to be put up across them, to support and afford facilities for nailing down the sill of the partition.

In floors of great span, girders, which are large beams usually supported by templates let into the walls [Building, P. C. S., p. 248], or by iron columns, are used in conjunction with binding, bridging, and ceiling joists. *Girders*, which are used for longer bearings or spans than binding-joists can be trusted for, are, when of timber, made of one or more pieces according to the length required and the size and strength of timber that can be obtained; but in modern buildings they are very frequently made of cast-iron, pieces of wood being sometimes bolted along each side, to afford facilities for fitting the binding-joists, which are usually secured to the girders by tusk-tenons. By the aid of trussing, which, however, is of very doubtful value if the depth of the truss be, as it frequently is, limited to that of the beam, girders may be strengthened to any required degree, whether they be made of wood or iron. The principles upon which this is effected are explained under Trussing, P. C., pp. 318, 319, where is also a notice of Mr. Smart's suggestions for the further introduction of wrought-iron into floors and roofs.

The size or scantling of the various timbers in a double framed floor must of course vary with circumstances. Nicholson, in his 'Architectural Dictionary,' art. 'Carcase Flooring,' says that binding-joists may be about ten inches by four, bridging-joists five inches by two and a half, and ceiling-joists about three inches by two inches and a half; the intervals being from four to six feet between the binders and eleven or twelve inches between the bridging and ceiling-joists. In the article 'Naked Flooring' in the same work he gives a minute account and illustrations of plans for constructing floors with very short timbers only; but however valuable such plans may be in peculiar cases, they are, so far as the ordinary operations of the carpenter are concerned, more curious than useful.

Thorough seasoning is highly important for all the timbers of a floor, and especially so for the boards which constitute the flooring itself. For this purpose yellow deal is considered the best, especially when exposed to damp. For good work, flooring-boards should be planed and exposed to the air for at least twelve months before they are used, the reason for planing them before this exposure being that the operation of planing opens the pores and causes the sap to flow. Many builders rear up their flooring-boards against a rack formed of scaffold-poles, the boards being placed alternately on each side of the rack, with their edges presented outwards, and a sufficient space between them to allow the air to circulate freely. The chief objection to this plan, as commonly practised, is that the lower ends of the boards become damp by resting on the ground; but this is easily remedied hy the simple plan of laying a horizontal pole along the foot of the rack to support the lower ends of the planks, and securing it a few inches above the ground, either hy lashing it to the rack or propping it up with hricks. The laying of the floors should in no case be commenced until the building is covered in, and is better delayed until the windows are glazed and the plaster dry; it being very essential both to appearance and comfort that the shrinkage of the boards after they are laid should be reduced to the least possible amount. On this account, also, narrow boards are preferred for flooring, battens of seven inches wide being very extensively used. Sometimes much narrower pieces, formed by cutting planks into two or more widths, are employed, especially in superior houses, where a second planking of wide but very thin boards is laid over the principal floor as a kind of veneering or finish. An inch may be considered the least thickness which can be proper for flooring-boards, although, as shown under BATTENS, P. C., p. 42, inferior rooms are frequently laid with boards of which three are cut from a batten originally undor three inches thick. Ingenious machinery has been contrived and extensively used for the sawing and planing of flooring-boards; but such machines are frequently ohjected to as causing a considerable waste of timber, by cutting away much more, in width as well as in thickness, than it is needful to do in dressing them by hand. Hebert (*Engineer's and Mechanic's Encyclopædia*, art. 'Flooring-Machine') gives a description and representation of such a machine, invented hy Mr. Muir, of Glasgow, and which has been hrought into use in several extensive estahlishments, by which, whilo the simple planing of the surface may be performed with facility, it is also easy to saw the edges at the same time, and, if required, to cut grooves in them for the purpose of tongueing the joints.

The most common mode of laying floors is by the operation termed *folding*, the floors thus laid being termed *folded floors*. In this operation one board is first laid down and secured firmly by nailing to the joists. Another is then laid down and fastened in like manner precisely parallel with it, but at such a distance from it as barely to leave room for two, three, four, or any other determinate number of intervening boards. When, therefore, these intervening boards are laid in the place provided for them, being rather too wide for the space, they buckle up in the form of an arch. Boards arc then laid across them, and upon these boards two or three men jump until the flooring-boards are forced down flat to the joists, to which they are securely nailed. Another portion of the floor is then laid in the same manner.

The edges of the boards in a folded floor must of necessity be plain or square, and the boards must be nailed to the joists near both edges, in consequence of which it frequently happens that in shrinking they split or crack along the middle. In superior floors joints formed hy ploughing and tongueing, or by rebating and lapping the adjoining edges, are often used. Boards thus jointed may be nailed at one edge only, therehy allowing for the movement consequent upon shrinkage, without impairing the air-tight character of the floor, which is not only important for comfort, but also as a check to the progress of fire. The best floors are dowelled, and nailed at one edge only, the nails being driven in ohliquely through the edge, so as not to show at all on the surface. Some workmen insert the dowels over the joists only, and others only over the interjoists, but perhaps tho best way is to put them sufficiently close to have one over every joist, and one over every interval or interjoist. The gauge for the dowels should be run from the under surface of the board, which should be straightened for the purpose. Flooring-boards, when worked hy hand, are generally left rough on the under surface, excepting for a short distance from each edge, the intervening portion being merely smoothed with an adze at the points where the board crosses the joists, to enahle them to find a level bed. In order to force the boards of a floor laid otherwise than hy folding up to one another as close as possihle, some carpenters employ an ingenious and very efficient machine called a *flooring-cramp*, invented by Mr. Andrew Smith, and fully described, with an engraving, in Hebert's work above referred to. It consists of a lever of what is termed the second class, in which the fulcrum is at tho lower end, pivoted to an iron box made to fit and slide upon one of the joists, upon which it may be fixed at any desired point by driving a wedge. Being brought close to tho edge of a fresh-laid board, the workman seizes a handle at the end of the lever, and by drawing it towards him, forces a plate of iron with great energy against the edge of the board, and makes the joint exceedingly close. In using either this cramp, or the cheaper substitute for it called a *dog*, it is wel. to lay a loose fillet between the cramp and the edge of the board, to preserve it from injury by the force exerted. Any floor thus laid a plank at a time is said to be *straight-jointed*, as distinguished from a folded floor.

The heading-joints, or those between the ends of the flooring-boards, may be either square, bevelled, or ploughed and tongued. In dowelled floors the heading-joints must be hroken, or so arranged as not to come opposite to one another, and the same precaution is advisable in other floors also, though impossihle in a folding floor.

Flooring is measured hy the *square* of 100 square feet.

Respecting the construction of floors with special reference to safety from fire something is said under FIRE-PROOF BUILDINGS, P. C. S., p. 576. The mere circumstance of a floor being air-tight, which it can only be hy virtue of excellent workmanship and some peculiarity of construction, is a very important preservative against the spread of fire, and is also useful hy enabling the builder to introduce a current of air among the timbers hy means of iron air-hricks, without occasioning any unpleasant draught in the rooms. It is always highly important, for the preservation of the timber, to do this in the case of floors laid in a basement story, which rest upon what are termed *ground-joists* laid upon brick or stone piers or dwarf walls; and in many of the best London houses it is also done for upper floors, the air-hricks being sometimes concealed hy architectural decorations. Besides preserving the floor, the air thus admitted is sometimes allowed to enter the chimneys through the jambs for the sake of producing a good draught, while the connection with the atmosphere affords the means of ventilating the rooms beneath by concealed apertures in the ornaments of the ceiling. A method of laying floors which is adopted in some buildings of a superior character, and which is very effectual both in rendering the floor air-tight and in checking the transmission of sound through it, consists in laying a kind of secondary floor of short rough pieces of wood upon fillets nailed to the sides of the joists, about midway between their top and bottom edges, and covering it with a kind of coarse mortar called *pugging*, which is allowed to dry before the flooring-boards are laid, and upon which is sometimes laid a stratum of hroken sea-shells. This secondary floor, or *sound-boarding*, consists of thick laths, or slips of wood not exceeding an inch or an inch and a half in width, with the joists a little open, that the pugging may key to it like plaster to the laths of a ceiling. In the first-rate houses in which this plan is adopted, the floor is first laid with very narrow boards, often not exceeding two or three inches, between which, at intervals of a few feet, a small opening is left to allow the perfect evaporation of moisture from the pugging. This first floor of narrow boards, which, from their trifling width, are incapahle of warping to any serious extent, is the only one laid until the completion of the painting, and all that is likely to occasion injury to the boards, after which they are covered with a surface flooring of thin boards of superior quality, which, if it be desired in order to produce any ornamental pattern, may cross the joints of the under flooring in any direction.

Tho practice of laying wooden floors above a vaulting of hrickwork is alluded to under FIRE-PROOF BUILDINGS. This is accomplished in various ways, the joists frequently resting upon wooden sleepers laid along the crowns of the arches and the upper ribs of the iron girders from which they spring; dwarf walls or piers being raised where it is necessary to provide a level support for the sleepers. Though the spandrils may be filled up with brickwork or concrete, a space for the free passage of air should always be left between the hrickwork and the timbers of the floor. Stone floors or pavements are also noticed in the article above referred to. Under ordinary circumstances they are laid upon brick arches, hut they are occasionally laid upon timber framework. Slate pavements are occasionally used in puhlic buildings, and have been very highly recommended for the floors of warehouses. The extraordinary strength and durahility of this material, which may be safely employed much thinner than the best flagstones, render it peculiarly fit for such an application; and the facility with which, owing to its non-absorbent character, it may be cleaned by washing, has been found a great recommendation for the floors of dock-warehouses, where sugar and other things are liable to be spilt. Floors of sheet-iron have been constructed in some fire-proof huildings, the Pantechnicon, for example; but they are inconvenient from their extreme slipperyness.

In the basement story of some houses, and more especially in out-buildings, floors or pavements of bricks and tiles are used. Brick paving may be either flat or on edge, and may be laid either in dry sand, in mortar, or in cement. The better kinds of brick pavement are laid with a peculiar kind of hard brick made for the purpose, and sometimes used also in building, under the name of *marl* or *malm paviours* or *pavers*. Flat brick pavement is very fragile, and is damp from the earth upon which it is laid; but brick-on-edge pavement is in some cases superior to stone, supposing the stone to be laid immediately upon the ground. When used for beer-cellars, pantries, dairies, or stables, brick-on-edge pavement laid in dry sand is convenient from the facility which it affords for the escape of fluids spilt upon it. Some paving bricks are made to differ from common bricks in having both sides flat, and being only two inches or two inches and a half thick. A small hard kind, called Dutch clinkers, is used almost exclusively for brick-on-edge *herring-bone* pavements, in which the bricks of each course are inclined at an angle of 45° to the direction of the course; and each course is inclined in the opposite direction to the adjoining one. Square paving tiles, laid in courses like stone pavements, make a very neat-looking but not very durable pavement. Brick-and-tile pavements admit of considerable variety and ornament in the colours and disposition of the component parts, especially in connection with the use of encaustic or enamelled tiles bearing devices in several colours. [TILES AND PAVEMENTS, P. C. S.]

Floors of cement are occasionally used in fire-proof buildings over brick vaulting, the spandrils being filled up with concrete to form a level surface to receive the cement. This is occasionally done in private houses in preference to surmounting the vaulting with a wooden floor. In some places floors, even for upper stories, are formed of a kind of coarse plaster, spread upon laths or reeds. Such floors are cheap, and in some degree fire-proof, but their surface is very apt to wear into holes. Floors of tempered earth, or of various compositions of lime, sand, and ashes, thoroughly incorporated with each other and bound together by mixing with ox-blood, are also occasionally used for cottages and agricultural buildings, and may be made very durable. Floors or pavements of asphalte are noticed under ASPHALTE, P. C. S., p. 145.

(Nicholson, *Architectural Dictionary*, arts. 'Floor,' 'Carcase Flooring,' and 'Naked Flooring;' *Encyclopædia Britannica*, art. 'Building,' by Mr. Hosking; &c. &c.)

HOUSE-BREAKING. [LAW, CRIMINAL, P. C. S.]

HOUSE-LEEK. [SEMPERVIVUM, P. C.]

HOWELL, JAMES, the son of a clergyman in Wales, was born near Brecknock, about the year 1596. He was educated at Jesus College, Oxford, where, in 1613, he took his bachelor's degree, but then left the university. His father's family was numerous, and he had to shift for himself. Several men of rank having set up a patent glass-manufactory in London, Howell was appointed to be their steward or manager; and in 1619 he undertook for his employers a tour on the continent, in the course of which he visited Holland, Flanders, France, Spain, and Italy. Returning home in 1621, he was elected a fellow of Jesus College. He next travelled as tutor to a young gentleman; after which he was sent to Madrid to negotiate the restoration of a confiscated merchant vessel. His skill and activity in business had now made him well known. In 1626, after having been treated with for a diplomatic appointment, he became secretary to Lord Scrope, the president of the North, and was next year chosen to sit in parliament for the borough of Richmond. In 1632 he went to Denmark as secretary to an extraordinary embassy; and on his return he continued to be for some time unemployed, visiting Ireland to seek service under Strafford, but being disappointed by that nobleman's fall. In 1640 his diversified services were rewarded by an appointment to the clerkship of the council at Whitehall; but the breaking out of the civil war soon made his place dangerous, and in no long time deprived him of it. In 1643 he was committed to the Fleet, where he was detained till after the king's death. He was penniless, and even in debt; but, with his characteristic versatility and spirit, he set about writing for the press, by which he contrived to maintain himself, both during his imprisonment and afterwards under the Protectorate. A little flattery which he had found it convenient to administer to Cromwell was forgiven at the Restoration, when the place of historiographer royal was created as a means of providing for him. He retained this office till his death, which happened in November, 1666. He was buried in the Temple church. Howell's writings are very numerous. A few of them are in verse, the principal being his 'Dodona's Grove, or the Vocal Forest,' 1640, which he himself translated into French. But his prose works alone deserve remembrance; and of these there are not a few which either were pamphlets of temporary interest or translations of historical pieces from the French and Italian, and were forgotten even in his own time. Howell's name is preserved by the good sense, sagacity, and liveliness of his letters, which were the earliest collection of the kind published in our country. They were whimsically called 'Epistolæ Ho-Elianæ; familiar Letters, domestic and foreign, partly historical, partly political, and partly philosophical.' The first volume appeared in 1645, the fourth and last in 1655, and they have since gone through many editions.

HUCHTENBURG, JOHAN VAN, a celebrated Dutch battle-painter, was born at Haarlem in 1646. He studied with Vandermeulen at Paris, and etched some of his designs. In 1708 or 1709 he was commissioned by Prince Eugene to paint the series of battles which he and the Duke of Marlborough had gained together. Huchtenburg himself made etchings of these battles in copper: they were published at the Hague in 1725. His pictures are much in the style of Wouverman, and are scarcely inferior to the works of that master. He lived chiefly at the Hague, but died at Amsterdam in 1733.

(Van Gool, *Nieuwe Schouburg*, &c.)

HUDSON, THOMAS, was born in Devonshire in 1701. He came to London and became the pupil of Richardson the painter, and married his daughter. After the death of Jervas and Richardson, Hudson was the most successful portrait painter in London, and, notwithstanding the rivalry of Vanloo and Liotard, he enjoyed the chief business in portrait painting until the return of his pupil Reynolds from Italy, when, though he professed not to admire his pupil's innovation in portraiture, he gave up business and retired to his villa at Twickenham. Northcote describes an interview between Hudson and Reynolds in 1752, soon after the return of the latter from Italy, though he does not vouch for the fact: —Hudson called on Reynolds to see a much-talked-of head of a boy with a Turkish head-dress—it was the portrait of the Italian boy Marchi, whom Reynolds had brought with him from Italy; 'perceiving,' says Northcote, 'no trace of his own manner left,' Hudson exclaimed, 'By God, Reynolds, you don't paint so well as when you left England!' Hudson himself had also just returned from Italy: he visited Rome, together with Roubiliac. He entered Italy as Reynolds was leaving it, and the rising and setting stars of portraiture in England met on Mount Cenis in their passage over the Alps.

There is little to be said of Hudson's style: he was of the Kneller school; he made fair transcripts of his models, with little variety of posture, and not much more of costume. His masterpiece is the family piece of Charles Duke of Marlborough, now in the hall at Blenheim: many of his works were engraved in mezzotint by the younger John Faber. There is a portrait of Handel by Hudson in the Picture Gallery at Oxford, which is said to be the only portrait that the great composer ever sat for: there is a portrait by him of Archbishop Potter in the same collection. Hudson was rich and contented. He had at his villa at Twickenham a very good collection of cabinet pictures and drawings by great masters; many of the latter were purchased at the sale of Richardson's excellent collection. He survived Richardson's daughter, and married Mrs. Fiennes, a lady of fortune, and to her he bequeathed his villa. He died in January, 1779.

(Walpole, *Anecdotes of Painting*, &c.; Northcote, *Life of Sir Joshua Reynolds*.)

HUGHES, JOHN, the son of a respectable citizen of London, was born in 1677, at the town of Marlborough, in Wiltshire. He was educated in London, chiefly at a dissenting academy, where Isaac Watts was one of his fellow-pupils. His natural turn for study was encouraged by the delicacy of his health, which made his friends well pleased to obtain for him a small income in the public service. He held a clerkship in the Ordnance-office, and was secretary to several commissions issued under the great seal for improving harbours. In 1717, too late to permit him to enjoy affluence long, he was appointed by Earl Cowper to be clerk to the commissions of the peace. Several occasional poems and translations, the earliest of which, in 1697, celebrated the peace of Ryswick, introduced him to the acquaintance of Addison, Pope, and other literary men, whose liking he was well qualified to secure by his good temper and want of pretension. When Addison's critical friends, on reading the first four acts of

'Cato,' had condemned it, Hughes dissented, and insisted on its being completed; and although the author afterwards completed it himself, yet Hughes was in the first instance intrusted with that task. Hughes wrote a tragedy called 'The Siege of Damascus,' which is inserted in several modern collections, and merits its place for the excellence it possesses in language and in lofty and refined feeling. It was acted for the first time on the 17th of February, 1720, and received much applause. The author that night lay on his death-bed; and he e.pired before morning. Hughes was skilled also in music, and was frequently employed to write poetical pieces for musical accompaniment. Among his productions of this kind wore English operas on the Italian model. But his best claim to remembrance rests on his having been one of the most frequent assistants of Addison and Steele in their periodical essays. He wrote some papers for the 'Tatler' and 'Guardian;' and to the 'Spectator' he contributed eleven numbers and a good many letters, being more than the quantity furnished by any other of the minor writers, except Tickell and Budgell. He edited respectably the works of Edmund Spenser, and translated Molière's 'Misanthrope,' and Fontenelle's 'Dialogues of the Dead.'

HUMBOLDT, KARL WILHELM, BARON VON, one of the most distinguished linguists of his time, was born at Potsdam, near Berlin, on the 22nd of June, 1767, and after having received a careful education, together with his celebrated younger brother, the Baron Alexander von Humboldt, studied law in the universities of Göttingen and Jena. At Jena he formed an intimate and lasting friendship with the poet Schiller, who had great influence over him, and early turned his attention towards those studies in which he afterward rose to great eminence,—philology, philosophy, and æsthetics. Humboldt wrote at an early age several essays and memoirs, and made translations from the Greek philosophers and poets, which appeared in different Reviews in Germany; but though he was distinguished by his talents from most of his equals in age, he examined himself carefully before he entered upon any subject with a view to publish his ideas. He was thirty-three when he published his first great production, a critical essay on Göthe's poem Hermann and Dorothea: but this work at once established his fame, and it is still considered as a model of æsthetical criticism. After Humboldt had left Jena (1793) he carried on a correspondence with Schiller, which was published at Stuttgart, in 1830, and which is one of the most remarkable collections of private letters that have ever been printed. They exchanged their ideas on various topics, especially on metaphysics, poetry, and history; the letters are extremely clear and well written, and those of Humboldt are quite as interesting as those of Schiller. It is pleasant to see that these two eminent men were just towards each other with regard to their respective accomplishments and deficiencies, as will be seen from Schiller's judgment of Humboldt in another part of this article. In 1802 Humboldt was appointed resident, and a few years afterwards minister plenipotentiary at the Holy See. After his return from Rome, in 1808, he was made chief of the departments of religion and public instruction in the home ministry, but tendered his resignation two years afterwards, and for some time retired to his seat at Tegel, near Berlin, where he devoted his time exclusively to literature, till, in 1812, he was sent as ambassador to Vienna. In this capacity he took part at the Conferences of Prague in the summer of 1813, where, after long negotiations, Austria gave up her neutral position and espoused the cause of Prussia and Russia. During the campaigns of 1813 and 1814 he was in the head-quarters of the King of Prussia, Frederic William III.; assisted at the conferences of Châtillon; signed with Hardenberg the Treaty of Paris; and after the peace returned to Vienna, where he discharged the functions of minister-plenipotentiary of Prussia, together with Hardenberg, at the Congress of Vienna. The treaty of 1815, through which the King of Saxony lost one-half of his kingdom, which was given to Prussia, was contrived and signed by Humboldt. He continued his diplomatic career at Frankfort, where he made himself conspicuous through his conciliatory eloquence in the delicate business of dividing Germany among its princes, and afterwards as ambassador at the court of St. James's, which he left during a short time in order to assist at the Congress of Aix-la-Chapelle. In 1819 he was appointed minister and a privy councillor at Berlin. The retrograde policy of the King of Prussia was supported by the state-chancellor, Prince Hardenberg; but Humboldt and the ministers von Beyme and von Boyen tried to persuade the king to be faithful to those liberal principles which he had proclaimed in 1813, and especially advised him to keep the solemn promise he had given to introduce a general national representation. Unable to oppose a barrier to the king's policy, Humboldt, Beyme, and Boyen tendered their resignation, and Humboldt again retired to Tegel, where he henceforth devoted all his time to literature: he died on the 8th of April, 1835. During forty years he had enjoyed the well-deserved reputation of one of the greatest philosophers and linguists of Europe, and he was certainly an extraordinary man. The number of languages, most of them barbarous or half civilized, which he had thoroughly studied, besides the classical languages, was very great. He acquired the most difficult languages, as, for instance, the Basque, in fewer months than others would have spent years in learning them. He was equally distinguished for the views he took in comparing the development of languages with the development of the human mind, as well as in comparative grammar; and as a critic of the ideal in poetry, philosophy, and the fine arts, he had few equals in Germany. Humboldt was mediocre as a poet, and it seems he felt his inferiority in this respect, for after having published a few poems, he stopped. He left a great number of poems in MS., chiefly sonnets, most of which were afterwards published by his brother Alexander; but though they are beautifully written and of a most elegant and delicate versification, they are decidedly vague and too sentimental. Schiller, in a letter which was written when Humboldt first attempted authorship, speaks thus to his friend:—'I am convinced that the principal cause which seems to prevent your success as an author is the predominance of the reasoning faculties of your mind over the creating faculties, and consequently the preventive influence of criticism over invention, which always proves destructive to mental production. Your "subject" becomes immediately an "object" to you, although even in abstract sciences nothing can be created but by "subjective" activity. In many concerns I cannot call you a genius; yet I must avow that you are a genius in others. For your mind is of so particular a description that you are sometimes exactly the contrary of all those who are merely conspicuous through their reasoning faculties, through learning, or through abstract speculation. You will of course not attain perfection within the sphere of mental creation, but within the sphere of reasoning.' Schiller's judgment was at once frank and correct: the spirit of universal criticism was embodied in Humboldt, who, with the exception of one large work which he left unfinished in MS., composed only minor works, most of them critical essays, which he published at different periods. The greater part of them was collected by his brother Alexander, and published under the title, 'Wilhelm von Humboldt's Gesammelte Werke,' Berlin, 1841, 4 vols. 8vo.

The principal productions contained in the first volume are —Two Memoirs on the 'Bhagavadgita,' a Sanscrit poem, the first of which was first printed in the Memoirs of the Royal Academy of Berlin, and in Schlegel's 'Indische Bibliothek;' A Critique on F. A. Wolf's second edition of Homer's Odyssey, previously printed in the 'Jenaische Literatur-Zeitung' (1795); 'Rom,' a poem, first published at Berlin, 1806; 'Die Sonne' (the Sun), a poem, first published at Berlin, 1820; Twenty-five Sonnets, not printed during the author's lifetime. Those of the second volume are—'Prüfung der Untersuchungen über die Urbewohner Hispaniens vermittelst der Vaskischen Sprache' (Examination of the Researches on the Aborigines of Spain, by means of the Basque Language), first published at Berlin, 1821, 4to. This is a celebrated work, and has become the type on which many similar investigations have been modelled. Humboldt purposely went to the Basque provinces in order to learn the Basque language, and he confounded for ever the absurd theories of Laramendi and many other Basque and Spanish scholars on the origin of the Basque language, which most of them endeavoured to establish as the primitive language of mankind, and consequently of paradise. Humboldt's opinion is that the present Basques are the only unmixed descendants of the antient Iberians, and he shows that in remote times the Iberians inhabited the whole peninsula south of the Pyrenees, the southernmost part of France (Aquitania included), Liguria in Italy, and the islands of Sardinia, Corsica, part of Sicily, and the Baleares. In the time of the Romans the central part of Spain was inhabited by Celtiberians, a mixture of Celts and Iberians: the limits assigned by Humboldt to this mixed race, that is, the extent of country where the antient local names were not purely Iberian or Celtic, but mostly Celtic and Iberian compounds, correspond with those assigned to the Celtiberians by

Cæsar, Strabo, and other antient writers. In the countries inhabited by the Celtici (the southernmost part of Portugal) and tho Tamarici (Galicia), the antient names are so exclusively Celtic that the author concludes that both those nations were pure Celts. The Iberians, according to Humboldt, were of North African origin, and 'Berber' and 'Iber' are probably the same. The second volume also contains a Memoir on the Limits within which Governments ought to confine themselves in their care for the welfare of their Subjects; A metrical German translation of the 1st-6th, the 12th and 14th of Pindar's Olympic Odes; the 1st, 2nd, and 4th-9th of the Pythian Odes, among which No. 4 appeared first, with a commentary, in the 'Neue Deutsche Monatsschrift' (1795), and No. 9, with a commentary, in Schiller's 'Horen' (1797); the 4th, 6th, and 10th of the Nemean Odes; Forty-one Sonnets printed from MS., &c. The contents of the third volume are :—A metrical German translation of the Agamemnon of Aeschylus, first published, Leipzig, 1816, 4to., considered to be a masterpiece; a metrical German translation of the Choruses of the Eumenides; An Essay on the Drama in Franco, first printed in Goethe's 'Propylaeen;' Travelling Sketches from Biscay; A most interesting Memoir on Comparative Linguistic, treated historically, and first printed in the Memoirs of the Royal Academy of Berlin; Forty-two Sonnets from MS.; &c. The fourth volume contains—the celebrated critical essay on Goethe's 'Hermann and Dorothea' (268 pages), which the author first published in the first volume of his 'Aesthetische Versuche,' Brunswick, 1799, 2 vols. 8vo; An Essay on the influence of different Sexes on Organic Nature; Fifty-seven Sonnets, from MS. Humboldt's Essay on the Dual (Ueber den Dualis), Berlin, 1828, 4to., is not in this collection. During the last ten years of his life Humboldt was actively engaged in investigating the Malay and American languages; but finding the task above his strength, he abandoned the American languages to his friend Dr. Buschmann, for whom he afterwards obtained the place of chief librarian of the Royal library at Berlin, and he devoted his time exclusively to the Malay languages, on which he intended to write an extensive work. When he died, the first volume was nearly finished, and it was prepared for the press by Dr. Buschmann and Alexander von Humboldt, who published it, with a preface of his own, under the title, 'Ueber die Kawi Sprache auf der Insel Java,' Berlin, 1836, 8vo., which attracted the attention of all Europe. The greater portion of this work comprehends investigations of the progress of civilization from the continent of India towards the large islands in the Indian Sea, which he traces in the monuments, the languages, and the literature of the different Malay nations; and only a small portion is devoted to the examination of the Kawi language. The death of the author is the cause of this imperfection; but there is reason to hope that the subject will be thoroughly treated in a second volume, the materials of which he collected, but left in such a state as to require the labour of a perfect scholar before they can be published. Humboldt bequeathed all these and many other valuable materials, as well as a collection of rare MSS. and books, chiefly on linguistic, to the Royal Library at Berlin.

(*Neuer Nekrolog der Deutschen; Allgemeine Deutsche Real-Encyklopädie.*)

HUME, JAMES DEACON, born 28th of April, 1774, at Newington in the county of Surrey, was the son of Mr. James Hume, sometime secretary and afterwards a commissioner of the customs, and who was nephew of Dr. Hume, bishop of Salisbury. The subject of this notice was sent when very young to Westminster School, and in that establishment received during the head mastersships of Dr. Smith and Dr. Vincent the whole of his school education.

In 1790, when at the age of sixteen, Mr. Hume was appointed to a clerkship in the Custom House, where he soon became conspicuous for that energy of character which accompanied him through life, so that at an unusually early age he was appointed to fill an office of much responsibility in the department. It was a maxim with him, which he frequently uttered, that a man should never content himself with performing merely his own duty, but that he should at all times show alacrity in assisting every one requiring assistance, and in extending to the utmost of his ability the field of his usefulness. By carrying this maxim into his every-day practice, Mr. Hume undoubtedly secured his own advancement in life, and attained to his deservedly high reputation.

In 1798 Mr. Hume married. He had twelve children, eight of whom (daughters) lived to be women, and seven, with his widow, survived him. Shortly after his marriage he fixed his residence at Pinner, near Harrow, where he rented a considerable extent of land, and commenced practical farmer upon a large scale, not however neglecting his official duties, but giving daily attendance at his office, for which purpose he was, during a part of the year, obliged to leave home before daylight, returning to it after dark. He was always deeply interested in the science of agriculture in all its branches, and frequently in after-life referred to his practical experience as a farmer in support of those doctrines of political economy of which he became a zealous and enlightened advocate. In 1822 he was induced to relinquish his rural pursuits and again to take up his residence in London. By this time, his value had come to be highly appreciated by the government, by means of reports which it became his duty to prepare upon subjects connected with the revenue; and in the following year he was appointed to reduce into one simple code the many hundred statutes (upwards of 1500), often contradictory of each other, and not unfrequently unintelligible, which at that time formed 'the intricate and labyrinthine chaos' of our custom-house legislation. This work had become one of necessity for the guidance as well of tho government as of tho commercial world. To no other man could its performance have been intrusted with anything like the same propriety. Three of the most valuable years of his life were devoted to the task; and to the unremitting labour which he applied to its accomplishment, his friends attributed that inroad upon his bodily powers which was visible in the latter years of his life, and which, too probably, brought him to the grave sooner than with his originally excellent constitution was to be expected. The labour of the task was intense. During its progress he allowed himself no relaxation, and acquired the habit, which he afterwards continued, of working through the hours of the night and far into the morning. Of tho value of the work thus performed it is hardly possible for any one to form an adequate estimate who should not have been practically acquainted with the condition of disorder that previously accompanied an important branch of the public business, and into which the acts prepared by Mr. Hume introduced clearness, harmony, and regularity. In the eleven intelligible acts of parliament prepared under Mr. Hume's direction, and passed in 1825, everything was preserved that it was desirable to retain, while all that had become worthless in the many hundreds of repealed statutes was discarded. So intricate and confused had the laws indeed been rendered by successive patch-work pieces of legislation, that even those persons who had made it the study of their lives were often at fault in its application, and the practice of our tribunals upon this branch was frequently contradictory.

So sensible were the ministers by whom this work was intrusted to Mr. Hume of the ability with which it was performed, that he was presented by the treasury on its completion with the sum of 5000*l*. over and above the salary of his office, from the duties of which he had been relieved during the period devoted to the task; and thereafter scarcely any question of importance was decided having reference to the trade of the country without his opinion concerning it having first been obtained. So frequent did these consultations become, that a room was fitted up for his use in the office of the Board of Trade; and at length, in July 1829, his services were wholly transferred to that department, where an office was created for him as Joint-Assistant Secretary. In the performance of tho important duties thus intrusted to him, Mr. Hume used the same degree of zeal and intelligence which had marked his previous course, and which secured for him the respect and confidence of the successive chiefs of the department.

At the beginning of 1840 the inroads upon his health, caused by a long life of unremitting labour, were so apparent, that Mr. Hume's retirement from the public service became in a manner necessary. By this time he had completed forty-nine years of active service, forty-four of those years having been passed in situations of responsibility, and he was allowed to retire on a pension of the same amount as the salary attached to his office, which appears by a treasury minute presented to parliament, in which was expressed their lordships' 'full approval of his long and faithful services, accompanied by their regret that the public service would be deprived by his retirement of his great experience and of his profound and intimate acquaintance with the mercantile system of this country.' The regret thus expressed was in effect uncalled for, as on all occasions, up to the close of his life, on which his advice and experience were desirable, they were freely sought and communicated; and it is probable that at no time during his active career was he able to render more essential services to the best interests of commerce, than by the suggestions made by him after his nominal retirement, and especially by the evidence given by him before the Import Duties Committee of 1840, evidence which, having been frequently quoted with commendation by all parties in the House of Commons, has been brought forward to support measures of reform in our fiscal system proposed and carried in conformity with his recommendations.

After an illness of some weeks' duration, but from which no serious result was apprehended, Mr. Hume was seized with a stupor of an apoplectic character, and two days thereafter died, on the 12th of January, 1842, in the sixty-eighth year of his age.

Although Mr. Hume may be almost said to have lived with the pen in his hand, he published but little, the object of his labours being for the most part confined to the preparation of official papers, which may, nevertheless, have exercised a greater influence upon society than could have followed from the publication of his opinions. He wrote several papers upon subjects connected with commerce, which appeared from time to time in the British and Foreign Review. One of these papers, on the timber trade and duties, may be said to have exhausted the subject. He is better known as the author of a series of letters which, under the signature H. B. T., appeared first in the 'Morning Chronicle' and have since been collected, and more than once reprinted. These letters contain, within a very small compass, the most admirable and unanswerable arguments for various changes in our fiscal system, many of which have since been carried out, while others are evidently on the eve of adoption. Mr. Hume's style partook of the characteristics of his mind, which was vigorous and original.

In the private relations of life, Mr. Hume was remarkable for the most perfect sweetness of temper. With fewer of human weaknesses than are usually found to accompany even the more correct among us, he was ever indulgent to the failings of others; just in his dealings; true to his promises; with a largeness of generosity that, as such things are usually measured, ran beyond his means, and that was ever attended by the most scrupulous delicacy towards those who were its objects. His attachments were strong and stable, and he was the object of the most earnest affection to all who enjoyed the privilege of his close acquaintanceship.

HUMIDITY is that property of a substance by which it communicates to a body in contact with it some of a liquid which it may have absorbed; and the term is commonly applied to the atmosphere when it is in a state to deposit moisture upon bodies in it.

The humidity of the atmosphere is caused in a great measure by the evaporation of water from the seas, lakes, &c. of the earth; and the quantity of moisture which a volume of air is capable of containing depends upon the temperature: when the latter is low at any part of the earth's surface, the air may be saturated with moisture so as to be incapable of holding any more, but the quantity of moisture in a given volume will then be small. If the temperature be increased, the atmosphere, becoming thereby comparatively dry, acquires immediately the power of receiving more vapour, and the power increases with the temperature, so that, in a given volume of air, the quantity which consists with the state of saturation is also increased. Whatever be the quantity of vapour which constitutes the state of saturation, if the temperature be suddenly lowered, or if there be presented a body which has an affinity for water, a precipitation of the latter takes place, or water becomes absorbed in the body. [Dew, P. C.; Rain, P. C.]

The temperature of the atmosphere over any place on the surface of the earth diminishes as the distance of the stratum of air from the surface increases: the power of the air to hold vapour diminishes accordingly; and, as a general law, it may be stated that the humidity of the atmosphere decreases from the surface of the earth upwards. The great dryness of the atmosphere near the summits of mountains has been frequently remarked by travellers, but the quantity of moisture in the different strata is, from local influences, subject to many irregularities. The temperature of the lower strata of the atmosphere diminishing as the latitudes of places on the earth increase, a given volume of air, as a cubic foot, when completely saturated, will contain less water as a station is farther from the equator; and the like may be said of the entire column of the atmosphere over a station. This may serve to account for the fact that, in general, the weather becomes fine when the mercury rises in the tube of a barometer; for then, by the increased density of the air, the clouds are made to ascend in the atmosphere to a region where, the dryness being great, they are readily dissipated. On the contrary, when the mercurial column diminishes in length, the clouds descend; and arriving near the earth, they enter a region in which the atmosphere is at or near the state of saturation; when, consequently, the vapours are easily precipitated. Biot observes, on this subject, that the descent of the mercury is a more certain prognostication of rain than its ascent is of fair weather; the ascent of the clouds in consequence of an increased density of the air not being necessarily accompanied by their dispersion. From the agitation produced by high winds, the upper regions of the atmosphere are often charged with aqueous vapour; and rain may then fall while the top of the column of mercury is above its mean height, and even while it is rising in the tube.

The atmosphere often becomes humid from the evaporation of liquids by artificial means. In establishments for brewing, dyeing, and the like processes, the vapours produced from liquids which are constantly in a state of ebullition rise in the atmosphere, and even render it opaque. The breathing of men and animals produces a watery vapour which renders the atmosphere humid; and when a number of persons are assembled in a close apartment the humidity is sometimes so great that water flows down the walls. The leaves of plants also discharge, in the form of vapour, the water which is imbibed by the roots; and in conservatories this effect is particularly sensible.

In order to determine the quantity of water which is contained in earth when completely saturated with rain, Dr. Dalton took a quantity of garden mould, on which rain had fallen copiously during the preceding day, and exposed it to different degrees of heat. When it seemed to have about the same degree of moisture as soil at the depth of two inches from the surface in dry summer weather, he weighed it, and found that it had lost one-twelfth of its weight; and when it had lost two-ninths of its weight it seemed like the upper soil in summer. His conclusion is that a body of earth one foot in depth, when saturated with moisture, contains seven inches in depth of water, and that it may lose one-fourth or one-half of that quantity without becoming incapable of supporting vegetation.

The effects of humidity on the dimensions of bodies are various: when a watery vapour penetrates between the twisted fibres of cordage, which are vegetable materials, the cordage swells out transversely, and thus becomes shortened; while cords made of animal substances become relaxed by humidity and increase in length. Most salts absorb water, and thereby increase in weight.

HUMIRIA'CEÆ, a natural order of plants belonging to the syncarpous group of Polypetalous Exogens. It has the following essential character:—the calyx is in 5 divisions; the petals alternate with the lobes of the calyx and equal to them; the stamens hypogynous, 4 or many times as numerous as the petals, monadelphous; the anthers 2-celled, with a fleshy connective, extended beyond the 2 lobes; the ovary superior, usually surrounded by an auricular or toothed disk, 5-celled, with from 1 to 2 suspended ovules in each cell; the style simple, the stigma lobed; the fruit drupaceous, with 5 or fewer cells; the seed with a membranous integument, the embryo straight, oblong, lying in fleshy albumen; the radicle superior. The plants belonging to the order are trees or shrubs abounding in a resinous juice, with alternate, simple, coriaceous exstipulate leaves, and axillary corymbs of flowers.

The affinities of this order are not well made out. In their albuminous seeds and slender embryo they agree with Styraceæ, as also in their balsamic wood. They resemble Meliaceæ very much in habit and in their fructification, but the anthers and seeds of Humiriaceæ differ very much from those of Meliaceæ. Von Martius compares this order with Chlenaceæ, whilst Lindley thinks that their real affinity is with Aurantiaceæ; 'an affinity,' he observes, 'indicated by their inflorescence, the texture of their stamens, their disk, their winged petioles, and their balsamic juices.' There are three genera belonging to this order, *Humirium*, *Helleria*, and *Sacoglottis*.

Humirium (from *Oumiri*, the Guyanese name of one of the species) has 20 stamens joined into a tube, the alternate ones shortest, ciliated above, an annular disk 20-lobed, the stigma 5-lobed, the fruit containing a 5-celled nut, the cells 2-seeded. One of the species, *H. balsamiferum*, is a tree forty feet in height, with ovate oblong leaves half-clasping the stem, with a decurrent nerve on the back, the inflorescence longer than the leaves, the peduncles smooth as well as the petals This tree is a native of Guyana and Cayenne. Its bark is thick, and abounds with a red balsamic fluid, which resembles styrax in smell; after it has exuded from the tree it becomes hard and transparent, and when burnt affords an agreeable odour. The negroes and natives of Guyana use the bark in slips for the purpose of flambeaux; they also use the wood in building their houses. We have no account of the composition of this resinous juice, but Aublet suggests that it might be used as a substitute for the Peruvian balsam. The Creoles call this tree 'Red-wood,' on account of the colour of the wood. The other species of Humirium, and also those of Helleria and Sacoglottis, yield resinous juices.

HUNGARY. Among the kings of Hungary there are three of the name of Andrew, or Andreas, who deserve a short notice.

ANDREW I., the son of Prince Ladislaus the Bald, and the fourth king of the house of Arpad, reigned from 1046 till 1061. His predecessor, King Peter, in 1045, had offered Hungary as a fief to the Emperor Henry III. of Germany; but Andrew refused to take the oath of vassalage, and after a protracted war with the emperor, made a peace with him, in 1052, through which all feudal ties between Hungary and the empire were abolished. During the reign of this king the majority of the Hungarians were still pagans; but Andrew succeeded in introducing the Christian religion throughout his kingdom. Andrew fell in a battle with his brother Bela, who succeeded him on the throne.

ANDREW II., surnamed Hierosolymitanus, was the son of King Bela III.: he succeeded his elder brother Emeric in 1205, and reigned till 1235. During his long reign Hungary was shaken by disturbances and civil and foreign wars, caused by the reckless and ambitious character of Andrew, whose passions however were more violent than strong. Previous to his accession he waged war with his own brother Emeric, and raised a numerous army. They were encamped in sight of each other, when Emeric, a noble minded man, who knew that the partisans of Andrew followed him only through fear, went alone and unarmed, with only a white staff as the symbol of peace in his hand, to the camp of the rebels. When he was in sight of them, 'I shall see,' said he, with quiet dignity, 'whether you will shed royal blood.' None of them dared to stop him, and he thus surprised his brother Andrew in his own tent, and after having reproached him for his conduct, prevailed upon him to submit without making even an appeal to his followers. In this way Emeric carried Andrew from the midst of his own army, and kept him in prison till 1204, when Emeric, feeling his end approach, ordered Andrew to be brought before him, and appointed him guardian of his son Ladislaus, who was a minor. After Emeric's death, Andrew seized the royal authority and reigned in his own name, and fortunately for Hungary, the young Ladislaus died in 1205, so that Andrew became legally possessed of the supreme power which he had usurped. Andrew was a slave to his beautiful but ambitious queen Gertrud, a princess of Meran, whose conduct became so unsupportable that the principal Hungarian nobles conspired against her life, and during the absence of Andrew in Galicia, in 1213, they surprised her and put her to death. The conspirators were headed by the Magnate Banco, whom the queen had mortally offended; for in order to take revenge for a slight offence which she pretended to have received from Banco's wife, who was famed for her beauty and virtue, she prevailed upon her brother Berthold to violate the person of this lady, and she afforded him an opportunity of effecting his purpose in the queen's own apartments in the royal palace. In 1217 Andrew undertook a crusade, and made himself conspicuous in Palestine through his gallant deeds, but his final success was trifling, and he returned in 1222: thence he was called 'Hierosolymitanus.' Andrew took an important part in the Byzantine affairs of his time. After the death of the Latin Emperor of Constantinople, Peter of Courtenay, in 1217, the crown of Greece was offered to Andrew, who however declined it, and, in 1218, made a treaty of alliance with Theodore Lascaris, the Greek Emperor of Nicæa, who gave his daughter Maria in marriage to Andrew's eldest son Bela. When Andrew returned from Palestine, he found this prince at the head of an army of rebels, and his kingdom disturbed by a civil war. The power of the nobles was so great that in the diet in 1222, which Andrew convoked immediately after his return, they forced the king to subscribe the 'Aurea Bulla,' or 'Golden Bull,' which has justly been compared with the English Magna Charta, and by which great privileges were given to the Hungarian nobles, while the royal authority was curtailed. This Aurea Bulla is still the charter and fundamental law of the kingdom of Hungary and its appurtenances. During the following years Hungary continued to be shaken by civil factions, which the king was unable to quiet, since his natural abilities and his good will were not supported by sufficient steadiness of character. Andrew II. died in 1236, and was succeeded by his eldest son Bela IV.

ANDREW III., the son of Prince Stephanus, who was the posthumous son of King Andrew II., succeeded King Ladislaus IV. in 1290. His short reign of ten years was signalized by civil disturbances and foreign wars. Andrew compelled Duke Albert of Austria to give up his claims upon Hungary, with which he pretended to have been invested by his father the Emperor Rodolph I. of Germany; whereupon the two princes joined against Charles Martel, Prince of Naples, who founded his claim to the Hungarian crown upon his descent from Maria the sister of the late king Ladislaus IV. Charles Martel having died before he was able to prepare an expedition against Hungary, his case was taken up by his son Charles Robert, who, having found support among a powerful faction of the nobles and the clergy of Hungary, entered that country in 1300, and took the field against Andrew. The failure of the royal arms against the invader preyed upon the mind of Andrew, and he died through grief in the same year. Andrew III. was the last king of the house of Arpad, the founder of the Hungarian kingdom: and his successor, the fortunate Charles Robert, was the first king of the Anjou or Neapolitan dynasty which reigned over Hungary during nearly a century.

(Mailáth, Count of, *Geschichte der Magyaren*; Pray, *Historia Regum Hungariæ*.)

HUNTINGTON, ROBERT, D.D., was born in February, 1636, at Deorhyrst, in Gloucestershire, where his father, of the same names, was parish clergyman. After having received the rudiments of a classical education at the free school of Bristol, he was admitted in 1652 a portionist of Merton College, Oxford; and, having taken his bachelor's degree in 1658, he was soon after elected to a fellowship in that college. He took his degree of Master of Arts in 1663; and, having then applied himself with great success to the study of the Oriental languages, he was in 1670 appointed to the situation of chaplain to the English factory at Aleppo. This post he held for above eleven years, during which time he visited Jerusalem, Galilee, Samaria, Cyprus in 1677, and Egypt in 1680, and again in 1681, besides making an unsuccessful attempt in 1678 to reach Palmyra. He returned home in 1682, through Italy and France, and, resuming his college life, accumulated the degrees of bachelor and doctor in divinity in June of the following year. In the latter part of that year he was prevailed upon with much reluctance to accept the place of provost or master of Trinity College, Dublin; but, after first taking flight on the invasion of Ireland by the deposed king after the Revolution, and then returning to that country for a short time, he resigned in 1691, and once more came over to England. In August, 1692, he was presented by Sir Edward Turner to the rectory of Great Hallingbury in Essex; and while here he married a sister of Sir John Powell, one of the justices of the King's Bench. He seems still, however, to have felt uncomfortable in what he describes in some of his printed letters as a rustic solitude, where he was banished alike from books and friends, from the living and the dead; and, although he had some years before refused the bishopric of Kilmore in Ireland, his aversion to that country gave way so far that in 1701 he consented to accept of that of Raphoe. But he died there on the 2nd of September in the same year, twelve days after his consecration.

The only literary performance that Bishop Huntington published was a short paper in the 'Philosophical Transactions' (No. 161), entitled 'A Letter from Dublin concerning the Porphyry Pillars in Egypt.' The writer of his Life in the 'Biographia Britannica' states that some of his observations are printed in Ray's 'Collection of curious Travels and Voyages,' 2 vols. 8vo., 1693; but all which that work contains is the Letter on the Porphyry Pillars, which is in volume ii., pp. 149-155. At the end of the reprint is a notice extracted from the 'Journal des Sçavans' (No. 25, A.D. 1692), of a letter from M. Cuper to the Abbé Nicaire, intimating that he had just heard from Aleppo 'that some English gentlemen, out of curiosity going to visit the ruins of Palmyra, had found 400 marble columns, of a sort of porphyry, and also observed some temples yet entire, with tombs, monuments, Greek and Latin inscriptions,' of all of which he hoped to get copies. This would probably be the earliest information received by the English public of the successful accomplishment of the first modern journey to Palmyra, which was achieved by some gentlemen of the factory at Aleppo in 1691, and of which a full account was given in the 'Philosophical Transactions' for 1695. Ray's book may have been printed in the latter part of 1692, though not published till May, 1693, on the 3rd of which month the imprimatur is dated.

Dr. Huntington is principally remembered for the numerous Oriental manuscripts which he procured while in the East and brought with him to this country. Besides those which he purchased for Archbishop Marsh and Bishop Fell, he obtained between six and seven hundred for himself, which are now in the Bodleian Library, to which he first presented thirty-five of them, and then sold the rest in 1691 for the small sum of 700*l.* Huntington, however, missed what was the principal object of his search, the very important Syriac version of the epistles of St. Ignatius, a large portion of which was at length recovered in 1843 by Mr. Tattam from one of the very monasteries in Nitria which Huntington had visited in the course of his inquiries, and, having been deposited by him in the British Museum, has been published in the present year under the care of the Reverend William Cureton, keeper of the Oriental manuscripts in that establishment. Several of Huntington's letters, which are addressed to the Archbishop of Mount Sinai, contain inquiries about the MS. of St. Ignatius; and the same earnest inquiries are made in his letters to the Patriarch of Antioch.

There is a Life of Bishop Huntington, in Latin, by Dr. Thomas Smith, at the end of which are thirty-nine of his Letters, all in Latin, published in 8vo. at London, in 1704; and he is the subject of an article in the 'Biographia Britannica.'

HURA, a genus of plants belonging to the natural order Euphorbiaceæ. It has monœcious, amentaceous flowers; the staminiferous flowers with the calyx truncate; the stamens united into a solid column; the pistiliferous flowers with the style single, and the stigma with 12-18 rays, and the capsule with 12-18 cocci. *H. crepitans* is a tree abounding with milky juice. It is a native of the West Indian Islands, Mexico, and Guyana, where it is called 'Sandbox,' or 'Monkey's Dinner-Bell.' It has cordate, acuminate, entire or very slightly toothed, stalked, smooth, coriaceous leaves, with simple veins passing from the midrib to the margin in a curved direction, within a quarter of an inch or so of each other, and connected by numerous oblique veinlets; large, ovate, leafy, deciduous stipules, and petioles as long or rather longer than the leaves, with 2 glands at the apex. The fruit of this tree is a depressed umbilicated woody capsule, about the size of a middling apple, with from 12-18 furrows which separate into as many cocci; each of these separates into 2 valves, and flies asunder with great elasticity when dry and fully ripe. The noise the fruit makes during this process has obtained for the tree its common names. The juice of the plant, like that of the allied genus Excæcaria [EXCÆCARIA, P. C. S.] is exceedingly acrid, and a small quantity touching the eye will produce blindness. The seeds, like those of Croton and Ricinus, contain an acrid oil which is a drastic and dangerous cathartic.

(Lindley, *Flora Medica*; Burnett, *Outlines of Botany*.)

HURRAR, called also *Harrar* and *Adhari*, is a country with a large commercial town in the eastern part of Africa, and situated between Ankober, the capital of Shoa [ABYSSINIA, P. C. S.], and the harbour of Burburah. As the place has not been visited by Europeans, its true situation is not known, and our information about it is derived from the accounts of some natives of the adjacent countries.

According to these accounts, the town is so large that it takes two hours to go round it at a quick pace. It is surrounded by a wall of stone and mud, which is about twelve feet high and three feet thick, and kept in good repair. There are five gates. The houses are generally built of stone and whitewashed, with flat roofs. There are however some few huts resembling those in Shoa. The emir and the principal inhabitants have houses of two stories. There are said to be many mosques within the town, forty-four of which are the abodes of learned men. The town is well supplied with water from numerous springs in its vicinity. Close to the town is a river called Sambi

The inhabitants are rigid Mohammedans, and pay strict attention to the fasts and ceremonies enjoined by that religion. According to D'Abbadie there is a law in force which prohibits any white man, that is, any Turk or European, from entering the town; but this is very doubtful. The population must be large, as the houses are said to be built very close together. The principal occupation of the people is that of tilling the soil, which for several miles around is highly cultivated, producing coffee, wheat, jowari, barley, and a variety of fruits and vegetables. The *kaat* (a small plant, the leaves of which are said to possess an intoxicating quality, and of which the Arabs in Yemen, where it is also found, are exceedingly fond) is said to be very abundant. The ground is irrigated by artificial means from numerous springs. Coffee is the most important article produced; at least 2000 bales are annually exported to the sea-coast, to the ports of Burburah and Zeila, and thence to Arabia, where it is mixed with that of Mocha, which is improved by it. It is said to differ from that of Arabia, the fruit being a large flat berry. A few families are occupied in manufacturing industry. There are weavers, blacksmiths, and gold and silver smiths. The lances made in Hurrar are in high estimation.

Hurrar may certainly be considered, for that country, a great commercial town. Kafilas arrive there or depart at all seasons. The principal are those which pass between Hurrar and Burburah and Zeila, which two last-mentioned places may be considered as the ports of Hurrar. Three kafilas depart for Burburah between the months of October and March. That of March is the largest, and consists usually of 2000 camels. They export coffee, jowari, ghee, ostrich feathers, gum, myrrh, and *wur;* the last-mentioned article is like saffron in appearance, and is used by the Arabs as ointment for cooling the body; it is also mixed up with flour and made up into cakes, which are said to be very palatable. They export also to Burburah slaves, both male and female, and receive in return blue and white coarse cloth, Indian piece goods, European prints, silk, silk-thread, red cotton-yarn, beads, zinc, copper-wire, frankincense, and some smaller articles. There are also annually three kafilas to Zeila. The imports are the same as those from Burburah, but the exports are increased by some articles, as wheat, millet, beans, &c.

Smaller kafilas depart almost every month to Shoa, except during the rainy season. They chiefly export articles obtained from Burburah and Zeila, especially blue cloth, red cotton-yarn, &c., and receive in return slaves, mules, and horses. Other kafilas trade between Hurrar and Arusic and Chercher, two towns or encampments of the Galla, situated west and south-west of Hurrar; the articles of export and import are imperfectly known.

The climate of Hurrar is said to be similar to that of Shoa, but not quite so cold. The language bears an affinity to the Amharic [ABYSSINIA, P. C. and P. C. S.], but the Arabic character is used in writing. The ruler of Hurrar has the title of Emir, and the succession is hereditary. He is frequently at war with the Galla tribes which surround his country, but he keeps them in check by a small force armed with matchlocks, as the Gallas have a great dread of fire-arms.

(Barker, *Report on the probable Geographical Position of Hurrar*, in *London Geographical Journal*, vol. xii.; Christopher, *Account of the North-East Coast of Africa*, in *London Geographical Journal*, vol. xiv.; D'Abbadie, *Letter;* Rigby, *Remarks on the North-East Coast of Africa*, in the *Transactions of the Bombay Geographical Society*, vol. ii.)

HUSKISSON, WILLIAM, was born March 11, 1770, at Birch Moreton Court, Worcestershire, where his father occupied an extensive farm. The family had long been settled in Staffordshire, and for several generations had been in the possession of a moderate landed estate on which they resided. On the death of his mother, in 1774, his father removed into Staffordshire, married a second wife, and resided upon his patrimony until his death in 1790. He had alienated a considerable portion of his property in order to make provision for his younger children. The entailed property descended to the subject of the present notice, who cut off the entail and disposed of the landed property altogether.

In 1783, when in his fourteenth year, William Huskisson was sent to Paris, at the request of his maternal uncle, Dr. Gem, physician to the English Embassy. Dr. Gem was on terms of intimacy with Franklin and Jefferson, and the party known as the 'Encyclopædists.' William Huskisson, as was natural to a young man, became an enthusiast in the cause of the French Revolution. He was present at the taking of the Bastile in 1789, and became a member of the 'Société de 1789,' established in 1790. The object of this club was to sustain the new constitutional principles. His connexion with it led to the charge which was often brought against him of having been a member of the Jacobin Club. In August, 1790, he pronounced a 'Discours' at the 'Société de 1789' against the proposed creation of paper-money to a large extent, which obtained for him at the time considerable celebrity in the French capital. He withdrew from the 'Société' after the legislature had determined upon the issue of assignats. In the same year (1790) he became private secretary to Lord Gower (afterwards the Marquis of Stafford), who was then the English ambassador. A letter dated a few days after the attack on the Tuileries on the 20th June, 1792, shows that Mr. Huskisson's views respecting the Revolution had undergone a change. After the events of the 10th of August, 1792, the English ambassador was recalled, and Mr. Huskisson returned with him to England. He continued to pass the greater part of his time with Lord Gower at Wimbledon, where he often met Mr. Pitt and Mr. Dundas. In January, 1793, by desire of Mr. Dundas, he undertook the duties of a small office which had just been created for investigating the claims of French emigrants who were then thronging in crowds to England. Early in 1795 he was appointed under-secretary of state in the department of War and Colonies under Mr. Dundas. In this situation he soon became distinguished by his talents for business. In the 'Biographical Memoirs,' attached to the edition of his 'Speeches,' it is stated that he was often called to the private councils of Mr. Pitt. He conducted the equipment of Sir Charles (afterwards Earl) Grey's expedition to the West Indies. Towards the end of 1796 he was brought into parliament as member for Morpeth, by the Earl of Carlisle; but he does not appear as a speaker before February, 1798. On the retirement of Mr. Pitt he resigned his official situation. He was unsuccessful in procuring a seat at the general election in 1802, and did not appear again in Parliament until 1804, when he sat for Liskeard. He was secretary of the Treasury under the administration formed by Mr. Pitt in 1804; and after the death of that minister, and during the Whig administration of 1806-1807, he was an active member of the opposition. At the general election in 1806 he was re-elected for Liskeard; and after the dissolution of parliament in 1807 he sat for Harwich, and continued to do so until 1812. From this period until 1823 he represented Chichester, in which neighbourhood he had, in 1801, purchased a small estate. From 1823 until his death he represented Liverpool. On the retirement of the Whigs from office, in 1807, Mr. Huskisson resumed his former post as secretary of the Treasury. In 1807 he was strongly invited by the Duke of Richmond, then viceroy of Ireland, to become chief secretary; but his services could not at the time be dispensed with in the office he already filled. He resigned office in 1809, along with Mr. Canning, when the latter left the ministry on account of differences with Lord Castlereagh. He refused from motives of friendship and personal attachment to accept any official appointment during Mr. Canning's exclusion from power; and it was not until Mr. Canning accepted the post of ambassador at Lisbon, that Mr. Huskisson again entered the public service. In August, 1814, he was appointed Chief Commissioner of Woods and Forests. In 1823 he became President of the Board of Trade, and Treasurer of the Navy. His predecessor had been a cabinet minister, and Mr. Huskisson considered that his position entitled him to the same distinction, and after some delay, occasioned by the cabinet already consisting of a larger number than usual, he became one of its members. After the death of Mr. Canning, in 1827, Mr. Huskisson held the office of secretary for the Colonies in Lord Goderich's cabinet; and he retained his post when this cabinet was broken up and the Duke of Wellington became the head of a new ministry. He had to defend himself for remaining in office after his friends in the former cabinet were excluded from power; and he did so on the ground that the measures to which he was more particularly pledged would be followed up by the then existing administration. On the 19th of May, 1829, the debate on the East Retford Disfranchisement took an unexpected turn, and Mr. Huskisson was called upon to redeem a pledge which he had given in a former discussion on the question; and he accordingly voted in favour of the bill and in opposition to his colleagues. After the debate, at 2 A.M. he wrote a note, as a matter of delicacy and courtesy to the Duke of Wellington, the head of the cabinet, placing his resignation in his hands. Without any communication with Mr. Huskisson, the duke laid it before the king. In the correspondence which ensued it is evident that the Duke of Wellington was desirous of getting rid of Mr. Huskisson. He had once before voted against his ministerial colleagues, in opposing, in 1822, Lord Londonderry's resolutions for relieving the agriculturists; but at the request of Lord Liverpool, the prime minister, he remained in office. The resignation of Mr. Huskisson was followed by that of Lord Palmerston, Mr. Grant, and several others who had belonged to what was called 'Mr. Canning's party.' In the session of 1830 he appeared on several occasions as a formidable opponent of some of the measures of the government, and, but for his death so soon afterwards, there is every probability that he would have become a member of the Whig cabinet. His commercial principles were held by him in common with them, and in his general views he was approximating towards the Whig party. He had always been in favour of the Catholic claims, and in opposing the repeal of the Corporation and Test Acts, he did so on the ground of its being a partial measure, and likely to retard Catholic emancipation. He supported in May, 1829, Mr. Grant's bill for relieving the Jews of their disabilities. He had left the ministry for having supported a measure of reform, and in the same session he had voted in favour of giving representatives to Manchester, Leeds, and Birmingham.

In parliament Mr. Huskisson seldom spoke except upon financial or commercial subjects. He was an active member of the Bullion Committee, and defended the principles in the Report of that committee in a pamphlet entitled 'The Question concerning the Depreciation of our Currency stated and examined,' which was published in 1810. In the debates on the corn laws, in 1814, he supported the system of protecting agriculture by high duties, on the ground that commerce and manufactures were similarly protected, and that our whole system was one of artificial restraints. He was at that time merely for free trade in the abstract. He alluded to the possibility of imported corn becoming one-fifth, instead of one thirty-fifth of our consumption, if proper means were not taken to encourage the home cultivation. He was averse to the country being dependent on foreigners, and thought such a circumstance might be used to the injury of its interests. He proposed a sliding scale of duties, according to which the duty would be 24*s.* 3*d.* when the average price of wheat per quarter was 63*s.*; and as the price rose the duty would fall, so that at 86*s.* there would be no duty at all. Corn from the colonies he would have admitted at one-half the rates of foreign corn. The question was postponed to the following year, and he supported the corn-bill of 1815, and thought that less than 80*s.* as a protecting price would not remunerate the farmer. In the session of 1822 he moved a series of resolutions on the state of agriculture, one of which proposed that when wheat should again reach 70*s.* the quarter, a fixed duty of 15*s.* should be permanently charged on the importation of foreign wheat. The experience of the last twenty-five years does not prove the profoundness of Mr. Huskisson's views on this subject. In 1827 however he acknowledged that the policy of the corn-laws must be viewed in relation to the changes in the growth and price of corn abroad as well as at home; and he abandoned the corn-bill which had been brought in by the government, after the Duke of Wellington had carried an amendment the effect of which would have been to prohibit the release of bonded wheat so long as the price should be less than 63*s.* the quarter. In 1819 he was appointed a member of the Committee of Finance. It is understood that he was principally concerned in drawing up the long Report of the Committee of Agriculture which sat in 1821. It advocated a relaxation of the corn-laws, for which he was never forgiven by the landed interest. In 1822 Mr. Wallace and Mr. Robinson (now Earl of Ripon) had taken some preliminary steps for relaxing restrictions on commerce; and these efforts were carried on more actively and on a larger scale by Mr. Huskisson. In 1823 he carried through parliament an act for enabling the king in council to place the shipping of foreign states on the same footing with British shipping, provided that similar privileges were given to British ships in the ports of such states. He abandoned the old restrictive system of colonial trade, and, under certain regulations, threw open the commerce of the colonies to other countries. He reduced a great number of duties which had been imposed for the protection of the home produce. The shipowners, and the silk manufacturers, and a host of other interests were now in arms against him. They represented him as a cold and heartless theorist, and he was attacked very generally, both in and out of parliament, for his departure from the antient commercial policy of the country. His speeches in Parliament in defence of his measures are his best; and his expositions of the commercial condition of the country always excited great interest. Sir H. Parnell (Lord Congleton) has denied that Mr. Huskisson established free trade, but he states that in his speeches in 1825 he certainly proclaimed and proved the policy of this system. He adds—'He did no more than strike a balance between the free-traders and the prohibitionists in taking a duty of 30 per cent. as the standard of regulation;' and hints, that had he ever thoroughly espoused the cause of free trade, he would not have thrown away as he did the opportunities he had of making improvements in his plan of 1825. (*Financial Reform*, p. 73.) But even the reforms which he did effect excited great clamour and opposition; and the advantages of the changes he had effected were not recognised until some time afterwards. Mr. Huskisson was active in procuring the repeal of the combination laws; and he relaxed the restrictions on the exportation of machinery.

At the close of the session of 1830 Mr. Huskisson left London to be present at the opening of the Liverpool and Manchester Railway, on the 15th of September. When the train reached Parkside, near Newton, he got out of the carriage with many others, and had just been speaking to the Duke of Wellington, when an alarm was raised on the approach of an engine on the other line. Mr. Huskisson attempted to regain his seat, but fell to the ground at the moment the engine passed, and was dreadfully injured. He was conveyed to the house of the Rev. Mr. Blackburne, of Eccles, but the shock to the system was so great, that after enduring great agony with much fortitude and resignation, he died at nine o'clock the same evening. At the request of a large and influential portion of the mercantile classes of Liverpool his remains were interred in the new cemetery, where a handsome monument with a statue was erected to his memory by his constituents.

Mr. Huskisson was married in 1799 to the youngest daughter of Admiral Milbanke, but had no family. On retiring from office in 1828 he entered upon the receipt of one of six pensions of 3000*l.* a year, which the Crown was empowered to grant for long public services. He was nominated for this pension by Lord Liverpool shortly before his political demise. He was for many years Agent for Ceylon, the salary of which was increased from 800*l.* to 1200*l.* a-year: he resigned this post when appointed to the Board of Trade in 1823.

(*Speeches of the Right Hon. W. Huskisson, with a Biographical Memoir*, 3 vols. 8vo., London, 1831.)

HUTCHINSIA. [Thlaspideæ, P. C.]

HUTTON, WILLIAM, was born at Derby, of poor parents, September 30th, 1723. By frugality, industry, and integrity he raised himself to opulence and eminence. It has been said of him that 'in many particulars of energy, perseverance, and prudence he deserves to be called the English Franklin.' At the age of seven he was sent by his father to work in the silk-mill at Derby, which occupation he quitted at seventeen, and was bound apprentice to an uncle at Nottingham, who was a stocking-maker. He ran away during his apprenticeship, and wandered as far as Birmingham, the town in which he subsequently acquired a fortune; but distress compelled him to return to his uncle. The poor remuneration which he obtained for his labours at the stocking-frame induced him to look anxiously towards some other means of gaining a livelihood; and in 1746 he bought an old worn-down press, and taught himself the art of bookbinding. In 1749 he walked to London and back to purchase a few bookbinders' tools. In the same year he commenced attending Southwell, fourteen miles distant from Nottingham, on the market-day; and here he rented a shop at twenty shillings a year, and opened it for the sale of books. In his autobiography he says: 'During this rainy winter I set out at five every Saturday morning, carried a burthen of from three pounds' weight to thirty, opened shop at ten, starved in it all day upon bread, cheese, and half a pint of ale, took from one to six shillings, shut up at four, and by trudging through the solitary night and tho deep roads five hours more, I arrived at Nottingham by nine, where I always found a mess of milk-porridge by the fire, prepared by my valuable sister.' Hutton's sister was a woman of superior mind, and he owed much to her encouragement. His object was to save a small sum to enable him to commence business in a large town; and in 1750, after having twice visited Birmingham in order to see the chances of success which the place offered, he on the third visit took the lesser half of a small shop, at a rent of one shilling per week, and furnished it with a small supply of books. The overseers teased him for two years under the idea that he would become chargeable to the parish. Five shillings a week covered all his expenses, and at the end of the first year he had saved 20*l.* Fortune continued to smile upon him, and in 1755 he married. In 1791 his property was destroyed during the Church and King Riots at Birmingham in that year, but after great difficulty he succeeded in recovering 5390*l.* from the county. He now relinquished business in favour of his son. He had filled successively all the local offices of the town. In 1781 he published his 'History of Birmingham;' and this was followed by other works in the following order: 'Journey to London,' 1784; 'The Court of Requests,' 1784; 'The Hundred Court,' 1788; 'History of Blackpool,' 1788; 'Battle of Bosworth Field,' 1789; 'History of Derby,' 1790; 'The Barbers, a Poem,' 1793; 'Edgar and Elfrida, a Poem,' 1793; 'The Roman Wall,' 1801; 'Remarks upon North Wales,' 1801; 'Tour to Scarborough,' 1803; 'Poems, chiefly Tales,' 1804; 'Trip to Coatham,' 1808.

Mr. Hutton died September 20th, 1815, a few days before the completion of his ninety-second year. In 1816 his daughter published 'The Life of William Hutton, Stationer, of Birmingham, and the History of his Family: Written by Himself.' This work is one of the most entertaining and instructive pieces of autobiography in the language. An edition of this work was published in 1841, in the series of 'Knight's English Miscellanies.' This edition contains some interesting notes by Catherine Hutton, Mr. Hutton's daughter, who was then in her eighty-fifth year; and passages of a personal nature from Hutton's works are added as notes.

HYBRID PLANTS. [Sexes of Plants, P. C.]

HYDA'TICA, a genus of fossil plants (probably aquatic) from the coal formation. (Artis.)

HYDE, SIR NICHOLAS, was appointed chief justice of the King's Bench in 1626. He was the uncle and preceptor of the first Earl of Clarendon, whose mind he had great share in forming, by proposing daily to him legal questions for solution. He owed his promotion to the patronage of the Duke of Buckingham, who having employed him to draw his successful answer to the impeachment of the House of Commons, afterwards procured him to be appointed chief justice, when Sir Randulph Crewe was removed from that post in consequence of his lukewarmness in advancing a loan which Charles I. attempted to raise without the authority of parliament. The most important trial upon which Sir Nicholas Hyde presided after his elevation to the bench was the one in which Eliot, Hollis, and Valentine were indicted for forcibly holding down in his chair the speaker of the House of Commons, at the violent close of the parliament of 1627. The court refused to allow to the prisoners their Habeas Corpus, and inflicted fines upon them of considerable amount. This conduct (Sir Nicholas Hyde's curious apology for which may be seen in Rushworth, vol. i. p. 461) was afterwards voted by the long parliament a delay of justice. He died at his seat (Hinton Lodge), in the parish of Catherington, Hampshire, on the 26th August, 1631, aged 59.

Whitelock, his colleague on the bench, and political opponent, records that 'the cause of his death was a hot fever, rendered incurable by reason of an imposthume breaking in his head; and that he lived in his place of chief justice with great integrity and uprightness, and with great wisdom of temper, considering the ticklishness of the times.' (Rushworth, vol. ii. p. 111.) Four of his letters are extant in the Bodleian library. A very beautiful full-length marble effigy of him still exists in the obscure parish church of Catherington, Hants. He was succeeded in his estate by his son,

Lawrence Hyde, who became principally remarkable for the personal share which he had in furthering the escape of Charles II. after the battle of Worcester. The king in his memorable wanderings was concealed for a night at the house of one of Mr. Hyde's tenants. But as this tenant was too hot-headed a royalist to be safely intrusted with the secret of his guest's quality, the king was accordingly passed off as a roundhead, and was in that character compelled to drink what must then have appeared hopeless success to the royal cause. After some difficulty Charles was withdrawn from the man's house by Lord Southampton and Mr. Hyde, and by them safely conducted the next day to Shoreham, where they succeeded in procuring a passage for him to Fécamp. The circumstances are told in detail in a manuscript written by Mr

Hyde's cousin Colonel Gounter, himself an actor in the events. This manuscript is now deposited in the British Museum, and contains the only authentic account of the escape of the king. There are notices of it in Jesse's 'History of the Stuarts;' and in Parry's 'Account of the Coast of Sussex.' Lawrence Hyde was M.P. for Winchester after the Restoration; he married the only daughter of Sir John Grenville, the negociator between General Monk and Charles II. for the restoration of the king; and died in 1682: his granddaughter married Mr. Tooker, a Somersetshire gentleman, in whose family the estate still continues.

HYDRASTIS. [WARNERA, P. C.]

HYDROCOTYLE (from ὕδωρ, water, and κοτύλη, a cavity), a genus of plants belonging to the natural order Umbelliferæ, and to the sub-order Orthospermeæ. It has the tube of the calyx rather compressed, the limb with an obsolete margin, the petals ovate, entire, acute, with a straight apex; the fruit flatly compressed from the sides; the carpels without vittæ; the 5 ribs or nerves nearly filiform, the carinal and lateral ones usually obsolete, and the two intermediate ones joined. The species of this genus are generally bog-herbs; but few of them are under-shrubs. The umbel is single, surrounded by a few-leaved involucrum. The flowers sessile or pedicillate, white.

Upwards of 90 species of plants have been referred to this genus. It is not however improbable that a more attentive study of them will lead to the distinction of other genera amongst them.

H. vulgaris has peltate, orbiculate, double crenate leaves; the umbels capitate, of 5 flowers, often proliferous; the fruit emarginate below. This plant is a native of Great Britain and throughout nearly the whole of Europe, in marshy boggy places, and on the margins of rivulets on a peat soil. This plant is commonly called 'Pennywort,' on account of its leaves lying flat on the ground and having the size and form of a piece of money. It is also known by the names of 'water pennywort,' 'sheep-killing pennygrass,' 'white-rot,' 'fluke-wort,' and 'sheep's-bane.' These latter names it has obtained on account of its being supposed to produce the rot and other diseases in animals that feed on it. This is, however, an error, as this plant will not produce disease in animals, but it occurs in damp moist situations, where animals that feed are likely to be attacked with rot and other diseases. It is in this way that other marsh plants, as the species of Drosera and Pinguicula, have been supposed to cause disease in sheep and oxen.

Of the large number of species of this genus few if any are used in the arts or medicine, and none of them are sufficiently ornamental to lead to their cultivation. *H. Asiatica* is said to be used in India as a diuretic and occasionally as a culinary vegetable. *H. umbellata* is recommended by Martius as a remedy in hypochondriasis, but on what grounds is not stated. The fresh juice acts as an emetic. It is said to possess an aromatic odour and an agreeable taste. The species of Hydrocotyle are easily cultivated; they must all be kept moist. The stove-greenhouse and frame kinds should be grown in pots placed in pans of water.

(Don, *Gardener's Dictionary*; Burnett, *Outlines*; Babington, *Manual of British Botany*.)

HYDROCYANIC ACID. [PRUSSIC ACID, P. C. S.]

HYDROSTATIC BED. [BEDSTEAD, P. C. S.]

HYGROMETRY is that part of natural philosophy which relates to the determination of the humidity of bodies, particularly of the atmosphere: it comprehends also the theory of the instruments which have been invented for the purpose of ascertaining the quantity of water contained in a given volume of air.

The experiments of Dr. Dalton have proved that the water received from the earth is not dissolved in the atmosphere, and that it exists there in the form of vapour. That philosopher discovered also that the quantity of vapour contained in a portion of the atmosphere depends greatly upon the temperature of the latter, and that it is very variable even when the temperature is constant. He ascertained moreover that when a quantity of aqueous vapour at a given temperature is diffused through any space, it will support the same external pressure, whether previously that space had been void or occupied by air. On these principles are founded the methods which have been used for determining the absolute quantity of moisture in a given volume of air by means of the hygrometer: the requisite data being the elasticities of aqueous vapour at different temperatures, and the corresponding indications of the instrument.

The tension or elasticity of watery vapour corresponding to every degree of Fahrenheit's thermometer, from zero to the point of boiling water (measured by the height in inches of the column of mercury which the vapour will support when the density of the atmosphere is represented by 30 inches), has been determined by Drs. Dalton and Ure, who for this purpose introduced a small quantity of water into the vacuum of a barometer, and observed how much, at different temperatures, the vapour arising from it depressed the column of mercury; and a table of such tensions is published in the fifth volume of the 'Manchester Memoirs.'

Previously to stating the manner of determining the relation between the indications of an hygrometer and the state of aqueous vapour with respect to tension, it will be proper to notice the following circumstances:—When an hygrometer, like that of Saussure or De Luc [HYGROMETER, P. C.], is introduced in a close vessel, or in any part of space fully saturated with aqueous vapour, it is observed that, whatever be the temperature, the index points to the same graduation: from which it may be inferred that equal quantities of vapour have been absorbed by the material (hair or whalebone) of which the instrument consists, notwithstanding the difference of temperature. In fact the vapour in the vessel, or space, is in such a state that the presence of a material having the least possible affinity for water is sufficient to produce a precipitation of the latter: the hygroscopic material has an affinity for water, and thus it absorbs that which is precipitated. But the quantity absorbed is so small as not to diminish sensibly the elasticity of the vapour in the vessel; and therefore the absorption continues to the full extent of the affinity of the material: the quantity thus absorbed is necessarily constant, unless the affinity undergo some change by a change of temperature; but experience proves that the affinity of the material is not sensibly altered by such change within the limits of the usual thermometric scale.

When the vessel into which the hygrometer is introduced is not completely saturated with water, the quantity of water absorbed by the hygroscopic material is limited by the power of the latter to absorb the precipitated moisture: that power diminishes in proportion to the quantity received, so that the affinity of the material for water ceases to act when it is equivalent to the pressure which the vapour can support without becoming liquid; and the elongation of the hair or whalebone then ceases, or the index remains stationary on the scale.

In order, then, to determine the law according to which the affinity of the hygroscopic material for water diminishes as the precipitated water is absorbed by it, or, in other words, to find on the scale of the hygrometer a number of points corresponding to any given elasticities of the vapour, Gay Lussac put water into a vessel of glass; and, having determined the elasticity of the vapour arising from it, he suspended from the upper part of the vessel a delicate hygrometer of the kind invented by Saussure. The vessel was then closely covered, so that there might be no communication between the vapour within and the external air; when, after a short time, the index of the hygrometer became stationary at a certain point on the circumference of the graduated ring which served as a scale; this point thus became an indication of the elasticity of the vapour. Experiments of the like kind being made with vapour of equal temperature, but in different states of elasticity, between those which correspond to extreme dryness and complete saturation, there were obtained so many points on the scale of the instrument as indications of the elasticities of the vapour.

From the results of these experiments M. Biot found, by interpolation, a table of the elasticities of vapour for every degree of Saussure's hygrometer, the temperature being 10° of the centigrade thermometer (50° Fahr.). He also formed a table showing the degrees of the hygrometer corresponding to every degree of elasticity. The extremes of dryness and moisture on the scale, and also the corresponding extremes of elasticity, were indicated respectively by 0 and 100 (Biot, *Traité de Physique*, liv. i. ch. 13); but the elasticities or tensions would be more conveniently expressed in terms of the elasticity at the point of complete saturation, which is then represented by unity.

The numbers in the table are formed from the observed tensions at a constant temperature equal to 50° (Fahr.); and it might be supposed, since the index of the hygrometer stands constantly at 100° when the material is acted on by vapour in the state of maximum tension whatever be the temperature, that the index should stand at one point on the scale when the tensions of the vapour have the same proportion to the maximum tension at their respective temperatures: this supposition is not quite correct; but it may be presumed that, in using Biot's table for temperatures differing from 50° (Fahr.), the error in the tensions will not be considerable.

Gay Lussac having proved that vapours, whether those of pure water or such as consist of different kinds intermixed, while they retain their character of elasticity, suffer the same variations of volume by variations of pressure as are suffered by permanently elastic fluids, determined, by subsequent experiments, the volumes of the vapour produced by a given weight of water at given temperatures and under given atmospherical pressures; and thus, consequently, obtained the quantity of moisture in a given volume of vapour. The results of his experiments were reduced to a formula by Biot; and subsequently, with certain modifications, to one in English weights and measures by Dr. Anderson, the writer of the article on Hygrometry in the 'Edinburgh Encyclopædia.' This formula is

$$G = \frac{10953\ B.F}{447{\cdot}4 + t};$$

in which G is, in grains, the quantity of moisture in a cubic inch of vapour at the temperature represented by t (Fahrenheit's scale), F is the elastic force of the vapour at the same temperature, and B is the height of the barometrical column in inches at the time of the experiment. It agrees nearly with that which was obtained by Dalton from experiments on the state of the thermometer at the dew-point [HYGROMETER, P. C.], the height of the mercurial column in that result being 30 inches. From this formula, the temperature t being 50° (Fahr.), $B = 30$ inches, and $F = 0{\cdot}375$ (from Dalton's table of the elastic force of vapour corresponding to that temperature and that density of the air), we have $G = {\cdot}002477$, the grains of moisture in a cubic inch of the vapour.

The value of G being thus found for any given states of the barometer and thermometer; the weight of moisture, in grains, in a cubic inch of air of the like density and temperature, and corresponding to any observed degree of Saussure's hygrometer may be obtained on multiplying that value by the number in Biot's table corresponding to the observed degree and dividing the product by 100; this division must be made because, in that table, 100 represents the elasticity of the vapour when in the state of complete saturation.

The extreme points on the scale of an hygrometer acting by the elongation of a material, like those of Saussure and De Luc, may be found in the following manner: the instrument is to be placed under a receiver in which is a certain quantity of dry caustic alkali; when, after a time, the material will contract in length as much as its nature will permit; the point on the scale at which the index stands is that of extreme dryness, and constitutes the zero point. The instrument may then be placed in water, or in a receiver filled with vapour completely saturated with moisture, when the material will expand to the greatest extent possible: the place of the index is then to be considered as the point of extreme humidity, and is usually indicated by 100.

Leslie's hygrometer consists of a glass tube bent so as to form two equal branches parallel to one another, and each terminating with a hollow ball in which is introduced sulphuric acid, coloured. One of the balls is covered with cambric, which is kept constantly moist by water from a neighbouring vessel; and the evaporation of the water, by cooling that ball, allows the air in the other, by its superior elasticity, to depress the acid in the tube below and force it to rise in the other. The degree of evaporation depends partly on the temperature, and partly on the state of the surrounding atmosphere with respect to humidity; and hence the depression of the acid in the tube, being measured by a convenient scale, affords an indication of the relative dryness of the air. In order to determine the absolute quantity of moisture in a given volume of the atmosphere by the state of his hygrometer, Leslie, having found from some experiments that the capacity of air for caloric was $\frac{8}{3}$ of that of water, and having ascertained that the quantity of caloric necessary to convert a given volume of water into vapour was expressed by 6000 degrees of his instrument; concluded that the same quantity of caloric would raise an equal volume of air to a temperature expressed by $\frac{8}{3} \times 6000$, or 16,000 degrees of the instrument; and consequently that, at the temperature of the wet ball, atmospheric air contains a quantity of moisture equal to $\frac{1}{16000}$ part of its weight for each degree; the scale between the points of extreme dryness and extreme moisture being divided into one thousand parts. (Treatise 'On the Relations of Air to Heat and Moisture.')

From the fact that the elastic forces of pure vapour and of vapours mixed with atmospheric air are equal to one another, the expansion which air undergoes in consequence of being saturated with moisture may be found. For if V represent a given volume of dry air, V′ the volume, when saturated, and B, in inches, the height of the barometrical column; then the elastic force of the air under the increased volume V′ is $\frac{V.B}{V'}$. Now F representing the elastic force of the vapour in inches of mercury, which, for the given temperature, may be found from Dalton's table; the sum of the elastic forces of the air and vapour will be expressed by $F + \frac{V.B}{V'}$; and this being made equal to B, the pressure of the atmosphere, the value of $V' - V$ may be found. Making $V = 1$, that value expresses the expansion in a fractional part of the volume of dry air.

At any place on the surface of the earth, the mean temperature at which moisture begins to form in the atmosphere may be found from Dalton's formula $E = \frac{1}{30} M (F - F')$, in which E is the number of grains evaporated in one minute from the surface of water in a cylindrical vessel 6 inches in diameter and one inch deep, F is the elastic force of vapour in the atmosphere at a given temperature, which may be the mean annual temperature at the place (50° Fahr., for Great Britain), and F′ the elastic force exerted at the time that the moisture begins to form: M is, in grains, the evaporating force in an atmosphere supposed to be perfectly dry; and Dalton has given a table of such forces for different temperatures, the atmosphere being at rest, in gentle, and in violent motion. In the table, the temperature being 212°, the height of the barometrical column 30 inches, and the wind blowing moderately, the value of M is 154; and substituting this value in the formula, we have $F' = F - \frac{1}{5} E$.

The mean annual evaporation in Great Britain is ·0000456 inches or ·01155 grains per minute: this last number being multiplied by the area of a circle 6 inches in diameter, gives 0·3236 grains per minute (= E) from a vessel of that magnitude; hence $F' = F - 0{\cdot}0647$. But, by Dalton's table, the elastic force (F) of vapour at a temperature equal to 50° is expressed by 0·375, in inches of mercury; hence $F' = {\cdot}3103$ inches. Substituting in the above formula for G this value of F′ in place of F, and 30 inches for B, we get ·00205 for the number of grains of moisture in a cubic inch of air corresponding to the elasticity F′. To this number corresponds the temperature 44° 16′; which may be found by inspection in a table formed to contain the values of G for different degrees of temperature.

HYMENÆA (from *Hymen*, in reference to its twin leaflets), a genus of plants belonging to the natural order Leguminosæ. It has a calyx furnished with two bracts at the base; the tube turbinate, coriaceous; the limb 4-5 parted, deciduous, with 2 lobes sometimes united into one; 5 petals nearly equal, glandular; 10 stamens distinct, inflated in the middle; the style filiform; the legume woody, oblong, many-seeded, containing fecula; the embryo straight. The species are trees, with bifoliate leaves, and corymbs of white or yellow flowers.

H. Courbaril, Locust-tree, or Gum-Anime Tree, has oblong ovate leaflets, unequal-sided, and unequal at the base, ending in a long point; with the legume oblong, compressed, yellowish, shining. It is a fine lofty spreading tree, and grows in the tropical parts of America and in Jamaica. The seeds are enveloped in a cellular mealy substance, which is sweet like honey, and is eaten by the Indians with great avidity. When fresh it is slightly purgative, but by keeping it loses this property. A decoction of this substance, when allowed to ferment, forms an intoxicating drink resembling beer. From between the principal roots of this tree there exudes a fine transparent resin, with a red or yellowish red colour, and which is collected in large lumps and sold under the name of *Gum Anime* or *Gum Animi*. This resin resembles amber, is very hard, and sometimes contains leaves, insects, or other objects imbedded in it, which remain in a perfect state of preservation. It burns readily, emitting a very fragrant smell. Dissolved in rectified spirits of wine it makes one of the finest kinds of varnish. According to Lindley, this resin is called *Jatahy*, *Jatchy*, or *Copal*, and in Minas Geraës *Jatoba*. *Courbaril* is the name of the tree in some parts of South America. In countries where this tree grows the resin is used medicinally, and has also been employed in that way in Europe. It acts as a stimulant when taken internally, and as an irritant when applied externally. In fumigation it has been employed for persons labouring under asthma and dyspnœa. Dissolved in spirits of wine or oil it is used as an embrocation in rheumatism. Internally, it has been recommended as a substitute for guaiacum, in venereal disease and chronic rheumatism. The inner bark, either in the form of tincture or decoction, is administered as a vermifuge. The curadores have a method of mixing it with sugar and rum, so as to make a very agreeable emulsion or syrup. The wild bees are fond of building their nests in the trunk of this tree. The timber of the old trees is very hard and tough, and is in great request for wheelwork, particularly for cogs. The wood is so heavy that a cubic foot is said to weigh a hundred pounds; it takes a fine polish.

Several other species of Hymenæa are described, but of these comparatively little is known.

(Don, *Gardener's Dictionary;* Lindley, *Flora Medica.*)

HYMENOMYCE'TES, the first suborder of the Fungi, a natural order of plants. [Fungi, P. C.] They are characterized by their reproductive organs, called the hymenium, being naked. This suborder is divided by Fries into four tribes [Fungi, P.C.]; by Berkeley into six tribes. Those of the latter are, Pileati, Clavati, Mitrati, Cupulati, Tremellini, and Sclerotiacei.

The tribe *Pileati* contain the following British genera:—

Agaricus, in which the hymenium consists of plates radiating from a common centre, with shorter ones in the interstices, composed of a double closely connected membrane, more or less distinct from the pileus: the veil is various or absent. [Agaricus, P. C.]

Cantharellus has the pileus furnished below with dichotomous, radiating, branched, subparallel folds, not separable from the flesh, sometimes anastomosing or obsolete.

Merulius has the hymenium veiny, or sinuoso-plicate; the folds not distinct from the flesh of the pileus, forming unequal angular or flexuous pores. [Merulius, P. C.]

Schizophyllum has the gills radiating from the base, composed of a folded membrane, which is ruptured along their edge; the two portions of the fold being revolute, bearing asci only on the outer surface.

Dædalea has the hymenium composed of anastomosing gills, or flexuous elongated pores formed out of the corky substance of the pileus.

Polyporus has the hymenium concrete, with the substance of the pileus consisting of subrotund pores with their simple dissepiments.

Boletus has the hymenium distinct from the substance of the pileus, consisting of cylindrical separable tubes, with oblong sporidia. [Boletus, P. C.]

Fistulina has the hymenium formed of a distinct substance but concrete with the fibres of the pileus; the tubes at first wart-like, somewhat remote, closed, radiate-fimbriate, at length approximated, elongated, open.

Hydnum has the hymenium of the same substance as the pileus, composed of free spine-like processes.

Sistotrema has the hymenium somewhat distinct from the pileus, composed of irregularly-disposed, curved, and gyrose lamellate teeth.

Irpex has the hymenium concrete with the substance of the pileus, torn into distinct spines, disposed in rows or in a reticulate manner, their bases connected together by lamellate, sinuous, or porous folds; the asci slender, situated only on the toothed processes.

Radulum has the hymenium tuberculated; the tubercles shapeless, resembling papillæ or rude somewhat angular spines, more or less obtuse, distant, distinct or irregularly fasciculate, the inner substance homogeneous with the receptacle; the asci occupying indifferently all parts of the hymenium.

Phlebia has the hymenium homogeneous and concrete, with the pileus smooth, venoso-rugose, wrinkles interrupted, disposed irregularly, straight or flexuous, bearing asci all over.

Thelephora has the hymenium homogeneous and concrete with the pileus, even or papillate, the whole surface bearing asci.

Of these genera Agaricus contains by far the greatest number of species. On this account it has been found necessary to class the species under various subgenera. The following table contains the subgenera of Fries arranged in eight series:—

AGARICUS. Lamellæ simple, unequal, juiceless, persistent, discrete from the pileus.	*Leucosporus.* Lamellæ unchangeable; veil variable or none; sporidia white.	Amanita. Lepiota. Limacium. Tricholoma. Clitocybe. Omphalia. Collybia. Mycena. Ompbalia. Pleurotus.
	Hyporhodius. Lamellæ changeable in hue; veil none; sporidia rose-coloured.	Cliptopilus. Eccilia. Leptonia. Nolanca.
	Inocybe. Lamellæ changeable; veil springing longitudinally from the innate fibres of the pilcus; sporidia tawny brown.	Inocybe.
	Derminus. Lamellæ discoloured; veil floccose; sporidia subferruginous.	Pholiota. Hebeloma. Flammula. Naucoria. Galera. Tapinia. Crepidutus.
	Phæotus. Lamellæ changeable, nebulous; veil various; sporidia dark brown.	Pratellarius.
	Pratellus. Lamellæ, changeable, lax, nebulous; veil floccose; sporidia brownish purple.	Volvaria. Psalliota. Gompbus. Hypholoma. Psilocybe. Psathyra.
	Coprinarius. Veil partial; lamellæ lax, nebulous; sporidia black.	Coprinarius.

Most of the species included under the series Leucosporus are eatable, and contain those species which are mentioned as edible in the article Agaricus, P. C. It also contains the various species of Amanita, which are among the largest and most remarkable forms of the fungi. *A. cæsarea* is remarkable for its beauty, but not so much so as for the traditional belief that it was in a dish of these mushrooms, which were regarded by the Romans as one of the greatest luxuries of the table, that Agrippina administered poison to her husband Claudius Cæsar, in order to hasten her son's accession to the Imperial power. *A. muscaria* possesses an intoxicating or narcotic property. It is used by the inhabitants of the north-eastern parts of Asia in the same manner as wine, brandy, arrack, spruce, &c. are by other nations. One large or two small fungi is a common dose to produce a pleasing intoxication for the whole of the day.

Upwards of 700 species of the genus Agaricus have been described; of these 333 are natives of the British Islands.

Eight species of the genus *Cantharellus* inhabit Great Britain. The *C. aurantiacus* is said to be a poisonous plant. It is common in fir-woods and pastures. It has a beautiful orange colour and a strong smell. *C. cibarius*, the common Chanterelle, is common in woods in the summer and autumn. The pileus is of a pale yellow colour, and the whole plant has an agreeable smell like that of apricots. On the continent of Europe this fungus is eaten, but is not often used in Great Britain. It is however dangerous when eaten raw, and should always be cooked. They form a delicious ingredient in rich gravies.

One of the species of *Merulius* has been supposed to be the cause of dry-rot. [Dry-Rot, P. C.; Merulius, P. C.] Berkeley describes five species of this genus as natives of Great Britain.

Of *Schizophyllum* but one species has been found in Great Britain, the *S. commune*. It is a very beautiful fungus, and has been found in almost every part of the world.

The genus *Dædalea* has been so named from the remarkable sinuosities and sculpture-like pores of its hymenium. *D. quercina* is found commonly on oak-trees or stumps and roots of that wood. It is an astringent and has been applied to wounds to arrest hæmorrhage. It is commonly called 'the lungs of the oak,' and was formerly on this account used as a remedy in phthisis. It is at the present day sold in Covent Garden market for that purpose. There are several other species of this genus which are indigenous in Great Britain

D. suaveolens is a northern plant. It yields an agreeable perfume.

Upwards of forty species of the genus *Polyporus* are found in Great Britain, and many more European species have been described. Many of the species are used in arts and medicine. *P. igniarius* has long been famed as a styptic. Amadou, or German tinder, is made from this plant by separating the porous hymenium from the harder parts and steeping it in a solution of nitre after it has been beaten into a soft spongy state. Many other species of Polyporus may be used for the same purpose. The Laplanders also use them for applying the actual cautery in the same way as the Japanese and Chinese use the moxa. When they suffer from pain in the limbs, they pull the fungus in pieces and placing it on the skin, set fire to it and allow it to burn away till it blisters the skin, when it acts as a counter-irritant. *P. officinalis* is a cathartic. *P. suaveolens* has a pleasant smell. Some of the species secrete acids, and boletic, fungic, and oxalic acids have been obtained from them. *P. squamosus* is one of the largest of British fungi, weighing sometimes as much as thirty pounds. *P. destructor* is one of the fungi found on decaying timber when it is attacked with what is called dry-rot.

Many of the plants formerly included under the genus *Boletus* are now referred to *Polyporus*. Berkeley enumerates sixteen species of the genus Boletus as natives of Great Britain. [Boletus, P. C.]

The genus *Hydnum*, although named after ὕδνον, the truffle, includes a different series of plants. The hymenium is formed of spinous bodies which give to the species of this genus a very formidable appearance. Hence they are called in the country spine-stools, prickle-stools, &c. Several species are natives of Great Britain. Some are eatable, but caution should be used in their selection. De Candolle says that those which have a dark colour are dangerous.

The genus *Fistulina* has one representative in Great Britain, *F. hepatica*, the pipe-stool. It grows upon the trunks of old oaks and other trees. It is eaten in France. When cut into it is beautifully marbled with red and white streaks resembling a fine piece of beef. It is called in France *Foie de Bœuf*, *Langue de Bœuf*, *Glue de Chêne*, &c. It has an acid taste, but is rather tough. It has been known sometimes to attain the weight of thirty pounds.

The genera *Sistotrema*, *Irpex*, *Radulum*, and *Phlebia* are small genera, and not used as food, or in any other way. *Thelephora* is an extensive genus, and forty-two species are indigenous in Great Britain. They are common on decaying branches of trees, &c., and exhibit a variety of colours.

The tribe *Clavati*, which are distinguished by a single or branched vertical receptacle, embrace the following British genera:—*Clavaria*, *Calocera*, *Geoglossum*, *Spathularia*, *Mitrula*, *Typhula*, and *Pistillaria*. These plants, in their branched and club-shaped forms, resemble the corals, and were actually placed by the older naturalists in the same class. Some of the species of the *Clavati* are edible. All the Clavaria are esteemed as food. *C. rugosa* has an agreeable flavour like that of the common mushroom. *C. flava* and *C. pyxidata* are prized on account of their taste. *C. cinerea* is the species most commonly eaten on the Continent.

The *Mitrati* have a bullate, fileiform, margined receptacle. They embrace five British genera: *Morchella*, *Helvella*, *Veapa*, *Leottia*, and *Vibrissea*.

The genus *Morchella* yields the esculent fungus morel. [Morel, P. C.] Three species are found in Great Britain. There are also three British species of Helvella as that genus is at present defined. The species of Helvella are edible. *H. crispa* is considered the best species for eating, but none of the species, foreign or British, are poisonous.

The tribe *Cupulati*, which has a patelliform margined receptacle with a superior hymenium, contains the following British genera:—*Peziza*, *Patellaria*, *Ascobolus*, *Bulgaria*, *Ditiola*, *Tympanis*, *Cenangium*, *Stictis*, *Cryptomyces*, *Cyphelia*. Of these *Peziza* is the most extensive genus, containing upwards of 300 species, of which 106 are natives of Great Britain. Some of these plants are very remarkable from the regular cup-like form and the deep colours they present. *P. coccinea* is perhaps the most elegant plant belonging to the natural order of Fungi. The outer surface of the cup which it forms is white and downy, whilst the inside is of the richest carmine. It frequently grows on sticks covered with moss, the green colour of which forms a beautiful contrast with the white and crimson of the Peziza. *P. æruginosa* has a deep green colour, and possesses the property of staining wood on which it grows of the same colour as itself. The Pezizæ are not generally eaten, but none of them are poisonous.

The fifth and sixth tribes of the Hymenomycetes are the *Tremellini* and *Sclerotiacei*. The Tremellini embrace six British genera. [Tremellini, P. C.] The British genera included under Sclerotiacei are *Pyrenium*, *Acrospermum*, *Sclerotina*, *Periola* and *Spermoedia*. These are amongst the lowest forms of the Hymenomycetous fungi, and include species which are found attacking the various Cerealia, producing the disease called ergot. [Ergot, P. C.; Spermoedia, P. C.] An account of the remaining forms of the Fungi is given under Gasteromycetes, P. C. S.

(Burnett, *Outlines of Botany*; Berkeley, *English Flora*, vol. v.; Fries, *Systema Mycologicum*.)

HYNDFORD, JOHN CARMICHAEL, third EARL OF, a Scottish nobleman of some diplomatic celebrity in the reign of George II., was born in 1701, and succeeded to the family honours in 1737. He represented, as one of the Sixteen Peers, the Scottish nobility in several parliaments, acted for two successive years (1739, 1740) as royal Commissioner to the General Assembly of the Church of Scotland, and held the dignity of lord lieutenant of the county of Lanark, in the upper district of which the family estates were situated. His diplomatic life began upon the occasion of the seizure of Silesia by Frederick the Great in 1741, when his lordship was deputed envoy extraordinary and plenipotentiary to the Prussian court. In this mission he succeeded in effecting an accommodation between that unscrupulous prince and the Empress-Queen Maria Theresa, by a treaty concluded the following year at Breslau. So sensible were the contracting parties of the value of his lordship's mediation and services, that by a grant from the King of Prussia, ratified subsequently at Vienna by the Empress-Queen, he was permitted to assume, in addition to the family armorial bearings, the Silesian eagle, with the motto 'ex bene merito,' and was moreover honoured by his own king with the national decoration of the order of the Thistle. At Berlin he became acquainted, through the introduction of Frederick, with the famous Baron Trenck, who gratefully acknowledges in his Memoirs, the 'parental trouble' which his lordship took in counselling him and promoting his interests when they met some years after at Moscow. In 1744 Lord Hyndford was sent ambassador to Russia, where he became a great favourite of the Empress Elizabeth, who took an active part in behalf of Maria Theresa; and he was highly instrumental in bringing about, in 1748, the peace of Aix-la-Chapelle, which terminated what is known in history as the war of the Austrian Succession. In this mission his lordship continued till the end of 1749, and on his return was constituted a privy councillor and lord of the bed-chamber. In 1752 he was sent to the Court of Vienna on his third embassy, with which, after a few months, his career as a diplomatist terminated, though he did not altogether withdraw from political life. In 1764 he received a further mark of the king's esteem in the appointment of lord vice-admiral of Scotland. After his return from Vienna, his time was divided between London and the family seat at Carmichael, in the vicinity of which the memory of the 'Ambassador' is still cherished with almost filial regard by the descendants of those who benefited by the munificence and public spirit which he never ceased to manifest in promoting the interests of his county. During his whole lifetime, and particularly his latter years, his attention was unremittingly devoted to his estates, which he enhanced in value by extensive improvements, and enlarged by judicious purchases and advantageous exchanges. He died in 1767, leaving no issue. His official correspondence, extending to twenty-three volumes in manuscript, is now deposited in the British Museum, to which it was secured by purchase in 1838.

HYPANTHO'CRINUS, a genus of fossil Crinoidea, from the Silurian strata.

HYPERBOLOID. The conditions under which the equation of the second degree belongs to an hyperboloid are given in Surfaces of the Second Degree, P. C. Of the two kinds of hyperboloids there mentioned, one, the *single* hyperboloid, has the remarkable property that straight lines can be drawn upon it. Through every point of the surface two straight lines can be drawn, which are entirely upon the surface, and which are also in its tangent plane. When the surface is one of revolution, that is, when it is formed by the revolution of an hyperbola about its minor axis, these straight lines are all divided into two sets, each set consisting of lines symmetrically disposed with respect to the axis, but never meeting it: so that if one of either set were to revolve about the axis, it would describe the surface. Consequently a straight line revolving about an axis which is not in its plane, describes a single hyperboloid of revolution. This surface is therefore easily turned: the outside of a dice-box is generally nearly a specimen of it.

HYPE'RICUM, a genus of plants belonging to the natural order Hypericineæ. The calyx is 5-parted, or it has 5 sepals; 5 petals; 3 styles, and a 3-celled capsule. The flowers of the species are mostly yellow. There are 13 British species of this genus, and 172 are enumerated by Don as growing in various parts of the world: St John's Wort is the common name of all the species.

H. maculatum has an erect quadrangular stem, elliptical ovate obtuse leaves with a few pellucid dots, reflexed ovate lanceolate sepals having pellucid streaks, obtuse petals with purple streaks and dots beneath. It is the *H. quadrangulum* of Fries, and is found in moist places by ditches and rivers.

H. perforatum has an erect 2-edged stem, ovate or elliptical leaves with numerous pellucid dots, anthers with black dots, the styles as long as the capsule. It is found in large quantities in Britain and throughout Europe; also in the north of Asia and Africa. The flowers are of a bright yellow colour, dotted and streaked with purple; when rubbed they emit a powerful lemon-like scent and stain the fingers with dark purple. The whole of the plant contains a powerful volatile oil, which is aromatic and possibly astringent, though as yet it has been but little used in medicine. Its sensible qualities however, and the few instances in which it has proved beneficial, entitle its virtues to a further trial. When boiled with alum this plant yields a yellow dye which is used for colouring wool. The common people of Germany and France gather this species of St. John's Wort with great ceremony on St. John's day, and hang it in the windows and about their houses as a charm against evil spirits, storms, thunder, and all other calamities, mistaking the meaning of some medical writers who fancifully called the plant Fuga Dæmonum, from a notion that it was a remedy in maniacal disorders. At one time the people of Scotland used to carry it about their persons as a protection against witchcraft and enchantment, and they fancy it prevents ropy milk by milking upon the fresh herb. Cows and goats will eat the plant, but horses and sheep refuse it. It is the ἄσκυρον of Dioscorides (iii. 162). It is found at the present day on the high hills of Attica.

H. laxiusculum has a smooth herbaceous stem, rather distant obtuse leaves, full of pellucid dots; the lower leaves narrow and lanceolate, segments of the calyx equal, nearly linear and acute. It is a native of Brazil, in the provinces of St. Paul and Minas Geraes, where a decoction of the leaves is used as a remedy against the bites of serpents.

H. crispum has a round branched stem, sessile lanceolate leaves sinuately waved at the base, full of dots, small blunt sepals. It is native in the regions of the Mediterranean, and is the ὑπέρικον of Hippocrates (*Morb. Mul.* i. 610); also of Dioscorides (iii. 161), and the Hypericon 'quod alii chamaepityn, alii corion appellant' of Pliny (xxvi. 8; xxvii. 4. 5). At the present day it grows near the sea in Attica.

H. perfoliatum, the ἀνδρόσαιμον of Dioscorides (iii. 163). It has a 2-edged stem; ovate, clasping, dotted leaves; fringed and dotted sepals and petals, and sessile flowers. It is a native of Italy.

H. Coris has a shrubby erect round stem, linear leaves in whorls with revolute margins, and a bluntish linear calyx. It is the κόρις of Dioscorides (iii. 174), and the Coris of Pliny (xxvi. 3). This species is a pretty little shrub, native of the Levant, and in dry places in the south of Europe.

H. origanifolium is distinguished by its ascending downy stem, ovate blunt and pubescent leaves full of pellucid dots, numerous stamens, and many black dots in the corolla. It is a native of the East, about Constantinople, Thrace, and Armenia, and is frequently found on high mountains in company with *H. perfoliatum*. It is probably the ἀγήρατον of Dioscorides (iv. 5), and undoubtedly the *Ageratum* of Pliny (xxvii. 4).

H. Olympicum has elliptical lanceolate leaves full of pellucid dots; a round stem, and withering corolla and stamens. It is a native of Mount Olympus and of China. Fraas thinks it probable that this is the πολεμώνιον of Dioscorides (iv. 8).

Most of the species of Hypericum are showy, and deserve cultivation. The hardy herbaceous kinds will thrive in any common garden soil, and are easily propagated by dividing the roots or by seeds. Those that require the greenhouse or frame will thrive best in a mixture of loam and peat and strike root readily in sand under a bell-glass.

(Don, *Gardener's Dictionary*; Babington, *Manual Brit. Bot.*; Fraas, *Synopsis Plantarum Floræ Classicæ*.)

HYPO'CHARIS, a genus of plants belonging to the natural order Compositæ, to the suborder Cichoraceæ, and to the section Hypochœrideæ, which has a scaly receptacle and a feathery pappus. The heads are many-flowered, the involucre is oblong and imbricated, the fruit glabrous, muricated, and beaked; the pappus in two rows, the outer short and setaceous, the inner long and feathery. There are two British species of this genus—*H. glabra*, with oblong dentate-sinuate leaves, and *H. radicata*, with runcinate obtuse leaves. They are found on dry and gravelly places and waste places.

(Babington, *Manual of British Botany*.)

HY'PODON. [FISHES, FOSSIL, P. C. S.]

HYPONITROUS ACID was discovered by Gay Lussac, who obtained it by adding nitric oxide gas in excess to oxygen gas, confined in a glass tube over mercury, containing a concentrated solution of potash; under these circumstances 50 volumes of oxygen gas unite with 200 volumes of nitric oxide gas, which forming hyponitrous acid unite with alkali. This acid may also be obtained by long exposure of nitric oxide gas to solution of potash, or by exposing to intense cold a mixture of 50 volumes of oxygen gas with 200 volumes of nitric oxide gas. By this operation the acid is obtained in a liquid state and possesses the following properties:

At common temperatures it is green, but at 0° it is colourless; it is very volatile, so that when exposed to the air, it is rapidly converted into an orange vapour, the density of which is stated to be 1·72, air being 1. When water is added, the acid is decomposed and converted into nitric acid and nitric oxide, the latter escaping with effervescence. It is composed of

Three equivalents of Oxygen	=	24
One equivalent of Azote	=	14
Equivalent . .		38

This acid does not combine directly with bases to form salts, being on their admixture converted into nitric acid and nitric oxide. Hyponitrites may however be formed by moderately heating certain nitrates, the acid of which losing two equivalents of oxygen, hyponitrous acid remains, and in combination with the base. Hyponitrite of lead may be formed by heating metallic lead in a solution of the nitrate of that metal.

HYPOTHEC (from the Greek ὑποθήκη, a security, literally the subjection of a thing to the authority of another person) is a term derived from the civil law, still in use in the law of Scotland, and in that of France with the lingual variation hypothèque; while, though in the law of England it is not a received technical expression, it is occasionally used for describing any species of security holding the character which the word was employed by the civilians to represent. Hypotheca in its proper acceptation signified a right of security over something which was not placed in the creditor's possession, in contradistinction to pignus, which applied to what is now termed a pledge. See the distinction pretty clearly drawn in book iv. c. 6 of the Institute, and in the Pandects, xiii., tit. 7, s. 9, *De Pignorat. Act. vel contra.* Propriè pignus dicimus, quod ad creditorem transit; hypothecam, cum non transit nec possessio ad creditorem. But the distinction is often lost sight of, even in the original authorities of the civil law. See Brissonius de Verborum Significatione, *voce* Hypotheca. Hypothecs were distinguished into those created by contract, and the tacit or prætorian, admitted in certain circumstances without stipulation. The law on the subject will be found in the Pandects, lib. xiii. tit. vii. De Pignoratitia Actione, &c. (above referred to), and in lib. xx. de Pignoribus et Hypothecis.

The several securities over real property in various parts of the empire, which can be completed without the absolute transfer of the property to the creditor, are so many illustrations of consensual hypothecs in that description of property. Consensual hypothecs in moveables are nearly unknown in the British Empire, as the law, studying the interests of commerce, has discouraged any latent right in favour of an individual over merchandise and other moveable goods while they are left apparently at the disposal of the original owner, and are liable to be viewed by all who transact with him as his property. Bottomry and Respondentia are perhaps the only instances in which it is countenanced. But there are still some tacit hypothecs created by the operation of law, affording a preference to particular creditors over the property of a person who cannot or will not pay all his debts. Used in this sense, hypothec is properly the counterpart of lien, the former being a tacit security over property which is in the debtor's hands, the latter over property in the creditor's hands. Those provisions in the excise laws which give the revenue a preference over exciseable commodities, and the instruments used in their manufacture, are strictly the creation of tacit hypothecs. The provisions in the bankrupt acts for paying servants' wages and other debts out of the readiest funds of the bankrupt are the establishment of a general hypothec over the estate.

In Scotland the landlord's privilege to seize the tenant's goods for arrears of rent is called a hypothec while it is unexercised—that is to say, before execution against them is commenced the landlord is said to have a hypothec over the goods. On an agricultural farm the crop stands hypothecated for the rent of the year of which it is the produce. The landlord's right exists so long as the crop is on the farm, and it extends to the revindication of it even from a bonâ fide purchaser within three months after the rent has fallen due, unless he have been a purchaser by bulk in open market. The hypothec for other effects—as the cattle on a farm, the tenant's furniture in a house—subsists over the whole for each term's rent, and gives a preference for three months after the rent is due. The landlord's hypothec is not affected by the bankrupt statutes. Another right of a different description is called a hypothec in Scotland—viz. the right of a law agent to take his client's decree for expenses, or judgment for costs, in his own name, in order that he may recover payment of his account as taxed by the auditor of court. This right cannot be defeated by a collusive settlement. In Scotland a law agent, whether employed to conduct a litigation or in other professional business, such as conveyancing, is entitled to retain his employer's title-deeds and papers until his just account is paid. This right has also been called a hypothec, but it is clearly a lien.

In France there is a distinction between privilèges and hypothèques. All tacit hypothecs, according to the division above kept in view, are included under the former, which are subdivided into a general preference over all the moveables or personal property in the debtor's possession, and limited preferences over particular articles of property for particular obligations. This last named, in so far as it affects moveable property, is the class of rights which has been spoken of above as tacit hypothec, and it includes the landlord's security for his rent. There is also a classification of privilèges sur les immeubles, consisting of tacit preferences over what is in England called real property, and of privileges which extend to both moveable and immoveable property. The term hypothèque is applied to conventional securities over immoveable or landed property, and is the object of much useful legislation, such securities being, from the efforts to give virtual effect to the law for partition of successions, without reducing them below the proper extent for agricultural operations, more common in France than perhaps in any other part of the world. See on the matter of the immediately preceding remarks, *Code Civil*, lib. iii. tit. 18.

HYPOTHECATION. [Mortgage, P C.]

INDEX TO THE LETTER H.

VOLUME II.

I

ICE-HOUSE, a building constructed for the purpose of keeping ice through the summer, by excluding, as perfectly as possible, the influence of changes in the temperature or humidity of the external atmosphere. Such structures are not only useful for preserving ice which is to be applied to the cooling of liquors, or to the preparation of articles of confectionary, but also as affording the most effectual means known for keeping meat, fish, game, vegetables, and fruit sweet and fresh in hot weather. In Loudon's 'Encyclopædia of Cottage, Farm, and Villa Architecture,' where (sec. 736-738) a detailed account is given of various modes of constructing ice-houses, it is observed that although these important conveniences are rarely to be found among the buildings of an English farm, they are frequent in those of North America, and might be advantageously introduced in this country, especially upon such farms as are connected with inns. To a gentleman's country residence an ice-house is always an important, and, in some cases, almost an indispensable appendage.

One of the simplest modes of preserving ice, alluded to in the work above mentioned, consists in enveloping the ice in a great quantity of straw, above the surface of the ground, in such a position that moisture, which is even more injurious than heat, may drain off freely. For this purpose the ground should be raised in the form of a flattened cone, upon which should be laid a stratum of faggots. Straw is laid upon the faggots to the thickness of a foot or more, and the ice is piled upon it in a compact conical mass, the larger the better. Over the ice is laid first about a foot thickness of straw, then faggot-wood to a further thickness of two feet, the interstices of which have the effect of keeping a stratum of confined air round about the pile of ice; and finally two or three feet of straw arranged as a thatch. The best situation for such an ice-stack or mound is stated by Loudon to be under the shade of trees, or, where such shelter cannot be obtained, under a kind of shed roof, with an opening to the north only. Some writers, however, among whom may be mentioned Cobbett, who notices the subject in his 'Cottage Economy,' considers that, in consequence of their tendency to increase the humidity of the air, the vicinity of trees is objectionable. On the same principle some recommend an eastern or south-eastern, in preference to a northern aspect, for the entrance to an ice-house, in order that the morning sun may dissipate the damp air from it.

An underground ice-house may, according to Loudon, be simply a large cellar, with hollow or double walls, floor, roof, and doors, and furnished with a trapped drain to allow the escape of such water as may be produced by a partial thaw, without admitting any air. Such ice-houses are usually formed in the shape of an inverted cone, which is considered the most advantageous because it keeps the ice more compactly together than any other form, and because, in case of any thaw taking place, the remaining ice will naturally slip down, so as to keep the mass solid. This advantage, however, Loudon does not conceive sufficient to compensate for the greatly increased expense of construction involved in the adoption of the conical form. 'A plain square room,' he observes, 'with double side walls, say a foot apart, a double arch over, and a double floor under, which can be built with the same ease as any common cellar, will, all other circumstances being alike favourable, keep the ice as long as any conical form whatever.' In all cases it is well to interpose a layer of straw, reeds, or chaff, which is preferred to straw in Italy, where it is used for packing ice for travelling, between the walls and the ice; and by the use of faggots as well as straw any perfectly dry cellar in a suitable situation may be used as an ice-house. In some situations a sufficient degree of hollowness in the walls may be produced by the adoption of the plan of building with bricks on edge (noticed under BUILDING, P. C. S., p. 250), or by some similar contrivance. One mode of building hollow walls which may be thus applied, consists in the use of half-bricks, divided longitudinally, as stretchers, leaving a space equal to the full width of a brick between them. Such half-bricks are easily produced by nearly cutting the brick in half with a wire before burning, when, after paying duty only as a single brick, it may, when burnt, be easily broken in two. Hollow floors for ice-houses may be constructed in various ways with bricks on edge and tiles or flags. Whatever be the construction of the ice-house itself, there should be no opening by which it can communicate with the external air excepting through the entrance passage, which is usually at least two or three yards long, and furnished with two, three, four, or more doors, of which not more than one must be opened at a time. Where a portion of the passage is fitted up with shelves to serve as a pantry, four doors are necessary, and the space between the first or outer and the second doors, and also, if possible, that between the second and third doors, should be filled up with straw, which, for convenience of removal, may be made up into great bags or cushions, and suspended from the ceiling. For this purpose barley-straw is, owing to its softer nature, preferable to that of wheat, rye, or oats. The space between the third and fourth doors then constitutes the pantry, the temperature of which may be reduced by occasionally opening the fourth or innermost door for a time. Sometimes pantry-shelves are placed in the body of the ice-house itself. Where the difficulty of excluding external temperature is very great, treble walls, roofs, and floors may be used, and the entrance-passage may be made crooked, with a door at every turn.

Loudon gives a ground-plan and section of a complete ice-house of approved construction, of the inverted conical shape, with an arched roof, which it is proposed to cover with two or three feet of earth, or more in hot climates, over which he suggests the propriety of training ivy, for the sake of excluding solar heat. In this design a small pump is shown communicating with a well in the drain of the ice-house, for the purpose of raising the thaw-water for drinking or other use. Dr. Ure, in his 'Dictionary of Arts,' &c., art. 'Ice-house,' gives a section of a similar structure, but with solid walls and a conical roof of timber, which may be simply thatched, or covered with brickwork and thatched, and which should have a gutter round it to collect and conduct to a distance all rain that falls upon it, that the circumjacent ground may be kept dry; and in Hebert's 'Engineer's and Mechanic's Encyclopædia,' under the same head, is an account of a plan proposed by Mr. David Gordon, for constructing an ice-house of similar form, principally of timber. In this plan the excavation is made considerably larger than the ice-house, which consists of a framework of strong timbers, roughly boarded outside, and lined with straw set on end and confined by laths nailed to the timbers. The conical roof is thatched with straw or heath, and the space between the outer boarding and the surface of the excavation is filled with heath, brushwood, or fir-tops, and neatly thatched or turfed over. In some situations simple excavations in calcareous soils, with a long circuitous passage by way of approach, are used instead of more regular ice-houses.

In filling an ice-house, the ice should be broken with mallets to a coarse powder, which, according to Loudon, should be 'composed of particles not larger than those of sand or salt,' and well rammed down as it is thrown into the ice-well, its upper surface being kept of a concave shape, and a little water being occasionally added to fill up all interstices, and to facilitate the congelation of the whole into a solid mass. A better method, according to the same authority, is to sprinkle the ice with water saturated with salt, by dissolving it at the rate of a pound of salt to a gallon of water. This salt and water may be applied by a common watering-pot upon the surface of the ice at intervals of two feet from bottom to top of the mass, an extra quantity being poured on when the filling is completed. By this means the ice becomes so firmly compacted as to need the force of a pickaxe to break it up, in the heat of summer. 'Thus prepared,' observes Loudon, quoting from the 'Gardener's Magazine,' 'it will be found to keep three times as long as by the common method in the house, and it will also keep three times as long when exposed to the air, from salt water, and consequently salted ice, having a less capacity for heat than fresh water or fresh ice.' Snow is occasionally preserved in a similar manner to ice, it being carefully compressed into a solid mass. Some curious particulars respecting the use of ice and snow for refrigerating liquids, in antient as well as modern times, are given in a long paper in the third volume of Beckmann's 'History of Inventions' (English edition of 1814, pp. 322-355), in which reference is made to antient writers who allude to the preservation of snow in pits or trenches; and it is stated that a similar method is pursued in Portugal, where, when the snow has been collected in a deep gulf, some grass or green sods, covered with dung from the sheep-pens, is thrown over it; and under this covering the snow is so well preserved that it may be taken up and transported to a considerable distance throughout the summer.

In connection with the subject of this article, Loudon describes a kind of pantry intended to serve some of the purposes of an ice-house, in which the evaporation of water, constantly trickling down the outside of a close conical chamber elevated above the ground, is employed as a means of refrigeration; and also, in section 2536 of his 'First Additional Supplement,' an ice-box which might almost be termed a portable ice-house. It consists of an inner and outer casing, six inches apart, the interval between which is filled with burnt cork reduced to powder, this being found to possess higher non-conducting properties than the charcoal of wood. The lid is double, and is filled with the same substance; and it is made perfectly air-tight by means of projecting ledges, which, when shut, dip into a gutter filled with water. Ice may be preserved for several weeks in such a box, in which also bottles, dishes, &c. may be placed. Similar to this contrivance is the American ice-safe lately introduced into this country.

ICE-PLANT. [MESEMBRYACEÆ, P. C.]

ICHNEUMON, a genus of insects belonging to the order *Hymenoptera*, section *Terebrantia*, and family *Pupivora*, in the arrangement of Latreille. The genus, as defined by Linnæus, included such pupivorous hymenoptera as are furnished with veined wings (the anterior pair presenting in their disk several complete or closed cells), filiform or setaceous vibratile antennæ composed of a great number of articulations, and an ovipositor of various length and complicated structure. The Linnæan genus now constitutes a group including a great many well marked genera and an immense assemblage of species. All these are remarkable for the habits of their larvæ, which are parasitic *in* the bodies of other insects. These bodies the perfect ichneumons perforate by means of their ovipositors, and there lay their eggs. This destructive habit gave rise to the name by which they are known; a comparison being drawn between them and the Egyptian ichneumon (*Viverra Ichneumon*), the quadruped celebrated as the destroyer of serpents and crocodiles.

The history of these insects has attracted much attention among naturalists, and many elaborate memoirs have been written upon them. The purpose they serve in the economy of nature has been well described by Kirby and Spence: 'The great body of the ichneumon tribe is principally employed in keeping within their proper limits the infinite host of lepidopterous larvæ, destroying, however, many insects of other orders. Such is the activity and address of the *Ichneumonidæ* that scarcely any concealment, except perhaps the waters, can secure their prey from them; and neither bulk, courage, nor ferocity avail to terrify them from effecting their purpose. They attack the ruthless spider in his toils; they discover the retreat of the little bee, that for safety bores into timber, and, though its enemy ichneumon cannot enter its cell, by means of her long ovipositor she reaches the helpless grub, which its parent vainly thought secured from every foe, and deposits in it an egg which produces a larva that destroys it. In vain does the destructive *Cecidomya* of the wheat conceal its larvæ within the glumes that so closely cover the grain; three species of these minute benefactors of our race, sent in mercy by Heaven, know how to introduce their eggs into them, thus preventing the mischief they would otherwise occasion, and saving mankind from the horrors of famine. In vain also the *Cynips*, by its magic touch, produces the curious excrescences on various trees and plants, called galls, for the nutriment and defence of its progeny; the parasite species attached to it discovers its secret chamber, pierces its wall, however thick, and commits the destroying egg to its offspring. Even the clover weevil is not safe within the legumen of that plant; nor the wireworm in the earth from their ichneumonidian foes.' (*Introduction to Entomology*, vol. i. p. 267.) In the third volume of the Transactions of the Linnæan Society, in a Memoir by Mr. Marsham, may be found a full account of the operations of one of these insects, the *Pimpla manifestator*, observed by him in Kensington Gardens. The details of its proceedings there given are exceedingly interesting, and present a remarkable picture of insect instinct. The larvæ of ichneumons are in some cases solitary, in others gregarious. Those of some species quit the bodies of their victims and spin a cocoon of silk before being transformed into the chrysalis state. Those of others, remain and use the skin of the caterpillar as a covering. By a wonderful instinct, when the grub leaves the egg, instead of attacking the vital organs of the caterpillar, within whose body it has been hatched, and thereby destroying its food, it confines itself to the fatty parts until it has nearly attained its full size.

ICHNOCARPUS (from ἴχνος, a 'footstep,' vestige, and κάρπος, a 'fruit,' in reference to the slender follicles), a genus of plants belonging to the natural order Apocynaceæ. It has a salver-shaped corolla, 5-cleft calyx, and inclosed stamens; sagittate anthers free from the stigma. The species are climbing shrubs with opposite leaves; the flowers in branched terminal panicles, white, and inodorous.

I. frutescens has a turning stem, oblong lanceolate leaves tapering to both ends, axillary peduncles very long and racemose. It is a native of Ceylon and Nepaul. The flowers are small and purple; the leaves deep green above and pale beneath. According to Professor Royle, it is sometimes used in India as a substitute for sarsaparilla, and it is also mentioned by Afzelius in his Remedia Guinensia as a medicinal plant.

I. fragrans has oblong lanceolate leaves tapering to both ends, and axillary trichotomous spreading peduncles. It is a native of Nepaul, and has large handsome flowers.

I. Afzelii is a glabrous shrub with turning stems, oval acute leaves at the base, oblong or lanceolate as they approach the top. The corollas are white and sweet-scented. It is a native of Sierra Leone, and about the river Bascha, in woods and among bushes.

I. Loureirii has a frutescent stem, ovate oblong leaves, lateral 3-flowered peduncles. It is a native of Zanzibar. All the species of Ichnocarpus grow well in a mixture of loam, peat, and sand, and cuttings strike readily in sand under a hand-glass.

(Don, *Gardener's Dict.*; Lindley, *Flora Medica.*)

ICHTHYOLOGY, RECENT ADDITIONS TO. The researches of naturalists in all parts of the world have of late years greatly added to our knowledge of fishes, and revived the interest attached to this important branch of vertebrate Zoology. The connection which the genius and labours of Agassiz have established between Ichthyology and Geology has not a little tended to promote research in this direction, and the results are beginning to hold no unimportant place in natural-history publications. Moreover, now that philosophic Zoology is fast gaining ground, and mastering the species-making and mere collecting, which had so long taken the name and usurped the place of the science, the study of a class of animals including the links between the vertebrata and invertebrata, is assuming a degree of importance to which it formerly could lay no claim. On the much-neglected subject of the classification and the distribution of fishes, some important researches have been recently made known, of which, as they will probably materially affect the future progress of Ichthyology, we shall here give a brief summary.

Classification of Fishes.—The natural arrangement of fishes has recently engaged the attention of two of the most eminent and philosophical naturalists of our time, W. S. Macleay and J. Muller. Mr. Macleay's views on this subject are made known in a letter to an eminent Indian naturalist, Mr. M'Clelland, and were published in the Calcutta Journal of Natural History for July, 1841. Throughout they are influenced by the quinarian hypothesis, of which he is the distinguished author. He bases his classification on three generally admitted facts, which he holds to be incontestable. The first is the near approach of fishes to Batrachian Amphibia, which, with Swainson, he considers to be made by means of *Lophius* and *Malthe*. 2nd. The near approach of fishes to the Cetaceous Mammalia, the viviparous sharks constituting the connecting link. 3rd. 'As the grand character of fishes as a class is their being the most imperfect of vertebrata, the most typical of fishes ought therefore to be the most imperfect of them, *i. e.* the furthest removed from the type of vertebrata;' a position which many naturalists will be inclined to combat. He regards as examples of such fishes the *Cyclostomi*. Bearing the above 'fundamental facts' in mind, he constitutes the following primary divisions:—

Aberrant group. CTENOBRANCHII. Gills pectinated.

1. *Plagiostomi.* Cartilaginous fishes with fixed branchiae, leading to *Mammalia.*
2. *Sturiones.* Cartilaginous fishes with free branchiae.
3. *Ostinopterygii.* Bony fishes with free branchiae, leading to *Amphibia.*

Normal group. ACTENOBRANCHII. Fish breathing with gills, not pectinated.

4. *Lophobranchii.* Bony fishes breathing by tufts arranged in pairs along the branchial arches.
5. *Cyclostomi.* Cartilaginous fishes breathing by a series of cells.

Mr. Macleay has not yet presented an analysis of the families and genera included under the above five orders, with the exception of those of the third, *Ostinopterygii*, a term by which he proposes to denominate the osseous fishes having pectinated gills. The following table of his subdivisions of this important order will convey to the naturalist a clear idea of his system.

OSTINOPTERYGII.

A.

Aberrant group. ACANTHOPTERYGII. Spines in the first dorsal fin hard.

Tribe 1. *Balistina.* Maxillary bones soldered to the intermaxillaries, and both to the palatine arch; opercula and gills concealed beneath the skin. Includes the families *Balistidae*, *Ostraciontidae*, *Cephalaspis*, *Orthagoriscidae*, *Diodontidae.*

Tribe 2. *Percina.* Bones of the jaws free and complete. Operculum distinct. Operculum or preoperculum generally with dentated edges, or with spines. Includes *Chaetidontidae*, *Percidae*, *Scorpoenidae*, *Cirrhitidae*, *Sparidae.*

Tribe 3. *Fistularina.* Bones of the jaws free and complete. Operculum distinct. Operculum and preoperculum generally with smooth edges. *Scombridae*, *Fistularidae*, *Gobioidae*, *Lophiidae*, *Labridae.*

B.

Normal group. MALACOPTERYGII. Spines in the dorsal fins soft.

Tribe 4. *Pleuronectina.* Ventral fins, when existing, inserted under the pectorals, and directly suspended to the bones of the shoulder. *Anguillidae*, *Echeneidae*, *Cycloptеridae*, *Pleuronectidae*, *Gadidae.*

Tribe 5. *Abdominales.* Ventrals suspended behind the pectorals, and not attached to the bones of the shoulders. *Siluridae*, *Cyprinidae*, *Esocidae*, *Clupeidae*, *Salmonidae.*

Geographical Distribution of Fishes.—This branch of ichthyology is beginning to attract the attention and research which the interest of the subject demands. Within the last five years the example of Yarrell has been followed in many countries, and valuable local monographs published, with excellent illustrations. In the north of Europe, besides the writings of Nilson and Eckstrom, the fishes of Denmark are in progress of illustration by Henrik Kroyer. Those of Belgium have been carefully examined by M. de Selys Longchamps. In that naturalist's *Faune Belge* fifty-three fresh-water fishes and forty-one species inhabiting the sea are enumerated. Of the former, forty-three live only in fresh water; six in fresh water, but go to the mouths of rivers in winter; and four live in the sea, but migrate to the rivers in spring or summer. Of the sea-fishes thirty pass up the Scheldt as far as Antwerp. The fresh-water fishes of central Europe are engaging the attention of Agassiz, and his work on them is in progress of publication. Freyer has published an account of those inhabiting Carniola, amounting to thirty-two species. Italian ichthyology has been admirably illustrated by Charles Bonaparte, the Prince of Canino. In Asia the fishes of the Caspian have been described by Eichwald in his 'Fauna Caspio-Caucasica,' published in 1841. Those inhabiting the rivers of Syria have been enumerated by Heckel (1843) from the collections of Kotschy. Fifty-seven species inhabit the rivers Orontes and Euphrates, of which no fewer than forty-five are Cyprinidae. Indian ichthyology has received valuable contributions from M'Clelland, whose papers have been chiefly published in the Calcutta Journal. In Siebold's 'Fauna Japonica' (1842) are accounts and figures of Japanese fishes by Temminck and Schlegel. The most valuable contribution ever made to our knowledge of the ichthyology of Eastern Asia was communicated to the British Association at Cambridge in 1845, in the form of a report on the 'Ichthyology of China,' by Dr. Richardson. From his researches it would appear that the fishes of that region are not only very numerous as regards species, but also very valuable on account of the extensive fisheries there carried on. His remarks on their distribution are highly interesting. It would appear that chains of islands or coasts having an east and west extension determine the extent of the range of species and groups of species. For example, to take the intertropical zone of the ocean, we find a great number of fishes common to the Red Sea, the coasts of Madagascar, the Mauritius, the Indian Ocean, the south of China, the Philippines, the Malay Archipelago, the northern coast of Australia, and the whole extent of Polynesia, including the Sandwich Islands. As regards the generic forms of the fresh-water fishes, China agrees with the peninsula of India. Were the vast zone in question, embracing more than two-thirds of the circumference of the globe, to be suddenly elevated, we should find the remains of fishes similar everywhere throughout, the species which have a local distribution being few and unimportant. This result of Dr. Richardson's researches is of the highest importance when brought to bear on geological considerations. Dr. Richardson has also been engaged in the special investigation of the ichthyology of Australia, and his many valuable memoirs on that subject may be consulted in the 'Transactions of the Zoological Society,' and in the 'Annals of Natural History.' In Dieffenbach's 'Travels in New Zealand' (1843), the same indefatigable and philosophic zoologist has published, in conjunction with Mr. Gray, a list of the fishes of New Zealand. Ninety-two species are there enumerated. In Smith's 'Illustrations of the Zoology of South Africa,' figures and descriptions are given of the fishes of the Cape of Good Hope. The researches of Dr. Peters on the eastern coast of Africa, at present in progress, promise to make us well acquainted with the ichthyology of that interesting region. With those of the northern part of Western Africa we have had ample information in the valuable memoirs of Lowe on the fishes of Madeira (*Zoological Transactions and Proceedings*).

The labours of Jenyns on the fishes collected during Captain Fitzroy's voyages have contributed materially to our knowledge of the ichthyology of the southern extremity of South America, whilst that of Guiana has been illustrated by Sir Robert Schomburgk, in the 'Naturalist's Library.' De Kay's 'Zoology of New York' (1842) has made us acquainted in detail with the fishes of the United States. They amount, so far as known, to 440 species, distributed through 156 genera and 32 families. In the State of New York there are 126 *Acanthopterygii*, 115 *Malacopterygii*, 3 *Lophobranchii*, 18 *Plectognathi*, 3 species of sturgeon, and 27 cartilaginous fishes. It is to be regretted that the researches of Dr. Parnell on the West Indian fishes are still unpublished, since they would go a long way towards enabling us to gain a connected view of the ichthyology of the new world.

As far as we can judge from the materials as yet collected, the distribution of fishes appears to be determined by the same laws which regulate that of other aquatic animals. Climate, composition of the element in which they live (whether salt, brackish, or fresh), and conformation of the sea or river bed, on which the depth of water depends, are the great regulating influences. The great distinctions of form and colour between fishes of tropical and those of temperate regions, evince the influence of climate; the fact of the fisheries for certain species commonly used for food being invariably conducted in deep water, whilst others can only be maintained among shallows, shows the influence of depth; the fact pointed out by Dr. Richardson that the seas, by ranges of land or reefs extending for great distances under the same climatal parallel, are peopled by the same species of fishes, is an instance of the action of the combined influences of climate and depth. The distinctness as to genera and species of the greater number of river and lake fish from those inhabiting the sea depends on the second of the three great influences enumerated—that of the composition of the element in which they live. Great depths cut off the range of species even when climatal conditions are similar. Hence the fishes of the coast of the United States are for the most part distinct from those on our own side of the Atlantic. Some fishes have very limited ranges in depth compared with others, and, generally speaking, it may be assumed that those having the greatest vertical range (*i. e.* range in depth) have also the widest horizontal extension, a fact depending on the capacity of such species for living under a greater variety of conditions. Barriers of land, as chains of mountains, determining the courses of rivers, are often the boundaries between two distinct specific assemblages of fresh-water fish, and in like manner a very narrow strip of land may divide two very distinct marine faunas. The distribution of marine vegetables, affecting the distribution of numerous marine invertebrata which feed on those vegetables, and in their turn serve to furnish food for fishes, will materially affect the distribution of many species of the latter. So also will the presence of currents, and even the agency of man, assisting often unintentionally in the conveyance of ova from one country to another. Distant regions, presenting similar conditions, such as the Arctic and Antarctic Seas, are inhabited hy species representative hut not identical, and presenting a general aspect very similar, depending on characters of form and colour, &c. It is probable also that the fishes inhabiting the greater depths of tropical seas resemble those of temperate climes, and that those of the latter in like manner approach Arctic forms.

A brief glance at the range and distribution of the principal genera will best serve to illustrate the above positions.

The lowest and most anomalous of all the species of fishes, the *Branchiostoma*, is generally distributed through the seas of Europe. Only one species is known, yet we cannot but hope that the researches of the many active naturalists now occupied with the study of marine zoology will bring to light forms connecting the Lancelet with other genera. The *Myxine*, or glutinous hag, almost equally strange in form and structure, is confined to the most northern and most southern seas, and is replaced in the higher parts of the southern hemisphere by the equally curious and nearly allied genus *Heptatrema*. The Lampreys inhabit the fresh waters of Europe and North America, but the species in each are quite distinct. *Lepidosiren*, the connecting link between fishes and reptiles, so dubious in organization that its position is still disputed, is an inhabitant of the west of Africa, and a genus closely allied has just (1845) been discovered hy Dr. Peters on the eastern coast of the same continent.

The rays and sharks are universally distributed, but many of the genera and species are very local and apparently regulated in their range hy climatal zones. The seas of Europe can boast of the greater number, though fortunately the most formidable of the species are exotics. The largest species, as the great *Silachus maximus*, the basking shark, are harmless, and have their favourite habitats in the temperate zone. Size among fishes does not appear to hear any relation to latitude. *Chimaera* is northern and southern, extending from the frigid zone. The *Sclerodermi* are for the most part southern and tropical, especially the curious forms of *Cestracion* and *Astracion*. *Monacanthus* inhabits the American and Chinese seas; *Triodon*, the Indian ocean; *Tetrodon*, *Diodon*, and *Balistes* have wider ranges. The typical genus of pipe-fishes, *Syngnathus*, is cosmopolitan, and has a very wide geographical distribution. Six species are found in the British seas, two on the coast of the United States, and Mr. Jenyns has described new forms from Valparaiso, Tahiti, and Patagonia. *Hippocampus* is of the temperate zones of both hemispheres, and in the tropical seas is replaced by *Solenostoma* and *Pegasus*. The sturgeons inhabit the Western European seas, the Caspian, the Black Sea, and the Mediterranean. Three species are North American.

Of the eels, *Anguilla*, *Conger*, and *Muræna* are typical and cosmopolitan. *Gymnarchus* is Egyptian, *Gymnotus* (the electrical eel) South American, both inhabitants of fresh water. The osseous flat fishes are very generally distributed; the largest species are inhabitants of northern seas. The Mediterranean boasts of many species of *Pleuronectes*. Species of sole are found in both northern and southern hemispheres. The *Gadidæ* are inhabitants of northern and temperate seas, and certain species, as the Tusk, do not range farther southwards than Norway and Scotland. *Lepisosteus*, one of the few remaining genera of Sauroid fishes, which appear to have played a most important part in the waters of antient geological epochs, is confined to the rivers of America, and some allied forms to northern Africa. The herring tribe, *Clupeidae*, has a wide distribution, and forms of the typical genus *Clupea* are found in the southern as well as in the northern hemisphere. The species however are locally distributed; thus the true herring is unknown in the Mediterranean, where its place is taken by the Sardine, and the herrings of the South American coasts are quite distinct from those of the north. Even within very limited areas, as in that of the British seas, the species have peculiarities of distribution, as we see in the prevalence of the herring, properly so called, on the coasts of Scotland and in the Irish sea, while it is replaced by the Pilchard on the south-west coasts of England and south of Ireland: the white-bait is also a remarkable instance of local distribution. *Mormyra*, *Exocætus*, and *Esox* are the typical forms of pikes; the first is North African; the flying fishes are oceanic and Mediterranean, and the pikes proper are inhabitants of the temperate zones. The restricted genus *Esox* is confined to fresh water.

The important family of *Salmonidae* has its most valuable members in northern regions, some with a wide range, the same species of trout occurring in Lapland and in Switzerland. In North America the trouts are represented by very similar hut distinct species. M'Clelland has described a true salmon from India inhabiting the tributaries of the Oxus. This instance, however, does not affect the essentially temperate and subarctic character of the distribution of the *Salmonidae*, for this Indian species was found at an elevation of 11,000 feet, where we must expect to find temperate forms prevail. Jenyns has made known a peculiar genus of *Salmonidae*, which he has named *Aplochiton*, inhabiting the seas of the Falkland Islands and Tierra del Fuego. *Bajore* is a genus constituted by De Kay, and confined to the United States. The *Argentines* are Mediterranean, and *Sternoptyx* is oceanic.

Among the most characteristic fishes of the fresh waters of tropical countries are the *Siluridae*, which abound in the regions of Central Asia, where almost all the species of the typical genus *Silurus* occur. A single offset finds its way to Europe. *Pimelodus* and *Callichthys* are American genera of this family; the electrical *Malapterurus*, North African; *Loricaria*, South American. Equally interesting and well marked in distribution is the fresh-water family *Cyprinidae*. The true carps are characteristic of the old world; *Catastoma* and *Anableps* of the new.

Of the Acanthopterygious fishes the genera *Centriscus* and *Fistularia* are, with the exception of a single Mediterranean species, tropical. The genera of *Labridae* have well-marked provinces. Thus the numerous species of *Scarus* are grouped together in tropical seas, being replaced in temperate regions by *Labrus* and *Crenilabrus*. There are offsets, however, of each. The frog-fishes *Lophius* and *Chironectes* are chiefly represented in Africa and South America. A single *Lophius* is a native of European seas. De Kay enumerates seven Lophiadae as inhabitants of the United States, and Richardson has described some Australian species. The Goby tribe prevails in Europe and Asia. Some of the species of *Gobius* are remarkable for the depth at which they live. The Blennies are truly European, with very few exceptions. The Gunnels are mostly of northern seas. Some species of the Goby tribe inhabit fresh water, as the genus *Tuenioides*, which is found in marshes in India. *Comepturus* lives in Lake Baikal, and one or two species of *Gobius* proper live in rivers.

The *Mugiloidae* are very generally extended. They have been said to be absent from North America, hut this is incorrect, four species of *Mugil* inhabiting the United States. *Atherina* is also a cosmopolitan genus.

The Labyrinthiform Pharyngeans are essentially tropical, being all natives of the eastern regions of Asia. Their organization is peculiarly adapted to their climatal range. The *Teuthyes* are fishes of warm climates, and many species inhabit the Australasian seas. The Mackerel tribe includes a number of genera, which have very various areas of distribution. Among them the Dolphins (*Coryphaena*) are Mediterranean and Oceanic; the Dories (*Zeus*) mostly European; *Vomer*, exotic; *Notacanthus*, arctic; *Lichia*, Mediterranean. *Scomber* and the allied typical genera of the tribe are mostly cosmopolitan. The *Chetodans* are essentially equatorial.

The family of *Sparoideae* gives the most prominent feature to the ichthyology of the Mediterranean and seas of Southern Europe. *Pagrus* has a wide range, hut chiefly through warm regions. The *Scienoideae*, very numerous in species, are mostly equatorial. The important family of *Triglidae*, of which the Gurnard is the type, has a very extensive distribution. The true gurnards are mostly European; *Scorpaena* ranges from Europe to Australia. *Platycephalus* is peculiarly Indian. *Sebastes* is a genus of the old world, with one or two exceptions.

The *Percoideae*, chief of the Acanthopterygious families, is partly composed of marine and partly of fresh-water genera. The genus *Perca* is characteristic of the northern temperate zone. *Mesoprion*, *Diacope*, *Plectropomus*, and *Serranus* are cosmopolitan. *Mullus* and *Paralepis* are European genera. *Holocentris*, *Myripristis*, *Priacanthus*, and *Dules* are represented in both hemispheres. *Ambassis* is an Indian fresh-water genus. *Percophis*, *Pinguipes*, *Centrarchus*, and *Pomotis* are American. *Beryx*, *Trachichtes*, *Helotes*, *Pelotes*, and *Chironema* are Australian

I'CICA, a genus of plants belonging to the natural order Burseraceæ. It has a small obtusely 5-toothed calyx; 5 petals inserted under the disk, recurved, sessile, valvate; 10 stamens shorter than the petals inserted with them; a cup-shaped disk with 10 crenatures at the margin; a sessile 5-celled ovary with two collateral pendulous ovules in each cell; a very short style; a 5-angled stigma; a globose obtuse 1-3-celled drupe with thick and fleshy dissepiments; resinous seeds without albumen. The species are shrubs or trees with unequally pinnate leaves, and white flowers seated on panicled racemes which are terminal or axillary.

I. heterophylla has ternate or pinnate leaves, with stalked ovate, acuminated, entire, simply-veined leaflets; the racemes simple, rather shorter than the leaves. This plant is the *I. Aracouchini* of Aublet. It is a tree 50 feet in height, growing in Guyana, on the banks of the river Couron, where it is called by the natives Aracouchini. When an incision is made in the bark of this tree, a yellow balsamic aromatic fluid exudes, which retains its fluidity a long time after exposure to the air. This fluid is used by the Guyanese as an application to wounds. A resin is found also in the seeds, and the natives of Guyana carry the nuts about with them on account of the scent they give out. These nuts they often send as presents to their friends. The Caribs also use the exudation for mixing with oil with which they anoint their bodies.

I. heptaphylla has 5-7 stalked oblong acuminated leaflets, with the racemes few-flowered, somewhat corymbose, and 6 times shorter than the petiole. It is a small tree, a native of the woods of Guyana, where it is called *Arbre d'Encens.* The whole plant is sweet-scented, and like the last species yields a clear balsamic fluid when it is wounded. It is burned as a perfume, and used as a remedy in dysentery. The seeds are contained in a viscid pulp which hardens into a grey resin, and is used by the natives for burning as a perfume. The Carib name of this tree is *Arouaou.*

There are several species of Icica, all of which yield the same transparent fluid, resembling turpentine in many of its properties.

I. Icicariba, a native of Brazil, yields a resin, which is brought into the market under the name of gum elemi, but it is not the true gum of that name. *I. decandra* is found in the woods of Guyana, where it is called *Chipa.* The fluid which exudes from it yields on evaporation a resin. *I. altissima* grows in Guyana. There are two varieties of this tree, known by the name of white cedar and red cedar. The latter is a very durable wood, and is used for making household furniture, boats, canoes, &c.

IDENTITY. [SAMENESS, P. C. S.]

IDIOT. [LUNACY, P. C.]

IGNATIUS, Patriarch of Constantinople. The schism of the Greek and Roman churches, which began under Photius, who persecuted this prelate, and usurped his see [PHOTIUS, P. C.], gives importance to the life of Ignatius. He was born in 799, and was the son of the Emperor Michael Curopalates, and his mother Procopia was the daughter of the Emperor Nicephorus. On the revolt of Leo the Armenian, Michael surrendered to him the throne, which he had occupied during only a year and nine months, and embraced the monastic life. His sons followed the example of their father, and the youngest, Nicetas, then aged fourteen, changed his name into that of Ignatius. The new emperor, in order not to be disturbed in the possession of power, separated the several members of the family of Michael, and caused his two sons Eustratius and Nicetas to be made eunuchs.

During the reign of the three emperors Leo, Michael II., and Theophilus, they were allowed to enjoy in tranquillity the monastic life to which they had devoted themselves. Ignatius was admitted into the order of priesthood by Basil, Bishop of Paros in the Hellespont, a prelate who had suffered much persecution in opposing the Iconoclasts, and to whom Ignatius was much attached.

On the death of Theophilus, the Empress Theodora was declared regent in the name of her son Michael III. Being opposed to the Iconoclasts, she banished John, the Patriarch of Constantinople, and caused Methodius to be elected in his place. Four years after, on the death of Methodius, the patriarchal dignity was bestowed upon Ignatius, who was compelled to leave his monastery, where he had acquired a high reputation for piety and talent, and to accept this perilous honour.

He had not long enjoyed this see when the possession of it was troubled by his contest with Bardas, the brother of the empress, whom he had excommunicated on account of his scandalous excesses. Bardas having obtained considerable influence over the mind of the young Emperor Michael, whose vices he flattered and encouraged, induced him to take the reins of government, and to compel his mother to withdraw to a convent, and to accept the vows. Ignatius, when summoned to lend his authority to this unfilial act, did not content himself with remonstrating against it, but gave them a stern refusal. He was in consequence banished to the isle of Terebinthos, and deprived of his see, which he had held for eleven years; every means were afterwards employed, but without effect, to induce him to resign. Photius, a eunuch related to Bardas, and a person of considerable learning, who favoured the Iconoclasts, was by the will of the emperor, but without the consent of the church, appointed to the Patriarchate of Constantinople. The controversy of Photius with the Church of Rome, and its issue, are fully detailed in the article PHOTIUS, P. C.

In the year 866 Bardas was put to death; and Basil, the Macedonian, became possessed of the supreme power. One of the first acts of his reign was to banish Photius and to recall Ignatius, who was triumphantly reinstated in his patriarchal dignity on the 3rd of November, 867. At his suggestion a Council was assembled at Constantinople, which ranks in the Roman Church as the eighth Oecumenical. It was presided over by the legate of Pope Adrian II., and in it Photius and his partisans were excommunicated, and their opinions condemned.

From this time Ignatius was allowed to rule the Greek Church without opposition, and his episcopacy was adorned by many Christian virtues, and by a piety which long and severe persecution had chastened. He died on the 23rd of October, 878, on which day the Greek and Roman Churches still celebrate his memory. He was buried in the Church of St. Sophia; but his remains were afterwards transferred to that of St. Michael, near the Bosporus. The details of his life are chiefly drawn from Nicetas David, who had known him personally. It has been published by Rader, Ingolstadt, 1604.

(Le Beau, *Histoire du Bas Empire*, liv. lxvi.—lxx.; Fleury, *Hist. Eccles.*, vol. x.; Alban Butler, *Lives of the Saints.*)

IGNIS FA'TUUS, a meteor resembling a flame, which floats in the atmosphere at a few feet above the surface of the ground. It is generally observed by night, either stationary or in motion, over marshes or burial grounds; but in the 'Philosophical Transactions,' for 1694, there is an account of some ricks of hay being burnt at Dolgelly, in the preceding year, by a vapour like a weak blue flame which came from the sea: Derham (*Phil. Trans.* 1729) relates that he observed about a decayed thistle a flame in motion, which receded from him as he advanced towards it; and Beccaria states that he saw one which seemed fixed to a spot about two feet above some stones near a river: this philosopher observes that such meteors are most usually witnessed during a fall of rain or snow; he adds that they often appear on clayey soils, and that they have been seen to give out sparks. Trebra (*Deutscher Merkur*, Oct. 1783) mentions that he saw at Zellerfeld a meteor which at first approached him and afterwards receded from him to a distance of 500 paces; he adds that it then disappeared, and at the end of half an hour it again became visible.

Occasionally such meteors have been observed to follow or advance towards a spectator; but in general they appear to recede on being approached, and it has happened that from their resemblance to the flame of a distant lamp, they have led the unwary traveller into dangerous swamps. Little confidence can be placed in the descriptions given of them, as few persons have been able to examine them with due attention; and commonly they have been observed under the influence of an ill regulated imagination rather than a philosophical spirit.

A plausible hypothesis which has been proposed in order to account for this phenomenon is that a phosphuretted or a carburetted hydrogen gas, produced by the decomposition of animal or vegetable substances, rises from the ground or from stagnant water, either small in quantity and occupying a single spot, or in great abundance and then becoming a train or a horizontal column of vapour of variable dimensions: such gas may take fire by electricity or spontaneously, at a spot where the atmosphere is particularly free from moisture; and the flame communicating itself successively to other parts of a line or column, the latter being in a state of undulation from the agitations of the atmosphere, will give rise to the appearance of a motion from place to place. The brightness of the meteor will change with the varying quantity or purity of the gas; and its temporary disappearance may be caused by the quantity being in some places too small to render the flame visible. Spontaneous ignition is well known to take place occasionally in a number of vegetable and animal substances while undergoing decomposition, in consequence of the inflammable matter coming in contact with common air or with oxygen gas.

ILFORD. There are two places of this name in Essex, both in the hundred of Becontree. Great Ilford is a village included for civil purposes in the ward and former chapelry of Ilford in the parish of Barking; it forms a respectable street along the road from London to Chelmsford and Colchester, about 8½ miles from the General Post Office. It is on the left or east bank of the river Roding, which is here crossed by a bridge. The river is navigable for small craft up to the bridge, under the name of Barking creek. The name Ilford is derived by Morant from the *ill ford* that must have been here before the causeway and bridge were erected; and by Mrs. Ogbourne from 'a ford at the hill, written *Hyle-ford*.' Great Ilford has a new church, erected in 1831 by the aid of a grant from the commissioners for building new churches. The chapelry was then constituted a distinct parish for ecclesiastical purposes. The church is in the 'gothic style, with tower and spire,' and is capable of accommodating about 850 persons. Mr. Wright describes it as a handsome building. There is also a small chapel (St. Mary's) belonging to an antient hospital, of later (or perpendicular) English architecture; and a new church or chapel (Trinity Chapel) has been erected at Barking-side in the parish of Ilford, capable of accommodating 466 persons, to which a district chapelry has since been assigned. The chapel is in the Anglo-Norman style, with a small belfry. There are also in the village two dissenting chapels. Ilford ward contained in 1831, 725 houses, namely, 668 inhabited by 701 families, 4 houses building, and 53 uninhabited; with a population of 3512: in 1841 it contained 771 houses, namely, 721 inhabited, 32 uninhabited, and 18 building; with a population of 3742, showing an increase in ten years of 230. The living of great Ilford is a vicarage of the clear yearly value of 430*l*., in the rural deanery of Barking, the archdeaconry of Essex, and the diocese of London. The educational returns for 1833 do not distinguish the ward of Great Ilford from the other divisions of Barking parish.

Little Ilford is a parish separated from that of Barking by the river Roding. The parish has an area of 750 acres, and contained in 1831, 22 houses inhabited by 23 families, and 1 house building: the population was 115: in 1841 it contained 23 inhabited houses, with a population of 189; of whom 36 were prisoners or officers in Ilford gaol, which is a house of correction for the county, erected in 1831. The church is dedicated to St. Mary the Virgin. It contains a monument to Smart Lethieullier, Esq., the antiquary. The living is a rectory of the clear yearly value of 408*l*., with a glebe house in the same ecclesiastical divisions as Great Ilford. There was no school in the parish in 1833, but the children 'were taught to read every Sunday morning and afternoon in the church.'

(Morant, *History of Essex*; Mrs. Ogbourne, *History of Essex*; Wright, *History of Essex*; *Reports of Commissioners for Building New Churches*; *Population Returns, and other Parliamentary Papers*.)

ILICINEÆ. [AQUIFOLIACEÆ, P. C. S.]

ILLEGAL CONTRACT. [PUBLIC POLICY, P. C. S.]

ILLICE'BRUM, a genus of plants the type of the natural order Illicebraceæ. It has five sepals slightly cohering at the base and horned at the back. Petals absent or five subulate inserted with the five stamens on a perigynous ring; a one-celled one-seeded furrowed capsule bursting along the furrows. The only species is a small trailing shrub with opposite leaves having scarious stipules at the base.

I. verticillatum, Whorled Rush-grass. It has a trailing glabrous stem, roundish leaves, verticillate whorled white minute flowers. It is found in bogs and wet marshy places, chiefly in Cornwall and Devonshire. The seeds of this shrub should be planted in a moist situation, and, if allowed to sow themselves, will spring up regularly every season. It is worth cultivation on account of the delicacy and beauty of its blossoms.

(Babington, *Manual of British Botany*; Don, *Gardener's Dictionary*.)

ILLICIEÆ. [WINTERACEÆ, P. C.]

ILMEN, LAKE. [RUSSIA, P. C.]

I'MOLA, INNOCE'NZIO DA, a pupil of Francia, and a distinguished painter, of the early half of the sixteenth century. His family name was Francucci; he was born in the latter part of the fifteenth century, at Imola, whence his surname, but he lived chiefly at Bologna. He painted from 1506 until 1549: Vasari says he died aged fifty-six, but this is apparently an error, or he must have commenced to paint when only thirteen years of age. However, about 1506 he was placed with Francia, and, according to Vasari, he studied also with Albertinelli at Florence. In 1517 he produced what is now considered his masterpiece. It is a large picture, now in the Academy at Bologna, but formerly over the great altar of San Michele in Bosco, representing, in the lower part, the Archangel Michael vanquishing Satan, Saints Peter and Benedict at the sides, and above in the clouds the Madonna and Child surrounded by angels; the whole is treated much in the second manner of Raphael. It has been engraved by A. Marchi for the 'Pinacoteca di Bologna.' There is also a very superior work by him in the cathedral of Faenza. Da Imola's style is termed by Lanzi *Raffaellesco*, and it appears that several of his works have passed for the works of Raphael, that is, for works of his second style. He was also a good fresco painter.

(Vasari, *Vite de' Pittori*, &c.; Lanzi, *Storia Pittorica*, &c.: Giordani, *Pinacoteca di Bologna*.)

IMPEACHMENT. [PARLIAMENT, P. C., p. 279.]

IMPERATO'RIA (so named from its supposed imperial virtues in medicine), a genus of plants belonging to the natural order Umbelliferæ. It has no calyx; obovate petals contracted into an inflexed segment. The fruit flattened at the back with a dilated flat border. The species are glabrous perennial herbs with erect hollow terete striated stems. The umbels are large and compound, and the flowers white.

I. Ostruthium has a tuberous fleshy and somewhat creeping root of an aromatic and acrid nature. The lower leaves biternate, the upper ones less compound. The flowers are small and of a white or pale flesh-coloured hue. It is a native of Europe and Newfoundland in damp meadows and woods. This species is the Masterwort of old English herbalists, and the root has been much celebrated as an antidote against poisons, a diuretic, and sudorific; and Lerango affirms that an infusion of it in wine has cured agues which have resisted quinine. When chewed, it excites a copious flow of saliva, and acts as an agreeable stimulant to the gums. It is recommended in cases of rheumatic toothache, and is cultivated in many places for the London market.

I. angustifolia, the Narrow-leaved Masterwort, has biternate leaves, oblong leaflets attenuated at the base and deeply serrated. It is a native of the Alps and Piedmont. The blossoms appear in June and July, and are of a white colour. The species of this genus are of easy culture, and may be propagated either by dividing the roots or from seed.

(Don, *Gardener's Dic.*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany*.)

IMPRESSMENT. [SEAMEN, P. C. S.]

IMPRISONMENT, FALSE. [FALSE IMPRISONMENT, P. C. S.]

INCENDIARY. [ARSON, P. C.; LAW, CRIMINAL, P. C. S.]

INCEST. During the Protectorate in the year 1650, incest and adultery were made capital offences, but at the Restoration this law was not confirmed. Incest in England is now only punishable by the ecclesiastical courts, according to the rules of the canon law. This law also determines what kind of sexual connection is incest. Incest may be committed either by married persons or persons unmarried. If adultery is committed, it may also be incest; and if fornication is committed, it may also be incest. The notion of incest is founded upon the degree of consanguinity or affinity between the parties who have had the sexual connection.

The term Incest is from the Roman term Incestum, which is the same as Non Castum, 'not pure,' and in its most general sense signified any offence against positive morality, or religion. Persons within certain degrees of consanguinity could not contract a marriage; and if they did contract a marriage or live together as man and wife, such a marriage was called incestuous (Incestae Nuptiae). The affecting to marry was not necessary to constitute Incestum. It would be Incestum whenever there was sexual connection between a man and woman, whether married or not, who were incapable of contracting a lawful marriage by reason of consanguinity. If the parties were capable of contracting such marriage, the connection would be Stuprum, which, in its limited sense, partly corresponds to fornication.

The Roman notion of Incestum was not confined to the case of blood relationship. Persons who stood in the relation of parent and child by adoption could not contract a marriage, even after the adopted child was emancipated.

The Romans do not appear to have had any direct legislation on this subject till the Imperial period, and the rules of law that were in force were founded upon positive morality and usage. The Lex Julia which was enacted in the time of Augustus treated of incest only indirectly, and so far as it concerned the object of that law, which was the punishment of adultery.

In some cases of incest at Rome, there was capital punishment. (Dion Cassius, lviii. c. 22; Tacitus, *Annal.*, vi. 19.)

The subject of the Roman Incestum is treated copiously by Rein, *Criminalrecht der Römer*, and with a reference to the numerous authorities.

INCH OF CANDLE. [Auction, P. C.]

INCHBALD, MRS. ELIZABETH, whose maiden name was Simpson, was the daughter of a Suffolk farmer residing near Bury St. Edmunds. She was born in 1753. Prone to romantic notions, and losing her father in youth, she ran away at the age of sixteen to seek her fortune, and endeavoured to procure an engagement as an actress in London. After several adventures, she obtained a place in a country theatre, and soon married Mr. Inchbald, a respectable actor, much older than herself, with whom she lived for some years in mutual regard and comfort. Mr. and Mrs. Inchbald performed for four seasons in Edinburgh, and, after an engagement at York, went to France for a time. In 1779 Mr. Inchbald died at Leeds; and in the winter of 1780-81 Mrs. Inchbald began to play secondary parts at Covent-Garden. She continued on the stage till 1789, but always owed her favour with the public less to her merits as an actress than to the sweetness of her face and manner, and to the blameless character which she was known to maintain in private life. She had begun to write dramatic pieces several years before her retirement from the stage: the first of these, a slight afterpiece, was acted and printed in 1784; and from that time till 1805 she wrote plays in rapid succession, producing nineteen in all, one of which, 'Lovers' Vows,' is an adaptation from Kotzebue. Her dramatic genius was not of a very high class: but several of her comedies had much success, and one or two of them still keep their place on the stage. They gained for her the means not only of supporting herself with honourable economy, but of making a handsome allowance to an invalid sister, and of saving a considerable sum. Her melo-dramatic comedy of 'Such Things Are' gained for her more than four hundred pounds: as much was produced by 'Wives as they Were and Maids as they Are;' and for 'Every One has His Fault,' the most strongly characterised of her plays, she received seven hundred pounds. She edited, with biographical and critical remarks, 'The British Theatre,' a collection of acting plays, 25 vols., 1806-1809; 'The Modern Theatre,' 10 vols., 1809; and a collection of 'Farces,' 7 vols. Mrs. Inchbald's literary talents are best exhibited by her two novels, 'A Simple Story,' first published in 1791, and 'Nature and Art,' in 1796. Both became extremely popular, and deservedly so, and have been reprinted in our time in collections of standard novels. She died on the 1st of August, 1821, in a boarding-house at Kensington, leaving nearly 6000*l.* in legacies to her relatives and friends, to the Roman Catholic poor, to the Covent-Garden Theatrical Fund, and small sums to her laundress and hairdresser, 'provided they should inquire of her executors concerning her decease.' She had written an account of her own life, but had refused an offer of a thousand pounds for it; and, in obedience to her will, it was destroyed after her death. But her journal, kept regularly for many years, was preserved; and from it and her letters were written Mr. Boaden's 'Memoirs of Mrs. Inchbald,' 1833.

INCLOSURE. The term Inclosure is applied to the inclosing and partitioning of lands in England and Wales, which are comprehended under the general name of Commons or Common Lands. A knowledge of the present condition of the lands comprehended under this term enables us to form a better estimate of the state of agriculture in England and its capabilities of improvement. We thus learn also what was the general condition of the lands in England before inclosures were made.

It is necessary to define the terms Commons, and Commonable and Intermixed Lands. Commons or Common Lands are lands in a state of nature or waste, of which individuals have not the severalty. Commonable Lands are those lands which during a part of the year are in severalty, that is, occupied severally by individuals as their own, to the exclusion for the time of other people. The amount of common land in England is not known, but it is conjectured that it may be about 8,000,000 of acres: the total area of England and Wales is supposed to be about 37,000,000 acres.

The amount of commonable and intermixed lands is not known. The nature of these commonable and intermixed lands may be collected from the following instances. 'There are many parishes in the kingdom that consist altogether of intermixed or commonable lands; there are others in which there is a great intermixture of common land with the commonable and intermixed land. The township of Barmby on the Marsh in Yorkshire contains 1692 acres. There are 1152 pieces of open land, which contain 1015 acres, giving an average size of 3 roods and 23 perches, and there are 352 old inclosures containing 677 acres. In the parish of Cholsey in Berkshire, the total contents of which are 2381 acres, there are 2315 pieces of open land, which contain 2327 acres, giving an average size of one acre.' This open land generally consists of long strips, which are so narrow that it is impossible to plough them across. Yet much of this land is the best in the kingdom for natural fertility, and is the oldest cultivated land.

There is a great variety in these commonable lands; but they may be divided into three classes, exclusive of woodlands. First, there is open arable and meadow land, which is held and occupied by individuals severally until the crop has been got in. After the crop has been removed, that is, during the autumn and winter, it becomes commonable to persons who have severalty rights in it, and they turn on to it their cattle without any limit, or without stint, as it is termed. Thus there is a divided use in these open lands: individuals have the exclusive right to the enjoyment of one or more of these strips of open land for a part of the year; and during another part of the year all these individuals enjoy this open land in common. Second, there is open arable and meadow land that is held in severalty during one part of the year, like the first class; but after the crop is removed, it is commonable not only to parties who have severalty rights, but to other classes of individuals: these lands are generally called Lammas Lands.

These commonable rights may belong to a particular class, as a body of freemen, or to all landholders. There is great variety in these two classes as to the severalty holdings also. 'There are many cases in which the severalty holding varies year by year. There are in these open lands what is called a pane of land, in which there may be 40 or 60 different lots. It is reported to be a remnant of an old military custom, when on a certain day the best man of the parish appeared to take possession of any lot that he thought fit; if his right was called in question, he had to fight for it, and the survivor took the first lot, and so they went on through the parish. It often happens that in these shifting severalties the occupier of lot one this year goes round the whole of the several lots in rotation; the owner of lot one this year has lot two the next, and so on. When these lands are arable lands, they do not change annually, but periodically, according to the rotation of the crops. Then there is the old lot meadow, in which the owners draw lots for the choice. There are a great variety of circumstances under which the severalty ownership of these lands shifts from time to time; but after the severalty ownership has ceased, and after the crop has been removed, they all become commonable.'

This is one among many instances of the existence of antient usages in England, which are the same or nearly the same as the usages of nations that we call barbarous. Tacitus (*Germania*, c. 26) says of the antient German mode of agriculture, 'The lands, in proportion to the number of cultivators, are occupied by all in turns, which presently they divide among themselves according to their rank (merit). The extensive plains offer facility for division. They change the cultivated fields yearly; and there is still a superfluity of land.' The meaning of Tacitus is not clear. The following passage in Cæsar's account of the Gauls (vi. 22) is more distinct: 'They pay no attention to agriculture, nor has any man a fixed quantity of land and boundaries of property: but the magistrates annually assign to the clans and tribes who have come together as much land as they please, and where they please, and in the next year they compel them to move to another spot.' Herodotus (ii. 168) says that each member of the military caste in Egypt had a certain portion of land assigned to him; but they enjoyed the lands in a rotation, and the same persons did not continue in the enjoyment of the same lands. Strabo (p. 315) mentions a custom amongst the Dalmatians of making a division of their lands every eight years.

'The third class is that of grazing lands, where the rights of parties are settled and defined, the ordinary stinted pasture. The commonable lands are subject to very great variety and peculiarity; for instance, in some of these lands the right of grazing sheep at all belongs to a man called a flock-master, and he has the power, during certain months of the year, of turning his own sheep exclusively on all the lands of the parish; or, according to particular circumstances, his right is limited and restricted to turning sheep upon a certain portion of it, with a view to giving parties an opportunity of putting in a wheat crop. In those parishes where there is a flock-master who has a right of depasturing his sheep during a certain portion of the year over all the land of the parish, it is clear that no one can sow any wheat without having made a bargain with him for shutting up his own particular fields, or some proportion of them.'

'There is a very large extent of wood-land in this kingdom that is commonable, strange to say, where certain individuals have a right during the whole year to turn on stock, the owner of the wood having no means of preserving his property except by shutting out other commoners' stock by custom for some two or three years after felling. There is that right, as also the old right of estover, which is a very great inconvenience, viz. where parties have the right of cutting house-bote, and plough-bote, and fire-bote, and so on in woods belonging, *quâ* wood, to another party. There is a great deal of land subject to that ruinous custom. There are many varieties of these commonable lands, but these are the most prominent and remarkable of them.'

Under such a system as this, it is obvious that these common fields must be ill cultivated. The intermixed lands cannot be treated according to the improved rules of good husbandry. It is stated that the simple re-distribution of intermixed lands, now held in parcels so inconvenient in form and size as to be incapable of good husbandry, would in many instances raise the fee-simple value of the lands from 15*s*. or 17*s*. an acre to 30*s*.

It is the opinion of witnesses examined before the parliamentary committee of 1844, on Commons' Inclosures, that judicious inclosure would make a large portion of common lands much more productive. At present open arable lands are so intermixed that effectual drainage is nearly impossible. One witness says: 'I have had occasion to go over two small properties, about 150 acres each; one I found in 301 different pieces, and the other in a little more than a hundred. I mention this to show how the lands are frequently intermixed; they are therefore farmed at much greater expense; and it is impossible to drain them on the present improved mode of drainage, inasmuch as other parties are occupying the furrow by which the water should pass off.' In the Midland counties, where there are these open arable fields, the course is two crops and a fallow, and every third year the flocks run over the whole field. The same witness considers that a fourth of all the open arable land is at present totally unproductive. In cases where common arable fields have been subdivided and allotted, 'the great improvement is, that in the first place every man has his allotment, and he deals with it as he pleases; he drains it, and crops it upon a proper course of cropping; he puts it in seed and keeps sheep upon it: he grows turnips and clover, or whatever he thinks proper.' The same witness is of opinion that the average improvement in the value of common fields which have been inclosed is not less than 25 per cent. Indeed the evidence that was produced before the committee establishes to a degree beyond what otherwise would be credible, the immense inconvenience and loss which arise from the system of intermixed lands, and their being also subject to commonage.

As to Common Rights, that is, rights of pasture and so forth on commons or waste lands, they are described generally under COMMON, RIGHTS OF, P. C. As to the common pasture lands, they also require an improved management. It is stated that commons are generally overstocked, partly in consequence of persons turning out more stock than they have a right to do, and partly by persons putting their stock on the common who have no right. In consequence of commons being overstocked, they are profitable to nobody; and a rule for regulating the quantity of stock would therefore be beneficial to all persons who are entitled to this right of common. Violent disputes also frequently arise in consequence of the rights of parties to commonage not being well defined. It is the opinion of competent judges that very great advantage would result from stinting those parts of commons that are not worth inclosure; and that 'it would be in many instances highly desirable to inclose portions of a common for the purpose of cultivation, and to allot such portions of it, whilst it would be impolitic to do more than stint other portions of it.' A *stint* may be defined to be 'the right of pasturage for one animal, or for a certain number of animals, according to age, size, and capability of eating.' The commons in fact are not now stinted by the levant and couchant right, a right which cannot be brought into practical operation; and besides this there are many commons in gross. [COMMON, RIGHTS OF, P. C.]

Inclosures of land have now been going on for many years. It is stated that since 1800 about 2000 inclosure acts have passed; and prior to that time about 1600 or 1700. It seems doubtful from the evidence whether the 1600 or 1700 comprehend all inclosure acts passed before 1800. These inclosure acts (with the exceptions which will presently be mentioned) are private acts, and the expense of obtaining them and the trouble attendant on the carrying their provisions into effect have often prevented the inclosure of commons.

In 1836 an act (6 & 7 Wm. IV. c. 115) was passed for facilitating the inclosure of open and arable fields in England and Wales. The preamble to the act is as follows:—'Whereas there are in many parishes, townships, and places in England and Wales, divers open and common arable, meadow, and pasture lands and fields, and the lands of the several proprietors of the same are frequently very much intermixed and dispersed, and it would tend to the improved cultivation and occupation of all the aforesaid lands, &c., and be otherwise advantageous to the proprietors thereof, and persons interested therein, if they were enabled by a general law to divide and inclose the same,' &c. Inclosures have been made under the provisions of this act, but the powers which it gives are limited, for the 'act applies solely to lands held in severalty during some proportion of the year, with this exception, that slips and balks intervening between the cultivated lands may be inclosed.' The lands which cannot be inclosed under the provisions of this act are 'the uncultivated lands, the lands in a state of nature, intervening between these cultivated lands, beyond those that are fairly to be considered as slips and balks.' However, it was stated in evidence before the committee of the House of Commons in 1844, that a large extent of common and waste land has been illegally inclosed under the provisions of the act, and the persons who hold such lands have no legal title, and can only obtain one by lapse of time. The chief motive to this dealing with commons appears to have been, that they thus got the inclosure done cheaper than by applying to parliament for a private act.

In 1844 a select committee of the House of Commons was appointed 'to inquire into the expediency of facilitating the inclosure and improvement of commons and lands held in common, the exchange of lands, and the division of intermixed lands, and into the best means of providing for the same, and to report their opinion to the House.' The committee made their report in favour of a general inclosure act, after receiving a large amount of evidence from persons who are well acquainted with the subject. The extracts that have been given in this article are from the printed evidence that was taken before the select committee.

In pursuance of the recommendation of the committee, an act of parliament was passed in 1845 (8 & 9 Vict. c. 118), the object of which is thus stated in the preamble:—'Whereas it is expedient to facilitate the inclosure and improvement of commons and other lands now subject to the rights of property which obstruct cultivation and the productive employment of labour, and to facilitate such exchanges of lands, and such divisions of lands intermixed or divided into inconvenient parcels, as may be beneficial to the respective owners; and it is also expedient to provide remedies for the defective or incomplete execution, and for the non-execution of powers created by general and local acts of inclosure, and to authorize the renewal of such powers in certain cases,' &c.

It is not within the scope of this article to attempt to give any account of the provisions contained in the 160 sections of this act; but a few provisions will be noticed that are important in an economical and political point of view.

The 11th section contains a comprehensive description of lands which may be inclosed under the act; but the New Forest and the Forest of Dean are entirely excepted. The 14th section provides that no lands situated within fifteen miles of the city of London, or within certain distances of other towns, which distances vary according to the population, shall be subject to be inclosed under the provisions of this act without the previous authority of parliament in each particular case. The 15th section provides against inclosing town-greens or village-greens, and contains other regulations as to them. The 30th section provides that an allotment for the purposes of exercise and recreation for the inhabitants of a neighbourhood may be required by the commissioners under the act, as one of the terms and conditions of an inclosure of such lands as are mentioned in section 30.

The 108th section makes regulations as to 'the allotment which, upon any inclosure under this act, shall be made for the labouring poor;' and (section 109) 'the allotment wardens (appointed by section 108) shall from time to time let the allotments under their management in gardens not exceeding a quarter of an acre each, to such poor inhabitants of the parish for one year, or from year to year, at such rents, payable at such times and on such terms and conditions not inconsistent with the provisions of this act, as they shall think fit.' Section 112 provides for the application of the rents of allotments; the residue of which, if any, after the payments mentioned in this section have been defrayed, is to be paid to the overseers of the poor in aid of the poor-rates of the parish.

Sections (147, 148) provide for the exchanges of lands not subject to be included under this act, or subject to be inclosed, as to which no proceedings for an inclosure shall be pending, and for the division of intermixed lands under the same circumstances.

Under section 152 the commissioners are empowered to remedy defects and omissions in awards under any local act of inclosure, or under the 6 & 7 Wm. IV. c. 115; and under section 157 the commissioners may confirm awards or agreements made under the supposed authority of 6 & 7 Wm. IV. c. 115, if the lands which have been illegally inclosed or apportioned or allotted, shall be within the definition of lands subject to be inclosed under this act.

The provisions of this act seem to be well adapted to remedy the evils that are stated in the evidence before the select committee; and there can be no doubt that agriculture will be greatly improved, the productiveness of the land increased, and employment given to labour by this judicious and important act of legislation. The 'London Gazette' of August 22nd, 1845, notified the appointment by the Secretary of State of two Commissioners of Inclosures.

(*Report from the Select Committee on Commons' Inclosure, together with the Minutes of Evidence and Index.* The Report is accompanied with maps which explain various parts of the evidence. A complete digest of these Minutes of Evidence would form a very instructive article on the state of agriculture in England. The little that has been here attempted is of necessity very incomplete. The witnesses appear to agree in the main, but there are some differences of opinion which a reader of the Minutes will not fail to see.)

INCUBATION, ARTIFICIAL. [POULTRY, P. C., pp. 477, 478.]

INCUMBENT. [BENEFICE, P. C.]

INDIA. It was intended to give, under this head, a general view of all the territories of Hindustan, their areas, population, revenue, by whom held, names of the great divisions, and other details political and statistical. It will be convenient, for the sake of bringing down the information to the latest date, to postpone the article by referring it to TERRITORIES OF INDIA, P. C. S.

INDIA LAW COMMISSION. The act of the 3 & 4 Wm. IV. c. 85, by which the privileges of the East India Company are regulated, provides for the establishment of a Law Commission in India. The 53rd section recites that it is expedient, subject to such special arrangement as local circumstances may require, that a general system of judicial establishments and police, to which all persons whatever, as well Europeans as natives, may be subject, should be established in the East Indies, and that such laws as may be applicable in common to all classes of the inhabitants, having a due regard to the rights, feelings, and peculiar usages of the people, should be enacted, and that the laws, and customs having the force of laws, should be ascertained and consolidated. For this purpose the appointment of a commission of five members was authorized, to be called 'The Indian Law Commissioners.' They were to report from time to time, and to suggest such alterations as they should consider could be beneficially made in the courts of justice and police establishments, in the forms of judicial procedure and laws, due regard being had to the distinction of castes, difference of religion, and manners and opinions prevailing among different races, and in different parts of India. By subjecting the European population of India to the same system of laws as the native population, the influence of the opinion of the former in the administration of justice will prevent abuses to which the latter might be exposed without having the opportunity of urging their complaints in this country. Mr. T. B. Macaulay was the chief member of the first commission. The report of a penal code was presented to the Governor-General on the 15th of June, 1835. The groundwork of it is not taken from any system of law in force in India, though compared with and corrected by the practices of the country. The principles of the British law, the French code, and the code drawn up by Mr. Livingston for the State of Louisiana, are the foundations of it. Most of the articles which it contains are accompanied with illustrations to facilitate the application of the law, and it is thus a statute-book and a collection of decided cases. This report was signed by Messrs. Macaulay, J. M. Macleod, G. W. Anderson, and F. Millett. The progress of the present commissioners in dealing with the general law of India has not been published. (*Penal Code, Parliamentary Paper*, 1838, No. 673.)

INDUCEMENT. [PLEADING, P. C.]

INFAMY (from the Roman Infamia) in English law is not easily defined. Certain offences were formerly considered such that conviction and judgment for such offences rendered a man infamous and incompetent to be a witness. But the endurance of the punishment, or reversal of the judgment, restored a man's competency as a witness. The 9 Geo. IV. c. 23, § 3, enacts, that when a man convicted of a felony shall have undergone the legal punishment for it, the effect shall be the same as a pardon under the Great Seal; and (§ 4) no misdemeanour, except perjury or subornation of perjury, shall render a man an incompetent witness after he has undergone his punishment. The 6 & 7 Vict. c. 85, enacts, that no man shall be excluded from giving evidence, though he may have been convicted of any crime or offence. [EVIDENCE, P.C.S.]

Certain offences enumerated in the 7 & 8 Geo. IV. c. 29, § 9, are infamous crimes, with reference to the provisions of that act. Though infamy does not disqualify a man from being a witness, it may be urged as an argument against his credibility.

The only satisfactory definition of infamy would be a permanent legal incapacity to which a man is subjected in consequence of a conviction and judgment for an offence, and which is not removed by suffering the punishment for the offence. By 2 Geo. II. c. 24, § 6, persons who are legally convicted of perjury or subornation of perjury, or of taking and asking any bribe, are for ever incapacitated from voting at the election of members of parliament. They are therefore infamous: they labour under infamy: and have lost part of their political rights.

The Roman term Infamia is the origin of our term infamy. Infamia followed in some cases upon condemnation for certain offences in a judicium publicum; and in other cases it was a direct consequence of an act, as soon as such act became notorious. Among the cases in which Infamia followed upon condemnation, were, insolvency, when a man's goods were taken possession of by his creditors in legal form and sold; the actio furti, and vi bonorum raptorum; actio fiduciae, pro socio, tutelae, &c. In all these cases a judicial sentence, or something analogous to it, was necessary, before Infamia could attach to a person. Among the cases in which Infamia followed as an immediate consequence of acts which were notorious are the following: the case of a woman caught in adultery, of a man being at the same time in a relation of a double marriage, of prostitution in the case of a woman, or when a man or woman gained a living by aiding in prostitution. The consequence of Infamia was incapacity to obtain the honours of the state, and probably the loss of the suffrage also; and it was perpetual. The Infamis was still a citizen (civis), but he had lost his political rights. The infamous man was also under some disabilities as to his so-called private rights. He was limited by the Prætor's edict in his capacity to postulate (that is, take the initial measures for asserting or defending his rights in legal form), to act as the attorney of another in such cases, to be a witness, and to contract marriage.

The rules of the Roman law as to Infamia are chiefly contained in the *Digest*, iii. tit. 1 and 2.

(See Savigny, *System des heut. Röm. Rechts*, ii. § 76-83; Becker, *Handbuch der Röm. Alterthümer*, ii. 121; Puchta, *Institutionem*, ii. 441.)

INFANT HEIR. [HEIR, P. C.]

INFANT TRUSTEE. [TRUSTEE, P. C.]

INFANT WITNESSES. [AGE, P. C.]

INFEFTMENT, in the law of Scotland, from the same origin as the English term feoffment, expresses the ceremony by which a person succeeding to another by descent, settlement, or conveyance, is invested in any heritable or real property. Down to the year 1845 this ceremony was as pure a feudal usage as it ever had been in the days when the almost universal inability to write suggested symbolical modes of changing possession. Suppose a very ordinary case—that a person purchases a piece of ground from one who holds it of a superior. According to the system of sub-infeudation preserved in Scotland, he may either be put in tho seller's place and hold of the same superior, or be may hold a sub-feu under the seller. Whoever is to be the superior, the title deed contains an authority from him to invest the vassal. Until the late change, a number of persons had to proceed to the ground, consisting generally of the attorney who prepared the titles, and his clerks, who had the following parts to act. One was the bailiff of the superior, and a commission authorizing him to act in that capacity was read over. Another party acted as the procurator or representative of the vassal or purchaser. The bailiff lifted some fragments of earth and stone from the soil and handed them to the procurator, as symbols by which, according to the authority given to him, he made over possession of the lands to the new owner. The receiver of the symbols then placed a coin of the realm in the hands of another party, who must have been a notary public—this being the form in which a protest is taken in the hands of a notary in Scotland. Two other parties acted as witnesses. The ceremony, with the authority on which it proceeded, was narrated in a deed called an instrument of sasine, in which the notary publicly attested tho transaction. The preservation of this cumbrous ceremony down to so late a period was owing to its connection with the admirable system of registration which has kept the commerce in real property in Scotland on so clear and secure a position. The whole ceremony went for nothing unless the instrument narrating it were recorded in the Register of Sasines within sixty days after the ceremony. The registration was and is the criterion of preference. If land should be sold or mortgaged to any number of different people, the person whose sasine is first registered has the absolute title, and all questions as to the fairness of the transaction, are pecuniary questions to be settled apart from the titlo to the lands. The cumbrous ceremony mentioned above was rendered no longer necessary by the 8 and 9 Vict. c. 35, passed 21st of July, 1845, and called 'An Act to simplify the form and diminish the expense of obtaining infeftment in heritable property in Scotland.' It simply provides that 'it shall not bo necessary to proceed to the lands in which sasine is to be given, or to perform any act of infeftment thereon; but sasine shall be effectually given therein and infeftment obtained, by producing to a notary-public the warrant of sasino and relative writs, as now in use to be produced at taking infeftment, and by expeding and recording * * * an instrument of sasine, setting forth that sasine had been given in the said lands, and subscribed by the said notary-public and witnesses.' There has been little opportunity of observing the working of this act, but it is expected that it will materially reduce the expense of transferring interests in landed property in Scotland. A costly ceremony and a long deed, essential to the durability of every title of a new holder, are abolished by it. The act at the same time contains some methods of remedying mistakes and omissions which under the old law were fatal flaws.

INFORMER. An informer is a man who lays an information or prosecutes any person in the King's courts for some offence against the law or a penal statute. Such a person is generally called a common informer, because he makes a business of laying informations for the purpose of obtaining his share of the penalty. [INFORMATION, P. C.] Persons are induced to take the trouble of discovering offences, for which a pecuniary penalty is inflicted on the offender, by the promise of the reward; and if the penalty is imposed for the public interest, he who makes the offender known does the public a service. But still the business of a common informer is looked on with dislike, and he who follows it is generally despised; and perhaps tho character of common informers is generally such that they deserve all the odium they receive. They stand in a like situation to the common hangman. This dislike of informers, simply as such, is one of the anomalies of society, who hate their benefactor. The real foundation of the dislike however among those who can form a just judgment of things is, not the act of information, but the devices, tricks, and meannesses to which a man must often resort in order to know the facts on which his information must be founded. It is the same principle which often leads us to condemn a man for making certain statements in public, not because of the statements, but because of the means by which he may have obtained his knowledge. When a penalty is too heavy, or when the law that imposes it is generally disliked by the people for any reason, good or bad the popular dislike finds a definite object in the informer who gives effect to the law. The legislature that made the penal law is overlooked, because the legislature is a number of persons; the informer is one, and his agency is seen and felt.

In absolute governments there are spies and political informers, who are the tools of a government which has no rule but its own pleasure. Some peoplo have been dull enough to confound all informers in one class; not seeing that there is a difference between an informer who helps to give effect to the law, and an informer who helps a tyrannical government to entrap and punish persons suspected of disaffection to the government or of designs against it.

INFUSO'RIA, FOSSIL. The *geographical distribution* of living infusoria corresponds in extent with the abundance of reproduction, and the facility of diffusion through water and air, which belong to these microscopic creatures. Frequent in all the varieties of water which have been exposed to air and light, and in all the conditions of this element between the extremes of terrestrial temperatures, not absent even from snow, ice-covered streams, or the ejections of volcanoes, they have been recognised in all the regions of the globe. Lakes, rivers, and the sea are in places richly replenished by them, and their siliceous integuments falling through the water accumulate into extensive deposits. In regard to such accumulations in the sea, we have the evidence of soundings by Captain Sir J. Ross in the course of the antarctic voyage (*Annals of Nat. History, Oct.*, 1845) and Ehrenberg's examination of the deposits at Cuxhaven; and their abundance in fresh waters is matter of universal occurrence. These deposits consist of the siliceous integuments of the infusoria, and as only a small proportion of the families are protected with siliceous coverings, and as the waters which nourished them contain but little silica, while the deposits are very extensive, we naturally associate with these facts the idea of long-elapsed time.

But on turning to the marine and fresh-water deposits of earlier date, this impression of the long duration of natural agencies becomes much heightened. When, conducted by Ehrenberg, we find beneath the Bohemian mountains, and in the plains of North Germany, pleiocene deposits many feet in thickness, composed of little else than the thin flinty loricæ of microzoaria, and, following Professor Rogers and Mr. Bailey, who dug up myriads of other forms from the meiocene strata of Virginia, while Mantell and Reade exhibit to us infusoria from the chalk and the Kimmeridge clay of England, we must add to the historic time during which it can be proved these animalcula have lived the large indefinite geological periods of Cainozoic and Mesozoic formations.

The *source* of the siliceous matter, which enters the organization of the infusorial races, is not difficult of discovery. Most of our fresh waters contain silica, though not in abundance, derived, it is probable, from the decomposition of felspar and other mineral silicates. Silicate of soda and silicate of potash, thus occasioned, may by intermediate vegetative processes yield the silica in a state suitable for being organically solidified. Experiments on this subject, which may be easily made, are quite satisfactory in showing that myriads of silicated infusoria (Brachioni) may be generated in a few days in a sandstone trough, supplied with water and decaying vegetation. The animalcula being dried on the field-glass of the microscope, their beautiful transparent siliceous loricæ remain in abundance. In the hot waters of volcanic foci, silica is dissolved abundantly, and it is necessary to keep this fact in view while considering the extensive flint beds in chalk, the thick Polierschiefer beds of Bilin, and other siliceous masses, the result of organization. The distinction of *marine and fresh-water races*, which runs through all the larger animals and plants with such regularity as to be termed a law of nature, obtains also, but less absolutely, in the infusoria. Some species live both in fresh and salt water, and many at the junction of rivers with the sea. By comparing the living oceanic and lacustrine races on a large scale, enough of difference appears in their siliceous shields to authorize conclusions more or less positive as to the marine or fresh-water origin of infusorial deposits, which contain identical or analogous forms belonging to earlier periods. Thus the rich deposits of Richmond in Virginia appear to have been formed beneath the sea; the famous deposits of Bohemia, Berlin, and Santa Fiora contain *admixtures* of marine and fresh-water tribes; while those of Bann, in the county of Down, and Gainsborough and Bridlington, contain a more considerable proportion of fresh-water species.

Infusoria of marine or estuary origin have been found in a fossil state very extensively in Europe, Asia, Africa, and America. Ehrenberg has described many species from Greece (Zante and Egina), Italy (Caltasinetta and Cattolica), and Africa (Oran), which occur in calcareous marls, referred by Ehrenberg to the age of the true chalk deposits. These deposits are very extensive in Africa, occupying the whole coast of Oran and large tracts in Egypt and Arabia. (Portions of this tract have, however, been described by M. Rozet as tertiary.) In the undoubted white chalk of Denmark (Rügen), of France (Meudon), of England (Gravesend and Brighton), infusoria also occur, but less abundantly. North America has yielded a great variety of marine or partly marine infusoria, especially at Richmond and Petersburg in Virginia, at West Point, in Connecticut, Rhode Island, Massachusetts, and Maine. Brazil has also yielded similar deposits.

Infusoria partly of marine and partly of fresh-water origin have become familiar to us in the Polierschiefer (polishing slate) of Bilin and Planitz in Bohemia, and of the Habichtwald near Cassel, the Bergmehl of Santa Fiora in Tuscany, the white marls in the peat of Franzenbad near Egra in Bohemia, the peat deposits of Gainsborough in Lincolnshire, and at the base of the Mourne Mountains in Ireland. We find them to occur also in considerable plenty, but in limited distribution, in the lacustrine deposits of the East coast of Yorkshire. The Isle of France is added to these localities by Ehrenberg, and New Zealand by Mantell, all the occurrences belonging to supra-tertiary æras.

Infusorial remains are very unequally congregated. The siliceous marl (Kieselguhr) of Franzenbad consists mainly of Navicula viridis (fig. 6) (now recent); that of the Isle of France, of Bacillaria vulgaris (fig. 7); that of San Fiora, of Synedra capitata (fig. 9); while that of Bilin is composed of Gaillonella distans (fig. 8) almost exclusively. (Ehrenberg.)

Infusoria are mentioned in the moya (volcanic mud) of Mexico, and in the edible clay of the Amazons River, by Ehrenberg; in the rock salt and the marl which accompany it at Cardona in Spain, by Marcel de Serres; they are assumed by Ehrenberg to enter largely into the composition of flint, which indeed readily shows Xanthidia and Pyxidiculæ. The bog-iron ore (Raseneisenstein) common near Berlin is composed chiefly of Gaillonella ferruginea. A kind of semiopal lying in nodules in the Polierschiefer of Bilin is composed of the same siliceous reliquiæ (Gaillonellæ), as the true polishing slate, but they are cemented together and filled by infiltrated siliceous paste. With the Gaillonellæ Ehrenberg finds spicula of sponges. The precious porphyry opal of Kaschau, and the serpentine opal of Kosernitz in Silesia, has appeared to Ehrenberg of analogous composition. The following tabular view given by Ehrenberg of some of these facts will be useful:—

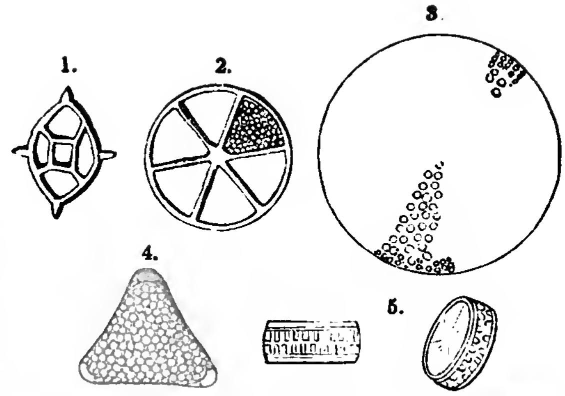
1. Bergmehl	Newest formation.
2. Kieselguhr	
3. Polierschiefer	Tertiary formation.
4. Saugschiefer	
5. Semiopal of Polierschiefer	

The above consist entirely or partly of the shells of Shield-Infusoria.

6. Semiopal of the Dolerite	Pyrogenous rock.
7. Precious opal of the porphyry	
8. Flint of the chalk	Secondary strata.
9. Gelberde (yellow earth)	Newest formation.
10. Raseneisenstein	
11. Certain kinds of Steinmark, investing the opal of Kaschau	

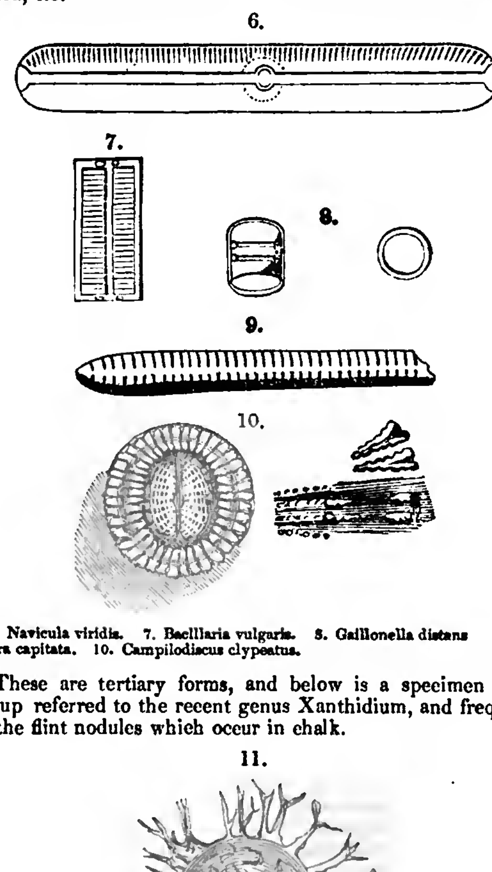
The above are *probably* of the same nature.

As examples of undoubted marine infusorial fossils we give below figures of some of the forms most frequent in a white deposit from Richmond.



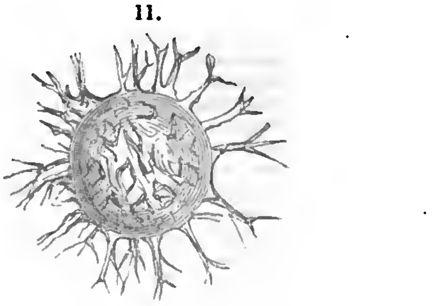
1. Dictyocha fibula. 2. Actinocyclus senarius. 3. Coscinodiscus radiatus. 4. Triceratium favus. 5. Gaillonella sulcata.

And for comparison the following outlines of mixed marine and fresh water species common in the Polierschiefer of Bilin and the Peat and Kieselguhr of Franzenbad, Egra, San Fiora, &c.



6. Navicula viridis. 7. Bacillaria vulgaris. 8. Gaillonella distans 9. Synedra capitata. 10. Campilodiscus clypeatus.

These are tertiary forms, and below is a specimen of a group referred to the recent genus Xanthidium, and frequen in the flint nodules which occur in chalk.



11. Xanthidium ramosum.

List of species of infusoria from the Kieselguhr of Franzenbad.—Navicula viridis (plentiful), N. gibba, N. fulva, N. librile, Gomphonema paradoxum, Gomphonema clavatum (fresh water species now living near Berlin); N. viridula, N. striatula (now living in the sea, the second also lives in the Carls bad water); Gaillonella varians?

Species of infusoria in the peat bog of Franzenbad,—Eunotia granulata (plentiful), Navicula viridis (rare), Bacillaria vulgaris, Cocconeis undulata, Gomphonema paradoxum.

Species which occur in the Kieselguhr of the Isle of France,—Bacillaria vulgaris? (plentiful), B. major, Navicula fulva? N. gibba, N. bifrons (living near Berlin).

In the Bergmehl of Santa Fiora:—

Synedra capitata (plentiful); with this are S. ulna (living both in fresh water and the sea); Navicula inæqualis, N. capitata, N. viridis, N. gibba (fresh water species); N. viridula (living in Baltic); Eunotia granulata, Navicula follis (extinct); Cocconeis undulata (marine); Gomphonema paradoxum, G. clavatum, G. acuminatum (living near Berlin); Cocconema cymbiforme (fresh water); Gaillonella italica; Spicula of spongiæ or spongillæ.

In the Polierschiefer of Bilin:—

Podosphenia nana (plentiful), Gaillonella distans, Navicula scalprum, Bacillaria vulgaris? (probably all marine!).

In the Leaf Tripoli:—

Gaillonella distans (plentiful), Podosphenia nana, Bacillaria vulgaris? (probably marine).

At Bann, in the county of Down, Captain Portlock found under peat, Naviculæ, Bacillariæ, Eunotiæ, with fragments of achnanthes and confervæ. (*Microscopical Journal*, 1841.) At Gainsborough, Mr. Binney found under peat, abundance of Gaillonella. At Bridlington, we have observed in white and brown marls, Eunotia serra? Bacillaria vulgaris, Navicula inæqualis, N. viridis, N. phœnicenteron, Cocconema lanceolata, a new and beautiful Campilodiscus (C. zonalis), &c.

The North American localities have yielded to Bailey and Ehrenberg a large catalogue of infusoria. Ehrenberg enumerates:—

Amphiphora—one species.
Cocconema—two species.
Eunotia—seven species.
Fragillaria—three species.
Gomphonema—four species.
Himantidium—one species.
Navicula—eighteen species.
Staurosira—two species.
Tabellaria—three species.

With these are three forms of spongoid spicula, and two species of Thylacium.

These are mostly derived from beds lying under peat,—.

The Richmond earth (of miocene date) yields—

Coscinodiscus radiatus and other species (*fig.* 3) . . Actinocyclus senarius and others (*fig.* 2) . . . . Naviculæ, several species . Gaillonellæ . . . . . Dictyocha fibula (*fig.* 1) .	M. Queckett has found several of these recent in the North Sea. Mr. Lee has discovered Coscinodisci and Dictyochæ in the barnacle and scallop.

In the chalky marls of Oran, Sicily, Greece, &c. occur many living forms, as—

Actinocylus—ten species.
Amphitetra—two species.
Biddulphia—one species.
Cocconema—one species.
Coscinodiscus—seven species.
Dictyocha—four species.
Eunotia—two species.
Gaillonella—one species.
Grammatophora—four species.
Haliomma—one species.
Navicula—six species.
Striatella—one species.
Synedra—one species.
Tessella catena—one species.
Triceratium—one species.

In the white chalk and flint of Europe, and also living,—

Fragillaria rhabdosoma—Gravesend.
striolata—Gravesend.
Gaillonella aurichalcea—Rügen.
Peridinium pyrophorum—Gravesend.
Xanthidium furcatum—Gravesend.
hirsutum—Gravesend.

Dr. Mantell has been unable to discover Fragillaria in the chalk of Gravesend, but Xanthidia occur in the chalk of Dover. (*Ann. Nat. Hist., Aug.* 1845.) Gaillonella aurichalcea has been regarded as an Oscillatoria; and it appears doubtful whether the so-called Xanthidia of the flints and chalk are really to be referred to that fresh-water genus.

From the preceding notices we may gather as general facts the occurrence of infusorial remains in the following stratifications:—

Cainozoic period	Recent Fluviatile and other sediments. Lacustrine deposits of the Elk period. Deposits of the 'Lehm' period. Miocene Tertiaries Eocene Tertiaries.
Mesozoic period	Chalk deposits. Oolitic deposits.

The relative abundance of the Infusoria in these several deposits is inversely as their antiquity; they are rare in the oolitic and cretaceous rocks, and abundant in the upper tertiaries. It is true that Ehrenberg, by assigning to the cretaceous æra the calcareous marls of Oran, Sicily, and Greece, gives a large catalogue of Mesozoic infusoria, and that in favour of such reference of those marls are the Rotaliæ, Textilinæ, &c. which occur both in the true chalk and in such marls. But on the other hand, remembering the long scale of geological time through which these genera of Polythalamiæ extend, and taking into consideration the fact that some species which occur in the chalk of Europe are quoted by Ehrenberg from unquestionably miocene strata in America, we shall hesitate to admit those richly infusorial marls as truly coeval with the white chalk in which comparatively very few remains of the group occur, and these not of the same species as those which abound in the other deposits.

Another point on which the authority of Ehrenberg has not been received without hesitation, is the *absolute specific identity* of a large proportion of the fossil and recent infusoria. The previous discoveries of geology had prepared an easy admission for the opinion that many of the tertiary forms of infusoria were undistinguishable from living races; such is the fact in regard to all the invertebral races; but with very few, and those not always allowed, exceptions, the secondary strata had been found to contain only extinct forms of life, till Ehrenberg examined the minute Polythalamiæ and found many of them similar to living types, and confirmed this inference by independent researches among the infusoria. Supposing these opinions of the Prussian microscopist to be confirmed by future inquirers, we shall find that they involve no infraction of the relations of zoological forms to geological time, which have been established from examinations of the other classes of the animal kingdom. The systems of life in each successive system of strata *are not separate and distinct creations*, but successive terms of a *creative series;* each of these terms is compound, and (to speak exactly), its constituent quantities (the several *classes, orders, families, genera, or species*) have their own coefficients and exponents; that is to say, *have their own times of duration, their own periods of abundance, their own peculiar relations to earlier and later organizations.*

A rule drawn from Fishes cannot be applied to Mollusca, a law based on Crustacea cannot be received for Microzoaria, without scrupulous examination; and Palæontology is full of examples of the unequal periods of duration which belong to the different organizations, and the unequal degree of development, and unequal geographical diffusion, which characterize these organizations at the same epochs and during the same periods.

Admitting the authority of Ehrenberg's determination of species, we find another curious and unexpected result—the frequent, if not general, admixture of marine and fresh-water tribes—in the comparatively level regions of Europe. In the plains of North Germany, round the Bohemian and Harz mountains, in Tuscany, and Yorkshire, we find this admixture of supposed marine and supposed fresh-water races, in the supra-tertiary deposits. Is this to be explained by supposing those deposits to have happened while the relative level of land and sea was different from what it is at present, and the sea was *near* to the place of deposition, so that by some of the many natural modes of diffusion which are effective in this class of life, the organisms of the sea might be carried into lakes, as well as mixed in estuaries, and along the course of languid rivers? Probably so. The deposits of infusoria which now happen so abundantly at the mouth of the Elbe are mostly derived from the sea; and it has been found in the River Hudson that species once imagined to be truly marine live in juxtaposition with the species of fresh waters. There may probably be, in a class of beings associated with silicated waters, a greater independence of the saline qualities of water than in other races which have little need of silica, and which require the extrication of lime from a state of solution in the waters which they inhabit. In confirmation of this view, we find the spongiæ of the sea matched by the spongillæ of fresh water, each extracting silica from the liquid, but the calciferous Polypean races of the ocean are almost unrepresented in our inland lakes and streams.

(Ehrenberg, *Die Infusionthierchen; Memoirs of the Berlin Academy*, and Translations in Taylor's *Scientific Memoirs*; Reade, Queckett, &c., *in the Microscopic Journal;* Mantell, *Medals of Creation and Annals of Natural History;* Prichard, *Infusorial Animalcula*, &c.)

INGEN-HOUSZ, JOHAN, a distinguished natural philosopher, was born at Breda in 1730: for some years he practised medicine in that city, and employed his leisure in the performance of experiments in chemistry and electricity; but, at length, quitting his native country he came to London, where his discoveries in those branches of science soon attracted the notice of the English philosophers, and led in 1769 to his being elected a Fellow of the Royal Society. He had the good fortune to obtain an introduction to Sir John Pringle; and this celebrated physician, immediately appreciating his merits, warmly encouraged him in the prosecution of his researches, and honoured him with his esteem and friendship: he appears also occasionally to have corresponded with Franklin on the subject of electricity, which was, at that time, rapidly rising in importance.

The reputation of Ingen-housz as a physician must have been great, for the Empress Maria Theresa, who had lost two of her children by the small-pox, having directed her ambassador in London to consult Sir John Pringle respecting the choice of a physician whom she might invite to her court for the purpose of inoculating the young princes and princesses of the imperial family, Sir John, then president of the Royal Society, without hesitation recommended Dr. Ingen-housz: the latter, accepting the invitation, set out, in 1772, for Vienna, where he performed the operations with complete success. The example of the sovereign was followed by the nobility of Austria, and the children of the highest families of the country were inoculated by Ingen-housz or under his immediate inspection. The empress, in testimony of her sense of his merit and attention, gave him the titles of aulic councillor and imperial physician; and accompanied these honours with the grant of a pension, which he enjoyed during the rest of his life.

During his residence on the continent, Ingen-housz visited Italy, France, and various parts of Germany; and, at intervals, continued to prosecute his researches in electricity and magnetism, and on the air produced by plants. While at Vienna, the emperor Joseph II. honoured him with especial notice, inviting him frequently to the palace, and occasionally visiting him at his own house, in order to witness the performance of his philosophical experiments. During a visit to Italy in 1773, Dr. Ingen-housz had an opportunity (at Leghorn) of making some experiments on the torpedo: he found that the animal gave the shocks most frequently when he attempted to bend its body; these shocks were sometimes so strong that he was almost obliged to quit his hold, and he remarks that they resemble the discharge of a number of small Leyden jars through the hands.

After an absence of several years, Dr. Ingen-housz returned to England, where he continued to prosecute his experiments; and an account of an electrophorus, which he had invented, is described in the 'Philosophical Transactions' for 1778. About the same time he made the discovery that plants exposed to the light while growing, discharge oxygen gas from their leaves into the atmosphere; and an account of his researches relating to this subject was published in London in 1779, under the title of 'Experiments upon Vegetables, discovering the power of purifying the Air in the Sunshine and of injuring it in the Shade,' &c. The work was translated into French by the author, and published in Paris in 1780.

In the 'Philosophical Transactions' for 1779, there is an account of an electrical machine which, about that time, Dr. Ingen-housz had constructed; this consisted of several pasteboard disks, about four feet in diameter, which being covered with varnish were fixed upon an axis; between every two of them was a board covered on both sides with flannel and then with hare's skin; and the friction produced when the disks were made to revolve enabled the operator to obtain from the machine sparks above a foot in length. This probably led to the invention of the plate electrical machine, which is generally ascribed to Ingen-housz: it consists of a circular disk of glass, which, being made to turn on its axis between two cushions, forms a very elegant and, if made of considerable magnitude, a very powerful apparatus.

Dr. Ingen-housz published in English a work entitled 'New Experiments and Observations concerning various physical Subjects,' which was translated into French and published in Paris. He also published, in French, a work entitled, 'Essai sur la Nourriture des Plantes,' which was translated into English and published in London in 1798.

Dr. Ingen-housz died Sept. 7, 1799, at his country-house, near London, in the sixty-ninth year of his age.

(*Biographie Universelle; Philosophical Transactions.*)

INHIBITION, in the law of Scotland, is a writ by which a creditor may prevent his debtor from alienating property either to favoured creditors or to other persons. Nominally it affects all property, but it is only in the case of heritable or real property that, from its standing on the register, it is efficacious. The debt on which inhibition may proceed must be founded on some obligatory written document, or established by the decree of a court. It may be recalled if improperly awarded. It conveys no specific security to the person who holds it, but it gives him a right to impugn every act which the debtor does to his prejudice regarding his real estate. It does not affect the validity of a sale for a fair price, but it gives the inhibiter a right to draw the price so far as his debt extends. If the inhibition be followed by proceedings to attach the estate at the instance of the other creditors, the inhibiter has a preference over them if the debts have been incurred subsequently to the inhibition, but not otherwise. The mixed rights thus occasioned are often productive of very intricate questions.

INJURY, INJURIES. As these words are vaguely used, it is as well to explain them.

Blackstone, after treating of Rights, proceeds in his Third Book (c. 1) to 'consider the wrongs that are forbidden and redressed by the laws of England.' He then divides Wrongs into two sorts or species:—Private wrongs and Public wrongs. To Private wrongs he also gives the name of Civil Injuries, as being 'the infringement or violation of the private or civil rights belonging to individuals considered as individuals.' Public wrongs are 'a breach and violation of public rights and duties,' and 'are distinguished by the harsher appellation of Crimes and Misdemeanours.'

This is a confused statement. The true nature of Injuria is however contained by implication in another expression in Blackstone:—'the contemplation of what is Jus is necessarily prior to what may be termed Injuria.'

The English law has in fact adopted many terms of the Roman law; and if Blackstone had always traced their meaning correctly, he would have written less confusedly. As Jus is law, so Injuria is something that is not Jus, or is forbidden by Jus. An Injury then, in the English law, is some illegal act; but the word is commonly used to express an illegal act done to a man or his property, for which he may by legal process get compensation. The English legal maxim that a man cannot recover damages or compensation when there is a 'damnum absque injuria,' contains in it the true meaning of injuria or injury. The act must be an illegal act in order to entitle a man to compensation. If a man's acts damage the property of another, without being such acts as are forbidden, the person who is damaged can get no compensation. For instance, a man may set up a grocer's shop next door to another shop, and get all his neighbour's custom, which is a grievous 'damnum,' but no 'injuria.' It is true that the nature of the damage may in some cases help to determine whether it is a legal injury or not; but the true question always must be whether the act complained of is either at common law or by statute an injuria, an unlawful act.

The Roman word Injuria, as already observed, signifies generally anything which is done contrary to law (quod non jure factum est, hoc est contra jus). In its narrow sense, Injuria was limited to unlawful acts that affected a man's person, not his property, at least not directly. It comprehended personal violence, such as beating a man, and using abusive words to him, and libelling him. Injuria might be done to a man either in his own person or in the person of those who were in his power, as his children and slaves, or in his hand (manu), as his wife. The mode of proceeding was by the Actio Injuriarum. (Gaius, iii. 220-225.)

The nature of Roman Injuria in its limited sense is, therefore, it appears, different from that of Injury in English law, as properly understood. For Injuries in English Law, or Civil Injuries, or Private Wrongs, as Blackstone calls them, comprehend all the wrongs that are treated of in his Third Book, that is, all wrongs except Crimes and Misdemeanours. The Roman Injuria belongs both to the head of Law Criminal and Non-Criminal. In some cases damages were got: in others the offender was punished in his person: in some cases he might be punished by a pecuniary penalty and in his person also.

The common, the non-legal, use of the words Injury and Injuries is as vague as people's notions of Right and Wrong generally. But people have often a clear perception that a damage is done for which no compensation can be got by legal means, though compensation is due according to those universal principles on which the common notions of right and wrong are based. The popular judgment here is often right, and is a foundation on which good and efficient legislation can be securely based.

INN. The responsibility of innkeepers for the safe custody of the goods and chattels of their guests is one out of the numerous classes of cases that arise upon the law of bailments, and is placed by Sir W. Jones, in his Treatise, under the second subdivision, *Locatio Operis*, of the general head *Locatum*. The law makes the innkeeper responsible for the safety of the goods of persons coming to his house, in the language of the antient writ, *causâ hospitandi;* but he may be released from his liability either by inattention on the part of the guest to such reasonable rules as the innkeeper may think proper to lay down for the protection of the property of his guests; by any act of negligence on the part of the guest himself, or by his making use of the house not, as it is before said, *causâ hospitandi*. Thus, if an innkeeper requires his guest to put his goods under lock and key, and the guest leaves them in a passage, whereby they are lost; or the goods are stolen by the guest's own servant; or the guest uses his room in the inn as a show-room, into which a number of people are allowed to have access, and not as a lodging-room, the responsibility of the innkeeper ceases. The general interest seems to require that the law should be made still more strict as against innkeepers, as the good faith and responsibility of the innkeeper form the only security of the traveller. The Roman law on this subject is contained in the Digest iv., tit. 9.

(Smith's *Leading Cases*, 'Calye's Case;' *Treatise on the Law of Bailments*, by Sir W. Jones.)

INSANITY. [LUNACY, P. C. S.]

INSCRIPTIONS (*Inscriptiones*), that is, records of public or private occurrences, of laws, decrees, and the like, engraved on stone, metal, and other hard substances, exhibited for public inspection. The custom of making inscriptions was infinitely more general in the states of antiquity than in any modern country, as we see from the innumerable inscribed monuments which still exist in Persia, Egypt, Greece, Italy, and other countries subject to or colonized by the Greeks and Romans. A great number of inscriptions, especially those recording great events, laws, or decrees of the government, which it was important for every citizen to know, supplied to some extent the want of the art of printing. When, for example, the laws of the twelve tables at Rome were set up in public, this public exhibition was equivalent to their publication by means of the art of printing, for every Roman might go and read them, and, if he liked, take a copy of them for his private use. Previous to the invention of the art of printing, inscriptions set up in a public place were the most convenient means of giving publicity to that which it was necessary or useful for every citizen of the state to know. Inscriptions therefore are, next to the literature of the antients, the most important sources from which we derive our knowledge of their public, religious, social, and private life, and their study is indispensable for every one who desires to become intimately acquainted with the history of antiquity. For the history of the languages they are of paramount importance, since in most cases they show us the different modes of writing in the different periods, and exhibit to us the languages in their gradual progress and development; though it is manifest that the antients did not bestow that care upon the accuracy of the language and orthography which we might expect, and in many cases they seem to have left these things to the artisan who executed the inscription. After the overthrow of the Roman empire in the west, inscriptions still continued to be made very frequently; but as the ignorance of the middle ages increased, and as all knowledge became more and more confined to the priesthood, the custom of making certain things known by means of inscriptions gradually fell into disuse, until the art of printing did away with it almost entirely.

In order to render inscriptions as permanent as possible, the antients chose such materials as were least subject to destruction, viz. stone or metal. The stone most commonly used was marble cut in slabs, but sometimes inscriptions were engraved upon a flat surface of the unhewn rock. The most common metal was brass or bronze, though we have instances also of lead, tin, and gold being used. If we believe the accounts of the antients, inscriptions were made even in the mythical ages (Herod., v. 59, &c.; Pausan., viii. 14, 4; ix. 11, 1); but such inscriptions, existing in later times, were probably forgeries, and we cannot suppose that inscriptions were made until the art of writing was pretty generally known.

We shall here pass over the arrow-headed inscriptions of Persia [ARROW-HEADED CHARACTERS, P. C.], the hieroglyphics of Egypt, and the now unintelligible inscriptions of Etruria, Lycia, and other countries, and confine ourselves to those written in Greek and Latin.

Greek Inscriptions.—The earliest Greek inscriptions which we may safely take to have been genuine, but all of which have perished, were the lists of the victors in the Olympian games (Paus., iii. 21, 1; v. 4, 6, &c.), the records of the musical contests at Sicyon (Plutarch, *De Mus.*, 3, 8), and the chronicle of the priestesses of Hera (Juno) at Argos. The earliest among the extant inscriptions do not seem to have been made much before the year B.C. 580.

All inscriptions are composed either in prose or verse, but the former compose by far the greater number. The prose of the public documents is usually stiff, and their style is not unlike that of official documents of our own time. All Greek inscriptions are written in capital letters, and without any punctuation or separation of the several words, which often renders it difficult to read and understand them properly. Some of the earliest inscriptions are written, like the Hebrew, from the right to the left; others varied their lines, the first being written from the left to the right, and the next from the right to the left. In this manner, which is called βουστροφηδὸν, the laws of Solon were written, and some specimens are still extant. [ALPHABET, P.C.] The method of later times was to write, like ourselves, from the left to the right. But besides these general distinctions, there occur a great variety, and some modifications of writing which are the result of mere fancy. Another important point which it is necessary to know before attempting to read Greek and more especially Roman inscriptions are the abbreviations of names and words (sigla), which have been described and explained in several works, such as Nicolai, 'De Siglis Veterum,' Lugdun. 1703, 4to.; Maffei, 'De Graecorum Siglis Lapidariis,' Verona, 1746; E. Corsini, 'Notae Graecorum,' Florence, 1749, fol.; Placentinus, 'De Siglis Veterum Graecorum,' Rome, 1757, 4to.; but the best work on this subject is Franz, 'Elementa Epigraphices Graecae, Berlin, 1840, 4to., which is at the same time the most complete introduction to the study of Greek inscriptions.

Public or state documents were exhibited in Greece in certain places of great publicity, as the Acropolis at Athens, and sometimes whole walls were set apart for the purpose of receiving marble or metal slabs with inscriptions. Market-places and temples likewise served as repositories for inscriptions. When it was intended that an inscription should be understood by two different nations, it was written in the languages of both (*inscriptiones bilingues*), as in Greek and Assyrian (Herod., iv. 87), Greek and Phoenician (Gesenius, *Monum. Phoenic.*, i. p. 93, &c.), Greek and Latin, Greek and Lycian (Grotefend in the *Transactions of the Royal Society*, iii. 2, p. 317, &c.), and Greek and Egyptian, as on the Rosetta stone in the British Museum, of which another copy has recently been discovered by Lepsius.

The necessity of making collections of the most important inscriptions, such as contained public decrees, or interesting epigrammatic poems (of which many have found their way into the Greek Anthology), was felt by the Greeks themselves. The earliest collection we know of is that of Philochorus, under the title of Ἐπιγράμματα Ἀττικά; his example was followed by Polemon in a work Περὶ τῶν κατὰ Πόλεις Ἐπιγραμμάτων, and especially by Craterus in the important collection entitled Συναγωγὴ Ψηφισμάτων. Although public inscriptions were under the protection of the state, and although their violation was severely punished, we nevertheless know of several instances in which they were maliciously or frivolously destroyed or mutilated. In certain cases the state itself ordered the destruction of public documents, as when decrees were annulled or abolished. In times of war and in the destruction of towns, innumerable inscriptions must have perished. Athens, as early as the time of the Persian wars, gives us an example of the destruction of public monuments, as pillars, and tombstones with inscriptions, for the purpose of building walls for the protection of the city. In the fourth century of our æra religious fanaticism caused still greater havoc among the antient monuments, which were frequently used as building materials for all kinds of edifices; and if, in addition to all this, we consider the ravages of time and the destructive influence of rain and air, it is astonishing to see the immense number of inscriptions that have been preserved down to our own time.

The first modern writer who conceived the idea of making a collection of ancient inscriptions was Cyriacus of Ancona, who undertook, in A.D. 1435, a journey through Italy, Greece, and Asia Minor, and brought back a great number of inscriptions, which he collected in 3 vols. MS., which are still extant in the Barberini Library at Rome, and have often been used by subsequent collectors. After Cyriacus a long time elapsed, during which the attention of the learned was chiefly directed towards Roman inscriptions. Scipio Maffei, and after him J. Carcagni and T. M. Raponi, formed the plan of a complete collection of all inscriptions, but none of them were able to carry it into effect, and people were satisfied with books containing such inscriptions as their authors happened to meet with, or thought of particular interest. Works of this kind are:—Janus Gruter, 'Inscriptiones Antiquae totius Orbis Romani,' Heidelberg, 1602, 2 vols. fol.; 'Marmora Arundeliana' (also called 'Oxoniensia,' containing twenty-nine Greek and ten Latin inscriptions), edited by J. Selden, London, 1628, 4to., by Prideaux, Oxford, 1676, by Maittaire, London, 1732, and by Chandler, Oxford, 1763; Oct. Falconerius, 'Inscriptiones Athleticae Graecae et Latinae,' Rome, 1668, 4to., is the first attempt at a systematic collection; J. Spon, 'Itinerarium in Italiam, Illyricum, Graeciam, et Orientem,' Lugdun., 1678, 3 vols. 8vo.; Thom. Reinesius, 'Syntagma Inscriptionum Antiquarum,' Lipsiae, 1682, fol.; W. Fleetwood, 'Inscriptionum Antiquarum Sylloge,' London, 1691, 8vo.; R. Fabretti, 'Inscriptiones Antiquae,' Rome, 1699; A. van Dale, 'Dissertationes Antiquariae et Marmoribus cum Romanis tum Graecis illustrandis inservientes,' Amsterdam, 1702, 8vo.; A. F. Gori, 'Inscriptiones Antiquae Graecae et Romanae quae extant in Etruriae Urbibus,' Florence, 1727, 3 vols. fol.; L. A. Muratori, 'Novus Thesaurus Veterum Inscriptionum,' 1739, &c., 4 vols. fol., with a Supplement by S. Donatus, Lucca, 1765, &c., 2 vols. fol.; E. Corsini, 'Inscriptiones Atticae nunc primum e Maffei Schedis editae,' Florence, 1752, 4to. The material collected in these works was greatly enriched by the collections of inscriptions made by travellers, as Pococke, P. M. Paciaudi, Torremuzza, Passionei, Walpole, C. Vidua, and others. With the assistance of these further accessions, F. Osann began, in 1822, his 'Sylloge Inscriptionum Antiquarum Graecarum et Latinarum,' of which eight fasciculi in fol. appeared; and F. G. Welcker published a smaller collection of metrical inscriptions, 'Sylloge Epigrammatum Graecorum ex Marmoribus et Libris collecta,' Bonn, 1828, 8vo.

But in the meantime the Berlin Academy had formed the plan of publishing a complete collection of all the known Greek inscriptions, of which A. Boeckh undertook the editorship. It bears the title, 'Corpus Inscriptionum Graecarum.' Vol. i. appeared in 1828, and besides the most antient inscriptions, it contains those of Attica, Megaris, Peloponnesus, Boeotia, Locris, Phocis, and Thessaly; the second volume, which appeared in 1843, contains the inscriptions of Acarnania, Epirus, Illyricum, the islands of the Ionian Sea, of Macedonia, Thrace, Sarmatia, the islands of the Aegean, Rhodes, Crete, Cyprus, Caria, Lycia, Mysia, and Bithynia. This great work, in two huge folios, is now the most complete collection of Greek inscriptions. They are arranged, as appears from the above enumeration, according to the countries and localities in which they were found; and in each particular where it is feasible, as in those of Athens, Boeckh has judiciously classified them into ten sections:—1, Acta senatus et populi, universitatum et collegiorum; 2, Tabulae Magistratuum; 3, Tituli Militares; 4, Magistratuum Catalogi; 5, Agonistica et Gymnastica; 6, Honores Imperatorum et aliorum ex domo Augusta et decreta imperatoria; 7, Tituli Honorarii; 8, Donariorum Tituli et Operum Publicorum; 9, Ordo Sacrorum, Termini, Defixiones Magicae, Supellex varia; 10, Monumenta privata, maxime sepulchralia. It is partly owing to the influence which Boeckh's 'Corpus Inscriptionum' exercised upon the scholars of our time, and partly to the political condition of Greece, that since the publication of the first volume of Boeckh's work a prodigious number of inscriptions have been brought to light by travellers, which were before unknown. Some of them have been incorporated in the second volume of the 'Corpus Inscriptionum,' but others were published too late for insertion, and will be published in a supplementary volume. The principal among these subsequent works are:—Ph. Lebas, 'Inscriptions Grecques et Latines recueillies en Grèce,' Paris, 1835, &c.; Janssen, 'Musei Lugduno-Batavi Inscriptiones Graecae et Latinae,' Lugdun. Bat., 1842, 4to.; L. Ross, 'Inscriptiones Graecae ineditae,' Naupliae, 1834, 4to.; H. N. Ulrichs, 'Reisen und Forschungen in Griechenland,' vol. i., Bremen, 1840, 8vo.; L. Stephani, 'Reisen durch einige Gegenden des nördlichen Griechenlands,' Leipzig, 1843, 8vo.; E. Curtius, 'Anecdota Delphica,' Berlin, 1843, 4to.; the same, 'Inscriptiones Atticae nuper repertae duodecim,' Berlin, 1843, 8vo.; the travels of Colonel Leake, Fellowes, and Hamilton; the work of Mr. Hamilton contains a large number of inscriptions from Asia Minor; and lastly Letronne, 'Recueil des Inscriptions Grecques et Latines de l'Egypte,' vol. i., Paris, 1842, 4to.; and the Philological Journals of Germany, France, and England.

Latin Inscriptions.—These are not less numerous than those of Greece, and are found in great numbers at Rome, in Italy, and all the countries which were once subject to Rome. They embraced the same variety of subjects as the inscriptions in Greece, and if only the principal ones had been preserved the early constitution of Rome would be comparatively clear, whereas now there are a vast number of questions to which we can only answer by conjectures. Some of the Roman writers have, it is true, made use of the most important inscriptions for the early history of Rome, but not by any means to that extent which we could wish. The attention of Roman writers does not appear to have been so much directed towards this source of information as that of the Greeks, for there is no instance of any collection having ever been made by the Romans themselves, although some of them were of the very highest importance in a constitutional as well as legal point of view. At the time of the overthrow of the Western Empire thousands of inscriptions must have perished, especially those engraved on metal, as the material attracted the avarice of the barbarians. But a great number was still preserved in Rome and Italy, which attracted the attention of the learned even in the early part of the middle ages.

The oldest collection of inscriptions found at Rome, exists in the monastery of Einsiedeln; it is written on parchment, and probably belongs to the tenth or eleventh century. It is printed in Mabillon (*Veterum Annal.*, p. 358, &c.). At the time of the revival of letters, the attention of the learned was chiefly directed towards the authors of antiquity, but ever since the fifteenth century attention has also been bestowed upon inscriptions. The man who first formed the idea of a comprehensive collection was the above-mentioned Cyriacus of Ancona, who undertook his travels at the request and the expense of Pope Nicolas I. The first printed collection of Latin inscriptions is that of Peutinger, who collected and published those which were found at Augsburg and in its neighbourhood on seven folio leaves, under the title of 'Romanae Vetustatis Fragmenta in Augusta Vindelicorum et ejus Dioecesi,' Augsburg, 1505. Another collection, which is now extremely rare, was published by Laurentius Ahstemius, at Fani in 1515, of which a second edition by F. Polyardu appeared in the same year. The collection published by the bookseller Mazocchi, at Rome, in 1520, in folio, under the title 'Epigrammata Antiqua Urbis Romae,' contains scarcely any other than sepulchral inscriptions.

After these collections of local inscriptions, B. Amantius and P. Appianus, supported by the liberal merchant Raimund von Fugger, published a general collection under the title of 'Inscriptiones Sacrosanctae Vetustatis,' Ingolstadt, 1534, fol. Soon after, the learned George Fabricius published a considerable collection of Latin inscriptions which he had made in his travels, and which had been communicated to him by his friends, in the second volume of his 'Roma,' Basle, 1550, reprinted in 1587, and at Helmstädt, 1660, fol. Martin Smetius of Bruges, during a stay of six years in Italy, made a very careful collection of inscriptions, which however were not published till after his death by Janus Douza, and with an auctarium by J. Lipsius, Lugdun.-Bat. 1588, fol. The work of Laurentius Schrader, 'Monumenta Italiae,' has one volume which contains only inscriptions which he had collected during his visits in Italy; they are arranged according to the towns in which they were found, but he does not distinguish between the earlier and later inscriptions, and he has some which are evidently not genuine. After that of Schrader followed that of Thom. Reinesius, which was mentioned above. A somewhat more complete and accurate collection of 4688 inscriptions was published by Fabretti under the title 'Inscriptionum Antiquarum, quae in Aedibus Paternis asservantur Explicatio et Additamentum,' Rome, 1699, fol. (some copies bear date of 1702, but this is only a bookseller's imposition).

But all the works here mentioned are eclipsed by the undertaking of Janus Gruterus, which was to contain all the inscriptions that had until then been made known. He took the work of Smetius as his foundation, and was actively assisted by Joseph Scaliger. The collection appeared under the title 'Inscriptiones Antiquae totius Orbis Romani,' Heidelberg, 1603 and 1663, fol. J. G. Graevius afterwards undertook to edit a still more complete and corrected edition, but he did not live to complete his task, which fell into the hands of P. Burmann, who, assisted by many other scholars, published the new edition of Gruter, under the title 'Inscriptiones Antiquae totius Orbis Romani, in absolutissimum Corpus redactae, olim auspiciis J. Scaligeri et M. Velseri, industria autem Jani Gruteri, nunc notis Marquardi Gudii emendatae, cura J. G. Graevii,' Amsterdam, 1707, fol. Marquard Gude, who had travelled in Italy, likewise prepared a collection of inscriptions for publication, which however was edited after his death by F. Hessel, Leovardiae, 1731, fol. This collection however contains many forgeries made by the notorious Ligorius. A collection of 2000 inscriptions which had been gathered by Doni, was published by Gori, 'T. B. Donii Inscriptiones Antiquae,' Florence, 1731, fol. In 1739, L. A. Muratori published his 'Novus Thesaurus Veterum Inscriptionum,' Milan, 1739, 4 vols. 4to., with a supplement by S. Donatus in 2 vols., Lucca, 1765, &c. Among the collections of inscriptions published at a later time, few are of great importance, with the exception of the selection from all the known inscriptions which was published by J. C. Orelli, under the title 'Inscriptionum Latinarum selectarum amplissima Collectio ad illustrandam Romanae Antiquitatis Disciplinam accommodata, &c.; cum ineditis Hagenbuchii suisque Annotationibus,' Zürich, 1828, 2 vols. 8vo. This collection is extremely useful, but it is to be regretted that the editor has not always published the incriptions with that accuracy and exactness which are required in works of this kind.

In modern times the number of Latin inscriptions found in the various parts of the world which once were subject to Rome, has been increased enormously, and will increase every year, as archaeological societies are formed in all parts of Europe, with the express object of searching after, preserving, and publishing the Roman monuments existing in the particular districts in which those societies are formed. The number of Latin inscriptions now known amounts to about 60,000, and the want of a new and complete collection has long been felt. The Danish scholar Olaus Kellermann, who lived in Italy for some time, formed the plan of publishing a collection of Latin inscriptions similar to the 'Corpus Inscriptionum Graecarum' of Boeckh, but his untimely death in 1837 prevented the carrying out of his plan. O. Jahn honoured his memory by the publication of his 'Specimen Epigraphicum in Memoriam Olai Kellermann,' Kiel, 1841, 8vo. But a fair prospect of the publication of a complete collection of all the known Latin inscriptions has recently been held out. On the 6th of July, 1843, Villemain, the French minister of public instruction, requested the Academy of Inscriptions at Paris to prepare such a collection, and a commission of French savans has been appointed to conduct and superintend the work. Several pamphlets have since appeared both in France and Germany, containing suggestions respecting the principles which should be followed in the arrangements of the inscriptions.

Among the works to be consulted by those who wish to acquire a facility in reading and understanding Latin inscriptions, the following are of importance: Zaccaria, 'Instituzione Lapidaria,' Rome, 1770, and Venice, 1792; Morcelli, 'De Stilo Inscriptionum Latinarum Libri Tres,' Rome, 1781, and reprinted in his 'Opera Epigraphica,' Patavii, 1819, 5 vols. 8vo.; Kopp, 'Palaeographia Critica,' Mannheim, 1829, &c. 4 vols. 4to.; and Orelli's Introduction to his Collection.

INSECTA, FOSSIL. Until within a few years the occurrence of insects in a fossil state could only be substantiated by reference to a small number of localities, situated (as at Aix in Provence) among lacustrine tertiary strata, or (as at Stonesfield in Oxfordshire and Solenhofen in Franconia) among marine oolitic beds. But Mr. Prestwich has added traces of coleoptera from the coal formation of Coalbrook Dale, and Mr. Strickland parts of neuroptera from the lias of Warwickshire; Dr. Buckland obtains neuroptera from the oolite of Stonesfield, and Mr. Brodie portions of insects belonging to various natural orders from the lias of Somersetshire, Gloucestershire, and in the Wealden deposits of the Vale of Wardour in Wilts, and the Vale of Aylesbury.

Still the number of fossil insects, whether we estimate individuals or species, is very small compared to the probable number of anciently existing races; a circumstance quite explicable by reference to the phenomena which are now taking place in nature; for of upwards of 12,000 British species of insects there is reason to believe that but a very minute proportion is buried and preserved in lacustrine, estuary, or marine deposits now in progress. Only one elytron of a small beetle was observed in a deposit of the Elephantoidal æra in Yorkshire, and one seed of some umbellate plant, along with hundreds of shells which inhabited the lake.

No doubt vast numbers of insects, wandering by caprice or drifted by winds, pass from the shore and fall in the sea—as we learn from the first voyage of Cook, who sailed through myriads of insects, some on the wing and others in the water, even thirty leagues from land off the coast of South America; but few of these escape the watchful finny races, or ever reach the bottom of the sea.

In like manner we find land insects heaped in profusion by winds on certain tracts of fresh water, and borne down the course of rivers by inundations; and these cases, by the aid of particular suppositions, such as evaporation or slow draining off of the water, may offer the nearest analogy to the facts actually observed in the greater number of insect deposits.

The occurrence of fossil insects, especially in marine strata, is therefore to be regarded as an exceptional case, and this makes the circumstances brought to light concerning them remarkable and difficult of interpretation. We find however from Mr. Brodie that the insects lie in a certain bed or mass of thin beds in the lias; similarly they occupy particular layers in the oolite, the Wealden deposits, and in the tertiary accumulations of Aix, Oeningen, and Auvergne. In the latter region the calcareous incrustations gathering on the indusiæ or larva-cases of Phryganidæ have caused the formation of a peculiar limestone ('Indusial Limestone').

In the following summary of the groups of fossil insects in Britain, the most recent stratifications come first. The catalogue commences with the Elephantoidal era. The authorities and localities are given for each case. (See Morris's *Catalogue of Fossils;* Brodie's *Fossil Insects;* Lyell, in *Geol. Pro.;* Phillips, *Geol. Yorkshire;* Strickland, in *Mag. of Nat. Hist.;* Buckland, in *Bridgwater Treatise;* and *Geol. Proceed.*)

1. *Ossiferous fresh-water deposits* (Pleistocene).

Elytron of a Chrysomela. Bielbecks, in Yorkshire. (Phillips.)
Remains of Copris lunaris. Mundesley, Norfolk. (Lyell.)
" Donacia. " " "
" Harpalus. " " "
" Coleoptera. Southwold, Suffolk. (Alexander.)

(No truly aquatic beetle is mentioned among these. Donacia haunts aquatic plants. The others are strictly terrestrial. They must have been drifted into the lakes in which the Planorbes, &c. lived.)

2. In the Cretaceous System, no insects yet found.

3. In the Wealden strata of the Vale of Wardour (found by Mr. Brodie and examined by Mr. Westwood)—

Land Coleoptera, of the families—Carabidæ? Harpalidæ? Staphylinidæ? Buprestidæ? Tenebrionidæ? Elateridæ? Curculionidæ? Cantharidæ? Helophoridæ.

Aquatic Coleoptera of the families—Hydrophilidæ? Dyticidæ? (Colymbetes.)

Orthoptera, of the genera Acheta and Blatta.

Hemiptera and Homoptera, including land tribes, as—Cimicidæ, Cicada, Cercopis (Larva), Aphides, &c., and the aquatic races of Velia and Hydrometra.

Neuroptera. In this water-haunting order occur Libellula and Æshna, Corydalis, Libellulidæ, Termes? and Leptoceridæ. Trichoptera? Phryganidæ?

Diptera. Simulium? Platyura? Tanypus? Chironomus? Culex? Tipulidæ, &c. (Aquatic larva) Empidæ?

4. In the *oolitic strata*, insects occur in the laminated probably littoral beds of Stonesfield and some other localities in Gloucestershire and near Bath. Dr. Buckland has described several species in the Geological Proceedings and in his Bridgwater Treatise on Geology, and Mr. Brodie has added others. The remains are chiefly Elytra of Coleoptera

and wings of Neuroptera. The following is abstracted from Mr. Brodie's list.

Coleoptera, of the families Prionidæ, Buprestidæ, Pimelidæ? Chrysomelidæ? Coccinellidæ.

Neuroptera. Hemerobioides giganteus. (Buckland.)

5. *In the Upper Lias* at Dumhleton and Churchdown. (Brodie.)

In the Lower Lias—above the bone-bed of Aust Cliff, Wainlode Cliff, &c. on the Severn; Coombe Hill, Cracombe; Hasfield, Corsewood Hill, &c. in Gloucestershire. (Brodie.)

(Mr. Westwood has examined 300 specimens of insects from the Lias beds.)

Coleoptera, of the families Buprestidæ? Elateridæ; Curculionidæ or Chrysomelidæ; Carabidæ; Telephoridæ; Melolonthidæ, &c.; a species of Gyrinus?

Orthoptera, including Gryllidæ and Blattidæ.

Hemiptera and Homoptera. Cicada? Cimicidæ?

Neuroptera. These are the best determined of the fossil groups, owing to the structures of the wings being clear and characteristic:

Libellula, Brodiæi (Br.): in upper Lias.	Dumhleton, Glouc. (Brodie.)
Hopei (Brodie).	Strensham, Worcestershire. (Brodie.)
Agrion, Buckmanni (Br.), in upper Lias.	Dumhleton. (Brodie.)
Aeshna, liassina (Strickland).	Bidford, Warwickshire.
Orthophlebia communis (Westwood).	Wainlode, Forthampton, Strensham, Cracombe, Bidford.
Hemerobius Higginsii (Br.).	
Chauliodes	Hasfield, Strensham, Bidford.
Ephemera	Strensham.
Diptera	
Asilus? ignotus (Brodie).	Forthampton.

It is in the lower lias beds that the insects are most abundant. They occur in this part (between the ordinary lias limestones and the bone bed) so extensively as to justify the application to this genus of the term 'insect limestone' used by Mr. Brodie. As a whole the lias insects appear to contain larger proportions of aquatic tribes than the Wealden. There is no decided evidence amongst them of the prevalence of a warm climate at the time and in the place of their existence. They are usually of small size, not so entire as to forbid the supposition of having been *drifted* (the Neuroptera may have been less drifted than the Coleoptera); and if there were islands or high coasts adjacent, these might nourish, and in time of floods send down the small coleopterous insects to be imbedded with the fucoids, oysters, and modiolæ of the coasts, and ferns and other plants of the land and streams.

6. In the ironstone nodules lying in the carboniferous deposits of Coalbrook Dale, Mr. Prestwick has discovered Coleoptera, Curculioides Ansticii (Buckl.), C. Prestvicii (Buckl.); and Mr. Murchison, Sil. Syst. p. 105, mentions an insect to which the name of Corydalis Brongniarti is assigned. It is very possible that the laminated limestone deposits of Burdie House near Edinburgh and Ashford in Derbyshire may yield insect remains older than any yet mentioned. And seeing the frequent connexion or proximity of fossil insects to fossil fishes, it may be worth while to search the lower beds of the mountain limestone where the rich fish-beds occur in it, on the Avon, in Caldy Island, and in Fermanagh. The fish-beds of the magnesian limestone (marl slate) may also be indicated for further research. A very interesting addition to the fossil insects of Aix has been made known by M. Coquand. It is a butterfly, and has been carefully examined by M. Boisduval, who has been able to recognise perfectly its generic and specific characters. It belongs to one of those genera the species of which are not numerous, and are at present confined to the islands of the Indian Archipelago, or the warmest countries of the Asiatic continent. It belongs to the genus Cyllo—it is an extinct species—and is named C. sepulta. M. Boisduval has examined the other fossil insects of Aix, and differing both from Curtis and Marcel de Serres, refers them to the extra-European genera, and to extinct species.

(*Bulletin de la Soc. Géol. de France*, Avril, 1845, and *Ann. of Nat. Hist.*, Nov. 1845.)

INSECTS, GEOGRAPHICAL DISTRIBUTION OF. The various kinds of insects, even when furnished, as the greater number of them are, with powerful organs for flight, are each and all distributed within as certain bounds as the most stationary animals or plants. Independent, then, of its great interest as a part of philosophical zoology, the study of the range and specific centres of the forms of insect life becomes of great importance as an aid in the definition of tribes, genera, and species. As yet, however, entomologists have done comparatively little in this department of their science, and have rather occupied themselves in recording the distribution of specimens in cabinets than of species on the earth's surface.

Climate and the extension or form of land are the chief influences regulating the distribution of insect life. The constitution of the soil affects it also, but in a secondary manner, through its influence on the vegetation, on which many insects feed. When from the intervention of tracts of water, of mountain barriers, or other causes depending on antient geological events anterior to the origin of the existing fauna of the earth, tracts of land presenting exactly similar conditions of climate and soil are placed far apart, we then have, not a repetition of the same forms among their insect population, but a representation by similar forms. This we see also in the fauna of the several zones of climate belting mountains at different heights. Man's agency and the transporting power of currents of wind modify the distribution of many species of insects. In the following brief glance at the distribution of the principal genera of insects, examples of all these influences will be met with.

Coleoptera.—From the facility with which insects of this division may be preserved and transported from place to place, we have more detailed accounts of their distribution than of any of the species of other orders. The *Cincindelidæ* are dispersed over most parts of the globe, the typical genus being cosmopolitan, whilst other groups are more limited. Among the *Carabidæ* are many genera peculiar to Europe. *Chlænius*, *Agonum*, and *Amara*, are common to both hemispheres. *Harpalus* and *Brachinus* are cosmopolitan. *Cnemacanthus* occurs in Africa and Chili. The *Carabidæ* of Western Asia agree remarkably with those of Europe. Erichson has remarked that *Carabi* are very constant to certain soils: the vertical distribution of the species is also very constant. The water-beetles allied to *Dytiscus*, itself universal in the old world, are mostly European: several of the species live in salt or brackish waters. *Gyrinus* ranges from Northern Europe to New Holland. The *Brachelytra* have their chief centre in Europe. The typical genus *Staphylinus* appears however to be represented everywhere: many species occur in South America. A species of *Aleochara* is found in Van Diemen's Land. *Elater* and *Buprestis*, types of families, are both cosmopolitan: the species are often local, and their distribution depends, in many cases, on that of certain plants on which the larvæ prey. Among the fire-flies (*Lampyridæ*) the genus *Lampyris*, which is European, is represented in the tropics by *Photinus*, and in the New World by *Aspisoma*. The *Malachii* are found everywhere, except in South America. *Ptinus*, a genus chiefly European, has a single representative in Australasia. Of the *Necrophagi*, the genera *Cryptophagus*, *Strongylus*, and *Silpha* are found everywhere, ranging from Britain to China, and from Brazil to Lapland. *Hister*, the type of a family, is also a cosmopolitan genus. *Byrrhus* belongs to the northern hemisphere, and has its chief centre in Europe. Among the *Coprophagous Lamellicornes*, the genus *Aphodius*, though represented in most countries, is chiefly developed in temperate regions; whilst *Ateuchus*, on the other hand, is mainly tropical. *Geotrupes* is cosmopolitan. *Copris* ranges to New Holland, where however it is confined to the north coast. *Scarabæus* is subtropical. *Pelidnota* is American. The beautiful *Cetoniae* appear to be of universal distribution. The strange forms of *Goliathus* are South African. Of the cockchafers, *Melolontha* is cosmopolitan; *Macrotops* and *Anoplognathus*, confined to Australia; *Hoplia*, with one exception, European; *Amphicoma* is Mediterranean; *Anisoplea* and *Serica* natives of the warm and temperate regions of both hemispheres; whilst *Euchlorus*, occupying the same range, extends beyond in a northern direction. Of the *Melasomæ*, *Blaps*, and *Pimelia*, both extensive genera, have their chief development in the warmer regions of the Old World. Of the *Stenilytra*, *Helops* is cosmopolitan, *Œdemera* European. Of the *Anthicidæ* the numerous species of *Anthicus* are chiefly inhabitants of temperate regions. The blistering beetles of the genus *Meloë* are very generally distributed.

Of the ten thousand species of weevils the great genera *Ceutorhyncus*, *Cryptorhyncus*, *Calandra*, *Otiorhyncus*, and *Clionus* are all cosmopolitan. *Platysomis* and *Cyphus* are South American; *Brachycerus*, South African and Mediterranean, *Brentus*, mainly confined to the tropical regions of both hemispheres; *Apion* and *Rhynchites*, chiefly European. The distribution of the species of weevils depends in a great measure on that of plants.

The most beautiful and vividly coloured forms of Longicorn beetles are mostly tropical. The presence of forests determines that of many of the genera. Of the seventy genera of *Cerambycidæ*, the typical one, *Cerambyx*, is cosmopolitan. Others have defined centres, as *Clytus* in Europe, *Trachyderes* in South America.

Of the *Chrysomelinæ*, the typical genus *Chrysomela* is cosmopolitan. The presence of certain plants determines the distribution of the species. From this cause, species of limited distribution are sometimes multiplied far from their aboriginal centres. Thus *Galeruca calmariensis*, introduced from Europe into America, multiplied so at Baltimore in the years 1838 and 1839, that the elm trees of the district were eaten bare by their larvæ, and probably they will henceforth become a constant annoyance in the New World. *Lema* and *Donacia* are instances of cosmopolitan genera having distinct centres in temperate climates. *Cassida*, on the other hand, has its centre in the tropics.

Of the *Trimera*, *Coccinellæ* are found everywhere. *Eumorphus* is Indian and Polynesian.

Orthoptera.—Though by no means an extensive order either as to genus or species, the *Orthoptera* are of very general distribution. Representatives of the genera *Gryllus* and *Acheta*, the grasshoppers and crickets, are found in most countries. The *Locusts* are mostly exotic. The strange *Phasmæ* are mostly tropical, as are also the greater number of *Mantidæ*, known popularly as 'walking leaves.' The cockroaches, *Blattæ*, are very general, and have been greatly diffused from their original centres by unintentional human agency. The earwig tribes, *Forficulidæ*, including more than fifty species, are in great part European, but range even to Van Diemen's Land.

Erichson notices the curious fact respecting the Orthoptera of Van Diemen's Land, that only one fourth of the species are completely winged and capable of flying.

Neuroptera.—The number of known species in this order is short of one thousand. The section of *Plicipennes* is almost entirely European; the genus *Macronoma*, including species from Madagascar and Brazil, is an exception. The *Planipennes*, a great part of the genera of which division are now considered by many naturalists *Orthopterous*, have a much more varied distribution. Thus the *Myrmelionidæ* are cosmopolitan, the *Perlæ* and *Nemouræ* chiefly European, the *Panorpæ* characteristic of the temperate regions of both the old and new world, the *Termites* of the tropics. In the section of *Subulicornes*, the *Ephemeridæ* are European; the *Aeshnidæ*, cosmopolitan; as also the true dragon-flies, *Libellulæ*, of which near two hundred species are known. Other allied genera are more limited.

Hymenoptera.—Among the sting-bearing species, the true bees are characteristic of the antient continent, those now dispersed in America having been transported from Europe. The genera *Centris* and *Euglossa* are exclusively American. *Nomia* is Asiatic. *Allodape* is south African. *Andrena*, *Xylocopa*, and several other extensive genera, are cosmopolitan. A great many genera of wasps are peculiar to South America. The ants are most developed in Europe. *Bembex* is a tropical genus. The terebrating Hymenoptera are both very numerous and widely distributed, especially the great genus *Ichneumon*. Certain genera forming the family *Oxyuræ* are exclusively European, as are also a great part of the numerous family of *Chalcididæ*. *Cynips* is European, and the greater number of *Tenthredinidæ*.

The distribution of the *Strepsiptera* depends on that of the insects on which they are parasitic.

Lepidoptera.—When the distribution of the butterflies shall have been worked out, it will doubtless prove very interesting. At present our knowledge of this subject is imperfect. The *Papilionidæ* are very numerous specifically, and for the most part tropical. Some of them possess great ranges. Thus certain species of *Pieris* are found over all Europe, and great part of Asia and Africa. Other forms are constant to mountainous regions. Of the *Nymphalidæ* the greater number and more gorgeous forms are tropical. In this family there are some remarkable instances of extensive distribution of species. Thus *Vanessa Cardui* (a common British butterfly) is found in every part of the world, and *Vanessa Atalanta* ranges over all Europe, part of Asia and Africa, and to North America. In the remaining tribes the typical genera are almost always cosmopolitan, whilst others have more limited areas.

The *Sphingidæ* and *Zygenidæ* are in great part European; the *Castnidæ* mostly tropical.

Among the moths, the *Phalenidæ* are chiefly European, and the species are usually widely distributed. This appears to be the case also with the other families of Nocturnal Lepidoptera, probably rather in consequence of our imperfect knowledge of exotic forms, than because it is really so, for we find types and species in distant regions wherever they have been even casually explored, as in the instance of Asiatic Russia, where the researches of Eversmann among these insects have brought many new forms to light.

Diptera.—One-half of the described species of two-winged flies (about eight thousand) belong to Europe. This disproportion arises from our comparative ignorance of the exotic forms. The small group of *Ornithomyzidæ*, parasites on quadrupeds and birds, has representatives of all its genera in Europe, the few remaining species being natives of eastern Asia, Western Africa, Australia, or Brazil. The flies forming the family of *Muscidæ* include a great number of genera, both European and exotic, the former being most prolific in species, some of which have wide ranges. The *Syrphidæ* are in the same category. The genus *Chrysops*, equally developed in Europe and America, and represented in a less degree in Africa and Asia, does not appear in Australia nor in the islands of the Pacific. *Tabanus* is more widely distributed. *Ommatius*, a genius of *Asilidæ*, has its members in all parts of the world. A great many genera are peculiar to South America, and several to Africa, hot, woody, and moist regions favouring their diffusion. *Tipula*, presenting numerous and varied forms in most parts of the world, is excluded from Australia and the Pacific, which region seems to be the least prolific in *Diptera*. *Culex* is very generally distributed.

Hemiptera.—Of the two great divisions of this order, the *Hemoptera* and the *Heteroptera*, the first is the smallest and also the most tropical. The distribution of the insects comprising them depends mainly on the fauna and flora of the countries they inhabit. Thus each species of *Coccus aphis* has a range correspondent to that of the plant upon which it feeds; and of the *Coræidæ* and *Lygæidæ* with the presence of their favourite animal food. Among the most interesting of the families of *Hemiptera* are the *Cicadeidæ*, of which the genus *Tettigonia* includes 200 species, centred in America, but having members also in the Old World; the *Fulgoridæ*, or Lantern-flies, very generally distributed through warm climates; *Scutelleridæ*, remarkable for brilliancy, and mostly equatorial; and *Cimex*, of which the only true species is the common bed-bug, a pest spread over all Europe. Of the Aquatic *Hemiptera* *Gerris* and *Nepa* are cosmopolitan; *Pelognus* and the *Nectonectidæ*, mostly European; *Galgulus* and *Mononyx*, American; and *Halobates*, equatorial.

Thysanura.—As yet the distribution of these minute insects has been scarcely attended to. The species of *Lepisma* range from Europe to China. *Padura* and *Smynthura* are European; a single species of the last-named genus occurs in North America.

Anoplura.—These disagreeable parasites have lately been honoured by the attention of some excellent naturalists, especially Denny and Gwilt. Their distibution corresponds with that of the animals upon which they are found. Of the equally annoying order *Aphaniptera* three-fourths of the known species are European. The common flea is a cosmopolite, and the Chigo is confined to South America.

INSOLVENCY. From August, 1842, to August, 1845, three acts have been passed relating to insolvent debtors; these are 5 & 6 Vict. c. 116; 7 & 8 Vict. c. 96; and 8 & 9 Vict. c. 127.

The act 5 & 6 Vict. c. 116, which came into operation 1st November, 1842, enabled a person who was not a trader within the meaning of the bankrupt laws, or a trader who owed debts which amounted in the whole to less than 300*l.*, to obtain by petition a protection from the Court of Bankruptcy in London or the Commissioners of the District Courts of Bankruptcy in the country, from all process whatever (except under a judge's order), either against his person or property until the case was adjudicated by the court. In the interim the insolvent's property was vested in an official assignee appointed by the court. If, on the hearing of the petition, the commissioner were satisfied with the allegations which it contained, and that the debts were not contracted by fraud, breach of trust, or by any proceedings for breach of the laws, he was empowered to make a final order for the protection of the petitioner from all process, and to cause his estate and effects to be vested in an official assignee, together with an assignee chosen by the creditors.

The act 7 & 8 Vict. c. 96, passed 9th August 1844, is entitled 'An act to amend the law of Insolvency, Bankruptcy, and Execution.' It enacted that any prisoner in execution upon judgment in an action for debt, who was not a trader, or whose debts, if a trader, were under 300*l.*, may, without any previous notice, by petition to any court of bankruptcy, be protected from process and from being detained in prison for any debt mentioned in his schedule; and if so detained, the commissioners of any bankruptcy court may order his discharge.

The property of the insolvent may be seized for the benefit of his creditors with the exception of the wearing apparel, bedding, and other necessaries of the petitioner (the insolvent under 7 & 8 Vict. c. 96) and his family, and the working tools and implements of the petitioner not exceeding in the whole the value of 20*l.* Under the 7 & 8 Vict. c. 96 (§ 39) if a petitioner for protection from process (pursuant to the provisions of that act) shall wrongfully and fraudulently omit in the schedule, which schedule he is required to make (5 & 6 Vict. c. 116), any property whatsoever, or retain or exempt out of such schedule any wearing apparel, bedding, or other necessaries, property of greater value than 20*l.*, he shall, upon conviction, be liable to be imprisoned and kept to hard labour for any period not exceeding three years.

The 7 & 8 Vict. c. 96, made a great alteration as to debts under 20*l.* The 57th section is as follows: 'Whereas it is expedient to limit the present power of arrest upon final process, be it enacted, That from and after the passing of this act, no person shall be taken or charged in execution upon any judgment obtained in any of her Majesty's superior courts, or in any county court, court of requests, or other inferior court, in any action for the recovery of any debt wherein the sum recovered shall not exceed the sum of 20*l.* exclusive of the costs recovered by such judgment.' The 58th section provided that upon application to a judge of one of the superior courts of law at Westminster, or to the court in which such judgment as is mentioned in section 57, shall have been obtained, all persons in execution at the time of passing this act be discharged, when the debt, exclusive of costs, did not exceed what is specified in the 57th section. Accordingly, such persons, on making application pursuant to the 58th section of this act, were discharged from prison in England and Wales.

The consequences of the legislation contained in the 57th and 58th sections of 7 and 8 Vict. c. 96, were these. All persons who were in confinement for debts under 20*l.*, exclusive of costs, might get their liberty; but the judgment upon which the debtor was taken in execution remained in force (§ 58), and the judgment creditor or creditors had their remedy and execution upon every such judgment against the property of the debtor, just as they might have had if he had never been taken in execution upon such judgment. The 59th section gave to the judge who should try such cause (§ 58), being either a judge of one of the superior courts or a barrister or attorney at law, power to imprison the defendant (debtor) for such times as are mentioned in § 58, if he should appear to have been guilty of fraud in contracting the debt, or had contracted it under the other circumstances mentioned in the 59th section.

The amount of debts in England and Wales under 20*l.* must always form a very considerable proportion of all the debts that are at any time due in England and Wales. Such debts comprehend a large part of the dealings of shopkeepers and petty tradesmen; probably in a very large number of cases debts under 20*l.* may comprehend every debt that is due to a large body of petty tradesmen. The tradesmen no doubt do in many cases give credit to persons who have no reasonable means of payment, and with whose character and condition they are very imperfectly acquainted. Many persons are always willing to contract a debt, but never intend to pay if they can help it. Another class of debtors consists of those whose morality is not so well fixed as to make them good and willing payers, but who will pay and do pay under the combined influence of some feeling of honesty and some fear of the consequences of non-payment. A third class, which we hope may be the most numerous of all, is willing to pay, but often requires time, and must be deprived of many comforts if they cannot command the credit which their character and earnings fairly entitle them to. [CREDIT, P. C. S.]

The 57th and 58th sections of the 7 & 8 Vict. c. 96, deprived creditors of their hold upon their debtors for sums under 20*l.*, and left to all persons who had claims upon persons in prison for sums above 20*l.*, the power of still keeping their debtors there. As to debts under 20*l.* existing before the act, and for which the debtor was not in execution, it left the creditor no remedy except against his property. And here we may remark that the question as to the imprisonment of debtors seems reducible within narrow limits, if we view it merely as it affects the interests of the community. The object in allowing a debtor to be seized is not to punish him as a debtor, but that he may be subjected to a complete examination for the purpose of discovering what his property is, that he has not parted with it to defraud his creditors, and that there was no fraud in the contracting of the debt. The simple fact of being indebted and unable to pay should not be punished. The contracting debts under such circumstances as amount to fraud ought to be punished. The principle then which should guide a legislator should be, not to punish a man simply because he is indebted and cannot pay his debts, but to punish him for any fraud that is committed either in contracting the debt or in attempting to evade the payment of it. Now in the case of a debtor, fraud, both in contracting a debt and in attempting to evade payment, is known by experience to be a thing of frequent occurrence; and it is therefore just and reasonable that judgment creditors should have the power to secure the person of their debtor until he has paid his debts or made a full and honest statement of his means of payment.

The effect of the last-mentioned act was of course to diminish the credit given by small dealers to all persons. The act also relieved many dishonest debtors from the payment of their past debts, for it deprived the creditor of his most efficient remedy; and as to all future dealings, it rendered the small tradesman less willing to give credit to those who, under the old system, had it. But the act did more: it encouraged fraud and a fraudulent system of trade. Persons who were refused credit by respectable tradesmen, who honestly paid for their goods, could still obtain credit of tradesmen whose practices were not so honest. The amount of mischief, both pecuniary and moral, caused by this unwise measure, may be estimated from the loud complaints against it from all parts of the kingdom, from a great variety of tradespeople, especially tailors, shoemakers, butchers, bakers, grocers, three-fourths of whose debts, and of retail tradesmen generally, are ordinarily in sums under 20*l.* In some wholesale trades three-fourths of the debts are also in sums under 20*l.* Their debtors set them at defiance, as, except in cases of fraud, there was no power of obtaining payment except by an action in one of the superior courts, in which case the creditor would have to pay the costs out of his own pocket, and in the end might be unable to obtain satisfaction for the debt. Many tradesmen had debts in sums of less than 20*l.* which in the aggregate amounted to a large sum, perhaps in some cases to 2000*l.* or 3000*l.* In some of the provincial towns it was stated that the aggregate amount owing in sums under 20*l.* was not less than 100,000*l.*

The legislature have now remedied the mischief which they did by a new act, 8 & 9 Vict. c. 127, which is intituled very significantly 'An Act for the better securing the Payment of Small Debts;' and it begins by declaring, which every thinking man will allow to be true, that 'it is expedient and just to give creditors a further remedy for the recovery of debts due to them.' The sums to which the act applies are debts under 20*l.*, exclusive of costs. The powers of 7 & 8 Vict. c. 96, and of the several acts relating to insolvency, are applicable to 8 & 9 Vict. c. 127.

The act (8 & 9 Vict. c. 127) gives to creditors the means of obtaining payment of sums under 20*l.*, besides the costs of suit, by the following process:—A creditor who has obtained judgment, or order for payment of a debt not exceeding 20*l.* (exclusive of costs), may summon his debtor before a commissioner of bankruptcy; or he may summon his debtor before any court of requests or conscience, or inferior court of record for the recovery of small debts, if the judge of such court is a barrister-at-law, a special pleader, or an attorney of ten years' standing. It may here be remarked that this part of the act which takes the jurisdiction of the courts of request out of the hands of non-professional commissioners is a new provision. The judges of these courts are made removeable for misbehaviour or misconduct, and the courts will be assimilated in some degree to the bankruptcy and insolvency courts.

On the appearance of the debtor before the commissioner or court upon summons, he will be examined by the court, or by the creditor if he think fit, 'touching the manner and time of his contracting the debt, the means or prospect of payment he then had, the property or means of payment he still hath or may have, the disposal he may have made of any property since contracting such debt.' The commissioner is empowered to make an order on the debtor 'for the payment of his debt by instalment or otherwise;' and if the debtor fails to attend or to make satisfactory answer, or shall appear to have been guilty of fraud in contracting the debt, or to have wilfully contracted it without reasonable prospect of being able to pay it, or to have concealed or made away with his property in order to defeat his creditors, the commissioner or judge of the court may commit him for any time not exceeding forty days; but such imprisonment will not operate in satisfaction of the debt. Wearing apparel and bedding of a judgment debtor, and the implements of his trade, amounting in the whole to a sum not exceeding 5*l.* in value, are exempted from seizure. The powers of all inferior courts under this act are assimilated; and a suit commenced in one small debt court cannot be removed to another similar court in the same town. When a debt exceeds 10*l.* the suit may be removed by certiorari to the superior courts. Any of her Majesty's secretaries of state are empowered to alter or enlarge the jurisdiction of all small debts and inferior courts. The act itself enlarges the jurisdiction of courts of request, where sums not exceeding 2*l.* could heretofore only be recovered, and now sums not exceeding 20*l.* may be recovered in them. It is provided by the act that all suitors' money paid into court and not claimed for six years is to go into a fund for the payment of the necessary expenses of carrying on the business of the court.

The act 7 & 8 Vict. c. 70, which came into operation 1st September, 1844, and is entitled 'An Act for facilitating Arrangements between Debtors and Creditors,' is of the nature of an insolvent act. Under this act a debtor who is not subject to the bankrupt laws may apply by petition to a court of bankruptcy and obtain protection from arrest, provided his petition be signed by one-third in number and value of his creditors. The debtor's petition must set forth the cause of inability to meet his creditors, and contain a proposition for the future payment or the compromise of his debts, and a statement of his assets and debts. Any one of the commissioners of bankruptcy may examine the petitioning debtor, or any creditor who may join in the petition, or any witness produced by the debtor, in private; and if he be satisfied with the statements made, he may convene a general meeting of all the petitioner's creditors, and appoint an official assignee, registrar, or a creditor to report the proceedings. If at the first meeting the major part of the creditors in number and value, or nine-tenths in value, or nine-tenths in number of those whose debts exceed 20*l.*, shall assent to the proposition of the debtor, a second meeting is to be appointed. If at the second meeting three-fifths of the creditors present in number and value, or nine-tenths in value, or nine-tenths in number of those whose debts exceed 20*l.*, shall agree to the arrangement made at the first meeting and reduce the terms to writing, such resolution shall be binding, provided one full third of the creditors in number and value be present. Under this arrangement the affairs of the debtor may be settled. When this has been effected, a meeting of the creditors is to be held before the commissioner, who is to give the debtor a certificate, which shall operate as a certificate under the statute relating to bankrupts.

The regulations of the 7 & 8 Vict. c. 96, as to debts under 20*l.*, caused universal dissatisfaction among creditors in England and Wales, as we have already observed. The evidence taken before the Lords' Committee in 1845 proved the necessity of amending this act. The history of this piece of unwise legislation and of its correction is useful. It shows how ill-considered measures may sometimes become law in this country, in which the mass of public business is so enormous that important statutes are sometimes enacted without due deliberation. It also shows that the force of opinion, when sustained by sound reasons and directed by men of judgment, is strong enough to induce the legislature to amend their mistakes.

The law of debtor and creditor has been a difficulty in all countries. In England an insolvent debtor may, in certain cases, be subjected to the operation of the bankrupt laws. If he cannot claim the benefit of the bankrupt laws, he is subject to the law that relates to insolvent debtors. The question of arrest and imprisonment for debt has been chiefly discussed with reference to insolvent debtors, that is, the class of debtors whose debts have not been contracted in the operations of trade or commerce, or under such circumstances as to bring them within the bankrupt laws.

Formerly there were two kinds of arrest in civil cases, that which took place before trial, and was called arrest on mesne process; and that which takes place after trial and judgment, and is called arrest on final process. In the arrest on mesne process it was only necessary for the plaintiff to make an affidavit that the cause of action amounted to 20*l.* (7 & 8 Geo. IV. c. 71), upon which he could sue out a writ called a *capias*, which was directed to the sheriff, who thereupon gave his officers a warrant for seizing the alleged debtor. The statute 1 & 2 Vict. c. 110, §§ 2, 3, 4, 5, 6, enacted that no person can be arrested for alleged debt before a judgment has been obtained against him, unless it can be shown to the satisfaction of a judge of one of the superior courts that the plaintiff has a cause of action against such person to the amount of 20*l.* or upwards, and that there is probable cause to believe that the defendant is about to quit England. A defendant may also be arrested upon mesne process when be has received an unfavourable judgment in the court for the relief of insolvent debtors (1 & 2 Vict. c. 110, § 85).

Arrest in execution is therefore now the only arrest that is of any practical importance: it means the arresting of a man after a court of justice has decided that he owes a debt. The ground of arresting the man is, that he does not pay the debt pursuant to the judgment; in other words, he disobeys the command of the court, which has declared that he must pay a certain sum of money to the plaintiff.

On the subject of maintaining the law of arrest in execution there has been difference of opinion. The best arguments in favour of it that we have seen are contained in a 'Supplementary Paper on Bankruptcy and Insolvency, by William John Law, Esq. Dissentient from the Report. Presented to both Houses of Parliament, 1841.' Mr. Law did not sign the report of the other commissioners on the subject because he did not agree with them; and the Supplementary Paper contains the reasons of his dissent.

With respect to arrest in execution, Mr. Law's intimate knowledge of the relation of debtor and creditor has enabled him to answer fully all the arguments of those who attempt to show the insufficiency of this final arrest. He has proved beyond doubt the justice of this final arrest, or if the word justice be objected to, its usefulness to the community. A man is not now arrested till he has disobeyed the judgment of a court of justice. It is his business to show why he disobeyed the judgment; and in the mean time either his person must be secured, or the judgment of the court must be treated as a mere idle form. It may be said, the plaintiff can proceed to take the debtor's property: but even visible property cannot always be got at; for when the sheriff goes to seize it, 'some one on the premises holds up a bit of parchment called a bill of sale, and frightens him out again; there is not one plaintiff in five hundred, great or small, who has courage enough to indemnify the officer, and defy the fraud.' If there is this difficulty as to the taking possession of a debtor's visible property, what must be the difficulty of getting at the property of the debtor which is not visible? And what other mode can be suggested of compelling the defendant to give a true account of all his property than to imprison him until he does? 'A defendant has always been prone to place his property out of reach of an execution, but there has been this one restraint: he says to himself, "If I make my property safe, they will take me, and then I must bring it forward." When property only can be touched, the argument is changed; it becomes this: "If I make my property safe, my enemy can do nothing." So necessary is process against the person for process against the property, and so unreasonable is it to require of the creditor by record the establishment of any further case, in order to entitle him to an execution. His judgment is his case: the clearest duty lies on the other party to establish his exemption from the task of satisfying it.'

The great argument of the Report from which Mr. Law dissents is this: that all execution against the person presumes fraud. This argument is very absurd. The presumption ought to be against the debtor who does not obey the judgment of the court. He may be guilty of fraud or he may not: it is his business to explain why he disobeys the order of the court. This argument against execution is founded on the presumption being in the debtor's favour, instead of being, as it is, against him. 'The practical justice and wisdom is in subjecting all (debtors) to searching inquiry, for the purpose of ascertaining whether they are dishonest or not. I am quite sure that in that court (the Insolvent Court) where searching inquiry is known and practised, it is found necessary to be applied to every case as the means of disclosing its true character and merits.'

'Blamelessness must not be presumed: faultiness is to be presumed: it may or may not be that which is told by the word fraud; the precise shade cannot be presumed; the character and degree are to be learned through a deliberate and forced inquiry. It is misrepresentation to say that fraud is presumed and punished on presumption; the coercion which was once purely punishment is now necessary coercion to the investigation of a question in which presumption is and ought to be against the party coerced. The debtor in execution is the applicant for indulgence; he has to establish his case; but he is at liberty to institute proceedings towards this question instantly on his arrest; and not only is he at liberty to seek exemption from the consequences of the injury which he has done to the particular party who has pursued him, but to use the same opportunity for acquiring a privilege against every person in the kingdom towards whom he stands in a similar predicament: on giving to the true owners a part of their property, or on showing that there remains no part to surrender, he receives, if excuse is found for granting it, this great boon—a total freedom for the future of person and property; save that if ever he become in the full and fair sense of the words of ability to pay, there will reside in a competent tribunal the power to ascertain that ability and to exact that payment.

'It is almost unnecessary to say that these results ought not to be enjoyed without that full disclosure of the history of his property which is found in the schedule of an insolvent debtor; that full opportunity for the creditors to challenge this history; and that fair, deliberate, and effective investigation of its truth which is made in that court.'

These general arguments in favour of the justice of final execution are supported by Mr. Law with facts equally strong, which also prove the efficacy of such arrest. The mode in which he has examined the arguments in favour of abolishing arrest, which are derived from certain returns, is completely convincing. The efficacy of arrest must not be estimated 'by the extent of dividends made in the Insolvent Debtors' Court, or the proportion of unfavourable judgments;' though it must be remembered that the dividends are not none at all, as some people suppose.

It is clearly shown by Mr. Law that arrest does make people pay, who do not pay till they are arrested; it is found that the examination to which insolvents are subjected exposes a great amount of fraud; and it is also certain that the number of those who are induced to pay by the fear of arrest is considerable, just as the fear of other punishment prevents many persons from committing crimes, who have no other motive to deter them. The fear of arrest is precisely that preponderating weight which is wanted to induce those whose honesty is wavering to incline to the right side.

The arguments of Mr. Law should be read by every man who wishes to form a sound judgment on the law of insolvent debtors in England; and so much of his arguments as have here been given, may help to diffuse some juster opinions on a subject in which a sympathy with debtors, to the total forgetfulness of creditors, has led many well-meaning people to adopt conclusions that tend to unsettle all the relations of society, and to confound honest men and rogues. Some valuable observations on the laws relating to Imprisonment for Debt by Mr. Commissioner Fane are printed in the 'Banker's Magazine,' No. xix., October 1845. He concludes 1st, That the remedy given to creditors by the seizure of goods under a *fieri facias* [FIERI FACIAS, P. C.] is a delusive remedy; and 2nd, That such remedy, instead of being beneficial to the creditor, whom it is intended and supposed to assist, actually prejudices him, by enabling the debtor more effectually to cheat him under the form of law; and, therefore, so far as relates to this branch of the subject, the power which each creditor now possesses of seizing his debtor's goods under a fieri facias *for his own exclusive* benefit, is a mischievous power which ought to be abolished.

INSURANCE, MARINE. [MARINE INSURANCE, P.C.]

INTEGRATION. In the article INTEGRAL CALCULUS, P. C., the meaning of an integral was explained. The present article is devoted to the operation of integration, that is, of finding the primitive function which has a given function for its differential coefficient. Having given P a function of x required Q so that $dQ : dx$ may be P. In the article QUADRATURES, METHOD OF, P. C., is given the mode to which we must have recourse, in order to find particular values of Q, when the general methods for determining it fail. In this article we confine ourselves to what is most useful in operation, as a summary for the advanced student, not an explanation for the learner. Properly speaking, the problem requires some addition to make it definite. Thus $2x$ has x^2 for a primitive function, and also x^2+C, C being any constant quantity whatever. In the present article, we shall neglect this constant altogether, reminding the reader that he must never omit it in any application. If he should find in different books different functions given as the primitives of one and the same function, he will always find that those different primitives differ only by a constant quantity. Thus $(1-x)^{-1}$ and $x(1-x)^{-1}$ both occur as the primitive of $(1-x)^{-2}$; but they only differ by a constant, namely 1.

In the common process of integration, the actual passage from the differential coefficient to the primitive is always an act of memory. The algebraical work which occurs is always used either to reduce a form in which memory will not serve into one in which it will, or else to reduce the given differential coefficient to two terms, one of which can be integrated by memory, and the other of which is more simple than the original quantity.

The functions in which the simple remembrance of the forms of the differential calculus is of use are as follows:—

$$\int dx=x,\ \int a\,dx=ax,\ \int x^n dx=\frac{x^{n+1}}{n+1},\ \int\frac{dx}{\sqrt{x}}=2\sqrt{x},$$

$$\int\frac{dx}{x^n}=-\frac{1}{(n-1)\,x^{n-1}},\ \int\frac{dx}{x}=\log x,\ \int a^x dx=\frac{a^x}{\log a}$$

$$\int\epsilon^{ax}dx=\frac{\epsilon^{ax}}{a}$$

$$\int\sin x\,dx=-\cos x,\ \int\cos x\,dx=\sin x,\ \int\frac{dx}{\cos^2 x}=\tan x$$

$$\int\frac{dx}{\sqrt{(1-x^2)}}=\sin^{-1}x,\ \int\frac{-dx}{\sqrt{(1-x^2)}}=\cos^{-1}x,$$

$$\int\frac{dx}{1+x^2}=\tan^{-1}x$$

To these should be added the following, which may be obtained in various ways from the methods of this article, or from peculiar artifices which are found in works on the subject.

$$\int\frac{dx}{\sqrt{(a^2-x^2)}}=\sin^{-1}\frac{x}{a},\ \int\frac{-dx}{\sqrt{(a^2-x^2)}}=\cos^{-1}\frac{x}{a}$$

$$\int\frac{dx}{\sqrt{(x^2\pm a^2)}}=\log\{x\pm\sqrt{(x^2-a^2)}\}$$

$$\int\frac{dx}{a^2-x^2}=\frac{1}{2a}\log\left(\frac{a+x}{a-x}\right)\quad\int\frac{dx}{x^2-a^2}=\frac{1}{2a}\log\left(\frac{x-a}{x+a}\right)$$

$$\int\frac{dx}{x^2+a^2}=\frac{1}{a}\tan^{-1}\frac{x}{a}\quad\int\frac{dx}{(a^2\pm x^2)^{\frac{3}{2}}}=\frac{1}{a^2}\frac{x}{\sqrt{(a^2\pm x^2)}}$$

$$\int\frac{dx}{\sin x}=\log\tan\frac{x}{2}\quad\int\frac{dx}{\cos x}=\log\cot\left(\frac{\pi}{4}-\frac{x}{2}\right)$$

$$\int\tan x\,dx=-\log\cos x\quad\int\cot x\,dx=\log\sin x.$$

Among the peculiar artifices of integration may be reckoned the following, which are perhaps nearly all that can be useful to a learner:—

1. The reduction of such a form as $\int X dx$ to another form $\int V dv$, in which v is a different variable. Thus $\int(a^2+x^2)^n x\,dx$ can be immediately reduced to $\frac{1}{2}\int(a^2+x^2)^n d.(a^2+x^2)$ or $\frac{1}{2}\int v^n dv$, where v means a^2+x^2. The second form is immediately seen to be integrable. Cases of this kind are so various that the student must form the habit of looking for them, and recognising them at sight. Sometimes a slight transformation is required, thus; $(1+a\epsilon^x)^{-1}dx$, when reduced to $(\epsilon^{-x}+a)^{-1}\epsilon^{-x}dx$ clearly shows the form $-v^{-1}dv$, where v is $\epsilon^{-x}+a$.

2. The reduction of algebraical to trigonometrical functions, and the converse. Thus $(a^2-x^2)^m x^n dx$, if x be made $a\sin\theta$, becomes $a^{2m+n+1}\cos^{m+1}\theta\sin^n\theta d\theta$. Also $f(\sin\theta,\cos\theta).d\theta$, if $x=\sin\theta$, becomes $f\{x, \sqrt{(1-x^2)}\}.(1-x^2)^{-\frac{1}{2}}dx$.

3. When rational powers appear in a denominator, they

should be transferred to the numerator by changing x into $1:z$. By such a transformation, we change

$$\frac{dx}{x^m\sqrt{(a+bx+cx^2)}} \text{ into } -\frac{z^{m-1}dz}{\sqrt{(az^2+bz+c)}}.$$

4. When an irrational root of a polynomial appears in the numerator, it should generally be transferred to the denominator: thus, $\sqrt{X}\,dx$ should be written $Xdx:\sqrt{X}$. By such a transformation, we change

$$\sqrt{(a^2+x^2)}.dx \text{ into } \frac{a^2dx}{\sqrt{(a^2+x^2)}}+\frac{x^2dx}{\sqrt{(a^2+x^2)}}.$$

5. When, by the addition of more simple terms to the numerator, it can be made the differential of the prominent function of the denominator, such additions, with compensating subtractions, will frequently reduce the question of integration to a more simple one. Thus we alter

$$\frac{xdx}{\sqrt{(a+bx+cx^2)}} \text{ into } \frac{1}{2c}\,\frac{2cx+b-b}{\sqrt{(a+bx+cx^2)}}$$

$$\text{or } \frac{1}{2c}\,\frac{d(a+bx+x^2)}{\sqrt{a+bx+cx^2)}}-\frac{b}{2c}\,\frac{dx}{\sqrt{(a+bx+cx^2)}}$$

the first term of which can be integrated as in (1), leaving the second term, which can be simply integrated.

6. The process known by the name of *integration by parts*, consists in reducing the form Xdx into any convenient form Vdv, and using the obvious theorem

$$\int Vdv=Vv-\int vdV,$$

thus the finding of $\int Vdv$ is reduced to that of $\int vdV$, which it may often happen is the more simple of the two. Thus to find $\int x^m \log x dx$, we have

$$\int \log x d\frac{x^{m+1}}{m+1}=\frac{\log x.x^{m+1}}{m+1}-\int\frac{x^{m+1}}{m+1}\,\frac{dx}{x}$$

about the second term of which there is no difficulty. But it often happens that this method succeeds by a succession of reductions. Thus it gives

$$\int\epsilon^x x^6dx=x^6\epsilon^x-6\int\epsilon^x x^5dx$$

in which the second term must be again treated in the same manner.

7. In the last mode of proceeding, it is best to form, in general terms, an *equation of reduction*, as it may be called, which furnishes the key to the reduction of each case to the one below it. Thus if $\int\epsilon^{ax}x^ndx$ be considered as a function of n, and called V_n, integration by parts gives

$$V_n=a^{-1}\epsilon^{ax}x^n-na^{-1}V_{n-1},$$

thus showing how to find $\int\epsilon^{ax}x^ndx$ as soon as $\int\epsilon^{ax}x^{n-1}dx$ is known.

8. The use of the equation of reduction depends upon our being able at last to reduce the question to that of finding a visibly known integral. Thus, if in the preceding n be an integer, we must at last come to $\int\epsilon^{ax}x^0dx$, or $\int\epsilon^{ax}dx$, which is known. But if n were a fraction, no reduction of the value of n by units at a time would lead to an integrable form.

9. The integrable form at which we arrive by successive reductions is called the *ultimate form*. It frequently happens however that the reductions proceed by two or more steps at a time, in which case two or more ultimate forms result. For instance $V_n=\int(a^2-x^2)^{-\frac{1}{2}}x^ndx$ has for its equation of reduction

$$V_n=-\frac{x^{n-1}\sqrt{(a^2-x^2)}}{n}+\frac{n-1}{n}a^2V_{n-2}$$

Accordingly, when n is even, we are brought at last to V_0, and when n is odd, to V_1, or to $\sin^{-1}(x:a)$ and $-\sqrt{(a^2-x^2)}$.

10. In using equations of reduction, it will be found more convenient to work upwards from the ultimate form to the case required, than in the contrary way. Thus if we want $V_4=\int\epsilon^xx^4dx$, the equation of reduction being

$$V_n=x^n\epsilon^x-nV_{n-1},$$

We should proceed as follows:—

$$V_0=\epsilon^x,\quad V_1=x\epsilon^x-\epsilon^x$$

$$V_2=x^2\epsilon^x-2(x\epsilon^x-\epsilon^x)=x^2\epsilon^x-2x\epsilon^x+2\epsilon^x$$

$$V_3=x^3\epsilon^x-3x^2\epsilon^x+6x\epsilon^x-6\epsilon^x$$

$$V_4=x^4\epsilon^x-4x^3\epsilon^x+12x^2\epsilon^x-24x\epsilon^x+24\epsilon^x.$$

11. There are several cases in which the following extension of the theorem known by the name of John Bernoulli may be useful. Let u', u'', &c. be the successive differential coefficients of u with respect to x, and let v_1, v_2, v_3, &c. be the successive integrals of v with respect to x: then

$$\int udv=uv-u'v_1+u''v_2-u'''v_3+\ldots\pm u^{(n)}v_n\mp\int u^{(n+1)}v_ndv.$$

This is particularly useful when u is a rational and integral function, and v is successively integrable with ease, as when u is ϵ^{ax}, sin ax, or cos ax. The process can then be continued until the remainder vanishes.

12. In the case of $\phi xdx:\psi x$, where ϕx and ψx are rational and integral functions, the integration is always possible as soon as all the roots of $\psi x=0$ are found. The process in FRACTIONS, DECOMPOSITION OF, P. C. S., must be applied. When this is done, and the function thereby reduced to the sum of terms of the form $A(x-a)^{-n}dx$, the integration gives no trouble.

13. In the case of a pair of irrational roots, $\alpha\pm\beta\sqrt{-1}$, each occurring once, the sum of the terms which they produce can be reduced to the form

$$\int(Ax+B)dx:\{(x-\alpha)^2+\beta^2\}$$

the integral of which is

$$\frac{A}{2}\log\{(x-\alpha)^2+\beta^2\}+\frac{B+A\alpha}{\beta}\tan^{-1}\frac{x-\alpha}{\beta}$$

14. When ϕxdx is a function of powers of any one case of $ax+b$, it can, if irrational, be reduced to a rational function by assuming $ax+b=v^m$, where m is the least common multiple of all the denominators in the exponents. For dx becomes $mv^{m-1}dv:a$, and every power of $ax+b$ becomes an integer power of v.

15. The function $x^m(ax+b)^ndx$ can be integrated when either m or n is a positive integer: when n is integer, by simple expansion; when m is integer, but not n, by making $ax+b=v$, and substituting. But when both m and n are negative integers, let $x=1:y$ and after substitution, make $a+by=w$, and substitute for y.

16. The function $\phi xdx:(x^n\pm a^n)$ can be easily integrated by decomposition of fractions, the denominator never having equal roots. The same may be said if we substitute $x^{2n}\pm 2ba^nx^n+a^n$ in the denominator.

17. In $x^r(a+bx^s)^tdx$ we have an integrable function, whenever either of the following is a positive integer:—

$$\frac{r+1}{s},\text{ or}-\frac{r+1}{s}-t$$

The substitutions which succeed in the two cases are

$$a+bx^s=v^\delta,\text{ and } ax^{-s}+b=v^\delta$$

δ being the denominator of t.

18. The following transformation involves a large number of obvious cases, and is constantly occurring. If $\int\phi xdx=\psi x$, then $\int\phi(ax+b)dx=\psi(ax+b):a$.

Thus in no list would $\int\cos(ax+b)dx$ be set down, after $\int\cos x\,dx$ has been given.

19. The following integrals are worth giving separately as ultimate forms:—

$$\int\frac{dx}{x\sqrt{(x^2-a^2)}}=\frac{1}{a}\cos^{-1}\frac{a}{x},$$

$$\int\frac{dx}{x\sqrt{(a^2\pm x^2)}}=\frac{1}{a}\log\frac{x}{a+\sqrt{(a^2\pm x^2)}}$$

$$\int\frac{dx}{\sqrt{(2ax-x^2)}}=\cos^{-1}\frac{a-x}{a}=\text{vers}^{-1}\frac{x}{a}$$

$$\int\frac{dx}{\sqrt{(2ax+x^2)}}=\log\{x+a+\sqrt{(2ax+x^2)}\}$$

$$\int\frac{dx}{a+bx+cx^2}=2\int\frac{d(2cx+b)}{(2cx+b)^2+4ac-b^2}$$

which comes under one or another of three previously given forms, according as b^2-4ac is positive, nothing, or negative.

$$\int\frac{xdx}{a+bx+cx^2}=\frac{1}{2c}\log(a+bx+cx^2)-\frac{b}{2c}\int\frac{dx}{a+bx+cx^2}$$

$$\int\frac{dx}{\sqrt{(a+bx+cx^2)}}=\frac{1}{\sqrt{c}}\log\left\{2cx+b+\sqrt{\{4c(a+bx+cx^2)\}}\right\}$$

$$\int \frac{dx}{\sqrt{(a+bx-cx^2)}} = \frac{1}{\sqrt{c}} \sin^{-1} \frac{2cx-b}{\sqrt{(4ac+b^2)}}$$

$$\int \sqrt{a^2+x^2}\, dx = \frac{1}{2}x\sqrt{a^2+x^2} + \frac{a^2}{2} \log (x+\sqrt{a^2+x^2})$$

$$\int \sqrt{a^2-x^2}\, dx = \frac{1}{2}x\sqrt{a^2-x^2} + \frac{a^2}{2} \sin^{-1} \frac{x}{a}.$$

Let $X=(a+bx+cx^2)$. Then

$$\int \sqrt{X}\,.\,dx = \frac{2cx+b}{4c}\,.\,\sqrt{X} + \frac{4ac-b^2}{8c}\int\frac{dx}{\sqrt{X}}$$

$$\int \sqrt{X}\,.\,xdx = \frac{1}{3c}X^{\frac{3}{2}} - \frac{b}{2c}\int\sqrt{X}\,.\,dx$$

$$\int \frac{xdx}{\sqrt{X}} = \frac{\sqrt{X}}{c} - \frac{b}{2c}\int\frac{dx}{\sqrt{X}}$$

$$\int \frac{dx}{x\sqrt{X}} = \frac{1}{\sqrt{a}} \log \frac{2a+bx-2\sqrt{(aX)}}{x}$$

$$= \frac{1}{\sqrt{-a}} \sin^{-1} \frac{bx+2a}{x\sqrt{(b^2-4ac)}}$$

$$\int X^{-\frac{3}{2}}dx = \frac{2(2cx+b)}{4ac-b^2}X^{-\frac{1}{2}}$$

$$\text{Let} \int \frac{dx}{a+b\cos x} = \frac{1}{\sqrt{(a^2-b^2)}} \cos^{-1} \frac{b+a\cos x}{a+b\cos x}$$

$$= \frac{1}{\sqrt{(b^2-a^2)}} \log\left\{\frac{b+a\cos x+\sqrt{(b^2-a^2)}\,.\sin x}{a+b\cos x}\right\}.$$

20. All that it remains to give are the equations of reduction for remarkable cases. Many other differentials can be integrated in a finite form: but it is impossible to give a list of all which are sometimes useful. The transformation of unknown to known forms is one of the most necessary studies of the young mathematician.

21. Let $V_{m,n}=\int(\log x)^m x^n dx$. Then

$$V_{m,n}=(\log x)^m \frac{x^{n+1}}{n+1} - \frac{m}{n+1}V_{m-1,n}.$$

22. Let P stand for Ax^a+Bx^b, (m, n) for $\int x^m P^n dx$, g and h for $m+1+na$ and $m+1+nb$, and c for $a-b$. We shall then have

$$h(m, n)+ncA(m+a, n-1)=x^{m+1}P^n$$

$$g(m, n)-ncB(m+b, n-1)=x^{m+1}P^n$$

$$gA(m, n)+(h-c)B(m-c, n)=x^{m-a+1}P^{n+1}$$

$$hB(m, n)+(g+c)A(m+c, n)=x^{m-b+1}P^{n+1}$$

from the first pair of which formulæ of reduction can be found for n, be it positive or negative, and for m from the second pair. The most useful cases are those in which $a=0$, $b=1$, and in which $a=0$, $b=2$.

23. Let $V_n=\int(x^2\pm a^2)^{-n}dx$. Then

$$V_n=\pm\frac{x(x^2\pm a^2)^{-(n-1)}}{(2n-2)a^2}\pm\frac{2n-3}{(2n-2)a^2}V_{n-1}.$$

24. Let $V_n=\int(x^2\pm a^2)^n dx$. Then

$$V_n=\frac{x(x^2\pm a^2)^n}{2n+1}\pm\frac{2na^2}{2n+1}V_{n-1}.$$

25. Let $V_n=\int(a^2-x^2)^{-n}dx$ or $\int(a^2-x^2)^n dx$. The equations of reduction are those in (23.) (using the $+$ in $\pm$) and in (24), and writing a^2-x^2 for $x^2\pm a^2$.

26. Let $V_{m,n}=\int x^m(a^2\pm x^2)^{-n}dx$. Then

$$V_{m,n}=\mp\frac{x^{m-1}}{2(n-1)}\,\frac{1}{(a^2\pm x^2)^{n-1}}\pm\frac{m-1}{2(n-1)}V_{m-2,n-1}$$

$$V_{m,n}=\frac{x^{m+1}}{2(n-1)a^2}\,\frac{1}{(a^2\pm x^2)^{n-1}}-\frac{m+3-2n}{2(n-1)a^2}V_{m,n-1}$$

$$V_{m,n}=\pm\frac{x^{m-1}}{m+1-2n}\,\frac{1}{(a^2\pm x^2)^{n-1}}\mp\frac{m-1}{m+1-2n}a^2V_{m-2,n}.$$

27. Let $V_m=\int x^m(a^2\pm x^2)^{-\frac{1}{2}}$. Then

$$V_m=\pm\frac{x^{m-1}(a^2\pm x^2)^{\frac{1}{2}}}{m}\mp\frac{m-1}{m}a^2V_{m-2}.$$

28. Instead of giving a large number of forms which are all derivable from (22.), it will be better to give an instance of the derivation in full. Let the case be $\int x^{-m}(2ax-x^2)^n dx$, and let the formula be required to reduce both m and n in numerical magnitude. Here, to transform the formulæ in (22.)

For m write $-m$; retain n.
For A write $2a$; for B, -1.
For a write 1; for b, 2.
For g, $-m+1+n$; for h, $-m+1+2n$.
For c write -1.

The first formula connects $(-m, n)$ and $(-\overline{m-1}, n-1)$, the second, $(-m, n)$ and $(-\overline{m-2}\ n-1)$; the third, $(-m, n)$ and $(-\overline{m-1}, n)$; the fourth, $(-m, n)$ and $(-\overline{m+1}, n)$. By either of the first two we can therefore reduce both; by either of the last two we can reduce m only. Observe that whenever a formula will serve to raise either exponent it will also serve to reduce it. Thus, if a formula were

$$V_m=\phi(m, x)+\psi m\,.\,V_{m+1}$$

write $m-1$ for m and we have, by transformation,

$$V_m=-\frac{\phi(m-1, x)}{\psi(m-1)}+\frac{1}{\psi(m-1)}V_{m-1}$$

The two first formulæ become (P being $2ax-x^2$)

$$(2n-m+1)\,(-m, n)\,-2an\,(-\overline{m-1}, n-1)=x^{-m+1}P^n$$

$$(n-m+1)\,(-m, n)\,-n\,(-\overline{m-2}, n-1)=x^{-m+1}P^n$$

from which, writing $V_{m,n}$ for $(-m, n)$ or $\int x^{-m}P^n dx$, we have

$$V_{m,n}=\frac{1}{2n-m+1}\,\frac{(2ax-x^2)^n}{x^{m-1}}+\frac{2na}{2n-m+1}V_{m-1,n-1}$$

$$V_{m,n}=\frac{1}{n-m+1}\,\frac{(2ax-x^2)^n}{x^{m-1}}+\frac{n}{n-m+1}V_{m-2,n-1}.$$

If it were required to reduce n in the preceding without altering m, throw the formula $x^{-m}(2ax-x^2)^n$, into the form $x^{n-m}(2a-x)^n$ and use the first of the four formulæ.

29. All the preceding forms involving x^mP^n, are particularly in use when n is a fraction, positive or negative, with the denominator 2. These in fact form the most usual cases. Formulæ involving the powers of $A+Bx+Cx^2$ are so little wanted, that they are better omitted in a work in which space is of importance.

30. Let s and c stand for $\sin\theta$ and $\cos\theta$. The integral $\int s^m c^n d\theta$, m and n being positive integers, can be immediately found if $s^m c^n$ be reduced to the sum of terms of the form $A\cos k\theta$ or $A\sin k\theta$. But this process is as laborious as that of integration, and is seldom used except when there is some particular reason for exhibiting the result in the form of simple sines and cosines.

31. The following equations of reduction are those which are most commonly used:—

$$\int s^m d\theta=-\frac{cs^{m-1}}{m}+\frac{m-1}{m}\int s^{m-2}d\theta$$

$$\int c^n d\theta=\frac{sc^{n-1}}{n}+\frac{n-1}{n}\int c^{n-2}d\theta$$

$$\int\frac{d\theta}{s^m}=-\frac{c}{(m-1)s^{m-1}}+\frac{m-2}{m-1}\int\frac{d\theta}{s^{m-2}}$$

$$\int\frac{d\theta}{c^n}=\frac{s}{(n-1)c^{n-1}}+\frac{n-2}{n-1}\int\frac{d\theta}{c^{n-2}}$$

$$\int s^m c^n d\theta=\frac{s^{m+1}c^{n-1}}{m+n}+\frac{n-1}{m+n}\int s^m c^{n-2}d\theta$$

$$=-\frac{s^{m-1}c^{n+1}}{m+n}+\frac{m-1}{m+n}\int s^{m-2}c^n d\theta$$

$$\int\frac{c^n d\theta}{s^m}=-\frac{c^{n-1}}{(m-1)s^{m-1}}-\frac{n-1}{m-1}\int\frac{c^{n-2}d\theta}{s^{m-2}}$$

$$\int\frac{s^m d\theta}{c^n}=\frac{s^{m-1}}{(n-1)c^{n-1}}-\frac{m-1}{n-1}\int\frac{s^{m-2}d\theta}{c^{n-2}}$$

$$\int\frac{d\theta}{s^m c^n}=-\frac{1}{(n-1)s^{m-1}c^{n-1}}+\frac{m+n-2}{n-1}\int\frac{d\theta}{s^m c^{n-2}}$$

$$=\frac{1}{(m-1)s^{m-1}c^{n-1}}+\frac{m+n-2}{m-1}\int\frac{d\theta}{s^{m-2}c^{n}}$$

$$\int\frac{c^{n}d\theta}{s^{m}}=\frac{c^{n-1}}{(n-m)s^{m-1}}+\frac{n-1}{n-m}\int\frac{c^{n-2}d\theta}{s^{m}}$$

$$=-\frac{c^{n+1}}{(m-1)s^{m-1}}-\frac{n-m+2}{m-1}\int\frac{c^{n}d\theta}{s^{m-2}}$$

$$\int\frac{s^{m}d\theta}{c^{n}}=-\frac{s^{m-1}}{(m-n)c^{n-1}}+\frac{m-1}{m-n}\int\frac{s^{m-2}d\theta}{c^{n}}$$

$$=\frac{s^{m+1}}{(n-1)c^{n-1}}-\frac{m-n+2}{n-1}\int\frac{s^{m}d\theta}{c^{n-2}}$$

$$\int\tan^{n}\theta\,d\theta=\frac{\tan^{n-1}\theta}{n-1}-\int\tan^{n-2}\theta\,d\theta.$$

32. We have given the last steps in various forms, because in fact all the integrals of the form $\int x^{m}(a^{2}-x^{2})^{n}dx$ depend upon them. For if $x=a\sin\theta$, the last integral becomes $-a^{m+2n+1}\int\sin^{-m}\theta\cos^{2n+1}\theta\,d\theta$.

We have now given most of the forms which will be useful in an ordinary work of reference. Further forms and examples will be found in many works on the integral calculus, but the largest collection is in Meier Hirsch's 'Integraltafeln,' Berlin, 1810, 4to., a work of which there is also an English edition.

We have omitted notice of a great many such forms as $\int x^{n}\varepsilon^{ax}dx$, $\int x^{n}\varepsilon^{ax}\cos nx\,dx$, &c. which are little used, except in particular cases. When $\phi x\,.\,\varepsilon^{ax}dx$ can be integrated, it follows that $\phi x\,.\,\varepsilon^{ax}\cos bx\,dx$, &c. can also be integrated, since the second can be made into the sum or difference of two functions of the first form, by putting for $\cos bx$ or $\sin bx$ their exponential values.

The question of the possibility of integration in finite terms can often be settled by the following theorem:—Integration and differentiation, with respect to different variables, are convertible operations; thus

$$\frac{d\int u\,dx}{dy}=\int\frac{du}{dy}dx$$

If therefore $\int u\,dx$ can be found, so also can $\int(du:dy)dx$, if y be not a function of x. From this it will be seen that whenever $\phi x\varepsilon^{ax}dx$ can be integrated so can $\phi x\varepsilon^{ax}x^{n}dx$, which is obtained by n differentiations with respect to a: and also that whenever $\phi x\,.\,x^{n}dx$ can be integrated, so can $\phi x x^{n}(\log x)^{m}dx$, which is obtained by m differentiations with respect to n.

Functions involving the transcendental forms $\sin^{-1}\phi x$, &c. can sometimes be reduced to more algebraical forms by integration by parts. Thus,

$$\int V\sin^{-1}X\,.\,dx=\sin^{-1}X\,.\int V dx-\int\frac{X'\int V dx}{\sqrt{(1-X^{2})}}dx$$

$$\int V\log X dx=\log X\,.\int V dx-\int\frac{X'\int V dx}{X}dx\text{ \&c.}$$

in which X' means $dX:dx$.

INTEGRATION, DEFINITE. In the preceding article we have given some idea of the usual modes of integration. The results, which in the present article are given under the name of *definite integrals*, are mostly cases in which it is possible to find an integral when both limits are given [INTEGRAL CALCULUS, P. C.]; but not possible to find the integral in all cases. If we can integrate $\phi x dx$ generally, that is, if we can find the function $\phi_{1}x$, of which ϕx is the differential coefficient, we can always express the integral, the limit of the summation in the article just referred to, as follows:—

$$\int_{a}^{b}\phi x dx=\phi_{1}b-\phi_{1}a$$

but it frequently happens that ϕx is a function for which this cannot be done in a finite form, except for certain values of a and b. And it happens almost as frequently that these practicable values are of particular importance.

But the view of definite integrals which best shows their utility is the consideration of them as fundamental modes of expression. The ordinary symbols of algebra, it is well known, are incompetent to express in finite terms by far the greater number of integrals. Consequently the integrals themselves become modes of expression, and frequently the only ones. When we find a language with which we have much to do, and which has words which cannot be translated, we adopt the words of that language into our own. Precisely the same thing is done in the case of definite integrals. Thus in FACTORIALS, P. C. S., we adopt the integral $\int_{0}^{\infty}\varepsilon^{-x}x^{n}dx$, as the fundamental mode of expression for a function till then inexpressible, which becomes $1.2.3\ldots n$ whenever n is an integer, and remains intelligible, though not very easily found, when n is a fraction.

Further to illustrate this, let us suppose that the integral calculus had made some progress before the conception of a logarithm had been formed: a thing which might easily have happened. It would then have been found that $\int x^{-1}dx$ was wholly unattainable, a function which algebra could not express in finite terms. It would therefore itself have become a mode of expression, and it would soon have been proved that

$$\int_{1}^{a}\frac{dx}{x}+\int_{1}^{b}\frac{dx}{x}=\int_{1}^{ab}\frac{dx}{x}.$$

Here then would have been an obvious indication of the existence of a function proper to be made use of in performing multiplication by means of addition, &c.; and tables of the values of $\int_{1}^{a}x^{-1}dx$ would have been formed by the method of quadratures [QUADRATURES, P. C.] or otherwise; which would, so it happens, have been a much easier task than that which fell on the first calculators of logarithms. For all this however it happens that we are prepared by knowing logarithms and their properties; so that $\int x^{-1}dx$ is seen to be $\log.x+C$, and $\int_{1}^{a}x^{-1}dx$ to be $\log a$: the logarithms throughout this article being Naperian. But we are not equally ready for $\int\varepsilon^{-t^{2}}dt$, or for $\int\varepsilon^{-x}x^{n}dx$ (except when n is integer) or for $\int\cos x^{n}dx$: and accordingly we are obliged to study the properties of these functions as fundamental modes of expression.

To give some idea of the use of this view, we exhibit a mode of solving the following partial differential equation,

$$\frac{du}{dt}=a\frac{d^{2}u}{dx^{2}},$$

the general solution of which cannot be expressed in finite terms. It will easily be seen that $C\varepsilon^{\mu t+\nu x}$ is a solution for any value of C and ν, provided only that $\mu=a\nu^{2}$, and also that the sum of any number of such terms is a solution. Hence we assume an indefinite number of such terms, giving to C the form $\phi\nu.d\nu$, and summing them with such values of ν as will make the whole represent

$$\int_{p}^{q}\phi\nu\,.\,\varepsilon^{\nu x+a\nu^{2}t}d_{\nu}:$$

and we then see that this integral is a solution or general value of u, whatever the function $\phi\nu$ may be, and whatever may be the values of p and q. By a reduction which is rendered easy by some of the results presently mentioned, this solution is thrown into the form

$$u=\int_{-\infty}^{+\infty}\psi\left(x+2v\sqrt{at}\right)\varepsilon^{-v^{2}}dv.$$

where ψ may be the symbol of any function. From this it is clear that the given differential equation has numberless solutions which ordinary symbols are incapable of expressing in finite terms. The treatise in the Library of Useful Knowledge on the Differential Calculus, Gregory's 'Examples of the Differential Calculus,' and the 'Cambridge Mathematical Journal,' contain various examples of this mode of expression applied to differential equations.

We now proceed to give a selection from the enormous number of definite integrals which has been given. They have been found by detached methods, so that we could not attempt to give anything more than the results. Our article is intended for reference to the forms which it is probable will be noted in future elementary works, and which the mathematical reader may also wish to refer to. In order to avoid risk of broken or dropped letters, in an article in which the correct printing of the limits is of the utmost importance, we shall print what is usually denoted by $\int_{a}^{b}\phi x dx$ in the following way, $\int\phi x dx\,[a,b]$. Any conditions as to the values of constants will be expressed before the integral.

It need hardly be said that the article FACTORIALS, P. C. S., must be considered as a part of the present one.

Among the integrals which clearly depend on, or are connected with, factorials, are the following:—

$$(m+1<n)\int\frac{x^m dx}{1+x^n}[0,\infty]=\frac{\pi}{n\sin\left(\frac{m+1}{n}\pi\right)}.$$

$$(m+1<n)\int\frac{x^m dx}{(1+x)^n}[0,\infty]=\frac{\Gamma(m+1)\Gamma(n-m-1)}{\Gamma n}$$

$$(m \text{ and } n \text{ positive})\int x^{m-1}(1-x)^{n-1}dx\,[0,1]=\frac{\Gamma m.\Gamma n}{\Gamma(m+n)}$$

$$\int\frac{x^{m-1}(1-x)^{n-1}}{(x+a)^{m+n}}dx\,[0,1]=\frac{\Gamma m.\Gamma n}{a^n(1+a)^m\Gamma(m+n)}$$

$$(n \text{ positive})\int(-\log x)^{n-1}dx\,[0,1]=\Gamma n$$

$$(m \text{ and } n \text{ positive})\int x^{m-1}(-\log x)^{n-1}dx\,[0,1]=m^{-n}\Gamma n$$

$$(a \text{ and } n \text{ positive})\int x^{n-1}\varepsilon^{-ax}dx\,[0,\infty]=a^{-n}\Gamma n$$

$$(n \text{ positive})\int\varepsilon^{-x^n}dx\,[0,\infty]=\frac{1}{n}\Gamma\frac{1}{n}$$

$$\int\varepsilon^{-x^2}dx\,[0,\infty]=\tfrac{1}{2}\sqrt{\pi}.$$

Tables of the value of $(2:\sqrt{\pi})\int\varepsilon^{-x^2}dx\,[0,a]$, which are of great importance in the theory of probabilities, are given in modern works on that subject. The following expression by means of a continued fraction is useful. Let $q=1:2a^2$, then

$$\int\varepsilon^{-x^2}dx\;[a,\infty]=\frac{\varepsilon^{-a^2}}{2a}\;\frac{1}{1+}\;\frac{q}{1+}\;\frac{2q}{1+}\;\frac{3q}{1+}\;\frac{4q}{1+\&c.}$$

$$(n>-1)\int\frac{1-x^n}{1-x}dx\,[0,1]=\gamma+\frac{d\log\Gamma(1+n)}{dn};$$

γ being as in FACTORIALS, P. C. S.

One of Euler's integrals, generally called the second Eulerian integral, the factorial integral being the first, he denoted by the symbol

$$\left(\frac{n}{m}\right);\text{ it is}\int x^{n-1}(1-x^k)^{\frac{m}{k}-1}dx\,[0,1],$$

and it is included in those already given.

There is a class of multiple integrals closely connected with factorials, which may be made to save much trouble in applications to geometry. We shall take three variables as a specimen, but the same formulæ may be written with any number. The triple integration being made for all positive values which give $x+y+z$ not exceeding l, we have (a, b, c, being positive)

$$\int x^{a-1}y^{b-1}z^{c-1}dxdydz=\frac{\Gamma a.\Gamma b.\Gamma c}{\Gamma(a+b+c+1)}l^{a+b+c}$$

$$\int x^{a-1}y^{b-1}z^{c-1}f(x+y+z)\,dxdydz$$

$$=\frac{\Gamma a.\Gamma b.\Gamma c}{\Gamma(a+b+c)}\int x^{a+b+c-1}fxdx\,[0,l]$$

Similarly, the condition being that

$$\left(\frac{x}{\mathrm{P}}\right)^p+\left(\frac{y}{\mathrm{Q}}\right)^q+\left(\frac{z}{\mathrm{R}}\right)^r$$

shall not exceed l, wo have

$$\int x^{a-1}y^{b-1}z^{c-1}f\left\{\left(\frac{x}{\mathrm{P}}\right)^p+\left(\frac{y}{\mathrm{Q}}\right)^q+\left(\frac{z}{\mathrm{R}}\right)^r\right\}dxdydz$$

$$=\frac{\mathrm{P}^a\mathrm{Q}^b\mathrm{C}^r}{pqr}\;\frac{\Gamma\frac{a}{p}.\Gamma\frac{b}{q}\Gamma\frac{c}{r}}{\Gamma\left(\frac{a}{p}+\frac{b}{q}+\frac{c}{r}\right)}\int x^{\frac{a}{p}+\frac{b}{q}+\frac{c}{r}-1}fxdx\,[0,l]$$

We shall now give some specimens of the results of functions involving trigonometrical quantities. One of the most important of this class is the following:—

$$\int x^{-1}\sin bx\,dx\,[0,\infty]=\pm\tfrac{1}{2}\pi$$

according as b is positive or negative.

$$(a\text{ pos.})\int\frac{\cos ax\,dx}{1+x^2}[0,\infty]=\int\frac{\sin ax.xdx}{1+x^2}[0,\infty]=\frac{\pi}{2}\varepsilon^{-a}$$

$$\int\varepsilon^{-ax}\cos bxdx\,[0,\infty]=a:(a^2+b^2)$$

$$\int\varepsilon^{-ax}\sin bxdx\,[0,\infty]=b:(a^2+b^2):$$

from these come

$$\int\cos bxdx\,[0,\infty]=0,\ \int\sin bxdx\,[0,\infty]=1;$$

and from these come two equations which have been much used, long before they were openly expressed,

$$\sin\infty=0,\ \cos\infty=0.$$

Some difference of opinion exists abont these equations, which in fact involve a great deal of what has been done by mathematicians* in the last twenty years.

When a and n are both positive

$$\int\varepsilon^{-ax}\cos bx.x^{n-1}dx\,[0,\infty]=\frac{\Gamma n.\cos\{n\tan^{-1}(b:a)\}}{(a^2+b^2)^{\frac{n}{2}}}$$

$$\int\varepsilon^{-ax}\sin bx.x^{n-1}dx\,[0,\infty]=\frac{\Gamma n.\sin\{n\tan^{-1}(b:a)\}}{(a^2+b^2)^{\frac{n}{2}}}$$

$$\int\cos x^m.x^n dx\,[0,\infty]=\frac{1}{m}\Gamma\left(\frac{n+1}{m}\right)\cos\left(\frac{n+1}{2m}\pi\right)$$

$$\int\sin x^m.x^n dx\,[0,\infty]=\frac{1}{m}\Gamma\left(\frac{n+1}{m}\right)\sin\left(\frac{n+1}{2m}\pi\right)$$

$$a<b\int\frac{\sin ax}{\sin bx}\;\frac{dx}{1+x^2}[0,\infty]=\frac{\pi}{2}\;\frac{\varepsilon^a-\varepsilon^{-a}}{\varepsilon^b-\varepsilon^{-b}}.$$

But when $a=2mb\pm c$, m being an integer, the preceding integral is

$$\frac{\pi}{2}\;\frac{\varepsilon^c+\varepsilon^{-c}-2\varepsilon^{-a}}{\varepsilon^b-\varepsilon^{-b}}.$$

This is a specimen of a sort of discontinuity which very frequently occurs, and from not attending to which mistakes have often arisen.

If we call $\frac{1}{2}(\varepsilon^x+\varepsilon^{-x})$ and $\frac{1}{2}(\varepsilon^x-\varepsilon^{-x})$ the *hyperbolic* cosine and sine of x, and denote them by h. cos x and h. sin x, we have, the limits being 0 and ∞, and a being less than π,

$$\int\frac{\text{h. sin }ax}{\text{h. sin }\pi x}\cos cx\,dx=\frac{1}{2}\;\frac{\sin a}{\cos a+\text{h. cos }c}$$

$$\int\frac{\text{h. cos }ax}{\text{h. cos }\pi x}\cos cx\,dx=\frac{\cos\frac{1}{2}a.\text{h. cos }\frac{1}{2}c}{\cos a+\text{h. cos }c}$$

$$\int\frac{\text{h. cos }ax}{\text{h. sin }\pi x}\sin cx\,dx=\frac{1}{2}\;\frac{\text{h. sin }c}{\cos a+\text{h. cos }c}$$

$$\int\frac{\text{h. sin }ax}{\text{h. cos }\pi x}\sin cx\,dx=\frac{\sin\frac{1}{2}a.\text{h. sin }\frac{1}{2}c}{\cos a+\text{h. cos }c}$$

$$\int\frac{\sin cxdx}{\varepsilon^{2\pi x}-1}[0,\infty]=\frac{1}{4}\;\frac{\varepsilon^c+1}{\varepsilon^c-1}-\frac{1}{2c}.$$

The integral $4n\int\frac{t^{2n-1}dt}{\varepsilon^{2\pi t}-1}[0,\infty]$ is the nth number of Bernoulli [NUMBERS OF BERNOULLI, P. C.], meaning that opposite to which $2n-1$ is written in the article cited.

As specimens of the reduction of definite integrals, the integrals

$$\int\frac{\varepsilon^{-a^2t^2}\cos axt\,dt}{1+t^2}[0,\infty]\text{ and }\int\frac{\varepsilon^{-a^2t^2}\sin axt\,tdt}{1+t^2}[0,\infty],$$

are severally equal to

$$\frac{\sqrt{\pi}.\varepsilon^{a^2}}{2}\left\{\varepsilon^{-ax}\int\varepsilon^{-t^2}dt\;[-\infty,\tfrac{1}{2}x-a]\right.$$

$$\left.\pm\varepsilon^{ax}\int\varepsilon^{-t^2}dt\;[\tfrac{1}{2}x+a,\infty]\right\}$$

the first having +, the second −. Also

$$\int\frac{\varepsilon^{-a^2t^2}dt}{1+t^2}[0,\infty]=\sqrt{\pi}.\varepsilon^{a^2}\int\varepsilon^{-t^2}dt\,[a,\infty].$$

The following is fundamentally important,

$$\int\varepsilon^{-a^2x^2}\cos bxdx\,[0,\infty]=\frac{\sqrt{\pi}}{2a}\varepsilon^{-\frac{b^2}{4a^2}}$$

* With regard to these equations, it must be observed that they are not to have their algebraical consequences; thus, $\sin^2\infty$ is not 0, but $\frac{1}{2}$. The truth seems to be, as far as yet appears, that any function ϕx, which becomes indefinite in form, by the angle x becoming infinite, is properly represented by $\int\phi xdx\,[0,2\pi]$.

The integral $\int \frac{dx}{\log x}[0, a]$ has been tabulated [Diff. Calc., L. U. K., p. 662] by Soldner, and a great many integrals may be found from it. Soldner proposes to call it the *Logarithm-integral* of a, and to denote it by the abbreviation li. a. Adopting this notation, we have then, both in definite and indefinite forms,

$$\int \frac{x^m dx}{\log x} = \text{li. } x^{m+1} \qquad \int \frac{\epsilon^{\pm x} dx}{x} = \text{li. } \epsilon^{\pm x}$$

$$\int \frac{dx}{\log (a+bx)} = \frac{1}{b} \text{ li. } (a+bx) \qquad \int \epsilon^{\epsilon^x} dx = \text{li. } \epsilon^{\epsilon^x}$$

and so on.

Of miscellaneous integrals there is an immense number, of which we give a few instances:

$$\int \frac{(1-v^m)(1-v^n)\,dv}{(1-v)\log v}[0, 1] = \log \frac{\Gamma(1+m)\,\Gamma(1+n)}{\Gamma(1+m+n)}$$

$$(a \text{ pos.}) \int \frac{x \tan x\, dx}{a^2+x^2}[0, \infty] = \frac{\pi}{\epsilon^{2a}+1}$$

$$(a \text{ pos.}) \int \frac{x \cot x\, dx}{a^2+x^2}[0, \infty] = \frac{\pi}{\epsilon^{2a}-1}$$

$$(a \text{ pos.}) \int \epsilon^{-ax} \sin bx . x^{-1} dx\, [0, \infty] = \tan^{-1}(b : a)$$

$$\int \frac{\epsilon^{-ax} \cos bx - \epsilon^{-\alpha x} \cos \beta x}{x} dx\, [0, \infty] = \frac{1}{2} \log \frac{\alpha^2+\beta^2}{a^2+b^2}$$

if neither a nor α be negative.

$$\int \epsilon^{-x^2-\frac{a^2}{x^2}} dx\, [0, \infty] = \frac{1}{2} \sqrt{\pi}\, \epsilon^{-2a}$$

$$\int \frac{x \sin x\, dx}{1-2a \cos x+a^2}[0, \pi] = \frac{\pi}{a} \log (1+a) \text{ or } \frac{\pi}{a} \log \left(1+\frac{1}{a}\right)$$

according as a is less or greater than unity.

Among the means of producing or using definite integrals which are comprehensive enough to deserve the name of methods, there are four which particularly deserve the attention of elementary writers.

The first is Laplace's mode of finding the approximate value of a definite integral in which large constant exponents occur. Let ϕx be a function of x, such as $\epsilon^{-x}x^n$ or $x^n(1-x)^m$, &c., in which n, m, &c. are considerable exponents. Let this function vanish when $x = a$ and $x = b$, and, continuing positive and finite throughout the interval, let it come to its maximum Y, when $x = \text{X}$. Let v_2 mean the value of the second differential coefficient of $\log \phi x$, when $x = \text{X}$, and assume $\phi x = \text{Y}\epsilon^{-t^2}$. Then

$$\int \phi x\, dx = \text{Y} \sqrt{\left(-\frac{2}{v_2}\right)} \int \epsilon^{-t^2} dt \text{ nearly,}$$

provided that the limiting values of t on the second side are those which, in the equation $\phi x = \text{Y}\epsilon^{-t^2}$, belong to the limiting values of x taken on the first side. The best approximating cases are as follows. First, when a and b are the limiting values of x, in which case $-\infty$ and $+\infty$ are those of t, and the result is

$$\int \phi x dx\, [a, b] = \text{Y} \sqrt{\left(-\frac{2}{v_2}\right)} . \sqrt{\pi}.$$

Secondly, when the limiting values of x are $\text{X} \pm \xi$, ξ being small. In this case

$$\int \phi x dx\, [\text{X} \pm \xi] = \text{Y} \sqrt{\left(-\frac{2}{v_2}\right)}\, 2 \int \epsilon^{-t^2} dt \left[0, \xi \sqrt{\left(-\frac{v_2}{2}\right)}\right]$$

This method is found, by itself, almost sufficient to meet the wants of the more complicated problems in the theory of probabilities.

Secondly, Fourier's theorem, as it is usually called, by which a discontinuous function can be expressed. This theorem is as follows,

$$\phi x = \frac{1}{\pi} \iint \cos w\,(x-v) . \phi v . dw dv,$$

from $v = -\infty$ to $v = +\infty$, and from $w = 0$ to $w = \infty$. Or thus: the equation

$$\phi x = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^{+\infty} \cos w(x-v) . \phi v . \epsilon^{-kw} dw dv.$$

is one which, for all values of x, approaches without limit to truth, as k is diminished without limit positively. But if instead of the limits $-\infty$ and $+\infty$, for v, we write a and b, a being less than b, then

$$\frac{1}{\pi} \int_0^\infty \int_a^b \cos w(x-v) \phi v dw dv$$

is a discontinuous function, as follows:—From $x = -\infty$ to $x = a$ exclusive, it is nothing: when $x = a$, it is $\frac{1}{2}\phi a$; from $x = a$ to $x = b$ both exclusive, it is ϕx; when $x = b$, it is $\frac{1}{2}\phi b$; and from $x = b$ to $x = \infty$ it is nothing.

Thirdly, the following methods of expanding a function in series of sines and cosines has been extensively used by Lagrange, Poisson, and Fourier. We give it in the most general form after the manner of Poisson. Let

$$\phi x = \text{A}_0 + \text{A}_1 \cos \frac{\pi x}{l} + \text{A}_2 \cos \frac{2\pi x}{l} + \ldots$$

then for every value of x from $x = 0$ to $x = l$, both inclusive, this equation is true if

$$\text{A}_0 = \frac{1}{l} \int \phi v dv\, [0, l], \quad \text{A}_m = \frac{2}{l} \int \cos \frac{m\pi v}{l} \phi v dv [0, l].$$

Again, the equation

$$\phi x = \text{B}_1 \sin \frac{\pi x}{l} + \text{B}_2 \sin \frac{2\pi x}{l} + \ldots.$$

is true from $x = 0$ to $x = l$, both exclusive, if

$$\text{B}_m = \frac{2}{l} \int \sin \frac{m\pi v}{l} \phi v dv [0, l].$$

Further, the equation

$$\phi x = \text{A}_0 + \text{A}_1 \cos \frac{\pi x}{l} + \text{A}_2 \cos \frac{2\pi x}{l} + \ldots.$$
$$+ \text{B}_1 \sin \frac{\pi x}{l} + \text{B}_2 \sin \frac{2\pi x}{l} + \ldots.$$

is true for all values of x from $x = 0$ to $x = l$, both exclusive (becoming $\frac{1}{2}\phi l$ when $x = l$) if

$$\text{A}_0 = \frac{1}{2l} \int \phi v dv [0, l], \quad \text{A}_m = \frac{1}{l} \int \cos \frac{m\pi v}{l} \phi v dv [0, l]$$
$$\text{B}_m = \frac{1}{l} \int \sin \frac{m\pi v}{l} \phi v dv [0, l]$$

But write $2l$ instead of l, *in the limits only*, or write $[0, 2l]$ instead of $[0, l]$ and the equation becomes true for all values of x from 0 to $2l$, both inclusive.

Fourthly, we shall give two cases of the method deduced by Cauchy, as specimens: the complete method itself has some difficulties which are not yet overcome.

First, let ϕx be such a function of x that $\phi(x+y\sqrt{-1})$ vanishes when $x = -\infty$ or $+\infty$, whatever y may be, and when y equals ∞, whatever x may be. For every root of the form $a+b\sqrt{-1}$ (a being either positive or negative, and b being positive, but both finite) which makes ϕx infinite, let $(x-a-b\sqrt{-1})\phi x$ be finite; calculate the value of this last product for each root. For every real root a, of $\phi x = \infty$ ($x = 0$ not being one) calculate half the value of $(x-a)\, \phi x$. Let the sum of all these values and half values be P. Then

$$\int \phi x dx[-\infty, +\infty] = 2\pi\sqrt{-1} . \text{P}.$$

Secondly, let ϕx be such a function that $\phi(x+y\sqrt{-1})$ vanishes when $x = +\infty$ or $-\infty$ independently of y, and when $y = +\infty$ or $-\infty$ independently of x. Take the imaginary roots only which make ϕx infinite, and let $(x-a-b\sqrt{-1})$ ϕx be always finite when $a+b\sqrt{-1}$ is one of those roots, and $x = a+b\sqrt{-1}$. Let the sum of all the values of the last product, for the cases in which b is positive, be P; and for the cases in which b is negative let it be Q. Then

$$\int \phi x dx[-\infty, +\infty] = \pi\sqrt{-1} . (\text{P}-\text{Q}).$$

The subject of definite integrals is one in which the difficulties which have always appeared at the boundaries of mathematical knowledge are constantly met with. The consequence is, considerable difference of opinion about many points. On these the student who desires to use the higher parts of analysis must hope to form his opinion independently, when his reading and reflection are sufficient for the purpose. Most of these difficulties belong, in principle, to that which accompanies the use of divergent series, which is the most important mathematical question now under discussion. If we were to judge of the future by the past, we should prophesy that divergent series would one day take their undisputed place among well understood objects of analysis, as negative quantities and their logarithms, imaginary quantities and their exponentials, infinitely small quantities with their different orders, discontinuous solutions of differential equations, &c. have successively done, each under a fire of objections which has well served the progress of science, by the defensive researches which it has rendered necessary. It is fortunate for analysis that so many of those who find difficulties propose the entire rejection of the symbols or methods in which the difficulties exist: the proposition excites those who are against any rejection to efforts which they perhaps would not make, if they had only to meet the doubts of allies, instead of the attacks of opponents. That the symbolic expressions of which we are speaking, will never vanish out of remembrance, we may confidently predict: of all the points of difficulty of which we have spoken, it may be said, in the words of Horace

'Naturam expellas furca, tamen usque recurret;'

they will come, and will demand explanation until they get it. They will conquer by numbers, as Fontenelle said the symbol of infinity had done. And it is to be hoped and expected, that no difficulty will be completely resolved, without the appearance of a successor, to excite new efforts, and be the stimulating cause of further progress. We should be sorry to think we had arrived at the 'last impossibilities* of pure mathematics.'

INTERDICT, in the law of Scotland, supplies the place of an injunction from a court of equity in England. It is a prohibitory order, forbidding some act from being done, and it is obtained on the application of the party who would be injured by the performance of the act. It may be issued by the Court of Session, or by the Sheriff's Court. Interdicts in the Court of Session are frequently obtained for preventing inferior courts, or courts of limited operation, such as the ecclesiastical courts, from exceeding their jurisdiction. To this end the form was frequently adopted in the late dispute in the Church of Scotland, which ended in a secession. [Free Church, P.C.S.] Interdict is applied for by what is called a 'Note of Suspension and Interdict' presented to the Lord Ordinary on the Bills. In pressing matters, interim interdict is awarded before the parties are heard, but in the general case intimation is given to the other party, who gives in answers. If there are means by which the applicant's interests can be kept safe, as by the finding security, or otherwise, the interdict will not be granted, but the 'vote will be passed to try the question,' and the matter will proceed as an ordinary litigation.

INTERMENT. [Interment, P. C.] Of late years the subject of interment has attracted much attention in England, and a great amount of information has been collected. Though opinions are not unanimous, the evidence, the further it is examined, appears to prove that emanations from crowded burial-grounds and from the vaults of churches do injuriously affect the health of persons who live near them; and that these emanations when sufficiently concentrated may produce speedy death. The general 'conclusion that all interments in churches or in towns are essentially of an injurious and dangerous tendency' (*Report on the Practice of Interment in Towns*), is at least made a strong probability, and strong enough, coupled with other reasons, to justify the legislature in forbidding such interments, and placing all burying-grounds under such regulations as may prevent the effluvia from the dead from becoming detrimental to the health of the living. The Report to which reference has been made contains, in addition to the evidence on the injurious effects of crowded burial-places, much valuable information on the injury to health caused, particularly among the poor, by the delay in interments. The following remark will show the nature and extent of this evil: 'In a large proportion of cases in the metropolis and in some of the manufacturing districts, one room serves for one family of the labouring classes: it is their bed-room, their kitchen, their wash-house, their sitting-room, their dining-room; and when they do not follow any out-door occupation, it is frequently their work-room and their shop. In this one room they are born, and live, and sleep, and die amidst the other inmates.' Among the poor in some parts of London the average time that a body is kept is about a week, which sometimes arises from inability to raise money for the funeral expenses, as well as other causes; and where there is only a single apartment, the dead and the living occupy it together. The injurious consequences to health from the presence of a dead body sometimes in a state of rapid decomposition, in a small ill-ventilated apartment, and particularly when death has been the consequence of malignant disease, cannot be disputed; and the effect on the living is demoralizing. The expense of funerals is another head which is examined in this Report, where it is well remarked that 'the expense of interments, though it falls with the greatest severity on the poorest classes, acts as a most severe infliction on the middle classes of society' (p. 46). The cost of interment in London varies from 4*l.* for a labourer to 1000*l.* for a gentleman: for persons of the condition of a gentleman it is stated that 150*l.* would be a low average. But these charges do not include anything but the undertaker's bill. The account of the details of an expensive funeral, 'which is strictly the heraldic array of a baronial funeral, the two men who stand at the doors being supposed to be the two porters of the castle, with their staves in black,' &c., is ludicrous enough; but the disposition to laugh is checked by considering the pecuniary embarrassment which this absurd display often entails on the survivors. Many persons incur a heavy debt by the expenses of interment. It is not unusual for poor people to liquidate such debt by instalments paid weekly, or at other short periods.

The subject of interment, like many others relating to the economy of society, may at first sight not seem to require any particular attention on the part of the state. It may be said, let every man bury his dead as he best can, and as he chooses. With respect to the rich, the expense is an absurd waste of money, and the example is bad; with respect to the middling classes, it is a heavy burden; but to the poor, interment of their dead is often almost an impossibility. To diminish these expenses, to secure the decency of interment amongst all classes, and particularly among the poor, and to prevent the contamination of the living by the dead, are objects well worthy of the attention of a legislator. The information collected in the report above alluded to lays bare a revolting picture of moral and physical facts; but it is truly said, 'General conclusions can only be distinctly made out from the various classes of particular facts, and the object being the suggestion of remedies and preventions, it were obviously as unbecoming to yield to disgusts or to evade the enumeration and calm consideration of these facts, as it would be in the physician or surgeon, in the performance of his duty with the like object, to shrink from the investigation of the most offensive manifestations of disease.'

The Report makes a proximate estimate of the total expense of funerals in London, which, according to the estimate, amounts to 626,604*l.* per annum; and a like estimate of the expense of all the funerals in England and Wales in one year is 4,870,493*l.* This sum, enormous as it is, may be considered an under estimate. 'The cost of the funerals of persons of rank and title varies from 1500*l.* to 1000*l.* or 800*l.* or less, as it is a town or country funeral. The expenses of the funerals of gentry of the better condition vary from 200*l.* to 400*l.*, and are stated to be seldom so low as 150*l.*' The average cost of funerals of persons of every rank above paupers in the metropolis may be taken at 14*l.* 16*s.* 9*d.* per head. But owing to circumstances, fully explained in the Report, even this lavish expenditure does not secure the proper and solemn discharge of the funeral ceremony, which, in crowded and busy districts seems to be totally impracticable. It is fully shown that the expenses of funerals may be greatly reduced, and the due performance of the religious ceremonies may be secured by other arrangements. The establishment of cemeteries by Joint Stock Companies has done something by diminishing the amount of interments in crowded places, but the expenses of interment have perhaps not been at all diminished by them.

The Report concludes (p. 197) with a summary of the evils which require remedies; and there is not one of the evils which has not been proved to exist. There may be difference of opinion as to the degree in which the evils exist; but none as to the existence itself. The remedies that are suggested for these evils appear to have been well considered, though, when an evil is ascertained to exist, people are not always agreed as to the best remedy. One of the proposed remedies, which involves many important considerations, and would probably meet with some opposition, is 'that r tions.

* These are the words of Mr. A. F. Vogel, of Leipsic, who has recently published in this country a tract on the resolution of all kinds of equations, printed at Leipsic, in his own English.

cemeteries of a suitable description ought to be provided and maintained (as to the material arrangements) under the direction of officers duly qualified for the care of the public health.' Another is, 'that for the abatement of oppressive charges for funeral materials, decorations, and services, provision should be made (in conformity to successful examples abroad) by the officers having charge of the national cemeteries, for the supply of the requisite materials and services, securing to all classes, but especially to the poor, the means of respectable interment, at reduced and moderate prices, suitable to the state of the deceased and the condition of the survivors.' The numerous matters contained in the Report can only be indicated here. It should be consulted by all who take an interest in the well-being of society, as a most valuable contribution to the statistics of civilized life.

(*A Supplementary Report on the Results of a Special Inquiry as to the Practice of Interment in Towns, made at the request of her Majesty's principal Secretary of State for the Home Department*, by Edwin Chadwick, Esq. Barrister-at-Law. London, 1843.)

INTERNATIONAL LAW. This term was originally applied by Bentham to what was previously called the 'law of nations,' and it has been generally received as a more apt designation than that which it superseded. When the term 'law of nations' was in use, that of 'law of peace and war' was sometimes employed as a synonyme, and as indicative of the boundaries of the subject. It was thus in its proper sense restricted to the disputes which governments might have with each other, and did not in general apply to questions between subjects of different states, arising out of the position of the states with regard to each other, or out of the divergences in the internal laws of the separate states. But under the more expressive designation, International Law, the whole of these subjects, intimately connected with each other as they will be found to be, can be comprehended and examined, and thus several arbitrary distinctions and exclusions are saved. To show how these subjects are interwoven, the following instances may be taken:—A port is put in a state of blockade; a vessel of war of a neutral power breaks the blockade: this is distinctly a question between nations, to be provided for by the law of peace and war, in as far as there are any consuetudinary rules on the subject, and the parties will submit to them. But suppose a merchant vessel belonging to a subject of a neutral power attempts an infringement of the blockade, and is seized—here there is no question between nations in the first place. The matter is adjudicated on in the country which has made the seizure, as absolutely and unconditionally as if it were a question of internal smuggling; and it will depend on the extent to which just rules guide the judicature of that country, and not on any question settled between contending powers, whether any respect will be paid to what the party can plead in his own favour, on the ground of the comity of nations, or otherwise. But there is a third class of cases most intimately linked with these latter, but which are completely independent of any treaties, declarations of war, or other acts by nations towards each other. They arise entirely out of the internal laws of the respective nations of the world, in as far as they differ from each other. The 'conflict of laws' is a term very generally applied to this branch of international law, and the circumstances in which it comes into operation are when the judicial settlement of the question takes place in one country, but some of the circumstances of which cognizance had to be taken have occurred in some other country where the law applicable to the matter is different. One of the most common illustrations of this subject is,—a judicial inquiry in England whether a marriage has taken place in Scotland according to the law of that country; or an inquiry in Scotland whether a marriage has taken place according to the law of England; in either of which cases there will generally be the further and nicer question, Which country's law ought to prevail as the criterion?

Thus the three leading departments of international law are—

1. The principles that should regulate the conduct of states to each other.

2. The principles that should regulate the rights and obligations of private parties, arising out of the conduct of states to each other.

3. The principles that should regulate the rights and obligations of private parties, when they are affected by the separate internal codes of distinct nations.

The first of these has been the principal subject of the well-known works of Grotius, Puffendorf, Vattel, and other publicists, who have derived from general principles of morality and justice a series of minute abstract rules for the conduct of nations towards each other, and subsidiarily for the conduct of their subjects in relation to international questions. It has been usual to call this department the 'Law of Nature,' as well as the Law of Nations, on the supposition that, though it has not the support of the authority of any legislature, it is founded on the universal principles of natural justice.

It is clear that thus in its large features, as a rule for the conduct of independent communities towards each other, the Law of Nations wants one essential feature of that which is entitled to the term law—a binding authority. Nations even the most powerful are not without checks in the fear of raising hostile combinations and otherwise; but there can be no uniformity in these checks; and in general when the interest is of overwhelming importance, and the nation powerful, it takes its own way. The importance of the questions which may be involved in the Law of Nations thus materially affects the question how far it is uniformly obeyed. In a set of minor questions—such as the safety of the persons of ambassadors, and their exemption from responsibility to the laws of the country to which they are accredited, and in other matters of personal etiquette, a set of uniform rules has been established by the practice of all the civilized world, which are rarely infringed. But in the more important questions, regarding what is a justifiable ground for declaring war? what territory a nation is entitled to the sovereignty of? what is a legitimate method of conducting a war once commenced? &c. —the rules of the publicists are often precise enough; but the practice of nations has been far from regular, and has been, as every reader of history knows, influenced by the relative strength of the disputing parties more than by the justice of their cause. The later writers on this subject have from this circumstance directed their attention more to the means by which any system of international law can be enforced, than to minute and abstract statements of what may be theoretical justice, but has little chance of being enforced. They have found several circumstances which have an influence in the preservation of international justice, though of course no sanctions which can give it the uniformity and consistency of internal laws.

The combinations for the preservation of what is called the Balance of Power [BALANCE OF POWER, P. C.] are among the most useful restrictions of ambition. All periods of history furnish illustrations of this principle. Hume found that the Peloponnesian war was carried on for the preservation of the balance of power against Athens. The late war exhibited a noted illustration of combination to prevent universal conquest on the part of the French. The safety of small states from being absorbed by their larger neighbours, is in the jealousy which these neighbours feel of each other's aggrandisement. Thus the jealousy of rulers is one barrier to national injustice. Another is public opinion: sometimes that of the nation whose rulers would be prepared to commit injustice—sometimes that of other nations. Of course it can only be to a very limited extent that the public feeling of a despotic government can check the grasping spirit of its rulers; but the public feeling of the constitutional and democratic states is the great check on the injustice that might be perpetrated by a nation when it becomes so powerful as Great Britain.

The seizure of the Danish fleet by the English has been a subject of warm censure in this country. Necessity—even the plea that Napoleon would have used the fleet to invade our own shores—has not been accepted in palliation of the act; and the manner in which it has been canvassed is very likely to prevent any British government from adopting the precedent. The partition of Poland is an instance of national injustice condemned by the public feeling of countries other than those by which it was perpetrated; and it may be questioned whether the states which accomplished the partition may not yet suffer by it. Good fame in the community of nations is like respectability in private circles, a source of power through external support; and the conduct of Russia towards Poland has frequently diverted from the former country the sympathy of free nations. It need scarcely be observed that the press, whether fugitive or permanent, is the most powerful organ of this public opinion, and that the views of able historians, jurists, and moralists, have much influence in the preservation of international justice. Among the principal subjects of dispute in this department of international law are—the sovereignty of territory and the proper boundaries of states, as in the question at present under debate regarding the Oregon territory in North America; questions as to discovery and first occupancy of barbarous countries; questions as to any exclusive right to frequent certain seas,—and here there is a well-known distinction between the broad ocean and the narrow seas that lie close to particular territories; questions regarding the right of navigation in rivers which may be either between the upper and lower territories, or between states on opposite banks; questions as to the right of harbour or fishing, &c.; and questions as to the right of trading with particular states. A very advantageous method of adjusting minor international disputes has been frequently had recourse to of late in a submission to the arbitration of a neutral power. Pride and the spirit of not yielding to intimidation or aggrandisement have often more influence in a nation's resistance of another's claim, than the desire to keep what is demanded. In such a case the national pride is not injured when that which is yielded to is the award of a neutral party, not the demand of an opponent. It has been suggested by Bentham and Mill that the civilized states of the world should establish among themselves a congress, which should adjudicate on all disputes between its members, the members being excluded from voting in their own disputes.

The Second department into which we have considered international law divided—the rights and obligations of individuals as affected by the conduct of states towards each other—has, like the first, been examined by the publicists in their theoretical manner; but it has never, perhaps, received so much practical illustration as it did in the British courts, particularly the Prize Admiralty Court, during the late wars. In a despotic country it would of course scarcely ever occur that the bench should fail to give effect to the national policy of the government, whatever that may be. But in England it was the rule that foreigners as well as natives were entitled to the rigid administration of the law, and that, if the proceedings of the government were at variance with the rights of parties according to the law of peace and war, individuals might have redress. Thus, when Great Britain, in opposition to the Berlin decrees, tried to establish a 'paper blockade,' that is to say, by force of orders in council to declare places to be under blockade, whether there were a force present to support it or not, Sir William Scott found that 'in the very notion of a complete blockade, it is included that the besieging force can apply its power to every point in the blockaded state. If it cannot, it is no blockade of that quarter where its power cannot be brought to bear.'

It has frequently been observed, that as to all departments of the law of nations, uncivilized countries are at the mercy of the civilized: that not having any means of reciprocating the action of international laws, from their having no systematic judicatories of their own, they have not even the frail tenure of generally received opinions as to what the conduct of independent nations towards each other ought to be, for their protection. This is in some measure true. If a weak civilized nation, which can eloquently appeal to the law of nations, is feebly protected against the injustice of a strong nation, still less effectually are a barbarous community, who never heard of international law, and know not how to appeal to its acknowledged principles, protected by it; and, in regard to them, the humanity and conscience of the powerful nations coming in contact with them are their protection, rather than any rules of international law. Thus when, as in the instance of a colonial government or otherwise, such a nation as the British has to deal with the inhabitants of a barbarous country, it cannot be said that these inhabitants have the law of nations to appeal to if they are unjustly treated, and there is no sanction for their being well and humanely used but the morality and conscience of the British nation and its government. How far civilized nations had in former times disregarded all feelings of common humanity in their intercourse with inferior races, the history of colonization, and especially that relating to the continent of America, is a horrible record. In later days higher notions have been entertained of the responsibility of superior power, and the civilized man has in some measure ceased to make his first advances to the notice of the barbarian in the character of a murderer and a pillager. Britain has in this improved morality so far advanced before other nations, as to be the protector of barbarous races from the oppression of others, in her efforts for the abolition of the slave trade and the preservation of aboriginal nations. These efforts, in so far as they are an anomaly in the general conduct of nations, have introduced some necessary exceptions to the rules of international law applicable to the rights of persons. This has consisted in the necessity of treating those who are injured by the slave trade, viz. the slaves carried off, as if they were subjects of this country subjected to injury, while the deporters have likewise been of necessity treated in the general case as if they were subjects of this country doing the injury. The effect of this state of matters, as an exceptional principle in international law, sometimes occasions difficult questions. In the late case of the Felicidade, a foreign slaver had been captured and taken possession of. The crew rose, and putting the captors to death, recaptured the vessel. They were tried and condemned to death for murder in an English court; and the judge who conducted the trial would not admit the plea that, as the capture had taken place under our laws, not their laws, they were entitled to regain possession by any means which they might choose to adopt. He held it right, in fact, to treat the ship as a prison, and the captured seamen as persons in a British prison. On the question however coming before all the judges, the conviction was declared invalid, the principal ground of the reversal being, that the vessel not having slaves on board was not legally liable to seizure. In those cases where it is necessary to diverge from the general principle of international law, for the protection of the weak, it is fortunate that the humane and enlightened motive of proceeding is a guarantee for its being beneficially exercised.

The rights of individuals have sometimes been so much affected by the conduct of nations towards each other, that their own nation has been induced to make war against the nation aggressing. This has twice occurred in our intercourse with America: one war was caused by our restrictions on the commerce of America by the orders in council; another by our searching American merchant vessels for British seamen. On the subject of the present unsatisfactory state of the question as to this right of search, Mr. Reddie, in his 'Maritime International Law' (ii. pp. 43-44), says, 'Unfortunately this claim of right was left undecided either way even by the hastily concluded treaty of Ghent in 1814, which terminated the war between the parent state and what were originally her colonies. And as the divergence in the personal appearance, language, habits, and manners of the inhabitants of the two countries was not likely, for generations, to be such as to facilitate the discrimination of the subjects of the two states, it is to be regretted the question was not subsequently settled by the negotiations of 1818 upon the equitable footing of regular authentic lists or registers of British and American seamen being made up and kept, and of the nationality of the seamen being thereby determined.'

The Third division of international law is that which most properly comes under the head 'Conflict of Laws,' viz. the principles that should regulate the rights and obligations of private parties when they are affected by the separate internal codes of distinct nations. This has some points in common with the preceding department of the subject. It involves questions with individuals, and not, at least in the first instance, questions with states; and the adjustment of each question depends on the view taken by the law of the country to which the individual or his property is amenable. But it has this distinctive feature, that the circumstances under which disputes may arise are not in the conduct of one nation towards another, but in differences between the internal laws of the countries, which internal laws disagree, not because the one nation has a dispute with the other, but in the general case because its legislators have taken its internal situation solely into consideration, and have overlooked the existence of other nations. There can be no part of the world where this species of international law can be so well illustrated as in the United States—a collection of communities, each having an internal system of administration, but each acting on principles of harmony and alliance with the other states of the Union. It is thus natural that America should have produced the best work on the subject, in Professor Story's 'Commentaries on the Conflict of Laws Foreign and Domestic, in regard to Contracts, Rights, and Remedies; and especially in regard to Marriages, Divorces, Wills, Successions, and Judgments,' of which two editions are now known and esteemed in this country. The leading rule of international law in this department is, that each civilized nation is to give efficacy to the laws of another country, unless its own laws or the general principles of justice are thereby invaded. We have the broadest and most distinct illustrations of this rule in the criminal law. The progress of opinion has lately been in favour of each nation rendering back fugitive criminals, to be dealt with according to the law of the country where they have committed any private crime against person or property. In conformity with this principle, treaties were lately made with France and the United States of America, for enforcing which, in this country, two acts of parliament were passed (6 & 7 Vict. c. 75 and c. 76), by which a secretary of state, on the requisition of the ambassador or other representative of France or the United States, might issue a warrant to magistrates to seize a person accused of a crime, a magistrate being enjoined to put it in force on his being satisfied that the charge is of such a nature as would authorise him to commit a person charged with perpetrating it in his own jurisdiction. [CONVENTION TREATIES, P. C. S.] But it has been a rule in many countries, and particularly in our own, that no aid is to be given for the enforcement of the political laws of foreign states. As in other branches of international law, our enlightened principles on the subject of slavery have here been the cause of perplexing difficulties. With slave-holding countries slavery comes to be a question of property, but with us it can only be a question of government; and we cannot view any rules regarding property in slaves as laws relating to private rights, an infringement of which, when held to be criminal in the slave-holding country, must be so also here. Accordingly, in the celebrated case of the Creole, in November, 1841, when certain American slaves escaped and found protection in a British settlement, it was found that we could not send them back to their owners as robbers who had with violence stolen their own persons from the custody of their proprietors.

As on the one hand the criminal law is that to which this department of international law most broadly and distinctly applies, on the other hand the position of real or landed property is that to which it has generally the least reference. The reasons of this distinction are very obvious: his own personal conduct is that object of the law which a man most completely carries about from one country to another; his connection with landed property is the relation in which a tribunal out of the country in which the property is, can have the least chance of adjudicating. Between these extremes there are many questions regarding persons in their relations to each other, and regarding contracts as to moveable or personal property. It came thus to be a general principle, that rights connected with landed property must always be settled by the law of the place where the land lies, while questions regarding other property might be subjected to other criterions of jurisdiction. Perhaps historical circumstances in the early history of the European nations favoured this division. The various tribes which occupied the territory of the Roman empire appear to have carried with them their own peculiar laws and customs. Savigny quotes a letter from Bishop Agobardus, in which he says it often happens that five men, each under a different law, may be found walking or sitting together—a state of society at this day exemplified in some oriental nations. Among all these distinct tribes the feudal system arose as the general and uniform territorial law. Through a series of circumstances which need not be here narrated, the civil or Roman law became the ruling principle as to persons in their relation to each other when that relation was not of a feudal character, and as to claims regarding moveable goods. The common law of England has perhaps had the least affinity with the other European codes. But it has fortunately happened that those departments of the law with which international questions are chiefly concerned,—the consistorial and the admiralty law, have been considered as the legitimate offspring of the civil law, and have adopted in a great measure its principles as they have been in practice throughout Europe. The mercantile law in general of England has accommodated itself to the custom of merchants; and this custom has in a great measure arisen out of the adaptation to modern commerce of the principles of the civil law. The portion of the commercial code of England which is least in harmony with that of other countries is perhaps the bankruptcy law, which, being statutory, has not so pliantly adapted itself to the exigencies of foreign commerce as the consuetudinary portions of the commercial law have done. Thus, under the old sequestration or bankruptcy statute of Scotland, which was supposed to give the trustee or assignee full power for obtaining possession of the bankrupt's property in all parts of the world, it was found that he had no right of action for a debt due to the bankrupt in England—the right of the trustee being that of an assignee merely, and a right to a debt being a chose in action, and therefore not capable of being assigned by the law of England. See Jeffrey *v.* M'Taggart, 6 M. & S. (K. B.), 126. The law of bankruptcy appears to be one of the most difficult of adjustment to international principles. There are clauses in the bankruptcy and insolvency acts of England by which, through registration of the vesting order, the assignee becomes invested with all real or landed property in any part of the British dominions where a conveyance of such property requires to be recorded. (See 1 & 2 Wm. IV. c. 56, § 27, and 1 & 2 Vict. c. 110, § 46.) It could not have been the intention of this provision to give an English assignee privileges which a trustee of a bankrupt estate does not hold in Scotland; but while the latter requires to make up a feudal title before he can be the recorded proprietor of real property, it was found by the Court of Session in the strict interpretation of the English provision that no such preliminary was necessary, and that the registration of the vesting order was sufficient. (Rattray *v.* White, 8th March, 1842, 4 D., 880.)

The conflicts of laws between England and Scotland are of course in this part of the world the most important and interesting. The consuetudinary or unstatutory law of England has perhaps fewer principles in common with that of Scotland than the latter has with the law of any other country in Europe; and this divergency has been the cause of many difficult questions. In these the law of marriage and that of succession have been particularly fertile. In the former the difference between the institutions of the two countries, when subjected to the principles of international law, has been productive of very remarkable effects. In England there are certain acts which are necessary ingredients, by the statute law, of a valid marriage. In Scotland the consent of parties to hold each other as man and wife, when sufficiently attested, is, according to the doctrines of the civilians, sufficient. But in England it is a principle of international law that a marriage valid in the place where it is contracted is valid in England; the consequence is, that the lax principle of marriage by simple attested consent would have probably fallen into desuetude and oblivion in Scotland, were it not kept up by English parties, who thus evade the restrictions of their own law. On the subject of succession, a series of decisions in both countries has settled two very important principles—that in the case of landed property it follows the *lex rei sitæ*, or the law of the place where the property is; while in moveable or personal property it follows the *lex domicilii*, or law of the domicile in which the person leaving it died.

INTERROGATORIES. [EQUITY, P. C.]

INVENTION. [PATENT, P. C.; COPYRIGHT, P. C. S.]

INVENTION AND DISCOVERY. The rights of individuals, as to the honour due to the origination of new views, processes, or methods, are matters of constant discussion in the history of letters and science. It is strange that the subject should never have been generally treated: and in default of better, we intend to put together some rude materials for consideration, which may perhaps help the young reader of the history of science (from which our examples will mostly be drawn) in forming his opinion of the controversies which there abound.

Invention and discovery are, for our present purpose, synonymous terms. As commonly used, the first word signifies the formation of something which would not necessarily have existed, but for the invention; the second means the finding out that which always did exist, and would have existed whether the discovery had been made or not. We all perfectly see the error in the assertion, set down for correction in the English exercise-books, that 'Galileo *discovered* the telescope, and Harvey *invented* the circulation of the blood:' and also the propriety of the assignment of words made by Mr. Macaulay, when he says that the terms in which Machiavelli is usually described would seem to import that he was 'the discoverer of ambition and revenge, the original inventor of perjury.' We can imagine the possibility of a telescope having never been framed, or a false oath having never been sworn; but as long as man exists, and his blood circulates, feelings of ambition and revenge will spring up in his mind. The words have some analogy with those of problem and theorem in geometry: and particularly in this, that invention must be ultimately a suggestion of discovery. The inventor of modern ink, which till his time had never existed, discovered that a mixture of galls and sulphate of iron would produce a durable dark fluid: his invention consisted in the application of his discovery to the art of writing. In this manner it may be asserted by some [BACON, ROGER, P. C.] that Roger Bacon discovered the telescope. There must be a discovery preceding every invention; but it does not follow that every discovery leads to invention. But yet there are some cases in which the preceding definitions fail to describe the actual use of words: for example, bichromate of potash was never found in nature, never discovered: its elements were compounded in the laboratory by its inventor. But the chemists would not call this an invention, nor anything but a discovery: we should recommend them to draw the distinction, as useful to the memory in relation to the history of their science.

There is in the words discovery and invention a tempting resemblance, often just, and often fallacious, to those of theory and practice. But in fact each of the things must be subdivided into theoretical and practical. The effect of the non-spherical form of the earth upon the moon's motion was discovered theoretically: the variation and the evection were discovered practically. As to inventions, we call Davy's safety lamp a theoretical invention: for the question given was how to overcome a certain danger, generally; and it was not even assumed that a lamp was to be constructed. But the common story of the boy who saved his labour by tying a string from the valve he was employed to open and shut to a part of the machinery which moved in such a manner as to do it for him, is, if true, a record of a practical invention. Still there is truth in this, that practical men, properly so called [THEORY AND PRACTICE, P. C.], have invented oftener than they have discovered; and that theoretical men have discovered more often than they have invented.

It is no wonder that the early history of discovery should be confused and uncertain: the loss of documents, which operates on all our first knowledge of antiquity, is a sufficient explanation. Nor is it surprising that first writers should be persons of unsettled claims; that in the case of Euclid, for example, we should not be so well able to say where his discoveries began as where they ended. But it does seem strange that in matters of our own day, or that immediately preceding, it should be a question to whom a right of discovery should belong, when the only tangible matter is a book, to the date of the publication of which there is every possible attestation.

There is one most important preliminary consideration, which will, in the minds of those who for the first time give it due attention, change the face of the whole question. When the period arrives at which a discovery becomes possible, there are many courses which lead to it, and many ships sailing on each of these courses. The analogy may be carried further. When a new island is discovered in or near a frequented track, as soon as a ship of some one country casts anchor in a port and takes possession, it may be afterwards found in some logs that something like land had been suspected before, in others that land birds had been seen, in others that the colour of the water was noted, in others that an alteration of the current was observed, and so on, all near the same point, and any one of which might have led to the discovery, if the hint had been followed. It is the same in matters of science, to an extent which will not be easily credited by those who are unacquainted with its history. And this greatly enhances the merit of most original researches. It is much to the credit of Newton that Huyghens had gone as far as to determine the conditions of circular motion, that Grimaldi had noted the effect of the prism on light, that Fermat and Cavalieri had all but discovered the method of fluxions. The character of accidental good fortune disappears when we see that the progress of knowledge seems to bring new results within the possible reach of many, but within the actual grasp only of one. Is there then nothing accidental in discovery and invention? We answer that there is something, but that the accidents which *might* produce discovery are happening to all, and frequently; while the accidents which *do* produce it happen to those only who are ready to take advantage of them. But this it may be said is reasoning in a circle; for if we are asked how we distinguish the person who is ready to take advantage from the one who is not, we have only the discovery to point to. We reply, that it generally happens that the persons who can thus fix a casualty, are also those who give evidence of successful research in cases where fortune shows no special favour. It was by a mere accident that Mr. Baily [FLAMSTEED, P. C.; BAILY, P. C. S.] bought a house opposite to the possessor of a large bundle of Flamsteed's letters, and nothing more than the fact of their existence came to his ears. Many perhaps had seen them, and either taken it for granted that the contents were all in print, or been unable to judge of their value. But the life of Flamsteed is not the only evidence of Mr. Baily's success in a point of astronomical history: there was no accident about the editorship of the old catalogues. It is said to have been by a casual effect of sun-light at a window that Malus discovered the polarisation of reflected light; but then Malus was a profound optical investigator. It is our conviction that no accidents are valid except those which happen to the proper men at the right times; and that there are usually other means of showing this besides the success of the accidents themselves.

Before we can examine the title to a discovery, it must first be settled what the discovery is: and this is frequently the greatest difficulty. The case of the steam-engine is constantly under discussion; and the principal point at issue is, what is the steam-engine. Heron of Alexandria certainly produced rotatory motion by steam, and, with sufficient funds, could have ground all the corn in Egypt by his method. If we assign the merit to the person who contrived such an economy of fuel as to place the use of steam on something like its present footing of convenience, it then becomes a doubt whether any except Watt has the claim. M. Arago remarks on this subject, that a watchmaker would be struck dumb by the question, who invented a watch? The thing as it now exists is not the invention of any one person. As long as there is any national feeling in the discussion, one or another definition will be proposed, constructed to suit the advocacy of one or another claim. We have not here to settle the cases which we cite; it is enough that they illustrate our point.

It may happen that in a complicated instrument or method, the perfecting of which extends over a long period, there is some one distinguishing characteristic the introduction of which marks the main epoch of the invention. In the case of the watch, for instance, if we ask for the distinctive definition of the term, we find that it is not merely an instrument for measuring time, which would include the clepsydra, nor an application of wheel-work for that purpose, which would include the clock; but it is the use of a spring for the regulator, in which consists the distinction between a watch and other horologes. In a similar manner we look upon the additions made by Vieta to the mechanism of algebra as constituting the main groundwork of what now bears the name. But it would be exceedingly wrong to say that Hooke invented a watch, or that Vieta invented algebra: things done before and after both essentially belong to the ideas we mean to convey by the words. But it is not an uncommon practice of writers to strip a word of all its accessories, and to attribute (justly enough perhaps) the invention so cut down to some one person, and then to clothe the word with all its most modern associations, and the favoured inventor with all the glory which ought to be divided among many. When the steam-engine is reduced to a teakettle, or at most to a pump, it is Avery, or De Caus, or Worcester, or Newcomen, or Papin, &c. &c. who invented it, according to the country or the fancy of the writer; but when once the claim is established, the teakettle throws out a condenser, and the pump runs along the railroad at sixty miles an hour.

The common sense of the law requires that the applicant for a patent should make a distinct specification, not merely of what he intends to construct, but of that particular part of the contrivance which he claims as his own; and here a claim upon anything old, or an omission of anything new, vitiates the patent. [PATENT, P. C.] The cases which have occurred under this law would be good study for those who write on discovery.

It may indeed happen that the amount of claim may be materially augmented by the view which the discoverer takes of his title. Columbus inferred, on true principles, the possibility of crossing the Atlantic, spent the energies of a life in procuring the means of making a trial, and is therefore properly and truly the discoverer of all the new world: the Northmen who had visited it long before did not promulgate their discovery, and it might as well be given to the aboriginal inhabitants of the continent itself as to them. It does not depreciate the merit of Columbus that he could not but suppose he should reach India or China: these were the certainties at which he aimed, and which he would have reached had he not been stopped by the intermediate continent which ought to bear his name. Had Heron, when he first announced and executed his revolving boiler, been able to point out that it was a method of producing force from fuel, which might supply the place of human labour—that all which remained was adaptation—and that skill in the use of this new kind of force would make it a substitute for the strength of men and beasts—it would have been difficult to have denied him the title of the discoverer of the steam-engine, and the inventor of the first step. Among the consequences of attempting to describe discoveries under too general terms, is this, that both things and persons are allowed to clash unnecessarily.

It is not always, to be sure, that this goes such a length as procuring for Dalton's atomic theory the character of being a republication of the notions adopted by Epicurus from his predecessors; if it did there would be the less harm: there are many theories between which mischievous confusion is more easily brought about than between those of the philosophers of Athens and of Manchester. The nomenclature of science is perplexed by phrases of no precision—as that Newton discovered gravitation, instead of a true explanation of the heavenly motions by means of gravitation—that he first advanced the true theory of astronomy, which he did in one sense, and Copernicus in another; whence the provinces of the two are frequently confounded. It must also be noticed that a mere opinion, the result of choice between several, one or other of which must have been taken, is confounded with the same opinion advanced and supported by reasons. Thus Philolaus and Aristarchus asserted the motion of the earth, and Copernicus is said to have only revived their opinion. The difference between the two cases lies in this, that the antient philosophers merely asserted their belief, the modern one made his hypothesis the means of accounting for all the known motions of the heavens, diurnal, annual, and precessional.

The specification, to borrow a term, having been agreed upon, the next question is, what constitutes a claim to discovery? The answer is, priority of publication. If, as has often happened, two persons should discover the same thing about the same time, the one who first publishes is universally recognised as the discoverer. Of course, if a fraud can be proved, if it can be satisfactorily shown that the first publisher stole his matter from another, he would not be allowed the advantage of his wrong: but the onus of proving the fraud lies entirely upon the assertor of it, and, until the evidence and verdict arrive, the first publisher is in possession. The reasons for this rule are not altogether those which exist for the rule in law. The objects of the latter are the protection of private rights and public peace; or rather the assignment of private rights in such a manner, as best, in the long run, to promote the welfare of the community, and particularly its peace, without any great shock to the natural feelings of equity. It is not difficult to conceive a case in which men would gladly give up a small per centage of decisions consonant to natural justice, or what is so called, for the sake of a rule which would present decided advantages as a rule, in the imperfect state of private morality. But the object of the scientific historian is truth for its own sake; he has nothing to do with conventions made for the sake of peace.

This rule, that first publication gives the right, until the contrary is proved, is adopted for the sake of its own probability, as a starting point. Select, at hazard, the name of a result, and of its first announcer; no doubt will exist in the mind of any one, used to the history of science, that it is at least fifty to one the name of the real discoverer is thus given. But if it be *the fact* that the discovery was made at an earlier period, and if that fact can be established, the history of the human mind must not be falsified by adherence to a rule. If, for example, it could be made out, from internal evidence, that Archimedes must have had an algebra and a differential calculus, which deference to the notions of his time prevented him from publishing, it would never do to let the formal claims of Leibnitz and Newton prevent the allowance of that of Archimedes: for then would result the suppression of the actual fact, which, if true, would be of great consequence, namely, that the Greek mathematics were powerful enough to lead their best minds to the discoveries of modern times. We insist upon this because we have observed a considerable tendency in writers of history to establish a rule on legal grounds of peace and convenience. There is also a confusion between two distinct things; the claims of history, and the claims of the individual: the former demands true facts, the latter just appreciation of his merit. By a perversity of the human mind, Newton and Leibnitz would lose fame to-morrow, more or less,—that is, more with some and less with others—if an undoubted manuscript of Archimedes were to turn up, showing that he possessed a formal differential calculus. We are apt to assign praise to mere priority, independently of originality, and to withdraw it on failure of priority. But it is forgotten that the merit of priority only lies in this, that the earlier an invention or discovery is made the ruder are the methods and instruments, and the fewer the hints to which it is due. For example, D'Alembert reinvented Taylor's theorem [TAYLOR, P. C., p. 126] in, or shortly before, 1754. He has all the merit due to the discovery, as n 1754. But could it be proved now that Taylor's works, &c. were recent forgeries, so that D'Alembert should stand as the original inventor, it would be impossible to put him in Taylor's place; the differential calculus was in two very different states in 1716 and in 1754.

There is also an injurious tendency to stand by the fixed rule as a thing of good consequences, in the way of punishment or stimulus: and certainly there is no denying that if it were but right to substitute, in history, the thing which is not for the thing which is, there are advantages arising from the adoption of the rigid rule of first publication. Tartaglia [TARTAGLIA, P. C.] suppressed his method for cubic equations from a selfish motive: Cardan, to whom he had communicated it under promise of secrecy, published it, with a sufficient acknowledgment; nevertheless the rule always goes by Cardan's name. There is little to regret here: Tartaglia was willing, simply that he might be able to puzzle his contemporaries, to retard the progress of algebra; it is not certain that he ever would have published his discoveries. The public has rewarded the individual to whom they were indebted for knowledge by affixing his name to the rules he announced. If it were understood that the name attached to any scientific result was always that of the first publisher, saving all the rights of history over the truth of the discovery, this and similar acts of nomenclature might be a satisfactory use of the *norma loquendi*. It has sometimes happened that individuals have deposited sealed packets with public scientific bodies, to reserve their rights in the event of any one else arriving at results which they wished to avoid making public until they had followed them out to their remote conclusions. This practice is one which would not prevent the name of any other person from being attached to the contents of the packet, if he came independently by the same results, and published them before the packet was opened.

The next question is, what constitutes a sufficient publication. And here the answer is, that the only mode which can give the discoverer no further duty in the matter, is the press. If any one should prefer written correspondence, public lectures, or oral conversation, it must be at his own risk. A printed book, pamphlet, magazine, or newspaper which any one who likes may buy, is a record of the court of history from the day of its appearance: but any other mode of communication, which is of its own nature not addressed to the public at large, must be put in. and proved before it can be available. A communication to a scientific body, for example, is only so much better than a letter to a friend, as it is more public and more easily proved: but unless it be published in the transactions of that body, in which case it ranks with a book from the date of publication, it will require subsequent establishment. There is, however, always a difficulty with regard to such communications, particularly when the transactions of the academy in question do not appear till some time after the reading of the memoir. It is impossible to know what an author has added as the paper went through the press: that is, if a contest of dates should arise, it will always be necessary to assume the date of publication, unless some proof can be given that the memoir as published is, in the matter under dispute, the same as that which was originally communicated. It has happened before now, that a communication presented has been almost entirely remodelled before it was printed We have little doubt that, in course of time, bodies which publish transactions will find it necessary to require that authors shall either print their communications as presented, or date such additions as they feel desirous of making.

The most remarkable question of publication that ever arose was that relative to the invention of fluxions. [FLUXIONS, P.C.; COMMERCIUM EPISTOLICUM, P. C.] There never was a case in which it was more necessary to consider the rights of history, and not to judge by any fixed rule. Newton, unquestionably the first inventor, made no publication whatever at the time: an anagram, or transposed sentence, cannot be looked upon in any other light than as a sealed packet. Leibnitz has accordingly the full merit of an inventor, and priority of publication. Newton has given proof that he could have published it, if he had chosen.

It frequently happens, as before observed, that independent discoveries take place about the same time: there is no doubt that such is the fact. When the publications take place very nearly at the same time, particularly when they are in different countries, it is easy enough to admit the real independence of the two. If the same thing should appear in the notices of the Royal Society and the Comptes Rendus of the French Institute within a few weeks of each other, the presumption is strong in favour of neither writer having had a communication, directly or indirectly, from the other: and this presumption must be rebutted by any one who desires to prove plagiarism. But as the interval of time becomes greater, the presumption, so far as it is derived from time only, is weakened. In such a case, the internal evidence of the writings themselves must be carefully looked at. There is usually a very great difference between the modes in which different investigators arrive at, and even in which they state, the same conclusions: those who would do a dishonest thing might know this as well as others, and might endeavour to counterfeit originality. To detect the base metal is not always easy: to prove its baseness is next to impossible. But it mostly happens that really independent investigators carry their results to different lengths; one will go further in one part of the subject, another in another.

As may be supposed, the most disputed cases are national ones; including in that term the schisms of different classes in the same country, as the scientific feuds of universities, of literary societies, &c. And between people of different countries and governments, the question arises in two distinct ways, not only as to the definition of the discovery itself, and the priority of publication, but as to the country to which the discoverer is to be said to belong. And here there seems to us to be a necessity for a distinction which is rarely made, and no wonder; national pride is the mortal enemy of discriminative argument. All people like to believe that their race is gifted by nature with talent, and that their public policy is calculated to draw it out. For proof of this they appeal to their great writers and thinkers, among whom they include all whom they have drawn into their country, and all whom they have driven out. Now it is clear that the eminent men who have been induced to settle in a country not their own, may be a credit to the institutions, but can be none to the race, of their adopted country: while those who are driven away may do honour to the race but not to the institutions of the land from which they are exiled. Take the cases for instance of Lagrange and De Moivre. Lagrange, who, of many offers made to him when he left Prussia, preferred that of the king of France, resided in that country from 1787 till his death in 1813, was exempted from the expulsion of foreigners ordered by Robespierre, and received, during all governments from the old monarchy to the empire, every possible honour and aid,—is a greater credit to French institutions and feelings than if he had been born in their country. But as far as blood is concerned, he is almost wholly Italian, having been born, and established his first reputation, at Turin: it is said, we do not know on what authority, that his great grandfather was a Frenchman, which may entitle France to claim the eighth part of him. De Moivre, on the other hand, born of French parents and educated in France, was driven from his country by religious fanaticism, and none of his works were published either in France or in French. Whatever credit his talents may do to his race, he is the disgrace of their institutions, as to the time in which he lived. Not that he received such encouragement here as would entitle us to say that the honour lost by France was wholly gained by England.* While picking up a scanty living by private teaching, the only way in which he could find time to read the Principia was by tearing it leaf from leaf, and carrying a leaf in his pocket to look at while walking from one pupil to another, or at any other chance interval.

There is much absurdity in the mode by which national prowess in matters of discovery is tested. A few of the very first names are made the only subjects of comparison. There is some presumption, certainly, that the great names are the best of many, and that the plants most abound where the largest plants are found. But this presumption must not be urged when an attentive consideration will settle the question without it. Archimedes was the greatest of the Greek mathematicians; but Sicily was not therefore the most celebrated in science of all the countries in which Greece had colonized. So far from it, that when in the sixteenth century, Maurolico lived and wrote, the following epigram was made upon him—

Te quoque Zancla tulit, Maurolyce, ne sit in uno
Clara Syracosio Sicelis ora sene.

The most difficult question of all is undoubtedly what degree of merit belongs to a discovery, and the settlement of the question where in the list it places its author. The public in general judges by utility; whereas it is notorious that many discoveries show more power of mind than others of much greater value to the world. The rule of utility is a good one for mankind in general; but it must be taken with modification by the historian of science. Who has most benefited his species, and who has shown himself most above his species in intellect, are two different questions. The merit of the inventor, and his genius, are not comparable quantities. The former is determined by the study, the personal risk or inconvenience which it was requisite to undergo, the patience and perseverance which must have been shown, and the goodness of the motive which appears to have actuated. The latter is the greater the less the pain and labour, and is wholly independent of moral considerations. A patient schoolboy who multiplies one number by another with time and care, has more merit than the wonderful youths who have sometimes appeared, and who can do it in their heads; but the first has far less mental power, in this one line, than the second. All these things are plain on the first statement; but they are far from receiving due attention, and will so remain until the history of discovery is written without too much deference to popular reputation.

We may mention, as a thing to be guarded against, the disposition to depreciate a discovery because it is not something more than it pretends to be, which is frequently combined with a wish to judge of its merit by an arbitrary *à priori* standard of what it ought to have been. Sturm's theorem is a very pretty instance. Before it appeared, a purely theoretical and strictly certain method was eagerly sought after, and any such, however difficult, would have been held a great gain. The object is at last attained, but in a manner which is troublesome to use. To look at the way in which some writers now mention it, one would suppose they had entirely forgotten how many investigators of the first order had given up the subject without producing any method at all.

INVESTITURE. [FEUDAL SYSTEM, P. C.]

INVOLUTION AND EVOLUTION. In our article under this head, we gave an account, with instances, of the method of solving equations, which is commonly known by the name of the late Mr. W. G. Horner, schoolmaster, of Bath. We believe we may usefully give that article a considerable extension: first, because the method [COMPUTATION, P. C. S.] is one of the best exercises in computation; secondly, because neither its meaning nor its history is very generally understood, and the latter is very instructive. We suppose the reader of this article familiar with the one which preceded it.

The process of *involution*, as defined in the article cited, is the formation of the value of a rational and integral algebraical expression, such as ax^3+bx^2+cx+d, by a succession of multiplications separated by additions, as in

$$\{(ax+b)x+c\}x+d.$$

Horner's mode of doing this, takes the figures from left to right, or takes those of largest value first; and exhibits a plan of performing the operation, which combines the result of each figure with the joint result of all that come before. Thus in finding the value of the preceding when $x=123{\cdot}456$, the value is first found when $x=100$; then, by help of the preceding, when $x=120$; then, when $x=123$; then when $x=123{\cdot}4$; and so on. By this means we are enabled to proceed, when the value of the succeeding figures depends upon the results of those already found, as happens in all the cases of *evolution*, the inverse process. To take, however, the direct process first, we shall exhibit at length the finding of $9x^3-3{\cdot}141x^2+{\cdot}009x-1427{\cdot}499$, when $x=121{\cdot}23$; or, to avoid decimals in the expression, we may consider this as the thousandth part of $9000x^3-3141x^2+9x-1427499$. The process is as follows: a great many figures (about 115) being repeated twice over, in a manner wholly unnecessary in computation, in order to facilitate the explanation.

* We take this opportunity to correct an insinuation against a statement made by Newton which appears in FLUXIONS, P. C., p. 832. According to the registers of the Royal Society, as cited by Dr. Thomson and Sir David Brewster, the committee appointed to report on the dispute about the invention of Fluxions consisted of Arbuthnot, Hill, Halley, Jones, Machin, and Burnet. This, we said, is what Newton called a committee of different nations. We could not suppose that the list in the Royal Society's own records was incorrect: nor that all the English historians had failed to discover an existing minute. But in the life of De Moivre, written by 'Mr. Maty,' as he calls himself, but who must have been Dr. Matthew Maty, who was secretary of the Royal Society, and was the friend of De Moivre, we find it stated that the committee consisted of Arbuthnot, Hill, Halley, Jones, Machin, Burnet, Robarts, (the father of Lord Radnor), *Bonet, (the Prussian Minister), De Moivre*, Aston, and Taylor (no doubt Brook Taylor). On making inquiry at the Royal Society, we find that Maty's statement is correct, and that the five last names were subsequently added. Newton was therefore justified in saying that the committee was composed of 'gentlemen of different nations,' though the negligence of those who ought to have searched all the minutes which intervene between the first appointment of the Committee and its Report has made him appear to state what was absolutely false, in a matter of which he must have known the truth.

	326952900		
	326979900		
	328006900		

We first put down the coefficients as usual, not changing the sign of the last (which is only a convenience for *evolution*, and does not alter any figure). The value of x heing 121·23, we begin with 100, which, having two ciphers, we mark off by commas from the several coefficients 0, 2, 4, 6 places. We then proceed hy Horner's process with the figure 1 (not 100), taking care to make commas fall under commas, or to use the commas as if they were decimal points (which they are in fact, though not *unit-points*). As soon as we have done the first process, containing all that comes before the lines A, we learn as follows. Let

$$\phi x = 9x^3 - 3{\cdot}141x^2 + {\cdot}009x - 1427{\cdot}499$$

then, x being 100, ϕx, $\phi' x$, $\frac{1}{2}\phi'' x$ and $\frac{1}{6}\phi''' x$ are severally 8967163·401, 269371·809, 2696·859, and 9. We then write down the results again, after the lines A (which is not necessary in calculation), merely to show the new disposition of the commas. We are now to proceed with 20 (from the first 2 in 121·23), which, having one cipher, we mark off 0, 1, 2, 3 places in the several columns. Immediately before the lines B we learn that when $x = 120$, ϕx, $\phi' x$, and $\frac{1}{2}\phi'' x$ are severally 15505343·181, 388046·169, and 3236·859. We then write down these results without any commas, and proceed with the second 1 in 121, from which we find that when $x = 121$, the functions are 15896635·209, 394546·887, and 3263·859. We then begin to provide for the decimal point, hy annexing one, two, and three ciphers to the working columns, and taking the second 2 in 121·23 to work with, and applying Horner's process, we find, when $x = 121{\cdot}2$, that ϕx, $\phi' x$, and $\frac{1}{2}\phi'' x$, are severally (remembering that all the annexed ciphers are so many additional decimal places) 15975675·212760, 395853·51060, and 3269·2590. Finally, we annex the ciphers again, and with the 3 we find that $x = 121{\cdot}23$ gives 15987553·760654100, 396049·6904400, and 3280·06900.

Let us now compare the trouhle of this process with that of any other method of doing the same. If we throw out all the figures which we have written twice over merely for explanation, and also the last two and one lines in the second and third columns, which are only wanted to go on further with, we have written down about 280 figures. The ordinary verification costs about 340 figures. It is true that every step is both a multiplication and an addition in one: but this can be done and ought to be done in the use of this method, and is not done in the ordinary method. And we have not only the advantage of a purely mechanical method, in which the first arrangement causes the succeeding steps to require nothing except a look at the successive figures of the value, hut the still greater advantage of being able, at the end of the process, to make any small alteration of value with ease. If, for instance, having discovered that 121·297 would do better than 121·23, we wish to get additional accuracy, we have but to ruh out the last 3-process, and proceed with 9 and 7. In the ordinary mode, we must either repeat the whole process again, or correct approximately by substituting 121·23 − ·003, which will reqnire us to calculate $\phi' x$, and perhaps $\frac{1}{2}\phi'' x$.

We will now exhibit a common multiplication, and the formation of a square: not, of course, that we attach any particular value to these simple cases, but that we may show the uniformity of the process. Required 14796 × 32316, or the value of $14796x + 0$ when $x = 32316$. We repeat the lines as before, which is more than is necessary, and makes this process look very long.

	55892	

The process here described is one which, we venture to say positively, has neither been put in its right place, nor received its due reward. It is the natural extension of the common process of multiplication, and its inversion is as naturally and necessarily the proper mode of solving equations, as that of multiplication is the same for the simple equation $ax = b$, or common division. The inventor of it must rank, not with the analyst or the algebraist, commonly so called, hut with the discoverer of the process of multiplication and division, and the extraction of the square root.

The application of this method to the solution of $\phi x = 0$ consists in finding the first figure hy trial, and making use of the Newtonian approximation to find successive figures; namely, that if a be nearly a value of x, $a - \phi a : \phi' a$ is more nearly so. This method becomes difficult when two roots are nearly equal; hut the difficulty lies in what may be called Newton's part of the complete method, not in Horner's part. When the difficulty of algehra shall he conquered, the process of arithmetic may easily be amended in the *trial part;* but to suppose that a capital improvement in the manner of conducting computations is little worth, because it is not accompanied hy a victory over difficulties of quite another kind, is as unreasonable as to quarrel with a calculating-machine because it is not an inventing-machine. This much can be said, that, with a little more trial, Horner's method may be applied to the case of nearly equal roots; and that, as it is, it is more efficacious in discovering them than any other method.

To what is said in INVOLUTION and EVOLUTION, P. C., we may add the following remarks:—1. When the last term is positive, and would in the ordinary process be made negative, it is better, instead of changing the sign of the last coefficient only, to change the sign of all but the last. Thus in solving $x^3-11x+1=0$, the heads of the columns should be -1, 0, 11, and 1, instead of 1, 0, -11, and -1. Also, that if at any period of the process the divisor and dividend columns should become negative, the signs of all should be immediately changed.

2. In making the contractions, it will be advisable to make the figure which comes next after the separating line correct, to continue it, in fact, till the next contraction, and to use it to carry from. This is not done in our main article (P. C.), but it is done in the instance in COMPUTATION, P. C. S. In that instance, the following figures, seen one over the other in the last column but one, as follows 3, 5, 7 — 6, 9, 1, — 2, 2, 2, are figures cut off by the contraction, but made up from the second column to carry from into the fourth.

3. If, at the beginning of the process, all the beads of the columns be multiplied by 9, the root will not be altered, and, until the contraction begins, the verification by casting out nines is rendered easy, since every result in every column is divisible by 9.

We shall now show how the process works in some equations which have equal, and nearly equal, roots.

Let $x^4-6x^2+9=0$, which has two roots, each equal to $\sqrt{3}$.

−1	0	6	0	9 (1·7320
	−1	5	5	40000
	−2	3	8000	1210000
	−3	000	5697	5041
	−40	−329	748000	3
	−47	−707	401653	
	−54	−113400	49132	
	−61	−115449	25190	
	−680	−117507	1220	
	−683	−119574		
	−686	−11971		
	−689	−11985		
	−692	−11999		

The existence of equal roots, or of nearly equal roots, might be here suspected from the slow increase of the divisor column; but the method could not verify the fact of their being two absolutely equal roots. The column preceding the divisor column being large and negative, requires us to make trial of figures above, not below, those which the divisor column seems to indicate. But nearly equal roots may sometimes be detected, as in the following instance. Let $7x^3-10x^2-14x+20=0$, of which it is known that ono root lies between 1 and 2. The ordinary process gives

−7	10	14	20 (1·41421356
	3	17	3000
	−4	1300	8000
	−110	748	1547000
	−138	8400	61608
	−166	6453	3859
	−1940	449900	1013
	−1947	371348	160
	−1954	292684	18
	−19610	288745	1
	−19638	284806	
	−19666	28460	
	−19694	28440	

Tbis root may be carried on without difficulty. But at the end of the second process, when tbe dividend is reduced to 8000, the divisor only 8400, and the preceding column as much as -1940, it may be worth whilc to try another figure. This state of things gives a suspicion tbat there is another root in the immediate vicinity of the one in hand. If the three last columns be $+a$, b, and c, and if wo find that $pa+b$ is nearly $c\div p$, whicb is tbe trial test of p being a new figure of the root, we are sure that $(p+1)\,a+b$ will not be near $c\div(p+1)$: and moreover $p\,(pa+b)=c$ has not two positive roots. But if the three last columns be $-a$, b, and c, it may very easily bappen that $b-pa$ may be nearly $c\div p$, and $b-qa$ nearly $c\div q$; for $p\,(b-pa)=c$ has two positive roots. Perfect certainty, in the absence of an easy algebraical criterion, may only be attainable by trying every figure. In the instance before us, finding 1·41 succeed, with a presumption of a larger root, we try 1·43, beginning with

−7	−1940	8400	8000
	−1961	2517	449
	−1982	−3429	
	−2003		

Tbis figure will not do, for now a permanent difference of sign is established between the dividend and divisor columns. We then try 2, as follows:—

−7	−1940	8400	8000
	−1954	4492	−984
	−1968	556	
	−1982		

There is now a difference of sign between the two last columns, but, looking at tbe second column, we see that agreement may be restored by the next figure. The figure 8 will do it, as follows:—

−7	−19820	55600	−984000
	−19876	−103408	−156736
	−19932	−262864	
	−19988		

and 26286400 is not contained 10 times in 156736000. All the signs being now negative, we may chsnge them all. If we had tried 7 instead of 8, we should bave had

−7	−19820	55600	−984000
	−19869	−83483	−399619
	−19918	−222909	
	−19967		

But now 22290900 is contained more than 10 times in 399619000, which shows that 7 is not high enongh. If we try 9, we have

−7	−19820	55600	−984000
	−19883	−123347	+126123

and a permanent difference of sign is establisbed between tho two last columns, whence 9 is too high. Proceed then with

7 199880 26286400 156736000 (1·428

and we find 1·42857142857 ... for a root. Tbe reader msy watch tbe operation in the following equation:

$$2430x^3-8667x^2+10293x-4070=0$$

the roots of which are 1·111 ..., 1·222..., and 1·233 ...

Whatever common figures two roots of $\phi x=0$ may have begun with, there must be a root of $\phi' x=0$ wbich begins with these figures. And whatever common figures three roots may begin with, there must be two roots of $\phi' x=0$, and one root of $\phi'' x=0$ which begin with those figures: and so on. If tbere were a difficult equation having three roots nearly equal, no method of detecting them would be easier, of all those known at present, than solving contemporaneously the tbree equations $\phi x=0$, $\phi' x=0$, $\phi'' x=0$, not making any step in one till all had been brought np; that is, one step of each first, then the second of each, and so on.

It may happen that a finite root is establisbed, and yet that the process must be continued to obtain another root beginning with the same figures. For example,

$$9x^3-46x^2+75x-38=0$$

It will be seen in the following process that 2 is a root, with a presumption, from the appearance of the divisor column and thc one beforo it, that there is another root beginning with 2. And by trial 2·1111 ... is found to succeed.

9	−46	75	38 (2·11111

	1088	11087	
	1097		

We shall now proceed to a snort account of the bistory of tbis problem, and of the controversies which have existed, and to some extent still exist. For a fuller account of it up to the time of Mr. Horner, see an article in the 'Companion to the Almanac' for 1839.

Before the time of Vieta, evolution consisted in the rules for the performance of division, and extraction of the square and cube roots, in forms probably derived from the East. To him [VIETA, P. C., p. 315] we owe the first publication of a numerical method of finding the successive figures of the root of an algebraical equation by means of the value of the function equated to zero in the equation. This method of Vieta is in fact that which Horner's process now makes so easily practicable. If $\phi x=0$ be the equation, and a a part of the root, it uses ϕa, and $\phi\,(a+1)-\phi a$ as a divisor. The process is so cumbersome, that Vieta does not attempt to apply it to equations having more than two figures in the root.

This method attracted but little attention on the continent:

but in England, where everything relating to numerical calculation has been always diligently studied, it was much noticed, and received extensions of power. In the posthumous work (1631) of Harriot [Harriot, P. C.] examples of it are given with the improvement of forming only so many figures of the divisor as are wanted: and he ventures upon roots of three places. In the second edition of Oughtred's 'Clavis Mathematica' (1647) Vieta's method is given without Harriot's improvements. But we did not find till very recently that the first who used Vieta's method to any great extent was Briggs, in the calculation of the sines, &c., in the 'Trigonometria Britannica.' In the preface the method is applied to equations of the third and fifth degree, and partially described for the seventh and higher degrees: with examples carried to fifteen and sixteen figures of the root. It is for the facilitation of these solutions that the *Abacus* παγχρηστος is given, which some have unreasonably interpreted as giving Briggs a claim on the binomial theorem. Gellibrand tells us that Briggs formed his tables of sines by algebraic equations and differences about thirty years before his death. Now Briggs died in 1630, and Vieta's tract appeared in 1600: the former must then have received the work soon, immediately seen the importance of the method, and commenced operations by means of it. We cannot give Briggs any independent title to the invention; for it is likely enough that he was in correspondence with Vieta, whose works he certainly knew. One of his examples is the solution of what would now be written

$$x^3-3x=1{\cdot}298896096660366$$

for which he gets $x=1{\cdot}917639469736386$. He puts down the work as far as... 697, proceeding towards the end by several figures at a time: and he has got what Vieta had not, the Newtonian divisor $\phi'x$ instead of $\phi(x+1)-\phi x$. Of course it adds materially to the historical value of this method that it was thus used in an operation of so much importance to the progress of mathematics in general. The dates above given may even cause a suspicion that it was the power of solving equations thus suddenly acquired, which first suggested the calculation of the natural sines, &c., in the 'Trigonometria Britannica.'

Wallis, in his Algebra (1684), gives the method of the '*numerose exegesis*,' as he calls it (Vieta had called it *potestatum adfectarum ad exegesin Resolutio*) with an example of the fourth degree worked to seventeen places of the root. He makes use of the method of contracting the figures towards the end. In this same Algebra appeared, for the first time, Newton's method of approximation, which soon superseded the exegesis, into which however it had been virtually incorporated by Briggs. Newton's approximation, at least in the general form which it took in the hands of Taylor, is as follows. If a be a near value of x in $\phi x=0$, then, except when there are two nearly equal roots, a nearer value is

$$a-\frac{\phi a}{\phi' a} \text{ or } a+\frac{-\phi a}{\phi' a}$$

The old exegesis, and especially Briggs's form of it, employs this principle; $-\phi a$ is calculated, and either $\phi' a$ or $\phi(a+1)-\phi a$. Briggs, who proceeds by several figures at a time, and uses $\phi' a$, does really use what was afterwards called Newton's method.

When the exegesis was abandoned by Raphson and others, in favour of Newton's form of operation, no further improvement was made in the direct numerical solution of equations, until the time of Mr. Horner; at least no further improvement was published. Mr. Henry Atkinson, a young man of Newcastle, re-invented the whole method in 1801, applying Newton's divisor, and giving rules by which one divisor was made to help in forming the next. This was read to the Philosophical Society of Newcastle in 1809, and published posthumously, as 'A new Method of extracting the Roots of Equations,' Newcastle, 1831, 4to. In our article in the 'Companion to the Almanac,' already cited, we have supposed that no one can be shown either to have used $\phi' a$, or to have made each value of it help the next, before Mr. Atkinson: but we now find that Briggs was before him in both points.

Lagrange's method of transforming the root into a continued fraction [Theory of Equations, P. C.] does not need notice here, because it beloogs to another mode of expression. But it ought to be noticed that Horner's process very much abridges the labour of Lagrange's method, as much indeed as it does that of Vieta's exegesis, and for the same reason. Mr. Exley, of Bristol, in the 'Imperial Encyclopædia,' article Arithmetic, improved (according to Horner himself) the common method of extracting the cube root, so as to precede Horner in this particular case. We believe more than one method had been given for reducing the enormous labour of the ordinary extraction of the cube root: we may mention one, which is ingenious and effective, and almost exactly a particular case of Horner's method, given by Mr. A. Ingram, in his edition of Hutton's Arithmetic, Hawick, 1811, 8vo.: and Mr. Horner himself refers to an edition of Melrose's Arithmetic, by Mr. Ingram (the same, we suppose) as containing such a method.

Mr. Horner's paper was read to the Royal Society on the 1st of July, 1819, and was published in the current volume of the Transactions, on the 1st of December. These dates are of importance: the publication of the above paper was the signal for more than one person to make a nibbling claim to the invention. Mr. Horner was unfortunate in two points. First, he had not sufficient knowledge of antient algebra to be aware that his method contained the process of Vieta, and that his real claim consisted in the discovery of the beautiful process by which the labour is immensely reduced, and completely systematized. Secondly, he appears to desire to be the analyst rather than the arithmetician, and will not show anything except to those who can take all. It is true, beyond a doubt, that his method is adapted to every sort of equation, and that it is as great a help to the person who desires to solve $\tan x-ax=0$, or $\varepsilon^{\sin x}=x$, as to the other who wants nothing but a common algebraical equation. So far, then, it is more than Vieta's method simplified; it is the same also extended. But if the inventor had proceeded from simple algebra to the more complicated cases, his merits would have been more rapidly appreciated. He did not well see that his mode of solution applies as well to the integer part of the root as to the fractional; nor did he fully comprehend how much of his own discovery consisted in the general mode of calculating the value of ϕx, as given at the beginning of this article. But that we may not do him injustice, and still more that we may enable those of our readers who have not access to the original paper to see how completely he had got hold even of the most convenient arithmetical process, we give his solution of the famous Newtonian instance $x^3-2x=5$. After reducing the root by 2, the heads of his columns are 1, 6, 10, and 1 (the first column, which is always vacant, he does not set down). He then annexes either dots or ciphers, and proceeds exactly as follows

```
  6..          10....              1000000(·0945514815

```

As soon as Mr. Horner's paper had been published six months appeared 'A new Method of Solviog Equations,' by Theophilus Holdred, London, 1820, (preface dated June 1,) 4to. The method is taken from Harriot; and a supplement is added, which gives Horner's method. Both are claimed as independent inventions, and Horner's name is not mentioned. Mr. Holdred asserts that, after having had his method for forty years, he was led to that in the supplement* by a mistake he committed in solving an equation sent him by one of his subscribers. We have given, in the article of the 'Companion to the Almanac,' already cited, our reasons for coming

* We cannot but believe that Mr. Holdred did see Mr. Horner's paper. Had he mentioned it, and the name of the subscriber, his equation, the mistake made, &c., &c., distinctly declaring when and where he first saw Horner' paper, he might have possibly established a claim to be a second inventor.

to the conclusion that Mr. Holdred took his first method from Harriot, and his second from Horner.

A claim was made by Mr. Peter Nicholson in various places, which is quite futile. We acquit Mr. Nicholson (a highly respectable man, eminent in the application of mathematics to the arts) of all unfair intention: and we must remind our readers of a point without the knowledge of which the various controversial writings on this subject will be full of confusion. Hardly any one knew of Vieta's Exegesis, which there is little doubt that both Horner and Atkinson reinvented. In fact, so completely had this exegesis dropped out of sight, that even Dr. Peacock, in his short account of Horner's method ('Report on Analysis to the British Association') does not allude to it. Accordingly, all the re-inventors of Vieta's method speak of quite new rules discovered for the solution of equations, and treat Horner's process as a constituent part of one of the new inventions. But a person acquainted with the history of the subject finds nothing new except Horner's process. Vieta had the main system, Briggs had the Newtonian divisor, Wallis had the method of contraction, Briggs had *a* method of making one divisor help the rest: Horner had *the* method which must finally be adopted. Budan, as we shall see, had only a particular case of that method, and did not apply it to any mechanical process of numerical solution.

Mr. Nicholson claims Horner's identical process, and fairly refers to the very place in which he says it is to be found. But on looking there (see the article already cited in the 'Companion to the Almanac'), we find that he has been deceived by a distant resemblance, and that, though he has given a new and useful process for a useful purpose, neither the process nor the purpose is Horner's. At the same time it is but justice to Mr. Nicholson to say, that in his 'Elements of Algebra,' London, 1819,* 12mo, he made as near an approach to Horner's method as could well be done, and applied it in the case of equations of the second and third degrees. The succession of columns is seen, each column helps the next, and each step in any one column helps the next step. But the grand simplification, which the controversialists called the 'non-figurate method,' is wanting: so that this process of Nicholson's is perhaps hardly more than Briggs was in possession of. Mr. Nicholson had received Mr. Holdred's method, whose name he properly mentions in the preface. This method he had greatly improved; and it seems he wished that Holdred should publish his amended methods; but he asserts (in the preface to his work on Involution and Evolution) that the latter refused, alleging that his own credit would be diminished, unless he could pass them as his own.

Dr. Peacock had never seen Holdred's tract, and his result, derived from the assertions of Mr. Nicholson and from Horner's paper, is that Nicholson, by a combination of the methods of Holdred and Horner, reduced the method to its present practicable form. But any one who will solve $x^3-2x=5$ in the systematic form we have given, will see that Horner had that form. Nicholson was, we believe, the one who first clearly saw that the method, in its simplest organization, applies as well to the integer as to the fractional portion of a root. All Mr. Nicholson's simplifications, as given in his latest writings, consist in doing in the head some of the things which Horner put down on paper. The form we give carries this still further; and those who can do what we have recommended all arithmeticians to practise in COMPUTATION, P.C.S. can follow us: but there is no invention in this.

Some have been disposed to give a good deal of the merit of this system to Budan; and his claim must be considered. Two editions of the 'Nouvelle Méthode pour la Résolution des Equations numériques,' Paris, 4to., were published in 1807 and 1822. The basis of M. Budan's operations is the simple case of Horner's process in which the root of an equation is diminished by unity. This is done exactly in the mode by which Horner afterwards proceeded. Thus to lessen the root of $x^3-2x-5=0$ by unity, Budan proceeds thus:—

$$
\text{(A)}\quad
\begin{array}{l}
1+0-2-5\\
1+1-1-6\\
1+2+1\\
1+3\\
1
\end{array}
$$

Answer $x^3+3x^2+x-6=0$

But to lessen the root by 2, Budan is never able to arrive at the process on the left, which is Horner's: he must repeat the process of diminishing the last root by one, as on the right.

$$
\text{(B)}\quad
\begin{array}{l}
1+0-2-5\\
1+2+2-1\\
1+4+10\\
1+6\\
1
\end{array}
\qquad\Bigg|\qquad
\begin{array}{l}
1+3+1-6\\
1+4+5-1\\
1+5+10\\
1+6\\
1
\end{array}
\quad\text{(C)}
$$

Accordingly Budan has both (A) and (C) to do, where Horner has only (B). To diminish a root by 3, Budan has three processes, and so on. To diminish a root by 10, 20, &c., he divides the roots of the original equation by 10, then diminishes by 1, by 1 more, &c., and then multiplies the resulting roots by 10; and similarly for 100, &c. It is obviously possible, by a large amount of calculation, to obtain the root of an equation in this manner; but Budan is not only obliged to call in other methods, and even thus to spend very great labour, but he ends by presenting the root in the form of a sum of common fractions, each of which must be reduced to a decimal. Thus for $x^3-2x=5$, he gets

$$x=2+\frac{1}{11}+\frac{1}{275}+\frac{1}{165925}=2\cdot094551481364$$

Budan's method is not then even of the same species* as Horner's. In an appendix added to the edition of 1822, two years after Horner's paper, there is the method extended to the process for diminishing the root by n (Horner's process), but no use is made of it, and singularly enough the only example given is one in which n is -1.

Mr. Horner ('Leybourn's Repository,' page 38, of part ii., vol. v.) denies ever having seen Budan's work until 1818, after his method was finished. This, in one point of view, counts for nothing; for every discoverer has a right to have it supposed that those who come after him have used his works: that is to say, he would have a right to the credit therefrom arising, even though it could be shown that subsequent discoveries were made without his aid. If a partial or unfinished method turn out to have a value of quite a new character when made complete, it is impossible to deny to its author the credit of having been further than his contemporaries on the road towards the complete method: consequently, Budan must have, in one sense, the merit of having proposed a particular case of that which Horner afterwards used. But, as it happens, a contemporary of Mr. Horner, in trying to insinuate that he had taken his method from Budan, has furnished independent evidence to the contrary. Mr. Nicholson, in a note to the preface (page ix.) of his essay 'On Involution and Evolution' states: "I am informed by Mr. Dickson that about twelve months ago he (Horner) purchased at his shop, in St. Martin's-le-Grand, an 'Essay on the Numerical Solution of Equations,' by Budan; at which time he mentioned that he was engaged expressly on this subject." This called forth the preceding statement from Mr. Horner, who, had he had any unfair intention, and had he really been indebted to Budan, would have argued from the date of Mr. Nicholson's preface that he must have bought Budan only just time enough to insert the note about him in his paper before he sent it to the Royal Society. Instead of this, he answers in the most straightforward manner, that he bought Budan about July, 1818, nearly *two* years before Mr. Nicholson wrote; but avers that his method was then finished. And this we entirely believe; and also that it would have been impossible for him, fully engaged as he was in teaching a school, to have produced his method, so as to send it to the Royal Society in the spring of 1819, if he had only seen the first hint in the summer of 1818. But had he seen Budan's work, and had he thence derived the hint which he improved, his merit would not have been the less: Lagrange, the greatest writer on equations then existing, had seen it, Legendre had seen it: and both had closely examined it, and reported to the Institute upon it. The members of the Institute had seen it. Lagrange, too, knew of Vieta's Exegesis. But no one,

* The preface is dated May 17, 1819, and the publication took place early in July, Mr. Horner's paper having been publicly read at the Royal Society on the first of that month.

* He recommends that when more than *two* or *three* decimals of a root are wanted, the work should be turned over to *workmen* (*manœuvriers*) who are to be a distinct class from the mathematicians. The best comment on this will be to insert in this little foot note every figure of the work for *six* places of the equation on which this remark was made with a guess at the *seventh*.

except the Bath schoolmaster, ever brought forward Budan's method, or any extension of it, either from Budan, or independently, to the improvement of Vieta. Fourier had seen Budan's book, and had invented a method of his own of solving equations; or rather had given his own mode of conducting Newton's approximation; but this method is far below that of Horner.

We have written so much on the discovery of this method, because unfair attempts were made by claimants who had no title whatever to deprive the author, who was a man of real genius, of his rights over his own discovery. We refer to MM. Holdred and Nicholson: though we do not believe the second was knowingly unfair. Mr. Atkinson, when he first saw the 'non-figurate method,' (as some called the subject of this paper,) saw and said that it was a 'capital improvement.' We have written also because it can hardly yet be said that mathematicians are alive to the value of this grand completion of the system of arithmetic. The continental writers show no knowledge of it; the Oxford and Cambridge elementary works do not yet recognise its existence. The fact is, that mathematicians dislike calculation, and are apt to form hasty opinions on numerical methods before they have given them sufficient trial. The first elementary writer who brought Horner's method into instruction was Mr. (now Professor) Young, in his 'Elements of Algebra,' published in 1823.

In 1831, eleven years after this method was published, appeared Fourier's posthumous work on equations, containing an extended use of Newton's method. It amounts to employing ϕa, $\phi' a.h$, $\frac{1}{2}\phi'' a.h^2$, &c., to calculate the value of $\phi\,(a+h)$, and $\phi' a$, $\phi'' a.h$, &c., *separately*, to calculate $\phi'\,(a+h)$; and so on. Fourier was an expert arithmetician, and in this very work shows his power of suggesting new forms of arithmetical process; but he does not come near anything like making the previous calculation of $\phi^{(n)}\,(a+h)$ give assistance to that of $\phi^{(n-1)}(a+h)$. The equation $x^3-2x=5$, which Wallis happened to take as his instance of Newton's method, has always been the example on which numerical solvers have shown their power. No one can be said to have carried a method beyond those which preceded, unless he has solved this equation to more places than they have done. Fourier went to thirty-two decimal places, which we do not know that any one had done before. Some students of University College, London, (and one of King's College) none exceeding eighteen years of age, carried Horner's process further still, their independent calculations giving, as the root to 52 figures;—

2·09455,14815,42326,59148,23865,40579,30296,38573, 06105,62824,2

Mr. Nicholson gives, as the work of a young computer, the following solution of

$$4x^6+7x^5+9x^4+6x^3+5x^2+3x=792$$

$$x=2{\cdot}05204,21768,79605,36521,40434,01281,20197,34602, 75599,54554,17242,14$$

We have left entirely out of sight all the irrelevant controversy relating to the method of finding the limits of the roots, conducting the process when two roots are nearly equal, and so on. The claims of Budan, Fourier, Horner, &c., are here mixed up in a manner which requires a sifting investigation. Very frequently the value of Horner's method is stated as depending upon points of this kind. When any of the doubtful cases arise, which we noticed at the beginning of this article, we find, for ourselves, that the ease with which repeated trials are made by Horner's process gives us more command of these questions than anything else; in fact Fourier's theorem [STURM'S THEOREM, P. C.] is very easily brought to bear by means of it. But it must be admitted, that all methods which in any way include the Newtonian approximation are imperfect, when roots are nearly equal, in not having a better addition to the root a already obtained than $-\phi a:\phi' a$. Let a better method come, and we have no doubt that Horner's process is more ready to make easy use of it than any other. A student who is very slow at finding out the trial figures of common division, might as reasonably depreciate the rule of division altogether, as quarrel with Horner's method because there is now and then a difficulty in ascertaining whether or no more than one figure will do to proceed with. The same difficulty must exist in every method, as matters now stand. In the meanwhile, we think the discoverer of the process, which is now beginning to take its proper place, deserves attention to his request when he says, speaking of the antagonist claims which had started up—"All I ask of them [mathematicians] in recompense for the facilities consigned to their use in the non-figurate method, is to bear in mind that I alone am the author of it." And we have no doubt whatever, and are willing to stake our credit upon it, that when the inertia of the higher mathematicians in matters of computation is overcome, and when the mode of solving equations has reached the schoolboys, as it is rapidly doing, the name of Horner will be one of the household words of pure arithmetic, and himself looked upon as one of the greatest of its modern benefactors. Justice requires that his name should remain attached to his process.

INWOOD, the family name of three architects, father and two sons, who constructed many public and private buildings in London and elsewhere.

WILLIAM INWOOD was born about the year 1771. His father, Daniel Inwood, was bailiff to Lord Mansfield, at Caen Wood, Highgate, near London. William Inwood was brought up to the professions of architect and surveyor. He was employed as steward to Lord Colchester, was surveyor to a large number of persons, and several architects now living were instructed by him. He had two sons, one or other of whom was employed conjointly with himself in most of his larger works of architecture, and he was assisted generally in all his professional pursuits by both. He died March 16, 1843, aged about seventy-two. He was the author of 'Tables for the Purchasing of Estates, Freehold, Copyhold, or Leasehold; Annuities, and for the Renewing of Leases held under Cathedral Churches, Colleges, or other corporate Bodies, for Terms of Years certain and for Lives, &c.,' London, 1811, 8vo., a work founded on those of Baily and Smart. It principally differs from previous works in giving the values to years and quarters, as well as to decimals of a year; the former being intended for those who cannot read decimal fractions.

HENRY WILLIAM INWOOD, the eldest son of William Inwood, was born May 22, 1794. He was brought up by his father to his own professions. He was several years in Greece, and examined with great care the architectural remains at Athens and elsewhere, and made plans and drawings of them. He assisted his father in most of his architectural pursuits, especially in designing and constructing St. Pancras Church, and had he not suffered so much as he did for many years from ill health, would probably have attained to great eminence as an architect. His death is supposed to have occurred March 20, 1843, about which time a ship in which he had sailed for Spain was wrecked, and all on board perished.

Henry Inwood published in 1827 'The Erectheion at Athens, Fragments of Athenian Architecture, &c., illustrated with Thirty-nine Plates.' The work, which consists of 162 pages exclusive of the plates (engraved by Nicholson), is printed on elephant paper of very large size, and was published by subscription. He had also commenced a work entitled 'Of the Resources of Design in the Architecture of Greece, Egypt, and other Countries, obtained by the Studies of the Architects of those Countries from Nature,' 4to. London, 1834, with explanatory engravings. Two parts were published, but owing to ill health and his untimely death the work was never completed. He collected many fossils and remains of antient art, most of which are now in the British Museum.

CHARLES FREDERIC INWOOD, second son of William Inwood, born November 28, 1798, besides assisting his father in his works, was the architect of the church of All Saints at Great Marlow, in Buckinghamshire, which was completed in 1835. He also built the St. Pancras National School, in Southampton Street, Euston Square, a large plain brick building of little architectural pretension. He died in May, 1840, aged forty-two.

St. Pancras Church, New Road, London, which was the conjoint work of William Inwood and his son Henry, is in its kind and in its peculiar beauties unique among the churches of the metropolis. The building was commenced July 1, 1819, was completed May 7, 1822, and cost 76,769*l*. The exterior of the body of the church is, with certain necessary deviations, an imitation of the Ionic temple called the Erectheion on the Acropolis at Athens [ERECTHEION, P. C.]; the tower is an adaptation from the building commonly called the Tower of the Winds, also at Athens, which is properly the Horologium, or water-clock, of Andronicus Cyrrhestes. The measurements and drawings of these buildings were made by Henry Inwood on the spot. The semicircular apsis at the east end of the church supplies the place of the straight west wall of the Pandrosion, or temple of Pandrosos, which adjoined the Erectheion at the west end. The two covered buildings which project from each side of the east end, forming the entrances to the catacombs of the church, are adaptations from the south portico of the Pandrosion. The caryatid figures, of which there were six, four in front and one at each side, were in the place of columns, and supported the pediment of the south portico of the Pandrosion; the opposite north portico had columns. There is one of the original caryatid figures in the Elgin Room of the British Museum. The sarcophagus beneath each roof indicates the purpose for which the projecting buildings have been constructed. The two Ionic half columns engaged in the walls on both sides of the west end are additions made to form an apparent basis for the tower. The windows are adaptations modelled in accordance with the form of the doors. Grecian temples had no windows; large temples had a central portion of the roof open to the sky; small temples generally received light only from the door, which was wide and lofty. The octagonal tower, with its two ranges of eight columns each, in its form and general effect, combines well with the building and portico, and is in itself an object of peculiar beauty. In the interior the galleries are supported by very elegant slender columns. The ceiling is flat, and formed into a number of ornamented pannels. The general effect of the interior is good, though rather deficient in light, especially below the galleries, from the small size of the windows.

The Westminster Hospital, near the west end of Westminster Abbey, was built by William Inwood in conjunction with his son Charles. It was begun in 1832, completed in 1834, and cost 27,500*l*. The architecture is Tudor Gothic, the material is gray Suffolk brick, with stone facings. It is quite plain except the front and the truncated angles which connect the front with the two ends. The front extends about 200 feet in length, and is 72 feet high in the centre, which projects slightly and is a story higher than the two wings. The entrance is by a flight of stairs beneath a large stone porch constructed in three divisions with flat pointed arches, enriched pinnacles, and other appropriate ornaments. Above the porch is an oriel window which extends to the height of the two upper stories; and at each of the truncated angles is an oriel window similar to the one over the porch. The flat windows are deeply indented, and are divided into four equal compartments by a mullion and transom, but the two upper compartments are distinguished from the two lower by trefoil tracery at the tops, and each window is surmounted by a weather-moulding. There are in all 260 windows. The brick harmonizes well with the stone portico and dressings, and the general appearance of the front is very handsome. Perhaps the battlemented parapet may be objected to as inappropriate to the purposes of the building, and as less handsome than a parapet of open-work would have been, similar, for instance, to that of Westminster Abbey in the part which has been renewed, where such a pierced parapet occupies the place of the old battlement. The interior arrangements and ventilation are excellent. There are 19 wards and about 250 beds.

William Inwood also built the Regent Square Chapel, opened in 1826; the Camden Town Chapel, opened in 1824; and Somers Chapel, in Seymour Street, opened in 1826, all of which are chapels of ease to St. Pancras Church. He also built numerous other structures, mansions, villas, barracks, warehouses, &c.

(*Written Communication*; *Companion to the Almanac*; Knight's *London*; 'Elgin Marbles,' in *Library of Entertaining Knowledge*.)

IOWA, a territory of the United States of North America, is bounded on the west by the Missouri river and the White Rock river; on the east, by the Mississippi and a line drawn direct north from the sources of the Mississippi to the Lake of the Woods; on the north, by the parallel of 49° N. lat., which separates it from the British possessions; on the south, by the parallel of 40° 35′ N. lat., which separates it from the State of Missouri. The area has been estimated at 200,000 square miles, which is nearly four times the area of England, exclusive of Wales.

Of the northern part of the territory a very large portion is occupied by a vast extent of high ground, called the Coteau des Prairies, which commences about 48° N. lat., and terminates about 43° N. lat., extending in width more than fifty miles between 98° W. long., and 99° W. long. This huge mass, which is said to rise more than 1000 feet above the surrounding country, has generally a rounded surface, with few irregularities, and is for the most part destitute of trees. East of the Coteau des Prairies is an extensive valley, in which the Red River runs northward to Lake Winnipeg, and the St. Peter's River south-east and then north-east to the Mississippi. West of Coteau des Prairies is a broad valley of prairie land traversed by the James River, and this valley is separated from the Missouri by a high range of ground similar to the Coteau des Prairies. The upper parts of both of these great river-valleys have been estimated to be more than 1000 feet above the level of the sea. The rest of the country between the Mississippi and the Missouri contains no mountains nor even hills of large size, but consists of rounded sweeps with broad valleys in which rivers flow, the upland tracts being connected with the valleys by gentle slopes. Belts of forest occur near the rivers, especially contiguous to the Mississippi and the Missouri, but the rest of the country either consists of prairies or is covered with brushwood. The south-east part of the territory, which is the only part in which the settlers are numerous, and where the lands have been sold by the federal government, is generally undulating, interspersed with timber-lands and prairies, and abounding in springs and streams. This tract, which is very fertile, extends from the Des Moines River south to the Turkey River north, and westward from the Mississippi fifty or sixty miles to the Indian boundary.

In Iowa there are numerous rivers, which rising in the elevated grounds of the northern parts of the territory, flow respectively eastward into the Mississippi, westward and southward into the Missouri, and northward into the British possessions. Those which flow into the Missouri are comparatively small, except the James River, which has a course southwards of upwards of 400 miles, and falls into the Missouri where that river flows to the east some distance below Grand Detour. Of the rivers which fall into the Mississippi, one of the largest is the Des Moines River, which is navigable for 300 miles from its mouth at the south-eastern extremity of the territory. Next in size is the St. Peter's River with its numerous tributaries, which rises in the Big-Stone Lake, flows about 300 miles south-east, then about 200 miles north-east, and falls into the Mississippi a little below the Falls of St. Anthony; its course is very winding, so that if measured in a straight line, its length perhaps does not exceed 300 miles. The Skunk River, the Lower Iowa, with its affluent the Cedar River, the Wabepisipimecon River, the Great Macquoquetois River, the Turkey River, and the Upper Iowa, are also rivers of large size. Of the rivers which flow northward the Red River is the largest; it rises in the same valley as the St. Peter's River, in Lake Travers, which is near the Big-Stone Lake, and has a course of from 300 to 400 miles northward before it enters the British possessions, through which it flows to Lake Winnipeg. In the most northern and north-eastern part of the territory, though the elevation above the sea is not much less perhaps than 1000 feet, the country is flat and swampy, and there are numerous lakes. There is a lead-mine district in the south-eastern part of the territory, and considerable quantities of the metal are obtained.

There are no towns yet of sufficient size to require description; the largest are Burlington, Bloomington, Iowa city, Du Buque, and Fort Madison. There is a newspaper published at Burlington. Iowa, the capital, is in 41° 28′ N. lat. and 13° 45′ W. long. from Washington.

Iowa was constituted a territory by an Act of Congress, dated June, 1838, and the government commenced July 4, 1838. It was then divided into sixteen counties, and the population, according to the census, was 22,859; in 1840 the population was 43,112; in 1844, it had become 81,920, a rapidity of increase probably exceeding that of any other state or territory in the Union.

The legislative power is vested in a governor, a council of 13 members elected for two years, and a house of representatives consisting of 26 members elected annually. The governor's salary is 2,500 dollars a year, and there is a secretary who receives 1,200 dollars a year. The members have three dollars a day, and three dollars for every twenty miles of travelling. There are three judges, who are appointed for four years, and who each receive 1,800 dollars a year; the territory is divided into three judicial districts, in which the judges perform circuit duties; the supreme court, composed of all the judges, meets annually in July at Iowa city. Congress voted 20,000 dollars for the erection of public buildings at the seat of government, for which Burlington was first chosen, but it has been since fixed at Iowa city, where the legislative assembly meets annually on the 1st of December. Congress voted also 5000 dollars towards the purchase of a territorial library. The territory sends one member to the House of Representatives.

On the 5th of April, 1844, the people of Iowa passed a vote, by a majority of 2,400, for forming the Territory into a State, which they were entitled to do when the population reached 60,000. A convention met in October, formed a constitution, afterwards submitted it to Congress, and claimed to be admitted into the Union as a State. A law was passed by Congress for that purpose, March 3, 1845, which fixed the boundaries of the State thus:—From the mouth of tho Des Moines River to a parallel of latitude passing through the mouth of the Munkato, or Blue-Earth River; thence west along this parallel of latitude to where it is intersected by a meridian line 17° 30′ W. from Washington; thence due south to the northern boundary-line of the State of Missouri; thence east along that boundary to where it intersects the Des Moines River. The Blue-Earth River falls into the St. Peter's River near the point where the St. Peter's changes its course from south-east to north-east. The boundaries fixed by Congress not only very greatly reduced tho size of the Territory, as was expected, but differed so materially from the boundaries proposed by the convention, that the people of Iowa refused to be formed into a State on the conditions laid down in the Act of Congress, and Iowa therefore remains still a Territory.

The quantity of public lands sold in Iowa from 1838 to 1844 (but including only the two first quarters of the latter year) was 1,462,624 acres, which produced to the public treasury of the United States 1,829,426 dollars, which is rather more than a dollar and a quarter per acre. There are still a great number of squatters.

The inhabitants of the Territory of Florida had applied for admission to the Union as a State, in January, 1839, but the application was not granted till March 3, 1845, when it was constituted a state by the same Act which would have admitted Iowa. Florida made no objection to the terms of admission, and is therefore now one of the United States of North America. A sketch of the new constitution of Florida and other particulars is given under UNITED STATES OF NORTH AMERICA, P. C. S.

(American Almanacs, 1839 and 1846; Buckingham's *America (Eastern and Western States)*, vol. iii.; *Geography of America*, published by the Useful Knowledge Society; Flint's *History and Geography of the Western States.*)

IRIS, a genus of plants the type of the natural order Iridaceæ. It has a tubular perianth with a petaloid membranous limb, the segments of the sepals revolute, often bearded, those of the petals erect and converging; three stamens, concealed beneath the lobes of the style; the style 3-parted near the upper end with petaloid segments overarching the anthers and bearing a two-lipped transverse stigma below their ends; the capsule 3-celled, bursting through the cells into three valves, coriaceous, with numerous flat or round and fleshy seeds.

I. versicolor, Blue Flag, has sword-shaped striated leaves sheathing at the base, a stem two or three feet high, round on one side and acute on the other, and bearing from two to six flowers. This plant is a native of swamps and wet meadows in the United States. The rootstock has a nauseous acrid taste. It acts as a cathartic, and its action is attended with great depression of the nervous system and prostration of strength. It also acts upon the kidneys, and is useful in cases where diuretics are indicated.

I. pseud-acorus, Yellow Flag, has sword-shaped leaves; the stem round; perianth beardless, its inner segments narrower and shorter than the stigmas. It is a native of wet places in Great Britain, France, Germany, and most countries of Europe. The rootstock is acrid and possesses an emetic and purgative action. The seeds when roasted are said to form a good substitute for coffee.

I. Florentina, Florentine Iris, has broad and somewhat falcate leaves shorter than the stem, the petals two inches long and one inch broad, reflexed at the edge and rather plaited towards the base. The dried rootstock is known in the shops under the name of *orris-root*. The plant is a native of the southern parts of Europe and the islands of the Mediterranean. The rootstock has an aromatic odour and subacrid taste, and is employed as a dentifrice. It enters into the composition of Ruspini's tincture and tooth-powder, and other popular dentifrices. It was at one time used in medicine and admitted into the British Pharmacopœias. The fresh rootstock acts as a purgative, and was also employed as an expectorant in diseases of the chest. When dried and turned into small balls it is used for issue-peas. According to Sibthorp this plant is found in Greece at the present day. It is the ἶρις of Hippocrates (*Morb. Mul.*, 2, 673) and the ἶρις ἰλλυρική of Theophrastus (*Hist. Plant.*, 7, 12).

I. fœtidissima, Stinking Flag, has sword-shaped leaves, the stem compressed, the perianth beardless, its inner segments about as long as the stigmas. This plant is a native of Great Britain and other parts of Europe. It has a peculiar smell, which some have compared to roast beef, but which to others suggests much less pleasant associations. It is the ἶρις ἀγρία of Theophrastus (*Hist. Plant.*, 9, 8) and ξυρίς of Dioscorides (4, 12).

I. tuberosa has tetragonal leaves, the segments of the perianth acute, the roots tuberose. It is not a common plant in Europe, but has been naturalised at Penzance in Cornwall, and near Cork in Ireland.

Many other species of Iris have been described. *I. Germanica* has been used for the same purposes as *I. Florentina*, and they are considered by some botanists as identical. The roots of many of them contain starch, and Pallas says that the roots of *I. dichotoma* are eaten in Siberia. *I. edulis* is eaten by the Hottentots of Africa, where it is called *Oenkjes*. All these species are cultivated in gardens on account of handsome showy flowers.

IRISH MOSS. [CETRARIA ISLANDICA, P. C. S.; SEA WEEDS, P. C.]

IRON BOATS AND SHIPS. [SHIP-BUILDING, P. C., p. 395.]

IRRADIATION denotes, properly, the emission of rays from a luminous object, but tho word is generally used to signify an apparent enlargement of the disc of a celestial body: this enlargement being caused either by a deviation of the rays of light from a rectilinear direction, or by some illusion arising from the action of light on the eye.

When rays of light from points at the surface of an object fall on the retina, there may be produced on the latter an agitation extending within short distances about the points to which the rays in the pencils are made to converge by the humours of the eye: hence there may arise a perception of a fringe or border about a luminous body, and consequently an apparent enlargement of such body. Thus the image of a star, when seen by the eye, appears to be a disc of sensible magnitude, instead of a mere point; which, on account of its remoteness, would be the case if the rays of each pencil produced no effect beyond their mathematical point of convergence: the disc of the sun or of the moon is conceived to be, in like manner, apparently enlarged; and thus, also, tho part of the moon which, when the latter is nearly new, is enlightened by the sun, appears to be a portion of a sphere of greater diameter than the part which is more faintly enlightened by the rays reflected from the earth.

A species of irradiation is caused by the blending together, upon the retina, of the circles of light produced by the pencils which fall upon it either before or after the rays in each have converged to a point; the humours of the eye not permitting that convergence to take place exactly on the membrane. [ENLARGEMENT OF OBJECTS, P. C. S.]

Before the invention of telescopes, the apparent magnitudes of celestial bodies were very erroneously estimated; thus, Tycho Brahe made the diameter of Venus twelve times, and Kepler made it seven times as great as it is now known to be. Telescopes do not entirely remove the cause of such error, but, by diminishing the apparent brightness of the bodies, the error in the estimation of their apparent magnitudes is proportionally diminished. Du Séjour, Lexell, and other astronomers, on comparing the calculated with the observed times ot the contacts of the sun and moon in eclipses of the former, have, in order to produce an agreement between them, found it necessary to diminish tho apparent semidiameters of the luminaries by $3\frac{1}{2}$ minutes each; on account, it is supposed, of the effects of irradiation.

It is a consequence of irradiation, that objects which are in reality of equal magnitudes appear frequently to differ in size according to their colour or to the quantity of light which falls upon them. Sir William Herschel remarked (Phil. Trans., 1783) that when a bright circle was viewed together with a dark one on a bright ground, the latter always appeared smaller than the other; and, in order to correct the erroneous estimate of the magnitudes of the columns about temples when they are seen against a bright ground, it appears that the antients made the thickness of the columns to increase proportionally to the distance between them. The reason assigned for this practice by Vitruvius ('De Architectura,' lib. 3, cap. 2) is that the columns with wide intervals, being more surrounded by the air than those which are closer, appear on that account to be more slender: it must be observed, however, that the perceptions of magnitude depend partly on those of distance; and a contrary effect frequently takes place with objects viewed against the sky when conceived to be more remote than they really are.

ISA'TIS. [WOAD, P. C.]

ISCHY'ODUS, a genus of fossil fishes included in Chimæra by Agassiz.

ISNARDIA, a genus of plants named by Linnæus in memory of M. Antoine Dante Isnard, member of the Academy of Sciences. It belongs to the natural order Onagrarieæ, and has a 4-cleft calyx, 4 petals, 8 stamens, and a filiform style, with a clavate or cruciform stigma. There is one British species of this genus. *I. palustris* has a procumbent rooting glabrous stem, opposite ovate acute leaves, terminating in a petiole axillary solitary sessile flowers, with the petals absent. It is found in pools and marshes in Europe, Siberia, and Persia, and in Sussex in England.

I. alternifolia has an erect branched stem, alternate leaves, rather scabrous on the margins, and hoary beneath. It is a native of Virginia and Carolina, in marshy places, and has oval yellow petals. The root is used as an emetic, and is called Bowman's Root.

None of the species of this genus possess qualities which entitle them to cultivation except in botanical gardens. They may, however, be reared in a hot-bed, and then planted in an open border in a moist situation.

(Don, *Gardener's Dictionary;* Babington, *British Botany.*)

ISOCHROMATIC LINES are those coloured rings which appear when a pencil of polarized light is transmitted along the axis of a crystal, as mica or nitre, and is received in the eye after passing through a plate of tourmaline. If a plate of nitre having its surfaces perpendicular to the axis of the natural prism, and highly polished, be placed between two plates of tourmaline having their axes at right angles to one another, and a lens of short focus be placed so as to transmit the light of the sky through the plates to the eye of the observer, that focus falling a little below the surface of the nitre, the rays of light will be polarized by passing through the first plate of tourmaline, and there will be seen a series of oval rings, about each of two points as poles, forming together figures which may be considered as resembling *lemniscates.*

By the nature of the lemniscate, the rectangle contained by two lines drawn from the poles to any point in the curve is constant; and the curves have received their designation from the circumstance that the tint of any one is represented by the equivalent of such rectangle for that curve: when the light is viewed through plates of nitre of different thicknesses, the tint depends also on the thickness of the plate.

The curves are conceived to exist on the surface of a sphere of which a point in the crystal is the centre; and when the optical axes of the crystal are at a considerable distance from one another, if the curves be projected on a plane, the tint in each curve will depend on the product of the sines of the angles subtended by two lines drawn from the poles to a point in its periphery, and also upon the length of the path described by a ray of light in passing through the crystal.

ISOCRINITES, a genus of Crinoidea (Goldfuss).

I'SOETES (from ἴσος, equal, and ἔτος, year), a cryptogamic genus of plants, belonging to the natural order Lycopodiaceæ. The capsule of the plant does not open, and the fructification is enclosed within the swollen base of the leaves; it has sporules of two kinds, which are attached to filiform receptacles. The organs of fructification in this plant are small cases, which are situated in the angles formed by the union of the leaves and the contracted stem; those seated in the axillæ of the outer or inferior leaves are divided into three cavities, containing about fifty spherical bodies (granules); the cases in the axillæ of the internal or superior leaves are divided by numerous transverse partitions into many cavities, all of which are filled with an impalpably fine powder, in the early stages of its development white, but subsequently becoming black.

The species of Isoetes grow at the bottoms of ponds and lakes, and are said to afford excellent food for fish. They are called Quillworts from the rush or quill-like appearance of the leaves.

I. lacustris, Quillwort, has subulate roundish-quadrangular leaves with four longitudinal jointed tubes. The rhizoma of this plant is a blunt tuber; the leaves are slender, broad and flat at the base, but elsewhere between cylindrical and quadrangular. It is found in Great Britain, at the bottom of lakes and ponds in hilly districts. The structure of the fructification of this plant, and other species of the genus, is only imperfectly understood. It is on this account refered to Marsilleaceæ by some authors, and made to form an independent order by others. Lindley refers it to Lycopodiaceæ, and observes, 'I follow De Candolle and Brongniart, in referring it here. Delile has published an account of the germination of Isoetes setacea, from which it appears that its sporules sprout upwards and downwards, forming an intermediate solid body, which ultimately becomes the stem or cormus, but it is not stated whether the points from which the ascending and descending axes take their rise are uniform; as no analogy in structure is discoverable between these sporules and seeds, it is probable that they are not. Delile points out the great affinity that exists between Isoetes and Lycopodium, particularly in the relative position of the two kinds of reproductive matter. 'In Lycopodium,' he says, 'the pulverulent thecæ occupy the upper ends of the shoots and the granular thecæ the lower parts; while in Isoetes the former are found in the centre and the latter at the circumference. If this comparison is good, it will afford some evidence of the identity of nature of those thecæ, and that the pulverulent ones are at least not anthers, as has been supposed; for in Isoetes the pulverulent inner thecæ have the same organization, *even to the presence of what has been called their stigma*, as the outer granular ones: so that if Isoetes has sexes, it will offer the singular fact of its anther having a stigma.'

(Babington, *Manual of British Botany;* Newman, *History of British Ferns;* Lindley, *Natural System;* Burnett, *Outlines of Botany.*)

ISO'TELUS, a genus of fossil Crustacea (Trilobites) from the Silurian strata, especially of North America (Green).

ISSUE PEAS are round bodies employed for the purpose of maintaining irritation in a wound of the skin which is called an issue. [ISSUE, P. C.] It is a matter of indifference of what substance the peas are composed, so long as they do not introduce poisonous matters into the wound. The seed of the common garden pea is frequently used. It is however more common to use the young unripe fruits of the common orange (*Citrus aurantium*). The fruits are dried and afterwards turned in a lathe before they are used as issue peas. The unripe oranges, dried, are sold under the name of orangettes or Curaçoa oranges. The rootstock of the *Iris Florentina* is also formed into peas and used for keeping up the discharge from issues.

(Lindley, *Flora Medica;* Christison, *Dispensatory.*)

IU'LUS, a genus established by Linnæus for such *Insecta Myriapoda* as now form the order *Chilognatha* (χεῖλος, γνάθος), the first division of *Myriapoda* in the arrangements of Leach and Latreille. The *Chilognatha* have crustaceous and usually cylindrical bodies, formed of numerous unequal segments, very short feet, each terminating in a single hook; a vertical rounded head, furnished with two mandibles, which are either thick and robust or united with the labium and elongated. They have no palpi. The antennæ are two, very short, either slightly thickened towards their extremities, or filiform throughout, and composed usually of seven, more rarely (as in the genus *Sphæropœus*) of six joints. Their eyes are smooth and vary greatly in number. These animals move slowly and with a gliding motion. When disturbed, they roll themselves up spirally, or into a ball. They feed on decomposing animal and vegetable matter.

The position assigned to the Chilognatha, at the head of the Myriapoda, by Latreille and others, has recently been disputed by Professor Brandt and by Mr. Newport. The following remarks on this subject by the latter naturalist, of all living zoologists the most competent to decide in questions affecting this difficult class, are taken from his catalogue of Chilognatha in the British Museum, published in the 'Annals of Natural History for April, 1844,' and afford in a brief compass much information respecting these curious animals.

'The Chilognatha have usually been regarded by naturalists as the first order of *Myriapoda*, partly in consequence of the more compact form of the head, and its similarity to that of the larva state of hexapod insects, and partly from the general form of their bodies being similar to that of the larvæ. This was the view taken of these animals by Latreille, Leach, Gervais, and some others, and very recently by Lucas. But a different and, as I believe, more correct view and arrangement have been followed hy Professor Brandt, who regards the *Chilopoda* as the first, and the *Chilognatha* as the second division of the class. Although I cannot entirely agree with Brandt in his division of the *Chilognatha* into masticating and sucking species, because, as Lucas has recently remarked, there are species even among the *Chilopoda* which have the external organs of nutrition fitted only for taking liquid food, as in the little *Scolopendrella*, I fully agree with him in the superiority of the *Chilopoda*, as an order, over the *Chilognatha*, notwithstanding the less compact structure of the head in the former. The general characters of the *Chilopoda* certainly point them out as the most perfect animals of the osculant class of Articulata. The more compact frame of body, the reduced number of the organs of locomotion, the greater activity, and the predaceous habits of the higher species, approximate the Chilopoda to the predaceous insects on the one hand, and to the Arachnida on the other. The form of the head, in the two divisions of *Myriapoda*, seems to have reference chiefly to the particular habits of the species. Thus, in those which seize their prey and subsist like the Arachnidans on living objects, those segments which in reality compose the whole head are not all anchylosed together, but are in part freely moveable on each other, and thus allow of a more prehensile function to the large forcipated foot-jaws, the true mandibles of the Articulata. Some naturalists have believed that these foot-jaws in the *Chilopoda* are not the true analogues of insects and of *Chilognatha;* but I am satisfied, by recent examinations, that this is truly the case. In the *Chilognatha* the foot-jaws have the form of true mandibles, because the habits of the species require that compact form of the organ which alone can be subservient, not to the seizing and piercing of living prey, but to the grinding or comminuting of more or less solid vegetable matter, on which most of the genera of *Chilognatha* entirely subsist. In all other respects, both in their internal as well as their external anatomy, and in their physiology and mode of growth, the *Chilognatha* are decidedly inferior to the *Chilopoda.* They seem to conduct us down to the Annelida from the vegetable-feeding crustacea, as the *Chilopoda* do from the *Arachnidans* to the same class.'

Tho Chilognathous Myriapoda are found in all parts of the world, certain genera, however, affecting certain geographical divisions. Thus the species of *Glomeris* are European; those of *Spirastreptus* and *Sphæropœus* African and Eastern. The genus *Iulus*, in its most limited sense, includes European, Asiatic, and North American species. *Iulus terrestris* is a familiar British example.

A synopsis of the genera of Chilognatha will be found in the third part of the nineteenth volume of the 'Linnæan Transactions,' appended to a valuable memoir on the Myriapoda by Mr. Newport. Professor Brandt's papers on these animals are published in the 'Transactions and Proceedings of the Imperial Academy of St. Petersburg.'

IVORY, JAMES, a distinguished British mathematician, was born at Dundee, in 1765, and received the rudiments of education in the public schools of that town. At fourteen years of age he was sent to the university of St. Andrew's; his father, who was a watchmaker, intending that he should become a clergyman of the church of Scotland. In that university the young man remained six years, during four of which he was occupied with the study of mathematics, languages, and philosophy; but the first of these subjects, from a natural inclination to that branch of science, particularly engaged his attention: he was encouraged and ably assisted in his favourite pursuit by the Rev. John West, one of the instructors at the university; and his great progress, which is said to have excited considerable notice, gave already indications of the eminence which, as a mathematician, he was afterwards to attain. The two following years were passed in the study of theology; and Mr. Ivory then removed, in company with Mr. (afterwards Sir John) Leslie, who had been his fellow-student at St. Andrew's, to the university of Edinburgh, where he spent one year in completing the course of study required as his qualification for admission to the office of minister in the Scottish church.

It is not known what circumstances prevented Mr. Ivory from carrying out the intentions of his father in this respect; but, on quitting the university, in 1786, he accepted an appointment as an assistant teacher in an academy then recently established in Dundee, and he continued to fulfil the duties of that post during three years. At the end of that time he engaged with some other persons in the establishment, at Douglastown in Forfarshire, of a factory for spinning flax; and of this association he appears to have been the principal person.

During fifteen years (from 1789 to 1804) Mr. Ivory was employed daily in operations apparently very uncongenial with the taste of a man of science; but it may be presumed that all his leisure hours were devoted to the prosecution of scientific researches. It must have been at this time that, though residing in a retired district, he diligently studied the writings of the English mathematicians, together with those of the illustrious foreigners whose works were in the public libraries of Scotland; also that he obtained access to, and made himself thoroughly acquainted with, the later productions of the continental mathematicians.

It is scarcely to be expected that a factory carried on under the superintendence of a man the greater part of whose time was probably spent in researches which require nearly a total abstraction of the mind from the ordinary concerns of life, should have succeeded; accordingly we find that in 1804 the company ceased to exist; and Mr. Ivory, who then obtained the appointment to a professorship of mathematics in the Royal Military College, quitted Scotland, and went to reside at Marlow, in Buckinghamshire, where that institution had, a few years previously, been formed. On the removal of the college to its present site (Sandhurst in Berkshire), Mr. Ivory accompanied it to the latter place, where he remained till his retirement from public service. He fulfilled the duties of his professorship to the great satisfaction of the governor; his attention to the students who were placed under him was unremitting; and it should be remarked that, however irksome it might have been to a man of high attainments in science to communicate the elements of knowledge to young persons, Mr. Ivory always evinced the utmost readiness to assist, by the most appropriate and familiar illustrations, in smoothing the path of science to his pupils. An edition of Euclid's 'Elements,' which is known to have been his work, though his name does not appear on the title-page, was prepared by him for the use of the students in the college; and the manner in which he has treated the book on proportion, and those which relate to solids, must have greatly diminished the difficulties which the generality of learners experience in acquiring a knowledge of those parts of elementary mathematics.

In the beginning of the year 1819 Mr. Ivory, feeling his health decline under the great exertions which he made in carrying on his scientific researches and performing his duties as a professor, those duties leaving him but short intervals of leisure, was induced to resign his professorship and retire into private life. In consequence of his great merit there was granted to him the pension due to the full period which, by the regulations, the civil officers of the institution are required to serve previously to obtaining such pension; and which period he had not completed. After his retirement from Sandhurst, Mr. Ivory devoted himself wholly to scientific researches, and the results of his labours have been printed chiefly in the volumes of the 'Philosophical Transactions.' In 1831, in consideration of the great talent displayed in his investigations, he was by Lord Brougham, to whom he had been known in early life, recommended to the king (William IV.), who, with the Hanoverian Guelphic Order of Knighthood, gave him an annual pension of 300*l.*, which he enjoyed during the rest of his life; and, in 1839, the University of St. Andrew's conferred on him the degree of doctor in laws. He lived in great privacy in or near London till the time of his death, which happened September 21st, 1842, in the seventy-seventh year of his age.

Mr. Ivory's earliest writings were three Memoirs which he communicated in the years 1796, 1799, and 1802 to the Royal Society of Edinburgh: the first of these was entitled 'A New Series for the Rectification of the Ellipse;' the second, 'A new Method of resolving Cubic Equations;' and the third, 'A New and Universal Solution of Kepler's Problem;' all of them evincing great analytical skill, as well as originality of thought. He contributed fifteen papers to the 'Transactions of the Royal Society of London,' nearly all of them relating to physical astronomy, and every one containing mathematical investigations of the most refined nature. The first, which is entitled 'On the Attractions of Homogeneous Ellipsoids,' is in the volume for 1809, and contains investigations of the attractions of such ellipsoids on points situated within them and on their exterior: the former case presents few difficulties; but the process used by Laplace for the solution of the other was very complex, and Mr. Ivory had the merit of discovering one which is remarkable for its simplicity. A given point being on the exterior of an ellipsoid, he imagined another ellipsoid having the same centre and the same foci as the first to pass through the point; then taking, on the surface of the interior ellipsoid, a point so situated that the co-ordinates of the two points are in the ratio of the semiaxes to which they are parallel, he showed that the attraction in the direction of each axis which one of the two bodies exercises upon a point on the surface of the other, is to the attraction of the latter body on the corresponding point at the surface of the first, as the product of the two other axes of the first ellipsoid is to the product of the two other axes of the second. A direct investigation of this case has since been given by M. Poisson.

In the volumes for 1812 and 1822 there are three papers on the Attractions of Spheroids, in which Mr. Ivory substituted a refined analytical process for the indirect method of Laplace: the papers contain also some observations on the method employed by that great geometer in computing the attractions of spheroids of any form differing but little from spheres. The analytical skill shown by Mr. Ivory in these papers was frankly acknowledged by Laplace himself in a conversation which, in 1826, he had with Sir Humphry Davy.

The Transactions for 1814 contain an investigation, by Ivory, relating to the orbits of comets, on the supposition that these orbits are parabolical: the paper is entitled 'A New Method of deducing a first Approximation to the Orbit of a Comet from three Geocentric Observations.' And the volumes for 1823 and 1838 contain his investigations relating to Astronomical Refractions: in the first of these the temperature of the air is supposed to decrease uniformly with a uniform increase of height; and in the other the expressions are rendered general for all laws of temperature. The volumes for 1824, 1831, 1834, and 1839 contain, each, a paper on the equilibrium of fluid bodies; and in the volume for 1838 Mr. Ivory demonstrated that a homogeneous ellipsoid with three unequal axes may be in equilibrio when revolving about one of the axes: he also examined in detail the limitations of the proportions of the axes. The subject of planetary perturbations is treated by him in two papers which are contained in the volumes for 1832 and 1833; in the first he has simplified the theory of the variations of the elements, and in the other he has given some facilities for developing the excentricities and inclinations. He has given in the 'Transactions' only one paper which is purely mathematical, and this is contained in the volume for 1831: it is entitled, 'On the Theory of Elliptic Transcendants.'

Mr. Ivory contributed several papers to the 'Philosophical Magazine:' in the number of that work for August, 1821, is his method of finding the latitude of a ship by two observations of the sun's altitude, with the time elapsed between them; and in the volumes for 1825 and 1827 are his investigations relating to sound and heat. Several valuable communications from his pen are contained in Maseres's 'Scriptores Logarithmici;' in Leybourn's 'Mathematical Repository;' and in the Supplement to the sixth edition of the 'Encyclopædia Britannica.'

In estimating the merits of Mr. Ivory as a mathematician, it must be borne in mind that his researches were conducted by a most refined analysis at the time when even the notation of the differential calculus was not familiar to the English mathematicians; and that, when he wrote the papers relating to the attraction of spheroids, the volume of the 'Mécanique Céleste,' in which that subject is treated, had probably not been read by any person in this country except himself.

In 1815 Mr. Ivory was elected a fellow of the Royal Society of London: he was also an honorary fellow of the Royal Society of Edinburgh; an honorary member of the Royal Irish Academy, and of the Cambridge Philosophical Society; a corresponding member of the Institute of France, of the Royal Academy of Sciences of Berlin, and of the Royal Society of Göttingen. He received, in 1814, the Copley medal for his mathematical communications to the Royal Society: in 1826 one of the royal medals was awarded to him for his paper on Astronomical Refractions, published in 1823; and in 1839 he received another royal medal for his Theory of Astronomical Refractions, which was published in 1838.

(From the Marquis of Northampton's Address to the Royal Society, November 17, 1842.)

IVY. [HEDERA, P. C.]

IZALCO is the name of a village in the State of San Salvador in Central America, and remarkable for a volcano situated about three miles from the village, and between eight and nine from the town of Zonsonate. This volcano is of recent origin. It is stated that it was formed about sixty years ago, and it is to be regretted that no particular account has hitherto been published of such a remarkable event. It broke out on the top of a hill of moderate elevation, which however since that event has been increased in size by the addition of lava, scoria, ashes, and other volcanic matter, and at present it may be called a considerable mountain. It is one of the few volcanos which are in uninterrupted activity, like the Stromboli of the Lipari Islands. The eruptions are almost continual, and whenever they slacken the country in its vicinity is subject to almost continual earthquakes. Sometimes the activity of the volcano is increased, and then large quantities of lava inundate the country at its base, the greater part of which has thus been changed into a stony waste.

JACARANDA of commerce is said by Prince Maximilian to be the timber of a Brazilian Mimosa.

(Burnett, *Outlines of Botany.*)

JACKSON, JOHN, R.A., was born in 1778 at Lastingham, in Yorkshire, where his father carried on the business of a tailor, and he was himself bred to the same business. He however hated his occupation; he had seen the collection of Lord Mulgrave, and the pictures at Castle Howard, and he had a strong inclination to become a painter. An attempt which he made to imitate a picture by Reynolds was shown by his schoolmaster to Lord Mulgrave, who perceiving in it and others, notwithstanding their crudeness, some talent, supplied Jackson with proper materials, and encouraged him to go on. Lord Mulgrave and Sir G. Beaumont purchased the two years of Jackson's unexpired apprenticeship, and the latter in 1797 gave him an allowance of 50*l.* per annum, and an apartment in his house in town, to enable him to prosecute his studies at the Royal Academy.

Jackson soon obtained a name for his portraits in black lead-pencil and water-colours, but it took him many years to equal the successful oil-painters of that day. He first attracted notice in this department about 1806, and in 1817 when he was elected a member of the Royal Academy, his reputation was little inferior to that of Lawrence, though he was comparatively little patronized; his portraits were bold and effective, but they wanted the delicacy of the works of Lawrence: Jackson could paint five heads while Lawrence was painting one. In the summer of 1819 he visited Rome in company with Chantrey, and painted for him there a portrait of Canova. Jackson astonished the Roman painters, says Cunningham, by copying in four days the Borghese Titian of 'Sacred and Profane Love' as it is called, a picture which many Romans required two or three months to copy: Passavant says, the figure of Divine Love, in three days, which is more likely; the rest of the picture is scarcely worth copying. Jackson was elected a member of the Academy of St. Luke, at Rome. He was in all his works extraordinarily rapid and sure. A story is related, that he commenced and finished in a single summer's day, as a wager, the portraits of five gentlemen: he received 25 guineas for each of them—125 guineas in one day; probably no painter ever earned as much by his own labour before. The story is told by Passavant. Jackson died at his house in St. John's Wood on June the 1st, 1831. His best works are the portraits of Lady Dover, of Flaxman, and of himself, both painted for Lord Dover, and the portrait already mentioned of Canova. He painted in all the portraits of thirteen of his fellow Academicians, but that of Flaxman, is in all respects the best; Allan Cunningham truly observes of this picture, that there is a 'sombre grandeur about it which awes one;' it is certainly one of the finest portraits in the world.

Jackson exhibited in all, at the Royal Academy, between the years 1804 and 1830, one hundred and forty-five pictures; he of course painted very many portraits that were not exhibited, for he was latterly constantly employed. His nominal price for a head was fifty guineas, and though he must have been making a large income, he died without leaving a provision for his family. He was twice married; his second wife, who survived him, was the daughter of his fellow-academician, Ward.

(Cunningham, *Lives of British Painters*, &c.; Passavant, *Kunstreise durch England*, &c.)

JACKSON, ANDREW, the late American general and president, was himself a native of the United States; although his father, of the same names, was an Irishman, the youngest of the four sons of Hugh Jackson, a linendraper near Carrickfergus; and either the linendraper himself, or one of his recent progenitors, had come over from Scotland.* Andrew Jackson went over to America in 1765, taking with him a wife and two sons. With them he established himself in the Waxhaw settlement in South Carolina; and here his third and youngest son, the subject of the present notice, was born on the 15th of March, 1767. Andrew Jackson died soon after; and his widow found herself left with a half-cleared farm, without slaves, whereupon to bring up her three sons.

Andrew, her latest born, appears to have been his mother's favourite; and the original destination of the future General and President of the United States was to be a clergyman, we are not informed of what denomination. With this view, after having finished his school education, he was sent to the Waxhaw Academy; and here he seems to have studied theology for some years. When the war of independence, however, made all Americans soldiers, the young Jacksons did not hold back. Andrew is recorded to have fought, along with his next eldest brother Robert, under Sumter in his attack on the British garrison at Rocky Mount, on the 6th of August, 1780; at which date he would be little more than thirteen. And from this time he is stated to have taken a part in the campaigns as long as the war lasted. Nor did he altogether escape the usual dissipated habits of a military life; but, with the decision of character which was his most remarkable characteristic, he suddenly changed his course before it was too late, and, collecting what remained of his means, put himself, in the winter of 1784, into the hands of Spruce M'Cay, Esq., an eminent advocate and afterwards a judge, to be instructed in the practice of the law. This new study he prosecuted with so much success that in 1787 he was appointed solicitor for what was then called the Western District of North Carolina, and is now the State of Tennessee. The circumstances of the time, however, did not suffer him, even if he had been so inclined, to throw off his military character, or to let the experience he had gained in camps and campaigns go to rust. Although the war with the mother country was over, the borders of the republican territory were still infested with another most troublesome enemy in the original occupants of the soil; and Jackson, although he would only serve as a private, is said to have so much distinguished himself in the contest with those natural rivals of his race, that he was honoured among them with the titles, or descriptive appellations, of Sharp Knife and Pointed Arrow.

He continued to be thus employed till the year 1796, when, after having first acted as one of the members of the Convention for establishing a constitution for the state of Tennessee, he was, under that new arrangement, elected to a seat in the House of Representatives. The next year he was chosen a Senator; but he resigned his seat after holding it for one session. On this he was immediately appointed by the legislature of Tennessee Judge of the Supreme Court in that state; having also been shortly before chosen a Major General of the state forces. But he soon resigned his judicial office; and, settling himself on a farm, a few miles from Nashville, on the Cumberland river, he resided there in retirement till the breaking out of the war with England in 1812. With that event commences the most memorable portion of Jackson's career.

His first command was that of a body of between two and three thousand volunteers, who had assembled on his invitation, and with whom he was directed to proceed down the Mississippi for the defence of the lower country. This was in November, 1812. The next year he greatly distinguished himself by a campaign against the Creek tribes. An account of it may be found in a message from the President (Madison) to Congress, dated 7th December, 1813, in which it is stated that the best hopes of a satisfactory issue of the contest were already warranted by the complete success of a well-planned enterprise against the Indians, executed by a detachment of the volunteer militia of Tennessee under the command of General Coffee; 'and by a still more important victory over a larger body of them, gained under the immediate command of Major General Jackson, an officer equally distinguished for his patriotism and his military talents.' The Creeks were repeatedly afterwards defeated by Jackson. The war was terminated in August, 1814, by a treaty, by which they agreed to lay down their arms. (Message of President Madison, dated 20th September, 1814.)

In 1814 Jackson was appointed a Major General in the service of the United States; and, among other operations, he succeeded in taking Pensacola on the 7th of November, and raised himself to the highest point of reputation and popularity among his countrymen by the famous repulse of the British forces in their attack on New Orleans, on the 8th of January, 1815. The next military command which he held, was that of

* It is a remarkable fact that three of the Presidents of the United States have been descendants of Scottish colonists of the North of Ireland; Monroe, Jackson, and the present President, Polk. (1846)

the war against the Seminole Indians of Florida in 1818, for the details of which the reader may be referred to President Monroe's Message to Congress of the 16th of November in that year, and to the Report of the Committee of Senate on the Seminole war, dated 24th February, 1819. Jackson's proceedings in this war, from first to last, were extremely irregular and high-handed; the force at the head of which he placed himself was raised and officered not only without but in direct opposition to the orders of the general government; in carrying on his operations against the Indians, he did not scruple to seize, one after another, several forts and ports belonging to Spain, with which country the United States were at peace, and to put down the Spanish authorities by the power of the sword—conduct of which his government marked its disapproval in the most emphatic manner, by the immediate restoration of the places thus unwarrantably seized; but his most extraordinary act was the execution of the two Englishmen Arbuthnot and Ambrister. Alexander Arbuthnot was taken in the Spanish Fort of St. Mark's, along with two Indian chiefs, and Robert C. Ambrister, a few days afterwards, on an excursion which the force made from that post to destroy a neighbouring Indian village. The two Indian chiefs were hanged at once, and without trial; the justification urged being that by their own usual practice in like cases, and by the general manner in which they carried on war, the Indian tribes were to be considered as having put themselves beyond the pale of the ordinary law of nations. Arbuthnot and Ambrister were both, after a few days' confinement, tried at St. Mark's by court martial; when Arbuthnot was sentenced to suffer death, and Ambrister to be whipped and further confined; but General Jackson annulled the latter sentence, and Arbuthnot was hung and Ambrister shot. There is no doubt that these persons were acting in concert with the Indians; and, that being the case, it would perhaps be difficult to show that they were entitled to other treatment than those with whom they had associated themselves. But even to take the lives of Indian prisoners of war was an extreme proceeding, and one of very doubtful propriety; the charge upon which the two Englishmen were tried was only the very vague one of 'inciting the Indians to war;' in these circumstances it was certainly a startling exercise of military power for a general, under the most popular of all governments, to set aside the sentence of a court martial, as was done in the case of Ambrister. Besides, the principle upon which General Jackson took his stand was even less tenable than the one we have just stated; he himself vindicated what he had done, on the ground that Arbuthnot and Ambrister, by assisting in war against the United States while they were at peace with Great Britain, became outlaws and pirates; thus resting their liability to suffer death, when taken prisoners of war, not on the ground of their having united their fates with savages, but on that of their having been the subjects of a power with which the United States were at peace; a principle altogether unknown to the law of nations. However, although a stout fight was made in Congress by the opposite party, Jackson's friends, supported by the feeling out of doors, where his military reputation and his ultra-democratic professions bore down everything, carried a succession of votes in his exculpation by large majorities.

General Jackson afterwards acted as commissioner on the part of the United States in the negociation with Spain for the transference of Florida: and after the arrangement of the treaty to that effect, he was, in 1821, appointed the first governor of the province. He held this post for a year, and was then again elected a member of the Senate for the State of Tennessee.

When the election of a new president came on at the end of 1824, General Jackson was a candidate along with Mr. Adams, Mr. Clay, and Mr. Crawford; and on the first vote he had a large majority over the nearest of his competitors: the numbers being for Jackson 101, Adams 82, Crawford 41, Clay 37. No candidate, however, having the majority required by the Constitution, the election devolved upon the House of Representatives; and Adams and Clay having united their strength, the former obtained the votes of thirteen states against seven who voted for Jackson and four who voted for Crawford, and became president. Jackson, however, was triumphantly elected in 1828, and again in 1832; so that he was at the head of the government of his native country for the eight years from 1829 to 1837. His presidency was distinguished by the rapid growth and extension of democratic tendencies of all kinds: and, at the same time, of both the spirit of territorial extension, with its near consequences, conquest and war, and of the influence of the southern states and the slaveholding interest; but the subject in regard to which the president personally came forward in the most conspicuous manner was in the affair of the United States Bank. This bank, the renewal of the charter of which was the ostensible matter in dispute, was a powerful instrument in the hands of the general government; and hence the renewal of its charter, though supported by both Houses of Congress, was resisted, and successfully, both by the popular voice and by the president whom that voice had placed in office, and who had been one of the most ardent and resolute of the democratic leaders throughout his life.

General Jackson survived his presidency about eight years, and died at his seat called the Hermitage, near Nashville, in Tennessee, on Sunday the 8th of June, 1845. He was married, but had no issue.

(*Biographical Notice in* (*New York*) *Weekly Herald*, of 21st of June, 1845; *Funeral Oration delivered by* Mr. Bancroft *at Washington; Histories of the Time.*)

JACQUARD, JOSEPH-MARIE, was born at Lyon, on the 7th of July, 1752, of humble parents, both of whom were employed in operations connected with weaving. He is said to have been left to teach himself even to read and write; but at a very early age he displayed a taste for mechanics, by constructing neat models of buildings, furniture, &c. for amusement. At the age of twelve his father placed him with a bookbinder for a time, and he was subsequently engaged in type-founding and the manufacture of cutlery, in both of which occupations he gave evidence of talent. Owing to the death of his mother, young Jacquard returned to the house and occupation of his father, who also died some years after, leaving him a small property, which he employed in the attempt to establish a business in the weaving of figured fabrics. The undertaking failed, and he was compelled to sell his looms in order to pay his debts. He subsequently married, and hoped to receive a portion with his wife which might assist him out of his pecuniary difficulties; but this expectation proved delusive, and he was compelled to sell his paternal residence. His wife, to whom he is said to have been tenderly attached, is described as a model of patience, kindness, and activity; while he appears, without fortune, ambition, or foresight, to have occupied himself with ingenious schemes for improvements in weaving, cutlery, and type-founding, which produced nothing for the support of his family. Necessity at length compelled him to enter the service of a lime-maker in Bresse, while his wife remained at Lyon to attend to a small straw-hat business. In 1792 he ardently embraced the revolutionary cause, and in the following year he returned to Lyon, and assisted in the memorable defence of that place against the army of the Convention; his only son, then a youth of fifteen, fought by his side. Being denounced after the reduction of Lyon, they were both compelled to fly, and they then joined the army of the Rhine. His son was killed in battle, and upon this Jacquard returned to Lyon, where he found his wife, whom he had been unable to inform of his flight, earning her bread by plaiting straw, in which humble occupation he was compelled by poverty to assist. Lyon at length began to rise from its ruins, and its artisans returned from Switzerland, Germany, and England, where they had taken refuge. Under these circumstances, Jacquard applied himself with renewed energy to the perfection of the beautiful apparatus for figured weaving which bears his name, and which is described under WEAVING, P. C., pp. 178, 179. He had conceived the idea of such an apparatus as early as 1790, and he now succeeded, though but imperfectly, in accomplishing his end. His machine was presented, in September, 1801, to the national exposition of the products of industry, the jury of which awarded him a bronze medal for its invention. In the same year he obtained a patent, or 'brevet d'invention,' for a term of ten years. He set up a loom on his new principle at Lyon, which was visited by Carnot and several other of the statesmen who were assembled at that city in 1802 to arrange the affairs of the Cisalpine republic.

About this time the attention of Jacquard appears to have been directed, by the accidental perusal of a paragraph from an English newspaper, stating that a reward was offered by a society in this country for the invention of such an apparatus, to the construction of a machine for weaving nets for fishing and maritime purposes. From the account given by Dr. Bowring, who had conversed on the subject with Jacquard himself, before a Select Committee of the House of Commons on the silk trade, in 1832, and which is made the subject of an article in No. 50 of the 'Penny Magazine,' published in 1833, this would appear to have been Jacquard's first mechanical invention; but the more circumstantial account in the 'Supplément' to the 'Biographie Universelle,' to which we are chiefly indebted for the materials of this article, shows that such was not the case. He accomplished the desired object, but, having amused himself and his friends with his contrivance, he threw it aside. His machine-made net, however, fell into the hands of the préfet at Lyon, and the result was that, according to the arbitrary fashion of the time, he and his machine were placed under arrest and conveyed to Paris, where the invention was submitted to inspectors, upon whose report a gold medal was awarded to him in February, 1804. On occasion of this forced visit to Paris, Jacquard was introduced to Napoleon and Carnot, when the latter, not understanding his mechanism, roughly asked him if he were the man who pretended to do that impossibility—to tie a knot in a stretched string. Jacquard, not disconcerted at such a reception, explained the action of his machinery with simplicity, and convinced the incredulous minister that the supposed impossibility was accomplished by it. He was then employed for a time in repairing and putting in order the models and machines in the Conservatoire des Arts et Métiers, and while there he produced some ingenious improvements in weaving machinery, one of which was for producing ribbons with a velvet face on each side. He also contrived some improvements upon a loom invented by Vaucanson, which improvements have been stated to be the origin of the Jacquard machine. According to the French authority above referred to, however, this improvement upon Vaucanson's loom was not connected with his great invention; and, as its mechanism is very complex, its application limited to very small patterns, its action slow, and its cost very great, it is considered to belong rather to the class of curious than of useful machines.

In 1804 Jacquard returned to Lyon, where he was long engaged in superintending the introduction of his inventions for figured weaving and for making nets, in which he was powerfully aided by Camille Pernon, a rich manufacturer. Through his assistance, a commission of manufacturers was appointed to report upon the first-named invention, and eventually an imperial decree, dated Berlin, October 27, 1806, was issued to authorize the municipal administration of Lyon to purchase his invention for the use of the public. In the same year the Academy of Sciences and Arts at that city presented him with the prize medal founded by the consul Lebrun. For some years Jacquard had to struggle against much opposition and prejudice on the part of the Lyonese weavers, who conspired to discourage the use of his machinery, wilfully spoiled their work to bring it into discredit, and, through the Conseil des Prud'hommes, who were appointed to watch over the commercial interests of the city, had it publicly broken up and sold as old materials. Even his personal safety was at times endangered. At length, however, under the effect of foreign competition, the value of the invention was acknowledged, and it was brought very extensively into use, not only in France, but in Switzerland, Germany, Italy, America, and, according to the 'Biographie Universelle,' it has been introduced even into China.

Jacquard was solicited by the manufacturers of Rouen and St. Quentin to organize their factories of cotton and batiste, and he received a tempting offer of a similar nature from England; but he preferred remaining at Lyon, where he continued to exert himself in promoting the use of his great invention until, having lost his wife, he retired to Oullins, a village near Lyon, where he spent his latter years in retirement, and died on the 7th of August, 1834, at the age of eighty-two. During his life he received the cross of the Legion of Honour, and in 1840 a public statue was raised to his memory at Lyon. His 'Eloge Historique' has been published by M. de Fortis.

'The name of Jacquard,' observe the writers of his memoir in the 'Biographie Universelle,' 'has become, so to speak, technical in both the old and new world.' 'The happy continuator of the efforts of Vaucanson, who, like him, was engaged at Lyon in the improvement of weaving machinery, Jacquard has invented a simple and cheap machine, coming within the reach of the humble weaver, the introduction of which forms a memorable epoch—a new era—in the textile art.' By its agency the richest and most complex designs are produced with facility at the most moderate price; and, so far from diminishing employment, as some feared on its first introduction, it has, according to the writers just quoted, increased the number of workmen in the manufacture in which it is used tenfold.

JALNA (*Jâlnapoor*), a town of Hindustan, capital of the district of Jalna, is included in the province of Aurungabad. The district of Jalna is comprised chiefly of two large valleys, one of which is watered by the Pourna and the other by the Doudna. The town is situated about forty miles east from the city of Aurungabad, on the east bank of the Coundolga, an affluent of the Doudna, in 19° 52′ N. lat., 76° E. long. Jalnapoor is a fortified town of considerable size. It was taken from the Mahrattas by Colonel Stephenson in September, 1803, in the course of the military operations which immediately preceded the battle of Assaye, and was afterwards ceded to the Nizam.

JAMESONE, GEORGE, called by Walpole the Vandyck of Scotland, was the son of Andrew Jamesone, an architect, and was born at Aberdeen in 1586. Jamesone and Vandyck were about 1616 fellow-pupils of Rubens at Antwerp. When Charles I. visited Edinburgh in 1633, he sat to Jamesone, and presented him with a diamond ring from his own finger. His career is not exactly known, but it must have been a successful one, for he left his wife and family well provided for at his death in 1644; and he bequeathed also much in other directions. He was probably in Italy, for his portrait is in the painter's portrait gallery at Florence; he travelled in company with Sir Colin Campbell of Glenorchy. Many of the considerable families of Scotland possess portraits by Jamesone, but the greatest collection is at Taymouth, the seat of the Earl of Breadalbane. Sir Colin Campbell, the earl's ancestor, was Jamesone's first and chief patron. In a manuscript containing the genealogy of the house of Glenorchy, there is mention of several portraits painted by Jamesone for Sir Colin, with memoranda of the prices paid. For portraits of the kings David and Robert Bruce, Charles I. and his queen, and for nine queens of Scotland, painted in 1635, Jamesone received only 260 Scotch pounds, or 20 pounds per portrait, which is equal to 1*l.* 13*s.* 4*d.* sterling; the Scotch pound was twenty pence. All other portraits painted for Sir Colin, which were many, were paid for at the same rate. There are several of Jamesone's pictures also in the two colleges of Aberdeen. There is a portrait of Jamesone by himself at Cullen House; he appears to have often painted his own portrait, and he always painted himself with his hat on, which he may have done either in imitation of Rubens, or on having been granted that privilege by Charles I. when he sat to him.

Though the pupil of Rubens and the companion of Vandyck, Jamesone's works have neither the fulness nor richness of the former, nor the vigour of the latter; they are however painted very thinly and with much nature, but there is a sharpness in his outline which reminds of a very different school from that of Rubens. 'His excellence,' says Walpole, 'is said to consist in delicacy and softness, with a clear and beautiful colouring, his shades not charged but helped by varnish (*glazing?*), with little appearance of the pencil.' So far Walpole: Jamesone's countryman Cunningham in quoting this passage has added the following words to it as coming also from Walpole—"He had much of Vandyck's second manner, and to Sir Antony some of his works have been occasionally imputed.' These words are not in Walpole, at least not in the edition of 1782.

Jamesone's earliest works are painted on pannel; he used afterwards fine canvas, smoothly primed, and prepared in a shade tint. He painted occasionally history, miniature, and landscape. Walpole mentions a view of Edinburgh by him.

Cunningham has ascribed to Jamesone the illuminations of a manuscript of two hundred leaves of parchment, illustrating the Life of Christ, which belonged only to Jamesone, and which he valued at 200*l.* sterling. Jamesone himself describes it as a manuscript in his possession 'containing two hundred leaves of parchment of excellent write adorned with diverse histories of our Saviour curiously limned.' This memorandum was in the possession of his descendant, Mr. John Jamesone, a wine-merchant of Leith, from whom Walpole (or rather Vertue) obtained the particulars of his account of Jamesone. It is not known what has become of this manuscript.

Cunningham speaks of Jamesone as without a native rival in Great Britain; he appears to have overlooked Dobson, some of whose heads not only approach but equal Vandyck's.

Jamesone's daughter Mary excelled in embroidery, in textile paintings; some of her works are still preserved in the church of St. Nicolas, at Aberdeen.

(Walpole, *Anecdotes of Painting*, &c.; Cunningham, *Lives of British Painters*, &c.)

JAMIESON, JOHN, D.D., is best known as the author of the Scottish Dictionary, but he published many other literary works, and was a person of very considerable ability and acquirement in various departments. He left also, it seems, an autobiography, entitled 'Recollections of my past Life,' a manuscript of upwards of two hundred closely written folio pages, the composition of his later years, which, from the account that has been given of it, we should infer would well deserve to be sent to the press. We are indebted for the materials of the present short notice to a memoir abstracted from this manuscript in Tait's Magazine, No. 92 (for August, 1841), pp. 514-528.

Jamieson (so he himself spelt the name, though he made his children drop the *i*) was born in Glasgow, 3rd March, 1759. His father, the Rev. John Jameson, was pastor of one of the two congregations of Seceders (that is, Presbyterian dissenters from the Established Church), which then comprised all the persons of their denomination in that city: this office he held for many years, struggling with ill health and an income of less than a hundred a year. The Seceder minister's family connections, however, were very good; and the course of his son's life was much influenced and coloured by that circumstance. Mrs. Jameson had been a Miss Cleland, whose mother was a daughter of the Rev. Robert Bruce of Garlet, son of a younger brother of Bruce of Kennet, in Clackmannanshire, a family allied to many of the highest of the old gentry, and which disputes the chieftainship of the line of Bruce with the earls of Elgin. These Bruces of Kennet had always been staunch Presbyterians; but it is remarkable that the father of the Seceder clergyman, a respectable farmer of West Lothian, had been a zealous Episcopalian. His son was so ashamed of this fact, that young Jamieson never could learn from him of what religion his grandfather had been, and it only came accidentally to his knowledge late in life. In those days especially the Seceders were distinguished even among other Presbyterians for their rigid and exclusive Presbyterianism.

The subject of the present notice remained throughout his life a steady, but by no means a narrow-minded Seceder. His mother's relations, taking him by the hand, early introduced him extensively into general society, and his literary tastes and associations further helped to liberalize him. Yet even long after he numbered among his intimate acquaintances and friends many persons of great eminence and influence, and had become known in literature, his worldly circumstances continued extremely narrow. He was in fact kept back rather than brought forward by the governing bodies in his sect, in which, under a professedly more popular constitution, the authority of the clergy in their courts is, or at least was, nearly as absolute over individuals of their number as is that of the Conference among the Wesleyan Methodists.

The chronology of his life may be given in a few sentences. He was sent to the university of Glasgow when he was only nine years old, an unusually early age for the commencement of academic education even in Scotland. The urgent motive in this case seems to have been not any extraordinary precocity, or appearance of precocity, in the boy, so much as the anxiety of his father, who had no other son surviving and nothing to leave to his family, to see him established as a clergyman before he should be himself, and he was in very broken health, removed from the world. Among his teachers at Glasgow were Professor Muirhead, an enthusiastic Virgilian; Dr. Moor, the author of the Greek Grammar, an accomplished scholar and a man of talent, but indolent and dissipated; and Dr. Reid, the metaphysician. He commenced the study of theology at the age of fourteen, under the Rev. William Moncrieff, who lectured on that subject to the young men intended for the Secession ministry at Alloa. After having been a session at Alloa, however, he attended the lectures of Dugald Stewart in the university of Edinburgh. In July, 1779, having just completed his twentieth year, he was licensed as a preacher by the Seceder Presbytery of Glasgow. For some time he was employed, as the practice in his communion is or was, to do duty without any pastoral appointment; first at Clonmell in Ayrshire, then in the Isle of Bute, then at Cowal in Argyleshire, then at various places in Perthshire. At last he received at the same time calls, or popular invitations, from congregations in Forfar, Dundee, and Perth; upon which the synod, or governing body, appointed him to that at Forfar, the poorest and in all other respects the least desirable of the three. Here he managed to exist upon an uncertain stipend of fifty pounds a year, for a dozen years or more. About a year after settling at Forfar, he married, and he soon had a numerous family; his wife was the daughter of a country gentleman of Angusshire, but it is not stated that she brought him any money. It is intimated indeed that he got into debt; and it is quite clear that he must have either borrowed money or procured some beyond his regular professional income in some other way. While thus situated he made several journeys to London, and both there and in Scotland formed many literary acquaintanceships. He had when very young contributed some verses to Ruddiman's 'Weekly Magazine,' and he had also communicated some papers on the antiquities of Forfarshire to the Literary and Antiquarian Society of Perth, of which he was a member; but he first properly came out as an author in 1786, when he published, under the title of 'Socinianism Unmasked,' an examination of certain opinions deemed heretical which had been promulgated through the press by Dr. Macgill, one of the established ministers of Ayr. This work procured him considerable reputation in the religious world, and it was followed in 1789 by 'The Sorrows of Slavery, a poem;' in 1790 by two octavo volumes of 'Sermons on the Heart;' and in 1791 by 'Congal and Fenella,' a metrical tale, in two parts. The memoir before us is deficient in dates; but it would appear to have been after he had been ten or twelve years at Forfar that he received a call to be their pastor from the Seceder congregation of Nicolson-street, Edinburgh, which, however, the synod would not allow him to accept. But when, a few years after, he was again unanimously invited by the same congregation, it was not deemed decent or prudent by the reverend body to make any further opposition; and he accordingly removed to the metropolis with its literary society and other advantages of position, and exchanged his fifty pounds a year for an income of perhaps four times the amount. In this situation Jamieson remained for the rest of his life. To the last much of his time continued to be given to literature; and in addition to the works already mentioned, he published, among others of a slighter nature, in 1795, a 'Reply to Dr. Priestley,' in 2 vols. 8vo.; in 1798, 'Eternity: a poem;' in 1799, 'Remarks on Rowland Hill's Journal;' in 1802, 'The Use of Sacred History,' in 2 vols. 8vo.; in 1806, 'An important Trial in the Court of Conscience;' in 1808, his 'Etymological Dictionary of the Scottish Language,' in 2 vols. 4to.; in 1818, 'An Abridgment of the Scottish Dictionary,' in 1 vol. 8vo.; in 1811, 'An Historical Account of the Ancient Culdees of Iona;' in 1814, 'Hermes Scythicus, or the Radical Affinities of the Greek and Latin Languages to the Gothic,' 8vo.; in 1825, a Supplement to his Scottish Dictionary, in 2 vols. 4to.; and subsequently 'An historical Account of the Royal Palaces of Scotland.' He also produced, in 1820, an edition of Barbour's poem of 'The Bruce,' and Harry the Minstrel's 'Sir William Wallace,' in 2 vols. 4to. Here then was at any rate no want of industry. Neither Jamieson's learning, however, nor his critical acuteness, was of a high order; and scarcely anything that he has done, with the exception of his Scottish Dictionary, retains much value. His 'Hermes Scythicus' is founded upon a mere examination of the vocabularies of some of the northern languages, and has been long superseded. Nor has his Dictionary (of which a second edition has been lately published) any merit as a critical performance; but it is valuable as by far the most extensive collection that has been formed, both of old words and phrases, and of notices of old customs, peculiar to Scotland, a large portion of the matter it contains being derived from the people themselves, their conversation and traditions, and being thus rescued from the probably imminent danger of irrecoverable oblivion. Jamieson wrote verse apparently with facility, but not with much felicity. A favourable specimen of his style of performance in this line may be seen in his poem in the antient Scottish dialect (or language, as he considers it), called 'Water-Kelpie,' which he contributed to Scott's 'Minstrelsy of the Scottish Border.'

Jamieson early in life received the diploma of a doctor in divinity from the college of New Jersey in the United States; he was for many years secretary to the Society of Scottish Antiquaries; and he received a pension of 100*l.* a year as an associate of the Royal Society of Literature from its institution till the general withdrawal of the allowances on the accession of William IV. In 1833 a pension to the same amount was assigned to him from the Civil List. He died at Edinburgh, on the 12th of July, 1838, leaving only one son, Mr. Farquhar Jameson, a banker in Paris, of five that had reached the years of manhood. His second son, Mr. Robert Jameson, had died a few years before, after rising to considerable distinction at the Scottish bar.

JAN MAYEN ISLAND is an island in the Arctic Polar

Sea, lying between 70° 49′ and 71° 9′ N. lat., and between 7° 26′ and 8° 44′ W. long. It extends from south-west to north-east about thirty miles, and is in no place above nine in breadth; at some places it is less than two miles. On the northern extremity, where the island is widest, stands the mountain called Beerenberg or Bear Mountain, a peak rising to 6870 feet above the sea-level. It frequently shows its snow-capped summit above the clouds, and rests on a rocky mass 1500 feet high. In other parts the rocky masses appear to attain an elevation of between 1500 and 2000 feet. A large portion of the island is composed of lava and other volcanic matter, and two craters have been discovered on the eastern side; smoke and fire have been observed in these parts.

Even in the beginning of August all the high lands are found covered with snow and ice, and the low lands in those valleys and deep cavities where large beds of snow have been collected, retain part of their covering to the very border of the sea. At the foot of the Beerenberg are three very singular glaciers: they occupy recesses in the cliff where it is more than 1200 feet high, and nearly perpendicular. They are very rough on the surface, and of a greenish grey colour. They present the appearance of immense cataracts suddenly arrested in their progress and congealed by the power of an intense frost. Like cascades, their prominent greenish colour is variegated with snow-white patches resembling foam, which deeply contrast with the jet-black points of the most prominent rocks peeping through their surfaces.

The coast has several roadsteads with good anchorage in five to ten fathoms water, black sandy ground, but no harbour for a ship, all the anchorages being open to the sea in an angle of at least ten points of the compass. The soundings about the island are very irregular, and the bottom generally consists of rocks or black sand. The western navigation of Jan Mayen is preferred to the eastern, as being less encumbered with ice and less subject to calms, squalls, and whirlwinds, which are often encountered in passing to the east of Beerenberg. The whole island is generally surrounded in the spring of the year; but in autumn, and even in summer, the ice sometimes sets so far to the westward that it is not visible from any part of the land.

There are foxes and white bears, and perhaps also reindeer. Water-fowl are numerous, especially burgomasters, fulmars, puffins, guillemots, little auks, kittywakes, and terns. Several cetaceous animals abound, principally of the species Balæna Physalis. The vegetation is very scanty, and limited to a few species scattered widely about among the volcanic minerals. Iron has been observed at several places.

The island was discovered in 1611 by a Dutch navigator called Jan Mayen, and was much visited up to about 1640 on account of the great number of whales, which, however, afterwards retreated to other parts of the Arctic Sea. In this time (1633-1634) seven Dutch seamen wintered here, probably for the purpose of establishing a permanent colony, and they kept a regular journal. But on the arrival of the Dutch fleet in the following June all were found dead in their huts. From the journal, however, it appeared that they had not been killed by the frost but by the scurvy, which had attacked them for want of fresh provisions. Their journal terminated on the 31st of April.

(Scoresby, *Account of the Arctic Regions.*)

JARDYN, KAREL DE, one of the best of the Dutch landscape, pastoral, and *genre* painters, and the most distinguished of N. Berghem's scholars. He was a native of Amsterdam, and lived some time in Rome, where the Flemish painters gave him the nickname of Bokkebaart (goat-beard). He died at Venice in 1678, aged about forty. There are many spirited etchings by his hand.

(Houbraken, *Groote Schouburg*, &c.; Bartsch, *Peintre-Graveur.*)

JASIONE, a genus of plants belonging to the natural order Campanulaceae. It has a 5-leaved rotate calyx, anthers cohering at the base, a hairy trifid style, 2-celled capsules opening by a large and somewhat valvular pore at the base. There is but one British species of this genus.

J. montana has a simple root, bluntish oblong wavy leaves, and stalked flowers. The stems are from six inches to two feet long, pilose, simple, or branched: leafy below, bare and glabrous above, and ascend from the crown of the root. The flowers are small, in terminal bracteated heads, having a light blue corolla.

(Babington, *Manual of British Botany.*)

JAVOLENUS PRISCUS, a Roman jurist, from whom there are a few excerpts in the Digest. His period is not quite certain. He is mentioned by Pomponius (Dig. 1, tit. 2, s. 2, §47) as a successor of Caelius Sabinus, and he accordingly belonged to the Sabiniani; and some writers place him in the time of Nerva and Hadrian. He was the master of Salvius Julianus. It may be inferred from a passage of Julianus (Dig. 40, tit. 2, s. 5), that Javolenus some time held the offices of governor of Syria and Africa. He is probably the Javolenus Priscus mentioned by the younger Pliny (*Ep.* vi. 15), who stopped by a timely answer Passienus Paulus from inflicting his poetry on him. Javolenus is mentioned by Capitolinus in his Life of Antoninus Pius as one of the jurists who were the advisers of the emperor. But this would extend his life beyond probable limits; he who was the master of Julianus who drew up the Edictum Perpetuum under Hadrian, could not have been one of the advisers of Antoninus Pius. According to the Florentine Index, Javolenus wrote fifteen books 'ex Cassio,' that is, Caius Cassius Longinus, fourteen books of Epistolæ, and five books to Plautius. He was also the author of an Epitome of the Libri Posteriores of Labeo; and made notes on them (*Dig.* 40, tit. 12, s. 42).

JENKINSON, ANTHONY. [KIVA, P. C. S.]

JEREMIE, SIR JOHN, was born in Guernsey, August 19, 1795, and was the eldest son of the late John Jeremie, a distinguished advocate of the Royal Court of that island. At an early age he was sent to the Blundell grammar school, Tiverton, but his studies were soon interrupted by the premature death of his father. Upon his return to Guernsey he devoted himself to the study of the law, which he completed during a residence at Dijon, in France. As early as 1815, at the commencement of his public life, he distinguished himself before the royal commissioners, sent over to Guernsey to correct certain abuses in the laws and administration of justice in that island. He was afterwards retained in many difficult cases, both civil and criminal, and soon acquired a high character for independence and energetic zeal in the discharge of his professional duties. On more than one occasion he was chosen to plead cases of appeal before the Privy Council, where his talents and eloquence found a larger sphere for their action, and brought him before the notice of government.

In October, 1824, he was appointed to the office of Chief Justice of S. Lucia, in the West Indies. 'At the time the tender of an appointment was made to him,' he observes, in his Essays on Colonial Slavery, 'he was unacquainted with a single individual in the service of the colonial department, and his political opinions were rather opposed to the then existing government. On the question of slavery he was thoroughly indifferent; indeed, it was so remote from his usual pursuits, that he may fairly say he had never given it a thought. In the interval between the first proposal and his accepting office, his professional avocations brought him to England, and on this occasion, probably owing to this proposal, his curiosity prompted him to attend an anti-slavery meeting. The impression made upon his mind was rather unfavourable than otherwise to the abolitionists. He heard much declamation, much angry and eloquent declamation; but accustomed from early life to sift evidence, it struck him that there was a deficiency of facts and of evidence on which to found that declamation.' It was under this impression that he went to the colonies, and the candid expression of his feelings on the subject of slavery, which we have quoted, must acquit him of any bias in favour of its abolition, and proves that his subsequent devotedness to the great cause of emancipation was the entire result of a conviction pressed upon him by an actual knowledge of the evils of the system. No sooner, indeed, was the slave law of 1825 promulgated, and the slave enjoyed the liberty of freely communicating with his protectors, than numerous examples of revolting cruelty, brought before him in his official capacity, produced a rapid but lasting change in his opinions. In proportion to the extent of his inquiries was the depth of his conviction that the only remedy to the evil of slavery was the gradual emancipation of the slave. His views on this important subject are fully put forth in 'Four Essays on Colonial Slavery,' which he published on his return to Europe in 1831; in them he describes the general features of the slave communities, and the beneficial effect of the ameliorations already adopted, and he proceeds to show what he considers to be the further measures required for the entire annihilation of the system. The principle by which he was actuated in publishing these essays will be seen from the following extract. 'Such then,' he observes, 'is the unfavourable estimate reluctantly formed of the West Indian communities; nor can they complain that they are anonymously maligned, that they are maligned on rumour or insufficient evidence, or that sentiments are now expressed different from those which he was known to entertain when among them. Such as they are, he has urged them in the warmth and confidence of friendship; he has repeated them from the judgment-seat in the sternness of duty, with the still sterner proof before him. They are now published, neither vindictively nor in anger, but because, having tried every other method, be has acquired the painful conviction that publicity alone can lead to a thorough reformation.'

In the year 1832, he was appointed to the office of Procureur and Advocate-General of the Mauritius. He had there to contend not only against objections of a personal nature, arising from his known opinions on the slave question, but against national and deep-rooted antipathies of a population almost entirely of French origin, and strongly attached to French institutions. The office, moreover, which be held presented peculiar difficulties to one who was determined conscientiously to perform the duties it imposed. It were an error to assimilate it to that of an English attorney-general; they are only so far similar that they both fulfil the duties of a public prosecutor. The procureur-general, among the French, is an executive magistrate, and has to enforce the decrees of the courts, and he has under bis control the police force of the country. When the disaffected party at the Mauritius heard of Mr. Jeremie's appointment to an office which, we believe, had hitherto been held by members of their own community, they broke out into an almost open rebellion. On bis arrival before Port Louis, so great was the fear entertained for bis personal safety by the British authorities, that all access to the shore was, for a time, forbidden bim. The colonial assembly had petitioned the governor altogether to prevent bis landing; their request being refused, after a detention of two days he went on shore, under the protection of the whole naval and military force in the island, and on the same day was sworn into office, at a meeting of the legislative council.

The many scenes of violence which ensued are fully detailed in a pamphlet entitled 'Recent Events at the Mauritius,' which he published in vindication of his conduct. It will be sufficient to mention that the governor thought it advisable, for the security of the public peace, to order him to return to England, be having previously declined to do so, except a written command were given him to that effect. On his arrival in London he immediately reported bimself to the colonial office, adding, that he was ready to resume bis journey back to the Mauritius at an hour's notice. His request, though delayed, was granted, and his return to that island preceded by an additional military force. The feelings, however, originally excited against him did not easily subside, and his residence there, which terminated in 1835, was embittered by a series of painful events, arising from the fearless advocacy of his opinions. 'Within three years,' to use his own words, 'he had traversed fifty thousand miles, encountered the assassin on shore and the pirate at sea; for ten years had it been his fate to face, in the service of the crown, every peril to which life is subject, whether from the ocean, from climate, or from tho hand of man.'

In the year 1836, he was appointed to the office of puisne justice of the Supreme Court of Ceylon, and during the same year he received a gratifying proof that his devoted zeal in behalf of emancipation had been fully estimated by the British public. A valuable piece of plate was presented to him by the Anti-Slavery Society; the inscription upon it testifying that 'by bis disinterested, ablo, and energetic exertions in most critical and painful situations, both at home and abroad, negro freedom had been largely advanced, and the negro character raised to its just standard in public estimation.'

His residence during four years at Ceylon was the only tranquil period of his eventful life. Early in the year 1840, he published a 'Letter on Negro Emancipation, and African Civilization,' addressed to Sir T. F. Buxton. In it he describes the present, and shows what he considers will be the future effects of emancipation in the colonies, and gives a short outline of the practical steps which might be taken in order to advance the civilization of Western Africa. He looks upon the emigration of the emancipated negro of the West Indies to the land of his origin as one of the most likely means of attaining that important end. 'To the sons of Africa,' be says, 'we must look for the regeneration of Africa. To a reflux of the west upon the east, in moderate numbers, and managed with caution, must we look for the civilization of the east.'

It was to carry into effect the measures which had been suggested for ameliorating the condition of the liberated slaves that, undeterred by the perils of a pestilential climate, he accepted, in October, 1840, the important office of Governor and Captain-general of Sierra Leone and its dependencies, and be received at the same time the honour of knighthood. On the 23rd of April, 1841, only four months after his arrival at Sierra Leone, he fell a victim to the prevalent disease of the climate, while engaged in a government mission at Port Lago. His only son, John Robert Jeremie, a young man whose talents promised high success in a career of honourable utility, which had been opened to him in Europe, had, at his own earnest request, accompanied his father as private secretary, which appointment he held under the succeeding Governor until 1843, when he likewise fell a victim to the climate. Of Sir J. Jeremie's family, originally consisting of three children, his widow, the constant sharer of his perils, alone survives. The inhabitants of St. Lucia, when the news of his death reached them, marked their regret for his loss by a general mourning. But perhaps the most gratifying tribute to his memory is to be found in an address made on that occasion to the Royal Court of St. Lucia by his friend Dr. Reddie, who had succeeded him as chief justice of that colony. The following passages are contained in it:—'To say that Sir J. Jeremie was the ablest judge, was the most useful judge, who ever presided at St. Lucia, is saying little indeed. For the laws which he enforced, and the reforms which he introduced into the legal system of the colony, giving stability to commerce and security to the investment of capital, the planters and merchants recognise to him a deep debt of gratitude. Wherever you turn your eyes you meet the proofs of his activity in the discharge of the administrative duties which, at one timo, devolved on the first president;—the high roads opened up and levelled, the paving and drains for the salubrity of the town, the erection of the Protestant church, all attest his unwearied and zealous labours. His memory will long be cherished by that class of the colonists whose equal rights he secured, and whose social position he upheld and vindicated, both by precept and example, when, to use his own striking language, after having submitted to the minister of the crown (Sir George Murray) an argument on the grave colonial question, the distinction of colour, that eminent statesman recognised the policy and justice of a change, and the "curse of Heaven disappeared from the face of the Western world."'

JERVAS, CHARLES, the portrait painter, was born in Ireland about 1675; the exact date is not known. He studied a year with Kneller in London, copied the cartoons of Raphael at Hampton Court, in small, and studied also in Paris and at Rome. He returned to London about 1708, where, through the intimate friendship of Pope, and a fortune of 20,000*l.* which he acquired with his wife, a widow, he was enabled to overcome all the usual difficulties attendant upon a professional life in its up-hill career. His sole ability as a painter seems to have been bis power of copying: some of his copies after Carlo Maratta are, according to Walpole, equal to the originals. He appears to have been inordinately conceited, due no doubt in a great measure to the silly flattery of his friend and pupil Pope, in his 'Epistle to Jervas.' There are several anecdotes related of his vanity: on one occasion, when be had finisbed a copy after Titian, he said, looking with tho utmost satisfaction from one to the other, 'Poor little Tit, bow he would stare.' Jervas seems to have set up a coach rather early, and when Kneller was informed of it, the veteran exclaimed, 'Ach! mein Gott, if his horses do not draw better than he does, be will never get to his journey's end!' Jervas affected to be a free-thinker, and when he was once talking irreverently of tbe Scriptures, in the presence of Dr. Arbuthnot, the doctor observed to him, that he was notwithstanding both a speculative and a practical believer, for, said he, 'you strictly observe the second commandment—in your pictures you make not the likeness of anything that is in the heavens above, or in the earth beneath, or in the waters under the earth.' This deserved lash contains a better account of Jervas's style than the extravagant encomium of Pope. Jervas died Nov. 2, 1739.

(Walpole, *Anecdotes of Painting*, &c.)

JESIRA, AL. [MESOPOTAMIA, P. C.]

JOA'NES, or JUA'NES, VICENTE, a celebrated Spanish painter, was borne at Fuente la Higuera in Valencia, in 1523. Palomino's account, therefore, that he was the scholar of Raphael, is an error. He studied in Italy, and, as we may infer from his style, chiefly the works of the Roman school. He died December 21st, 1579, whilst engaged in finishing the altar-piece of the church of Bocairente, and was buried in that town, but his body was removed to Valencia and deposited in the church of Santa Cruz in 1581.

Joánes was one of the best of the Spanish painters: he is acknowledged as the head of the school of Valencia, and is sometimes termed the Spanish Raphael. His drawing is correct, and displays many successful examples of foreshortening; his draperies are well cast, his colouring is sombre (he was particularly fond of mulberry colour), and his expression is mostly in perfect accordance with his subject, which is generally devotion or impassioned resignation, as in the Baptism of Christ in the cathedral of Valencia. Joánes' subjects are exclusively religious, and if, says Cean Bermudez, Morales on this account deserved the title of El Divino, Joánes is equally entitled to it. Like his countryman Vargas and D'Amato of Naples, he is said to have always taken the sacrament before he commenced an altar-piece. His best works are in the cathedral of Valencia, and there are several good specimens in the Prado at Madrid. To mention a minor quality of his works, he excelled in painting hair.

Juánes had many scholars, among whom his son Juan Vicente was not undistinguished: his daughters also, Dorotea and Margarita, were well known for their ability in painting.

(Cean Bermudez, *Diccionario Historico*, &c.)

JODE, DE, PIETER, the name of two celebrated engravers of Antwerp, father and son.

The elder, the son of Gerard de Jode, likewise an engraver, was born in 1570. He was the pupil of Golzius, studied and worked in Italy and at Paris, and died at Antwerp in 1634.

De Jode engraved many plates in a good style, among them the remarkable picture of the Last Judgment, by Cousin, in twelve sheets, making altogether about sixteen square feet, four each way: it is one of the largest prints in existence.

The younger de Jode, or Petrus de Jode, Junior, as he signed himself on his prints, was born at Antwerp in 1606, and was instructed in engraving by his father, whom he soon surpassed in execution, especially in the nude, and equalled in correctness of drawing. He worked with his father in Paris. His numerous portraits after Vandyck are his best works; among them are his own, and those of Jordaens, Poelemburg, Suellina, De Coster, and others, painters of Antwerp. He executed also some good prints after Rubens. The date of his death is not known.

Arnold de Jode was the son of the younger Pieter, and was born at Antwerp about 1636. He is said to have been in London in 1667, and then to have engraved a print after the picture by Correggio, which belonged to Charles I., of Mercury instructing Cupid, which is now in the National Gallery. Scarcely anything is known of him personally: as an engraver he was inferior to his father and grandfather.

(Basan, *Dictionnaire des Graveurs*; Hubert, *Manuel des Amateurs*, &c.)

JOHN, KING OF SWEDEN. [Charles XIV., P. C. S.]

JOHNSTON, DR. ARTHUR, the fifth son of an ancient family possessing estates in Aberdeenshire, was born in that county in 1587. At an early age he went abroad for medical education: and the degree of Doctor in Medicine was conferred on him at Padua in 1610. He travelled in various parts of the continent, and resided for twenty years in France, marrying twice in the course of that period. He returned to his native country before the year 1625, and was soon afterwards appointed physician to King Charles I., probably through the influence of Laud. After this appointment he must have resided chiefly in the neighbourhood of the court. In 1641 he died at Oxford, while on a visit to a daughter married there. Johnston's name is preserved in the memory of scholars by his Latin verses. He was the most extensive contributor, and is not unusually called the editor, of Sir John Scot's collection of Latin poems, the 'Delitiæ Poetarum Scotorum hujus Ævi Illustrium,' Amsterdam, 1637, 2 vols. 12mo.; and besides several other volumes of compositions in Latin verse, he was bold enough to measure lances with Buchanan in a version of the Psalms, 'Paraphrasis Poetica Psalmorum Davidis, Auctore Arturo Jonstono, Scoto,' Aberdeen, 1637, 8vo. This ambitious attempt led, many years afterwards, to a protracted controversy on the merits of the rival versions. The history of the dispute is related, and Johnston's works fully described and justly estimated, in Dr. Irving's 'Lives of Scottish Writers,' 1839, 2 vols. 8vo. It is enough here to say, that Johnston's high rank among modern writers of Latin poetry is universally admitted; and that, although in Scotland his psalms have usually been estimated much below Buchanan's, the justice of this sentence has been questioned by critics of authority, of whom Mr. Hallam is one

JOINERY (French, *Menuiserie*) is the art of joining pieces of wood together for the interior fittings of buildings, for making articles of furniture, and for numerous purposes requiring greater neatness of workmanship than the operations of the carpenter. [Carpentry, P. C. S., p. 292.] As carpentry and joinery are in many cases carried on in the same establishment, and even by the same workmen, it would be difficult accurately to define the limits of these two kindred arts; but a good general distinction is drawn between them in Tredgold's article 'Joinery,' in the seventh edition of the 'Encyclopædia Britannica,' where it is stated that the art of carpentry is directed almost wholly to the support of weight or pressure, owing to which circumstance its leading principles belong to the mechanical sciences. The proper object of carpenter's work in a building is to give firmness and stability to the structure; and within its proper range may be embraced all the rough timber-work necessary for the support, division, or connection of the several parts of a building. Carpentry thus includes the construction of the framing of floors, partitions, and roofs. Joinery, according to the same authority, has for its object the addition of all the fixed wood-work necessary for convenience or ornament; and while it does not call for the application of much mechanical science, it requires, as Tredgold observes, much skill in that department of geometrical science which relates to the projection and description of lines, surfaces, and solids, as well as an intimate knowledge of the structure and properties of wood. The principal items of joiner's work in a building, as enumerated by Nicholson in his treatise on 'Carpentry,' in the 'Encyclopædia Metropolitana,' are the doors, windows, margins round plaster to protect it from injury at angles, &c.; decorations generally, such as architraves, bases, columns, and pilasters; boarding, skirting, and wainscoting. The boarding of floors, which is treated of under House, P. C. S., p. 52, and the construction of staircases [Staircase, P. C., p. 423], are considered as falling into the department of the joiner rather than the carpenter; and the construction of the hand-railing of staircases is a department of joinery which requires much ingenuity, and is treated at great length in many works on the subject. Tredgold observes that cabinet-making, or that department of wood-work which relates to the making of furniture, has little affinity with joinery, although the same materials and tools are employed in both descriptions of work. The line of demarcation, however, between joinery and cabinet-making would seem to be even more difficult to define than that between carpentry and joinery; and, with the exception of such matters as veneering and polishing, which relate only to the use of the harder and more valuable woods, the operations of the cabinet-maker and the joiner are nearly identical, the same means being adopted by both for the production of neat and strong joints, and for evading the injurious effect of shrinkage, warping, and hygrometric changes in the material operated upon. It is, indeed, remarked by the author of 'The Joiner and Cabinet-Maker,' in Knight's series of Industrial Guide-Books, that 'the same man will call himself a joiner when he is working in deal, or oak, or ash, and making a strong kitchen table, or a door, or a corn-chest, and a cabinet-maker when he is working in mahogany or rose-wood, and making a writing-desk or a cabinet.'

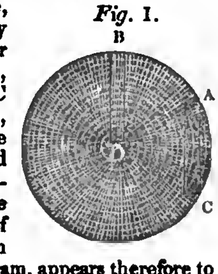
Tredgold, in the article above referred to, has collected numerous notices relative to the progressive improvement of the art of joinery, and the principal works which have been published on the subject. He traces the origin of the art in the thrones, stalls, pulpits, and screens of cathedrals and churches, in which, however, the joinery is of the most simple kind, and is indebted to the carver for its ornament. The earliest writer on joinery to whom he alludes is Joseph Moxon, in whose 'Mechanick Exercises,' published in 1677, the tools and ordinary operations of the joiner, and the technical terms then in use, are explained. He attributes the credit of establishing the principles of joinery, in this country, on the sound basis of geometrical science, to the valuable practical works of the late Peter Nicholson, who appears to have been the first English writer on the subject who derived assistance from the works of continental writers. The French, especially, have produced many valuable works on joinery, which show that some things given as new by English writers have long been known on the continent; bu Tredgold observes that in practice the French joiners are very inferior to our own. 'Their work,' he says, 'is rough, slovenly, and often clumsy, and at the best is confined to external effect. The neatness, soundness, and accuracy which is so common to every part of the works of an English joiner, is scarcely to be found in the works of a French one.' 'The little correspondence,' he adds, 'in point of excellence, between their theory and practice, leads us to think that their theoretical knowledge is confined to architects, engineers, &c., instead of being diffused among workmen, as it is in this country.'

In all the operations of the joiner it is of primary importance to know the peculiar properties of the material that is used. This subject is briefly noticed under Carpentry, P. C. S., p. 292, and some information bearing upon it is given under Wood, P. C., p. 518; while in Exogens, P. C., p. 120, is an explanation, illustrated by sectional diagrams, of the manner in which woody matter is formed, and of the arrangement of the component parts of the trunk of a tree. Tredgold gives much information relative to various kinds of wood in his 'Elementary Principles of Carpentry;' and, in his treatise on joinery in the 'Encyclopædia Britannica,' he gives the results of some important experiments on those peculiar properties of wood which lead to its warping and cracking. Of these the first in order was made by T. A. Knight, Esq., and communicated by him to the Royal Society in 1801 and 1817; and they appear to be opposed to some generally received opinions. In his first paper on the subject, printed in the ninety-first volume of the 'Philosophical Transactions' (p. 344, &c.), Mr. Knight observes 'that there is in every kind of wood what workmen call its grain, consisting of two kinds, the false or bastard, aud the true or silver grain.' 'The former,' he explains, 'consists of those concentric circles which mark the annual increase of the tree; and the latter is composed of very thin laminæ, diverging in every direction from the medulla (or pith) to the bark, having little adhesion to each other at any time, and less during the spring and summer than in the autumn and winter, whence the greater brittleness of wood in the former seasons.' His observations in this paper refer to English oak, but they are, he says, more or less applicable to every other kind of wood, the wood of exogenous plants only, of course, being included in this remark. The truth of his observations is illustrated by the fact that in drying whole trunks it is impossible to prevent the wood from splitting more or less, the cracks being in all cases directed towards the centre, thus indicating that the wood shrinks in a greater ratio in the direction of the circumference of the trunk than in the direction of its diameter, and that the radiating or diverging laminæ of what Knight styles the true or silver grain will readily separate from each other. In sawing the English oak into boards, Knight observes, 'it is usual to cut it, as much as possible, into what are called quarter-boards, which are so named because the tree is first cut into quarters.' 'In a perfect board of this kind,' he adds, 'the saw exactly follows the direction in which the tree most readily divides when cloven; in this case the laminæ of the silver grain lie parallel with the surface of the board, and a board thus cut, when properly laid in the floor, is rarely or never seen to deviate from its true horizontal position.' An American machine for cutting up trunks so that all the boards produced may possess this quality is noticed under Saw-Mill, P. C., p. 481. 'If, on the contrary,' to resume Mr. Knight's observations, 'one be sawed across the silver grain, it will, during many years, be incapable of bearing changes of temperature and of moisture without becoming warped; nor will the strength of numerous nails be sufficient entirely to prevent the inconvenience thence arising. That surface of a board of this kind which grew nearest the centre of the tree will always show a tendency to become convex, and the opposite one concave, if placed in a situation where both sides are equally exposed to heat and moisture.'

In the second paper of Mr. Knight on this subject, in the 'Philosophical Transactions,' vol. cvii. p. 269, &c., he states the result of similar experiments upon ash and beech. Some thin boards of these woods were, to quote his own words, 'cut in opposite directions relative to their medulla, so that the convergent cellular processes crossed the centre of the surfaces of some of them at right angles, and lay parallel with the surfaces of others; by which means I became enabled to mark the comparative extent of their expansion and contraction when they were subjected to various degrees of heat and moisture.' 'Both were placed under perfectly similar circumstances in a warm room, when those which had been formed by cutting across the convergent cellular processes soon changed their form very considerably, the one side becoming hollow and the other raised: and in drying these contracted nearly 14 per cent. relative to their breadth. The others retained, with very little variation, their primary form, and did not contract more than $3\frac{1}{2}$ per cent. in drying.'

Tredgold, after briefly noticing the above experiments, gives the result of another, conducted apparently by himself, which completes the application of the same important principles to the more ordinary materials of the joiner. 'As Mr. Knight,' he observes, 'had not tried resinous woods, two specimens were cut from a piece of Memel timber; and to render the result of our observation more clear, conceive *Fig.* 1 to represent the section of a tree, the annual rings being shown by circles. BD represents the manner in which one of our pieces was cut, and AC the other. The board AC contracted 3·75 per cent. in width, and became hollow on the side marked *b*. The board BD retained its original straightness and contracted only 0·7 per cent.' The difference in the relative amount of contraction between boards cut in the two ways indicated in the diagram, appears therefore to be even greater than in hard woods. 'From these experiments,' Tredgold observes, 'the advantages to be obtained merely by a proper attention in cutting out boards for pannels, &c. will be obvious; and it will also be found that pannels cut so that the septa are nearly parallel to their faces will appear of a finer and more even grain, and require less labour to make their surface even and smooth.' He considers that their results will be no less interesting to cabinet-makers, especially in connection with the making of tables. 'For such purposes,' he says, 'the planks should be cut so as to cross the rings as nearly in the direction BD as possible;' and he expresses his opinion that the great superiority of the billiard-tables of some makers to those of others is attributable to a knowledge of this property of wood. As affecting ornamental woods he remarks that where the transverse septa are large, a plank cut like BD will be figured, while one cut as AC will be plain.

Fig. I.



Reasonable and self-evident as the results of the experiments above detailed may appear, when the physiological structure of exogenous wood is taken into consideration, they are almost diametrically opposed to an opinion prevalent among joiners, that a plank or board cut as AC, which would be termed *mild*, is preferable to one cut in the plane of the axis of the trunk, like BD, which would be termed *strong*, not with reference to its actual strength in the ordinary sense of the word, but rather as a correlative to mild, as indicative of rankness, hardness, or coarseness, and its presumed tendency to warping.

Another kind of warping or irregular shrinkage, which often affects joists, door-posts or jambs, and other thick pieces of wood which are cut from one side of a trunk, is thus explained by Mr. Knight. (*Phil. Trans.* vol. cvii., p. 274.) 'The interior and older layers of wood,' he states, 'are much more solid and specifically heavy than the external layers in the same tree; and the latter consequently contract more longitudinally in drying than the former, and the edge of every board (that has been cut with surfaces nearly parallel with the line of the converging cellular processes) which lay nearest the medulla in the tree will therefore in drying become convex, whilst the opposite edge will become concave.' From these remarks it may be presumed that while, where flatness of surface is the principal object, a piece of wood cut like BD, *Fig.* 1, is preferable te one cut like AC, the latter would be preferable where the permanent straightness of the edges is of the greatest importance, because the fibres near its two edges, being equidistant from the pith or medulla, will shrink equally, while in BD those at the edge B will contract more than those at the edge D.

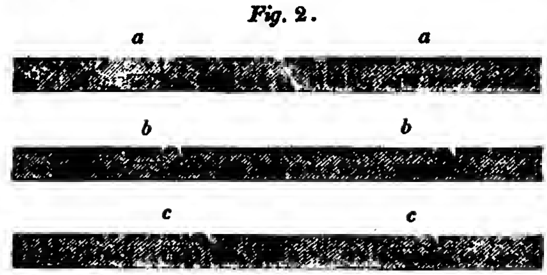
By paying due regard to such circumstances in the selection of wood, the joiner may, in a great degree, evade the inconvenience arising from irregular variations in the dimensions of his material. As an illustration of the application of such knowledge, we may refer to the method described in Dodd's 'British Manufactures,' series iv., p. 211, in Knight's 'Weekly Volume,' as occasionally adopted in the formation of large deal table-tops, for veneering with mahogany or rosewood. Owing to their great width and various other circumstances, such boards or slabs are peculiarly liable to warping; but the tendency is guarded against by selecting deals as free as possible from knots, and sawing them longitudinally into pieces four inches or four inches and a half wide. These are glued together side by side, an edge which has been nearest the heart of the tree being joined to an outside edge. When the glue is thoroughly set, the wide compound board thus produced is again cut up into slips, by sawing it longitudinally midway between the joints, and these slips are rejoined, with a further change in the order of placing the pieces. The table-top thus consists of pieces of wood not more than two inches wide, so arranged as mutually to counteract any inclination to warping. A due regard to the laws of warping and shrinkage is also very necessary in the construction of large mouldings and decorations, which are built up, as it were, of several distinct pieces of wood. In making wooden columns, for example, several pieces must be fitted together to form a hollow cylinder, in preference to using one large post; or, where large posts are used, they must, if appearance is to be regarded, be surrounded by a number of narrow pieces. Small columns may be made of a single piece, and prevented from splitting by boring a large hole down their axis.

The original shrinkage of wood in drying is not however the only change of dimension to be provided for, since, from its hygrometric properties, changes in the state of the atmosphere occasion even old and seasoned wood to vary in size from time to time. Of this we have a familiar illustration in the fact that doors, especially garden doors, which open and shut with facility in dry weather, frequently swell so as to become almost immoveable in a humid state of the atmosphere. From experiments made by M. Rondelet, quoted by Tredgold, it appears that in wood of a mean degree of dryness the extent of contraction and expansion produced by the usual changes in the state of the atmosphere was, in fir-wood, from $\frac{1}{550}$th to $\frac{1}{75}$th part of its width, and in oak, from $\frac{1}{412}$th to $\frac{1}{81}$th part of its width, showing a mean variation equal to $\frac{1}{131}$th part of the width in fir, and $\frac{1}{166}$th part of the width in oak. At this mean rate of variation the difference of width produced by the above cause alone in a fir board about $12\frac{1}{4}$ inches wide would be $\frac{1}{10}$th of an inch, an amount abundantly sufficient to cause the board to split or crack, if it were fixed immoveably at both edges.

For the above reasons it is always necessary to insert pannels in the framework in which they are mounted, in such a manner as to allow free motion at one or both edges. An ordinary framed door, such as that represented under Door, P. C., p. 86, affords a good example of pannelled work, and one in which this peculiarity may be readily observed. In this kind of door the styles, marked 2, 2, in the cut referred to, the rails, marked 5, 5, and the munions (or, as they are frequently called by workmen, the *muntins*), marked 6, 6, 6, constitute a strong framing of thick but comparatively narrow pieces of wood, the rectangular openings of which, marked 1, 1, 1, 1, are filled with thin boards called pannels, usually cut to one-third of the thickness of the framing. The pannels are slid, before the framing is completely put together, into grooves, ploughed or cut, about half an inch deep, in the inner edges of the framing, into which grooves they are made to fit with sufficient accuracy to prevent shaking or rattling, yet not so tight as to prevent their sliding a little in the grooves, as the pannel shrinks or expands. The usual practice is to fit them just so tight that a little force applied to the edge of the pannel with the palm of the hand, is sufficient to drive it into its place. In new houses it may often be perceived, by the appearance of the paint towards the sides, or rather edges, of the pannels of doors and window-shutters, that, even when not more than nine or ten inches wide, they have shrunk at least one-eighth of an inch since the completion of the painting, notwithstanding the care taken to season them previously; and if observations were made with sufficient accuracy, it would be found that the amount of shrinkage appears to be greater or less according to the state of the atmosphere. The addition of glue or nails to hold the pannel in its place would occasion the pannels to crack or split, which they occasionally do with a noise sufficiently indicative of the irresistible force with which the change of dimension takes place. In superior doors the angle formed between the inner edge of the framing and the face of the pannel is occupied by a moulding, put in with *mitred* joints, which are explained below; in such a case care must be taken so to insert the nails by which the moulding is held in its place, that they may enter *the framing only*, without touching the pannels. In bad work they are often driven carelessly into both, and the almost inevitable consequence is that the pannels crack, in consequence of their freedom of motion being interfered with.

In some cases partitions, wainscotings, and other pieces of joiner's work are framed and pannelled in the same way as ordinary doors, the pannels themselves being, when too wide to be cut out of a single board, composed of two or more pieces united with glue at their edges. Tredgold advises, however, that such pannels should never be made more than fifteen inches wide and four feet deep, and not so large if it can be avoided. A similar construction is also adopted in superior furniture for the backs of chests of drawers, book-cases, &c., as the plan is more effectual than any other for the exclusion of dust. By dividing the width of the back into two or more portions, it reduces the amount of possible shrinkage at any one point; and if the pannels be made to enter the grooves of the framing only a quarter of an inch at each side, each pannel may shrink nearly half an inch without producing any aperture between the pannel and the framing. A simpler but less effectual mode of attaining the same object, which is often adopted for the backs of furniture, and for some other purposes in which an extended surface of boarding is required at less cost than is involved in framing and pannelling, is to fix a series of narrow boards side by side, securing them with a few nails only, without glue, in order that they may retain as much freedom of motion as possible, and *rebating* the adjoining edges, as shown at *a*, *a*, *Fig.* 2. By this arrangement a considerable amount of shrinkage may take place without producing any opening between the adjoining boards, and, if the nails be not fixed too near their edges, sufficient play may be allowed to prevent the wood from cracking.

Fig. 2.



The appearance of such boarding may be improved by forming a bead with a moulding-plane along one edge of each board on the visible side, as at *b*, *b*, *Fig.* 2, because by that means the open joint is in some degree masked by the *quirk* or wide groove on the opposite side of the beading. The same means of avoiding the disagreeable appearance of the opening joint is adopted in some doors and shutters which are framed and pannelled in the usual manner, but in which the pannels are made two-thirds instead of one-third of the thickness of the framing. In this case the edges are rebated to the thickness of an ordinary pannel, and the rebated portion alone is inserted in the grooves of the framing, while the unreduced portion of the pannel is brought *flush* or even with the surface of the framing. This mode of construction is often adopted for external doors, as it allows them to be made strong without any great thickness of framing. At *c*, *c*, *Fig.* 2, is shown another mode of joining boards side by side, which is called *match-boarding*, and is applicable to wood, or *stuff*, of or exceeding half an inch in thickness. This plan is frequently adopted for the kind of inferior doors called *ledged doors*, which, to avoid the expense of framing, are made of narrow boards placed side by side, and held together by transverse pieces called ledges or battens, to which each of the boards is nailed. The joint, as shown in the cut, where it is represented as masked by a bead, consists of a groove cut in the edge of one board, receiving a projecting tongue formed on the edge of the adjoining one. Planes called *match-planes*, made in pairs, one for forming the groove and the other for forming the tongue, are made to facilitate the fitting of match-boarding; but where the joiner does not possess these the groove may be formed with the kind of grooving-plane called a *plough*, and the tongue by cutting away each side with a *rebate-plane*, which is more commonly, though incorrectly, termed a *rabbit-plane*. Similar to this kind of joint is that called *ploughing and tongueing*, in which both edges of every board are grooved, and a separate slip of wood is inserted between them to fill up the grooves. This plan, which involves no waste of material, is often employed in floors.

As indicated by its name, a very important department of the art of joinery is the formation of strong and accurate *joints.* The joints hitherto noticed are not intended so much for holding together the pieces of wood united by them, that object being effected by other means (by the framing, for example, in the case of a framed door or piece of pannelling, and by the ledges or cross-pieces in the case of a ledged door), as for evading the effect of changes of dimension; but we have yet to notice such as are intended to unite the several parts of a framing or other construction. On this branch of the art Tredgold well observes that while in carpentry framing owes its strength principally to the form and position of its several members, the strength of the framings in works of joinery depends wholly upon the joints.

The simplest mode of uniting two pieces of wood is to cut the meeting surfaces so as to fit each other accurately, and to cement them together with glue. [GLUE, P. C., p. 278.] When the glue is good and properly applied a glued joint is surprisingly strong—stronger indeed, in some cases, than the wood itself: if, for example, two boards be glued edge to edge, as for forming a pannel, the wood will break, if sufficient force be applied, without the joint giving way. In forming such a joint the adjoining edges must be planed perfectly straight and smooth, which may be readily done by the use of the simple contrivance called a *shooting-board*, which is a flat board with a perfectly straight edge, and with a cross piece fitted on near one end at right angles with that edge. This board being laid on the bench, the pannel is laid down upon it, with its end against the cross-piece or stop, and the plane, which is laid on its side on the bench, is rapidly slid or *shot* along, being guided by the edge of the shooting-board, and taking a shaving off that of the pannel. Both edges, being thus made true, are smeared with hot glue, and one is rubbed backwards and forwards a few times over the other, to distribute the fluid glue equally, to force it into the pores of the wood, and to squeeze all that is superfluous out of the joint. This done, the boards should be set aside until the glue is perfectly set. To prevent the possibility of any strain which might tend to open the joint while the glue is soft, it is well in such cases to fix the board up edge-ways, so that the weight of the uppermost piece may tend to keep the joint close.

In many other kinds of joint the hold of glue is less perfect in consequence of the impossibility of applying the *rubbing-down* necessary for the purpose above mentioned; and in such cases it is necessary to secure the parts united by it in their places by screwing the article up in an iron cramp, by weighting, or by wedging. From a carefully conducted experiment by Mr. B. Bevan, of which, as well as of his experiments on nails, which are referred to below, an account is given in the article 'Adhesion' in Hebert's 'Engineer's and Mechanic's Encyclopædia,' apparently on the authority of the 'Mechanics' Magazine,' it appears that the adhesion of glue, under favourable circumstances, is equal to a force of at least 715 lbs. per square inch. In the experiment referred to a force of 1260 lbs., applied gradually, was found necessary to separate two cylinders of dry ash-wood, the ends of which presented a surface equal to 1·76 square inch, and which were glued together end to end, and allowed twenty-four hours to set. Even this weight was sustained for two or three minutes before the joint gave way; and it was found, on examining the separated surfaces, that the glue was very thin, and had not entirely covered the surface. The cohesive strength of the glue appears therefore in this experiment to have been rather more than 715 lbs. per square inch, while the cohesive strength of the wood thus united, in a lateral direction, was found to be only 562 lbs., thus showing that, if the joint had been between the sides instead of the ends of the pieces of wood, the wood would have given way before the glue. In this case, however, the glue was newly made, and the season very dry; while in some former experiments, made in the winter season, with glue which had been frequently made, with occasional additions of glue and water, the cohesive force indicated was only from 350 lbs. to 500 lbs. per square inch. On the other hand, Mr. Bevan found the cohesive force of solid glue to be equal to 4000 lbs. per square inch, from which it may be inferred that its application as a cement is capable of such improvement as to show a more satisfactory result than even in the first mentioned experiment. Glue that has been made a long time and kept in store is found to possess greater tenacity than newly-made glue; and for the use of the joiner pale-coloured glue is preferred to that of a dark tint, as it produces neater and less apparent joints. Owing to the use of a darker material, and the less frequent employment of glue in joints exposed to the eye, the colour of his glue is a matter of less importance to the cabinet-maker.

Next to the formation of joints by the simple interposition of glue between the meeting surfaces, we may notice the use of nails or pins of metal, so inserted as to enter both pieces, and to bind them together with a force equal to that required for their extraction. Mr. Bevan's experiments on the adhesion of nails, and of screws, which are often used in superior work instead of nails, and of the manufacture of which an account is given under SCREW, P. C., p. 109, are briefly referred to under ADHESION, P. C., p. 119; but as their results are highly important to the joiner, we here subjoin a tabular view of the results obtained by his experiments on various kinds of nails, driven into dry Christiana deal, at right angles with the grain of the wood:—

Description of nails.	Number to the lb.	Length. Inches.	Depth forced into the wood. Inches.	Power required to extract. lbs.
Fine sprigs .	4560	0·44	0·40	22
Ditto . .	3200	0·53	0·44	37
Threepenny brads	618	1·25	0·50	58
Cast-iron nails .	380	1·00	0·50	72
Sixpenny nails .	73	2·50	1·00	187
Ditto . .	. .	. .	1·50	327
Ditto . .	. .	. .	2·00	530
Fivepenny nails .	139	2·00	1·50	320

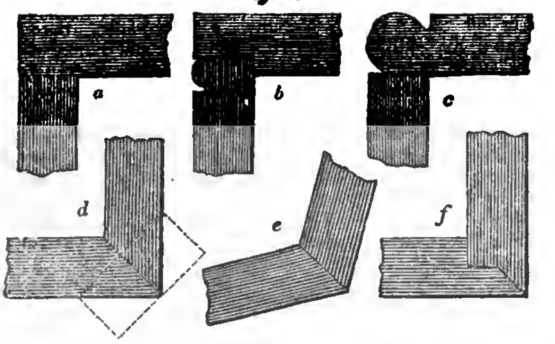
The amount of power required to force a sixpenny nail, of the dimensions above given, into Christiana deal, *by simple pressure*, which affords the most accurate test of the resistance to be overcome, was, for a depth of

One quarter of an inch, a pressure of .	24 lbs.
Half an inch	76 ,,
One inch	235 ,,
One inch and a half	400 ,,
Two inches	610 ,,

In the above experiments, it must be remembered, the nails were driven transversely, or across the grain. The same nails, driven endways, or longitudinally, into the same wood, required a force of only 87 lbs. to extract them from a depth of one inch, and 257 lbs. from a depth of two inches; showing that a nail driven endways into deal has rather less than one-half the adhesion that it has when driven across the grain. In dry elm the hold of the same kind of nail was found to be greater than in deal in both directions, but especially when driven along the grain; the force required to extract it from a depth of one inch, when driven transversely, being 327 lbs., and when driven longitudinally 257 lbs., the relative adhesion in the two directions being in this case rather less than as 4 to 3, whereas in deal it was more than 2 to 1. Experiments with the same kind of nail, driven also to the depth of one inch (transversely, we presume) into dry oak, showed that the force required for extraction was 507 lbs.; in dry beech, 667 lbs.; and in green sycamore, 312 lbs. Mr. Bevan's experiments on nails, of which his own account was published in the 'Philosophical Magazine,' vol. lxiii., p. 168, appear to have been made with *wrought* nails, which, for the ordinary purposes of the carpenter and joiner, have been in a great measure superseded of late years by nails *cut* cold by pressure from thin sheet metal, and subsequently headed by a separate machine. Such nails are cheaper than wrought nails, and, owing to their greater accuracy of form, their sectional form being a perfect rectangle, with sharp defined angles, they have a firmer hold in the wood. They are tougher than wrought nails; but, being softer and more easily bent, they are not adapted for using with hard woods.

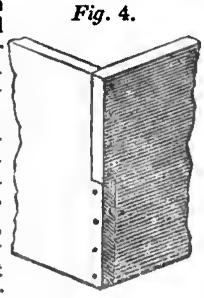
The simplest method of forming an angular joint, to be held together either by glue, or by nails or screws, or by a combination of glueing with nailing or screwing, is by the arrangement shown at *a*, *Fig.* 3, which, however, if nailed, can only be nailed in one direction. For rough work such a joint may do very well, although it is unsightly in consequence of showing the end of the grain of one of the members of the joint, and of the liability of the joint to open a little with shrinkage and warping. The appearance of such a joint may be in some measure improved by the introduction of a small bead on the abutting piece, as at *b*, *Fig.* 3, or, by converting the whole thickness of the end of the overlapping piece into what is termed a *staff-bead*, as at *c*, *Fig.* 3, a plan which is often adopted, with very good effect, in the interior fittings of a house. The kind of joint marked *d*, *Fig.* 3, which is called a *mitred* joint, is neater than the simple joint at *a*, as the end of the grain is nowhere exposed to view, and it allows nailing in both directions; but it is not so secure, and, owing to the

Fig. 3.



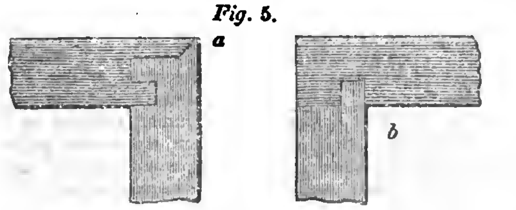
tendency of the inclined faces to slip upon each other, it is difficult to form it with accuracy. It is the joint used for the angles of picture-frames, and for many other purposes in which the joint is exposed to view in the same manner; and in such cases the strength of the joint is often increased by inserting, in a saw-cut made for the purpose in a sloping direction, a thin slip or key of hard wood in the direction indicated by the dotted lines. This key is inserted with glue, and when that is dry, the superfluous corners are cut off. At *e*, *Fig.* 3, is shown a mitred joint at an obtuse angle, to show that this form of joint is applicable to any angle, the plane of the joint being in all cases made to bisect the angle. To facilitate the accurate formation of mitred joints, joiners employ a contrivance called a *mitre-box*, by which they are enabled to saw and plane, or *shoot*, the inclined faces exactly to the required angle. The last joint represented in *Fig.* 3, that marked *f*, is a combination of the overlapping with the mitred joint, much neater, where the angle alone is visible, than the former, and stronger than the latter, like which it may be nailed both ways. *Fig.* 4 illustrates an arrangement almost too simple to need explanation, by which the strength of a nailed joint of the over-lap kind may, with very little extra trouble or waste of stuff, be greatly increased. Simple as it is, however, it is very rarely practised in this country, and, indeed, has never been seen by the writer excepting in tobacco-chests or packing-cases from America. For neater purposes it might be worth while to divide each joint into four or more portions, instead of two only, as in the cut, by which means the tendency of the joint to open by the warping of the wood, or in consequence of external violence, would be still further resisted, owing to the more frequent changes in the direction of the nails.

Fig. 4.



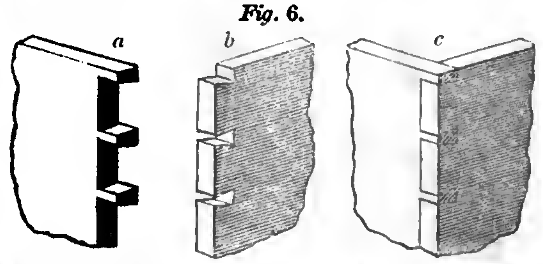
In all the angular joints above noticed, the two pieces of wood which form the members of the joint are held together by the glue, nails, or screws applied to connect them; but in the higher operations of the joiner and cabinet maker, the wood is so cut as in some degree to hold the construction together independently of such aid. In the joints shown in *Fig.* 5, for example, where *a* represents a joint adapted for external angles, and *b* a joint for internal angles, such as those of the skirtings of a room, the form of the joint alone would hold it together, irrespective of any fastenings. The same

Fig. 5.



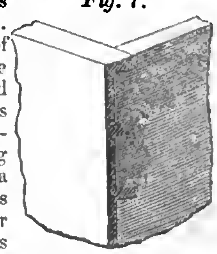
object is attained far more perfectly by the various modes of *dovetailing*, the simplest of which is illustrated by *Fig.* 6, in which *a* and *b* represent, in isometrical perspective, a portion of two boards, such as two sides of a box, or the back and one side of a drawer, cut ready for fixing together by an ordinary dovetailed joint, and *c* shows the joint as it appears when fitted together. It will be evident that, when thus united, the wedge-shaped projections from the end of the piece *a* (from the transverse sectional form of which, somewhat resembling that of a dove's tail, the joint takes its name) must powerfully resist any strain tending to separate the joint, unless that strain happen to be exerted precisely in one direction; while the accu-

Fig. 6.



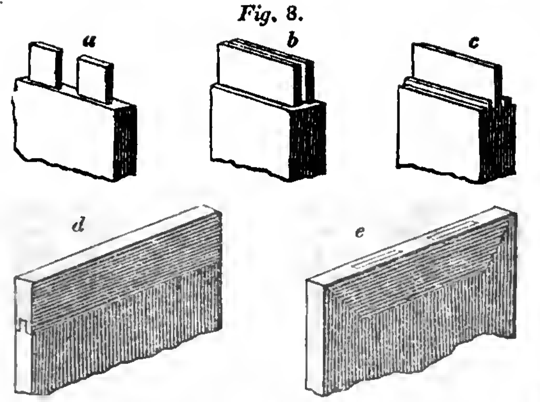
rate fit of the parts, aided by the glue, and in some cases by nails or screws, renders the joint so strong even in that direction that, if properly made, the wood will sooner break than separate at the joint. The small dovetail-shaped projections in the piece *a* are called *pins*, and the openings cut in the end of *b* to receive them, *holes*. When the boards which constitute the members of a long dovetailed joint are composed of two or more pieces glued together at the edges, it is well so to arrange the dovetailing that the glued joint, if in the piece corresponding with *a* in the cut, shall fall in one of the pins, and not in an interval between them, and if in the piece *b* in one of the intervening solid spaces between the holes, and not in the hole itself; because by such an arrangement the driving up of the dovetail tends to hold the glued joint together, while it might otherwise tend to split it open. In connecting the front of a drawer with its sides, it is desirable to conceal the joint entirely on the front face. This is done by the kind of joint shown in *Fig.* 7, which is termed a dovetail blind of one eye. In it the piece forming the front of the drawer is made thicker than the side, and the pins, which are formed on the front piece, are made only as large as if it were of the same thickness as the side, and the intervening spaces are not cut through the extra thickness of the wood. Similar to this is the dovetail *blind of both eyes*, or *mitred dovetail*, in which both pieces are of equal thickness, and the pin-holes, as well as the pins, are stopped about one-eighth or three-sixteenths of an inch from the outer or visible surface of the wood, the extra thickness of the wood thus left uncut being mitred; so that the joint is very secure, but the means by which it is rendered so are completely invisible. Such a joint of course requires very accurate workmanship, to enable all the parts to fit closely without being so tight in any part as to need injurious force in knocking up into its proper position.

Fig. 7.



The only other kind of joint that claims notice here is the *mortise and tenon*, which is the kind of joint usually employed for connecting the several members of the framing of a door or similar piece of pannelled work, as well as for many other purposes. A *mortise* is a deep and narrow groove cut in one member of the framing to receive a corresponding projection called a *tenon*, or, improperly, a *tenant*, formed on the end of another member of the framing which abuts upon it, usually at right angles. Tredgold recommends that the thickness of a tenon, and consequently the width of the mortise to receive it, should be about one-fourth of the thickness of the framing, and that the width of the tenon should never be greater than five times its thickness. A more general rule, however, is to make the tenon one-third the thickness of that part of the framing which it is to enter. When the members of the framing are wide, the tenon is divided by an intervening space into two parts, by which the necessity for weakening the frame by very long mortises is avoided. In *Fig.* 8, *a* represents a divided tenon of this kind, and *b* is what is termed a *double tenon*, which is sometimes used in very thick framing, especially in the framing of doors which are to receive mortise locks, or locks inserted in the thickness of the door, in which case the lock is placed in the interval between the two tenons. In some cases, where a single tenon is used in thick framing, a small projection called a *cross* or *feather-tongue* is formed on each side of it like a very short tenon, as in *c*, *Fig.* 8 shallow grooves or mortises being cut on each side of the principal mortise to receive them.

Fig. 8.



Clamping is an expedient resorted to by the joiner when he wishes to secure a broad board, whether formed of a single piece, or of two or more glued together at their edges (in which case, if the wood be thick, *dowels*, or pins inserted halfway into each of the adjoining pieces, may be used to aid the glue), from liability to warping. It consists in fitting on to each end a transverse piece. as at *d. Fig.* 8, the grain of which runs at right angles with that of the board. The connection between the board and the clamps is effected by a tongue formed on the end of the hoard, visible at the edge in the cut, and entering a groove ploughed in the edge of the clamp. In addition to this tongue, which extends across the whole width of the board, two or three tenons, which may or may not pass completely through to the external edge of the clamp, are frequently formed on the end of the board, in which case the joint is termed a *mortise clamp;* and in some cases where special neatness is required the ends of the clamp are mitred into the board, as at *e, Fig.* 8, which is called a *mitre clamp*, and in which both the tongue and the tenons, if tenons are used, may be made invisible.

Where it is necessary to curve boards by softening them, by boiling or steaming, and forcing them into the required shape (in which they are retained by glueing blocks underneath them and by other means), upon a saddle or mould, Tredgold observes that the process may be improved by saturating the convex side, while the wood is still confined to the mould, with strong glue, which may dry and harden in the extended pores, and thereby tend to keep the wood in the required shape when it is removed from the mould.

The plan of this article does not admit of more than a passing reference to the large subject of geometry as applied to the joiner's art; a subject which is treated at great length in the practical treatises of Nicholson and Tredgold; nor does it allow of any detailed explanation of the modes of executing the various departments of his work, which, together with a full account of the tools employed, may be found in Nicholson's 'Architectural Dictionary.' The tract entitled 'The Joiner and Cabinet-maker,' alluded to near the commencement of this article, will be found an admirable preparative for more expensive works: explaining, as it does by a few familiar examples, in terms easy to be understood, most of the ordinary operations of the joiner, and some of those of the cabinet-maker. Of some of the principal tools used in joinery accounts are given under SAW, P. C., p. 476; BORING INSTRUMENTS, P. C. S., p. 225; and BEVEL, P. C. S., p. 192. Of the other tools commonly employed, *planes*, of which a great number adapted for different uses are required, are the most important. An ordinary plane may be described as a broad and very sharp chisel mounted in a large block of wood in such a manner that it is always kept at a certain angle (varying according to the purpose to which it is to be applied, but commonly about 45°) with the face of the stock, which, by sliding along the board to which the plane is applied, keeps the blade always in the right position for cutting, and prevents it from digging too deep into the wood. The weight and size of the stock also enable the workman to apply the tool with greater effect and steadiness than he could a chisel held in the hand. The degree of projection of the blade from the face of the plane is capable of regulation, and the blade is held in its required position, by a wedge, which may be loosened and the blade caused to rise a little into the stock in case it should become too prominent, or technically, too *proud*, by striking the *heel* or hinder end of the stock with a hammer, or by striking in like manner on the upper surface of the front end of the stock. In planing a board to a smooth surface the workman commonly uses three planes: first, a coarse one, which takes off thick shavings, called a *jack-plane;* then one adapted for taking off very thin shavings and having a very long stock, called a *trying-plane.* The author of the 'Joiner and Cabinet-maker' thinks that this name means *true-ing* plane: the object of the instrument being to make the surface perfectly flat or *true;* but the ordinary name is still more applicable, since the workman in using this plane is continually *trying* where, by any undue prominence in the wood, he can take off a shaving; the length and straightness of the stock, with the angle of which he frequently tests his work as with a straight-edge, prevent the plane from *biting* or cutting where the board is hollow. So soon as the workman finds that he can take a continuous shaving off the whole length of the board with the trying-plane he knows that the surface is rendered sufficiently flat. The third plane used for ordinary work is a small short-stocked plane, called a *smoothing plane*, adapted for application in various directions to parts in which the grain may run irregularly, and for planing up small parts of the work for which the other planes are unsuitable owing to their large size. For such operations as rebating, grooving, or ploughing, and cutting beads and mouldings, other kinds of planes are used, in which both the cutting edges of the blades and the faces of the stocks are so formed as to be exact counterparts of the shape of the rebate, groove, bead or moulding required. In many planes of this character, which save an immense amount of work, besides enabling an ordinary joiner to perform work which even a skilful carpenter could not do so well by hand in ten times the time required with the use of the plane, the blade or *iron* is so fixed as to cross the face of the stock obliquely, that it may the better clear itself of shavings.

In planing a piece of deal or any similar soft wood, it is necessary to avoid meeting the grain, which would cause the plane to stick fast; and when this inconvenience is felt, it may almost always be avoided by turning the wood, and planing in the opposite direction. In planing mahogany and some other hard woods, it is more difficult to avoid meeting the grain, as it will often be found running one way in one part of the board and another way in another. 'To remedy this inconvenience,' observes the author of 'The Joiner and Cabinet-maker,' 'the cabinet-makers' planes are furnished with a double iron: that is, an iron with a flat dull edge is screwed on the face of the cutting-iron so as to prevent the shavings chipping up against the grain.' 'The more cross-grained the wood is,' he adds, 'the closer does the cabinet-maker bring down the dull iron towards the edge of the sharp one, and the finer are his shavings in consequence. The joiner's trying-plane and smoothing-plane, if not his jack also, are likewise furnished with these double irons to be ready to use with hard and cross-grained woods; but when he is planing straight-grained deal, he keeps the dull iron at a good distance, perhaps an eighth of an inch, from the cutting edge, so that the shaving comes off without touching it.' The cabinet-makers' planes are made of a steeper or more upright pitch than those of the joiner; and among the planes peculiar to his business is the *toothing-plane*, which has a nearly vertical blade with a notched or serrated edge, produced by furrows on the face of the iron. It is used principally for roughening the surfaces of veneers and of the wood upon which they are laid, to give a better hold to the glue.

Of turning, which though a totally distinct occupation is an essential adjunct to the art of cabinet-making, an account is given under TURNING, P. C., p. 418; and veneering, which is an important branch of the cabinet-maker's business, is briefly noticed under VENEERING, P. C., p. 206. The last-mentioned process, as applied to the large surface of the top of a chest of drawers, is minutely described in the 'Joiner and Cabinet-maker,' in which work, as well as in the fourth volume of Dodd's 'British Manufactures,' referred to in a previous column, details are also given respecting polishing with linseed oil (called *furniture oil*, when coloured dark to match the mahogany, to which it imparts a darker hue); bees'-wax and turpentine; and especially French polish, which is usually made of gum-shellac, gum-seedlac, and Venice turpentine, mixed in various proportions and dissolved in spirits of wine; but as those matters do not, strictly speaking, belong to the art of joinery, an incidental reference to them in this place is sufficient.

JONES, JOHN, LL.D., was born in the parish of Llandingat, in Caermarthenshire, where his father was a respectable farmer. He was educated at a grammar-school at Brecon, and afterwards became a student at the Unitarian New College, Hackney, where he was a favourite pupil of Gilbert Wakefield.

In 1792 Mr. Jones was appointed classical and mathematical teacher in the Welsh Academy, Swansea, which situation he held about three years, and then settled at Plymouth Dock as minister of the Unitarian congregation at that place, where he remained two years. He then became minister of the Unitarian congregation at Halifax in Yorkshire. In about three years he removed to London, where he resided during the remainder of his life, chiefly occupied as a classical teacher, and preaching only occasionally in the place of others: he never took charge of a congregation. Soon after he came to London he married the daughter of Dr. Abraham Rees; she died without issue in 1815. In 1817 he married again, and had two children, who survived him. He died January 10, 1827, in Great Coram Street, London, and was interred in the burying-ground of St. George's Bloomsbury. A few years before his death he received the diploma of LL.D. from the University of Aberdeen, and was soon afterwards elected a member of the Royal Society of Literature.

Dr. Jones was the author of several works, some of which are religious, chiefly in support or defence of the evidences of Christianity. Of these one of the most important was, 'Illustrations of the Four Gospels, founded on circumstances peculiar to our Lord and the Evangelists,' Lond., 1808, 8vo. In 1803 he published a short Latin Grammar for the use of schools; in 1804, a Greek Grammar, which has been frequently reprinted, but the year before his death he remodelled it, and changed the title to that of 'Etymologia Græca.' In 1812 he published a Latin and English Vocabulary, which he republished in 1825 as 'Anthologiæ Latinæ, or a Development of the Analogies by which the Parts of Speech are derived from each other.'

Dr. Jones's chief work, to which he devoted a great many years of his life, was his 'Greek and English Lexicon,' which was published in 1823, in one volume, 8vo., and again in 1826. Dr. Jones was one of the first to introduce into this country the practice of teaching Greek through the medium of English instead of Latin; and the first Greek and English Lexicon for general use was Dr. Jones's. He afterwards published an abbreviated edition for the use of schools, 'The Tyro's Greek and English Lexicon.'

There have since been several Greek and English Lexicons, not only in England, but in America. Soon after Dr. Jones's came out, Schrevelius's Lexicon was translated into English, and published by Valpy, a new edition of which came out in 1831. In 1826 Dr. Donnegan's Greek Lexicon appeared, and since that those of Groves, Ewing, Dunbar and Barker, Hincks's small School Lexicon, and lastly the Lexicon of Liddell and Scott, which is in one volume 4to., in small type, with many thousands of references, and has already (1845) reached a second edition. It is based on the German work of Passow.

The success of Dr. Jones's Lexicon was very great, and a large impression was soon disposed of. The work, as might be expected, was not without its faults, and was roughly treated in the second number of the 'Westminster Review.'

(*Gent.'s Mag.* 1827; *Journal of Education*, vol. iii., 1823.)

JOSQUIN, DEPREZ—the name which it appears to us, after having collated various authorities, is the true one of this celebrated composer of the most ancient school of part-music —was, there seems little reason to doubt, a native of the Low Countries, though the honour of his birth is indirectly claimed by many Italian writers, while its date still remains a matter of inference; M. Fayolle thinks that the year 1450 may be assumed as the period at which he was born, and we are not inclined to differ from this opinion.

Josquin was a disciple of Johann Ockenheim, 'the oldest composer in parts on the continent,' says Dr. Burney, 'of whose works I have been able to find any remains,' and much of whose reputation arises from his having been the instructor of one who became so eminent. The master and scholar were relatively to each other as Blow and Purcell. On the monument of the former, in Westminster Abbey, it is recorded that he was 'master to the famous Mr. Purcell.' It is probable that Josquin went into Italy when young, and there improved himself in the knowledge of his art; and this may have led to his having been thought a native of that country, a supposition to which the frequent addition to his name of Pratensis, or del Prato (a town in Tuscany), may be attributed. It is certain that he was a singer in the pontifical chapel in the time of Sixtus IV., who sat in the papal chair from 1471 to 1484, for Adami speaks of him, in that capacity, in high terms, as well as of his compositions, calling him 'uomo insigne per l' invenzione.' Quitting Italy, he was, according to Glareanus, appointed Maître de Chapelle to Louis XII., for whom he composed much music (concerning which some amusing stories are told), and a motet or two so contrived that the monarch was enabled to take a part in the performance. Louis had made him a promise of a benefice, but neglected to redeem it. To remind the king the composer produced a motet beginning 'Memor esto verbi tui,' &c. This not producing the intended result, Josquin wrote another, upon the words, 'Portio mea non est in terrâ viventium.' Louis then took the hint, bestowed a benefice, and the composer expressed his gratitude in a third motet, commencing, 'Bonitatem fecisti cum servo tuo, Domine.' But Glareanus remarks that desire proved more inspiring than gratitude, for the two first works very much surpassed the last.

The time of Josquin's decease is not known. He was buried in the church of St. Gudule, at Brussels, where his effigy and epitaph are, we believe, still to be seen. He was a very voluminous composer, and many of his works remain to attest his learning and genius. Hawkins gives a good specimen of them; Burney more than one example; and several are to be found in the British Museum. 'He may,' says Dr. Burney, 'be justly called the father of modern harmony, and the inventor of almost every ingenious contexture of its constituent parts, nearly a hundred years before Palestrina, Orlando di Lasso, Tallis, or Bird, the great musical luminaries of the sixteenth century, whose names and works are still held in the highest reverence, by all true judges and lovers of what appears to me the true and genuine style of choral compositions.'

JOUVENET, JEAN, a celebrated French painter during the reign of Louis XIV., was born at Rouen in 1644. He was first instructed by his father Laurent Jouvenet, but completed his studies in Paris, where he soon attracted the notice of Lebrun, who in 1675 procured him his election into the Academy of Painting for a picture of Esther before Ahasuerus, which is one of the best paintings of the Academy collection. Jouvenet had obtained considerable distinction two years previously by his picture of the Lame Man healed, which was the so-called May Picture (Le Tableau du Mai) of 1673. The May Picture is a painting which was formerly presented on the 1st of May of every year to the Virgin, in the cathedral of Notre Dame, by the Goldsmiths of Paris: the practice ceased in 1708. Jouvenet became successively professor, director, and perpetual rector of the Academy, and he was granted a small pension by Louis XIV. He died in 1717.

The French boast of Jouvenet, as of Le Sueur, because he never visited Italy; and it is for the same reason, according to some, that he is censured by Count Algarotti, who, they say, had no faith in an excellence that could be acquired out of Italy. The works of Jouvenet are not brilliant in any respect or even attractive, yet they possess all the greater merits of a picture in more than an ordinary degree. His style resembles that of Nicolas Poussin, especially in composition and colour; and he excelled in light and shade, but in expression he was never great.

Jouvenet's last work, the Visitation of the Virgin, or Le Magnificat, in the cathedral of Notre Dame, was painted with his left hand in 1717. He had a paralytic stroke in 1713 and lost the use of his right hand, but upon the first trial he found his left as obedient to his will as his right had been; one of the many proofs that, in art, it is not the hand but the mind that requires the education.

There are ten of Jouvenet's pictures in the Louvre, some of which are his best works, as the Miraculous Draught of Fishes, the Resurrection of Lazarus, the Sellers driven from the Temple, Christ in the House of Simon the Pharisee, and the Descent from the Cross. The first four have been worked in tapestry of the Gobelins, and they have all been engraved, as have also nearly all Jouvenet's best works, by some of the best French engravers—by H. S. Thomassin, J. Audran, E. Picard, L. Desplaces, A. Loir, A. Trouvain, and others. There are works by Jouvenet in many of the churches of Paris, mural and easel pictures. Of his mural paintings the principal are the colossal frescoes of the Apostles painted on the dome of the church Des Invalides.

(D'Argenville, *Abrégé de la Vie des plus fameux Peintres*; Watelet et Levesque, *Dictionnaire des Arts*, &c.; Gault de Saint-Germain, *Les Trois Siècles de la Peinture en France.*)

JOUVENCY, PIERRE, was born at Paris in 1643: he studied at Caen and afterwards at La Flèche, with considerable success, and was at an early age admitted a member of the Society of the Jesuits. He devoted himself chiefly to history, and is the author of the fifth part of the History of the Jesuits from 1591 to 1616, which was published at Rome in 1710. Though an agreeable writer, from the purity and elegance of his style, his facts are not to be implicitly relied on. So bigotedly was he attached to his order, that he has written an apology of the Jesuit Guignard, who was executed in the reign of Henry IV. of France, on account of his participation in the attempt made against the life of that monarch by Jean Châtel, who had been incited to commit the crime by the seditious writings of Guignard. An abridgment of his history was published at Liege in 1716, which is now rarely to be met with. The other works of Jouvency are—1, A Collecection of Latin Harangues, pronounced by him on different occasions; his Latinity, though it has been blamed by Vallart, is generally admired. 2, A treatise 'De Arte Docendi et Discendi,' which is in some esteem, but considered too superficial. 4, 'Appendix de Diis et Heröibus Poëticis,' a useful abridgment of mythology. 5, A Collection of Notes on Horace, Persius, Juvenal, Martial, and the 'Metamorphoses' of Ovid, which is considered his most valuable production. He died at Rome in 1719, while engaged in the continuation of the History of the Jesuits. His name is mentioned in the art. JESUITS, P. C., among the distinguished members of that Society.

JUDGE (from the French *juge*, which is from the Latin *judex*). [JUDEX, P. C.] A judge in England and Wales is a man who presides in a court duly constituted, declares the law in all matters that are tried before him, and pronounces sentence or judgment according to law. There are judges of the three Superior Courts of Law at Westminster, judges in the Courts of Equity, a judge in the Court of Bankruptcy, judges of the Insolvent Court, judges in the Ecclesiastical and Admiralty Courts, and some others. Some judges are called Recorders, and there are other names, but the name does not alter the nature of the offence. When the judges simply are spoken of, the judges of the superior courts of common law are meant. There are fifteen judges of these courts: five in the Court of Queen's Bench, five in the Court of Common Pleas, and five in the Court of Exchequer. There are at present five judges in Equity. [COURTS, P. C.; EQUITY, P. C.]

The judges of the superior courts of law are appointed by the crown. They hold their office during good behaviour, but they can be removed by the crown on the address of both houses of parliament (13 Wm. III. c. 2). Formerly their commissions ceased upon the demise of the crown, but by the 1 Geo. III. c. 23, they continue to hold their office during good behaviour notwithstanding any demise of the crown, and their salaries are secured to them so long as they hold their office. The judges of the courts of Equity are also appointed by the crown. [CHANCELLOR, P. C.; CHANCERY, P. C.]

By various acts of Parliament retiring pensions of a determinate amount may be granted to the fifteen judges of the three superior courts of law, and to the judges in Equity. The lowest retiring pension is 3500*l.*, and this amount may be given to all puisne judges of the three courts. The highest retiring pension is 5000*l.*, which may be granted by the crown to the lord chancellor upon his resignation. But to be entitled to these pensions all the judges of the superior courts of law, and the judges in Equity, except the lord chancellor, must have held the office for fifteen years, unless bad health has prevented them from holding office so long.

Judges of Courts of Record [COURTS, P. C.] are not liable to prosecution for anything done by them as judges, but they may be prosecuted in parliament. Nor are they liable to an action for any error in judgment or for wrongful imprisonment, at least when they are acting within their jurisdiction. Judges are punishable for bribery, by loss of office, fine, and imprisonment.

The powers and duties of judges would form the subject of an elaborate treatise. It may be sufficient to observe that in England the judges of the superior courts are so well protected in the discharge of their duty and so sure in their office, as to make them entirely independent of all political and private influence, and they are paid well enough to secure them against all temptation of lucre. Accordingly an instance of misconduct in any judge of the superior courts of law, or any judge who holds a high office, is now seldom or never heard of. The only question that can be raised is, whether the most competent persons are always appointed, and whether persons are not sometimes appointed who, though not absolutely incompetent, are much less competent than others, and sometimes hardly competent. The danger is somewhat limited by public opinion, and particularly by the opinion of the members of the bar, so that the risk of a totally incompetent person being appointed is not great. But as the appointment of the judges in the superior courts of law, and the judges in Equity, is really made by those who for the time act as the ministers of the crown, the appointments of judges are, like other appointments made by the ministers, nearly always conferred on those who belong to the political party which for the time is in power. This evil, so far as it is an evil, is inseparable from the practical working of the constitution, and is probably a much less evil than any other mode of appointment that could be suggested.

JUDGMENT is the sentence of the law pronounced by the court upon the matter in the record, and the remedy prescribed by law for the redress or punishment of injuries; the suit or prosecution being the vehicle by which the injury is brought before the court. Judgments are given under four heads of issues: on Demurrer, where the facts are confessed by the parties, and the law determined by the court; on Verdict, where the law is admitted and the fact disputed; by Confession or Default, where the defendant admits both the law and the fact; and on Nonsuit or Retraxit, where the plaintiff acknowledges that neither the law nor the facts are sufficient to support his case, and therefore abandons the prosecution.

Judgments are either interlocutory or final. Interlocutory judgments include all those which are given on account of the incomplete state of the case as brought before the court, and which do not go to the absolute merits of the case: such as judgments on pleas of abatement. But the largest class to which this term is applied are judgments which, although they decide the right between the parties, require some other proceeding to determine the amount to be recovered. This proceeding is commonly a writ of inquiry, directed to the sheriff, who therefore impannels a jury, and proceeds to assess the amount of damages to which the party in whose favour the interlocutory judgment has been given is entitled. If, however, the suit is for a specific thing or sum, the decision of the court determining whether the plaintiff is or is not entitled to recover the remedy he sues for, the judgment is final.

In cases of trial at Nisi Prius or at bar, after the expiration of four days from return of the writ of distringas in the former case, and of the delivery of the verdict in the latter, the party obtaining the verdict may sign judgment. During the lapse of these four days the opposite party may prevent judgment from being signed by moving the court for a new trial in case of any objection to the proceedings; for arrest of judgment, if anything bad appears on the record; for judgment *non obstante veredicto*, that is, that judgment may be given in his favour, notwithstanding the verdict, when the plaintiff conceives that a plea of confession and avoidance in which a verdict has been given for the defendant is improper; for repleader, when the pleading failed to raise the material question; or for a writ of *venire facias de novo*, when some form, as by improperly choosing the jury, has been violated. After the expiration of these four days, the plaintiff or defendant may obtain the signature or allowance of the proper officer of the court, stating that the judgment is in his favour. This is called signing judgment. By the statute 1 Wm. IV. c. 7, it is enacted, that if after any action or suit a judge certifies that execution should issue forthwith or at some time named in the certificate, judgment may be signed immediately, and entered upon the records as of the day on which judgment is signed.

The nature or form of the judgment varies according to the nature of the action, the plea, the issue, and the manner and result of the decision:

1st. If the issue be for the plaintiff.

If it be an issue at law arising upon a dilatory plea, the judgment is, that the defendant answer over, and is called a *respondeat ouster*. Upon all other issues in law, and generally in fact, the judgment is that the plaintiff do recover, which is called *quod recuperet*.

2nd. If the issue be for the defendant.

The issue being on a dilatory plea, whether of law or fact, the judgment is, that the writ or declaration be quashed or the suit be abated; if the issue be on a peremptory plea, the judgment is that the plaintiff take nothing, which is called a judgment *nil capiat*. When judgments are given by default, or confession without issue, if for the plaintiff, they are *quod recuperet*, if for the defendant, *nil capiat*.

Besides the question at issue being decided by the judgment, the costs of the suit are generally directed to be taxed and paid by the party against whom the judgment is delivered. In addition to this, the judgment, when given for the plaintiff, orders that the defendant 'be in mercy,' that is, amerced or fined for his delay of justice; and when for the defendant, that the plaintiff 'be in mercy' for his false claim.

Judgment being signed, the party in whose favour it is given may sue out execution thereon, directed to the sheriff of the county where the property to be taken is situated. At common law, the goods and chattels of a debtor under a writ of fieri facias, and the growing profits of the land under a levari facias, could alone be taken in execution by a judgment creditor for debt or damages. The remedy was extended by the 13 Edw. I. stat. 1, c. 18 (West. 2), to the creditor over a moiety of the real property of the debtor; for which purpose a writ called an elegit was created, including all freehold estates and interests which the debtor held in severalty, coparcenary, or in common, and all rent charges; but copyholds were held not to be liable to be taken in execution under this writ. By a fiction of the law, judgments were considered to take effect from the first day of the term in which they were signed, and therefore a purchaser might have his estate encumbered by a judgment acknowledged subsequently to the purchase. To remedy this injustice it was enacted by the Statute of Frauds (29 Car. II. c. 3), that any judge who should sign judgments, should at the time of signing set down the exact date thereof, which date should be also written on the margin of the record when the judgment was entered, and such judgments should operate from the date appearing on the margin. As, however, this did not compel the plaintiff to bring in the judgment roll, it was almost impossible for purchasers to discover what judgments existed against the lands about to be conveyed. An act, therefore, was passed (4 & 5 Wm. & Mary, c. 20), afterwards made perpetual by the 7 & 8 Wm. III. c. 36, which directed that the clerk of the Court of C. B., the clerk of the Dockets of the Court of B. R., and the master of the office of pleas in the Court of Exchequer, should keep an alphabetical list or docket of all judgments in their respective courts, entered according to the names of the defendants; and that no judgments should affect lands in the hands of bonâ fide purchasers, unless so docketed according to the act. How this law has been altered by recent statutes will be hereafter considered. For the purpose of discharging a judgment the proper mode is to enter up satisfaction on the court rolls, but a deed of release will have the same effect although the judgment be allowed to remain; and it has been held that a release of all suits is a complete discharge of all unsatisfied judgments. If execution be not sued out within a year and a day of signing the judgment, it must be revived by a writ of *scire facias*, and a judgment was presumed to be satisfied after a lapse of twenty years from the signing or the last revival, which is now confirmed by the statute of the 3 & 4 Wm. IV. c. 27.

The entering the judgment on record, except in the cases specified by the act, where the lands in the hands of purchasers are to be affected, is not absolutely necessary. But to support a writ even brought for the purpose of reversing the judgment, the judgment must be entered on the records of the court.

Recent statutes have introduced great changes in the law of judgments as they affect real property, but as the same rules which existed before those enactments are still under certain circumstances capable of application, it may be useful first to consider how judgments then stood.

A judgment at the time of entering up became a general lien upon all property, real and personal, which the debtor then held or subsequently acquired, and gave the creditor a legal right, so long as the judgment remained on the records of the court and unsatisfied, to enter upon and reduce into possession any such property, by suing out the writ of fieri facias, if the goods and chattels of the debtor were to be taken in execution, or the writ of elegit as to his real estate, thereby changing that which was before a naked right into an absolute interest, limited nevertheless to the amount of the debt or damages for which judgment was originally entered up.

As to personal estate, it was enacted by the 16th section of the Statute of Frauds, that the goods of the debtor should be bound by a judgment only from the time of taking out execution. And on the interpretation of this clause it was held that chattel interests in land were included under the term goods. This clause still remains in full effect, although in the case of a fraudulent assignment after entering up judgment and before execution, a court of equity would assist the judgment creditor to follow the goods into the hands of the assignee.

The rights of the judgment creditor existing only at law over the personal property of the debtor, which was afterwards extended to a moiety of the real estate, at law the legal estate was only affected, and therefore, by the subsequent creation of trusts, the judgment creditor was frequently prevented from obtaining that remedy at law against the debtor to which he otherwise would have been entitled. To remedy this inconvenience, and enable the judgment creditor to obtain execution on the beneficial interest in any portion of the property of the debtor, it was enacted by the Statute of Frauds that execution should be delivered of all such lands, tenements, rectories, tithes, and hereditaments, as any other person or persons should be seised or possessed of, in trust for him against whom execution was so sued, like as if the debtor had been seised of such lands and of such estate as they be seised of in trust for him at the time of the execution sued. On the interpretation of this statute, it was held that an equitable interest in a term of years was not included within its limits, and only such trust estate as the debtor was interested in at the time the execution was sued out, and in which he had the sole beneficial interest. In this case the judgment creditor had no execution at law, but he might come into a court of equity and claim the same satisfaction out of the equitable interest as he would have been entitled to at law if it were legal. As however the sole right of coming into a court of equity was based on the failure of the law, it was necessary that the judgment creditor should forfeit his title to the utmost by suing out his writ of elegit before the court would listen to any application to remove the legal impediment. Upon the same principle that it assisted the creditor who had no relief at law, the court of equity did not permit a judgment against a trustee, though at law a lien upon the estate to affect the beneficial interest of the cestui que trust.

As under the last mentioned clause of the Statute of Frauds a judgment did not affect the legal estate in the hands of the trustee, until the writ was absolutely deposited in the hands of the sheriff, a purchaser of the equitable estate without notice might by getting in the legal estate protect himself against prior judgments; but if the purchaser bought with notice of the judgment, no acquisition of the legal estate would protect him. Equities of redemption were decided to be not such trust estates as to be included by the Statute of Frauds, the debtor not having the sole beneficial interest.

In the case of lands contracted to be sold, the purchaser is relieved in equity against judgments entered up subsequently to the contract; and also where land is conveyed to trustees for sale, whose receipts are to be sufficient discharge, the purchaser will not be bound by any subsequent judgments of which he has even express notice.

Until the passing the acts of the 1 & 2 Vict. c. 110, 2 & 3 Vict. c. 11, and 3 & 4 Vict. c. 82, the law of judgments remained in the main unchanged. By them decrees and orders of Courts of Equity and rules of Courts of Common Law, and orders of the Lord Chancellor in matters of bankruptcy and lunacy, are given the effect of judgments, and the security of the creditor has been extended from a moiety to the whole of the debtor's lands, including copyholds, making leaseholds bound in the same manner as freeholds. And as all lands are included by the acts, over which the debtor may have a disposing power, judgments against a tenant in tail are binding on his issue; for the tenant might at any time have barred the entail. So also were equities of redemption and trust estates, in which the debtor had only a partial interest. After passing this act a question was raised whether stock was comprised, in which the debtor had only a partial interest, but this was set to rest by a clause of the second act, mentioned above, which distinctly declares that the interest of the judgment debtor, whether in possession, remainder, or reversion, in any stocks, funds, or shares, as also in the dividends and annual proceeds of such stocks, &c., is to be liable to the judgment, and that stock standing in the name of the accountant-general is to be in the same position. Money and securities for money (except where deposited in the hands of a third person as a trustee) can also be taken in execution. But the greatest alteration which recent statutes have worked is changing the effect of judgment before execution is sued out, from a general lien to a specific charge upon the 'lands, tenements, rectories, advowsons, tithes, rents, and hereditaments' of which the judgment debtor may, at the time of entering up judgment, or at any time afterwards be possessed, of any estate whatsoever, at law or in equity, or over which he may have any disposing power. All judgments are made binding on the persons against whom they are entered up, and against all persons claiming through them, the judgment creditor being entitled to the same remedies in a court of equity as if the debtor had by writing agreed to charge the lands, &c. The creditor is not however to proceed in equity to obtain the benefit of such a charge until the expiration of one year from the time of entering up such judgment; and in case of bankruptcy, the judgment, unless entered up one year, is to give no preference to the judgment creditor beyond creditors for simple contract. A special proviso excepts purchasers, mortgagors, or creditors previous to the time when the act came into operation; and with respect to purchasers for valuable consideration without notice, the rules of equity remain unaltered.

A judgment creditor, applying now for remedy to the Court of Chancery, will not be obliged to sue out the writ of elegit, for that which is agreed to be done is considered by a Court of Equity as actually performed, and the judgment creditor has therefore, by virtue of his judgment alone, an equitable estate. If however a judgment creditor, having obtained any charge, or being entitled to the benefit of any security, should, before the property so charged or secured is converted into money and applied towards the payment of the judgment debt, cause the judgment debtor to be arrested, the benefit of such charge or security is deemed relinquished. The extent of such charge goes now to the interest at the rate of four per cent. on the judgment debt, as well as to the debt itself.

The dockets which existed since the 4 & 5 W. &. M. are now finally closed, and no judgment, decree, or order, by virtue of the 1 & 2 Vict. c. 110, can affect purchasers, mortgagors, or creditors, unless and until a memorandum or minute of the judgment, &c., with the person's name against whom and the date when it was recovered, is left with the senior master of the Common Pleas at Westminster, who is to enter the same in a book kept for the purpose, in an alphabetical order by the name of the person whose estate is to be affected. In order to keep alive old docketed judgments, it was made necessary to register them according to this provision before a certain time fixed by the act, or they would be deemed satisfied.

Under the old law a purchaser was bound by undocketed judgments of which he had notice, and it would seem that an unregistered judgment is now entitled to the same consideration as an undocketed judgment was, it being expressly provided by the late acts that the judgment creditor shall not take advantage of the extended remedies unless the judgment be duly registered according to their provisions. [NOTICE, P. C.] The necessity for searching for judgments on the transfer of property is also greatly reduced, for the 2 & 3 Vict. c. 11 requires all judgments to be re-registered every five years from the date of the last registry, otherwise they are to be considered as void against purchasers, mortgagors, and creditors. But here again it may be presumed a purchaser with notice of a registered judgment more than five years old will be bound by all the remedies to which recourse might have been had by the judgment creditor previous to the passing of the late statutes. The provisions for registration, it must however be remembered, refer to the remedies which the judgment creditor may have against purchasers for valuable consideration with notice; but as between the creditor and the debtor, or his representatives or volunteers, the judgment remains in full effect until twenty years from the time of entering up or last revival. The position in general of judgment creditors among themselves before the late acts depended on the time when they respectively sued out execution; but in a suit for the general administration of assets the judgment creditors took priority according to time of the entering up their judgments. Now as they are entitled to such remedies in equity as if the debtor had by writing charged his land, they take priority in respect of their judgments from the times of registration. It has been questioned whether a subsequent judgment creditor without notice having sued out his writ of elegit is not entitled to priority over an equitable mortgagee, but the point has been decided in favour of the latter, upon the principle, that although the judgment creditor by his writ of elegit obtained possession of the legal estate, and thereby in equity, under the ordinary rules, could claim a priority to a prior equitable incumbrance of which he had no notice, yet that the legal estate which the creditor obtains under an elegit is only such a one as the debtor himself had power to grant, and therefore liable to all prior equities. (Whitworth *v.* Gaugain, 3 Hare, 461.)

By these statutes judgments of the courts of the counties Palatine of Lancaster and Durham are to have the same effect as judgments of the superior courts of Westminster. But no judgment of those courts is to affect lands in the hands of purchasers, mortgagors, or creditors, unless a memorandum of such judgment be left with the prothonotary or proper officer, who is to register the same in a book kept for the purpose.

Judgments or rules or orders of inferior courts of record, in which a barrister of not less than seven years' standing shall preside, may receive the same effect as those of a superior court by a judge's order to remove them into a superior court. But until execution be actually sued out, they will not affect lands in the hands of purchasers, mortgagors, or creditors, except so far as they would affect them as judgments of an inferior court.

In criminal proceedings, after trial the defendant can move in arrest of judgment at any time before judgment is pronounced, but this can only be done upon error appearing on the face of the record, and no motion of this sort can be made in the defendant's absence unless a verdict is found in which the jury reserve a point for the consideration of the court. After the judgment is recorded, a writ of error is necessary before it can either be reversed or altered. Formerly no judgment affecting the liberty of the individual could be pronounced in his absence, but this has been altered by the 11 Geo. IV. & 1 Wm. IV. c. 70, which enacts that upon trials for felonies or misdemeanors judgment may be pronounced whether the person affected be present or absent, except only in such cases of information filed by leave of the Court of King's Bench or in cases of information filed by the attorney-general where he prays that judgment may be postponed. The judgment of the court extends to the life and liberty of the offender according to punishment decreed to the offence against which the judgment is delivered. In some cases it extends to the compensation by forfeiture of the lands or goods, or both, of the offender; others induce a disability of holding offices or fix a lasting stigma on the offender; and a large proportion are merely pecuniary by stated or discretionary fines.

On the subject of judgments see Chitty's *General Practice*; Stephen, *On the Principles of Pleading in Civil Actions*; Sugden's *Vendors and Purchasers*; Prideaux, *On the Law of Judgments as they affect Real Property*.

JUGGURNAUTH, TEMPLE OF, in Hindustan, is situated in the province of Orissa and district of Cuttack, in 19° 47′ N. lat., 85° 53′ E. long., about 45 miles south from the city of Cuttack, and 311 south-west from Calcutta, direct distances. The temple, which is named after the Hindu idol Juggernauth (properly *Jagannatha*, 'lord of the world'), placed within it, stands on the coast of the bay of Bengal, and is a huge architectural mass, a sort of pyramidal tower, 200 feet high, built of coarse red granite, and covered with a rough coating of chunam. It stands in the centre of a quadrangle enclosed by a high stone-wall, each side of which is 650 feet long. It is a very conspicuous land-mark, and is of considerable importance to navigators on the flat and uniform coast where it is situated. The country, to the distance of about a mile from the sea, is a waste of deep loose sand; farther inland it consists of low sand-hills covered by a thick forest of dwarf trees. The quadrangular inclosure is at the end of the principal street of the sea port town of Pooree, or Jagannathpoor, a place of considerable size, but ill-built and dirty. The temple has no claim to very high antiquity, and Rennell supposes that it succeeded the Temple of Somnaut, in Guzerat, which was destroyed by Mahmood in the 11th century. All the authorities agree in stating that it was erected in the 12th century.

The festival of Jagannath takes place every year, and the number of pilgrims is still very great, though much less than formerly, when Dr. Carey estimated them at 1,200,000. Three idols, gigantic busts, hideously ugly, mounted on pedestals which are concealed by drapery, are placed on thrones on a lofty platform, which rests on sixteen wheels, each 6½ feet in diameter; and it forms altogether a monstrous car, or rath, 43 feet high and 35 feet square. Cables are attached to the car, and by these the pilgrims drag it about a mile and a half to its destination, and then back again, the whole procession occupying three days. The principal idol is a representation of Krishna; the others are Bala Rama his brother, and Soobhadra his sister.

Mill, in his 'History of British India' (b. ii. c. 6), says, 'It is customary for numbers of congregated persons to throw themselves under the wheels, and even fathers and mothers with their children in their arms. The chariot passes on, as if no impediment existed, and crushing them to death is supposed to convey them immediately to heaven.' On this passage Professor H. H. Wilson, in his new edition of Mill's work, has the following note (vol. i., p. 416):—'It is no little exaggeration to say that numbers of the congregated people throw themselves under the chariot wheels. Mr. Stirling, who was resident in Orissa for four years, mentions, that during that period there were no more than three such immolations; and of these one was possibly unintentional, whilst the other two were cases of painful and incurable disease. But this practice is modern: Jagannath himself is modern, and has no place in the Vaishnava Puranas. It is not improbable that the present shrine attained reputation as a place of pilgrimage no longer ago than a century' (that is, in 1740).

(Hamilton, *East India Gazetteer;* Emma Roberts, *Scenes and Characteristics of Hindustan;* Rennell, *Memoir of a Map of Hindustan*; Mill, *History of British India*, by Wilson; Wilson, *Sanscrit Dictionary*.)

JULIA'NUS, SALVIUS, was probably a native of Milan. He was the great-grandfather of the Emperor Didius Julianus. (Aelianus Spartianus, *Didius Julianus*.) Julianus was twice consul, and also Praefectus Urbi. He mentions his own consulship and office of Praetor Urbanus; and he also speaks of having been in Egypt (*Dig.* xlii. tit. 2, s. 5; xlvi. tit. 3, s. 36). Julianus was a distinguished jurisconsult, and one of the Consiliarii of Hadrian; and he may probably have attained the honour of the consulship under this emperor. Lampridius (*Commodus*, c. 3) speaks of the Emperor Commodus soliciting the chastity of a son of Salvius Julianus, and of his putting the father to death; but this cannot be the jurisconsult Julianus, who probably died in the reign of Antoninus Pius. The sepulchre of the Jurisconsult was on the Via Lavicana, five miles from Rome, according to Spartianus; and his descendant the Emperor Didius Julianus was buried in the same tomb. (*Didius Julianus*, c. 8.)

Salvius Julianus was a pupil of Javolenus Priscus, and therefore one of the Sabiniani. His authority was very great among the Roman jurists, and he is oftener cited than any other writer by the Roman jurists, even more frequently than Labeo. The great work with which his name is connected was the 'Edictum Perpetuum,' which was compiled in the time of Hadrian. [EDICTAL LAW, P. C. S.] His principal legal work was Ninety Books of Digesta. There are 457 excerpts from Julianus in the Digest of Justinian, and chiefly from the work just mentioned. There are also mentioned, in the Florentine Index, Six Books Ad Minucium, Four Books Ad Urseinm, and One Book On Ambiguities (De Ambiguitatibus).

JURIEU, PIERRE, was born in 1637, and was the son of a Protestant minister at Mer, in the diocese of Blois, and nephew of the celebrated Rivet and Du Moulin. When of age to enter the ministry, he succeeded his father in his pastoral office. His reputation for learning afterwards obtained for him the situation of Professor of Theology and the Hebrew language at Sedan. When in 1681 the Protestants were deprived of the permission to give public instruction in that town, he retired to Rouen, and from thence went to Rotterdam, where he was appointed Professor of Theology. In that city the ardour of his zeal soon drew him into controversy with Bayle, Basnage, and Saurin; in the heat of which he manifested the same rancour which unfortunately disgraces most of his polemical writings. He allowed himself likewise to fall into various errors by too much indulging a naturally lively imagination in the interpretation of prophecy. In his Commentary on the Apocalypse he even predicted the establishment of Protestantism in France during the year 1686. Those who differed from him in opinion, however high their character for learning and piety, he treated with a most unbecoming severity. Grotius and Hammond, perhaps the two greatest theologians of their age, because they differed from him on the subject of the Antichrist predicted in the Book of Revelations, he styles 'the disgrace of the Reformed Church, and even of Christianity.' The same spirit is manifested in his well-known controversy with Bossuet, Bishop of Meaux, whom he does not scruple to accuse of falsehood and dishonesty, though, on the other hand, it must be allowed that the recriminations of this celebrated defender of the Church of Rome, if more politely expressed, are equally severe and destitute of truth; the great object of Bossuet being, it would appear, to charge his antagonist with holding the heretical opinions of Socinus. (Bossuet, *Hist. des Variations*, vol. iv. p. 64; vol. v. p. 236-238.) With all these defects Jurieu stands deservedly high as a controversialist: his learning was most profound, he is generally exact in the citation of his authorities, and he had a special talent in discovering the weak point in the cause of his antagonists. In respect of style and eloquence he is immeasurably behind Bossuet, but he is at least his equal in polemical talent, and by some is considered his superior in erudition. Jurieu's private life was becoming that of a Christian minister: he was charitable to the poor almost beyond his means, and he employed the great influence he possessed with the foreign courts in alleviating the sufferings of his exiled brethren. He died at Rotterdam on the 11th of January, 1713. His works, which are very numerous, were extremely popular in their day, and many of them are still held in high estimation by theologians of every school, on account of the great learning which they display. The principal of them are—1, 'A Treatise on Devotion.' 2, 'Defence of the Morality of the Reformed Church,' Hague, 1685, in answer to a work by Arnauld, entitled 'Morality destroyed by the Calvinists.' 3, 'A Preservative against Change in Religion;' which was written to refute Bossuet's 'Exposition of the Catholic Faith.' 4, 'Letters against the History of Calvinism by De Maimbourg,' 2 vols. 5, Another collection of controversial letters, entitled 'The last Efforts of oppressed Innocence.' 6, 'A Treatise on the Church.' He considers it composed of all Christian societies who hold the common principles of the Christian faith. This treatise is sometimes accompanied by a Reply to Nicolle, who had written a work in refutation of it. 7, 'A History of the Doctrines and Worship of the Jews,' Amsterdam, 1704, with a Supplement published in 1705. 8, 'A Treatise on Mystical Theology,' composed on the occasion of the well-known controversy between Fénelon and Bossuet.

JURISDICTION. This term is the Latin word Jurisdictio, which simply signifies the 'declaration of jus or law.' He who had jurisdictio was said 'jus dicere,' to 'declare the law.' The whole office (officium) of him who declared the law was accordingly expressed by the word Jurisdictio. (*Dig.* 2, tit. *De Jurisdictione*.) Jurisdictio was either voluntary (voluntaria) or litigant (contentiosa). The jurisdictio voluntaria related to certain acts, such for instance as those forms of manumission and adoption which must be done before a magistratus in order to be valid. The jurisdictio contentiosa related to litigation, and such legal proceedings were said to be 'in jure,' before the magistratus, as opposed to the proceedings before a judex, which were said to be 'in judicio.' The magistratus was said 'jus dicere' or 'reddere,' when he exercised his functions; and 'magistratus' and 'qui Romae jus dicit' are accordingly convertible terms. Jurisdiction in England means an authority which a court of law or equity has to decide matters that are litigated before it or questions that are tried before it. The courts at Westminster have jurisdiction all over England and Wales; but the jurisdiction of other courts is limited by being confined to certain limits of space and to certain kinds of causes or matters in dispute. When the jurisdiction of a court extends all over England, it may still be limited as to the kind of causes which it tries. Thus the superior courts of law and the courts of equity have their several jurisdictions as to matters which they hear and determine. [EQUITY, P. C.] The ecclesiastical courts also have their separate jurisdiction; and other courts, such as the Court of Insolvency, Borough Courts, and others, have their several jurisdictions. It follows, that if proceedings are commenced against a man before a court which has no jurisdiction in the matter brought before it, the defendant may answer by alleging that the court has no jurisdiction; which is called pleading to the jurisdiction. When a party is convicted by a court that has no jurisdiction in the matter, the proceedings may be moved into the Court of King's Bench by the writ of Certiorari and quashed. [CERTIORARI, P. C.] Those who have limited jurisdiction are liable, it is said, to an action, if they assume a jurisdiction which they have not.

JUSTICES, LORDS. Our kings have been, ever since the Conquest, in the habit of appointing, as occasion required, one or more persons to act for a time as their substitutes in the supreme government either of the whole kingdom or of a part of it. When William I. returned to Normandy the year after the Conquest, he left his half-brother Odo, Bishop of Bayeux, and William Fitzherbert, to be *Custodes Regni*, or guardians of the realm, during his absence; and similar appointments were very frequent under the early Norman and Plantagenet kings. There is a commission of a Custos Regni in Rymer of the reign of John. One by Edward I. to the Earl of Pembroke describes the powers of the office in terms which imply that it had long been familiar, as extending over all those things which pertain to the said custody (quae ad dictam custodiam pertinent); and the same words are common in subsequent commissions. And down to the present time similar officers have been appointed under various names, and with more or less extensive powers according to circumstances. Protector, lieutenant, or locum tenens, and regent, have been among the other names by which they have been known. Regents and councils of regency, during the nonage of the king or queen, have been sometimes named by the preceding possessor of the crown; but in modern times such arrangements have been usually made by statute. Coke remarks (4 *Inst.* 58) that the methods of appointing a guardian or regent have been so various, that 'the surest way is to have him made by authority of the great council in parliament.'

The most familiar case of the appointment by the crown of a representative to exercise the supreme executive power, not in a colony or dependency, is that of the appointment of a governor for Ireland, who has commonly borne the name of the Lord Lieutenant or the Lord Deputy; or of a council of government composed of Lords Justices.

The governor-general of Ireland under the crown has been styled at different times custos (keeper or guardian), justiciary, warden, procurator, seneschal, constable, justice, deputy, and lieutenant. Viceroy is a popular name of modern introduction. Formerly, upon the avoidance of the king's lieutenant for Ireland by death or otherwise, the privy council there was authorised to elect a successor, with the restriction that he should be an Englishman and no spiritual person, who held office till the king appointed another. The antient powers of this officer were almost regal; he performed every act of government without any previous communication with England; and when he left the country he even appointed his own deputy. From about the time of the Revolution, however, till after the commencement of the reign of George III., the lord-lieutenant resided very little in Ireland; in several instances the person appointed to the office never went over; in other cases he went over once in two years to hold the session of parliament; and the government was very often left in the hands of lords justices, without a lord-lieutenant at all. In modern times the appointment of lords justices for Ireland has only taken place on the occasional absences of the lord-lieutenant, and during the interval which has sometimes occurred between the demise of one lord-lieutenant and the appointment of another. The lords justices have usually been the lord primate, the lord chancellor, and the commander of the forces.

In England lords justices and regencies have been repeatedly appointed since the Revolution, on occasion of the king going abroad; and the appointment has usually, if not always, been made by royal letters patent under the great seal, in the same manner as the lords-lieutenant or lords justices of Ireland have always been appointed. In some cases, however, the aid of parliament has been called in for certain purposes. When King William went over to Ireland, in 1689, he of his own authority appointed the administration of the government to be in the hands of the queen during his absence out of the kingdom, not, however, we suppose, by letters patent, but merely by declaration at the council-table; and at the same time an act of parliament was passed, 1 & 2 Wm. and Mary, sess. 2, in the preamble of which that declaration of his majesty's pleasure was recited, and it was enacted, that whensoever and as often as his majesty should be absent out of this realm of England, it should and might be lawful for the queen to exercise and administer the regal power and government in the names of both their majesties, for such time only, during their joint lives, as his majesty should be absent. This act was considered to be necessary or expedient, in consequence of the peculiar circumstances in which the queen was placed by the Act of Settlement, which had declared that the entire, perfect, and full exercise of the regal power and government should be only in and executed by his majesty in the names of both their majesties during their joint lives. It was at the same time provided, 'That as often as his majesty shall return into this kingdom of England, the sole administration of the regal power and government thereof, and all the dominions, territories, and plantations thereunto belonging or annexed, shall be in his majesty only, as if this act had never been made.' After the queen's death lords justices were repeatedly appointed by King William, on occasion of his going abroad, under the great seal, namely, 5th May, 1695; May, 1696; 22nd April, 1697; 16th July, 1698; and 31st May, 1699.

One of the provisions of the statute of 12 & 13 Wm. III (passed in 1700) for settling the succession in the House of Hanover, was, 'That no person who shall hereafter come to the possession of this crown shall go out of the dominions of England, Scotland, or Ireland, without consent of parliament.' This clause, however, was repealed in 1716, by 1 Geo. I. stat. 2, c. 51. The repealing act was passed to gratify the king, whose 'impatience to visit his German dominions,' says Coxe in his 'Life of Walpole,' i. 77, 'now became so great as totally to overcome every restraint of prudence and suggestion of propriety, and imperiously to demand indulgence.' 'The ministry,' continues the historian, 'were considerably embarrassed on this occasion; and drew up a strong remonstrance, representing the inconvenience which would result from the projected journey. The remonstrance, however, not only failed of success, but so far exasperated the king, that he declared he would not endure a longer confinement in this kingdom.' It was thought more respectful to his majesty to obtain a repeal of the restraining clause at once, than to ask parliament merely for the leave of absence; and the bill passed through all its stages in both Houses without a dissenting voice, the Tories being favourably disposed to the principle, and the Whigs averse or frightened to offend the king. His majesty, who was at variance with his eldest son, now interposed another difficulty, refusing to intrust the government during his absence to the prince, without joining other persons with him in the commission, and also limiting his authority by the most rigorous restrictions. Upon this point, however, he yielded at last to the representations of the ministers, who concluded a long exposition of reasons against his leaving the kingdom at all at that crisis by stating that, 'upon a careful perusal of the precedents, finding no instance of persons being joined in commission with the Prince of Wales' in the appointment of a regency, 'and few, if any, restrictions upon such commissions,' they were of opinion that the constant tenor of antient practice could not conveniently be receded from. (See the paper in Coxe, ii. 51-54.) Upon this the king submitted to give the prince the sole direction of affairs; 'yet,' says Coxe, quoting from the work called 'The Political State of Great Britain,' 'he appointed him *Guardian of the Realm and Lieutenant*, an office unknown in England since it was enjoyed by Edward the Black Prince.' In point of fact the title given to the prince in the original Latin commission was *Custos Regni nostri et Locum tenens*, which were the same words that had been commonly used in all such commissions down to the reign of Henry VIII., with this difference only, that one of the two titles (more frequently *Custos Regni*) was alone employed. The earliest use of the term *regent* appears to have been in the commission from Henry VIII. to Queen Katherine Parr, when he went over to Boulogne in 1544, in which she is styled *Rectrix et Gubernatrix Regni nostri*. Queen Mary, the wife of William III., whose case is the next that occurs, seems, as already stated, to have had no commission; and, being queen regnant in her own right, she was not even popularly styled regent.

When George I. went abroad the next time, in May, 1719, he intrusted the government during his absence not to a regent, or any single person, but to thirteen lords justices, namely, the Archbishop of Canterbury and the principal officers of the state. A translation of the commission issued on this occasion, or rather, of the warrant to the attorney-general to prepare the commission, has been printed in the report of a committee of the House of Commons which sat in December, 1788, and affords as probably the most complete information to be found, in a printed form, on the subject of the present article. The committee state that they had found no entry of any earlier commission, except of the one issued in 1695, and that that was nearly the same with this of 1719, which appears to have been also closely followed in others subsequently issued. The commission begins by reciting that his majesty had 'determined, for divers weighty reasons, speedily to go in person beyond the seas.' The persons commissioned are appointed to be 'our guardians and justices (*Justiciarii* must be the Latin term) of our said kingdom of Great Britain, and our lieutenants in the same, during our absence out of our said kingdom, or till further signification of our pleasure;' and they were authorized, four being made a quorum, 'to execute the office and place of guardians, &c., and to order, do, and perform all and every act and acts of government and administration of government, and all other matters and things whatsoever, which, by virtue or by reason of the aforesaid office or place, have been usual, or may be lawfully ordered, done, or performed.' Power is afterwards specially given to keep the king's peace, to cause the laws and customs of the kingdom to be specially observed by all, to punish criminals and offenders, to hold the parliament then existing, and to continue, prorogue, and dissolve it, and likewise to summon and hold another parliament and other parliaments, and the same to continue, prorogue, and dissolve; also to direct and grant authority to the lieutenant, or justices and general governors, of the kingdom of Ireland for the time being, to summon, hold, prorogue, and dissolve the parliament and parliaments in the said kingdom, and likewise to prepare and transmit the bills which may be proposed to be enacted in such parliaments, according to the laws and statutes of the kingdom of Ireland; to summon and hold the Privy Council, and to appoint committees of the same; with the advice of the Privy Council, to issue proclamations, 'and to do and perform all other things which have been usually done, or may be done, by us, by or with the advice of the same;' to appoint and authorize persons to treat with the ambassadors, commissaries, and ministers of emperors, kings, princes, republics, or states, and to make and conclude treaties, conventions, and leagues thereupon; to confer, grant, and present to all benefices, dignities, and ecclesiastical promotions, where the presentation is in the crown; to issue commands, authorities, orders, and warrants, under the privy seal or otherwise, to the treasurer, or commissioners of the treasury, and other officers, for and concerning the collection, levying, application, payment, and disposal of the royal treasure and revenue; to command the army; to suppress invasions and insurrections; to execute and employ martial law in time of war, if that should happen; in like manner to command and employ the naval forces of the kingdom; to appoint to and discharge from all offices at the disposal of the crown; to grant pardons for high treason and all other crimes and offences; and finally, to do all these things in Ireland as well as in Great Britain.

This enumeration is probably the most authentic compendium that has been published of the powers of government ordinarily exercised by the crown. It does not, however, profess to be an enumeration of all the powers resident in the crown; and it will be especially observed, that (besides, perhaps, some appertaining to the office of supreme head of the church) the power of creating peers and conferring honours is not made over to the lords justices. That is a power which, we believe, never has been delegated, or attempted to be delegated, if we except only the case of the patent granted by Charles I., in 1644, to Lord Herbert (better known as the Earl of Glamorgan), which, after the Restoration, he was compelled to resign by the interference of the House of Lords.

The Lords Justices are further required in the commission of 1719, in the execution of their powers, punctually to observe his majesty's will and pleasure, as it might be from time to time more clearly and distinctly expressed in instructions signed by the royal hand; and the commission was accompanied by a set of instructions, also printed in the Report of the Committee of 1788, and stated to be nearly the same that had been issued, as far as was known, on similar occasions before and since. The rules prescribed are twenty-one in number, the most important things directed in which are, that no livings or benefices in the gift of the crown which may become vacant shall be disposed of without his majesty's directions as to the persons, to be signified from beyond the seas under the sign manual; that no orders or directions concerning the disposition of money at the treasury shall be given before his majesty's pleasure shall have been signified thereupon; and that there must be no exercise of the power of dissolving the parliament, or calling a new one, without special signification of the royal pleasure. The same restriction is put upon the exercise of the power of pardoning, and some of the other powers. In case however they should hold it necessary or expedient for the public service, the Lords Justices are authorized to fill offices immediately, and also to reprieve criminals; and they are permitted to continue the existing parliament by short prorogations, until they should be otherwise directed under the royal sign manual, and to summon the privy council to meet as often as they shall see occasion.

The government was in the same manner intrusted by George I. to Lords Justices when he again went abroad in 1720, 1723, 1725, and 1727. It is strange that the Report of 1788 should notice only the second of the several regencies of Queen Caroline, in the earlier portion of the reign of George II. Her majesty so long as she lived was always intrusted with the administration of the government when the king went abroad; which he did in 1729, in 1732, in 1735, and in 1736. An act, the 2 Geo. II. chap. 27, was passed in 1729, 'To enable her majesty to be regent of this kingdom, during his majesty's absence, without taking the oaths;' on the 15th of May thereafter, according to Salmon's 'Chronological Historian,' a commission passed the great seal constituting her guardian and lieutenant of the kingdom during the king's absence; and the same authority states her to have been appointed guardian in 1732, and regent on the two other occasions. According to the Report of the committee of 1788, a patent, with the like powers as that issued to the Prince of Wales in 1716, passed in 1732, appointing Queen Caroline guardian and lieutenant of the kingdom in the king's absence. Most probably all the four appointments were made in the same manner and in the same terms. After the death of Queen Caroline, the government was always left during this reign in the hands of Lords Justices when the king went abroad; as he did in 1740, 1741, 1743, 1745, 1748, 1750, 1752, and 1755. On all these occasions the commissions and the accompanying instructions were nearly the same with those issued in 1719.

George III. during his long reign never left England. When George IV. went to Hanover in September, 1821, nineteen guardians and Lords Justices were appointed, the Duke of York being the first. In an important article which appeared in the 'Morning Chronicle' for August 11th, 1845, the writer, after stating that Lord Eldon considered it indispensably necessary that Lords Justices should be appointed on that occasion, adds:—'One good effect arose from their appointment, that the Lords Justices during his (the king's) absence signed an immense number of military commissions and other documents, which had been accumulating since his accession to the throne.' This writer contends that 'the royal authority of an English monarch cannot be personally exercised in a foreign country.' 'We take it,' he adds, 'to be quite clear, that a patent sealed with the great seal in a foreign country would be void. To guard against any such irregularity, the law requires that the patent shall state the place where it is signed and sealed as *apud Westmonasterium*.'

Nevertheless, no provision such as had been customary on such occasions was made for the exercise of the royal authority, either when her present majesty made her short excursion to the French coast in 1843, or when she made her late more extended visit to Germany (in August and September, 1845). On the latter occasion the subject was brought forward in the House of Lords by Lord Campbell, who, on the 7th of August (two days before the prorogation of Parliament), after stating at some length the course which he maintained had been uniformly taken down to the year 1843, asked if it was the intention that Lords Justices should be now appointed? The lord chancellor, however, replied that the government had no such intention. 'On the occasion of her majesty visiting the king of the French,' his lordship is reported to have said, 'the then law officers of the crown, the present lord chief baron and the late Sir William Follett, had been consulted. . . . And after mature deliberation, these learned persons gave it as their decided opinion that it was not at all necessary in point of law that such an appointment should take place. . . . In the present instance also, the law-officers of the crown had been consulted as to whether it was necessary in point of law for her majesty to appoint a regency during her absence, and their reply was that it was in no degree necessary; an opinion in which he entirely concurred.' Both the speech with which Lord Campbell prefaced his question, and the subsequent article in the 'Morning Chronicle,' well deserve to be consulted.

It ought to be mentioned that the seven persons appointed in 1705 by the 4 & 5 Anne, c. 8, and again in 1707, by the 6 Anne, c. 7, to administer the government along with other persons whom the new king or queen should have named, in case of his or her absence at the time from the kingdom, are styled Lords Justices in the act, although called regents by Burnet, and in the common accounts. These Lords Justices (twenty-six in all), who actually came into office on the death of Queen Anne, 1st August, 1714, and continued till the arrival of the king on the 18th of September, enjoyed more extensive powers than any others that have been appointed, at least in modern times. They were authorized, in the name of the successor, and in his or her stead, to use, exercise, and execute all powers, authorities, matters, and acts of government, and administration of government, in as full and ample manner as such next successor could use or execute the same if she or he were present in person within this kingdom of Great Britain,' until such successor should arrive, or otherwise determine their authority. The only restrictions laid upon them were, that they were not, without direction from the 'queen or king,' to dissolve the parliament; and that they would subject themselves to the pains of high treason if they gave the royal assent to any bill or bills for repealing or altering the Act of Uniformity, or the Act for the Establishment and Maintenance of the Presbyterian Church Government in Scotland.

We are not aware that these facts have ever before been put together. The most important of them have been derived from the Report of the Committee appointed by the House of Commons in 1788, 'to examine and report precedents of such proceedings as may have been had in the case of the personal exercise of the royal authority being prevented or interrupted by infancy, sickness, infirmity, or otherwise,' which is printed in the Journals of the House, vol. xliv. pp. 11-42. See also, besides the other sources that have been already referred to, an article 'On the Regency Question,' in the Edinburgh Review, No. XXXV. (for May, 1811), pp. 46-80. And some particulars may be gleaned from the accounts of the proceedings in the two Houses of Parliament on occasion of the king's illness in 1788, as reported in the 'Parliamentary History,' vol. xxvii. pp. 653-1297; and from the discussions on the Regency Bill from the beginning of November, 1810, to the middle of February, 1811, which nearly fill the 18th volume of the 'Parliamentary Debates.' One of the speeches which attracted most attention on the latter occasion for its argument and research was afterwards published in an authentic form; that delivered on the 31st of December, 1810, by John Leach, Esq. (afterwards Vice-Chancellor).

JUSTICIARY COURT in Scotland. To render the historical article on this subject under the head of JUSTICIAR [P. C.] fully intelligible, it may be mentioned that the High Court of Justiciary is the supreme criminal court in Scotland. It consists of the Lord Justice General, Lord Justice Clerk, and five other judges of the Conrt of Session. It sits at Edinburgh, from time to time during the year, according to the extent of business to be transacted. Offences committed in Edinburgh and within the district of the Lothians are tried before this court, and in cases where in other parts of the country waiting for the next Circuit Court would create too much delay, or where there is any other ground of expediency, the trial may proceed before the Central Court. Other trials in the provinces proceed before the circuit courts. These are held in spring and autumn, each by two judges deputed by the High Court of Justiciary. The southern circuit is held at Jedburgh, Ayr, and Dumfries; the western, at Glasgow, Inverary, and Stirling; and the northern at Perth, Aberdeen, and Inverness. An additional circuit is held at Glasgow in winter. Questions may be *certified* from the circuit courts to the High Court of Justiciary, that is to say, before being decided the matter may be reserved for the consideration of that court. But it is a peculiarity both of the central and circuit courts of Justiciary, that no decision once given can be reconsidered either by the court pronouncing it or a Court of Review. This principle is liable to many objections, but it is productive of one benefit, that no trial is thrown away by the subsequent discovery of flaws in initial procedure. Before the case goes to a jury, a judgment is pronounced 'finding the indictment relevant,' and virtually declaring that the initial procedure is regular; that the charge is properly laid, and that the offence if proved is punishable. If there be any objections to the regularity of the proceedings, they must be stated before this judgment, which when once pronounced is final. All cases before the Court of Justiciary are tried by a jury of fifteen, a majority returning the verdict where they are not unanimous. It has jurisdiction in all the more serious offences except high treason, which is adjudicated in the English manner by a Court of Oyer and Terminer.

JUSTIFIABLE HOMICIDE. [MURDER, P. C.]

JUVENTIUS CELSUS. [CELSUS, P. C. S.]

INDEX TO THE LETTER J.

VOLUME II.

K.

KAFFA, a country in the eastern parts of Africa, of which we have only lately got some information, and which hitherto has not been visited by any European traveller, so far as is known. It is said to be of considerable extent, larger than Shoa [Abyssinia, P. C. S.], and appears to occupy the space between 3° and 5° N. lat. and 30° and 34° E. long. It contains several high mountains, which are separated from one another by wide valleys. Numerous watercourses drain the country, and all of them join the Goshop, a large river originating in several branches to the south and west of Kaffa, which probably falls into one of the rivers whose embouchures have been recognised on the coast of Zanguebar. On the north of Kaffa is Enarea, and on the west a wilderness, in which numerous herds of large quadrupeds (elephants, giraffes, &c.) are found. The country is fertile, and partly well cultivated. Cotton is grown to a great extent. The coffee-tree is there, as well as in the neighbouring country of Enarea, indigenous and a forest-tree. It is not stated that coffee is an article of export, but it is thought that the coffee called in these parts *yava* has derived its name from this country, as the Arabs assert that it has been transplanted to Yemen from that part of Africa.

The capital is Soonec, a town which, according to the accounts of African travellers, has between 6000 and 7000 inhabitants. This place and some others are visited by the merchants of Enarea, who exchange their goods (rock-salt, copper, horses, cattle, and some India stuffs, brought from Gondar), for cotton, cotton-cloth, which is made in the country, and slaves; this is the only way by which the inhabitants dispose of their produce and obtain foreign goods. The inhabitants, it is said, call themselves Christians, but none of tho practices by which the Abyssinian church is distinguished are in use among them.

(Krapf, *Bericht von dem Flusse Goshop und den Ländern Enarea, Kaffa, und Doko*, in the *Monatsberichte der Berliner Gesellschaft für Erdkunde.*)

KAIN, LE, HENRI-LOUIS, a French actor, so often spoken of in tho memoirs of French literature in the middle of the eighteenth century, that some account of him may be useful. He was born in 1728, and died in 1778. He was a protégé of Voltaire, who observed the natural strength of his histrionic genius, and removed him from an humble operative profession. He acquired his chief celebrity in the characters of Voltaire's plays; yet, owing to a singular series of events, that author never saw him on the stage. He was unable to make his début until seventeen months after Voltaire's departure for Prussia, in 1750, and on the author's return, after an absence from Paris of twenty-eight years, he found the actor about to be buried. Louis XV. stamped the reputation of Le Kain, by saying, '*Il m'a fait pleurer; moi qui ne pleure guère.*' Like the English actor to whose name that of Le Kain bears a great resemblance, he was small in person, and his success arose from his power of representing deep passion and vehement emotion. The character of his acting was novel, and while it fascinated the audience, it did not at first satisfy the critics, who termed him *le convulsionnaire*. He was critical and accurate in costume, and attended minutely to its topical and chronological applicability.

(*Biographie Universelle.*)

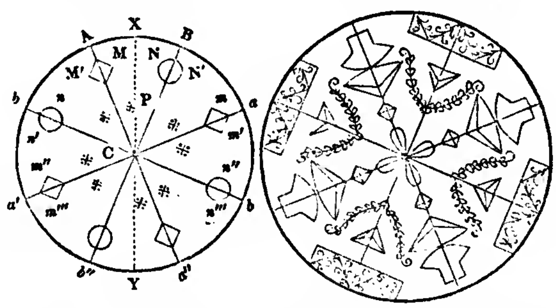
KALEIDOSCOPE, a name compounded of two Greek words (καλὸς and σκόπος), and denoting the exhibition of beautiful forms, is the designation of an optical instrument which was invented by Dr. (Sir David) Brewster, and made public in 1817.

About three years before that time Sir David Brewster, being engaged in making experiments on the polarization of light by reflexion from plates of glass, observed that when two plates were inclined to one another, and the eye of the spectator was nearly in the produced line of the common section of their planes, the farther extremities of the plates were multiplied by successive reflexions so as to exhibit the appearance of a circle divided into sectors, also that the several images of a candle near those extremities were circularly disposed about the centre; and these circumstances suggested to him the construction of an instrument of the kind above named.

It may be observed, however, that the multiplication of the image of an object by successive reflexions from mirrors inclined to one another had long before been a subject of investigation in treatises on optics; and both Baptista Porta and Kircher had given descriptions of instruments consisting of mirrors united at two of their edges, which, being opened like two leaves of a book, were capable of multiplying the images of objects. Bradley also, about the year 1717, constructed an instrument consisting of two plates of glass inclined to one another, which being placed on a drawing, with the line of section perpendicular to the paper, exhibited to the eye several images of the figures, disposed by successive reflexions about a centre. But the optical investigations alluded to are very remotely connected with the properties of the kaleidoscope; and the application of the latter to objects which may be moveable and situated at any distances from the observer, render Sir David Brewster's instrument very different from and far superior to the simple contrivances of Porta, Kircher, and Bradley.

The essential parts of the instrument consist of two plane mirrors of glass, having their posterior surfaces blackened in order to prevent any reflexion of light from thence; mirrors of polished metal would, however, be preferable: each mirror is from six to ten inches long, and of a trapezoidal form; the larger end about an inch and a half long, and the shorter end about three-quarters of an inch; and the two are placed in contact with one another at a long end of each, so as to form a dihedral angle, the like ends being placed together: the object to be viewed is disposed contiguously to the larger ends, and the eye should be near the opposite extremity, but a little above the line of contact. The effects produced by the reflexions of the light may be understood from the following considerations:—

Let A C, B C, in the first of the figures, be the two ex-



tremities of the mirrors on the side farthest from the eye of the observer, which is supposed to be near the opposite extremity of the line of section passing through C perpendicularly to the plane of the paper. These lines A C, B C, and the sectoral space between them (which in the figure is one-eighth part of a circle), will be visible by rays coming directly to the eye; and, at the same time, rays from the line A C falling on the mirror B C at a certain angle of incidence will, on being reflected from thence to the eye, give rise to the image C a of that line; in like manner rays from the line B C falling on the mirror A C at an equal angle of incidence will, after reflexion, give rise to the image C b of the line. These, with the intermediate rays, produce the first reflected sectors B C a and A C b. Other rays from the sector A C b at the surface of the mirror A C will fall on the mirror B C; and, while a portion of them arrive at such angles of incidence as to be reflected to the eye and produce the perception of the sector a C b', another portion of them will be reflected back to the mirror A C at such angles of incidence as to be re-reflected to the eye and cause tho perception of the sector a' C b''. In a similar manner the rays first reflected from B C a will, by subsequent reflexions, give rise to the perceptions of the sectors b C a', b' C a''.

Thus it is easy to perceive that an object, as M, on A C, with its immediately reflected image M', will give rise to the appearances of similar figures at $m\,m'$, $m''\,m'''$; and an object, as N, on A B, with its immediately reflected image N', will give rise to the appearances of similar figures at $n\,n'$, $n''\,n'''$: also an object, as P, between A C and B C, will appear by reflexion similarly situated in all the other sectors.

If the angle A C B be $\frac{1}{m}$th of four right angles, in which m is any term in the series of even numbers 4, 6, 8, 10, &c., the number of sectors will be m, and each of them will be equal to A C B, while C Y, the appearance of the line in which the mirrors meet each other, will, as in the figure, bisect the angle which is opposite to A C B; also if m be any term in the series of odd numbers 5, 7, 9, &c., the number of sectors will be m, and each of them will be equal to A C B, while C Y will coincide with the line in which the two lowest sectors join one another. It may hence be easily understood that if a flat object placed in the sector A C B, with its plane perpendicular to the mirrors, have its bounding-lines similarly situated with respect to A C and B C, the reflected images will be similar and equal to the original object; and the whole will constitute one symmetrical pattern, whether the value of m be odd or even: but if the bounding-lines are not similarly situated with respect to A C and B C, the reflected images will not, in the two lowest sectors, unite so as to correspond to the images in the other sectors, unless m be an even number. The second figure represents a pattern produced by the objects represented in the sector corresponding to A C B in the first figure.

In order that the whole pattern in the field of view might possess perfect symmetry about the centre C, it would be necessary that the eye should be exactly in the direction of the line in which the glass plates meet one another; but in such a situation the reflected images would not be visible: if the eye were far above the line of meeting, the visible field of view would be sensibly elliptical, and the brightness of the field would be diminished; it follows, therefore, that the eye should be near the smaller ends of the mirrors, and very little above the line of their junction. Again, it may be readily understood that, in order to permit the reflected images of objects to be symmetrically disposed about the centre of the field of view, the object should be exactly in a plane contiguous to the mirrors at the extremities which are farthest from the eye; for the line in which the planes of glass meet each other appearing to pass through the common centre of the visible sectors, if the object were placed on that line of junction, and either between the eye and those extremities or beyond the latter, it is evident, the eye being above the line of meeting, that the apparent or projected place of the object would not coincide with that common centre, but in the former case would appear below, and in the latter above, that centre. The length of the mirrors should be such that the object in the sector A C B may be distinctly visible; the eye may, however, if necessary, be assisted by a concave or a convex lens.

The first kaleidoscopes constructed by Sir David Brewster consisted simply of the two mirrors, which were fixed in a cylindrical tube; the objects were pieces of variously coloured glass attached to the farther ends of the mirrors and projecting on the sectoral space A C B between them; or the objects were placed between two plates of very thin glass, and held by the hand or fixed in a cell at the end of the tube. In some cases these plates were moved across the field of view, and in others they were made to turn round upon the axis of the tube. The pieces of coloured glass or other objects which were situated in the sector A C B were, by the different reflexions, made to appear in all the other sectors; and thus the field of view presented the appearance of an entire object or pattern, all the parts of which were disposed with the most perfect symmetry. By moving the glass plates between which the objects were contained, the pattern was made to vary in form; and pleasing variations in the tints were produced by moving the instrument so that the light of the sky or of a lamp might fall on the objects in different directions. When the objects in the sector A C B are confined near its upper part, the images evidently form an annular pattern; and, on placing the two mirrors parallel to one another, the successive reflexions of the objects produce one which is rectilinear.

Sir David Brewster subsequently found means to obtain multiplied images of such objects as flowers, trees, and even persons or things in motion: and thus the importance of the instrument was greatly increased. For this purpose he caused the two mirrors to be fixed in a tube as before, but this tube was contained in another from which, like the eye-tube of a telescope, it could be drawn at pleasure towards the eye: at the opposite end of the exterior tube was fixed a glass lens of convenient focal length, by which there were formed images of distant objects at the place of the sector A C B. These images thus became objects which, being multiplied by successive reflexions from the mirrors, produced in the field of view symmetrical patterns of great beauty.

Some kaleidoscopes have been executed in such a manner that the two mirrors may be placed at any required angle with one another, by which means the images in the visible field of view may be varied at pleasure. The instrument is capable also of being constructed so that the multiplied image may be projected on a screen, and thus made visible at one time to many spectators. In order to obtain this end, the rays of light from a powerful lamp are, by means of a lens, made to fall upon the object in A C B at the farther extremities of the two mirrors; and at the eye-end of the instrument is placed a lens of such focal length that the rays in each of the emergent pencils may converge at the screen: there will thus be formed on the latter a magnified image of the whole pattern. The tube containing the glass plates is frequently mounted on a stand having a ball-and-socket joint, on which it may be turned in any convenient direction; and the instrument being thus supported, the figures in its field may be easily sketched by a skilful artist, who by means of such an apparatus may be greatly assisted in designing beautiful patterns.

Sir David Brewster's account of his invention is contained in his 'Treatise on the Kaleidoscope' (Edinburgh, 1819): but Dr. Roget has shown ('Annals of Philosophy,' vol. xi.) that the properties of the instrument may be greatly extended by employing, instead of two, three and even four plane mirrors, united together at their edges so as to form a hollow prism, or a frustum of a pyramid, the reflecting surfaces being towards the interior. Of these, which are called Polycentral Kaleidoscopes, the instruments constructed with three plane mirrors appear to produce the most pleasing effects; the mirrors may be disposed so that a section perpendicular to the axis shall be an equilateral triangle, a right-angled isosceles triangle, or a right-angled triangle having its two acute angles equal to 30° and 60°. The first disposition of the mirrors affords regular combinations of images in three different directions which cross each other at angles of 60° and 120°; and to instruments of this kind Dr. Roget gave the name of Triascope. With the second disposition the field is divided into square compartments having the hypotenuse of the triangle for their sides: this is called a Tetrascope. The third disposition exhibits a field of view divided into hexagonal compartments; and hence the instrument is designated a Hexascope.

Sir David Brewster obtained a patent for the kaleidoscope, and several opticians of London and other places were duly authorized by him to execute and sell them: but the refinements of taste are too often disregarded in the purchase of works of art; and, apparently, the public did not adequately encourage the manufacture of the instruments of a superior kind; while, in violation of the patent, imitations of the kaleidoscope, rudely and inaccurately constructed, were sold at low prices, by unprincipled persons, in such numbers that it is doubtful whether the distinguished philosopher to whom optical science is on many accounts so highly indebted derived any pecuniary benefit from his invention.

KALENDAR, REVOLUTIONARY. It has been pointed out that there is a mistake in the commencement of the French revolutionary years as given in YEAR, P. C. On examination we find that not only the article cited, but many other works give an account of this kalendar which is more or less incorrect. The decrees of the National Convention, which fixed the new mode of reckoning, were both vague and insufficient, so that it is no wonder that many detailed accounts neither agree with each other nor with the truth. To learn what the truth was, we have recourse to a French work, in its sixth edition: 'Concordance des Calendriers Républicain et Grégorien,' par L. Rondonneau, Paris (6ième édition), 1812, 8vo. This work puts every day of every year, from An II. to An XXII. both inclusive, opposite to its day of the Gregorian calendar: it also gives the decrees of the National Convention.

By these decrees it appears that the year is to begin at the midnight of Paris Observatory which precedes the true autumnal equinox. It is to consist of 365 days, with 12 months of 30 days each (the 30 days being 3 decades of 10 days each), and 5 complementary days, which were tastefully called *sansculotides* (a name afterwards repealed). A sixth complementary day was to be added, not according to any rule, but *selon que la position de l'équinoxe le comporte:* and although it was stated that it would be *ordinairement nécessaire* to add this 366th day once in four years, yet it is not even stated in what particular coming years the necessity would arise. The first decree, dated October 5, 1793 (the new month not having been introduced), declares the year then current to be the second year of the French republic, and enacts that An I. began with September 22, 1792, and An II. with September 22, 1793. The second decree, fixing the months, is dated the 4th of Frimaire, An II. (November 24th, 1793). The Gregorian reckoning was restored from and after January 1, 1806, by an imperial ordonnance, dated 22 Fructidor, An XIII. (September 9, 1805).

It is to actual usage then that we must appeal to know what the decrees do not prescribe, namely, the position of the leap-years. For though every period of four years was a *Franciad*, and the last year of the Franciad was called *Sextile* (having six complementary days,) yet in fact An IV., An VIII., &c., are not leap-years. The following list, actually made from the work above mentioned, must be used as a correction of that in YEAR, P. C. For various matters connected with the public debt, &c., it was necessary to construct the table up to An XXII.

			Sept.				Sept.
An	I.	begins	22, 1792	An	XII.	begins	24, 1803
	II.	,,	22, 1793		XIII.	,,	23, 1804
Sext.	III.	,,	22, 1794		XIV.	,,	23, 1805
	IV.	,,	23, 1795	Sext.	XV.	,,	23, 1806
	V.	,,	22, 1796		XVI.	,,	24, 1807
	VI.	,,	22, 1797		XVII.	,,	23, 1808
Sext.	VII.	,,	22, 1798		XVIII.	,,	23, 1809
	VIII.	,,	23, 1799	Sext.	XIX.	,,	23, 1810
	IX.	,,	23, 1800		XX.	,,	24, 1811
	X.	,,	23, 1801		XXI.	,,	23, 1812
Sext.	XI.	,,	23, 1802		XXII.	,,	23, 1813

When the Gregorian year is not leap-year the beginnings of the months are as follows, according as the republican year begins on September 22, 23, or 24:—

1 Vendémiaire	is	Sept.	22,	23,	24
1 Brumaire	is	Oct.	22,	23,	24
1 Frimaire	is	Nov.	21,	22,	23
1 Nivose	is	Dec.	21,	22,	23
1 Pluviose	is	Jan.	20,	21,	22
1 Ventose	is	Feb.	19,	20,	21
1 Germinal	is	March	21,	22,	23
1 Floréal	is	April	20,	21,	22
1 Prairial	is	May	20,	21,	22
1 Messidor	is	June	19,	20,	21
1 Thermidor	is	July	19,	20,	21
1 Fructidor	is	Aug.	18,	19,	20

1 Jan.	is	Niv.	12,	11,	10
1 Feb.	is	Pluv.	13,	12,	11
1 March	is	Vent.	11,	10,	9
1 April	is	Germ.	12,	11,	10
1 May	is	Flor.	12,	11,	10
1 June	is	Prair.	13,	12,	11
1 July	is	Messid.	13,	12,	11
1 Aug.	is	Thermid.	14,	13,	12
1 Sept.	is	Fructid.	15,	14,	13
1 Oct.	is	Vendém.	10,	9,	8
1 Nov.	is	Brum.	11,	10,	9
1 Dec.	is	Frim.	11,	10,	9

But when the Gregorian year is leap-year the beginnings of the months are as follows, according as the republican year begins on September 22, 23, or 24:—

1 Vendém.	is	Sept.	22,	23,	24
1 Brum.	is	Oct.	22,	23,	24
1 Frim.	is	Nov.	21,	22,	23
1 Niv.	is	Dec.	21,	22,	23
1 Pluv.	is	Jan.	20,	21,	22
1 Vent.	is	Feb.	19,	20,	21
1 Germ.	is	March	20,	21,	22
1 Flor.	is	April	19,	20,	21
1 Prair.	is	May	19,	20,	21
1 Messid.	is	June	18,	19,	20
1 Thermid.	is	July	18,	19,	20
1 Fructid.	is	Aug.	17,	18,	19

1 Jan.	is	Niv.	12,	11,	10
1 Feb.	is	Pluv.	13,	12,	11
1 March	is	Vent.	12,	11,	10
1 April	is	Germ.	13,	12,	11
1 May	is	Flor.	13,	12,	11
1 June	is	Prair.	14,	13,	12
1 July	is	Messid.	14,	13,	12
1 Aug.	is	Thermid.	15,	14,	13
1 Sept.	is	Fructid.	16,	15,	14
1 Oct.	is	Vendém.	11,	10,	9
1 Nov.	is	Brum.	12,	11,	10
1 Dec.	is	Frim.	12,	11,	10

For instance, what is 14 Floréal, An XII. The republican year begins Sept. 24, 1803, so Floréal falls in 1804, which is Gregorian leap-year. Look at the third Table, and when the year begins Sept. 24, the first of Floréal is April 21; consequently the 14th is May 4, 1804. Again, what is June 17, 1800, in the French calendar? The year is not Gregorian leap-year; and An VIII. contains it, which begins Sept. 23. Look in the second Table, and in such a year it appears that June 1 is the 12th of Prairial; therefore June 17 is Prairial 28.

KALGUJEW is a considerable island in the circle of Mesen, in the Russian government of Archangel, and situated to the north of the peninsula of Schemonkonski. It lies between 68° and 69° 40′ N. lat., and 47° 30′ and 48° 10′ E. long., and is about 66 miles in diameter. The surface is undulating; it has some low mountains, which rise in the centre, two small rivers, and several brooks of fresh water. The surface is covered, as in Mesen, with mosses; there are extensive morasses; the ground bears nothing but berries, some anti-scorbutic plants, and stunted bushes. The surrounding sea is shallow, but swarms with fish; the coast abounds in seals, walrusses, and other such animals. The cliffs are covered with an incredible number of sea-birds; the interior is full of polar bears, foxes, &c. Except a few Samoides there are no settled inhabitants. A colony of Raskolnicks established themselves here in the 18th century: but soon left the island. At present it is only frequented by fishermen and seal-hunters from Mesen and Archangel. The little island of Plokti-Kockti and some others are near to Kalgujew.

(Hassel, *Handbuch*, vol. xi.; Cannabich, *Lehrbuch*.)

KALMIA, a genus of plants named by Linnaeus in honour of Peter Kalm, professor at Abo in Sweden. It has a small five-leaved calyx, a cyathiform corolla, with an angular very open limb having ten niches in its sides. The capsules five-celled and many-seeded. The species are evergreen shrubs with alternate or verticillate leaves.

K. latifolia has its leaves on long petioles, scattered or three in a whorl, smooth and green on each side. It is a native of N. America from Canada to North Carolina, on the sides of stony hills. It has various names in the United States, Laurel Ivy, Spoonwood, Calico-bush, &c. The flowers are red, and when in blossom have a very elegant appearance. The leaves of this species are said by Barton to be poisonous to man and beast, but their action can be but feeble and unimportant, for animals are known to feed on the plant without any evident effect. Bigelow however states that the flesh of pheasants having eaten this plant has produced some cases of severe disease attributable to this cause alone. The flowers of the *K. latifolia* exude a large quantity of sweet nectarous juice, which is greedily collected by bees and wasps, but the honey formed from it is injurious to man, and the juice, if swallowed itself, will produce an intoxication of an alarming kind. A brown powder which adheres to the shoots and branches is used as a sternutatory by the Americans.

K. angustifolia, Haulm-leaved Kalmia, has petiolate leaves, scattered or three in a whorl, oblong, obtuse, rather rusty beneath; corymbs lateral, bracts linear; peduncles and calyxes clothed with glandular pubescence. It is a native of North America from Canada to the Carolinas, in bogs and swamps, and sometimes in dry mountain lands. It is a shrub one or eight feet in height, with dark red flowers. It is called Sheep-Laurel in North America, as it is supposed to be very injurious to sheep. Several varieties of this plant with lighter and darker flowers have been described. There are several other species, all of them natives of North America. They are all remarkables for the irritability of their stamens, and each of the stamens has a little cavity formed for it in the corolla, to serve as a protection to the anthers.

They are handsome shrubs when in blossom, and are great favourites in gardens and shrubberies. They grow best in a peat soil, or they may be planted in a very sandy loam or vegetable mould. They may be propagated by layers or seeds. When the seeds are used they should be sown early in the spring in flat pans or pots filled with peat earth, and very slightly covered over; the pots may be then set in a close frame, or in the front of a hothouse, till the plants come up, when they may be transplanted to other pots, which should stand in a close frame till they have struck root; they should then be hardened to the air by degrees.

(Don, *Gardener's Dict.*; Burnett, *Outlines of Botany*.)

KATER, HENRY, an English mathematician of some eminence, and an excellent practical philosopher, was born at Bristol, April 16th, 1777. but of his early life very little is known. He obtained a commission in the army; and in 1808, while holding the rank of lieutenant in the 12th regiment (infantry), he became a student in the senior department of the Royal Military College, Sandhurst. During his residence at that institution he was promoted to a company in the 62nd regiment; and on quitting the College he received a certificate of the first class. He was afterwards made brigade-major of the eastern district.

Captain Kater was first engaged in making experiments to determine the relative merits of reflecting telescopes constructed according to the methods of Cassegrain and Gregory; and his conclusion was that the ratio of the illuminating power of the former to that of the latter kind was as 2½ to 1. On this subject he wrote two papers, entitled 'On the Light of the Cassegrainian telescope compared with that of the Gregorian,' which were published in the 'Philosophical Transactions' for 1813.

The determination of the precise length of the seconds' pendulum, an object of high importance in physical science, engaged the attention of Captain Kater during several years. The methods which had previously been employed to determine accurately the centre of oscillation in an irregular and heterogeneous body vibrating as a pendulum were found totally inadequate to this purpose; but Captain Kater succeeded in surmounting the difficulty by availing himself of a property of that centre which had been demonstrated by Huyghens: this property is that, if the centre of oscillation in a suspended body be made the point of suspension, the body will perform a vibration about it in a time equal to that in which it performs a vibration about the original point of suspension. The distance between the two points, experimentally obtained, is evidently equal to the length of a mathematical pendulum vibrating in the same time as the given pendulum. The *knife-edge* mode of suspension was first used by Captain Kater in these experiments; and the details of the construction of the pendulum are contained in a paper which was published in the 'Philosophical Transactions' for 1818. [PENDULUM, P. C., pp. 408, 409.]

A bill having been introduced into parliament for establishing a uniform system of weights and measures in this country, Captain Kater distinguished himself by the experiments which he made to ascertain the length of the seconds' pendulum, for the purpose of assigning the physical value of the English foot; and these experiments gave for the length of such pendulum, in London, in vacuo and when reduced to the level of the sea, 39·13929 inches. At the request of the Royal Society of London, Captain Kater proceeded, with the instruments, in July, 1818, to Dunnose in the Isle of Wight, to Arbury Hill, Clifton, Leith Fort, Portsoy, and the island of Unst, where he made the necessary experiments; and he subsequently computed for those places the several lengths of the seconds' pendulum: an account of the experiments, with the computed results, was published in the 'Philosophical Transactions' for 1819. Captain Kater also investigated, by the aid of Clairaut's theorem, the diminution of terrestrial gravity from the pole to the equator; and the great accuracy with which the force of gravity may be determined by means of his pendulum suggested to him the application of the latter to the important purpose of finding the minute variations of that force in different parts of a country whose substrata consist of materials having different degrees of density.

But the name of Captain Kater will be transmitted to posterity in connection chiefly with his invention of the floating collimator, an instrument which has conferred on practical science essential benefits, its object being the determination of the position of the line of collimation in the telescope attached to an astronomical circle; and this end is obtained by the collimator with greater certainty than by the spirit-level, the plumb-line, or by the reflexion of an object from the surface of a fluid. [COLLIMATOR, P. C.] Accounts of Captain Kater's horizontal and vertical collimators are given in the 'Philosophical Transactions' for 1825 and 1828.

The 'Philosophical Transactions' contain also a paper by Captain Kater on an improved method of dividing Astronomical Circles and other Instruments; one on the length of the French Metre estimated in parts of the English Standard; one on a remarkable Volcanic Appearance in the Moon in February, 1821; two papers on the comparison of British Standards of Linear Measures; one paper entitled 'An Account of Experiments made with an Invariable Pendulum belonging to the Board of Longitude;' and two papers on the 'Construction and Adjustment of the New Standards of Weights and Measures in the United Kingdom of Great Britain and Ireland.'

Besides these valuable papers, Captain Kater was the author of a large portion of the work entitled 'A Treatise on Mechanics,' constituting one of the volumes of Dr. Lardner's 'Cyclopædia'—this volume being the joint production of Lardner and Kater. In it is a chapter on the subject of pendulums constructed on the principle above mentioned; and it may be observed that, for the purpose of measuring the distance between the knife-edges, Captain Kater employed a scale furnished with powerful microscopes, to one of which a micrometer was adapted: with this apparatus the 10,000th part of an inch becomes a measurable quantity. He published in 1832 'An Account of the Construction and Verification of certain Standards of Linear Measures for the Russian Government,' 4to., London.

Captain Kater was a Fellow of the Royal Society of London, and in 1814 he received from the Emperor of Russia the decoration of the Order of St. Anne. After a life spent in philosophical research, he died in London, April 26, 1835, leaving behind him many proofs of his zeal for the promotion of physical science.

(From the papers in the *Philosophical Transactions*.)

KAUFMANN, MARIA ANGELICA, was born at Chur in the Grisons, or Graubündten, in 1741 or 1742. Her father, Joseph Kaufmann, was a portrait painter, of very ordinary ability; he, however, devoted unusual attention to the education of his daughter, who displayed uncommon abilities at an early age, both for painting and for music. He took her, while still young, to Milan, where they dwelt some time; and in 1763 they visited Rome, and there Angelica attracted universal notice among the virtuosi, and obtained considerable reputation for her portraits in oil: in singing too, according to Winckelmann, she was equal to any of her contemporaries. She painted a half-length of Winckelmann and made an etching of it herself. Winckelmann, in a letter to a friend, speaks in admiring terms of Angelica's accomplishments, especially her facility in speaking the German, Italian, French, and English languages.

In 1765 Angelica visited Venice, and in the same year came, in company, with Lady Wentworth, to England, where she was received in a most flattering manner: she was elected one of the original thirty-six members of the Royal Academy, founded in 1768. She returned to Italy in 1782, having in the previous year been married to Antonio Zucchi; she did not, however, change her name, but was always known as Angelica Kaufmann. She died at Rome in 1807, or according to some accounts in 1808. She etched several plates, and many of her own works have been engraved by Bartolozzi and other eminent engravers. Angelica is said, previously to her marriage with Zucchi, to have been cheated into a marriage with an adventurer who gave himself out as a Swedish count: as the story, however, though often repeated, does not appear to be sufficiently authenticated, an allusion to it is sufficient. The account of her which appeared in Huber's 'Manuel des Amateurs,' &c., in 1796, was declared to be wholly incorrect by Angelica herself, in an Italian periodical in 1806; but the story of the impostor does not occur in this notice.

Angelica, though not beautiful, had a very graceful person and most agreeable manners, and she was very highly accomplished generally. To these attractions must be attributed her success, for as a painter she did nothing of value beyond an elegant female portrait, or an occasional female figure. Her compositions are deficient in every essential quality of art; in drawing she was extremely feeble, and her male and female characters are not otherwise different than in costume.

(Goethe, *Winkelmann und sein Jahrhundert*; Fiorillo, *Geschichte der Zeichnenden Künste in Deutschland*, &c.; Nagler, *Künstler-Lexicon*.)

KEAN, EDMUND, was born about 1787, in London. His father, Edmund Kean, seems to have been a stage-carpenter; his mother was Miss Ann Carey, daughter of George Savile Carey, and grand-daughter of Henry Carey. [CAREY, HENRY, P. C. S.] George Savile Carey, who was born in 1743 and died in 1807, supported himself by delivering public lectures interspersed with recitations, songs, &c. He was the author of numerous songs and nine dramatic pieces. Miss Carey was an actress at minor theatres and with strolling players and in showmen's booths. Kean's father seems to have cared little about him, his mother neglected him, and when he was two years old Miss Tidswell, an actress at the large theatres, who was acquainted with Miss Carey, took charge of him, and, probably from this circumstance merely, was reported to have been his mother. He was sent to one or two day-schools in London, but, as may easily be supposed, got little literary instruction. His theatrical education, however, commenced early; Miss Tidswell instructed him in her art, and his mother, as soon as she found that he might be made useful, took him with her in her occasional occupation of selling flowers and perfumery from door to door, the beauty and intelligent countenance of the child pleading strongly for the mother; she afterwards took him with her in her rambles with strolling players and showmen. Master Carey, as he was then called, was so clever, that once, when Miss Carey and her son were performing in Richardson's booth at Windsor (the Richardson so well-known for his annual exhibitions at Bartholomew Fair), Master Carey was required to give his recitations before George III. at the Castle, which he did to His Majesty's great delight, and was dismissed with a handsome present. He continued his performances, sometimes with his mother and sometimes alone, at small places of public amusement in London and the neighbourhood till about the age of sixteen, when he left her entirely, and joined a company of strollers in Scotland.

Kean's first performance of a complete character was that of Young Norval, in 'Douglas,' in Richardson's booth; his first engagement with a regular company was in 1804, when he made his appearance at Sheerness on Easter Monday, on which occasion he played George Barnwell and Harlequin in a pantomime. He was still called Master Carey, and his salary was 15*s*. a-week. From this time till 1814, when he made his first appearance at Drury Lane Theatre, London, his life was a series of the vicissitudes, struggles, and privations incident to the profession of an actor in country theatres. In 1808 he became acquainted with Miss Chambers, an actress in the same company in which he had obtained an engagement at Gloucester. Maria Chambers, in July, 1808, became the wife of Edmund Kean, as he then called himself; and when she was near her accouchement with her first child they travelled together on foot from Bristol to Swansea, about one hundred and fifty miles, with only four pounds to pay their expenses on the road. On the 13th of September, 1809, Howard Kean was born. In the winter of the same year they passed over to Ireland, and at Waterford Kean became acquainted with Sheridan Knowles, then an obscure actor, or rather singer. Knowles wrote a drama in blank verse, called 'Leo, or the Gipsey,' which was performed at the Waterford theatre, and in which Kean played the chief character with great effect, and the drama was eminently successful. It has never been printed, but an analysis and extracts are given in the 'Life of Kean.' Charles Kean, the second son, was born at Waterford in 1810 or 1811.

Kean had a high opinion of his own powers, and in his country engagements always stipulated for the privilege of playing the first characters, as they are technically called, declaring that he would 'play second to no man except John Kemble.' On two different occasions when the managers, against his will, had announced him to perform with Master Betty, the Young Roscius, he disappeared till after Master Betty had gone away. One of Kean's best engagements was at Exeter, where his salary was 2*l*. a-week, for which he not only played the leading characters in tragedy, comedy, and farce, but Harlequin in the usual pantomime and the monkey in 'Perouse.'

While Kean was residing at Exeter, in 1813, he engaged to play four nights at Teignmouth; having completed his engagement, he had a benefit, on which occasion he played Rolla in 'Pizarro,' and then there was 'Chiron and Achilles,' in which his son Howard performed, and lastly there was a pantomime, in which he exhibited his usual grace and agility as Harlequin. On this occasion Dr. Drury, late head master of Harrow School, happened to be present, with his wife. On the following morning Mrs. Drury called to pay for the tickets, and told Mrs. Kean that Dr. Drury was much struck with Mr. Kean's performances, and intended to speak to Mr. Pascoe Grenfell, one of the Drury Lane Committee, in his favour. In November, 1813, while playing to a very thin audience at Dorchester, he observed a gentleman in the boxes who was very attentive to his performance, and who seemed to admire it, but who did not applaud. Kean saw that he was appreciated, and played his best. The gentleman was Mr. Arnold, manager of Drury Lane Theatre. On the following morning Mr. Arnold engaged him provisionally on behalf of the Committee of Drury Lane Theatre, for three years, at a salary of eight, nine, and ten pounds per week for each successive year.

A short time before Kean was seen by Mr. Arnold, Mr. Elliston had offered him an engagement at 3*l*. a week to play at the Olympic Theatre, in Wych-street, London, but the engagement had never been completed, and Kean thought no more about it. When he came to London however, and Elliston heard that he was to be brought out at Drury Lane, he claimed his man, appealed to Mr. Arnold, and threatened to appeal to the law, the consequence of which opposition was that from the 6th of December 1813 till the 26th of January 1814, poor Kean and his wife and child were almost famished, not having received a shilling of salary, except 8*l*. which were sent to him at Dorchester to pay their expenses to London.

At length Mr. Arnold ventured to complete his bargain, and the play-bills of Drury Lane announced 'The Merchant of Venice,' 'Shylock by Mr. Kean, from the Exeter Theatre.' There had been no previous puffing, and the house was thinly attended, but the applause was tumultuous; he repeated the character; the house was well filled, and his fame was thenceforth established. On his first night 164*l*. were paid at the doors; on the second, 324*l*.; afterwards the average was upwards of 500*l*. His performance of Othello on one occasion brought 673*l*. 18*s*. 6*d*. After his third performance of Shylock, Mr. Whitbread invited him to breakfast to complete his engagement for three years, at 8*l*., 9*l*., and 10*l*. a week. Immediately after the contract was signed Mr. Whitbread tore it to pieces in Kean's presence, and presented him with a sketch of a new engagement, by which the Drury Lane committee bound themselves to pay him a weekly salary of 20*l*. per week. Not long afterwards the Committee made him a present of 500*l*., and he received many valuable presents from individuals. Drury Lane Theatre was saved from the ruin which had previously threatened it, and rapidly advanced to a state of unexampled prosperity.

Kean's career of success, including a visit to America in 1820, was uninterrupted till his criminal connection with the wife of Alderman Cox became the subject of comment in the newspapers. On the 17th of January, 1825, the action of Cox *v*. Kean was tried, and a verdict of 800*l*. damages was pronounced against him. Some of the newspapers made a series of comments of unusual severity on his private character. The public were exasperated against him, and he was driven from the stage of Drury Lane and afterwards from that of Edinburgh. After some time however he was allowed to go on with his performances at Drury Lane, but he failed to reinstate himself in his former position, and therefore gladly accepted an invitation to pay a second visit to America.

After an absence of two seasons in the United States Kean returned to London, having during the time not only acquired but saved a considerable sum. The London public had relinquished their animosity, but it was in vain. He had always, in the time of his prosperity, been a dissolute man, but he had now fallen into habits of almost constant intoxication. His constitution was broken up, his memory was impaired to such a degree that he could not study a new part, his alacrity of spirit was gone, and his performances were little more than a faint reflection of what they had been. He had separated from Mrs. Kean after the trial with Alderman Cox, and allowed her 200*l*. a year; his mother was alive in 1832, and had from him an allowance of 50*l*. a year. His eldest son, Howard, died in 1813. His son Charles was at Eton College, and when Kean found that he was disposed to become an actor, he absurdly quarrelled with him, and abandoned him, and the young man was obliged to take to the stage in order to obtain the means of subsistence. Charles Kean was a year or two in America; after his return his father became reconciled to him, and in 1833 it was announced that Kean would play Othello, at Covent Garden Theatre, and that Charles Kean would play Iago with him. Kean struggled through the part as far as the speech 'Villain, be sure,' when his head sunk on his son's shoulder: he was borne off the stage, and his acting was at an end: the audience in kindness immediately left the theatre.

Kean lingered on at his residence at Richmond for a while, and before he died wrote to his wife to ask her 'to forget and forgive.' She immediately came to him, and attended him till his death, which took place May 15, 1833.

Kean in his person was small, but well-formed; his face was thin, but handsome; his eyes and hair were black; his countenance, in variety and intensity of expression, was wonderful; his voice, in its upper tones was somewhat harsh, in its lower tones it was soft and melodious; his action was free, graceful, varied, and appropriate; his conception of character was original and true, and evidently the result of observation and deep and careful study. He did not, as some have supposed, trust to the impulse of his feelings. He studied his characters much and anxiously. Frequently, after his family were retired to rest, he would act scene after scene before the pier-glass, endeavouring to produce, by expression of countenance, gesture, emphasis, and modulation of voice, the effect which his conception of the character required.

Kean was indisputably the greatest tragedian of modern times; perhaps, he has not been surpassed at any time. His Othello, in truth and vigour of conception, in brilliance of execution, and power of effect, was entitled to rank with the best of Mrs. Siddons's performances It was an exhibition of consummate skill. The audience was irresistibly swept along by his overpowering energy and pathos, and acknowledged by a series of bursts of applause the intense sympathy which he had infused into all ranks of society and all degrees of intelligence with which the theatre was crowded. In some of his other characters he exhibited the striking points rather than the whole of the character; but this reproach did not apply to his Othello, Richard III., Shylock, and Sir Giles Overreach. These characters were all pervaded with an intensity of passion which he exhibited with matchless energy and truth. His power indeed was in the display of character and passion in all their varied shades. In passages of declamation he had peculiarities of intonation and utterance which gave him a strong and by no means pleasing mannerism. His comedy appears to have been by no means equal to his tragedy. He played Abel Drugger on one occasion for his benefit, and though it was well received, he did not repeat it. Old Mrs. Garrick, who witnessed it, and who admitted that he rivalled Garrick in Richard III., told him that his Abel Drugger was decidedly inferior to her husband's.

Kean's accomplishments in arts connected with his profession were very varied. His fencing was much admired for skilful play and elegance of attitude. He played well on the pianoforte, and sang with exquisite taste and expression.

Of his private character little favourable can be said, though, if the circumstances of his early life be considered, much may be offered in excuse. He was profusely extravagant, spending the vast sums which he received in personal gratifications, and habitually indulging in dissipation among low society in taverns which are kept open to a late hour in the neighbourhood of the theatres.

(*Life of Edmund Kean*, London, 1835, 2 vols. 8vo.)

KEILL, JOHN, a distinguished British mathematician and natural philosopher, was born at Edinburgh in 1671, and having received the rudiments of education in that city, he completed his course of study in its university, of which the celebrated Dr. Gregory was then the mathematical professor. In 1694 he was entered in Baliol College, Oxford, where he distinguished himself by the lectures which he delivered in private on various subjects relating to natural philosophy, principally from the works of Newton; and in 1698 he published in London 'An Examination of Dr. Burnet's Theory of the Earth, with some Remarks on Whiston's New Theory.' In this work Keill pointed out, not without some harshness, the errors into which those theorists had fallen; and the severity of his strictures drew from each of them a reply: it is evident, however, that the advantage in the argument is on the side of Keill. In 1700 he was elected a Fellow of the Royal Society of London, and in the same year he succeeded Dr. Millington as Sedleian professor of natural philosophy. Two years afterwards he published a work in Latin under the title of 'Introductio ad veram Physicam,' which was well received in this country, and was also much esteemed in France—it being there considered as an excellent key to the 'Principia' of Newton. An edition of it in English was published in London in 1733, under the title of 'An Introduction to Natural Philosophy,' &c.

In 1709 Keill went to New England with the appointment of treasurer to the Palatines, who were sent to America as emigrants at the expense of the British government; these persons had been induced to leave Germany, and were living in London in great poverty: he returned, however, in the following year, and was immediately chosen Savilian Professor of Astronomy at Oxford. In the year 1711 he was charged by Queen Anne with the duty of deciphering papers; and it is mentioned as a proof of his sagacity that he once deciphered a letter written in Swedish, though he knew not a word of the language. He held this post about five years.

In 1713 the University of Oxford conferred on him the degree of Doctor in Physic; and in that year he published an edition of Commandine's 'Elements' of Euclid, with a tract on Trigonometry, and one on the Nature of Logarithms. In 1718 he published a work entitled 'Introductio ad veram Astronomiam,' which he afterwards translated into English, and published in 1721 under the title of 'An Introduction to the true Astronomy, or Astronomical Lectures delivered at Oxford.'

In the 'Philosophical Transactions' for 1708 there are two papers by Keill, of which the first is entitled 'On the Laws of Attraction and other Physical Principles,' and the other, 'Of the Laws of Centrifugal Force.' In the volume for 1713 there is a paper by him on 'The Newtonian Solution of Kepler's Problem,' &c. He also gave a paper entitled 'Theoremata quædam Infinitam Materiæ Divisibilitatem spectantia;' and one which is designated 'Observations on Mr. John Bernoulli's Remarks on the Inverse Problems of Central Forces, with a New Solution of the Problems;' both of these were published in the 'Transactions' for 1714.

Dr. Keill died Sept. 1, 1721, in the fiftieth year of his age.

A writer in the 'Acta Eruditorum' having, in a notice of Newton's Treatise on the Quadrature of Curves, stated that the English philosopher had taken the Method of Fluxions from Leibnitz, the indignation of Newton's friends was excited; and in the paper on the Laws of Attraction, &c., which, as above mentioned, was published in the 'Philosophical Transactions,' Keill formally asserted the claims of Newton to priority in the discovery. This paper gave offence to Leibnitz, who, in a letter to the Secretary of the Royal Society, required that Keill should be compelled to retract his assertion: this was not done; and Keill, in a letter to the Secretary, detailed the evidences of what he had stated. [COMMERCIUM EPISTOLICUM, P. C.]

Dr. Keill was not fortunate on another occasion. Entering into the war of problems which was at that time carried on between the English mathematicians and those of the Continent, he somewhat presumptuously challenged John Bernoulli to determine the path of a body when projected in a medium which exercised on it a resistance varying with the square of the velocity: the challenge was accepted, and before Keill could complete his own solution, Bernoulli announced that he had succeeded in obtaining one: the former was, in consequence, compelled to endure in silence the reproof which the foreign mathematician did not fail, unsparingly, to administer.

An edition, in Latin, of Dr. Keill's principal works was published at Milan, in 1742, in 4to., under the title 'Introductio ad veram Physicam et Astronomiam (Huygenii Theoremata de Vi Centrifuga) quibus accedunt Trigonometria; de Viribus Centralibus; de Legibus Attractionis.'

(From the *Philosophical Transactions*.)

KEY ISLANDS are a group of islands of considerable extent in the Indian Archipelago, situated between 5° 20 and 6° 30′ S. lat., and between 132° 30′ and 133° 40′ E long. Three islands are rather large, and called Great Key, Little Key, and Key Watela. The number of the smaller ones is not known, as they are rarely visited by Europeans.

They rise to a moderate elevation above the sea, and all the heights are overgrown with forest-trees, which constitute one of the principal sources of wealth to the inhabitants, who are engaged in ship-building to a considerable extent; a great number of country vessels that ply between Borneo and Timor on the east, and the coast of Papua on the west, are built on this island, especially in the harbour of Doola, which lies on the western coast of Little Key. These vessels are stoutly built, of excellent timber, and are sold for a moderate price. There is no town at Doola, but the harbour is large and surrounded by numerous villages. The native population of the island of Banda obtain from this place an abundant supply of provisions, especially cattle. The European and India goods obtained by this traffic are partly re-exported by the inhabitants to the Arroo Islands [SUNDA ISLANDS, vol. xxiii. p. 291] from the harbour of Elie, which lies on the eastern shores of Great Key. This place is also remarkable for the manufacture of earthenware, which is greatly prized by the inhabitants of all the neighbouring groups, and preferred to all other utensils of that description. Many of the inhabitants are occupied with fishing trepang, and there arrive annually several vessels from Macassar to fetch the produce of this fishery. Very little is known of the inhabitants of this group, except that a part of them have embraced the Islam. This is especially stated of the inhabitants of Elie. It is further stated, that a great number of families from Banda and Ceram have settled among them, and perhaps it may be attributable to these foreigners that the native population has attained a higher degree of civilization than their neighbours.

They are stated to be more friendly to foreigners, and to be more honest in their dealings.

(Kolff, *Reize door den weinig bekenden zuidelijken Molukschen Archipel.*)

KILIAN, the name of a distinguished family of engravers of Augsburg. There have been many engravers of this name and family, but four only were artists of superior ability: Lucas and Wolfgang, the sons of Bartolomaeus Kilian, a goldsmith, who was born in Silesia in 1548, and died at Augsburg in 1583; Bartolomaeus, the third son of Wolfgang; and Philipp Andreas Kilian, a more recent artist of the same family.

Lucas Kilian was born at Augsburg in 1579, and was educated as an engraver by his stepfather Dominick Custos. He studied also the works of Tintoretto and Paul Veronese at Venice, after which he engraved several prints which were sold at Augsburg and obtained him the reputation of one of the best engravers of his age; his style of drawing was however not quite correct, and was somewhat mannered. He died at Augsburg in 1637. Lucas had great command of the graver, and has been known to execute two portraits in a single week; his works are very numerous.

Wolfgang Kilian was born at Augsburg in 1581, was also instructed in engraving by his stepfather Custos, and, as his brother had done, studied also in Venice. The prints he there produced are the most carefully executed of his works. He was latterly compelled by the wants of a numerous family and hard times (it was during the Thirty Years' War) to look more to the quantity than the quality of his labour, and he accordingly executed chiefly portraits. His greatest work is the Celebration of the Westphalian Peace in Augsburg in 1649, in two sheets, after a picture by Sandrart: it contains about fifty portraits. He died at Augsburg in 1662.

Bartolomaeus Kilian, the third son of Wolfgang, was born at Augsburg in 1630, and was first instructed in engraving by his father, who afterwards by his son's request sent him to study with Matthaeus Merrian, a celebrated engraver at Frankfort on the Mayn. From Frankfort Bartolomaeus went to Paris, where he remained a few years, maintaining himself by his own labour; and he returned to Augsburg about 1655, a very able artist both with the graver and the etching-needle. Sandrart terms him a born engraver: his works are very numerous, but are chiefly portraits. He died at Augsburg in 1696.

Philipp Andreas Kilian, the son of Georg Kiliau, closely related to the above, was horn at Augsburg in 1714, and was taught engraving by G. M. Preissler in Nürnberg. He studied also in the Netherlands and in various parts of Germany, and became one of the most distinguished artists of his time; besides his technical skill in the use of the graver he had a good taste and was a correct draftsman, but his execution is somewhat peculiar and monotonous. In 1744 Augustus III., king of Poland and elector of Saxony, created Kilian his court engraver, and invited him to reside in Dresden, but Kilian preferred his native city. He however visited Dresden in 1751 for the purpose of conducting the execution of a collection of prints after the most celebrated pictures of the Dresden Gallery—'Recueil d'Estampes d'après les plus célèbres Tableaux de la Galerie de Dresde.' The completion of this collection was interrupted by the breaking out of the Seven Years' war, in 1756. Upon the cessation of this work he commenced an extensive series of illustrations of the Bible in quarto, which he accomplished by the assistance of various other artists, to the number of 130 prints, but they are not among his best works. He executed many portraits; two of the best of which are the emperor Francis I. and Maria Theresa, after G. von Mytens. Three days before his death he was engaged on a portrait of Pope Clement XIII., which he very nearly completed. He died in 1759.

Heineken enumerates twenty-one members of this family, of whom eighteen were artists, and fourteen of these engravers.

(Heineken, *Nachrichten von Künstlern und Kunstsachen.*)

KILLIGREW, THOMAS, a younger son of Sir Robert Killigrew, was born at Hanworth in Middlesex, in 1611. He travelled in his youth, was present at an exorcism of the nuns of Loudun, was appointed a page of honour to Charles I., and attended Charles II. during his exile, marrying one of the queen's maids of honour. His coarse and licentious wit qualified him peculiarly for securing the favour of his master, who in 1651, in spite of the remonstrances of his wiser counsellors, sent him as his envoy to Venice, where he used his place for raising money for himself, and was expelled with disgrace. On the Restoration Killigrew became groom of the bedchamber, and enjoyed an intimacy and influence with the king which the first men in the nation were unable to obtain. He has sometimes been said to have been officially appointed to be the royal jester; but for this assertion there is no ground, though he was in the way of taking such liberties as none but professional jesters would in any other reign have been allowed to take. He died at Whitehall in 1682. He wrote eleven plays, of which the first two were printed in 1641, and the whole collection in a folio volume in 1664. They do not by any means justify his reputation as a wit. A sufficient specimen of them is furnished by the comedy of 'The Parson's Wedding,' reprinted in Dodsley's 'Old Plays.' Killigrew's oldest brother, Sir William, a much more respectable person, was the author of four or five plays, and of two volumes of moral reflections. He died in 1693. The youngest brother, Dr. Henry Killigrew, wrote a tragedy in his youth, took holy orders, and held several preferments. He was Master of the Savoy at his death, which took place after Sir William's. Dryden's fine elegy on Mrs. Anne Killigrew celebrates a daughter of Dr. Henry.

KIN. [Descent, P. C; Intestacy, P. C.]

KING, PETER, LORD, was born in 1669, at Exeter, in which town his father, Mr. Jerome King, carried on the business of a grocer and salter, though said to be descended from a good family in Somersetshire. To this business he brought up his son, and the future Lord Chancellor of Great Britain served for some years in his father's shop. It was probably his relationship to the celebrated John Locke, whose sister was his mother, that put it into his head, while thus situated, to think of making himself a scholar; but the story told is, that he had by himself made extraordinary proficiency in learning, purchasing books with all the money he could procure, and devoting every moment of his leisure to study, before he was taken any notice of by Locke, by whose advice however he then went to the University of Leyden. How long he studied there we are not informed. He first made himself known by the publication, in an octavo volume, in 1691, of the First Part of his 'Inquiry into the Constitution, Discipline, Unity, and Worship of the Primitive Church;' in which with considerable learning he advocated the right of the Protestant dissenters from episcopacy to be comprehended in the scheme of the national establishment. The Second Part, occupied with the Worship of the primitive church, followed soon after. This work excited much attention, and, besides a correspondence between Mr. Edward Elys and the author, which was published in octavo, by the former, in 1694, drew forth, on its being reprinted in 1713, during the discussions on the Schism Bill, 'An impartial View and Censure of the Mistakes propagated for the ordaining power of Presbyters in a celebrated Book entitled An Enquiry, &c.' in an appendix to 'The Invalidity of the Dissenting Ministry;' and also 'An original Draught of the Primitive Church, in answer to a discourse entitled An Enquiry,' &c., 8vo., Lond. 1717. Both these answers professed to be 'by a Presbyter of the Church of England,' and the latter at least is known to be the production of a nonjuring clergyman named Sclater. Meanwhile King had entered himself at the Inner Temple, and was in due course called to the bar. He appears to have begun very early to make a figure in his profession; and he also soon entered upon a political career, having in 1699 obtained a seat in the House of Commons as one of the members for Beeralston, which he retained for seven parliaments, or to the end of the reign of Queen Anne. He did not yet, however, altogether abandon his first pursuit, but in 1702 published in octavo another learned theological work, 'The History of the Apostles' Creed, with critical Observations on its several Articles.' In July, 1708, he was chosen Recorder of London, and was soon after knighted. In 1709 he was appointed by the House of Commons one of the managers at the impeachment of Dr. Sacheverell, and in 1712 he gave his services, without a fee, as one of the counsel for Mr. Whiston, on his trial for heresy before the Court of Delegates. In November, 1714, a few months after the accession of George I., Sir Peter King was made Chief Justice of the Common Pleas; and he was sworn a privy counsellor in April of the following year. After the great seal had been taken from the Earl of Macclesfield, he was, in June, 1725, appointed Lord Chancellor, and was at the same time raised to the peerage as Baron King of Ockham in the county of Surrey. Lord King however did not as Chancellor satisfy the public expectation, or, it is supposed, his own; and he is said to have injured his health by his labours to make himself master of the department of professional learning necessary for his new duties. He resigned the seals on the 26th of November, 1733, and died at his seat of Ockham on the 22nd of July, 1734. By his wife Anne, daughter of Richard Seys, of Boverton in Glamorganshire, Esq., he left four sons, who all inherited the title in succession, and from the youngest of whom the present peer (created Earl of Lovelace in 1838) is descended.

(*Biographia Britannica.*)

KING'S COLLEGE, CAMBRIDGE, was originally a seminary for a rector and twelve fellows, founded by King Henry VI. in 1441; but in 1443 he changed its form, and endowed it for a provost, seventy fellows and scholars, three chaplains, six clerks, sixteen choristers, and a music-master (who is now also organist), sixteen officers of the foundation, twelve servitors for the senior fellows, and six poor scholars.

Eton College was founded by Henry VI. in 1441, and when he re-founded King's College in 1443 he placed it in immediate connection with Eton College for the supply of its scholars, each of whom at the end of three years from the day of his admission to King's College, is either elected a fellow or is no longer a member of the College. For the last twenty years the vacancies at King's College have been on an average less than four in the year. The process of electing the scholars on the foundation at Eton College for admission to King's College is described under ETON COLLEGE, P. C. S.

The Society, as at present constituted, consists of a provost, a vice-provost, a dean of divinity, two deans of arts, three bursars, a tutor and classical lecturer, a morning reader, a divinity lecturer, a lecturer in mathematics, a conduct, and an organist. The visitor is the Bishop of Lincoln.

A public examination takes place in the Hall of King's College at the end of Easter Term, when the students are divided into classes according to their respective degrees of proficiency; and books, to the value of 10*l.* and stamped with the College arms, are apportioned to the three first scholars in the classical and mathematical examination; the three scholars who are highest in the divinity examination receive prizes in three unequal proportions from the yearly interest of 500*l.* left for that purpose.

There are also other annual prizes which have been specially provided for, either by the College or by bequests of individuals:—20*l.* to be equally divided between such scholars as have in the course of the year been most distinguished for learning and regularity of conduct; 6*l.* to such scholar or scholars as shall be adjudged to have deserved well by application to study and good conduct; two 5*l.* prizes for Latin declamations; two 5*l.* prizes for English declamations: and one 5*l.* prize for the best translation of an English subject into Greek iambics.

King's College has some peculiar privileges. The provost has absolute authority within the precincts; the undergraduates (under certain restrictions) are exempt, within the limits of the college, from the power of the proctors and other university officers; they keep no public exercises in the University schools, nor are in any way required to be examined by the University for their degree of B.A.

King's College and Trinity Hall are the only colleges at which undergraduates can be elected fellows; in King's College, however, they are obliged to take the degrees both of B.A. and M.A. in the University when of sufficient standing, otherwise they are not entitled to the full proportion of their dividends.

There are thirty-six church livings in the patronage of the College,—two in Cambridgeshire, two in Devonshire, one in Dorsetshire, one in Essex, four in Hampshire, two in Hertfordshire, one in Lancashire, two in Lincolnshire, one in Middlesex, five in Norfolk, one in Northamptonshire, six in Suffolk, five in Surrey, one in Sussex, one in Warwickshire, and one in Wiltshire.

The original buildings of King's College consisted of the present chapel and a quadrangular court to the north of it, built of stone, 120 feet in length by 90 feet in breadth. The buildings which constituted this court having become much decayed, it was determined that a large quadrangle should be erected to the south of the chapel; Gibbs was appointed the architect. [GIBBS, JAMES, P. C.] The building was commenced in 1724, and he erected on the west side of the quadrangle the Fellows' Building, or Grecian Building, as it is commonly called. Nothing more was done till July 12, 1824, when the new buildings were re-commenced by Wilkins, and completed in 1828. [WILKINS, WILLIAM, P. C.]

The quadrangle is 280 feet in length by 270 feet in breadth, and consists of the Hall, Library, Chapel, and apartments for the fellows and scholars. It is separated from Trumpington Street on the east by a screen, in the centre of which is the entrance-gateway beneath a domed tower. The Hall, on the south side of the quadrangle, is 102 feet long, 36 feet wide, and 45 feet high, a noble room with a beautiful timber roof, similar to that of Crosby Hall in London, the arches terminating in pendants and adorned with elaborate tracery. There is a music-gallery at each end, and an elegant screen at the west end. The roof is surmounted by two stone lantern-towers, and there is an oriel window filled with painted glass. The Library is supported by buttresses on the exterior, and is ornamented with pinnacles and a pierced parapet. The interior is 93 feet long, 27 feet wide, and 18 feet high, and is handsomely fitted up with projecting book-cases of carved oak. The Grecian Building is 236 feet in length, 46 in breadth, and 56 in height. It is built of Portland stone, in three stories, with a lofty Tuscan portico, and comprises twenty sets of apartments for the fellows. The Provosts' Lodge, 98 feet in length, is a highly ornamented specimen of the Tudor domestic style. It has a lawn in front, and a bridge of one arch which connects it with the walks and fields on the other side of the river Cam. The interior contains some spacious apartments elegantly fitted up. The state-rooms are 35 feet long by 20 feet wide.

The Chapel, which is the only part of the original buildings now remaining, is the architectural glory of King's College. The first architect was Nicholas Cloos, and the first stone was laid in September, 1447. The walls were erected to a considerable height, but little progress was made during the latter part of the disturbed reign of Henry VI., and still less during those of his successors, till, in May, 1508, Henry VII. gave 5000*l.* towards the completion of the building, and his executors, in 1513, under a power conferred by his will, gave a further sum of 5000*l.* for the same purpose. In July, 1515, the exterior, including the roofs, was complete. In 1526 an agreement was made for the painted windows. The screen and stalls were not finished till about 1534.

This magnificent chapel, on the exterior, is 316 feet in length, 84 feet in width, and 90 feet in height to the top of the battlements; the height to the top of each of the four corner turrets is 146½ feet. The interior length is 291 feet, the width 45½ feet, and the height 78 feet. The exterior walls and the two roofs are supported by eleven vast buttresses on each side and four towers at the angles, and there are eight small chapels originally constructed for chantries, on each side between the buttresses. The exterior appearance of the chapel, with its towers and buttresses, lofty windows, pinnacles, and pierced battlements, is as beautiful as it is grand and imposing. In the interior the vast stone roof unsupported by pillars is one of the wonders of architectural skill. Eleven principal ribs spring from the buttresses on each side, forming an arch somewhat flattened at the centre, whence ponderous stones, each of which is said to weigh a ton, hang as pendants, and appear to be the key-stones of the arches. The pendants are carved with alternate roses and portcullises, the principal ribs are connected with each other by diagonal ribs, and the whole roof is formed into one great whole of the lightest and most richly carved fan-tracery, producing an effect of the strongest admiration and astonishment. It is stated that the stone pendants are not really key-stones, but might be safely taken away, together with the walls between the buttresses and the four towers, leaving, as it were, the skeleton of the building to support the roofs. The exterior roof, of light materials, is separated from the interior stone roof by a space of about six feet.

The great east window and twenty-four side-windows, each nearly 50 feet high, are filled with painted glass, and form a series of scriptural pictures of exceeding beauty. The great west window alone is of plain glass, probably for sake of additional light. The whole of the interior, with its screen in the centre, its walls of carved stone, and its stalls and tabernacle-work of carved oak, is worthy of the highest admiration.

(Lysons, *Cambridgeshire;* Dyer, *History of the University of Cambridge;* Wilson, *Memorabilia Cantabrigiæ; Cambridge University Calendar*, 1846; *Cambridge Guide*, 1845.)

KING'S COLLEGE, LONDON, an institution established in October, 1828, and incorporated by royal charter 14th August, 1829, as a college for the general education of youth, 'in which college,' says the charter, 'the various branches of literature and science are intended to be taught, and also the doctrines and duties of Christianity, as the same are inculcated by the United Church of England and Ireland.'

T 2

The charter precludes, in the following terms, persons who are not members of the Established Church from holding office in the college: 'Provided always, that no person who is not a member of the United Church of England and Ireland, as by law established, shall be competent to act as a governor by virtue of his office, or to be nominated or act as life-governor, or be eligible as a member of the council, or to fill any office in the college, except only the Professorships of Oriental Literature and Modern Languages.' King's College is therefore intended to be exclusively a Church of England institution; and in this respect only does it mainly differ from University College, London, which was established two or three years earlier, with the design of affording the advantages of a university education to persons who were excluded either entirely or partially from the universities of Oxford and Cambridge, on account of their not being members of the Church of England. [UNIVERSITY COLLEGE, LONDON, P. C.] The visitor appointed by the charter is the Archbishop of Canterbury for the time being, and the governors, ex-officio, are the Lord Chancellor, the Archbishop of York, the Bishop of London, the Lord Chief Justice of the Queen's Bench, the Secretary of State for the Home Department, the Speaker of the House of Commons, the Lord Mayor of London, and the Deans of St. Paul's and Westminster. There are also life-governors, but their number is limited to eight. The council consists of the governors and the treasurer, and a number of others. The proprietors are those who hold shares or have been donors to the amount of 50*l*. Proprietors are entitled for each donation of 50*l*. or upwards, or for each share, to nominate one student, either for general or medical education in the college, and one pupil in the school, or two pupils in the school. The chief officer of the college is the Principal.

The college was opened in 1831. There are five departments: the Department of General Literature and Science; the Department of Applied Sciences; the Medical Department; the Theological Department; and the School.

In the Department of General Literature and Science, matriculated students, not under the age of 16 (except in special cases), are admitted to a regular and prescribed course of general study, but are allowed to attend any particular lectures not prescribed in that course. 'Occasional students are admitted, who attend any particular course or courses of lectures given in the college. There are apartments fitted up in the college for a limited number of students not under eighteen years of age, who are required to dine in hall. The prescribed course of study comprises religious instruction according to the principles of the Established Church; the Greek and Latin classics; mathematics; English literature, and modern history. The course of religious instruction is given by the Principal and the chaplain, and consists of lectures and weekly examinations. All matriculated students are required to attend chapel daily, and a register of their attendance is kept. The academical year consists of the Michaelmas, Lent, and Easter Terms. Examinations take place at the end of the Michaelmas and Easter Terms, when the students are classed according to proficiency, and at the close of the academical year there is another examination, followed by a public distribution of prizes. After completing a three years' course, those students who have passed through it with credit, and have also attended three extra courses of lectures, are entitled to the diploma of 'Associate of King's College.' There are Professorships of Classical Literature, Mathematics, English Literature and Modern History, Natural Philosophy and Astronomy, Experimental Philosophy, English Law and Jurisprudence, Political Economy, Geology, Chemistry, Botany, Zoology, Fine Arts, Hebrew Language and Literature, Oriental Languages, and of the French, German, Italian, and Spanish Languages respectively, and also of Vocal Music, and Drawing and Perspective.

The Department of General Instruction in the Applied Sciences includes mathematics, general philosophy, chemistry, geology, and manufacturing art, with a special course for students in civil engineering and architecture. The course in this department is two years. Certificates of Approval and Certificates of Honour are granted to students who have distinguished themselves, and who are thus entitled to the diploma of Associate.

In the Medical Department all the usual branches of medical science are taught. The matriculated students are those who enter at once upon the course required by the College of Surgeons and the Society of Apothecaries; and the Occasional Students attend only the lectures of particular professors. At King's College Hospital some of the officers and all the dressers are selected from the pupils of the College.

The Theological Department was instituted in 1846, but has not yet (Jan. 26) been opened. It is intended for students of King's College who shall have passed three years in the department of general literature and science, and who have received a diploma; for graduates of Oxford and Cambridge; and for all persons who shall be approved by the Principal and recommended by a bishop. The course of study will be for six terms (two years), and the fees will amount to 80*l*. It is intended to employ the students as district visitors, and to instruct them in the best methods of conducting schools. They are also to be taught congregational singing. On the completion of the course of study the Principal is to be empowered to grant certificates of attainments and good conduct, which certificates are to be exhibited to the bishop on application for holy orders.

There are libraries attached to the several departments, and also a general library.

The School Department is for youths from nine to sixteen years of age, and the course of instruction comprises Greek, Latin, French, mathematics, writing, arithmetic, book-keeping, history, geography, and English literature; and for the first three classes German, and for the first four drawing. The terms are eighteen guineas annually, exclusive of books and stationery, with an entrance fee of one guinea. In 1845 the number of students and pupils was as follows:—

Matriculated Students.	
Department of General Literature and Science	125
Department of Applied Sciences	30
Medical Department	152
	307
Occasional Students.	
In the various classes, exclusive of the Medical	35
In the Medical Classes	36
School.	
Pupils	471
Total	849

There are several small endowments by benefactors of the college. The Worsley endowment is for the instruction in every department of two scholars, to whom a stipend of 25*l*. a year is paid, and who, on the completion of their studies, are sent out as missionaries; and there are several others for prizes for proficiency and good conduct. Three scholarships have been founded for matriculated medical students. The Master and Fellows of Magdalene College, Cambridge, have given an exhibition for students of the College. In 1835 Mr. Marsden left to the College a valuable library of about 3000 volumes, chiefly in Oriental literature and philology.

King's College forms the eastern wing of Somerset House, which was left in an uncompleted state. In 1830 the government granted this site to the college for one thousand years, on condition that the proprietors completed the building in a style corresponding to the other part of the edifice. The college buildings extend from the Strand to the Thames. They comprise lecture-rooms, a chemical laboratory, a workshop, museums of anatomy, materia medica, zoology, botany, geology, and mineralogy, and libraries, besides a dining-hall, apartments for a limited number of students, and various offices. The school-rooms are in the basement story.

KIVA, KHIVA, or KHYVA, a country in Asia, forming a part of that natural division which goes by the name of Turan, or Lower Turkistan, is situated on the east of the Caspian Sea, between 39° and 45° N. lat., and between 49° and 59° E. long. Its political boundary is not distinctly determined, as it mostly runs through deserts, inhabited by nomadic tribes, which only nominally acknowledge the sovereignty of the Khan, or pay no obedience to his orders. Only on the east, the boundary between Khyva and Bokhara is more exactly fixed. It traverses the river Oxus a few miles north-west of the Bokharian fortress of Charchui, and runs northward near the town of Karakol. On the north of Khyva is the desert called Kizil Cum, which is east of the Sea of Aral, this lake, and the table-land of Oost-oort, which extends from the Sea of Aral to the shores of the Caspian. The Caspian constitutes its western boundary. On the south of Khyva is the desert called Desht Cowas, and through it lies the boundary-line separating Khyva from Persia and Merve. The authority of the Khan of Khyva may extend over a country containing about 150,000 square miles, or over 30,000 more than the extent of the British empire in Europe.

Surface and Soil.—We begin with the wide isthmus which lies between the Caspian and the Sea of Aral. Between 44° and 45° N. lat., an extensive promontory projects into the Caspian. It is called Manghislak, and consists of a mountain-mass, divided into three chains, which according to an estimate rise to 1500 or 2000 feet above the level of the Caspian. From this place a mountainous country extends in a north-eastern direction towards the northern shores of the Sea of Aral; but with its nature we are totally unacquainted, as the caravans ascend it only at its eastern extremity, before they get to the table-land called Oost-oort. At this ascent the mountain-mass does not appear to be more than about 600 feet above the low steppe which extends along its northern base. The country south of this mountain-tract is unknown, with the exception of the eastern part, which is called Oost-oort, and which extends along the western shores of the Lake of Aral, to which it descends with steep cliffs. It is a table-land, about 500 or 600 feet above the sea, and consists of a calcareous formation, which probably is the reason that it has no river or wells, though it is annually covered with a thick layer of snow, and the surface is rather hilly than undulating. The scanty vegetation consists mostly of single plants of the family of the *Chenopodiaceæ*, and at some places tracts several miles in extent are overgrown with *Salsola arbuscula*, Lin., and *Atraphaxis spinosa*, Lin. In general however the soil is a red loam, and is entirely without vegetation. This table-land terminates on the east near 42° N. lat., but towards the Caspian it does not appear to go so far south, perhaps not farther than the Gulf of Kinderli (43° N. lat.).

To the south of the Oost-oort is a depression which appears not to be many feet above the level of the Sea of Aral. It begins on the east near Kana Oorgentsh, where it is only a few miles wide, but it grows wider in approaching the lagune of Kuli Daria, or Kara Boghaz, where it is more than twenty miles wide. The surface of this depression is covered with a minute sand, similar to that found at the bottom of the sea. It is therefore supposed by some writers that the river Oxus or Amoo Deria at some period sent its waters through this depression to the Kara Bogaz. This supposition is supported by the general opinion of the natives. The lagune of Kara Bogaz receives its waters from the Caspian by a narrow strait, and they are therefore brackish. According to the best authorities, the lagune is more than a hundred miles in length, and between twenty and thirty miles across. The banks and the adjacent countries are low.

Above thirty miles from the lagune, and south of it, is an isolated mountain-range running east and west. It extends along the northern shores of the Gulf of Balkhan, and is also called Balkhan. Near the Caspian Sea the hills are of moderate elevation, but north-east of the innermost recess of the bay are some summits called Great Balkhan, which appear to attain an elevation of at least 2000 feet above the level of the sea. This chain does not advance much farther east, but turns southward, and encloses the bay also on the east, where it is known by the name of Little Balkhan. At its southern extremity, south of 40° N. lat., another depression is said to exist, by which it is supposed that the Oxus may have discharged its waters into the Caspian, but this fact rests on information collected from the natives. Between 40° and 39° N. lat. the Caspian is skirted at no great distance from the shores by a chain of mountains, which do not appear to attain a great elevation. They are called the Lambuil mountains. At their southern extremity, near 39° N. lat, the third depression is said to occur. Farther south, to the boundary of Persia, or rather to the river Atreck, and the Gulf of Hassan Kuli, an uninterrupted ridge of sand-hills skirts the Caspian, about ten miles from its shores.

The country which extends from the shores of the Caspian Sea to the vicinity of the river Oxus, south of the Kara Bogaz, is called the Desert of the Truchmenes or Turcomans. With the exception of the mountains and hills already noticed, it is a plain, whose surface is only here and there interrupted by flat depressions, in which lakes are generally found, of which however the greater part is dried up during the summer. The northern part of it cannot properly be called a desert. There certainly are many sandy tracts, but they are not extensive, and the remainder consists of a loamy hard soil, impregnated with salt, which in spring and the beginning of summer is partly covered with grass; but later in the season is without vegetation. In the hot season the Truchmenes feed their herds of camels and horses on the leaves of the bushes and trees that grow in the depressions, or bring them to the boundary of Persia, or of the cultivated part of Khyva. The southern part however is almost entirely covered with sand, and is called Desht Kowar.

Khyva Proper, or the cultivated portion of the Khanat, consists of a comparatively narrow tract contiguous to the course of the river Oxus, and extending from Pitniak, the most southern town of the country (41° N. lat.), to that of Kungrad (north of 43°), a distance of about 150 miles. Its western boundary may be marked by a line drawn from the town of Khywa to that of Kana Oorgentsh, which falls short of a hundred miles. The mean distance of the two lines does not exceed 30 miles, and the area of this tract falls short of 4000 square miles. It is not equal to double the extent of Norfolk. This tract is thickly inhabited, and produces almost every kind of grain in abundance. But its fertility is properly not derived from the soil, which, where it is beyond the reach of irrigation, consists of a hard loam, impregnated with salt, and nearly without vegetation. But the whole region is traversed by so many canals, that it resembles a net. The water is drawn from the Oxus, and runs with a perceptible current to the west and north-west, where the canals terminate in a series of lakes at the foot of sand-hills which divide Khyva Proper from the Desert of the Truchmenes.

This description however applies only to the southern part of the region, or that which lies between 41° and 42° 10′ N. lat.: the delta of the Oxus, or that portion of the country which is enclosed by its arms, contains very little land fit for agricultural purposes. It is annually inundated by the river, and mostly overgrown with reeds and rushes, but there are considerable tracts which serve as pasture-ground for cattle, which is of great importance, as the southern country has no meadow land or pastures. Where the delta borders on Lake Aral, it is a complete swamp all the year round. This country is so low, that probably the whole delta would be laid under water if the level of the Sea of Aral were raised a few feet.

On the east of the river Oxus the cultivable ground is of small extent. About 42° 20′ N. lat. begins a tract of higher ground about two miles from the river, which runs parallel to it for about forty miles to the south-east. This ridge is about four miles wide, and is called Shikhodshelli; it rises about 600 feet above its base, and descends gradually eastward into the Desert of Kizil Cum. Where this ridge terminates (40° 35′), the cultivated land probably extends to five or six miles from the banks of the Oxus, and here also there are several smaller canals.

River and Canals.—The river Oxus, whose modern name is Amoo Deria or Gihon, originates in the elevated mountain region which divides Lower Turkistan from Chinese Turkistan, and which goes by the name of Bolor Tagh. There it issues from a lake, called Sir-i-kol, which is about fourteen miles long from east to west, with an average breadth of one mile, and near 37° 27′ N. lat. and 73° 40′ E. long. Pliny mentions the fact of its rising in a lake, which was supposed to be a blunder, until this lake was recently discovered by Lieutenant Wood. [Oxus, P. C.; Turkistan, P. C., p. 411.] This lake is 15,600 feet above the sea-level, and on three sides bordered by hills, about 500 feet above its level, whilst along its southern bank they rise into mountains, 3500 feet above the lake or 19,000 above the sea, and are covered with perpetual snow, from which never-failing source the lake is supplied. At Issar, about eighty miles from the place where the river leaves the lake, its surface is only 10,000 feet above the sea-level, and it continues to descend rapidly in traversing the mountain region, where it is called Panja. The mountains by which its course is enclosed, terminate at Kilah Chap, where the Oxus is joined by its first great tributary, the Kokcha, or river of Badakshan. Immediately above and below this place the river is fordable in summer. Higher up it cannot be forded on account of the rapidity of the current, nor lower down on account of the depth and the great volume of water, for in these parts it is joined by several large tributaries from the south and north. Where the river enters the lower country, it is from 300 to 400 yards wide, and runs about three miles and a half an hour. It certainly could be navigated in these parts, but it does not appear to be used for that purpose. The waters are led into several canals to irrigate the adjacent fields. The course of the Oxus within the mountain region exceeds three hundred miles, and its windings are large and numerous

From Kilah Chap its general course is to the west for about two hundred miles, through a country where cultivated tracts alternate with sandy deserts of moderate extent. After having passed the meridian of Balkh (67° E. long.), its course declines more to the north-west, and in that direction it continues to the boundary-line of Khyva, watering the adjacent country for more than two hundred and fifty miles. The country which it traverses is unfit for cultivation, except in the immediate vicinity of the river, where the fields are irrigated from the river. It is here still a rapid stream and navigable, but not far from the boundary-line between Bokhara and Khyva rapids are said to exist, which are full of rocks, and during low-water dangerous to be passed by boats. In this middle part of its course the Oxus is not joined by any permanent stream.

Tho lower course of the Oxus, from the above-mentioned rapids, above the Bokharian fortress of Charchui, to its mouth in the Sea of Aral, probably exceeds five hundred miles in length, so that its whole course amounts to nearly thirteen hundred miles. It therefore is larger than any river in Europe, except the Volga. Nearly two hundred miles of its lower course lie through a desert country, similar to that traversed by it in its middle course, but there does not occur any obstruction to navigation, and it is navigated. The river reaches Khyva Proper near 41° N. lat., and traverses it in one bed as far north as 42° 20′, or upwards of a hundred miles. It course is turned by the northern extremity of Mount Shikhodshilli to the west, and a few miles lower down the river divides into two arms, of which the smaller, called Lowdahn, continues to run in a western direction about fifty miles, when it falls into Lake Ak-Cheganak. This lake is situated near the base of the table-land of Oost-oort, and at a distance of more than a hundred miles from the Sea of Aral. It extends about thirty miles from east to west. On its northern side begins a deep depression, which extends along the base of the table-land to the Sea of Aral, and has a mean bread of fifteen miles. It is entirely filled with water even in winter, when the level of the Oxus is lowest, but only to a moderate depth. It is overgrown with reeds, rushes and other aquatic plants, with the exception of a comparatively narrow stripe in the middle, which is unincumbered, and where a perceptible current runs to the Sea of Aral. The water of this swampy tract is sweet. Nearly halfway between the place where the Lowdahn branches off from the Oxus and its influx into Lake Ak-Cheganak, it sends off a branch to the south-west, which is called Szarkrauk, and passes near the town of Kana (Old) Oorgendsh, but its farther course is not known. At Kana Oorgendsh it was, in September, 1842, a river about sixty or seventy feet wide, and two feet deep.

From the place where the Lowdahn branches off the main stream of the Oxns runs due north about ten or twelve miles, and then sends off an arm to the north-east, called Kook-usak, which after a course of more than thirty miles falls into a lake called Daukara. From this lake a swampy depression similar to that of lake Ak-Cheganak is stated to extend to the Aral; but this fact rests only on the information of the natives. From the efflux of the Kook-Usak the Oxus runs again north-west, and sends a branch, called Kara-Baili, to Lake Daukara, and two smaller ones, Kiatt Chargan and Kok-Daria, to the depression north of Lake Ak-Cheganak. Farther on, at a distance of about thirty miles, the Oxus divides into two arms, of which the smaller and western, called Taldyk Daria, reaches the Sea of Aral without dividing any farther, but the eastern, Ulu Daria, enters the sea by two arms, of which the eastern is known as Kasak Daria.

The Sea of Aral, into which the Oxus disembogues, is a great inland lake. [Aral.] It contains numerous islands, and some of them are inhabited and cultivated. The largest, called Tokmak Ata, lies opposite the mouths of the Oxus, and is about twenty miles long. It is partly cultivated and partly overgrown with wood. The distance from the shore is about fourteen miles; and it is stated that when the water of the sea is low a man on horseback can pass through this strait, so shallow is this sea.

The Aral is not mentioned by the classical writers: were they unacquainted with this sea? or did it then constitute a part of the Caspian? Some modern writers have maintained the latter opinion, and it has been asked, over which part of the isthmus lying between the two seas, the strait passed, which united them. It cannot have been the case between 42° 20′ and 46° 30′, as in these parts the isthmus is occupied by the table-land of the Oost-oort, in which no depression of such a description occurs as would be required to form a wide and deep strait. The Russian surveys of the Caspian have made us acquainted with its eastern shores and the countries immediately adjacent to them. The hills which skirt the shores are, as already observed, interrupted at three places. But the two southern openings are of small width, and at a distance of from 300 to 400 miles from the southern shores of the Sea of Aral, and it is hardly probable that a strait of such a length could have passed through the country without leaving indelible traces; but such traces have not been found.

The northern depression above noticed, which opens into the Caspian, with the extensive lagune of Kara Bogaz, may have formed a strait, for its soil consists of such sand as is left behind wherever the sea retires. It is also of considerable width, except towards the eastern extremity, west of Kuna Oorgensh, where it is only a few miles across. In these parts it appears rather to have formed the bed of a river than the receptacle of a strait. This leads us to another more complicated question. The antient authors, who mention the Oxus, state that it flowed into the Caspian Sea, and the Arabic geographers of the middle ages, who were better acquainted with these countries than the antients, hold the same opinion; it can therefore hardly be doubted that it was so. Arrian, whose authority is the best of all, distinctly states that it flowed into the Caspian Sea (*Anab.* iii. 29). But where did the river reach the Caspian? Some authors have maintained that it passed through the southern depression, and entered the Gulf of Khyva, or Ashaïh Beyuri, north of 39° N. lat., which is only one degree farther north than the place assigned to the mouth of the Oxus by Ptolemy. Others think that it reached the sea by the middle opening, and flowed into Balkan Bay. But Alexander von Humboldt is of opinion that historical facts prove that, as late as A.D. 1500, the Oxus still carried its waters to the Kara Bogaz. The most decisive proof he finds in the 'Theatrum Orbis Terrarum' of Ortelius (1570), where an account and map of Russia and Tartary are found, which both had previously (1562) been published in London, by Anthony Jenkinson, the agent of the Russia Company, who was sent to establish a commercial intercourse with central Asia by the way of the White Sea and Moskow. The title of Jenkinson's work is, 'Russiae, Moscoviae, et Tartariae Descriptio, Auctore Antonio Jenkinsonio, Anglo, edita Londini 1562, et dedicata Ill. D. Henrico Sydneo, Walliae Praesidi.' In this map the Oxus is laid down as falling into a large arm of the Caspian at 41° N. lat. This is evidently the lagune of the Kara Bogaz, but it appears that at the time of his travels (1559) the lagune advanced much farther eastwards, which change may have been produced by a change in the level of the Caspian. In his account Jenkinson states that tho water of the Oxus no longer reached the bay as it formerly did, and he attributes this change to the great volume of water which was drawn from the river to irrigate the adjacent countries. But Oorgendsh was at his time a large commercial town, built near the river, which was navigable at that place. In fact, he embarked here, and ascended it to the vicinity of Bokhara. In the history of Abul Ghasi it is stated that in 1575 the Oxus turned to the northward, and began to run into the Sea of Aral, and that the fertile country surrounding Oorgentsh was then converted into a desert. Since that time this place has presented only ruins to the travellers who visited it; no river has been found in its vicinity in the last three centuries. But it would appear that in the last fifteen years the river has mado some efforts to re-occupy its old bed. Several statements tend to prove it, and Basiner found, in Sept. 1842, that the Szarkrauk, near Kana Oorgentsh was from sixty to seventy feet wide, and two feet deep, and that tho place, which was formerly uninhabited, had again been settled, and contained a population of 1000.

A river like the Oxus, traversing such a level country as Khyva, must be subject to frequent and great changes in its course. The river, like the Nile, brings down during the freshets a great quantity of detritus; but, unlike the deposit which the Nile leaves on the field after having re-entered its bed, the earthy matter contained in the waters of the Oxus diminishes the fertility of the soil. To prevent inundations the banks of the river and of the larger canals have been raised considerably above the level of the country. The detritus is thus confined to their beds, and it leaves there a thick layer of mud mixed up with sand. The canals must annually be cleansed, and this is a laborious work. In spite of the embankments partial inundations are rather frequent, and destructive of life and property. In 1838 a considerable portion of the cultivated tract was laid under water, and it is stated that more than five thousand persons perished in this inundation. The level of the river is highest from May to July, and then its waters are very turbid; but in the remainder of the year they are clear and well-tasted. It runs with a considerable current, at least two miles an hour. Its depth varies between six and ten feet. It must be much navigated, as it is stated that there are more than a thousand river-barges in the country.

No country in the world has so many canals as Khyva. The number of the larger canals is stated to exceed twenty. In the southern districts they run westward, but farther north to the north-west, and terminate in that series of small lakes which, with the sand-hills contiguous to them on the west, separated the cultivated region from the Desert of the Truchmenes. Their width varies between seventy and a hundred feet, and their length is considerable; that of Shawat, which is the largest, is at least seventy miles long. From these larger canals others of minor dimensions branch off and water the country to tho distance of twenty miles. The canal of Palwan has twelve such lateral canals, of which one-fourth exceed twenty miles in length and about six are more than fifteen miles long. The water of these canals is brought to the fields by ditches. During the freshets a considerable current runs through the canals, and even at other seasons it is perceptible. The canals are still more navigated than the Oxus itself.

Climate.—Tho climate partakes of that excess of cold and heat by which the plain north and east of the Caspian is distinguished above all other parts of the globe. We have no regular meteorological obervations. On the 8th of October, 1842, the thermometer stood at $90\frac{1}{2}^{\circ}$ at two o'clock in the afternoon in the shade, and on the 22nd of December the same year it fell as low as 11° below zero of Fahrenheit. The summers are very dry; rains fall rarely, but gales are frequent. Frost is commonly experienced towards the end of October, and the lakes and canals are soon covered with ice. The Oxus however does not freeze before the end of the year. In the beginning of January, 1843, the ice of the river was found to be between thirteen and sixteen inches thick. Snow does not fall in large quantities, hardly more than four inches deep at once, and lies rarely more than four days on the ground, which is remarkable, if the frost is continuous. The climate is generally healthy; but in autumn fevers and agues are endemic.

Productions.—Agriculture is attended to with great care and industry; sometimes the fields are ploughed seven times. Great attention is paid to the preparation of manure. On the fields are cultivated rice, wheat, barley, millet, sesamum, cotton, jugari (Holcus saccharatus), peas, lentils, hemp, poppy, and clover; in the gardens, melons and water-melons, pumpkins, carrots, turnips, peas, onions, potatoes, and cucumbers; in the orchards, mulberries for rearing the silk-worm, apricots, apples, pears, plums, cherries, and vine, also currants. But the fruits are not distinguished by flavour, except the melons and water-melons. On the banks of the canals and ditches are alleys of aspen, ash, willow, and poplar. Forest-trees are only found on the eastern banks of the Oxus. In the lower region a plant grows wild, whose roots, *morena*, are used for dyeing red.

The horses of the Truchmenes are very beautiful, and held in great estimation, especially those which are called *argamaks*. Common horses are brought to Khyva by the Khirgis. Many camels are kept, even by the poorer people, and also asses. Few cattle are reared, on account of the want of meadows, except by the Karakalpakes, who import cows and oxen into the cultivated region. Sheep are reared by the Truchmenes, or imported from Bokhara, on account of the fleece: the Kirghis import a considerable number for slaughtering. Fowls are numerous; but turkeys, geese, and ducks, are only kept by the khan. Water-fowl are numerous in the delta, but other wild birds are rare. Of wild animals there are bears, wolves, foxes, wild cats, jackals, hares, wild goats, deer, and wild hogs, mostly in the delta, where also the tiger is sometimes met with. Fish abound in the lakes, river, and Sea of Aral; but are not much eaten, except by the Karakalpakes. Turtles and crayfish abound. Silk-worms are reared to a considerable extent.

Gold and copper are said to exist in the Shikhodshilli mountains, but are not worked. The other useful minerals are stone for building, limestone, pipeclay, salt, and sulphur.

Population and Inhabitants.—The whole population is estimated at 2,000,000, of which one-fourth are stated to be settled in Khiva Proper; so that in that part of the country about 125 persons live on a square mile, which does not appear to be an over-estimate, as there are several places containing some thousands of inhabitants. This region is inhabited by two nations—the Usbecks and the Sartes. The former are a branch of the Turks, whose language they speak, and are the ruling nation. They have abandoned the nomadic life and live in houses, and in summer frequently in tents erected on the fields which they cultivate. Many families of them inhabiting the delta east of Kungrad live on the produce of their herds and still lead a nomadic life. The Sartes are Persians, and the same race of men which, in other parts of Central Asia, are called Tajiks. It appears that they are the most antient settlers of the country. They speak the Persian language, and occupy themselves with the cultivation of the soil, commerce, and handicraft trades. They are a very peaceful and industrious race of men. Among these nations a few families of Jews, Armenians, Afghans, Aimaks, Kirghis, and Karakalpakes are settled; the three last have been imported as slaves.

The uncultivated portion of the Khanat is in possession of three nomadic tribes—the Truchmenes, Karakalpakes, and Kirghis. All three are Turkish nations, and speak dialects of the Turkish language. The Turkomenes (Truchmenes) or Turcomans, wander about in the wide region lying between Khyva Proper and the Caspian, and extending from the southern boundary of the table-land of Oost-oort to the mountains of Korassan and of the Aimaks. They live on the produce of their large herds of horses, camels, and sheep. Their women are very industrious, and make carpets, tents, felts, cloth, and girdles. Though they do not pay strict obedience to the orders of the khan, they admit a certain degree of dependence and acknowledge it by sending presents to him. The Karakalpakes (Black-caps) are numerous in the delta, especially to the east of Kungrad, and some families are found on the south of the Oxus and Lowdahn, north of 42° N. lat. They are, besides, dispersed over all the shores of the Sea of Aral, where they are especially occupied in fishing. At other places they cultivate a piece of ground, but rely for subsistence especially on their herds of cattle, sheep, and goats. They are peaceful and entirely dependent on the khan. The Kirghis, who call themselves Kasauks, wander about in that immense plain which extends from the banks of the Volga to Lake Balkash. Some of their tribes living in the vicinity of the Karakalpakes appear to be in some degree dependent on the khan of Khyva, but we do not know if that dependence is real or only nominal. They have numerous herds of horses and sheep, of which they annually import a great number into Khyva.

Towns and Villages.—It is observed as a very remarkable circumstance, that in no part of Central and Western Asia, except in Khyva, the country lying between two towns or large villages is interspersed with a great number of single farming establishments, which are situated in the centre of the lands belonging to them. This proves that the inhabitants must enjoy a considerable degree of security. The number of towns containing from 3000 to 10,000 inhabitants is rather great in proportion to the extent and population of the country.

Khyva, the capital and residence of the khan, consists of about 700 mud houses, but the suburbs contain 1500, and the population exceeds 12,000 individuals. The streets are crooked, and so narrow that a loaded camel cannot pass through them. The palace of the khan is only a large mud building. There are two colleges and three mosques, all built of brick. The karavansera is also of brick and arched over.

The other large towns are New Oorgentsh, Gurlan, Mai gyt, and Kiptshak, in the vicinity of the Oxus, and Shawat and Tasshathaus in the interior of Khyva Proper. The town of Kungrad may be considered the capital of the nomadic population of the delta. In summer it has very few inhabitants, but in winter it is the common residence of several nomadic tribes that inhabit the adjacent country. Its walls are stated to be more than twelves miles in circuit.

Manufactures.—The manufactures of Khyva are inferior to those of Bokhara, but still of some importance. The chief are those of cotton, of which several kinds of stuffs are made by the Sartes, who also work up all the raw silk made in the country, and they produce some very good articles. Worsted cloth and other articles of wool are made by the nomadic nations. In some places are large manufactures of earthenware. Several utensils of copper are made in the town of Khyva, but all articles of iron are imported, almost exclusively from Russia: only a few Kirghis settled in the khanat exercise the trade of blacksmiths.

Commerce.—In a country like Khyva, whose soil supplies its inhabitants abundantly with food, whilst its manufactures afford almost all the other necessaries of life, but do not yield any article for exportation, foreign commerce must be very inconsiderable. The most active is that with Bokhara, from which place also a few Indian goods are imported: we are however not acquainted with the details of this trade. From time to time a caravan goes from Khyva to Orenburg. It exports a few manufactured articles, sheep-skins, hides, and horses, and brings back utensils of cast-iron, some woollen cloth, and copper and other metals. It passes through Kana Oorgentsh, traverses the table-land of Oost-oort, near the shores of the Sea of Aral, and after descending to the low plain its route lies through the steppe of the Little Horde of the Kirghis The commerce between Khyva and Persia is still less important. Khyva sends there chiefly horses, and receives in return dried fruits and some silk goods.

History.—Khyva probably was a part of Bactria when that country submitted to the sway of Cyrus, the founder of the Persian empire, and constituted a portion of the province of Bactria at the time of the conquests of Alexander the Great. After his death it was united to the kingdom of Syria, but separated from it by the revolt of Theodotus of Bactria (256 before Christ), who founded a separate kingdom in these parts. But in the second century before Christ the nomadic nations of Upper Turkistan began to descend into Turan, and took possession of the countries north of the Oxus and south of the Sea of Aral. They seem to have laid waste the country and kept possession of it during more than two centuries. In the second century after Christ however they were subjected to the sway of the Chinese emperors, who at that period extended their dominions to the shores of the Caspian. It is not known at what time and in what way the Chinese were compelled to abandon this country. In the third century of our æra it was connected with Persia, and remained so up to the tenth century, when one of its governors acquired independence and erected the kingdom of Karizm or Khowarism, which appears to have remained an independent state until conquered by Gengis Khan (1218). The descendants of Gengis Khan remained in possession of the country, which continued to form an independent kingdom under the name of Khowarism, up to 1379, when the town was taken by Timur, and the country annexed to his possessions. Khyva remained a part of Mawar-el-nahr, or the kingdom of Samarkand, to the beginning of the sixteenth century, when a Turkish nation, the Usbecks, under the auspices of Shibani Khan, descended from Upper Turkistan, and by degrees took possession of the whole of Turan. Khyva, as it appears, soon became an independent state under an Usbeck prince, and has remained so up to this time. A few years ago Russia complained that the caravans passing between Orenburg and Bokhara, in travelling to the country east of the Sea of Aral, were frequently molested and robbed by the subjects of the Khan of Khyva; and as they knew that the khan was unable to restrain the nomadic nations from attacking the caravans, they resolved on taking possession of the country; probably also with the view of extending farther their conquests in this direction. In the autumn of 1839 Russia dispatched an army of 5000 men, under General Perowski, but they did not reach Khyva. They suffered greatly from want of water, fuel, and fodder for horses and camels during their passage through the Desert of the Little Horde of the Kirghis, and before they reached the base of the table-land of Oost-oort, they were overtaken by such severe cold that nearly all the camels (12,000) and a great number of the horses perished; and thus they were obliged to return to Orenburg, and when they arrived there it was found that one-third of the soldiers had died.

(Murawiew, *Reise in Chiwa;* Humboldt, *L'Asie Centrale;* Basiner, *Nachrichten über seine wissenschaftliche Reise nach Chiwa*, in Zimmermann's *Denkschrift über den untern Lauf des Oxus;* Abbo., *Narrative of a Journey from Heraut to Khiva, Moscow, and St. Petersburg*, &c.)

KLAPROTH, JULIUS HEINRICH VON, one of the most eminent Oriental scholars of modern times, was born at Berlin, on the 11th of October, 1783. He was the son of the celebrated chemist Klaproth, who wished to bring him up to his own profession, but the boy was little inclined to it, and employed most of his time on other pursuits unknown to his father. He was about fifteen when, during a public examination of the pupils of the college in Berlin where he received his instruction, he was so backward that one of his examiners cried out indignantly, 'Why, you know nothing at all.' 'Beg your pardon,' answered young Klaproth, 'I know Chinese.' His answer was received with astonishment and distrust, but he immediately gave proofs of his having made great progress in that difficult language, and he became henceforth an object of admiration to all who had an opportunity of witnessing his extraordinary talents. He had learned Chinese secretly without the help of a master, and, according to his own saying, he first began it in 1797, after he had found out a small and incomplete, but nevertheless valuable collection of Chinese books in the public library at Berlin. His father soon became reconciled to the pursuits of his son, but perceiving that he devoted his time exclusively to Oriental languages, he sent him, in 1801, to the university of Halle, with a strict injunction to study the classical languages. Klaproth remained several years at Halle, and in 1802 published the first number of his 'Asiatisches Magazin.' The learned Count John Potocki having heard of Klaproth, hastened to make his acquaintance, and was so struck with him that he immediately proposed to him to enter the service of the emperor Alexander of Russia. Klaproth accepted the proposition, and the count being in great favour with the czar, Klaproth was formally invited to settle in Russia. Upon his arrival at St. Petersburg, early in 1805, the Academy of Sciences presented him with a diploma of Adjunctus, for the Eastern languages and literature, and the Russian government being then engaged with the plan of sending an embassy to China, Count Potocki obtained for Klaproth the place of an interpreter. Klaproth actually got his commission before the appointment of an ambassador. This honour was finally bestowed upon Count Golowkin, a vain and ambitious man; and Count John Potocki was put at the head of a body of scholars who were to accompany the embassy. Klaproth set out alone, before the embassy was ready to undertake the journey, and after having traversed the Ural Mountains, and passed through Katherinenburg, Tobolsk, and Omsk, employing all his time in studying the country and its inhabitants, he finally arrived at Irkutzk, which was the place of meeting for all the members of the embassy. Count Golowkin and his suite arrived soon after him, in October, 1805, and after having been detained some time at Irkutzk and Kiakhta, the embassy crossed the Chinese frontier on the 1st of January, 1806. They had scarcely proceeded a hundred and eighty miles when they were again detained, Count Golowkin having refused to submit to the Chinese court-ceremonial, and after having remained a month in a miserable Mongol town, the count was informed that the court of Pekin did not wish to see him. The embassy consequently returned to St. Petersburg. Klaproth however did not accompany them, but took a solitary route through Southern Siberia, and only reached the Russian capital in the beginning of 1807. The information which he brought back to St. Petersburg was deemed so important, and his own abilities were so fully acknowledged, that before the end of the year he was sent on a scientific mission to the Caucasian provinces. He returned from this country in January, 1809, with a large stock of scientific and political knowledge, most of which afterwards formed the subject of separate works and articles in learned periodicals. The Academy of St. Petersburg chose him an extraordinary member, and the emperor conferred upon him the title of Aulic councillor, and made him a knight of the order of Wladimir, an honour which placed him among the Russian nobility. However, Klaproth had expected still greater distinctions, and the Russian government having secretly put a stop to his intended publication of his journey through the Caucasus, he began to feel uneasy in Russia. He was too frank, too liberal, and too bold to feel happy among slaves. He nevertheless prolonged his sojourn in Russia, and was active in establishing a school of Oriental languages at Wilna, and in making a descriptive catalogue of the Chinese and Mandshu MSS. in the imperial library at St. Petersburg. He was sent, in 1811, to Berlin, for the purpose of superintending the engraving of the characters which were intended for printing those MSS. In 1812 he tendered his resignation to the Russian government, and after a considerable time received his dismission, with the remark that by soliciting permission to retire he had forfeited all his civic and scientific titles and privileges in Russia. In St. Petersburg however there were strange rumours afloat as to the real cause of his disgrace, and it was said there, and afterwards repeated in foreign countries, that his love of rare MSS. and books went beyond mere scientific attachment. No sooner was Klaproth free than he began to bring out his journal of his travels in the Caucasus; but Germany became the theatre of a long and bloody war, and the learned Orientalist fled from place to place without finding repose for his pursuits. During this war he became acquainted with some of the most distinguished men in the French armies, and his name became known to Napoleon. Klaproth's admiration for the French emperor must have been great, for after Napoleon had been banished to Elba he suddenly left Germany and visited the fallen hero in his exile. Napoleon received him very well, and it appears that Klaproth, expecting the emperor's early return to France, offered him his services, and was chosen the future editor of one of the first newspapers in France. The 'hundred days' however passed away without any notice being taken of Klaproth, and when the Bourbons returned to Paris he was at Florence, in rather uncomfortable circumstances. Count John Potocki, having heard of this, invited him to settle in Paris, and there Klaproth lived some time by his pen, when he accidentally met with William von Humboldt, who, although he had seen him only once, employed all his influence to procure for him a situation suitable to his pursuits and his merits. It was at Humboldt's recommendation that the late King of Prussia, Frederick William III., conferred upon Klaproth the honorary title of royal professor of Oriental languages and literature, which was accompanied with a liberal pension, and a promise to defray the expenses of printing whatever works the professor might think fit to publish. Klaproth was further allowed to stay in Paris as long as he pleased. Placed beyond all want, and moreover enjoying an income which enabled him to gratify his love of pleasure and refined society, Klaproth now exhibited an extraordinary activity, and it was in the years subsequent to 1816 that he published most of those literary productions which established his European reputation. The life which Klaproth led in Paris, leaving his study only to plunge into the torrent of mental and physical excitement of the gayest capital of Europe, proved fatal to his health. In 1833 the symptoms of a dropsy of the chest becoming alarming, a tour to Berlin, where he was received with great distinction by the king and the public, produced a good effect; but shortly after his return to Paris the symptoms became worse, and his bodily sufferings were unfortunately accompanied by occasional derangement of his intellectual faculties. The skill of the first physicians of Paris proved ineffectual, and after long and painful sufferings Klaproth died suddenly, on the 27th of August, 1835, and was buried in the cemetery of Montmartre.

Klaproth was one of the best scholars and decidedly the best linguist of an age which can justly boast of great linguists. His penetration and sagacity, and the quickness of his perception, were extraordinary; clearness and perspicuity distinguish his style; and his memory was so happy and capable of retaining the most different impressions without ever confounding them, that he seldom made more than scanty extracts. When he began a work, it was already clear and distinct in his mind, and the composition did not take him more time than was required for the mechanical act of writing. If we compare Klaproth with William von Humboldt, we find that Klaproth had the superiority in analytical power, while Humboldt surpassed Klaproth in the synthetical. Klaproth's biographer in the 'Biographie Universelle,' says that he was naturally of a kind disposition towards everybody. Yet this kind-man was the dread both of his literary enemies and friends. The former dreaded his answers to their attacks, and the latter observed the greatest precaution in their intercourse with him, lest they should irritate his irascible temper; and it would seem as if he made no distinction between scientific and moral error, so severely did he handle those who incurred his scorn through a display of inaccuracy or ignorance in matters of learning. His controversy with Professor Schmidt, the Mongol scholar in St. Petersburg, is an instance of this.

It would take much space to give a complete catalogue of his numerous publications, especially as the majority of them consist of pamphlets, memoirs, and dissertations, many of which are not of any general interest. Previous to 1812 he had only published some minor works, as, for instance, 'Inschrift des Yü, übersetzt und erklärt,' Halle, 1811, 4to., being a German translation, with notes, of a Chinese inscription; and articles in different learned periodicals. The 'Asiatisches Magazin' was edited by himself. The following are his most remarkable works.

1, 'Reise in den Kaukasus,' with maps, Halle and Berlin, 1812-14, 2 vols. 8vo.: of these 'Travels in the Caucasus' a French translation, with valuable additions, appeared in Paris in 1823; 2, 'Exécution d'Automne (The Autumnal Execution), Peking, 20ème année Kia King, 8ème lune, jour malheureux:' this severe critique of Weston's translations from the Chinese was published in Paris in 1815; 3, 'Supplément au Dictionnaire Chinois-Latin du Père Basile de Glemona, imprimé en 1813, par les soins de M. de Guignes,' Paris, 1819, fol.; 4, 'Abhandlung über die Sprache und Schrift der Uiguren,' &c., Paris, 1820, 8vo. (a Treatise on the Language and the Characters of the Uigurs); 2nd edition, in French, Paris, 1823; 5, 'Asia Polyglotta,' in 4to., with tables, in folio, Paris, 1823; 2nd edition, Paris, 1829, with a Life of Buddha according to the legends of the Mongols: this is a classification of the Asiatic nations according to their languages, with a comparative vocabulary of most of the Asiatic languages; 6, 'Examen critique des Extraits d'une Histoire des Khans Mongols, inséré par M. Schmidt dans le 6ième vol. des Mines de l'Orient,' Paris, 1823, 8vo.; 7, 'Sur l'Origine du Papier Monnaie en Chine,' Paris, 1823, 8vo: this very interesting treatise on the origin of paper-money was shortly afterwards translated into English. Paper-money was known in China as early as 119 B.C., and was in general use in the tenth century of our æra, but it fell into disuse in the middle of the fifteenth century; Marco Polo mentions it 8, 'Tableaux Historiques de l'Asie depuis la Monarchie de Cyrus jusqu'à nos Jours,' with twenty-four maps, Paris, 1824-26. 9, 'Mémoires relatifs à l'Asie,' &c., Paris, 1824-28, 3 vols. 8vo., with maps and engravings; one of the most valuable works on Asia. 10, Dr. W. Schott's 'Angebliche Uebersetzung der Werke des Confucius aus der Ursprache, eine literarische Betrügerei,' Leipzig and Paris, 1825, 8vo.: 'Dr. W Schott's alleged translation of the works of Confucius, from the language in which they were originally written; a literary fraud,' by W. Lauterbach (the pseudonymous name of Klaproth). Two Chinese, the one a labourer and the other a cook, having arrived in Germany, got their livelihood by showing themselves for money. They excited the curiosity of the learned, whom they persuaded that they were priests of high rank, and the Prussian government believing their story, sent them to Halle, where they were to teach Chinese in the university. There Professor Schott became acquainted with them, and made use of their names and assistance in publishing a German edition of the works of Confucius, which however was little better than a re-translation of previous English translations. Klaproth, with his usual sagacity, discovered the fraud, unmasked the Chinese impostors, and chastised Schott most severely, but, in this instance at least, most deservedly. 11, 'Tableau historique, géographique, ethnographique, et politique du Caucase et des provinces limitrophes entre la Russie et la Perse,' Paris, 1827, 8vo.; one of the most important works on the Caucasus, especially at the time when it was written. 12, 'Vocabulaire et Grammaire de la Langue Géorgienne, publié par la Société Asiatique,' Paris, 1827: the first part is Georgian-French, the second French-Georgian. 13, 'Vocabulaire Latin, Persan, et Coréan, d'après MS. écrit en 1303,' Paris, 1828, 8vo. This vocabulary was copied from a MS. which once belonged to Petrarch, and was first published in the 'Journal Asiatique.' 14, 'Chrestomathie Mandchou,' Paris, 1828, 8vo.; 15. 'Aperçu de l'Origine des diverses écritures de l'ancien Monde,' Paris, 1832; 16, 'Lettre sur les Découvertes des Hiéroglyphes Acrologiques adressée à M. le Comte de Goulianoff,' Paris, 1827, 8vo., followed by a 'Seconde Lettre' on the same subject, addressed to Mr. D. S—, published in the same year; and, 17, 'Examen critique des Travaux de M. Champollion, jeune, sur les Hiéroglyphes,' Paris, 1832, 8vo. Klaproth is of opinion that although the younger Champollion deserves great credit for having improved and increased our knowledge of hieroglyphics, by correcting and extending the theory of Dr. Young, and discovering the signification of many new signs, yet Champollion's theory is only available for reading the names of kings and other high personages, and is useless with respect to ideographical and symbolical signs, which, according to Klaproth, Champollion unsuccessfully attempted to decipher. 'The system of Champollion,' says Klaproth, 'is not founded on a solid basis, and we thus see him altering, whenever he thinks fit, that signification which he laid down as the original meaning of the phonetical as well as symbolical characters. That scanty knowledge of the antient Egyptian language which we can derive from the Coptic language is quite insufficient for explaining the sense of an antient Egyptian inscription, even if it were written in phonetical characters; and the alterations made in the inscription of Abydos,' continues the reviewer, 'gives an adequate idea of the degree of confidence which we can bestow upon the theories of deciphering hieroglyphics.' Klaproth, of course, speaks of the state of knowledge of his time. 18, 'Notice d'une Mappemonde et d'une Cosmographie Chinoises, pubtiées en Chine, l'une en 1730, l'autre en 1793,' Paris, 1833, 8vo.; 19, 'Nipon o Daï itsiran, ou Annales des Empereurs du Japon, traduit par M. Isaac Titsingh, revu et corrigé sur l'original par M. Klaproth, et précédé d'une Histoire Mythologique du Japon,' Paris, 1834, 4to.

Among the publications edited or translated by Klaproth, we must mention the publications of the Asiatic Society of Paris, of which he was one of the founders; Güldenstädt's Travels in the Caucasus; Count John Potocki's Travels in the steppes of Astrakan and the Caucasus; Father Della Penna's description of Tibet; a description of the same country, translated from the Tibetan language into Russian, and thence into French; Timkowski's Travels to Pekin; 'Magazin Asiatique,' from 1825-27, &c. &c. Among his minor productions a letter to Baron Alexander von Humboldt on the invention of the Compass, and another on the art of printing and gunpowder, are both important and interesting. Klaproth's contributions to the learned periodicals of France, Germany, and Russia would fill moro than twenty octavo volumes. Klaproth was not only an Oriental scholar, but also an excellent theoretical as well as practical geographer, as appears from Critical Observations on Arrowsmith's Map of Asia; his 'Carte de l'Asie Centrale, d'après les cartes levées par l'ordre de l'Empereur Kiang-Loung, par les Missionnaires de Pekin,' Paris, 1835, in four large sheets: 'Carte de la Mongolie, du Pays des Mandchou, de la Corée, et du Japon,' Paris, 1833; and many others of a smaller compass, in several of his works. Klaproth left ready for the press 'Description géographique, statistique, et historique de l'Empire Chinois,' which was to appear in French and English, but has not yet been published. He left incomplete a MS. containing the plan of a new 'Mithridates,' and a Commentary on Marco Polo: both these works were completed in his mind, but as he was not in the habit of making many notes previous to writing, there is no hope of seeing these two MSS. ever made ready for the press. A complete catalogue of all his publications is contained in *Catalogue de la Bibliothèque de feu M. de Klaproth, par le Libraire Merlin*, Paris, 1839, 8vo.

(*Biographie Universelle; Neuer Nekrolog der Deutschen;* Quérard, *La France Littéraire.*)

KLE'BER, JEAN BAPTISTE, according to the best authorities, was born at Strasbourg in the year 1754, though some place the date of his birth three or four years earlier. He was brought up by his father, who was a domestic in the household of the Cardinal De Rohan, to the profession of an architect, and was sent to Paris at an early age to complete his studies. While there circumstances enabled him to render some important services to two young Bavarians, who, having interested themselves in his behalf, induced him to accompany them to Munich, and through their influence he entered the military college of that city. His rapid progress in acquiring the science of war gained him the patronage of General Kaunitz, son of the celebrated Austrian minister of that name, by whom, at the completion of his college career, he was appointed to a sub-lieutenancy in an Austrian regiment. He served seven years in that corps, which he left in 1783, in order to return to his native country. He there resumed his former profession, and obtained the situation of inspector of public buildings at Béfort in Upper Alsace.

The breaking out of the French Revolution opened to him a more brilliant career. He bad taken a prominent part in a revolt at Béfort in 1791, and had enabled the republicans of that town, by putting himself at their head, successfully to resist the regiment of Royal Louis, which had been called to suppress it. To screen himself from the consequences of this action he enlisted as a private soldier in the grenadier company of the battalion of volunteers which had been raised in the department of the Upper Rhine. By his bravery and talents he soon attained the rank of adjutant-major, in which capacity he acted for some time under General Custine, and when Custine was afterwards brought to trial, he had the courage to present himself before his sanguinary judges, and give testimony in his favour. At the siege of Mayence in 1793 he displayed considerable courage and judgment: his services were rewarded by the rank of adjutant-general, and shortly afterwards he became brigadier-general. From thence he was ordered to La Vendée to oppose the insurgent royalists; he led there the soldiers of the garrison of Mayence, on whose courage and devotion be could reckon. At the celebrated combat of Torfou (September 19, 1793), while charging the enemy at the head of the advanced guard of his regiment, he fell with several wounds, and his life was only preserved by the prompt assistance of his soldiers. The agents of the National Convention construed into a crime his humane interference in stopping the cruelties which were exercised towards the prisoners and the unoffending inhabitants of the country. However he was only removed to a command in the Army of the North, and afterwards in that of the Sambre and Meuse, when he rose to the rank of a general of division.

At the battle of Fleurus (June 26, 1794) he commanded the left wing of the French army, and by his skilful manœuvres greatly contributed to the victory. He then marched against Mons, which he retook from the Austrians, and having forced the passage of the Roer, he drove the enemy back to the right bank of the Rhine. Returning towards Maastricht, he took that strong fortress, after a siege of twenty-eight days.

In 1795 he directed the passage across the Rhine of the army of the Sambre and Meuse, and, when compelled to retire before superior forces, he effected a retreat in which his cool intrepidity and skilful dispositions were alike remarkable. In the year following he partook of the glory which attended the success of General Jourdan's operations at the opening of the campaign; and he afterwards refused the command of Pichegru's army, when this general was disgraced for holding treasonable communications with the enemy. [PICHEGRU, P. C.]

Discontented with the manner in which the Directory managed the military affairs, Kléber retired to Paris, where he spent the greater part of the year 1797, and occupied himself with writing his memoirs. When however Bonaparte was appointed to the chief command of the army for Egypt, he made it a special request to the Directory to be allowed to take him as one of his generals of division. Kléber joyfully accepted the companionship of arms with a chief whose brilliant achievements already prognosticated his future glory. The army likewise which he accompanied was in a great measure composed of the veteran soldiers who bad distinguished themselves in the plains of Italy.

At the siege of Alexandria, on the first landing of the French forces, he was wounded in the head while gallantly climbing the ramparts, but he did not retire from the conflict till he bad received a second and a severer wound. When the city was taken Kléber was appointed to the command of it, and of the whole province of which it was the head-quarters. He afterwards joined his division and took part in the expedition to Syria; he there distinguished himself by the capture of the forts of El Arish and Gaza, and was at the taking of Jaffa. He was also at the memorable siege of St. John of Acre, where he rendered himself conspicuous by his undaunted bravery, and shared every danger with the common soldiers. He was however withdrawn from the siege by order of Bonaparte, who desired him to march with his division to reinforce the troops stationed at Nazareth under the command of General Junot, and to repel the large army composed of the remnants of the Mamelukes under Ibrahim Bey, the Janissaries of Aleppo and Damascus, and numerous hordes of irregular cavalry, who were advancing to the support of their besieged countrymen at Acre. The arrival of Kléber's division was most opportune, for the enemy had already crossed the Jordan, and were rapidly pressing in considerable numbers towards the coast. Kléber left Nazareth with the entire body of his troops in order to make an attack upon the Turkish camp, but in attempting to do so he was anticipated by the enemy, who advanced against him with fifteen thousand cavalry and as many infantry. Kléber formed his small army of two thousand men in squares, and placed the artillery at the angles, which had scarcely been effected when he was fiercely attacked by the whole force of the enemy's horse. A deadly fire from the close ranks of the squares responded to this impetuous attack, and for six hours that the contest lasted not one square was broken nor a foot of ground lost. Succour at length arrived, and the battle of Mount Thabor (April 17th, 1799) terminated in the total defeat of the Turkish troops. The siege of Acre however was renewed in vain, every assault against it proved unsuccessful, and 'British valour, combined with Asiatic enthusiasm,' was finally triumphant. [ACRE, P. C.; BONAPARTE, P. C.]

The French on their return to Egypt obtained at Aboukir another signal victory over the Turks; and the day after this decisive battle Bonaparte returned to Alexandria, where he learnt the capture of Corfu by the Russians and Turks, and the close blockade of Malta by the same powers. These circumstances, combined with the loss of his fleet at the battle of the Nile, determined him upon leaving Egypt.

On the 22nd of August, 1799, he secretly embarked, accompanied by several of his generals, his secretary Bourrienne, with Berthollet and Monge, who had joined the expedition for the furtherance of science. Before leaving he signified his resolution to Kléber in a letter, by which he appointed him his successor in the chief command of the Egyptian army, and authorized him to conclude a convention for the evacuation of the country in the event of no succour arriving from France during the following spring, and if the mortality from the plague among his soldiers should amount to fifteen hundred men.

The sudden departure of Bonaparte spread anxiety and distrust throughout the camp; the reputation of his successor however, who enjoyed the highest confidence of the army, tended greatly to dissipate their fears. But the talents of Kléber did not at first appear to be equal to the difficult circumstances in which he was placed. He not only permitted himself to be swayed by feelings of indignation at what he deemed the abandonment of the army by its former chief, but he committed the fault, which in his position became a crime, of openly declaring his opinions to his dissatisfied colleagues in command; he thus caused the seeds of discontent and desire of home, which had been previously sown among the troops, to ripen to a maturity which soon threatened the ruin of the expedition. A letter addressed by him to the Directory contains many erroneous and exaggerated statements which had been furnished by Poussielgue the army administrator, and presents a most gloomy picture of the state of affairs in Egypt. A copy of it is in the Memoirs dictated by Napoleon at St. Helena to the Count de Montholon, and is rendered the more valuable on account of the copious comments which accompany it, and which, though written in no friendly spirit, are for the most part borne out by contemporary testimony. In this letter Kléber complains that his army is reduced to one-half; that it is destitute of the necessary stores and munitions, and that the greatest discontent prevails. He further asserts that the Mamelukes were dispersed but not destroyed, and that the Grand Vizier was marching from Acre at the head of thirty thousand men. Two copies of this letter were sent, one of which fell into the hands of the English, and was the immediate cause of the expedition under Sir Ralph Abercromby, by which the French were compelled to abandon Egypt. In justice however to Kléber it must be mentioned that his chief fault consisted in trusting too implicitly to the statements which had been given to him by one who, though loaded with favours from Bonaparte, made this ungrateful return to his absent benefactor in order to secure his present interests.

Kléber, under the influence of these despondent feelings, addressed proposals of accommodation to the Grand Vizier; though at the same time he made vigorous preparations to repel the Turkish army. An unexpected reverse moreover increased the necessity of a negotiation. The Grand Vizier with upwards of forty thousand men had crossed the desert, and, assisted by some British officers, had captured the fort of El Arish, justly deemed one of the keys of Egypt. General Dessaix was, against his will and contrary to his judgment, appointed negotiator on the part of the French, and, after many debates and frequent delays, a convention was signed at El Arish on the 28th of January, 1800, by which it was agreed that the whole of Kléber's army should return to Europe, with its arms and baggage, either on board their own vessels or some furnished by the Turks; that all the fortresses of Egypt, with the exception of Alexandria, Rosetta, and Aboukir, should be surrendered within forty-five days from the time that the convention was ratified; and finally, that the Vizior should pay a sum equivalent to about 120,000*l.* during the time that the evacuation was taking place. The English admiral, Sir Sidney Smith, though not vested with full authority from his government to conclude such a convention, had entered willingly into it, and was honourably preparing to see it carried into effect. Three months however before these events the British government had dispatched orders to Lord Keith, who had the command of the Mediterranean fleet, to refuse his consent to any treaty in which it was not stipulated that the French army should be considered prisoners of war; and a letter from this admiral reached General Kléber, warning him of his intention to detain any vessel returning to Europe by virtue of a capitulation. The French commander made a noble use of the opportunity which was now presented to him of retrieving his military character. Danger revived his energies and roused his courage. He immediately ordered the evacuation of the strongholds to be stopped, and prepared to resume hostilities. In one of those animating proclamations so common in modern French warfare, he indignantly declared to his soldiers that victory was the only answer to such insolence, and bade them be ready to fight. This appeal to their courage was received by the shouts of the army. On the night of the 19th of March, 1800, Kléber formed his army, which was 12,000 strong, into four squares, with the artillery at the angles, and the cavalry between the intervals; the two squares on the left were commanded by General Regnier, and those on the right by General Friant; the whole army was drawn up on the plain fronting the ruins of Heliopolis. Before them was the Ottoman army, amounting to upwards of forty thousand men; in their rear was Cairo with its three hundred thousand inhabitants, waiting only the signal of success to join the standard of their faith. The formation of the French had taken place by moonlight; perfect order and deep silence prevailed throughout the ranks, and every soldier felt that the fate of Kléber and of Egypt hung on the issue of the contest. A large body of Turkish troops had been stationed in the village of Matarieh, and a movement was made by the division of Regnier to cut it off before the remainder of the army could come up to its support. No sooner did the Janizaries perceive the approach of the hostile columns than, sallying forth from their entrenchments, they attacked them with desperate courage. Steadily onwards however moved the unbroken bands, pouring forth a rolling fire. They drove the enemy back to their entrenchments, while the grenadiers, pressing on over masses of the dead and dying, scaled the works, and became masters of the camp. This combat was but the prelude to a general attack, for the Vizier's army was marching to avenge the destruction of its advanced guard. Vast masses of Turkish cavalry soon enveloped the compact squares, by whose murderous fire they fell so rapidly that a barrier of bodies was formed around them, and impeded the renewed attacks of the impetuous horsemen. But Asiatic valour could not long withstand European discipline, and the Turks at last fled in confusion towards the desert. Kléber, following up his success, hastened to El Kangah, where was posted the remainder of the enemy's army, who seeing themselves so closely pressed, hastily retired, leaving behind them the whole of their baggage and munitions. Thus ended the battle of Heliopolis, important in its results, and attended by little loss to the French, who numbered only two or three hundred killed and wounded. The relief of Cairo, in whose citadel two thousand men under General Verdier were closely besieged, was the next object. The firing had scarcely ceased in the plains of Heliopolis when the sound of a distant cannonade was heard from Cairo; it informed Kléber that fresh exertions were required, and he instantly proceeded to the rescue of his countrymen. The Turks under Ibrahim Bey, who formed the besieging army, agreed, on hearing the result of the previous battle, to evacuate the town; but the excited populace of Cairo refused to listen to any terms, and prepared themselves for a desperate resistance. It became necessary to take by storm Boulak, a fortified suburb, and the French, who had returned from the pursuit of the Grand Vizier, invested the city. On a further refusal to surrender, a severe cannonade was directed against it, and it was finally entered by assault. A desperate struggle ensued between the besieged, who occupied the houses, and the besiegers, who were pressing on in the streets. Night alone terminated the contest; and, on the following morning the Turks offered to capitulate, and were permitted to do so on favourable terms. Kléber, in this instance, as in many others, enhanced his victory by his moderation and humanity.

About the time that these events were taking place, another body of the Turkish army had laid down their arms to General Belliard; and Mourad Bey, the chief of the Mamelukes, deprived of every hope of ultimate success, concluded an honourable convention with the French commander. Thus, within a month of the battle of Heliopolis, the French were again in possession of their previous conquests. With an army trifling in numbers, with a numerous enemy in his front, more than half composed of Mameluke cavalry, whose skill and courage are so greatly renowned, with all Egypt revolted in his rear, and when the English considered that he would be compelled to surrender on any conditions, in less than forty days he had overthrown the whole Ottoman force, and subjected the revolted Egyptians. A graphic description of the Turkish mode of warfare is to be found in the eighth volume of Alison's 'History of Europe,' to which valuable work we have been much indebted for the details of this narrative.

Released from immediate danger, Kléber now began to direct his energies to more pacific labours, and to apply them to the administration of the conquered country. His plan appears to have been to distribute portions of land among the veterans of his army, and to adopt the course followed by the British government in India of enlisting in his service the native troops. Scarcely however had he entered on this work when he became the victim of an obscure assassin. A young man, a native of Aleppo, named Suleiman, was incited to the atrocious act by religious fanaticism and the prospect of an ample reward. He had performed the pilgrimages of Mecca and Medina, and his mind was deeply imbued with the tenets of the Mussulmans' faith. He chanced to be wandering in Palestine, when the retiring remnant of the vizier's army was passing through that country, and he became acquainted with the aga of the Janizaries, at whose suggestion he consented to become the instrument of what he considered divine vengeance on 'the sultan of the French.' He was furnished with a sum of money, with which he proceeded to Cairo, and spent several weeks in seclusion in a mosque of that city. He had intimated his purpose to the four principal sheiks of the mosque, who, though they attempted to dissuade him from it, took no steps to prevent its execution. He armed himself with a poignard, and having followed Kléber several days without being able to effect his purpose, he at length determined upon concealing himself in an abandoned cistern in the garden attached to the mansion which the general occupied. On the 14th of June, 1800, Kléber was walking in that garden with Protain, the architect of the army, and he was pointing out to him some repairs which the building required, when Suleiman presented himself before him as a suppliant for alms; while Kléber was listening to his petition, he seized the opportunity of rapidly striking him several times with his dagger. The architect, who was armed with a stick, attempting to interfere, received a severe though not deadly wound. The guards having hastened at the cries of Kléber, secured the assassin, whom they found concealed behind some ruins. Universal sorrow spread through the army, and the Arabs themselves, who had frequently admired and experienced his clemency, joined in the regret. A military commission was immediately assembled to try the assassin, who boldly confessed, and even gloried in his crime. The four sheiks, the partakers of his confidence, were beheaded, and Suleiman was impaled alive.

Thus prematurely perished this distinguished general, and with him the hopes of the eastern expedition. He had formed many important designs for colonizing the country, and it is probable that, under his judicious rule, it might long have been preserved a valuable acquisition to the French Republic. 'There is no military man,' says Napoleon, 'who will deny that the army of Abercromby would have been defeated and destroyed if Kléber had lived. How material was the weight of a young fanatic, acting on the faith of a doubtful passage of the Koran, in the general balance of the world!' Though many may hesitate to agree with this assertion, there can be no doubt that the military talents of Kléber contrast very favourably with those of his successor General Menou, to whom by seniority devolved the chief command of the expedition. In a conversation with Dr. O'Meara, Napoleon further remarks that, of all his generals, Desaix and Kléber possessed the greatest talents. There was also a melancholy coincidence in their deaths: on the same day, and nearly at the same hour, that Kléber fell under the stroke of an assassin in Egypt, Desaix, who had left that country about three months previously, found a glorious death on the plains of Marengo.

'Kléber,' says a celebrated French writer, 'was the finest man in the army. His lofty stature, his noble countenance, whose features were animated by the fire of his soul, his valour at once bold and calm, his prompt and sure intelligence, rendered him on the field of battle the most commanding of commanders. His talents, though unaided by education, were brilliant and original. The works of Plutarch and Quintus Curtius were his constant and exclusive study; he sought in them that nurture of lofty minds which the records of antiquity present. His disposition however was capricious, indocile, and captious. It has been said of him, with truth, that he was as unwilling to command as to obey. He obeyed indeed under General Bonaparte, but it was discontentedly; when he commanded it was under another's name, as in the campaign with General Jourdan; it was in the midst of combat that, by a species of inspiration, he assumed the command, and exercised it with masterly skill; and, no sooner was victory obtained, than he returned to that subordinate rank which was the object of his preference. He was licentious in his conduct and language, but as upright and disinterested a chief as could be met with in an age when the conquest of the world had not yet corrupted the character of the conqueror.' (Thiers.)

His funeral eulogium, which was pronounced by J. B. Joseph Fourier, is published in the 12th vol. of the work entitled 'Victoires et Conquêtes des Armées Françaises.'

(Alison, *Hist. of Europe*, vols. iii. iv.; Thiers, *Hist. du Consulat et de l'Empire*, livre v.; *Dict. Historique des Batailles*, 4 vols., Paris, 1818; *Memoirs dictated by Napoleon at St. Helena to the Count de Montholon (Translation)*; *Précis des Evenemens Militaires, ou Essais Historiques des Campagnes, &c.* 1799 *à* 1814; Las Cases, *Mémorial de St. Hélène*, vol. i. p. 307, 308; *Biographie Universelle Classique*, &c., *deuxième Partie*, Paris, 1829; *Biographie Moderne*, vol. ii., Paris, 1815.)

KLINGENSTIERNA, SAMUEL, a Swedish mathematician and philosopher, was born in 1689 at Tolefors, near Linkoeping, and received his education at Upsal. It was intended by his parents that he should follow the law as a profession; but, after having made some progress in the study of jurisprudence, he abandoned that pursuit, his taste inclining him to the cultivation of the mathematical sciences.

His first production was a dissertation on the height of the atmosphere; and this was followed by one on the means of improving the thermometer: both dissertations were, in 1723, inserted in the Memoirs of the Royal Society of Upsal. In 1727 he set out from Sweden for the purpose of improving himself by travelling; and, after passing through parts of Germany and France, he made a visit to England, from whence he returned in 1730. At Marburg he became known to the celebrated professor Wolf, and applied himself diligently to the study of his philosophy with a view of introducing it into Sweden on his return. At Paris he was introduced to Clairaut, Fontenelle, and Mairan; and he is said to have communicated to those eminent mathematicians some useful remarks concerning the integral calculus and the figure of the earth.

Shortly after his return to Sweden he was appointed professor of mathematics; and being thwarted in his project of teaching the philosophy of Wolf, which was supposed to be in some respects at variance with the doctrines of Christianity, he devoted himself the more ardently to the immediate duties of his professorship. He numbered among his pupils Stroemer, Wargentin, Melanderheilm, and Mallet; and at the same time he contributed greatly by his writings to the improvement of mathematical science.

On the retirement of Dalin, the tutor of the Prince Royal of Sweden, afterwards Gustavus III., Klingenstierna, who for the correctness of his moral character no less than for his talents was highly esteemed by the influential persons of the country, was unanimously chosen to fill his post: he acquitted himself in the performance of this important duty with great success; and, as a recompense of his zeal, he received the title of Councillor of State and was made a Knight of the Polar Star. On the termination of this public duty, Klingenstierna, feeling his health decline, quitted the court and passed several years in strict retirement. The Academy of Sciences at St. Petersburg having, however, offered a prize for the best Essay on the means of correcting or diminishing the chromatic and spherical aberrations of light in refracting telescopes, he once more exerted himself; and, having collected his various papers on optics, he composed from them a general theory with relation to the proposed subject, which he sent to the 'Academy;' when the members of that body unanimously awarded him the sum of one hundred ducats. This work, which was entitled 'Tentamen de definiendis et corrigendis aberrationibus radiorum luminis sphæricis refracti, et de perficiendo telescopio dioptrico,' was published at St. Petersburg in 4to. in 1762.

While the improvement of refracting telescopes engaged the attention of mathematicians it happened that Dollond, in England, proposed objections to an assumption of Euler, that when light passes from air to glass and from air to water, the logarithms of the refractions of the mean refrangible rays are proportional to the logarithms of the refractions of the least refrangible rays; and assumed as a principle deduced from the experiments of Newton, that with a prism of glass contained in a prism of water, a constant ratio subsisted between the differences of the sines of the refractions of the red and violet rays in passing from air into the first medium and from that medium into the second. This principle, and the accuracy of

Newton's experiment on which it was founded, were impugned by Klingenstierna, who, from his own experiments, found that the light emergent after the refractions was affected with colour, under the circumstances in which Newton supposed that it would be wholly free from it. In 1754 he transmitted to Dollond an account of his experiments, together with some investigations relating to the dispersions of heterogeneous light in lenses, and these papers induced that distinguished artist to have again recourse to experiments with a view of discovering more precisely the phenomena of refraction. It was in the prosecution of these experiments that Dollond discovered that combination of lenses of flint and crown glass by which the dispersions of light have been so nearly corrected in optical instruments.

Klingenstierna published, in Latin, an edition of Euclid's 'Elements;' a translation in Swedish of Musschenbrock's Physics, and two discourses, in Swedish, which were delivered before the Academy of Stockholm: one of these is an éloge on the mechanician Polhen; and the other relates to some electrical experiments which had been made at that time. He was early made a member of the Royal Society of Upsal; and he was afterwards received in the Academy of Sciences at Stockholm. He was elected a fellow of the Royal Society of London in 1730; and in the 'Philosophical Transactions' for 1731 there is a paper by him on the quadrature of hyperbolic curves.

Klingenstierna died Oct. 28, 1785; and by order of the queen, the mother of his pupil Gustavus III., he was buried in the tomb of Dalin, who had died a short time before him.

(*Biographie Universelle.*)

KNAPPIA, a genus of plants belonging to the natural order Gramineae. It has an inflorescence, with a somewhat one-sided raceme. The flowers solitary; glumes not keeled, and blunt. It has 2 paleae, which are scarious, very hairy, obtuse, unequal, and without awns. There is but one species of Knappia.

K. agrostidea, an elegant but very small grass, with a small fibrous root, having numerous stems and short rough leaves. The spikes are slender, consisting of from 5 to 10 mostly sessile alternate spikelets. It is found in sandy maritime pastures, but is a rare grass.

(Babington, *Manual of British Botany.*)

KNAUTIA (named after Christopher Knaut, a German botanist), a genus of plants belonging to the natural order Dipsaceae. The inner calyx is cup-shaped, with radiant teeth, the outer one forming a thickened margin to the germen. It has a 4-fid corolla, a fruit with 4 sides and 8 little depressions, the receptacle with spinous scales shorter than the involucre.

K. arvensis, the Field Scabious, has its lower leaves simple, the stem-leaves pinnatifid, the inner calyx with 8 or 16 somewhat awned teeth. The stem rises from 2 to 3 feet in height, is slightly branched, and with but few leaves. The flowers are purple, in large convex long-stalked heads. This is the only British species of this genus. There are a few species of Knautia natives of Europe.

(Babington, *Manual of British Botany*; Don, *Gardener's Dictionary.*)

KNIBB, REV. WILLIAM. Of the early life of this devoted missionary few particulars have yet been made public, but the very brief interval which has elapsed between his unexpected death and the time of writing this article (January, 1846) is sufficient to account for the lack of such biographical information. From a sketch of his life and character in the 'Patriot' newspaper of December 22, 1845, to which we are mainly indebted for the materials of this notice, it would appear that he was born at Kettering in Northamptonshire (a place, it may be remarked, early connected with the history of Baptist Missions, as noticed under MISSIONS, P. C., p. 270), about the commencement of the present century. In due time he was apprenticed to a printer at Bristol, where he appears to have made an early profession of religion. His elder brother, Thomas, left England in December, 1822, to undertake the charge of a school connected with one of the Baptist Mission churches in Jamaica, where he died, in May, 1824. The intelligence of his death so excited the zeal of William Knibb, who is said then to have been little more than of age, that he offered himself to go out to supply the place of his deceased brother; and, his offer being accepted, he sailed, with his wife, in November, 1824. On his arrival he was very kindly received by the negroes at Kingston, who had become much attached to his brother. Towards the close of 1829 he removed, in consequence of delicate health, from Kingston to the north-western part of the island, where he took charge of the Ridgeland mission, in connexion with Savanna-la-Mar; and subsequently, on the death of Mr. Mann, another missionary of the same denomination, he accepted a pressing invitation to succeed him as pastor of the mission church at Falmouth, then consisting of between eight and nine hundred members. Shortly after Mr. Knibb's settlement at Falmouth he was brought into painful notoriety in consequence of the breaking out of an alarming spirit of insurrection among the slave population. A notion had by some means been widely circulated among the negroes to the effect that the King of England had determined to emancipate them from slavery, and that the *free paper*, as they termed the supposed authority for their liberation, had been actually sent to the West Indies, but had been suppressed or held back through the influence of the slave-owners; and, in consequence of this belief, the slaves upon several estates in Jamaica avowed, towards the latter end of December, 1831, their determination to do no work after Christmas. So soon as the missionaries became acquainted with this state of things, they endeavoured to remove the erroneous impression from the minds of such of the negroes as were under their influence, and were so active in their measures as to lead to a report among the disaffected slaves that the white people had bribed Mr. Blyth (a Presbyterian missionary) and Mr. Knibb to withhold their freedom. Insurrectionary movements were, in spite of all the efforts of the missionaries, actually commenced by the negroes, although the interposition of Mr. Knibb, who possessed great influence over the slaves, prevented their rising upon many estates. Notwithstanding this fact both he and his brother missionaries were regarded with great jealousy by the planters, overseers, and others in the slave-holding interest, whose enmity had been excited by their efforts for ameliorating the condition of the negroes, and by the part they had taken in exposing many cases of gross cruelty and oppression. On the 1st of January, 1832, Mr. Knibb was compelled, without regard to his sacred office, to join the militia, and while on service he was treated with marked indignity. Having, a few days later, memorialized the governor for exemption from military service, he was arrested, and debarred from any communication with his family, upon the plea of alarming intelligence by which, it was pretended, the missionaries were implicated in the rebellion. After suffering much persecution, he was released in February, no evidence being obtained to support a criminal prosecution; but in March fresh steps were taken to bring him to trial, though on the day appointed for trial the proceedings were abandoned upon the appearance of about three hundred witnesses who came forward, upon a few hours' notice, in his defence.

During the continuance of disturbances in the island Mr. Knibb's chapel and mission premises at Falmouth were razed to the ground by the men of the St. Ann's regiment, who had used them as barracks for a time; and as similar outrages had been committed on other missionary stations, it was determined that Mr. Knibb, accompanied by Mr. Burchell, should visit England to explain the circumstances of the mission. They accordingly reached England in the beginning of June. Down to that time the Baptist Missionary Society had carefully avoided taking any part in the question of emancipation, regarding it as one of the political questions on which it was desirable to observe a rigid neutrality. Mr. Knibb was accordingly cautioned not to commit the Society by his proceedings; but, warmed with enthusiasm excited to the highest pitch by his personal knowledge of the horrors of the system, he boldly declared that the Society's missionary stations in Jamaica could no longer exist without the entire and immediate abolition of slavery, and, feeling that the time for neutrality was passed, he declared his determination at the annual meeting of the Society on the 21st of June, to avow this at the risk of his connexion with the Society. Mr. Knibb carried the meeting, and subsequently the feelings of the greater part of the country with him, and his stirring appeals had no unimportant share in bringing about the Emancipation Act of 1833

In the autumn of 1834 Mr. Knibb returned to Jamaica, and in the following year the building of a new chapel at Falmouth, and of a new Lancasterian school for children of all denominations at Trelawney, was commenced under his superintendence. The same benevolence and energy which had led Mr. Knibb to take so determined a part in promoting the abolition of slavery, induced him now to expose the failure of the apprenticeship system established by the act of 1833, as a means of preventing the evils anticipated from sudden emancipation. He showed that many of the worst features of slavery were continued under the guise of apprenticeship, and induced some planters to anticipate the course of law by immediate emancipation. After the complete emancipation of the slaves or apprentices, on the 1st of August, 1838, Mr. Knibb purchased, by the aid of English friends, a tract of ground for the purpose of furnishing independent residence and occupation for the liberated negroes; and he erected a normal school at the village of Kettering, in Trelawney, for training native and other schoolmistresses for both Jamaica and Africa. In 1842, in consequence of the prosperous state of the mission churches in Jamaica, it was determined by the missionaries and congregations to separate themselves from the Baptist Missionary Society, so far as any dependence upon the Society's funds was concerned; and in the same year Mr. Knibb visited England to promote the establishment of a theological seminary in connexion with the native mission to Africa, which had been commenced about two years before, through his exertions. In the early part of 1845 he again visited England, to obtain pecuniary aid for the negroes connected with the Baptist churches in Jamaica, who were, in a new way, made the victims of cruel oppression, in consequence of the adoption, by the colonial legislature, of a system of taxation which bore upon the liberated negro labourers with extreme severity, by limiting the supply of food and other necessaries, and at the same time importing, by the aid of the revenue thus obtained, large numbers of foreign labourers, so as to overstock the labour-market, and reduce the persecuted negroes to the greatest distress. Having succeeded in obtaining both sympathy and pecuniary assistance, he returned to Jamaica in July, 1845. In the following November he was seized with yellow fever, and died, after an illness of only four days, on the 15th of that month, at the village of Kettering. Though his funeral took place on the following day, such was the respect entertained for his memory that not less than eight thousand persons are said to have assembled on the occasion.

It is yet, perhaps, too soon to form, between the enthusiastic panegyrics of his friends and admirers, and the bitter vituperations of his political opponents, and of the men whose oppressions he exposed with such unflinching courage, an accurate estimate of the character of William Knibb. Of a peculiarly ardent temperament, and feeling that he had undertaken the championship of a cause which demanded all the zeal and energy which could be called into exercise for the exposure of enormous wrongs, he sometimes exceeded, in the estimation of his best friends, the bounds of prudence, if not of charity; but it should never be forgotten that his long residence in Jamaica, and his intimate knowledge of the state of the negro population, caused him to feel with an intensity not to be realized by his friends in this country, the cruelties which he laboured to abolish or to mitigate. As an instrument in the mental and moral elevation of the negro character, the name of Knibb will long be honoured by the friends of the African race. A full account of the important transactions in which he was involved is given in the second volume of Dr. Cox's 'History of the Baptist Missionary Society.'

KNOLLER, MARTIN VON, a distinguished German painter of the eighteenth century, was born in the village of Steinach in the Tyrol, in 1725. His father appears to have been a poor painter of some sort, and he intended his son to follow his own pursuit. He was however in such circumstances as to make it necessary for his son to perform the menial work of the house, which Martin appears to have found particularly distasteful. The boy accordingly ran away from his home, and found shelter in the house of Hofkammerrath von Hormayr, at Innsbruck, who, when he had heard the boy's story, let his father know of his safety, and placed him with an ordinary painter of the name of Pögel, who thus became Knoller's first master, though he can have had but the slightest influence upon him, if any at all. Martin's father however required his son's services in every way, and he was forced to return home, where he divided his time between the pursuit of his art, in assisting his father, and in what other way he could, and in the performance of menial domestic offices. Such was the state of affairs when circumstances brought the painter Paul Troger, on his return to Vienna, to the village of Steinach, where he saw and admired some of the extraordinary productions of Knoller, then twenty years of age. Troger perceived the lad's ability, and offered to take him with him to Vienna. Young Knoller went with his patron, and in eight years from that time he had not a superior of his own age in the Austrian dominions. Already, in the years 1748-50, he assisted Troger in the frescoes of the cathedral church of Brixen; and in 1753 he obtained the great prize of the Austrian Academy for historical painting. In 1753 Knoller returned to the Tyrol, and in the following year painted in fresco the church of Anrass so much in the manner of Troger that it might pass for the work of that master. Troger, though correct, was cramped and formal in design and sharp in his outlines. In 1755 Knoller visited Rome, and greatly improved his style during the three years he spent in that city. From Rome he was invited to Naples by Count Firmian, the Austrian ambassador at Naples, who employed him much in that city, and in the decoration of his palace at Milan. Knoller visited Rome several times subsequently, and contracted a close friendship with Winckelmann and with Mengs. In 1764 he finished one of his principal works, the frescoes of the church of Volders near Hall, in the Tyrol, consisting of passages from the life of San Carlo Borromeo. In 1765 he returned to Milan to his former patron, Count Firmian, whose esteem and patronage induced Knoller to make Milan his head-quarters, and he there married, in 1767, the daughter of a merchant, by whom he had nine children. Knoller painted many works in Milan, in oil and in fresco, the best of which is a ceiling in the palace of the Prince Belgioioso, representing the apotheosis of one of his ancestors. The palace of the Count Firmian was rich in Knoller's works. His principal German works are the frescoes of the convent church of Ettal in the Bavarian Alps; and the seven cupolas of the church of Neresheim in Würtemberg, painted in 1770-75, for which he received 22,000 florins. He painted a large fresco, 110 feet by 33, in the town-hall at Munich, representing the Ascension of the Virgin; and there are altar-pieces by him in several churches in the south of Bavaria. He was much engaged also at Vienna, but chiefly in portrait painting: he was there ennobled, with the title of *von*, by Maria Theresa. There are many of his works in the Tyrol, at Innsbruck, Botzen, and other places. The church of his native place, Steinach, possesses three altar-pieces by Knoller. He died in 1804. He was gay in colouring, and correct and vigorous in design, and his works are chiefly characterised for their physical qualities—dramatic and effective composition, strong expression, and vigorous and uncommon attitudes. His sphere was almost exclusively the practical part of art; the true historical and aesthetical he hardly approached; but this might be said of many more eminent painters. A Life of Knoller was published in the 'Beiträge zur Geschichte und Statistik von Tyrol,' for 1831.

(Lipowsky, *Künstler-Lexicon*; Fiorillo, *Geschichte*, &c.; Nagler, *Künstler-Lexicon*.)

KNOWLTO'NIA, a genus of plants belonging to the natural order Ranunculaceae. It has 5 sepals, from 5 to 15 petals, with the margins naked. The stamens and ovaries numerous; many 1-seeded succulent fruits, not pointed by the style, which is deciduous. The species are 1-seeded perennial herbs, with greenish yellow flowers.

K. vesicatoria is a plant which has the appearance of an umbelliferous perennial. It has biternate leaves, the segments somewhat cordate, rigid, and smooth, the lateral obliquely truncate at the base. The umbels are nearly simple, and few-flowered. The leaves are used as vesicants in the Cape of Good Hope. There are four other species, natives of the Cape of Good Hope, where these plants grow in abundance. They will thrive well in a mixture of loam and peat, and may be increased either by dividing the root or by seed.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

KNOX, REV. VICESIMUS, D.D., was born at Newington Green, Middlesex, Dec. 8, 1752. His father was the Rev. Vicesimus Knox, LL.B., Fellow of St. John's College, Oxford, and head master of Merchant Taylors' School, London. Vicesimus Knox, the son, was also educated at St. John's College, Oxford, where he pursued his classical studies with great diligence, and became very skilful in Latin composition. Having taken his degree of B.A. and been elected to a Fellowship, he left the university, and in 1778 was elected master of Tunbridge School, Kent. He married about the time of his settling at Tunbridge, and his wife died in 1809, leaving two sons and a daughter. A short time after his marriage he received the degree of D.D. by diploma from the University of Philadelphia. After having been master of Tunbridge School thirty-three years, he retired, and was succeeded by his eldest son. He was rector of Rumwell and Ramsden Crays, in Essex, and minister of the chapelry of Shipbourne, in Kent. He performed the duties of a parish priest nearly forty years with great regularity. In the latter part of his life he resided in London. He was much admired as a preacher, and frequently gave bis aid in behalf of public cbarities by delivering a sermon. He died while on a visit to his son at Tunbridge, Sept. 6, 1821.

Dr. Knox's chief works were—1, 'Essays, Moral and Literary,' 12mo., 1777, which came out anonymously, and met with so much success that be republished them in 1778, with additional essays, in 2 vols. 12mo.; many editions have been since published. 2, 'Liberal Education, or a Practical Treatise on tbe Methods of acquiring Useful and Polite Learning,' 8vo., 1781, enlarged in 1785 to 2 vols. 8vo. This work was chiefly intended to point out tbe defects of the system of education in the English universities, and is said to have had some effect in producing a reformation 3, 'Elegant Extracts in Prose,' 8vo. 4, 'Winter Evenings, or Lucubrations on Life and Letters,' 3 vols. 12mo., 1788. 5, 'Elegant Extracts in Verse,' 1790, 8vo. 6, 'Sermons intended to promote Faith, Hope, and Charity,' 1792, 8vo. 7, 'Elegant Epistles,' 8vo., 1792. 8, 'Family Lectures,' 8vo., 1794. 9, 'Christian Philosophy, or an Attempt to display the Evidence and Excellence of Revealed Religion,' 2 vols. 12mo., 1795. 10, 'Considerations on the Nature and Efficacy of the Lord's Supper,' 12mo., 1799. Dr. Knox published a few other minor works, occasional sermons, and pamphlets.

Dr. Knox's writings were once much admired. His style has considerable neatness and elegance, but he has little originality or power of thought, and his popularity has for some years been gradually decreasing. The selections in the 'Elegant Extracts' were made with much taste and judgment. They were very useful works in their day, and had for many years a large circnlation.

(*Annual Biography and Obituary*, 1822; Watt's *Bibliotheca Britannica*.)

KOBELL, the name of several German and Dutcb landscape painters, of whom the two following are the most distinguished:—

Ferdinand Kobell was born at Mannheim in 1740, and was educated by bis father with a view to his obtaining an honourable position in the civil service of the Electoral government, under which he bimself held the place of hofkammerrath, or counsellor of the exchequer. Ferdinand however had an invincible passion for landscape-painting, which the encouragement of the elector palatinc, Karl Theodor, enabled him finally to follow, notwithstanding the opposition of his father. He studied eighteen months at Paris, in 1768-70, at the expense of the elector, who appointed bim his cabinet painter after bis return to Mannheim: be was also made a member of and secretary to the Academy of Mannheim. In 1793 he removed to Munich, where he died in 1799. Kobell was also a very able etcber: a set of his prints, 179 in number, was published in Nürnberg in 1809:—'Oeuvre complet de Ferd. Kobell, peintre de la Cour Electorale Bavaro-Palatine, et graveur à l'eau forte,' &c. In 1822 a 'Catalogue Raisonné' was published by Baron von Stengel, in which 267 prints are described. Nagler has printed a list of them in his Dictionary. Kobell's landscapes are well selected, true in colouring, and executed with care: the figures in them are painted by himself.

Franz Kobell, the younger brother of Ferdinand, was born at Mannheim in 1749. He was intended for a merchant, and spent four years in a merchant's bouse at Mainz; but his love for the arts, especially landscape and architecture, finally overruled all obstacles, and his brother's patron, the elector Karl Theodor, befriended him also, and enabled him, in 1776, to visit Italy, wbere he remained an entbusiastic student of Italian scenery, chiefly at Rome, for nine years. Franz Kobell, though he executed a few pictures in oil, was scarcely a painter, literally, for his works are almost exclusively drawings, chiefly with the pen, and tinted wlth sepia. He was so industrious in this stylo of art, that the number of his drawings is said to exceed ten thousand, the great bulk of which are in tbree collections—that of the Duke Albert of Sachsen-Teschen in Vienna, that of H. von Rigal in Paris, and that of Baron Stengel in Munich. He died at Munich in 1822; and a flattering notice of him appeared in the 'Kunstblatt' of the same year, from the pen of his friend Speth, tbe author of an excellent work on Italian art of the earlier ages—'Die Kunst in Italien,' 3 vols. 8vo., München, 1819-23.

(Meusel, *Miscellaneen Artistischen Inhalts*; Lipowsky, *Künstler-Lexicon*; Nagler, *Künstler-Lexicon*.)

KOBRE'SIA, a genus of plants belonging to the natural order Cyperaceæ. It has the spikes aggregate; the lower flower pistiliferous, the perigone of one scale inclosing tho germen and covered by the glume. The upper flower staminiferous without any perianth. Tbere is but one species of this genus, *K. caricina*, which has an erect stem from 6 to 12 inches in height, slender leaves shorter than the stem, from 4 to 5 spikes aggregated at the summit of the stem, and from 6 to 8 flowers. There is often an abortive stamen at the base of the nut. This plant is found throughout Europe and in Great Britain, on moors in Yorkshire, Durham, and Perthshire.

(Babington's *Manual of British Botany*.)

KOCH, JOSEPH ANTON, a celebrated German landscape painter, was born of poor parents at Obergiebln am Bach, in the valley of the Lech, in the south of Germany, in 1768. Some of bis early attempts attracted the notice of Bishop Umgelder, vicar-general of Augsburg, who placed Koch with a painter in that city and provided for his maintenance. He was shortly afterwards sent by the bishop to the Carls-Academie at Stuttgardt, where he remained seven years, and became in the meantime an able landscape painter. Koch tried his fortune in Rome at an early date, and be met with complete success; he married a Roman girl and settled himself fixedly in Rome, wbere he enjoyed a great reputation for, with tbe exception of a short interval, at least balf a century, and he was for many years looked upon as the Nestor of the German artists there. He died at Rome, January 12, 1839.

Koch was not exclusively a landscape painter, though he is chiefly distinguished as such. He is known for some clever illustrations to Dante. Among his pictures not exclusively landscapes are, Noah's Sacrifice, the Emancipation of the Tyrol by Hofer, the Flight of Laban, the fresco illustrations to Dante in the Villa Massimi, besides some others. He has painted several fine Alpine views; and many poetical landscapes, which are rather characteristic pictures of a peculiar class of scenery than prospects of particular localities. He frequently composed his landscapes out of such peculiarities of mountain scenery as were congenial with bis individual taste, and the parts were always well arranged, and true and characteristic in their details. In colouring he was not excellent, but rather heavy and monotonous. His latest works were comparatively careless in execution. Koch was also an etcher of considerable skill, and among his works in this class are 24 designs from the antient fable of the Argonautic expedition, after Carstens.

(Nagler, *Neues Allgemeines Künstler-Lexicon*.)

KOELE'RIA, a genus of plants belonging to the natural order Gramineae. It has unequal glumes, the upper one with 2 or 3 ribs, sborter than the spikelet, whicb is compressed. The outer palea is nerved, keeled, and acuminate; the seed loose, and the styles terminal. Tbere is but one British species of this genus.

K. cristata has a compact panicle, spiked, oval, and interrupted below, the outer palea 3-ribbed and acute; the leaves narrow, rough at the edges, and ciliated. In dry places the leaves are much shorter than the stem; in damper places elongated, and often nearly as long as the stem.

(Babington, *Manual of British Botany*.)

KONIGA, a genus of plants belonging to the natural order Cruciferae. It has an oval compressed pouch, from 1 to 2 seeds in each cell, simple filaments, and 8 hypogynous glands. But one Britisb species of this genus has been discovered, *K. maritima*, which is a procumbent plant, with bipartite bairs, linear lanceolate acute leaves, oval pointed glabrous pods. It is the *Lobularia* of Koch, and the *Glyce* of Lindley. Tbe flowers are white and sweet-scented.

(Babington, *Manual of British Botany*.)

KOTTBUS. [Cottbus, P. C.]

KRAFFT, ADAM, a celebrated old sculptor and architect of Nürnberg, wbere he was born about 1435; he married in 1470. There are several of his performances still extant in the city and churches of Nürnberg, but the principal is the remarkable tabernacle in stone, fixed against one of the columns of the choir of the churcb of St. Lawrence, Lorenzkirche. It is in the form of a square open Gothic spire, and is 64 feet bigh, the pinnacle being turned downwards, like the crook of the crosier or an episcopal staff, to avoid the arch of the churcb. The ciborium is placed immediately npon a low platform which is supported partly by the kneeling figures of Adam Krafft and his two assistants; the rail or baluster of the platform is richly carved, and is ornamented with the figures of eight saints. The whole tabernacle is also profusely ornamented with small figures in the round and bassi-rilievi:—immediately above the ciborium, on three sides, are representations in basso rilievo of Christ taking leave of his Mother, the Last Supper, and Christ on the Mount of Olives; high above these are—Christ before Caiaphas, the Crowning with Thorns, and the Scourging; above these is the Crucifixion; and, lastly, above that is the Resurrection, all in the round. This elaborate work was executed by Krafft for a citizen of the name of Hans Imhof, and for the small sum of 770 florins; if the ordinary florin, about 70*l.* sterling. There is a print of this tabernacle in Doppelmayr's work on the artists of Nürnberg. Recent writers have indulged in various conjectures regarding the time and works of Krafft, but the circumstances of both are still involved in their former uncertainty. He is supposed to have died in the Hospital of Schwabach in 1507. Sandrart has inserted the portrait of Krafft in his 'Academy,' from the figure mentioned above, under the tabernacle.

(Sandrart, *Teutsche Academie*, &c.; Doppelmayr, *Historische Nachricht von den Nürnbergischen Künstlern*, &c.; Füssli, *Allegemeines Künstler-Lexicon;* Nagler, *Allgemeines Künstler-Lexicon.*)

KÜGELGEN, GERHARD and CARL VON, twin brothers and distinguished painters, were born at Bacharach on the Rhine, in 1772. Their father was Hof-kammerrath, exchequer counsellor, in the service of the elector of Cologne, who in 1791 sent the twins to complete their studies in Rome after they had made sufficient progress at home. Gerhard painted history and portrait; and Carl, landscape. Gerhard was induced to try his fortune at St. Petersburg, whither he was soon followed by his brother Carl: they both met with great success, and married two sisters, of a noble family of Curland; but Gerhard, after a few years, removed in 1804 to Dresden; Carl remained at St. Petersburg, where he was appointed court painter. Gerhard had established himself, and a high reputation, at Dresden, where he held the appointment of professor of painting at the Academy, when his career was suddenly cut off in a most melancholy manner. He was brutally robbed and murdered on the road from Pillnitz to Dresden, not far from the capital, in 1820. It was a common highway robbery; the miserable wretch who committed the deed was not in the least aware of who his victim was. He was a private soldier, and his singular cupidity was the cause of his detection. He even drew off the boots of Kügelgen, and his afterwards taking these boots to be mended to the very man who had made them and who knew them, is said to have been the cause of his detection.

Kügelgen's works are of a very unpretending character; in most of them an abstract religious sentiment is the chief and characteristic motive; in execution they are careful, delicate, and somewhat formal, yet pleasing and impressive. He delighted in compositions of one or at most very few figures; often three-quarter lengths of the size of life. His biography, by F. Hasse, was published at Leipzig in 1824.

Carl Kügelgen painted many landscapes, and executed many drawings of the scenery of Russia, both in the northern and southern provinces. He made two journeys in the Crimea for the express purpose of painting its scenery; the first journey was made in 1804 by the desire of the Emperor Paul, the second by the express permission of the Emperor Alexander, in 1806. Thirty oil paintings and sixty sepia drawings, part of the fruits of the second journey, were purchased by the emperor, and placed together in a hall in Kammoi Oatrof. In 1818 Alexander sent Kügelgen for a similar purpose into Finnland, of which country he painted fifty-five pictures, which also were purchased by the emperor. Kügelgen executed in all 171 pictures and 290 finished drawings. He died at Reval in 1832. His Life is in the 'Neuer Nekrolog der Deutschen,' x. 1.

(Nagler, *Neues Allgemeines Künstler-Lexicon.*)

XUNDUZ. [TURKISTAN, P. C.]

KUPETZKY, JOHANN, a very celebrated portrait painter, was born at Bösing or Bozin, near Presburg in Hungary, in 1667 or 1666. His father, originally of a Bohemian family, was a poor weaver, and he intended his son to follow his own business; Kupetzky however had very different intentions: he fled from home when only fifteen years of age, begged his way to Switzerland, and there, at Lucerne, obtained admission into the house of a painter of the name of Klaus, who instructed him in painting, and was soon surpassed by his pupil. Kupetzky, after a time, found his way to Rome, where he underwent many hardships until he was relieved and introduced by his friend J. C. Füssli to the principal painters and virtuosi at Rome. Alexander Sobiesky became a valuable patron to him. After a stay of twenty-two years in Italy he was invited by the Prince Adam von Liechtenstein to Vienna, where he soon obtained the reputation of the first portrait painter of his time. He numbered among his patrons and admirers the emperors Joseph I. and Charles VI., and the Prince Eugene; and in 1716 he was invited by Peter the Great to Carlsbad. Peter wished Kupetzky to enter his service and to return with him to Petersburg, but Kupetsky was obstinately fond of his liberty, and would never enter the service of any prince. The Czar Peter gave him many commissions notwithstanding his refusal to enter his service. All that Kupetsky had ever required of the Emperor of Austria was, that he might be allowed to worship God in his own way. He belonged to the sect called the Bohemian Brothers. This liberty, however, very nearly involved him in serious difficulties, as he was accused or threatened to be accused, by some of his rivals, of malignant heresy; and fear of the Inquisition appears to have taken possession of him, and he secretly left Vienna and settled in Nürnberg, where he died in 1740. Kupetzky painted history and portrait, but chiefly portrait. His pictures have a great deal of character and much effect: his friend and admirer Füssli says they combine the vigour of Rubens, the truth and elegance of Vandyck, and the effect of Rembrandt. Many of his portraits and some of his pictures have been engraved, especially by Bernhard Vogel, in mezzotint. The prints engraved by Vogel were added to by V. D. Preissler and published in a collection in folio at Nürnberg in 1745, under the following title:—'Joannis Kupetzky, incomparabilis artificis, Imagines et Picturae quotquot earum haberi potuerunt, antea ad quinque dodecades arte quam vocant nigra aeri incisae, a Bernhardo Vogelio, jam vero similiter continuatae opera et sumptibus Valentini Danielis Preissleri, Chalcographi.'

Kupetzky's portrait of himself, in spectacles, a work of prodigious merit, has been copied by L. de Laborde, from Vogel's print, and is inserted as a specimen in his history of mezzotint engraving—'Histoire de la Gravure en Manière Noire.' J. C. Füssli published a Life of Kupetzky, with one of Rugendas, at Zürich, in 1758.

(Fiorillo, *Geschichte der Zeichnenden Künste*, &c.; Dlabacz, *Allgemeines historisches Künstler-Lexicon für Böhmen.*)

KURDISTAN (the country of the Kurdes) comprehends the larger portion of that mountain-region which divides the elevated table-land of Iran (Persia) from the low plains of Mesopotamia or Al-Jezireh. As it does not constitute a political division, its boundaries are not exactly determined. Some authors consider the country surrounding the lake of Van as forming a part of Kurdistan, but as that country is mostly inhabited by Armenians, and there are only a few Kurdes among them, the mountain-range of the Erdesh Tagh (38° 20′ N. lat.) must be considered as constituting the boundary-line between Armenia and Kurdistan. From this range it extends in a south-eastern direction to the province of Louristan, or to about 34° N. lat. The width of this mountain-region may be about a hundred miles. This gives an area of 28,000 square miles, or the extent of Ireland. About three-fourths are under the dominion of the Turkish sultan, and form portions of the eyalets of Bagdad, Mosul, and Van; the remainder belongs to Persia, and constitutes the province of Kurdistan, of which Kermanshah is the capital.

The higher mountain-region occupies the northern portion, and extends from the Erdesh Tagh to a range, which on the west approaches the banks of the Tigris south of Jezireh-ibn-Omar; from which point it extends in an east by south direction across the whole region, being overtopped near the boundary-line of Persia by the elevated peak of Rowandiz (10,120 feet above the sea-level). This range is called at its western extremity, where it hardly rises a thousand feet above the sea-level, the Soli Range, but in the middle, where it attains 3000 feet and more, the El Khaïr Mountains; it is still higher where it approaches the table-land of Iran. The whole country between this range and the Erdesh Tagh is mountainous. In the vicinity of its northern limits the rocky masses are rarely and not deeply furrowed by depressions in the shape of valleys. They form a table-land, from 6000 to 7000 feet elevated above the sea-level, whose surface presents a succession of low hills with gentle declivities and small plains between them. This is the table-land of Ali Baugh, on which very few lofty summits rise. The climate is very dry, and the vegetation scanty. It is mostly used as pasture-ground in summer. In proceeding southward the country gradually changes its features. The valleys sink deeper and the masses between them rise higher, and thus the table-land is changed into a mountainous country consisting of high ridges with steep acclivities and comparatively narrow valleys between them. Some of the ridges attain a great elevation, as the Marannan mountains, the Jawur Tagh, and the Jelooh mountains; the Jawur Tagh appears to be the highest, and to rise between 12,000 and 13,000 feet above the sea. The declivities of the ridges and the valleys present a vigorous vegetation in the numerous forests and in the growth of the different kinds of grain and vegetables which are cultivated. The forests chiefly consist of different kinds of oak (Quercus valonia and Q. infectoria), from which those immense quantities of gall-nuts are collected which constitute the most important article of commerce in this region. In the valleys the European cerealia are raised; and the orchards produce apples, pears, plums, and cherries. Many of the valleys open towards the plain of Mesopotamia, and these are wider, but the larger number extend from north to south, and are seldom more than two miles wide, and generally not half so much.

This portion of Kurdistan is in possession of some tribes of Kurds, which are independent when the pashas of Bagdad and Mosul are not in arms to punish the least act of disobedience. It is as difficult for the Turks to penetrate into the valleys of these regions as for the Russians to get possession of those of Circassia. Probably more than half the population are Mohammedans, and the other half Christians, among whom the Nestorians are the most numerous. Their patriarch resides in Julamerik, a small town situated in the vale of the river Zab Ala, or Great Zab, and enjoys almost the power of a sovereign. Near the southern extremity of this region are the towns of Amadiyah and Rowandiz, the two places whence the gall-nuts are exported. Amadiyah lies in a valley from five to six miles wide and very fertile, and is built on an isolated limestone rock elevated about 80 feet above the valley; it contains about 200 houses, many of which are inhabited by Jews. The town of Rowandiz is some miles west of the peak of Rowandiz. It is built on a tongue of land formed by the confluence of two rivers, and contains more than 1000 houses and perhaps 10,000 inhabitants. Numerous caravans pass between this place and Mosul. They export gall-nuts, madder, hides, and tobacco, and bring back several European and Indian articles.

The southern portion of Kurdistan, or that which lies between 36° and 34° N. lat., can hardly be called mountainous, except in its eastern districts, which are contiguous to the elevated table-land of Iran. The surface however is greatly diversified by several ranges of hills. Three such ranges may be traced between the banks of the Tigris and the eastern mountains. These three ranges go by the names of the Hamrin Hills, the most south-western, Ali Tagh, the central ridge, and Kara Tagh, the north-eastern. They run parallel to one another from north-west to south-east. The Hamrin Hills terminate on the banks of the Tigris between the town of Tekrit and the mouth of the Zab Asfal or Lesser Zab (near 35° N. lat.); the Ali Tagh, south of the confluence of the Zab Ala or Great Zab (near 36° N. lat.); and the Kara Tagh joins the El Khaïr mountains south-west of the peak of Rowandiz. These ridges are connected with each other at several places by hilly tracts. It appears however that the greater part of this region is occupied by plains of considerable extent. The hills as well as the greater part of these plains are either entirely sterile or possess only a soil of indifferent quality, but along the base of the hills, partly on their declivities and partly in the adjacent level country, there are lands of considerable fertility, well cultivated, and populous. The mountain-region which borders this country on the east varies from ten to twenty miles in width, and it contains several high ranges, as the Shahn mountains, the Azmir Tagh, and the Kurhur Tagh. In the second range is the Pir Omar Gudrun, an elevated mass which appears to rise above the snow-line, as it supplies the adjacent countries with ice all the year round. This mountain-region is united to the high masses surrounding the peak of Rowandiz. It is well wooded, whilst the lower western ridges are almost entirely destitute of trees.

The largest river of Kurdistan is the Zab Ala or Great Zab. It rises in the north-western corner of the table-land of Ali Baugh, within the boundary of Persia, at an elevation of about 7000 feet above the sea-level; receives by its numerous affluents the drainage of almost the whole of Northern Kurdistan, enters Southern Kurdistan by a narrow glen where the Kara Tagh mountains are connected with the Khaïr range, and joins the Tigris about 30 miles below Mosul. At the place of their confluence the rivers are nearly equal in size. The waters of the Tigris are highest in April and May, but in the Zab in June and July, for about that season the greater part of the snow with which the mountain-region is covered during the long winter dissolves, and thus the water brought down by this affluent serves during the summer to keep up the level in the lower part of the Tigris. The water of the Zab Ala is much colder than that of the Tigris. The other large rivers of Kurdistan are the Zab Asfal, or Lesser Zab, and the Diyálah. They rise in the elevated region dividing Southern Kurdistan from the table-land of Iran, and after draining the first-mentioned country, they fall into the Tigris; they break through all the lower ridges of Southern Kurdistan.

There are several considerable towns in Southern Kurdistan. The most northern is Arbil (Arbela) or Erbil, built between the Great and Lesser Zab, in a plain which has a very fertile soil, yielding rich crops without being irrigated. The town is built on some considerable hills, which all travellers consider as artificial. It contains 6000 people, three large mosques, and two baths. Altún Kupri, on the banks of the Lesser Zab, contains 8000 inhabitants. Kerkuk, farther south, is a rather large place, which carries on a considerable commerce with Suleimaniyah, to which place it sends large quantities of gall-nuts, honey, sheep, and cattle, brought from the mountain-region lying farther east, and whence it receives European, Persian, and Indian goods. Its population may amount to between 10,000 and 12,000 individuals. There are some manufactures of coarse calicoes.

Suleimaniyah, the modern capital of Southern Kurdistan, and the residence of the hereditary pasha or wali, who however is dependent on the pasha of Bagdad, is not far from the base of the Azmir range, and of the peak called Pir Omar Gudrun, which rises to more than 10,000 feet above the sea-level. The plain of Banna, at the eastern border of which it lies, is between 3000 and 4000 feet above the sea. It was built in 1788, and contains more than 2000 houses and about 10,000 inhabitants, six caravanserais, five baths, and five mosques. The commerce with the adjacent countries is considerable, and is concentrated in this place.

Little is known of the climate of Kurdistan, except that of Suleimaniyah, where the winters are very cold and the summers very hot. Snow covers the plain of Banna for six weeks, or even two months. In May the climate is very agreeable, the thermometer standing at six o'clock in the morning at 66°; at half-past one, at 78°; and at ten o'clock in the evening at 69°: but in July the heat is very oppressive, especially during the north-eastern winds, which are called *sherki*, and which affect the human body more than the samoun at Bagdad, as they suddenly raise the temperature ten degrees and more, and produce the most unpleasant feeling. They continue to blow sometimes for eight or ten days, and return frequently, even as late as the end of September. When the sherki does not blow, the changes of the atmosphere are very regular in summer. At sun-rise it is quite calm; but immediately afterwards a light breeze begins from the east, which increases gradually until the sun attains the meridian, when it blows a gale, or at least strong gusts of wind, from the south. Later in the day the wind turns to the west and moderates. The mornings are generally unpleasant, but the afternoons are very agreeable.

The fields of Kurdistan produce wheat, barley, and Indian corn; millet and rice are grown only in the lower districts towards the banks of the Tigris. Tobacco and cotton are largely cultivated, and supply articles of commerce. Legumes, especially lentils, are much grown. Melons, watermelons, and cucumbers are very abundant. The orchards yield figs, pomegranates, olives, oranges, walnuts, apricots, peaches, plums, apples, pears, cherries, and abundance of grapes of good quality; in some places there are plantations of dates. Poplar and chinar trees (plantanus orientalis) are planted, and among the forest trees are several kinds of oak, and also wild pear-trees of great size, and between them wild rose-bushes.

Sheep, cattle, and horses abound; the best horses are imported from Bagdad. There are bears, wild hogs, wild goats, antelopes, and jackals. Land-turtles are frequent, but of small size. Bees are very abundant, and honey is a considerable article of commerce; locusts sometimes lay waste a part of the country; birds are not numerous, except partridges and quails.

Minerals appear to be scarce, except building-stone. In the mountain-region iron and sulphur are met with; and in some places these mines are worked on a small scale. There are several salt springs in the hills between the lesser Zab and the Diyálah, from which large quantities of salt are obtained. Naphtha and petroleum abound, especially in the vicinity of Kerkuk, and some of the springs yield a considerable revenue to the wali; they are noticed by Strabo (p. 738, ed. Cas.).

As the passes through the ranges of mountains and hills are rather difficult, single travellers are subject to be robbed and murdered. Commerce is therefore carried on by caravans. At least one caravan departs every month from Suleimaniyeh for the Persian towns of Tabriz and Hamadan. They take to Tahriz chiefly goods obtained from Bagdad, as coffee, dates, and European and Indian manufactures; and bring back large quantities of silk for the manufacturers of Bagdad, and some silk stuffs. The exports to Hamadan consist partly of goods obtained from Bagdad, and partly of the produce of the country, as tobacco, fruits, honey, gall-nuts, &c.; the imports consist of hutter, hut especially of the manufactures of Kasbin, as velvets, brocades, cotton goods, &c. The commerce with Kerkuk, which is the chief market for the produce of Kurdistan, is very active; from that place are brought to Suleimaniyah gall-nuts, honey, sheep-skins, and cattle; and exchanged for fruits, rice, leather, coffee, cotton stuffs, &c. There is also much commerce with Bagdad, where coffee, dates, and European and India goods are obtained in exchange for the silk brought from Tabriz, and for the produce of the country, consisting of sheep, gall-nuts, sumach, cheese, hutter, gummi, tallow, soap, and tobacco. These articles are also taken to Mosul, where they are exchanged for calicoes and other cotton stuffs, silks of Damascus and Diarbekr, stuffs for turbans, boots, and shoes. The least active hranch of the commerce of Suleimaniyeh is that with Erzerum, to which place hardly anything is exported except those articles which are imported from Bagdad, for which the returns are iron, copper, and mules. Armenia supplies the whole of Kurdistan and some neighbouring countries with these animals.

The population of Turkish Kurdistan is estimated at about one million, of which four-fifths are Kurds, and the remainder Armenians, Persians, Jews, and Turks. The Kurdish population of Persian Kurdistan may amount to 20,000 individuals. But as a numerous colony of Kurds is found in Khorassan, and several tribes have also been dispersed over the hilly region in Mesopotamia, and as far west as Aleppo and the Taurus range, the whole population of the nation may perhaps not fall short of two millions. The Kurds are a stout race of men, of dark complexion, with black hair, a large mouth, small eyes, and a savage look. They are very regularly huilt, and attain a great age. Their language is derived from the same stock as that of the modern Persian, but not having been fixed by writing, it has degenerated much more. There are several dialects, which vary considerably in proportion to the distance at which the different tribes live from one another. The name of Kurd signifies a valiant warrior, and is therefore adopted as an honourahle denomination. In Turkish Kurdistan the nation is composed of two castes, the warriors, called Bebbehr or Babans, and the working people or agriculturists, called Guran. The latter are considered by the Behbehr as a race of men totally different from them, and are treated as slaves. The Bebbehr never cultivate the ground, and the Guran never serve as soldiers. A great portion of the population is still addicted to a migratory life. Even when settled in villages, they leave them in summer, and retire with their herds to the adjacent mountain-ranges, from which they return when the harvest time approaches. Though the Kurds are as good Mohammedans as their neighbours, their women enjoy a much greater degree of liberty, and are frequently met with in the streets. Ladies of rank wear a veil, but the women of the middling and lower classes go about without. The Kurds are much more inclined to associate than their neighbours the Persians or Turks.

The Kurds were known to the antients. Xenophen (*Anabasis*, iii. 5, 15, &c.) called them Carduchi (Καρδοῦχοι), and later historians Κορδιαῖοι, Γορδιαῖοι, Gordiani. When subject to the kings of antient Persia, they belonged partly to the province of Assyria, and partly to Media, as at present their country is divided between Turkey and Persia. The battle of Gaugamela (Arbela) was fought in Kurdistan, near the modern town of Arbil. After the time of Alexander their country was united to the kingdom of Syria, but was dismembered from it in the third century before Christ hy the Parthians. It afterwards became a part of the new Persian empire, and fell with it under the dominion of the caliphs of Bagdad. After the destruction of the caliphat, Kurdistan partook of the numerous revolutions in Persia and Mesopotamia. The famous sultan Saladin was a Kurd, of the tribe of Rewandooz, and appears to have got possession at least of a part of the country. But it soon passed under the dominion of the Moguls (1258), and finally (1388) was conquered by Timur. After the establishment of the Soofee dynasty (1502), Kurdistan constituted a part of Persia, and remained so till the seventeenth century, when the Kurds, oppressed by the Persians, revolted, and subjected themselves to the dominion of the Turkish emperor.

(Rich, *Narrative of a Residence in Kurdistan;* Heude, *Voyage up the Persian Gulf, and a Journey overland from India to England;* Ainsworth, 'Account of a Visit to the Chaldeans inhabiting Central Kurdistan,' in *London Geogr. Journal*, xi.; Ainsworth, *Travels and Researches in Asia Minor*, &c.; Shiel, 'Notes on a Journey from Tabriz, through Kurdistan, &c. to Suleimaniyeh,' in *London Geogr. Journal*, vol. vii.; Rawlinson, *Journey from Tabriz through Persian Kurdistan*, &c.; Ritter, *Erdkunde von Asien*, vol. ix. and xi.)

KYD, THOMAS, was one of those dramatic poets who immediately preceded Shakspere. Three plays of his are extant—1, 'Cornelia; or Pompey the Great, his fair Cornelia's Tragedy,' a translation, respectably executed, from the French of Garnier, printed in 4to. 1594, 1595; 2, 'The First Part of Jeronimo,' 1605, 4to.; 3, 'The Spanish Tragedy, or Hieronymo is mad again;' of which there are many editions, the oldest known being of 1599, though the play was certainly printed earlier. All the three are in Dodsley's Old Plays. 'The first Part of Jeronimo' is merely an Introduction to the 'Spanish Tragedy.' The former, and probably the latter also, must have heen on the stage about the year 1587 or 1588; and they kept their place in 1601 and 1602, when Ben Jonson was paid for making large additions to the Second Part, which are in the modern editions, and are quite worthy of his genius. The portions written by Kyd himself are the objects of continual ridicule to Shakspere and his contemporaries, whose comic characters parody the most extravagant speeches of the mad Hieronymo. Yet the play, even in its Introduction, and still more in the Second Part, possesses great vigour, both of imagination and of passion. It is an irregular and rude work, belonging essentially to the infancy of the drama, in its conception of character as well as in its plan and in its language. But it was hy no means unworthy of the great popularity which it enjoyed. It is a tragedy of bloodshed, after the manner of 'Titus Andronicus,' to which, however, it is much inferior; and it has been observed by more than one critic, that there are in it points which may naturally enough be supposed to have suggested thoughts for 'Hamlet.' Kyd has also been supposed to have heen the author of the old 'Taming of a Shrew,' 1594, and of the tragedy of 'Solymun and Perseda,' 1599. For the former supposition there is no ground; and for the other there is no better reason than the particular mention made of the story of a 'Solyman' in the 'Spanish Tragedy.'

INDEX TO THE LETTER K

VOLUME II.

L.

LAACHER SEE. [ANDERNACH, P. C.]

LABEO, QUINTUS ANTISTIUS, a Roman of some distinction as a jurist, was the father of a more distinguished son. He was at the battle of Philippi, on the side of M. Brutus and Cassius, and after the defeat he killed himself in his tent, and was buried there. (Appian, *Civil Wars*, iv. 135.) Q. Antistius Labeo, the son, was a pupil of C. Trebatius; but contrary to the practice of that time, instead of devoting himself exclusively to one master, he attended several. He lived in the time of Augustus. Labeo was distinguished for his knowledge of Roman law and Roman usages, and also for the freedom with which he expressed his opinions to Augustus (Suetonius, *Octavianus Caesar*, c. 54), to whose measures he set himself in opposition. Some critics suppose that he is alluded to by Horace (1 *Sat.* 3. 82); but there might be other persons of the name of Labeo. Ateius Capito, his rival in legal knowledge, was raised to the consulship by Augustus in order that he might have that superiority in rank which his talents alone could not give him. Labeo never enjoyed any higher honour than the praetorship. (Tacitus, *Annal.* iii. 75.) The character of Labeo is given by Gellius (xiii. 10): 'Labeo Antistius principally applied himself to the study of the civil law, and publicly gave his opinions to those who consulted him. He was also not unacquainted with other liberal pursuits, and he deeply studied grammar, dialectic, and antient learning; he was also well acquainted with the origins and principles of Latin words, and he availed himself of that kind of knowledge especially to clear up most legal difficulties.' He was confident in his abilities and acquirements, and bold enough to advance many new opinions. He was a copious writer, and is said to have produced four hundred different treatises, from which there are sixty-three excerpts in the Digest, and he is very often cited by the other jurists. Labeo wrote commentaries on the Twelve Tables, fifteen books at least on Pontifical Law, and fifteen De Disciplinis Etruscis. His works which are mentioned in the Digest are, eight books of Πιθανά, of which Paulus made an epitome with notes; and ten books of Posteriora, so called from having been published after his death, of which Javolenus made an epitome; but Gellius refers to the fortieth book of Posteriora. He also wrote Libri ad Edictum, Libri Praetoris Urbani, and thirty Libri Praetoris Peregrini.

A brief notice of C. Ateius Capito may be appropriately introduced here, for he was the rival of Labeo, and founded a sect or school which was opposed to that of Labeo. The father of Capito attained the rank of praetor; his grandfather was a centurion who served under L. Cornelius Sulla. Capito was made Consul Suffectus by Augustus A.V.C. 758, and it was during his term of office that he decided that a patron could not take his freedwoman to wife against her consent, a decision perfectly consistent with Roman principles. Capito was a flatterer; Labeo was an independent man and said what he thought. Instances of Capito's adulation are recorded by Tacitus (*Annal.* iii. 70) and Suetonius. He died in the time of Tiberius, A.D. 22. (*Annal.* iii. 75.)

Capito is often cited by other jurists, Proculus, Javolenus, Paulus, and once by Labeo: they always call him Ateius. Capito's reputation as a lawyer was very great. He wrote on Pontifical Law at least five books, as appears from Gellius (iv. 6), and numerous books of Conjectanea (Gellius, xx. 2; xiv. 7). He also wrote a single book De Officio Senatorio, from which Gellius gives an extract (iv. 10), and a book De Jure Sacrificiorum (Macrobius, *Saturn.* iii. 10). Gellius (xiii. 12) also quotes a letter of Capito, in which he speaks highly of Labeo's legal knowledge. There are no excerpts from Capito in the Digest.

From the time of Labeo and Capito we date the formation of two opposed sects or schools of law among the Romans. The nature of this opposition is collected from the words of Pomponius (*Dig.* i. tit. 2). Labeo was a man of greater acquirements than Capito and of a bolder temper. He applied to his legal studies the stores of knowledge that were open to him, and thus was led to many new views. Capito stuck close to what had been transmitted by his predecessors: he was one of those who appealed to authority. So far as concerns general principles, we cannot condemn the method of either of these great jurists. Each has its merit, but either of them, if carried too far, may be injurious to jurisprudence. He who handles the matters of law in an enlarged and comprehensive manner may improve jurisprudence; but if he does not well know what the law is, and if he is more eager to change what is established than to maintain its stability, he may destroy the edifice on which he is labouring. He who merely studies the laws of his country as they exist, and is satisfied if he can find authority for anything, however inconsistent with fair dealing and the general interests of society, may be a good lawyer of a kind, but he is a bad citizen. The Roman jurisconsulti were mainly engaged in writing on law and giving their opinions (responsa) to all persons who consulted them. Their business was not that of the modern advocate, who has to make the best of his client's case. The opposition then between Labeo and Capito, between him whose method, if judiciously practised, would lead to a progressive improvement of law, and him whose method would stop all such improvement, if strictly adhered to, hardly constitutes a ground of like comparison between lawyers in this country. Numerous questions divided the respective followers of Labeo and Capito; but it is not always easy to discover in the questions, so far as we know them, sufficient to enable us to trace the two opposing principles of the founders of the schools to their just consequences. Much has been written on this matter; and a great deal has been said for which there is little or no evidence.

The followers of Labeo were called Proculiani, from Proculus, one of the successors of Labeo. Those who attached themselves to the school of Capito were called Sabiniani, or sometimes Schola Cassiana, from Massurius Sabinus and C. Cassius Longinus. For further remarks on the subject of the two schools the reader may consult Puchta, *Cursus der Instit.*, i. 98.

LABIA'TÆ. [LAMIACEÆ, P. C.]

LA'BIDUS. [MUTILLIDÆ, P. C. S.]

LABYRI'NTHODON, a genus of fossil reptiles from the new red-sandstone strata. (Owen.) [SALAMANDROIDES, P. C.]

LACE-BARK-TREE. [DAPHNE, P. C.]

LACMUS. [LITMUS, P. C.]

LACTU'CA, a genus of plants belonging to the natural order Compositæ, the suborder Ligulifloræ, the tribe Cichoraceæ and the subtribe Lactuceæ of De Candolle. It has a cylindrical imbricated involucre with the scales membranous at the margin and few-flowered; the receptacle naked; the achenium compressed, wingless, with a long filiform beak, the pappus hair-like in several rows.

L. virosa, Acrid Lettuce, has leaves with a prickly keel, horizontal, oblong, auricled and clasping, mucronate, dentate or sinuated, the beak white, equalling the fruit, which is black. This plant is found on hedges, old walls, and the skirts of fields throughout Europe. It yields a milky juice, which when procured and dried has the name Lactucarium. [LACTUCARIUM, P. C.] This substance is also procured from the garden lettuce (*L. sativa*), and in the London Pharmacopœia the *L. sativa* is the only plant recognised for supplying this substance. Dr. Christison remarks, 'the London College however, and many cultivators, are wrong in restricting themselves to the garden lettuce, for the preparation of lactucarium. From information communicated to me several years ago by Mr. Duncan, chemist and druggist in this city (Edinburgh), who has often made lactucarium on a large scale, it appears that the *Lactuca virosa* yields a much larger quantity, and that the produce is of a superior quality. Nor is there any reason for dreading the narcotic properties of the wild lettuce, the scientific name of which has given rise to an exaggerated notion of its activity. The results obtained by Mr. Duncan have been since confirmed by those of Schultz in Germany; who found that a single plant of the garden lettuce yields only 17 grains of lactucarium on an average, while a plant of wild lettuce yields no less than 56 grains.'—Mr. Duncan has made the observation also that, 'although the milkiness of the juice increases till the very close of the time of flowering, namely in the wild-lettuce till the month of October in this climate, the value of the lactucarium is deteriorated after the middle of the period of inflorescence; for subsequently while the juice becomes thicker a material decrease takes place in the proportion of bitter extract contained in it.' For an account of *Lactuca sativa* and its uses as a salad, see

LETTUCE. This plant appears to have been cultivated amongst the Greeks, and also used in medicine. It is the θρίδαξ of Dioscorides, ii. 165, also of Theophrastus. Several varieties of the garden-lettuce were used both among the Greeks and Romans as salads.

L. scariola, Prickly Lettuce, has the leaves with a prickly keel, perpendicular, arrow-shaped at the base and clasping, sinuate, the beak white, equalling the pale fruit. It is found plentifully in waste places in many parts of Europe, but is a rare plant in Great Britain. It has a stem from 2 to 5 feet high, leafy and panicled. Its juice is not so acrid as that of *L. virosa*, but possesses the same properties. It is found on the higher hills of Greece, and is probably the θρίδαξ ἀγρία and θριδακίνη of Dioscorides. The θριδακίνη of Theophrastus, i. 8, and vii. 3, and of Galen, lib. 2, according to Fraas is the *L. coriacea* of Schultz.

There are two other British species of lettuce: *L. saligna*, with a white elongated beak, twice as long as the fruit, the upper leaves entire, acuminate, and *L. muralis*, with the beak much shorter than the fruit. [On the Cultivation of the Lettuce, see LETTUCE, P. C.]

(Babington, *Manual of British Botany*; Fraas, *Synopsis Plantarum Floræ Classicæ*; Christison, *Dispensatory*.)

LADING, BILL OF. [BILL OF LADING, P. C.]

LAGENA'RIA (from 'lagena,' a bottle), a genus of plants belonging to the natural order Cucurbitaceæ. The flowers are monoecious, the calyx campanulate, with subulate segments shorter than the tube. The corolla is white, with obovate petals spreading below the edge of the calyx. It has five triadelphous stamens, the fifth one distinct; three subsessile granulated stigmas, obovate compressed seeds tumid at the margin, 2-lobed at the apex.

L. vulgaris, common Bottle-Gourd, is a musky-scented plant, and clothed with a soft down. It has a climbing stem with tendrils from 3- to 4-cleft. The flowers are stellated, spreading, and in clusters; the fruit in shape like a bottle, when ripe of a pale yellow colour, sometimes six feet in length. When dried it becomes hard, and is used to contain water; it is then of a pale bay colour. In its wild state this plant produces a poisonous fruit, and Dr. Royle states that a very intelligent native doctor informed him that cases of poisoning have occurred from eating the bitter pulp in the district where it grows. Some sailors also are said to have died from drinking beer that had been standing in a flask made from one of those gourds. These injurious effects seem however to be removed by cooking, for Don says that the poor people among the Arabians eat it boiled with vinegar, or fill the shells with rice and meat, and so make a kind of pudding of it. The pulp of the fruit is often employed in poultices: it is bitter and purgative, and may be used instead of colocynth. This species grows abundantly in Egypt and Arabia: the Arabians call it Charrah; it thrives wherever the mountains are covered with a fit soil. There are three other species enumerated by Don growing in Guinea and the East Indies.

L. idolatrica is held in great veneration by the Hindus in their religious ceremonies.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*.)

LAGETTA. [DAPHNE, P. C.]

LAGU'RUS (from λαγώς, a hare, and οὐρά, a tail), a genus of plants belonging to the natural order Gramineæ. It has a spiked panicle 1-flowered, scarious glumes ending in a long fringed seta. The outer paleæ end in two long setæ and with a dorsal geniculated twisted awn.

L. ovatus is the only species, and has a stem from four to twelve inches in height. The leaves are broad and lanceolate, the spikes ovate and pubescent. It is found in sandy places in Guernsey and on the Continent of Europe.

(Babington, *Manual of British Botany*; Koch, *Flora Germanica*.)

LAING, MALCOLM, an historian, was born in Orkney, where he possessed a small patrimonial estate, in 1762. He received the rudiments of education at Kirkwall, and afterwards studied at Edinburgh, where he was one of the most active members of the 'Speculative Society,' an association in which many young men who became distinguished in after life first tried their prowess. In 1785 he joined the Scottish bar. He does not appear to have obtained much practice as a lawyer, and the only conspicuous occasion in which he was professionally employed seems to have been in the defence of some of the parties tried for sedition in Scotland between 1793 and 1795. He is one of the many instances where lawyers have in their works displayed peculiarly high forensic abilities, without, for some inscrutable reason, being able to rise in their profession. His first known literary effort was editing the last volume of Henry's 'History of Britain,' in 1793, after the author's death. He was charged with having spoiled the harmony of the work, as Henry's opinions were all in favour of despotic principles, while the additions made by Laing were of a democratic tendency. In 1800 he published 'The History of Scotland, from the Union of the Crowns on the accession of James VI. to the throne of England, to the Union of the Kingdoms in the reign of Queen Anne.' This was published along with two other works, the names of which appearing on the title of the History, are very characteristic of Laing's propensity to enter on disputed points in history or criticism with the spirit of a lawyer. The History as published in two volumes was accompanied by 'Two Dissertations, historical and critical, on the Gowry Conspiracy, and on the supposed Authenticity of Ossian's Poems.' Neither of these subjects came within the scope of his History—the former related to a period thirteen centuries earlier. To the second edition of his History, published in 1804, he added 'A Preliminary Dissertation on the Participation of Mary Queen of Scots in the Murder of Darnley.' He was a sagacious, honest, and able historical critic, but certainly too much inclined to take up a side in any question and to keep perpetually in view the circumstance that he was bound to defend that side. His style was harsh and formal, and sometimes obscure, from a pedantic adoption of the mode of the historical writers of his age, which evidently was not natural to him. He was for some time member of parliament for Orkney, and enjoyed the confidence and esteem of Fox. He died in 1818. His brother Samuel Laing, who has written some interesting travels, succeeded to his property.

LAMBERT, JOHN HENRY, a distinguished philosopher of Germany, was a descendant from a family which had been compelled to quit France in consequence of the persecutions caused by the revocation of the Edict of Nantes, and he was born at Mühlhausen in Upper Alsatia, August 29, 1728. He was sent to a school in the town, where he acquired the rudiments of a classical education; but the want of means obliged his father, who was by trade a tailor, to withdraw him from thence at an early age.

At home, however, the youth availed himself of every means in his power to preserve the knowledge he had acquired of the Latin tongue; and a great part of each night was spent in reading such of the Roman authors as he could procure, or in studying arithmetic and geometry: the money for the purchase of the books, and even of the candles by whose light they were read, being obtained, it is said, by the sale of drawings which he found time to execute.

A taste for literature and science in a young person so situated did not fail to attract notice; but the only immediate advantage which Lambert derived from that taste arose from the neatness which the practice of transcribing had given to his hand-writing: this qualification procured for him an appointment as a clerk in the office of a solicitor; and he was afterwards employed, in a like capacity, by an iron-master of the neighbourhood. At seventeen years of age he became the secretary of Dr. Iselin at Basle; and during the five years in which he held this situation he omitted no opportunity of extending his literary attainments. He then, also, began to acquire a knowledge of philosophy and logic by the study of the works of Locke, Malebranche, and Wolf; and he zealously cultivated the mathematical sciences, in which alone, it is observed, he found that the processes of investigation lead directly to truth.

In 1749 his patron recommended him to M. de Salis, who was then the President of the Swiss Confederacy, as a tutor to his children; and, having obtained the appointment, he went to reside with the family of that statesman at Coire. Being thus placed in a situation congenial with his taste, and having access to a considerable library—enjoying, moreover, the opportunity of conversing with learned men—he was enabled, while communicating instruction to his pupils, to study the Greek, Italian, and French languages; and particularly to advance his knowledge of optics, astronomy, and philosophy. He was admitted at this time a member of the Physico-Medical Society of Basle, to whose 'Acts' he afterwards contributed several memoirs on mathematical and physical subjects.

In 1756, Lambert accompanied two of the sons of M. de Salis to the University of Göttingen; and, proceeding from thence to Holland and France, he returned in 1758 to Coire. At Paris he had an opportunity of conversing with some of the celebrated men of the age, particularly D'Alembert and

Messier; by the former of whom he was afterwards recommended to the King of Prussia, Frederick III. He quitted the family of Count Salis in 1759, and, having been chosen a member of the Electoral Academy of Bavaria, he went to reside at Augsburg. In 1763 he was employed as one of the Commissioners in settling the boundaries between the territories of the Valais and the duchy of Milan; and in the following year, in consequence of an invitation from the King of Prussia, he proceeded to Berlin, where he passed the remainder of his life. He was elected a member of the Berlin Academy of Sciences, to whose 'Mémoires' he made many valuable contributions; and he was also appointed Chief Councillor in the department of Buildings, on the establishment of a commission for superintending the improvements of the kingdom.

While in Holland, Lambert published, at the Hague, a tract, entitled 'Les Propriétés de la Route de la Lumière,' &c. (8vo., 1758), in which he examines the path of a ray of light refracted in the atmosphere, and points out some corrections which should be made, on account of refraction, in determining the heights of mountains; and in the following year he published at Zürich one which was designated 'Freye Perspective.' But one of the most important of Lambert's works is his 'Photometria, sive de Mensura et Gradibus Luminis, Colorum, et Umbræ,' which was published both at Leipzic and at Augsburg in 1760. In this treatise the author states, from his own experiments, the quantities of light reflected from the exterior and interior surfaces of glass, and he gives formulæ for representing them. He compares the brightness of illuminated objects with that of the body which enlightens them; and he discusses the brightness of the image formed by a luminous object in the focus of a burning glass. He calculates the degrees of illumination on the different planets; and he describes instruments for measuring the intensities of differently coloured light.

In 1761 he published at Augsburg a valuable work entitled 'Insigniores Orbitæ Cometarum Proprietates,' 8vo., in which are contained a formula for determining, in a parabolic orbit, the perihelion distance in terms of two radii vectores and the difference between the anomalies, and one in which, the orbit being any conic section, the interval between two times of observation is expressed in terms of the two radii and the chord which joins their extremities. This is usually called 'Lambert's Theorem,' and it was certainly discovered by him, though Euler had, long before, given a like theorem for a parabolic orbit. In the same year Lambert published at Augsburg a small work entitled 'Logarithmische Rechenstœde,' in which are proposed some improvements on Gunter's 'Scale;' and one entitled 'Kosmologische Briefe ueber die Einrichtung des Weltbaus,' 8vo., in which he considers that the action of gravity extends to the fixed stars; and he expresses a conjecture that the solar system may be only a system of satellites with respect to some celestial body.

In 1764 was published, at Leipzig, in 2 vols. 8vo., Lambert's philosophical work entitled 'Neues Organon;' this is divided into four parts, of which the first contains the rules of thinking, and the second is on truth considered in its elements; the third is on the external characters of truth; and the fourth, on the means of distinguishing the real from the apparent. A sort of supplement to this work was published by him at Riga in 1771, in two volumes 8vo.; it is entitled Architektonik,' and treats of the metaphysics of mathematics; the subjects being Unity, Number, Dimensions, Continuity, Limits, and Infinity.

The first mathematical work which Lambert published after he went to reside at Berlin was his 'Beyträge zum Gebrauche der Mathematik und deren Andwendung' (3 vols. 8vo., 1765 to 1772). This contains some profound investigations relating to the theory of numbers, and a tract on trigonometry, with notices on what is called tetragonometry; in it are given also some remarkable propositions relating to the projections of the sphere. In the first of those years he published 'Description d'une Table Ecliptique formant un Tableau vrai de toutes les Eclipses, tant de la Lune que de la Terre;' and in 1770 appeared his 'Zusätze zu den Logarithmischen und Trigonometrischen Tabellen,' 8vo. He was joined with Bode, Schultze, and Lagrange in the publication (1776), under the direction of the Academy of Berlin, of a series of Astronomical Tables.

Lambert also wrote a tract on 'Hygrometry,' which was published at Augsburg in 1770; and he left one on Pyrometry, which was published at Berlin, in 1779, that is after his death; this last contains a biography of the author, by Everhard. Besides these works Lambert wrote numerous papers on scientific subjects, which were published in the 'Acta Helvetica' and in the 'Mémoires' of the Academy of Berlin. Among the 'Acta' are his 'Tentamen de Vi Caloris ejusque Dimensione;' a series which goes by his name, and which was afterwards generalised by Lagrange, and a 'Memoir on Vibrating Strings.' The 'Mémoires' of the Academy contain his papers on the Incommensurability of the Circumference of a Circle to its Diameter; on Human Strength; on Hydraulic Wheels; on Windmills; and on Friction. He moreover prepared two papers in which he had discussed all the known observations on Jupiter and Saturn; and these were published in the same 'Mémoires' two years after his death.

Lambert was endowed with a strong memory and a fertile and well regulated imagination: his manners were simple, and he is said, in his dress, to have disregarded the fashions of the time; but he was both esteemed and beloved by those who knew him intimately. He died Sept. 25, 1777, being then only forty-nine years of age. All the manuscripts left by him were purchased by the Academy of Berlin, and were subsequently published by John Bernoulli, a grandson of the celebrated John Bernoulli of Basle.

(The 'Berlin Mémoires.' *Biographie Universelle.*)

LA'MI, GIOVA'NNI, born at Santa Croce, in Tuscany, in 1697, studied law at Pisa, took a doctor's degree, and afterwards repaired to Florence, to exercise his profession. But his fondness for literature, and especially classical and ecclesiastical erudition, interfered with his professional pursuits, and he became an author. His first work was in defence of the Nicene Creed concerning the Trinity, and against Leclerc and other Socinian writers. Lami contended that the Nicene dogma concerning the Trinity was the same as that held by the early promulgators of Christianity in the Apostolic times. His work is entitled 'De recta Patrum Nicenorum Fide,' Venice, 1730. Lami travelled with a Genoese nobleman to Vienna, where he resided some time, and he afterwards visited France, whence he returned to Florence in 1732, where he was made librarian of the Riccardi library, and Professor of Ecclesiastical History in the Florence Lyceum. At Florence he published his work 'De Eruditione Apostolorum,' Florence, 1738, which is a sort of continuation of his former work. The Socinians having assumed that the notion of the Trinity had been derived from the 'Logos' of Plato, Lami undertook to prove, among other things, that the apostles and their first disciples were too ignorant of profane learning to be acquainted with the writings of the Greek philosophers. Lami's work also contains much miscellaneous and recondite erudition concerning the early ages of Christianity. The author treats of the style of dress, and of the manners of the primitive Christians, of the amanuenses of the apostles, and of the early translators of the Gospels and Epistles, of the apocryphal books attributed to the apostles and their disciples, and lastly he gives an historical account of the old MSS. of the Gospels, Epistles, and other parts of the New Testament which existed in the libraries of Florence.

In 1740, Lami began to publish a literary journal, entitled 'Novelle Letterarie,' which he carried on till the year 1760, at first with the assistance of Targioni, Gori, and other learned Tuscans of his time, with whom he afterwards quarrelled, and he then continued the work alone. This publication was the source of some annoyance to him, both from private animosity and from the jealousy of the censorship.

Lami made a selection of inedited works, or fragments of works, from the MSS. of the Riccardi library, of which he was keeper, and published it in a series entitled 'Deliciæ Eruditorum,' 18 vols. 8vo., Florence, 1736—69. He also edited the works of the learned John Meursius in 12 vols. folio. He wrote short biographies of many illustrious Italians of his age: 'Memorabilia Italorum Eruditione præstantium quibus vertens Sæculum gloriatur,' 2 vols. 8vo., Florence, 1743—7. He published in Greek the letters of Gabriel Severus, Archbishop of Philadelphia in Asia Minor, and of other Prelates of the Greek Church: 'Gabrielis Severi et aliorum Græcorum Recentiorum Epistolæ,' 8vo., Florence, 1754. He had undertaken to write a history of the Eastern Churches from the Council of Florence of 1439; a subject which he observed had been much neglected by writers of ecclesiastical history; but this undertaking was interrupted by Lami's death, which took place in 1770. He was buried in the church of Santa Croce; and the following sentence was engraved on his tomb: 'Doctissimo Polyhistori ætatis suæ nulli secundo.' He left all his property to the poor. Fabbroni and Fontanini wrote his biography. Besides the works already mentioned, Lami wrote satires both in Latin and in Italian, especially directed against the Jesuits, whom he strongly disliked. He also published, 1, 'Lezioni di Antichità Toscane,' 2 vols. 4to., 1766. 2, 'Richardi Romuli Richardii Vita,' Florence, 1748. 3, 'Catalogus Codicum MSS. qui in Bibliotheca Riccardiana Florentiæ adservantur,' with copious illustrations, fol., 1756, and other minor writings.

(Corniani, *I Secoli della Letteratura Italiana*, and the works of Lami above quoted.)

LA'MIUM, a genus of plants belonging to the natural order Labiatae. It has a 2-lipped corolla, the upper lip arched, lower lip trifid. The lateral lobes minute, tooth-like, or obsolete, rarely elongated. The anthers approach in pairs, and forming a cross, burst longitudinally. The calyx is 5-toothed and bell-shaped, the teeth nearly equal. This genus includes the dead, blind, and dumb nettles of our peasants, so called from their resemblance to the Urticæ in many points, except their stings.

L. amplexicaule has roundish cordate obtuse leaves, the lower ones stalked, the upper ones sessile and clasping; the teeth of the calyx are longer than the tube at length connivent, the lateral lobes of the lower lip of the corolla toothless; the nuts small, and of an obovate oblong shape. It is found in sandy and chalky fields in Great Britain, the North of Africa, and Middle Asia.

L. intermedium has reniform, cordate, obtuse leaves, and is distinguished by the teeth of the calyx being longer than their tube, hispid, and always spreading. The lateral lobes of the lower lip of the corolla with a short tooth, the nuts twice as large as those of the former species, and of an oblong shape. This species is common in Scotland, Sweden, and the North of Germany.

L. purpureum has a pale purple corolla, spotted with red, the lateral lobes of the lower lip having 2 teeth. The nuts oblong, or about twice as broad as long. It is found in Great Britain and Sweden, where, according to Linnæus, it is boiled and eaten. It was formerly used in medicine, but is not now prescribed.

L. incisum has but one tooth in the lateral lobes of the lower lip of the corolla. It is a British plant, and is likewise found in France, Germany, and Sweden.

L. album is distinguished by having the calyx teeth as long as the tube, all separated by acute angles, the upper one distant from the others. The corolla has 3 teeth, and is large and white. It was once used medicinally, but is now disregarded. Like *L. purpureum*, this species is eaten in Sweden as a pot-herb. It is found in Great Britain and the southern parts of Europe.

L. maculatum has the calyx teeth longer than their tube, the three upper ones separated from the others by broad obtuse angles; the lateral lobes of the lower lip of the corolla with one tooth. It is found in Great Britain and the continent of Europe.

L. striatum has deeply cut ovate leaves, the corolla 3 times as large as the calyx, which is glabrous. It is a native of Greece in waste places, and is supposed by Fraas to be the λευκὰς ὀρεινή of Dioscorides, 3, 103.

There are several other species of Lamium, growing chiefly in the southern parts of Europe. They are not worth cultivation for ornament, but will easily grow in any soil or situation, and are to be propagated either by division or by seed.

LAMNA, a genus of squaloid fishes. Fossil in the chalk, London clay, &c., and recent.

LAMOTTE. [MOTTE, LA, P. C.]

LAMP. [LIGHTS, ARTIFICIAL, P. C. S.]

LANCASTER, COUNTY PALATINE OF. [PALATINE COUNTIES, P. C.]

LAND-TAX. [TAXATION, P. C.]

LANDLORD AND TENANT. [TENANT AND LANDLORD, P. C.]

LANGBAINE, GERARD, D.D., born in Westmoreland about 1608, was successively a servitor, scholar, and fellow, of Queen's College, Oxford; and he held the places of keeper of archives to the university and provost of his college for a good many years before his death, which happened in 1658. He was a studious and timid man, who contrived to steer through the political storms of his time without giving serious offence to any party. He edited Longinus, and published several works of his own, chiefly on church questions. But his chief usefulness was in his unprinted collections, which included several catalogues of manuscripts, often referred to by Warton and others.

GERARD LANGBAINE, his son, was born at Oxford in 1656, and, after having received an elementary education, was apprenticed to a bookseller in London. An elder brother dying, he was recalled home, and entered, in 1672, a gentleman commoner of University College. He betook himself however to idleness and low extravagance, and spent a great part of his property; but after a time he reformed, and retained of his earlier tastes none but his love for the theatres. He made a very large collection of old plays, amounting, as he says, to almost a thousand. He made use of these, first, in a republication of a catalogue of plays made by Kirkman, a bookseller, which appeared under the title of 'Momns Triumphans,' 1687, 4to. This work, speedily sold off, was improved into 'A New Catalogue of English Plays,' 1688, 4to. Still further additions and amendments produced his 'Account of the English Dramatick Poets,' 1691, 8vo., 1699 (by Gildon), 1719 (by Giles Jacob, for Curl). The criticism contained in this work is shallow, prejudiced, and obsequious. The author pronounces Sir Robert Howard to be an admirable poet, and prefers Shadwell's plays to Dryden's. But, in relating facts and describing editions, he scrupulously sets down what was before him; and although the information he gives is very incomplete, his work is the most trustworthy of our catalogues of the kind, and has been of very great service. In the British Museum is a copy of it with valuable notes by Oldys. He published also an appendix to a catalogue of graduates.

LANGELAND, ROBERT. [LONGLAND, ROBERT, P.C.]

LANGSDORFIA. [RHIZANTHEÆ, P. C. S.]

LANIERE, NICOLAS, a painter, engraver, and musician, who was a favourite with Charles I. He was born in 1568, and was an Italian by birth. Laniere, says Walpole, 'understood hands,' by which he means that he was well conversant with the handling of various masters, and was a fit person to employ in the purchase of pictures, and for which purpose Charles employed him. Walpole supposes he was employed in the purchase of the gallery of the Duke of Mantua, for which Charles gave 20,000*l.*—it comprised the Triumph of Cæsar, by Mantegna. [HAMPTON COURT PICTURE GALLERY, P. C. S.]

Laniere was a better musician than a painter. He was appointed in 1626 Charles's chapel-master, for which he had a salary of 200*l.* per annum: he was also closet-keeper to Charles. There is in Ben Jonson's works a masque, which was performed in 1617 at the house of Lord Hay, for the entertainment of the French ambassador, and for which Laniere both painted the scenes and composed the music. He also set to music the hymn which was written by Thomas Pierce for the funeral dirge of Charles I.

Laniere lived to see the dispersion of the collection which he himself had been mainly instrumental in forming. He purchased four pictures at the sale of Charles's effects, for 230*l.*: others were purchased by his brothers Jerome and Clement. Laniere appears to have been a general dealer in pictures, and, according to Sanderson (*Graphice*, p. 16), to have been not over scrupulous, for that writer accuses him of passing copies as originals: the colours were obscured by soot, and he cracked the pictures by rolling them up face inwards. He purchased many pictures for Charles, and marked them with a rosette or a small figure resembling six radiating leaves—the mark is given by Walpole. Walpole buries Laniere on November 4, 1646, overlooking the somewhat glaring inconsistency of making him write the music to Charles's funeral dirge three years after his own burial: the date is not a misprint, because Walpole adds his age—seventy-eight years; still it ought probably to be 1649 or 1656. The date of Laniere's birth (1568) is correct, because in an engraving dated 1636 he writes himself at the juvenile age of sixty-eight—'à l' eta sua giovanile di sessanta-otto anni.' Vandyck painted Laniere's portrait during his first visit to England, and it was this picture which induced Charles I. to request Sir Kenelm Digby to invite Vandyck back again after his departure. There is a portrait of Laniere by himself in the Music School at Oxford, with palette and brushes in his hands, and some music-notes on a piece of paper.

(*Essay towards an English School; English Connoisseur*, &c.; Walpole, *Anecdotes of Painting*, &c.)

LANKESTER, JOSEPH. [SCHOOL, PRIMARY, P. C.]

LANNES, JEAN, Duke of Montebello and Marshal of France, was born at Lectoure in Guienne, on the 11th of April, 1769, a year rendered remarkable by the birth of Napoleon, the Duke of Wellington, and Marshals Ney and Soult. He was born of humble parents, and was at first brought up to the trade of a dyer, which he quitted in 1792 to join a battalion of volunteers raised in the department of Gers, of which he soon became sergeant-major. His first campaign was with the army employed on the frontiers of the Pyrenees, where his resolute character and soldier-like deportment obtained him a great ascendancy over his comrades. His military talents were soon discovered and appreciated, and by the suffrages of the army be rose so rapidly in command, that at the close of the year 1793 he had attained the rank of 'chef de brigade,' which nearly corresponds to that of major among the English troops. After the political crisis of the 9th Thermidor (July 27th), 1794, he partook in the disgrace of the Generals Bonaparte and Massena on account of their connection with the younger Robespierre; he then retired to Paris, where he formed an acquaintance with those two distinguished commanders, whose future glories he was destined to share. His calm and daring character especially attracted the notice of Bonaparte, who employed him in the affair of the Sections [Bonaparte, P.C.], and he afterwards with him joined the army of Italy. After the victories of Montenotte and Millesimo, April 26th, 1796, where he greatly distinguished himself, he was made colonel of the thirty-second demi-brigade, in the place of the gallant Rampon, who was raised to the rank of general. Among his many daring exploits in this celebrated campaign, at the crossing of the river Po, he was the first with a few grenadiers to arrive at the opposite bank; and likewise, on the bridge of Lodi, he was foremost in effecting the perilous passage. In 1797 he became general of brigade, in which capacity he served with distinction till the signing of the treaty of Campo Formio. [Campo Formio, P. C.] He afterwards formed part of the expedition to Egypt, where he rose to the rank of a general of division, and maintained his high reputation. He greatly contributed to the victory gained by the French at Aboukir, and was dangerously wounded at the siege of Acre.

When Bonaparte determined upon leaving Egypt, Lannes was one of the generals chosen to accompany him to France [Bonaparte, P. C.; Kleber, P. C. S.], where he rendered him material assistance in the revolution of the 18th Brumaire (November 9th), 1799, and as a recompense for his services on that occasion he was named commander of the Consular guard. He was afterwards employed in the south of France, at the head of the ninth and tenth military divisions, to suppress the insurgent Jacobins. From thence he was recalled by the First Consul, in the year 1800, to join the expedition to Italy, and he shared the dangers and labour which the French army underwent in crossing the Great St. Bernard. In this passage Lannes commanded the advanced guard, and on the 17th of May he arrived at Châtillon, where he attacked and defeated a corps of 5000 Austrians. On the 12th of June was fought the important battle of Montebello, in which the Austrians were signally defeated, and five thousand prisoners and six pieces of cannon were taken. The impression made on the mind of Napoleon of Lannes' skill and courage on this occasion was so great, that, some years afterwards, Montebello was the title chosen for the dukedom to which he was raised. After the battle of Marengo, in which he likewise greatly distinguished himself, he received a sabre of honour, and was selected to present to the government at Paris the standards that had been taken from the Austrians.

In 1801 he was sent to Lisbon by the First Consul in the capacity of minister plenipotentiary of France, a character for which his previous habits scarcely fitted him. The blunt frankness of a soldier, joined to his natural impetuosity of disposition, but ill accorded with the close reserve of conduct so essential in a diplomatist. This very defect however proved of service to the cause in which be was employed, and his determined bearing obtained from the feeble government of Portugal every measure which Napoleon at that time required. Several characteristic traits of General Lannes' behaviour at the court of Lisbon are to be found in the interesting Memoirs of the Duchess of Abrantes (Madame Junot), whose husband was sent to supersede him as ambassador.

On his return from Portugal in 1804, Napoleon, who was now emperor, created him Marshal of the Empire, and afterwards Duke of Montebello. In the Austrian campaign of 1805 Lannes was appointed to the chief command of the left wing of the French army, and was present at the battle of Wertingen, and at the taking of Braunau (October 29th, 1805). In the great and decisive battle of Austerlitz, December 2nd, 1805, where he manifested his usual courage and gave proof of increased skill and judgment, he had two of his aides-de-camp killed by his side.

In the Prussian campaign of 1806 and 1807 he performed many brilliant achievements: at the siege of Danzig he rendered, together with Oudinot, material assistance to Marshal Lefebvre, who commanded the besieging army, and he narrowly escaped death at the battle of Jena. [Lefebvre, P. C. S.] In June, 1807, a few months subsequent to the battle of Eylau, an unsuccessful attempt was made by Lannes upon the intrenched camp of Heilberg, and it occasioned a serious dispute between him and the Grand Duke of Berg (Murat), which gave rise to an incident showing the freedom with which he was accustomed to address Napoleon, whom, on this occasion, be openly accused of manifesting an undue partiality to his brother-in-law. The scene of bitter altercation between the emperor and his lieutenant is described with dramatic effect by the Duchess of Abrantes (*Mém.*, ix. 369-372), who however, according to Alison, erroneously states it to have taken place immediately after the battle of Eylau.

In the year 1808 Lannes accompanied Napoleon in the Peninsular campaign, and had the command of the third corps of the army. In crossing the mountains near Mon Dragon he met with an accident which might have proved fatal but for the skill of that eminent surgeon Baron Larrey (*Mém. de Larrey*, tom. iii. p. 243). In the battle of Tudela (November 23rd, 1808), at which Lannes was present, the Spaniards under Castaños were completely defeated, and seven standards, thirty pieces of cannon, and upwards of three thousand prisoners fell into the hands of the French. Lannes was afterwards appointed to the chief command of the army besieging Saragossa, and it was there especially that the influence of his military talents was felt and appreciated. For fifty days without intermission the French army had fruitlessly fought and laboured; he found the soldiers suffering from privations of every kind and deeply dispirited. They complained to him that, though the nature of the siege required at least fifty thousand men, they were only twenty thousand; that not more than a fourth part of the town was in their possession, and that, unless reinforcements arrived, they must perish under the ruins they had themselves occasioned. The details of this remarkable siege are eloquently and graphically described in General Napier's valuable History of the Peninsular War, vol. ii. c. 2, and also in art. Saragossa, P. C. On the 21st of February, 1809, the city was entered by a general assault, and from twelve to fifteen thousand of its courageous defenders, who were reduced to the lowest state of weakness by the sufferings and privations they had endured, laid down their arms. After the fall of Saragossa, Lannes returned to France, with the intention of spending some time upon his estate in the neighbourhood of Paris, but after a few weeks the second war with Austria broke out, and he was again called to share the fortune of his master on the field of battle.

In this campaign he had the command of the second corps of Napoleon's army, composed of fifty thousand men. At the battle of Eckmühl [Eckmühl, P. C.], April 22nd, 1809, his services proved of the greatest value. It was the intention of the French emperor to cut off the communications of the Austrians with the Iser and the Inn, and, by throwing them back upon Bohemia, to prevent them from defending Vienna. For this purpose he commenced the attack by advancing the right wing of his army under Lannes, together with part of Davoust's corps, to attack the Austrian left. This movement, which Lannes most skilfully conducted, was perfectly successful, and the enemy was driven back in confusion. His bravery also displayed itself in subsequent parts of this important battle, and he contributed greatly to the final issue, which was favourable to the French. The day after this engagement, in the assault on Ratisbon, Lannes, who conducted the operations, gave proof of a similar prowess to that which distinguished Bonaparte when he triumphantly bore the French standards on the bridge of Arcola. [Arcola, P. C.] Having perceived a large house which was situated against the ramparts of the town, he had caused several guns to play against it, and a breach was formed by which access might be gained to the summit. A heavy fire however was kept up from the ramparts, which rendered the crossing of the glacis extremely hazardous to the besiegers, and for some time no soldier could be found sufficiently bold to face the danger. The marshal at length, impatient at the delay, seized a scaling-ladder, and hastened forward through the thickest part of the shower of the enemy's balls. He was instantly followed by his men, whom the gallant spectacle of their leader's courage had animated, and, by this daring and decisive measure, the breach was quickly passed, and the town was gained.

The last but not least noble exploits of this distinguished general were the defence of the village of Essling, in the sanguinary battle which has been named from it, and the grand attack on the Austrian centre, which, though unsuccessful in its results, was conducted by Lannes with great skill and courage. When the French had been compelled to retire to the island of Lobau, their wearied bands were attacked by fresh troops, which the Archduke Charles brought up in constant succession in order to dislodge them from their position. Lannes, with the intention of resisting this attack, posted those of his soldiers on whom he could place most reliance in the rear of the columns, and supporting them with the troops which the emperor had sent to his assistance, seconded by Masséna, he checked the advancing numbers of the Austrians. The French had reserved their fire till the enemy had approached within a few yards of them, and then commenced a most deadly struggle. At that critical moment Lannes had dismounted from his horse, that he might be less exposed to the sweeping fire of the Austrian artillery, when he was struck by a cannon-ball, which carried away the whole of his right leg and the foot and ankle of the left. Napoleon was directing the position of some batteries, when he beheld the almost lifeless body of his heroic marshal borne off from the battle. The last scene in the life of Lannes has been very differently related, and some of these relations bear the impress of improbability and exaggeration. The description given of it by Alison, which is chiefly derived from the accurate narratives of Pelet, Savary, and Thibaut, is that which appears most consonant with truth. As Napoleon approached the litter which contained the shattered remains of his heroic companion, Lannes had still sufficient strength remaining to seize his hand, and, with a voice weakened by loss of blood, to bid him a last adieu. 'Live,' said he, 'for the sake of the world, and bestow a few thoughts on one of your best friends, who is shortly to be no more.' Beside the litter of his early friend, of the sharer of his perils, and the partaker of his fortunes, knelt and wept the conqueror of Europe. 'Lannes,' he exclaimed, 'do you know me? it is the emperor, it is Bonaparte, it is your friend; you will surely yet be preserved to us.' 'To live in order to serve you and my country is my wish,' he replied, 'but in an hour I shall be no more.' On no occasion had Napoleon evinced such deep emotion. 'Nothing,' he observed to Masséna, 'but so terrible a calamity could have withdrawn me for a moment from the care of the army.' Critical indeed were the circumstances in which that army was then placed, and the fate of Napoleon's empire was depending on the issue; but seldom can ambition, even amid its highest efforts, stifle the genuine emotions of the heart. For nine days Lannes lingered in the most agonizing sufferings, during which he was constantly visited by the emperor, and on the 31st of May, 1809, he expired. At the same time had fallen with him the brave General St. Hilaire, whom, like Bayard, the army had styled 'the knight without fear and without reproach.'

Lannes, unlike many of Napoleon's generals, had acquired a constantly increasing military reputation. In the first part of his career courage predominated over judgment; but experience was daily producing in his mind a more just equilibrium between those two qualities so essential to a commander. 'I found him a dwarf,' said the emperor to Las Cases, 'and I lost him a giant.' And in another conversation with this faithful companion of his exile, he remarked of this marshal that 'he had great experience in war, having been in fifty-four battles and three hundred combats. He was cool in the midst of fire; possessed of a clear penetrating eye, ready to take advantage of any opportunity which might present itself. Violent and hasty in his temper, even in my presence, he was however ardently attached to me.' His chief fault was a carelessness of the future, too common among the soldiers of that period; a large sharer in the rewards which Napoleon so lavishly bestowed upon his generals, he was as prodigal of his means as of his blood. But to his credit it must be remarked, that a considerable portion of his gains went to the relief and support of his poorer companions in arms.

Lannes had married Mademoiselle Louise de Ghéhénuec, a young woman of exquisite beauty and prepossessing manners. When she became a widow, Napoleon evinced by the most assiduous attention to her the high respect he bore for the memory of her distinguished husband. She was afterwards appointed a lady of honour to the Empress Maria Louisa. The present Duke of Montebello, Lannes' eldest son, has married an English lady, Ellen, the daughter of Charles Jenkinson, Esq.

The Military Life of Lannes, written by Mons. René Perin, was published at Paris, in 1810.

LANTERN. [SKYLIGHT, P. C.]

LANTERN, MAGIC. [MAGIC LANTERN, P. C. S.]

LANZARO'TE, one of the Canaries, lies about seventy miles from Cape Juby on the western coast of Africa, between 28° 52′ and 29° 15′ N. lat., and 13° 30′ and 14° W. long. It is separated from the island of Fuerteventura, which lies south of it, by a strait which is from four to six miles wide, and called La Bocayna. Lanzarote extends in a north-east and south-west direction about thirty-one miles, with a breadth varying between five and ten miles. The area is estimated at 325 square miles, or about forty miles more than the county of Middlesex.

North of Lanzarote are five small islands: the largest are Alegranza and Graciosa, which are inhabited, and produce barilla and orchilla; the others are only rocks. The strait which separates Graciosa from Lanzarote is called El Rio; it is in most parts rather more than a mile wide, and is the most spacious and only safe port for large ships in the Canaries, but useless as a harbour for trade, because the coast of Lanzarote rises here with basaltic cliffs almost perpendicularly to the height of 1500 feet. The mountain mass to which these cliffs belong contains an extinct volcano, called La Corona, whose edges rise to the elevation of 1958 feet above the sea. From this point the rocky mass gradually descends southward, and is furrowed by a few wide valleys which open to the south-west, and in which palm-trees and fig-trees abound. It terminates in an extensive sandy plain, which surrounds Teguise, the capital of the island. West of this place the country is covered by numerous hills surrounded by fields of lava. All these hills have a conical form, consist of scoria and ashes, and have craters. These hills were formed by a terrible eruption which took place in 1730. Such masses of lava were thrown out by them, that one-third of the island, and that the most fertile portion, was converted into a stony waste. The streams of lava ran into the sea, owing to which the whole western shore is precipitous in the extreme, with the exception of one little bay called Janubio, where was once a harbour for small vessels, which by the eruption was converted into a salt-water lake. The eastern shores are neither so steep nor so high, and there are many tracts of fertile ground. The highest land, called Montana Blanca, liest to the east of the lava tract, nearly in the centre of the island; it rises to 2000 feet above the sea, and is cultivated to the summit.

The climate is exceedingly hot, especially during certain seasons, when the south-eastern winds, having passed over the Sahara, extend to the island: these winds frequently bring hosts of locusts with them. In spring and the early part of the summer northern and north-eastern gales are frequent; they last for several days, and blow with such violence as to prevent the growth of trees, which are only found in the valleys of the northern tract, where they are protected by the high ground north of them. Rain is scarce, and the crops are uncertain. A drought which lasted from 1768 to 1771 compelled nearly the whole population to emigrate; the water in the cisterns had entirely dried up. There is only one spring on the island, and even that is inaccessible.

Wheat, barley, Indian corn, and potatoes are extensively cultivated. In some parts are large vineyards; the grapes are of a superior flavour, and the wine of Lanzarote is preferred to that of the other islands. The most important production is the barilla, which is obtained from the Mesembryanthemum crystallinum: this plant is indigenous, but has also become the object of extensive cultivation. In several places orchilla is gathered. Cattle are numerous, but very small: they are only kept for agricultural labour. Very few horses and mules are kept; but there are many dromedaries and asses. There are many goats and sheep. There are few hogs. On the strait called El Rio salt is made, and a considerable quantity is exported to the other Canaries.

The population is estimated at about 18,000 individuals. They are strong built, and of a dark complexion. Many have black curly hair, and some features which prove that the antient Spanish settlers have intermarried with the Moors and negroes of Africa. The inhabitants are mostly occupied with cultivating the ground; but several families gain their livelihood by fishing. Three vessels on an average are annually sent to the coast of Africa, where the fishing-ground extends from Cape Bojador to Cape Blanco; each vessel makes between eight and nine voyages, and has a crew of from thirty to forty men. They take chiefly cod and bream, and salt them. Salt-fish constitutes the principal food of the population.

The capital is Teguise, a small place consisting of about two hundred houses scattered over a small hill. On the eastern shore is the harbour, called Puerto de Naos, a small but secure harbour, formed by several rocky islets; it has two entrances, the northern has a depth of twelve feet, and the eastern of seventeen and a half at low-water, with a nine-feet rise of tide. The town of Arrecife is situated immediately to the southward of the port. It has several large houses and spacious streets. The population is 2500.

No foreign goods are allowed to be imported. The island receives them from Teneriffe and Grand Canaria. But English and American vessels resort to Puerto de Naos to export barilla and orchilla. The exportation of the first-named article amounts annually to 3500 tons, and that of orchilla to two or three hundred hundredweight. The number of foreign vessels visiting annually the island is stated to vary between twenty-five and thirty. Lanzarote exports to Teneriffe and Palma considerable quantities of grain, brandy for the West Indies, cattle for slaughtering, and salt. The imports consist of timber and firewood, besides foreign articles. From the small port of Papagayo, near the southern extremity of the island, a large quantity of brandy is sent to Fuerteventura, whence dromedaries, sheep, and cattle are received in return.

Lanzarote was the first of the Canaries which submitted to the Spaniards. They took possession of it in 1404. In the sixteenth and seventeenth centuries it was frequently laid waste by the Moors from the coast of Africa. This circumstance, with the terrible eruption of 1730, and the great dearth in 1768 to 1771, prevented the inhabitants from improving their agricultural condition. But in the middle of the last century the culture of the barilla plant was introduced, and since that time the condition of the population has improved.

(Humboldt, *Voyage aux Régions Equinoxiales du Nouveau Continent*; Von Buch, *Physikalische Beschreibung der Canarischen Inseln*; Arlett, *Survey of some of the Canary Islands*, &c., in *London Geographical Journal*, vol. vi.; Mac Gregor. *Die Canarischen Inseln nach ihrem gegenwärtigen Zustande*.)

LAPO, ARNOLFO DI, the name by which a very celebrated and one of the most early of the Italian architects is known. He is so called by Vasari, and is said by him to have been the son of Lapo, a German, whose real name was Jacob, and who was sometimes called in Florence Jacopo Tedesco, but more frequently Lapo. This Lapo, who executed many works in Florence, died there, according to Vasari, in 1262.

Recent researches however have shown that Arnolfo and Lapo were not otherwise connected further than that they were contemporaries in Florence. Arnolfo was the son of Cambio, a native of Colle, and, according to Vasari, was born in 1232. Arnolfo did for building, says Vasari, what Cimabue did for painting: he was the pupil of Cimabue in design. He was the greatest architect of his time in Florence, and was the architect of many important works. The walls of Florence, which were erected in 1284, were planned by Arnolfo. He built the hall of Or. San Michele, the old corn-market; the loggia and piazza de' Priori; and in 1294 he laid the foundations and built the great church of Santa Croce, now celebrated for its many magnificent monuments of distinguished Florentines. But his greatest work is the church of Santa Maria del Fiore, or the Cathedral of Florence, of which he laid the foundations in 1298, or, according to some accounts, in 1294. He raised the walls of the whole church, and covered part of it in, but the vast dome is the addition of Brunelleschi; it stands however on the foundations of Arnolfo, who also, according to his model, had intended to erect a dome in the centre, though lower and of less dimensions than the enormous pile of Brunelleschi, which is one of the largest domes in the world, and but little less than the gigantic vault of St. Peter's, which is an imitation of it. [DOME, P. C.] The models of Arnolfo and Brunelleschi are now both lost. For the erection of this immense church, a tax of two-pence per head was levied annually upon the citizens of Florence, and they were encouraged also by indulgences to make donations to its building-fund. The external marble facing of the walls is the work of Arnolfo. The old municipal palace, the Palazzo della Signoria, which still exists as a part of the old palace of the Florentine princes, in the Piazza Granduca, was also built by Arnolfo. And there are works by him in other Italian cities: he executed in 1285 the marble tabernacle of the Basilica of San Paolo, without the walls, at Rome; and shortly before 1290 he designed and executed the monument of the Cardinal de Braye in the church of San Domenico at Orvieto.

Arnolfo died, according to Vasari, in 1300, aged therefore sixty-eight, and not sixty, as Vasari says, if the year of his birth as given by Vasari himself be correct. Arnolfo's portrait by Giotto is in the picture of the death of San Francesco, in the church of Santa Croce at Florence: it is one of the group of figures conversing together in the foreground.

(Vasari, *Vite de' Pittori*, &c.; Richa, *Delle Chiese di Firenze*; Rumohr, *Italienische Forschungen*.)

LAPPA, a genus of plants belonging to the natural order Compositæ, the sub-order Tubulifloræ, the tribe Senecionideæ, and the sub-tribe Carduineæ. It has an equal and many-flowered homogamous head, a globose involucre, with imbricated coriaceous scales. The receptacle is rather fleshy, flat, and with stiff fringes. The corollas are 5-cleft, regular, and with a 10-nerved tube. The stamens have papillose filaments, with anthers terminating in filiform appendages. The fruit is oblong, laterally compressed, smooth, and transversely wrinkled.

L. minor has a tapering fleshy root, an erect stem, 3 feet or more in height, solid, leafy, round, and with many wide-spreading branches. The leaves are stalked, broad, heart-shaped, and being 3-ribbed at the base, somewhat hoary and downy beneath. The florets are axillary, with their anthers and stigmas purple. When in flower the involucre readily breaks from the stalk, and is known in the country by the name of a Bur. It adheres to the coats of animals and the hair and clothing of those who pass by, and it is almost impossible to become free from it without breaking the scales asunder and scattering the fruit. The root is reckoned tonic, aperient, and diuretic. It has had some reputation in the form of a decoction in rheumatism and diseases of the skin. Sir Robert Walpole recommends it as a remedy in gout, and some have used it as an excellent substitute for sarsaparilla. The fruit is bitter and slightly acid, and has been prescribed as a diuretic. It grows in waste places throughout Europe and the West of Asia.

L. major and *L. tomentosa* are species which are found in Germany and Switzerland, but are not used in the arts or in medicine.

(Lindley, *Flora Medica*; Koch, *Synopsis Floræ Germanicæ*.)

LA'PSANA, a genus of plants belonging to the natural order Compositæ, the sub-order Liguliforæ, the tribe Achoraceæ, and the sub-tribe Lampsanæ. There is but one British species of this genus—

L. communis, Nipple-wort. It has dentate or lobed stalked leaves, the lower leaves lyrate; the involucres glabrous and angular; the stem panicled. The stem is from one to three feet in height, branched above, with yellow small-headed florets. It is found in waste uncultivated land, and derives its common name from its reputation in village medicine, as a soothing application to inflamed nipples, and is used in many of our provinces as an external application in wounds and ulcerations.

L. fœtida is a species of this genus, which grows in Switzerland and the regions of the Alps.

(Babington, *Manual of British Botany*; Koch, *Synopsis Floræ Germanicæ*.)

LAPSE. [BENEFICE, P. C.]

LARDIZA'BALA, a genus of plants belonging to the natural order Menispermaceæ, and named by Ruiz and Pavon after Michael Lardizala, of Uribe, a Spanish naturalist. It has diœcious or polygamous flowers. The sepals and petals disposed in a ternary order in 2 or 3 series. The stamens 6, monadelphous. Berries 3- or 6-celled, the cells many-seeded. The pulp of the fruit sweet and eatable. It has leaves 2-3 ternate; the leaflets oblong, acute, unequal at the base, a little toothed; two large unequally cordate bracts situated at the base of the peduncle. This plant is a twining shrub, a native of Chili in woods at Concepcion, also in Peru about Arauco It has an eatable fruit, which is gathered and sold in the markets of Chili and Peru. The pulp of the fruit is sweet and grateful to the taste. It is called in Peru *Aguil-boguil* and *Guilbogui*; and in Chili by that of *Coquilvochi*. *L. triternata* and *L. trifoliata* are climbing plants, natives of Chili and Peru, but their fruits are not eaten.

(Don, *Gardener's Dictionary*.)

LARREY, DOMINIQUE-JEAN, BARON, was born at Beaudeau, near Bagnères de Bigorre, in France, in July, 1766. He studied the elements of medicine and surgery at the hospital at Toulouse, under the direction of his uncle Alexis Larrey, who practised medicine in that city. In 1787 he went to study his profession in Paris, and obtained the appointment of surgeon to the frigate Vigilante, in which he visited North America. He returned to Paris at the commencement of the Revolution, and in 1792 joined the French army which was then carrying on its operations on the Rhine. Here he distinguished himself by the invention of the *ambulances volantes*, by means of which the wounded, being first dressed, were carried off the field of battle, even under the fire of batteries. He was at the siege of Toulon, where he became acquainted with Napoleon Bonaparte, who was then a lieutenant of artillery. In 1796 he was appointed a professor in the school of medicine and military surgery at Val de Grace. In 1798 he accompanied the French army with Napoleon to Egypt, and on his return published an historical and surgical account of the expedition, with the title 'Relation historique et chirurgicale de l'Expedition de l'Armée d'Orient en Egypte et en Syrie,' 8vo., Paris, 1803. From this time he was advanced to various honourable positions; after the battle of Wagram he was made a Baron of the Empire, and in 1812 he was made surgeon-in-chief of the imperial army. 'He liked,' says Mr. Arnott, in the Hunterian oration for 1841, 'to be called by the title of nobility which he had earned, nor was this a childish vanity; for he knew that neither the chance of birth nor the favour of a court had made him a baron, but that the dignity had been bestowed by a discriminating hand which never conferred honours upon incompetency or inefficiency.'

An anecdote is related of Larrey which shows his courage, and proves that he did not obtain the good graces of the Emperor by any sacrifice of character. After the battles of Bautzen and Würchen it was suggested to Bonaparte that the number of the wounded had been increased by voluntary mutilation. He immediately ordered that the suspected, to the number of 1200, should be separated from the rest to be examined by the surgeons, and if found guilty they should be shot. Nobody doubted the guilt of the parties, and great anxiety was shown to put the sentence into execution, when Larrey demanded time to examine the suspected persons accurately, and he reported that all the accused were innocent. He addressed a report to this effect to Napoleon, expecting that his dismissal would follow. The contrary was the case, for Napoleon sent him a letter in return with a present of 6000 francs, and the warrant of a pension of 3000 to be paid from his own privy purse. Napoleon bequeathed to Larrey at his death 10,000 francs, at the same time expressing his conviction that 'Larrey was the most virtuous man he had ever known.'

Larrey published many works besides that above referred to, which contain a great mass of valuable surgical observations. One of his earliest publications was his 'Dissertation sur les Amputations des Membres à la suite des coups de feu, étayée de plusieurs operations,' Paris, 1796. In this work he demonstrated the necessity of immediate amputation after gun-shot wounds, and clearly pointed out the cases in which it was indicated. The propriety of such a practice had been previously suggested, but it is to Larrey that we are indebted for carrying it largely into effect. It was at one time the practice of surgeons, in all cases of mortification, to wait, previously to performing amputation, for the line of demarcation to form between the diseased and sound parts. Larrey proved that in cases of gun-shot wounds, the best practice consisted in operating immediately after the receipt of the wound.

In addition to these works he published 'Mémoires de Chirurgie militaire et Campagnes,' 8vo., Paris, 1812; 'Recueil de Mémoires de Chirurgie,' 8vo., Paris, 1821. A multitude of papers scattered throughout the medical and surgical journals of France, the Bulletins of the Academy of Paris, and other volumes, on almost every department of surgery, bear testimony to his industry and talent, and the enlightened principles on which he based the practice of his profession. Some of these have been translated into most of the languages of Europe, and have obtained for Larrey a first position amongst modern surgeons. He died at Lyon, on the 25th of July, 1841.

(*London Medical Gazette*, 1841; Kallisen, *Medicinisches Schriftsteller-Lexicon*; *Lancet*, 1841.)

LASER. [SILPHIUM, P. C.]

LASERPITIUM (the name of the antient Silphium), a genus of plants belonging to the natural order Umbelliferæ. It has a calyx with a 5-toothed rim; the petals obovate, emarginate, with an inflected lobe; the fruit compressed from the back, or somewhat taper, 8-winged, that is, the half-fruits with five primary filiform ridges, and four winged secondary ones; a vitta in the channel below each secondary ridge. The species are herbaceous plants, with 2-3-pinnate leaves, and entire toothed or cut segments; many-rayed showy umbels; the involucres many-leaved; the flowers white, rarely yellow.

L. glabrum, glabrous Laserwort, has bipinnate leaves, quite glabrous in every part; the leaflets obliquely cordate, here and there mucronate and toothed; leaves of the involucre setaceous; wings of the fruit equal, rather curled. This plant is a native of mountainous districts of Europe in dry and stony places. It attains a height of one or two feet on the Alps, but in cultivation is a much larger plant. The root is filled with a gum-resin, which is acrid, bitter, and even somewhat caustic. It is said to be a violent purgative. The French call it *Turbith aux Montagnes* and *Faux Turbith*.

L. Siler has bipinnate quite glabrous leaves; leaflets lanceolate or oval, quite entire, mucronate, sometimes confluent, and then 3-lobed; the leaves of the involucre and involucels linear-lanceolate, slightly awned, acuminate, the wings of the fruit narrow. It is a native of the mountains of the middle and south of Europe. The root is extremely bitter, and yields an aromatic resinous substance which has been supposed to be the Silphion or Laser of the antients. [SILPHIUM, P. C.; LASER, P. C.] *L. Siler* is supposed by Fraas to be identical with the λιγυστικόν of Dioscorides, 3, 51. Sibthorp found this plant in Greece. *L. gummiferum*, a native of Portugal and Spain, also yields a gum-resin. There are several other species of Laserpitium described, and many of them yield a gum-resin, which is one of the secretions of the order to which they belong.

(Lindley, *Flora Medica*; Don, *Gardener's Dictionary*; Fraas, *Synopsis Plantarum Floræ Classicæ*.)

LASTREA, a genus of Ferns, belonging to the tribe Aspidieæ. It has a reniform indusium attached by the sinus, the veins distinct after leaving the midrib, and not uniting with those of the adjoining pinnule.

The following species of this genus are described in Babington's 'Manual of British Botany:' *L. Thelypteris* (Marsh Fern); *L. Oreopteris* (Sweet Mountain Fern); *L. Filix Mas* (Male Fern); *L. cristata*; *L. rigida*; and *L. dilatata*. For the properties, &c. of the more important of these species see ASPIDIUM, P. C. S.

LATHE. [TURNING, P. C., p. 418; EARTHENWARE, P. C., p. 244; POTTERY, P. C., pp. 472, 473.]

LATHY'RUS. [VICIEÆ, P. C.]

LAVATE'RA (in honour of the two Lavaters), a genus of plants belonging to the natural order Malvaceæ. It has numerous styles, a double calyx, the outer one being three-leaved, the inner five-leaved; the capsules orbicular and many-celled; the cells circularly arranged, and one-seeded.

L. arborea (Tree Mallow) has a woody stem, the leaves seven-angled, plaited, and downy; the pedicels aggregate, axillary, one-flowered, and much shorter than the petiole. It is a native of Italy, Spain, Portugal, the north of Africa, and the Canary Islands, on maritime rocks; also in Britain, in the Isle of Wight, on Portland Island, in Cornwall, and Devonshire. It is the Μαλάχη of Theophrastus (*Hist. Pl.*, i. 5; i. 14).

L. Neapolitana has an herbaceous scabrous erect stem, with roundish seven-nerved leaves, and seven blunt crenated lobes; the pedicels axillary and aggregate, the involucel shorter than the calyx, the lobes of the calyx acuminated. The flowers are blue with obcordate petals. This species is a native of Naples, by the sea-side, and is much cultivated in our own gardens as an ornamental plant.

L. Olbia has a shrubby stem, rather scabrous, from distant fascicles of hairs; the leaves are soft, woolly, five-lobed, the upper ones three-lobed, with the middle lobe elongated; the uppermost leaves are oblong, almost undivided, the flowers solitary and sessile. It is a native of Provence, in hedges about D'Hières.

None of the species of Lavatera are of any importance or value, excepting as ornamental plants. Many of them are hardy, easily cultivated, and well adapted for shrubberies. The greenhouse and frame species will thrive well in a mixture of loam and peat, or any light soil; they may be planted out during the summer against a south wall, and if protected in the winter by a mat, will generally survive throughout the year. The perennial species grow in any kind of soil, and may be propagated either by dividing the plants at the root or by seeds. The annual and biennial kinds should be sown in the open border during the spring. The species chiefly worth cultivation in gardens are *L. Olbia*, *flava*, *unguiculata*, *Neapolitana*, *Cretica*, *Lusitanica*, and *trimestris*.

LAW, CRIMINAL. The object of the English as of every other system of Criminal Law is the prevention of injuries by the terror of punishment; but it is not every injury the commission of which the law thinks fit to prevent by such means; in most cases it is satisfied with the redress of injuries after they have been committed, by either restoring the party injured to his right, where that is possible, or by giving him compensation in damages. In law, an injury is any violation of a legal right or omission of a legal duty: a crime, then, may be defined to be such a violation of a legal right or omission of a legal duty as subjects the person guilty of it to punishment. Such acts or omissions for which the law affords redress only have, in England, been usually denominated civil injuries as contradistinguished from crimes. It is to be observed however, that, in strictness, every crime includes an injury, in respect of which some individual or the public may be entitled to redress. In felony, indeed, such injury is said to be merged in the crime; but this doctrine appears to have originated in the circumstance of all felonies having, with one or two exceptions, been originally punishable with death and having worked a forfeiture of all the offender's property, and so rendered redress impossible.

Crimes, according to the English law, are divisible into two great classes, which depend upon the mode of proceeding peculiar to each, viz. into

1st. Such as are punishable on indictment or information (the common law methods of proceeding).

2ndly. Such as are punishable on summary conviction before a justice or justices of the peace or other authorized persons, without the intervention of a jury (a mode of proceeding derived entirely from special statutory enactments).

It is proposed, in the first place, to treat of offences punishable on indictment or information, and afterwards to shortly refer to those punishable on summary conviction.

Offences punishable on Indictment or Information.

Indictable offences are distributable into four classes or divisions, viz.: Treasons, Præmunires, Felonies, and Misdemeanors. Persons who commit the offences which constitute the last-mentioned division may also be prosecuted by criminal information instead of being indicted.

The distinction between these classes is, for the most part, a merely arbitrary one, without any apparent reference to rule or principle, the consequence of which is that offences in their nature wholly undistinguishable are, in many instances, separated and subjected to punishments widely disproportionate, and to forms of procedure widely dissimilar. In fact, the only real distinguishing feature between one class of crimes and another, at the present day, is to be found in certain peculiarities of punishment and procedure incident to each. Formerly, however, the classes of crimes were marked by distinctive characteristics; but they have subsequently, either by artificial constructions of the courts or by legislative enactment, been made to embrace offences of a very different nature from those originally included within them. For instance, the crime of treason, whether high or petit, implied a violation of the allegiance due from an inferior to a superior. In the case of high treason, so called 'by way of eminent distinction,' it was the violation of the allegiance due from a subject to his liege lord and sovereign; and in case of petit treason, which was limited to the murder of a husband by his wife, a master by his servant, or an ecclesiastic by his inferior who owed him faith and obedience, it was the breach of the allegiance of private and domestic faith.*

The characteristic above pointed out can no longer be traced in many of the various constructive treasons which have been from time to time created by the courts. It will be sufficient here to give a single illustration of the mode in which the law of treason has been stretched to reach cases totally inconsistent with its original design. By one of the clauses of the statute of treasons (25 Edw. III. c. 2) it is declared to be treason *to levy war against the king*. A riotous assembly attempting by force to redress a public grievance, as, for example, to pull down *all* inclosures or to burn *all* meeting-houses, has been held to be *a levying of war* within the meaning of this clause, although there has been no direct intention or design whatever against either the state or the person of the king. This construction is said to depend upon the *generality* of the design. If the intention be to pull down *particular* inclosures or meeting-houses only, the offence is a mere riot, and in quality a simple misdemeanor. Although the generality of the design may be a reason for awarding a higher punishment in the former than in the latter case, there appears to be no foundation in reason or principle for construing an offence, which but for such generality would be a misdemeanor only, to amount to the crime of treason in levying war against the king. The Criminal Law Commissioners (4th, 5th, and 6th Reports) have recommended that this offence should no longer be considered to fall within the statute of treasons. They propose that the only assemblings or risings of the people which should amount to a levying of war against the king should be such as are against the person of the king, or against any army or force appointed by him in opposition to his authority, or with intent to do him bodily harm, or impose any restraint upon his person, or to depose him, or to dispossess or deprive him of any portion of his dominions or regal authority, or with intent by force or constraint to compel him to change his measures or counsels, or to put any force or constraint upon or to intimidate or overawe both houses or either house of parliament; and that no assembling or rising of the people should by reason of any illegality or generality of purpose be deemed to be a levying of war against the king, unless it be with one or other of the several intentions before mentioned. Such riotous and tumultuous meetings as have no such intention in view they recommend should be denominated felonies or misdemeanors merely, according to the circumstances by which they are attended.

Again, the term 'Præmunire' was originally applied to offences which consisted in the introduction of any foreign jurisdiction, more especially the authority of the See of Rome, into the kingdom; but has subsequently, to use the language of Mr. Serjeant Hawkins (*Pleas of the Crown*, b. 1, c. 19), 'been applied to other heinous crimes, for the most part having relation to the offences originally coming under the notion of præmunire, but in some instances none at all.' The Habeas Corpus Act (31 Car. II. c. 12) contains an instance of the latter mode of application. By the 12th section of that act it is made a Præmunire to send any inhabitant of England, Wales, or the town of Berwick-upon-Tweed, a prisoner beyond the seas in defiance of its provisions to the contrary.

The term 'Præmunire' was adopted from the first word of the original writ on which the subsequent proceedings were founded: '*Præmunire* (for *præmoneri*) *facias* A. B. quod sit coram nobis,' &c. [PRÆMUNIRE, P. C.] The Criminal Law Commissioners propose to abolish præmunires as a class of crimes. (Seventh Report.)

The crime of felony had its origin in very remote times, and was founded upon feudal principles. Its incidents were not formerly, as they are now, of a merely arbitrary nature, peremptorily annexed to certain criminal acts without reference to rule or principle. The crime originally consisted in a violation of the feudal contract by the misconduct of the lord or of the tenant; and where committed by the tenant, occasioned as a consequence the forfeiture of his feud to the lord. (4 Black. *Comm.*, p. 96; 4th and 7th *Repts. of Crim. Law Commrs.*)

Those crimes, therefore, which induced such forfeiture, and, by a small deflection from the original sense, those which induced the forfeiture of goods also, were denominated felonies; and afterwards, by long use the term *felony* came to signify the actual crime itself, and not the penal consequence. 'So that, upon the whole,' to use the words of Mr. Justice Blackstone (4 *Comm.*, p. 95), 'the only adequate definition of felony seems to be that which is before laid down, viz. an offence which occasions a total forfeiture of either lands or goods, or both, at the common law; and to which capital or other punishment may be superadded according to the degree of guilt.' Where the punishment is less than capital, the offender loses his goods only; where capital, his lands as

* Petit Treason was abolished by the 9 Geo. IV. c. 31, s. 2, and the offence constituting it declared to be murder only.

well as his goods. The crimes which occasioned such forfeiture were originally, with one or two exceptions, capital; but at the present day there are offences for which no greater punishment can be inflicted than imprisonment for a term not exceeding three years, which are felonies, and consequently occasion the forfeiture of all the offender's goods and chattels; whilst other crimes, for which the punishment may be as high as transportation for fourteen years, and in four instances *must be* for life, are misdemeanors only, and work no forfeiture. It is apparent from this that the present law is very defective, and that the amount of punishment is no longer the test of distinction between a felony and misdemeanor. It is proposed by the Criminal Law Commissioners (*Seventh Rep.* p. 16) to remedy this by making the liability to transportation the test of distinction, *i. e.* that all offences liable to a less punishment than transportation should be misdemeanors only.

The term 'Misdemeanor' is used in the English system of Criminal Law to denote such indictable offences as are of a lower degree than felony.

We shall now point out the peculiarities of punishment which distinguish one class of crimes from another at the present day. In order to this, the penal consequences incident to the whole body of offences constituting each class will be first stated, and then in what respects those consequences differ from each other. The classes will be taken in the same order as above.

1. *Treasons.*—Treasons, with one exception mentioned below, are capital: but whether capital or not, the offender, *upon conviction*, forfeits to the crown the personal estate of every description, whether in action or possession, or settled by way of trust, which the offender has otherwise than as an executor (*Cro. Car.* 566), or a trustee, or a mortgagee (4 & 5 Wm. IV. c. 23, s. 3) at the time of conviction; and in the case of capital treasons, *upon attainder by judgment of death or outlawry*, the blood of the offender is corrupted, but not so as to obstruct descents to such offender's posterity, when they are obliged to derive a title through such offender to a remoter ancestor (3 & 4 Wm. IV. c. 106, s. 10), and all the freehold lands and tenements of inheritance in fee-simple or fee-tail, and all other hereditaments (except copyholds), whether in possession, reversion, or remainder; and all the rights of entry on freehold lands and tenements which the offender has (otherwise than as a trustee or mortgagee, 4 & 5 Wm. IV. c. 23, s. 3) at the time of the offence committed or at any time afterwards, and also the profits of all freehold lands and tenements which the offender has in his or her own right for life, so long as such interest shall subsist, and, if the offender be a male, his wife's dower, are forfeited to the crown (4 Black. *Comm.*, 381; 26 Hen. VIII. c. 13, s. 5; 33 Hen. VIII. c. 20, s. 2; and 5 & 6 Edw. VI. c. 11, ss. 9 and 13); and all the copyhold estates belonging to the offender at the time of the offence committed are forfeited to the lord of the manor (*Com. Dig.* Copyhold (M) 1.). The above penal consequences are general to all capital treasons, unless, as is sometimes the case, the act which creates the particular treason expressly exempts from some of them. The before-mentioned non-capital treason renders the party guilty of it liable to those only of the above consequences which accrue upon conviction, since the others follow only upon the party's being attainted, that is, sentenced to death or outlawed, which latter, in the case of capital treasons and felonies, is of the same effect as being sentenced to death. The existence of this non-capital treason would appear to be the result of inadvertence. By the Forgery Consolidation Act (11 Geo. IV. & 1 Wm. IV. c. 66) it was declared to be treason and punishable with death to forge the great and other royal seals and the sign manual. By the 2 & 3 Wm. IV. c. 123, the punishment of death was repealed for forgery in all but the two cases of wills and powers of attorney to transfer stock (it has been since taken away in these cases also by the 7 Wm. IV. & 1 Vict. c. 84); but the *quality* of the offences enumerated in the Forgery Consolidation Act was left without alteration; so that to forge the royal seals, &c. would appear to be still treason, though no longer a capital offence.

The judgment of death in the case of treason is that the offender, if a male, be drawn on a hurdle to the place of execution, and be there hanged by the neck until dead; and that afterwards the head be severed from the body of such offender, and the body be divided into four quarters, to be disposed of as her Majesty shall think fit (54 Geo. III. c. 146); and, if a female, that the offender be drawn to the place of execution and be there hanged by the neck until dead (30 Geo. III. c. 48, s. 1). The queen, however, may, by warrant under her sign manual, countersigned by a principal secretary of state, direct, where the offender is a male, that he shall not be drawn, but taken in such manner as in the warrant shall be expressed to the place of execution, and that he shall not be hanged, but be beheaded, whilst alive, instead (54 Geo. III. c. 146, s. 2).

2. *Præmunires.*—The penalties of præmunire, as shortly summed up by Sir Edward Coke (1 *Inst.* 130 a.), are, 'that from the conviction the defendant shall be out of the king's protection, and his lands and tenements' (*i. e.* in fee-simple or for life, but not in tail beyond his life interest therein), 'goods and chattels, forfeited to the king: and that his body shall remain in prison at the king's pleasure, or, as other authorities have it, during life.' These penalties were first imposed by the stat. 16 Rich. II. c. 5 (commonly called the Statute of Præmunire); and it is by reference to that statute that all subsequent præmunires have been made punishable. It was formerly supposed that a person convicted of præmunire, being put out of the king's protection, might be killed with impunity, as being the king's enemy; but by the 5 Eliz. c. 1, ss. 21 and 22, it was enacted that it should not be lawful to kill any person attainted in a præmunire, saving such pains of death or other hurt or punishment as theretofore might, without danger of law, be done upon persons sending or bringing into the realm, &c. any process, &c. from the See of Rome. Præmunires, although they occasion a forfeiture of the offender's lands and goods, are not felonies. To constitute a felony the offence must have worked a forfeiture at the common law; but in the case of præmunire the forfeiture is made a part of the punishment by statute merely, which is not sufficient. (4 Black. *Comm.*, pp. 94 and 118.)

3. *Felonies.*—All felonies, as stated above, were originally, with one or two exceptions, punishable with death; but the offender, unless the felony was excluded from the benefit of clergy, was entitled, for a first offence, to be discharged from the capital punishment upon praying that benefit. [BENEFIT OF CLERGY, P. C.] But now, since the passing of the 7 & 8 Geo. IV. c. 28, no felony is punishable with death unless it was excluded from the benefit of clergy before or on the 14th Nov. 1826, or has been or shall be made punishable with death by some statute passed since that day. Where not capital, felonies are punishable either in the manner prescribed by the statute or statutes specially relating to such felonies, or, where no punishment has been or may hereafter be specially provided, with transportation for seven years, or imprisonment for any term not exceeding two years, with the addition, if the court shall think fit, of whipping, where the offender is a male, hard labour and solitary confinement, or any of them. (7 & 8 Geo. IV. c. 28, ss. 7 and 8.) Such confinement must not however be for a longer period than one month at a time, or three months in a year. (7 Wm. IV. & 1 Vict. c. 90, s. 5.) In the case of *all* felonies, whether capital or not, the offender immediately *on conviction* forfeits to the crown all the personal estate of every description, whether in action or possession, or settled by way of trust, which he has otherwise than as an executor (*Cro. Car.* 566), or a trustee or mortgagee (4 & 5 Wm. IV. c. 23, s. 3), at the time of conviction (Bac. *Abrid.*, 'Forfeiture' (B); Co.-Litt. 391 u); and in the case of all capital felonies, *upon attainder by judgment of death or outlawry*, forfeits to the crown the profits of all estates of freehold (4 Black. *Comm.*, 385), and of things not lying in tenure (Bac. *Abrid.*, 'Forfeiture' (A)), and to the lord of the manor the profits of all estates of copyhold (Hawk. *P. C.* b. 2, c. 49, s. 7; Lord Cornwallis's case, 2 Vent. 38-9), which the offender has, otherwise than as a trustee or mortgagee (4 & 5 Will. IV. c. 23, s. 3), at the time of the offence committed, during his life; and his blood is corrupted (but not so as to obstruct descents to the posterity of such offender where they are obliged to derive a title through him to a remoter ancestor (3 & 4 Will. IV. c. 106, s. 10), and after his death his copyholds which he holds in fee-simple are forfeited to the lord of the manor. (Scriven *On Copyholds*, 523, note (d).) And also in the case of murder, all his freehold lands and tenements in fee-simple escheat (subject to what is called the crown's year, day and waste) to the lord of the fee. (54 Geo. III. c. 145; Co.-Litt. 391 a; 4 Black. *Comm.* 385.)

The judgment of death in the case of all capital felonies, except murder, is that the offender be hanged by the neck until dead (2 Hale's *P. C.* 411); and, in the case of murder, it is the same, with the addition that the offender's body shall be buried within the precincts of the prison in which he shall have been confined after conviction. (2 & 3 Will. IV. c. 75, s. 16; 4 & 5 Will. IV. c. 26.) The court however is empowered, if it shall think that the offender is a fit subject to be recommended to the royal mercy, to abstain from pronouncing judgment of death upon him, and to order such judgment to be entered of record instead; and the judgment so recorded has the same effect as if pronounced and the party were reprieved. (4 Geo. IV. c. 48, ss. 1 & 2; 6 & 7 Will. IV. c. 30, s. 2.)*

4. *Misdemeanors.*—The punishment in the case of misdemeanors, where none is specially provided by statute, is generally fine and imprisonment.

From what has been stated, it will be seen that the circumstance, so far as punishment is concerned, which distinguishes misdemeanors from all the other classes of offences, is the absence of forfeiture as a necessary consequence of conviction. The distinction between præmunires and felonies (which term, it should be remarked, in its largest sense, includes treasons, on account of the forfeiture which that class of crimes occasions) is, that the forfeiture which ensues upon a conviction of the former is, as before observed, in pursuance of statutable provisions; whereas in the latter case it is a common law consequence of the offence, and follows as a matter of course whenever a crime is declared to be a felony. There appears to be no distinction as regards punishment, independently of special statutable enactment, between non-capital felonies (the term is used here in its ordinary restricted sense) and the non-capital treason above described; but the difference between felonies and treasons when punishable with death is very considerable. In the case of felonies the offender, upon attainder, *forfeits* to the crown the profits only of such freehold and copyhold lands as he had at the time of committing the offence, during his life, and after his death, his copyholds in fee-simple are forfeited to the lord of the manor; and even where attainted of murder, though his freehold estates in fee-simple fail after his death, it is not as a consequence of the law of forfeiture, but because they escheat for want of heirs capable of succeeding to them, owing to his blood being corrupted by the attainder; and it is on account of such estates escheating and not being forfeited that they go to the lord of the fee (that is, subject to the crown's year, day and waste), and not to the crown, unless there appears to be no intermediate lord between the offender and the crown, in which event the crown takes as ultimate lord of the fee. In the case of treason, however, the offender upon attainder, instead of forfeiting to the crown the profits merely of such freehold lands as he had at the time of committing the offence, during his life, forfeits all freehold estates of inheritance, as well those in fee-tail as those in fee-simple, and not only such as he had at the time of the commission of the offence, but those also which he may acquire at any time afterwards; and instead of forfeiting to the crown the profits of his copyholds during his life, and to the lord of the manor his copyholds in fee-simple only, he forfeits at once to the lord of the manor *all* the copyholds belonging to him at the time the offence was committed. Where the offender is a male, his wife's dower is also forfeited to the crown, which is not the case in felony. It is to be observed that the crown is now empowered (see 59 Geo. III. c. 94) to restore the whole or any part of any lands or hereditaments to which it becomes entitled by escheat or forfeiture to the family of the offender, a provision which has greatly mitigated the harshness of the law of forfeiture. The Criminal Law Commissioners however recommend the entire abolition of the confiscation of property as a necessary incident to convictions for treason or felony. (*Seventh Report on Criminal Law.*) The difference between the judgment of death for treason and that for felony requires no comment.

Besides the above peculiarities of punishment, these different classes of offences are distinguished by particular forms of procedure; but it will be more convenient to refer to these when describing our general system of criminal procedure.

Having pointed out the leading characteristics of the various classes into which indictable crimes are divisible by the law of England, it is now proposed to state shortly what are the different offences comprised under each of those classes. In this view the offences belonging to each class are arranged under their several punishments. The classes are taken in the same order as before. It will be proper, however, in the first instance, to show what persons are capable of committing crimes, to notice one or two provisions of general application, for the purpose of preventing repetition, and to make a few explanatory observations.

According to the law of England, all persons above the age of seven years, except such as by reason of unripeness, weakness, unsoundness, disease, or delusion of mind, are incapable of discerning, at the time they do an act, that the act is contrary either to the law of God or the law of the land, are criminally responsible for such act; but temporary incapacity wilfully incurred by intoxication or other means is no excuse. An infant of the age of seven and under fourteen years, however, is to be presumed to be incapable of committing a crime until the contrary be proved. Duress, also, inducing a well-grounded fear of death or grievous bodily harm, will excuse a person acting under such duress in all cases except treason and murder; and a married woman committing any offence, except those last mentioned, if her husband be present at the time, shall be presumed to have acted under his coercion, and be entitled to an acquittal, unless it appear that she did not so act. A married woman also shall not be liable to conviction for receiving her husband or any other person in his presence and by his authority.

The following provisions are of general application. By the stat. 7 Will. IV. & 1 Vict. c. 90, s. 5, it is enacted that no court shall direct any offender to be kept in solitary confinement for any longer period than one month at a time or than three months in the space of one year. Whenever, therefore, in the following statement solitary confinement is mentioned as part of the punishment for any offence, the periods during which it may be inflicted are to be understood as regulated by the above provision.

By the statute 7 Will. IV. & 1 Vict. c. 85, s. 11, power is given to the jury on the trial of any person for any felony whatever, where the crime charged shall include an assault against the person, to acquit of the felony, and to find a verdict of guilty of assault against the person indicted, if the evidence shall warrant such finding; and thereupon the court may imprison the person so found guilty of an assault for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

By the stat. 1 Geo. IV. c. 57, s. 3, it is provided that where the punishment of whipping on *female* offenders formed, before the passing of that act, the whole or part of the sentence to be pronounced, the court may pass sentence of confinement to hard labour for any time not exceeding six months nor less than one month, or of solitary confinement, in lieu of the sentence of being whipped. In all cases, therefore, where whipping is mentioned to be part of the punishment, without its being restricted to males, the above provision operates.

By the 3 & 4 Vict. c. 111, made perpetual by 5 & 6 Vict. c. 85, members of joint-stock or other banking companies, consisting of more than six persons, committing offences against or with intent to injure or defraud such co-partnerships, are made liable to the same punishments as if they had not been or were not members of such co-partnerships

In the following statement the general description only is given of any particular offence. It is to be observed, however, that where a crime is defined by statute, the enactment in most cases comprises, in fact, many other offences distinct from the general one, though in nature connected with it. For the details of such enactments, reference must be made to the statutes cited at the end of each offence. With respect to these statutes, those which define the crime, as well as those which declare the punishment, are referred to wherever the statutes are distinct, and these are arranged as regards any particular crime in the order of date; and generally, but not universally, where statutes of both descriptions are referred to, those by which the crime is defined stand the first in order. The following statement contains no offence contained in any merely temporary act, or in any local or private act, of a date subsequent to the period since which such acts have been printed separately from the public general acts.

I. Treasons.—(*Capital.*)

The following treasons are punishable with death,* viz:—

1. Compassing the death of the king (which term includes a queen regnant) or of his queen, or their eldest son and heir;

* See R. v. Hogg, 2 M. & Ro. 381, where it was held that since the passing of the 6 & 7 Will. IV. c. 30, death may be recorded in the case of murder as well as other capital felonies, notwithstanding the exception contained in the 4 Geo. IV. c. 48.

* To conceal or keep secret any treason committed or intended to be committed is termed misprision of treason, and is punishable with loss of the profits of lands during life, forfeiture of goods, and imprisonment for life. (See 1 & 2 Phil. and Mary, c. 10, s. 8.)

violating the king's companion, (*i. e.* his wife during the coverture,) or the king's eldest daughter unmarried, or the wife of the king's eldest son and heir; levying war against the king in his realm, or being adherent to the king's enemies in his realm, giving them aid and comfort in the realm or elsewhere, and being thereof attainted of open deed; or slaying the chancellor, treasurer, or the king's justices of the one bench or the other; justices in eyre or justices of assize, or any other justices assigned to hear and determine, being in their places doing their offices.* (25 Edw. III. st. 5, c. 2.)

2. Endeavouring to prevent the person next in succession to the crown, according to the Acts of Settlement, from succeeding thereto. (1 Anne, st. 2, c. 17, s. 3.)

3. Affirming, by writing or printing, that any other person has a right to the crown otherwise than according to the Acts of Settlement and the Acts for the Union of England and Scotland; or that the crown, with the authority of parliament, is unable to limit the descent of the crown. (6 Anne, c. 7, s. 1.)

4. Compassing or intending the death or destruction, or any bodily harm tending to death or destruction, maim or wounding, imprisonment or restraint of the person of the king; or to deprive or depose him from the crown; or to levy war against him, within the realm, in order to compel him to change his measures or counsels, or in order to overawe the parliament; or to move any foreigner to invade any of the British dominions; such compassing or intention being expressed by publishing some printing or writing, or by some overt act or deed. (36 Geo. III. c. 7, s. 1, made perpetual by 57 Geo. III. c. 6.)

5. Being married to, or being concerned in procuring the marriage of any issue of her present majesty whilst such issue are under eighteen (in case the crown shall have descended to any such before that age), without the consent in writing of the regent and the assent of both Houses of Parliament. (3 & 4 Vict. c. 52, s. 4.)

6. Knowing any person to have committed any of the before-mentioned capital treasons, receiving, relieving, comforting or assisting him, or aiding his escape from custody.

7. Bringing into the realm papal bulls or other writings or instruments from the See of Rome; or publishing or putting in use any such bulls, writings or instruments.† (13 Eliz. c. 2, ss. 2 and 3.)

Besides the last-mentioned offence, there also existed till very recently several other capital treasons relating to the See of Rome; but these were repealed by the 7 & 8 Vict. c. 102.

TREASON.—(*Non-Capital.*)

The following treason (the one already alluded to) is punishable with transportation for life or not less than seven years, or with imprisonment for any term not exceeding four nor less than two years, with or without hard labour or solitary confinement, or with both, viz:—

1. Forgery of the great seal, her majesty's privy seal, any privy signet of her majesty, the royal sign manual, the seals appointed to be used in Scotland, and the great and privy seals of Ireland. (11 Geo. IV. & 1 Wm. IV. c. 66, s. 2; 2 & 3 Wm. IV. c. 123; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3.)

II. PRÆMUNIRES.

The following are the offences coming under this denomination still in force:—

1. Derogating from the queen's courts. (27 Edw. III. st. 1, c. 1, s. 1.)

2. Deans and chapters omitting to elect a bishop; and archbishops or bishops to consecrate the person so elected, after receiving the queen's congé d'élire. (25 Hen. VIII. c. 20, s. 7; repealed by 1 & 2 Philip and Mary, c. 8, and revived by 1 Eliz. c. 7.)

3. Molesting the possessors of abbey lands contrary to the provisions of 1 & 2 Philip and Mary, c. 8. (1 & 2 Phil. and Mary, c. 8, s. 40.)

4. Obtaining any stay of proceedings, other than by arrest of judgment or writ of error, in suits for monopolies. (21 Jac. I. c. 3, s. 4.)

* By the 11 Hen. VII. c. 1, it is enacted that no person who attends upon *the king for the time being*, in his person, and does him true and faithful service of allegiance, or is in other places by his commandment, in his wars, in this land or without, shall for such deed and true allegiance be convicted or attainted of treason.

† The repeal of this offence is recommended by the Commissioners for revising and consolidating the Criminal Law. See their Report on Penalties and Disabilities in regard to Religious Opinions, dated the 30th May, 1845.

5. Procuring any stay of proceedings, other than by the authority of the court, in actions brought against persons for making provision or purveyance for the crown. (12 Car. II. c. 24, s. 14.)

6. Asserting maliciously and advisedly, by speaking or writing, that both Houses or either House of Parliament has a legislative authority without the crown. (13 Car. II. c. 1, s. 3.)

7. Sending any subject of the realm a prisoner beyond the seas in defiance of the Habeas Corpus Act. (31 Car. II. c. 2, s. 12.)

8. Asserting, maliciously and directly, by preaching, teaching or advised speaking, that any person, other than according to the Acts of Settlement and Union, has any right to the throne of these kingdoms, or that the queen and parliament cannot make laws to limit the descent of the crown. (6 Anne, c. 7, s. 2.)

9. Knowingly and wilfully solemnizing, assisting or being present at, any marriage forbidden by the Royal Marriage Act. (12 Geo. III. c. 11, s. 3.)

10. Aiding, comforting or maintaining persons who bring into the realm papal bulls or other writings or instruments from the See of Rome, to the intent to uphold the jurisdiction or authority of the pope.* (13 Eliz. c. 2, s. 4.)

III. FELONIES.—(*Capital.*)

The following felonies are punishable with *death*, viz.:—

1. Destroying ships of war or her majesty's arsenals, dock-yards, naval, military or victualling stores, or other ammunition of war, &c. (12 Geo. III. c. 24, s. 1.)

2. Murder. (9 Geo. IV. c. 31, s. 3.)

3. Unnatural offences. (9 Geo. IV. c. 31, s. 15.)

4. Attempts to murder by administering poison, or by wounding, or by any other means where bodily injury dangerous to life is caused. (7 Wm. IV. & 1 Vict. c. 85, s. 2.)

5. Burglary, aggravated by striking an inmate. (7 Wm. IV. & 1 Vict. c. 86, s. 2.)

6. Robbery, aggravated by wounding the person robbed. (7 Wm. IV. & 1 Vict. c. 87, s. 2.)

7. Piracy, aggravated by endangering the life of any person on board of the vessel in respect of which the piracy is committed. (7 Wm. IV. & 1 Vict. c. 88, s. 4.)

8. Setting fire to a dwelling-house, any person being therein. (7 Wm. IV. & 1 Vict. c. 89, s. 2.)

9. Destroying vessels with intent to murder, or whereby human life is endangered. (7 Wm. IV. & 1 Vict. c. 89, s. 4.)

10. Exhibiting false lights, &c. with intent to bring ships into danger, or unlawfully doing anything tending to the destruction of ships in distress. (7 Wm. IV. & 1 Vict. c. 89, s. 5.)

Besides the above offences, that of wilfully and without lawful excuse having or being possessed of any forged stamp used in pursuance of any Act relating to any duties on gold or silver plate made or wrought in Great Britain, for the purpose of marking or stamping such plate, appears to be still punishable with death.

That offence is contained in 55 Geo. III. c. 185, s. 7, by virtue of which enactment it was formerly also a capital crime to forge or utter the stamps provided for marking any such plate, or to fraudulently remove such stamps from one piece of such plate to another, or privately and secretly to use such stamps with intent to defraud the king. The punishment of death for these last-mentioned offences was repealed, however, by 11 Geo. IV. & 1 Wm. IV. c. 66, s. 1 (as to the forging and uttering), and by 4 & 5 Vict. c. 56, s. 1 (as to the removing and fraudulently using); but by some inadvertence (for it is clear that it can never have been intended) the offence of being possessed, without lawful excuse, of forged stamps for marking gold or silver plate (the least criminal of all the acts specified in 55 Geo. III. c. 185, s. 7) is still left capital.

There are two other enactments of capital offences, which also do not appear to have been repealed. The 2 Geo. II. c. 25, s. 2, and the 12 Geo. III. c. 48, s. 1, make it capital for offenders convicted under the provisions of those statutes, to escape or break out of prison; and these enactments do not seem to have been wholly repealed, either expressly or by implication. The Criminal Law Commissioners (7th Report) say, 'Although many Acts have been passed which punish prison-breach by penalties not capital, yet these seem to be confined to particular gaols and prisons, and not to

* The repeal of this offence is recommended by the Commissioners for Revising and Consolidating the Criminal Law.

affect the general enactments above referred to, as regards offenders against their provisions confined in other prisons.'

(*Non-Capital.*)

Non-capital felonies are punishable as follows, viz., with

I. *Transportation for life*, and previously thereto imprisonment, with or without hard labour, for any term not exceeding four years.

1. Offenders transported from Great Britain being found at large, without some lawful excuse, before the expiration of their term of transportation. (5 Geo. IV. c. 84, s. 22; 4 & 5 Wm. IV. c. 67.)

II. *Transportation for life.*

1. Rape. (9 Geo. IV. c. 31, s. 16; 4 & 5 Vict. c. 56, s. 3.)

2. Carnally knowing and abusing girls under ten years of age. (9 Geo. IV. c. 31, s. 17; 4 & 5 Vict. c 56, s. 3.)

3. Forgery of the name or handwriting of the Receiver-General of Customs, or of the Comptroller-General of Customs, &c., to any draft, &c. on the Bank. (8 & 9 Vict. c. 85, s. 26.)

III. *Transportation for life*, or not less than fifteen years, or imprisonment for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Piracy. (28 Hen. VIII. c. 15; 11 & 12 Wm. III. c. 7, ss. 8, 9, and 10; 4 Geo. I. c. 11, s. 7; 6 Geo. I. c. 19; 8 Geo. I. c. 24, ss. 1 and 3; 2 Geo. II. c. 28, s. 7; 18 Geo. II. c. 30; 7 Wm. IV. & 1 Vict. c. 88, ss. 3 and 5.)

2. Offences against the Riot Act.* (1 Geo. I. st. 2, c. 5, ss. 1 and 5; 7 Wm. IV. & 1 Vict. c. 91, ss. 1 and 2.)

3. Rescuing a murderer out of prison, or whilst going to or during execution. (25 Geo. II. c. 37, s. 9; 7 Wm. IV. & 1 Vict. c. 91, ss. 1 and 2.)

4. Seducing sailors or soldiers from their allegiance, or inciting them to mutiny. (37 Geo. III. c. 70, s. 1; 57 Geo. III. c. 7; 7 Wm. IV. & 1 Vict. c. 91, ss. 1 and 2.)

5. Administering oaths binding any person to commit treason or any capital felony. (52 Geo. III. c. 104, s. 1; 7 Wm. IV. & 1 Vict. c. 91, ss. 1 and 2.)

6. Any subject of her majesty, or any person residing in any of the queen's dominions, or in any place under the government of the East India Company, or upon the high seas, or within the Admiralty jurisdiction, carrying away &c. persons to make slaves of them. (5 Geo. IV. c. 113, s. 9; 3 & 4 Wm. IV. c. 73; 7 Wm. IV. & 1 Vict. c. 91, ss. 1 and 2.)†

7. Assembling armed, to the number of three or more, for the purposes of smuggling. (7 Wm. IV. & 1 Vict. c. 91, ss. 1 and 2; 8 & 9 Vict. c. 87, s. 63.)

8. Shooting at vessels belonging to the navy or in the revenue service, within 100 leagues of the coast; or shooting at revenue officers and others duly employed for the prevention of smuggling. (7 Wm. IV. & 1 Vict. c. 91, ss. 1 and 2; 8 & 9 Vict. c. 87, s. 64.)

9. Attempts to murder, by attempting to administer poison, or by shooting at or attempting to drown, suffocate, or strangle any person, although no bodily injury be effected. (7 Wm. IV. & 1 Vict. c. 85, ss. 3 and 8.)

10. Shooting at or attempting to discharge any kind of loaded arms at or wounding any person, with intent to do grievous bodily harm to such person, or to prevent lawful apprehension or detainer. (7 Wm. IV. & 1 Vict. c. 85, ss. 4 and 8.)

11. Sending explosive substances, &c. to any person, or throwing any corrosive fluid or other destructive matter upon any person, with intent to do grievous bodily harm, and whereby grievous bodily harm is done to any person. (7 Wm. IV. & 1 Vict. c. 85, ss. 5 and 8.)

12. Attempting to procure the miscarriage of women. (7 Wm. IV. & 1 Vict. c. 85, ss. 6 and 8.)

13. Robbery, aggravated by the offender being armed, by numbers, or by the use of personal violence to the person robbed. (7 Wm. IV. & 1 Vict. c. 87, ss. 3 and 10.)

14. Extorting property by threatening to accuse of unnatural crimes. (7 Wm. IV. & 1 Vict. c. 87, ss. 4 and 10.)

15. Setting fire to places of worship or houses, or to buildings or erections used for the purposes of trade, with intent to injure or defraud any person. (7 Wm. IV. & 1 Vict. c. 89, ss. 3 and 12.)

16. Setting fire to or otherwise destroying vessels, with intent to prejudice any person interested therein or in the goods on board the same, as an owner, part owner or underwriter. (7 Wm. IV. & 1 Vict. c. 89, ss. 6 and 12.)

17. Forcibly preventing a person endeavouring to save his life from a vessel in distress or wrecked. (7 Wm. IV. & 1 Vict. c. 89, ss. 7 and 12.)

18. Setting fire to coal-mines. (7 Wm. IV. & 1 Vict. c. 89, ss. 9 and 12.)

19. Setting fire to stacks of corn, grain, coal or wood, &c., or to any steer of wood. (7 Wm. IV. & 1 Vict. c. 89, ss. 10 and 12.)

IV. *Transportation for life*, or not less than fifteen years, or imprisonment for any term not exceeding three years.

1. Setting fire to farm buildings, or to buildings or erections used in farming land; or for the purpose of setting fire to such farm-buildings, setting fire to farm produce or implements being therein, with intent in any such case to injure or defraud any person.* (7 & 8 Vict. c. 62, ss. 1 and 2.)

V. *Transportation for life* or not less than ten years, or imprisonment for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Burglary. (7 Wm. IV. & 1 Vict. c. 86, ss. 3 and 7.)

VI. *Transportation for life* or not less than seven years.

1. Personating soldiers or other persons entitled to prize-money, &c. on account of military services, or their representatives; or

2. Forging the name or handwriting of any person so entitled, or of any officer or servant of Chelsea Hospital, &c., or any writing concerning the payment of any such prize-money, &c. (2 Wm. IV c. 53, s. 49.)

VII. *Transportation for life* or for any term of years.

1. Taking oath (not being compelled thereto) binding the person taking the same to commit treason or any capital felony. (52 Geo. III. c. 104, s. 1.)

2. Personating soldiers or other persons entitled to pensions, &c. on account of military services, or their representatives; or,

3. Forging the name or handwriting of any person so entitled, or of any officer or servant of Chelsea Hospital, &c., or any writing concerning the payment of any such pensions, &c. (7 Geo. IV. c. 16, s. 38.)

VIII. *Transportation for life* or for fourteen or seven years.

1. Aiding the escape of prisoners of war from prison or from the queen's dominions, if at large upon parole. (52 Geo. III. c. 156, s. 1.)

2. Subjects of her majesty aiding, upon the high seas, the escape of prisoners of war after they have quitted the coast. (52 Geo. III. c. 156, s. 3.)

IX. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding seven years, with or without hard labour.

1. Stealing or embezzling her majesty's ammunition, naval or military stores. (4 Geo. IV. c. 53; 7 & 8 Geo. IV. c. 27.)

2. Sending letters threatening to kill any person, or to burn his house, stacks, &c.; or rescuing a person in custody for any such offence. (4 Geo. IV. c. 54, s. 3; 7 & 8 Geo. IV. c. 27.)

3. Bankrupt not surrendering, or not discovering all his estate, or embezzling or concealing any part thereof to the amount of 10*l*. or upwards, &c. (5 & 6 Vict. c. 122, ss. 32 and 93.)

X. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding four nor less than two years, with or without hard labour or solitary confinement, or with both.

1. Forgery of the seal or bonds of the South Sea Company (6 Geo. I. c. 4, s. 56; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of receipts or warrants of the South Sea Company (6 Geo. I. c. 11, s. 50; 11 Geo. IV. & 1 Wm. IV. c. 66, s. 4; 2 & 3 Wm. IV. c. 123; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of seals, policies, &c. of the London and Royal Exchange Assurance Companies (6 Geo. I. c. 18, s. 13; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of certain Annuity Orders made forth in pursuance of 6 Geo. I. cc. 11 and 17, 7 Geo. I. st. 1, c. 30, 8 Geo. I. c. 20, or 9 Geo. I. c. 12, or of any authority to transfer the same (9 Geo. I. c. 12, s. 4; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of the name or handwriting of the Accountant-General, Registrar, or Clerk of the Report Office (of the Court of Chancery), or of any cashier of the Bank, to any instrument relating to the suitors' money or

* See also 17 Rich. II. c. 8; 13 Hen. IV. c. 7; 2 Hen. V. st. 1, c. 8. Also 33 Geo. III. c. 67, s. 1; 41 Geo. III (U K.) c. 19, s. 4, as to riots by keelmen.

† See also 3 & 4 Vict c. [illegible].

* Offenders, if males under eighteen years of age, may also be whipped in addition to any other punishment. (See s. 3.)

effects (12 Geo. I. c. 32, s. 9; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1, 26, and 31); of Mediterranean Passes (4 Geo. II. c. 18, s. 1; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of the common seal, bonds, &c. of the English Linen Company (4 Geo. III. c. 37, s. 15; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of certificates, &c. of the Commissioners for the Reduction of the National Debt (32 Geo. III. c. 55, s. 9; 11 Geo. IV. & 1 Wm. IV. c. 66, s. 4; 2 & 3 Wm. IV. c 123; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of the seal, policies, &c. of the Globe Insurance Company (39 Geo. III. c. 83, s. 22; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of the name or handwriting of the Treasurer of the Ordnance, &c., to any draft, &c. on the Bank (46 Geo. III. c. 45, s. 9; 11 Geo. IV. & 1 Wm. IV. c. 66, s. 4; 2 & 3 Wm. IV. c. 123; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of the name or handwriting of the Receiver-General of Stamps and Taxes, or of his clerk, or of the Commissioners of Stamps and Taxes, to any draft, &c. on the Bank (46 Geo. III. c. 76, s. 9; 11 Geo. IV. & 1 Wm. IV. c. 66, s. 4; 2 & 3 Wm. IV. c. 123; 3 & 4 Wm. IV. c. 44, s. 3; 4 & 5 Wm. IV. c. 60; 5 & 6 Wm. IV. c. 20; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of contracts, certificates, &c. relating to the redemption of the land-tax (52 Geo. III. c. 143, s. 6; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of stamps on vellum, parchment, or paper * (52 Geo. III. c. 143, s. 7; 55 Geo. III. c. 184, s. 7; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of debentures or certificates for the payment or return of money required by any Act relating to the Customs or Excise (52 Geo. III. c. 143, s. 10; † 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of stamps on gold or silver plate (55 Geo. III. c. 185, s. 7; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of certificates of Commissioners for the issue of Exchequer-bills for carrying on public works and fisheries in the United Kingdom (57 Geo. III. c. 34, s. 63; 3 Geo. IV. c. 86, s. 54; ‡ 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of the name or handwriting of the Accountant-General, Barons, or Clerk of the Reports (of the Court of Exchequer), or of any cashier of the Bank, to any instrument relating to the suitors' money or effects (1 Geo. IV. c. 35, s. 27; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of certificates or appointments relating to public salaries, pensions, and allowances (3 Geo. IV. c. 113, s. 23; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of orders for payments in connection with public salaries, pensions, and allowances (3 Geo. IV. c. 113, s. 23; 11 Geo. IV. & 1 Wm. IV. c. 66, s. 4; 2 & 3 Wm. IV. c. 123; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of certificates of certain stock, transferable at the Banks of England and Ireland respectively (5 Geo. IV. c. 53, s. 22; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of the name or handwriting of the receiver-general of Excise, or Excise comptroller of cash, &c. to any draft, &c. upon the Bank (7 & 8 Geo. IV. c. 53, s. 56; 11 Geo. IV. & 1 Wm. IV. c. 66, s. 4; 2 & 3 Wm. IV. c. 123; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of stamps upon or relating to cards or dice (9 Geo. IV. c. 18, s. 35; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26); of certificates, &c. as to annuities grantable by the commissioners for the reduction of the national debt, or of instruments made by them relating thereto (10 Geo. IV. c. 24, s. 41; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26; 2 & 3 Wm. IV. c. 59, s. 19; 7 Wm. IV. & 1 Vict. c. 84, ss. 1 and 3); of certificates snd other documents in order to obtain pay or prize-money, due in respect of services performed by any person in the navy (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 83 and 88; 2 Wm. IV. c. 40, s. 35); of Exchequer-bills,§ Exchequer debentures, East-India bonds, bank-notes, bills of exchange, promissory notes and warrants or orders for the payment of money (11 Geo. IV. & 1 Wm. IV. c. 66, s. 3; 2 & 3 Wm. IV. c. 123, s. 1; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of transfers of any public stock transferable at the Bank or South Sea House, or of the capital stock of any body corporate, &c. established by charter or act of parliament (11 Geo. IV. & 1 Wm. IV. c. 66, s. 6 in part; 2 & 3 Wm. IV. c. 123, s. 1; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3); of deeds, bonds, court-rolls, receipts for money or goods, or accountable receipts, or orders for the delivery of goods (11 Geo. IV. & 1 Wm. IV. c. 66, s. 10); of entries in registers of marriages heretofore kept, or in registers of baptisms or burials heretofore or hereafter to be kept by the officiating minister of the parish, &c., or of marriage licences (11 Geo. IV. & 1 Wm. IV. c. 66, s. 20 in part; 6 & 7 Wm. IV. c. 86, ss. 43 and 49); of wills and other testamentary writings, and of powers of attorney to transfer any public stock transferable at the Banks of England or Ireland or the South-Sea House, or to receive any dividend in respect of any such stock (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 3 and 6; 2 & 3 Wm. IV. c. 123, s. 2; 7 Wm. IV. & 1 Vict. c. 84, ss. 1 and 3); of certificates, &c. of the commissioners for granting relief to Trinidad, British Guiana, St. Lucie, and the island of Dominica (2 & 3 Wm. IV. c. 125, s. 65; 5 & 6 Wm. IV. c. 51; 7 Wm. IV. & 1 Vict. c. 84, ss. 1 and 3); of receipts or certificates of the Slave-Compensation Commissioners (5 & 6 Wm. IV. c. 45, s. 12; 7 Wm. IV. & 1 Vict. c. 84, ss. 1 and 3); of receipts for subscriptions towards the sum of four millions for funding Exchequer-bills (2 & 3 Vict. c. 97. s. 32).

2. Offending a third time* in uttering counterfeit gold or silver foreign coin not permitted to be current within this realm. (37 Geo. III. c. 126, s. 4; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 1 and 26.)

3. Personating seamen, marines, or other persons entitled to any allowance from the Compassionate Fund of the navy, in order to receive their pay or prize-money, or allowance from the Compassionate Fund. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 84 and 88.)

4. Taking false oath in order to obtain probate of the will or administration of the effects of deceased seamen or marines, or demanding their pay or prize-money by virtue of such will or administration, &c. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 85 and 88.)

5. Making false entries in the books of the Bank, or of the South Sea Company, or making transfers of stock transferable at either of those places, in the names of persons not being the true owners thereof. (11 Geo. IV. & 1 Wm. IV. c. 66, s. 5; 2 & 3 Wm. IV. c. 123, s. 1; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3.)

6. Personating the owner of any such last-mentioned stock, or of the capital stock of any corporate body, &c. established by charter or act of parliament, or of any dividend payable in respect of such stock, and thereby transferring or endeavouring to transfer such stock, or receiving or endeavouring to receive such dividend. (11 Geo. IV. & 1 Wm. IV. c. 66, s. 6 in part, and 7; 2 & 3 Wm. IV. c. 123, s. 1; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 84, ss. 2 and 3.)

7. Acknowledging any recognizance or bail, cognovit actionem, judgment, or deed to be enrolled, in the name of any person not privy thereto. (11 Geo. IV. & 1 Wm. IV. c. 66, s. 11.)

8. Destroying or injuring registers of marriages heretofore kept, or registers of baptisms or burials heretofore or hereafter to be kept by the officiating minister of the parish, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, s. 20 in part; 6 & 7 Wm. IV. c. 86, ss, 43 and 49.)

9. Officers of the Bank or South Sea Company secreting, embezzling, or running away with securities or effects. (15 Geo. II. c. 13, s. 12; 24 Geo. II. c. 11, s. 3; 35 Geo. III. c. 66, s. 6; 37 Geo. III. c. 46, s. 6; 4 & 5 Vict. c. 56, s. 1.)

* As to the forgery of stamps on newspapers, the 6 & 7 Wm. IV. c. 76, s. 1, appears to make that offence punishable under 55 Geo. III. c. 184, s. 7, *i. e.* in the same manner as the forgery of stamps on v llum, parchment, or paper. See Lonsdale's 'Statute Criminal Law,' p. 81, note (c.); the language of the Act, however, is very obscure.

† The 52 Geo III. c. 143, s. 10, appears to be repealed, so far as relates to the Customs, by 6 Geo. IV. c. 105, s. 297; at all events is so by 3 & 4 Wm. IV. c. 50, s. 3. Also, as to certificates relating to the duties of Excise, see 41 Geo. III. [U. K.] c. 91, s. 5.

‡ See also 57 Geo. III. c. 124; 1 Geo. IV. cc. 60 and 81; 1 & 2 Geo. IV. c. 111; 4 Geo. IV. c. 63; 5 Geo. IV. cc. 36 and 77; 6 Geo. IV. c. 85; 7 Geo. IV. c. 30; 7 & 8 Geo. IV. cc. 12 and 47; 1 & 2 Wm. IV. c. 24; 4 & 5 Wm. IV. c. 72; 7 Wm. IV. & 1 Vict. c. 51; 1 & 2 Vict. c. 88; 3 & 4 Vict. c. 10; and 5 & 6 Vict. c. 9, s. 14.

§ It is doubtful whether the forgery of Exchequer-bills, made out in pursuance of the annual Appropriation Acts, be not still punishable with death, notwithstanding the repeal of that punishment in case of the forgery of other Exchequer-bills. In those acts a clause continues to be inserted, notwithstanding the repeal by 11 Geo IV. & 1 Wm. IV. c. 66, so far as relates to any forgery, of the 48 Geo. III. c. 1 (which made the forgery of Exchequer-bills directed to be issued under that Act, a capital offence), that all and every the clauses, provisions, powers, privileges, advantages, penalties, forfeitures, and disabilities, contained in the 48 Geo. III. c. 1, shall be applied and extended to the Exchequer-bills to be made out in pursuance of such Appropriation Acts, as fully and effectually, to all intents and purposes, as if the said several clauses or provisoes had been particularly repeated and re-enacted in the body of those acts (See Lonsdale's 'Statute Criminal Law,' p. 99, in note.)

* The punishment for offending a second time is imprisonment for two years, and the offender to find sureties for good behaviour for two years more, to be computed from the end of the first two years; and for offending a first time is imprisonment for six months, and the offender to find sureties for good behaviour for six months more, to be computed from the end of the first six months. (37 Geo. III. c. 126, s. 4.)

10. Privately or secretly using stamps provided in pursuance of any Stamp Act, with intent to defraud her Majesty of any duties granted by such act. (52 Geo. III. c. 184, s. 7; 55 Geo. III. c. 185, s. 7; 9 Geo. IV. c. 18, s. 35; 4 & 5 Vict. c. 56, ss. 1 and 4.)

11. Fraudulently tearing off or removing stamps from vellum, parchment, paper, gold or silver plate, &c., with intent to use them again. (55 Geo. III. c. 184, s. 7; c. 185, s. 7; 4 & 5 Vict. c. 56, ss. 1 and 4.)

12. Offenders transported from St. Helena coming into England before the expiration of their term of transportation. (6 Geo. IV. c. 85, s. 18; 4 & 5 Vict. c. 56, ss. 1 and 4.)

13. Riotously destroying places of worship or houses, or buildings connected with trade or the business of mines. (7 & 8 Geo. IV. c. 30, s. 8; 4 & 5 Vict. c. 56, ss. 1 and 4; 6 & 7 Vict. c. 10.)

XI. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding four nor less than two years.

1. Being possessed, without lawful excuse, of forged dies, &c., or of any vellum, parchment, or paper having thereon the impression of any forged die, &c.; or fraudulently using any stamp which shall have been removed from any other vellum, &c.; or getting out of or from any vellum, &c., any matter or thing thereon expressed, with intent to use the stamp then being thereon, for any instrument or thing liable to stamp duty, &c. (3 & 4 Wm. IV. c. 97, ss. 11 and 12; 4 & 5 Wm. IV. c. 60.)

2. Forgery of postage stamps; or privately or fraudulently using such stamps, or, without lawful excuse, being possessed of any paper or other material so privately or fraudulently stamped. (3 & 4 Vict. c. 96, s. 22.)

XII. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding four years, with or without hard labour or solitary confinement, or with both; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment.

1. Sending threatening letters with intent to extort money, &c. (7 & 8 Geo. IV. c. 29, ss. 4 and 8.)

2. Corruptly taking any reward for helping to property which has been stolen, &c. (unless the person so taking such reward cause the offender to be apprehended and tried for the same.) (7 & 8 Geo. IV. c. 29, ss. 4 and 58.)

3. Destroying or damaging goods of silk, woollen, linen, or cotton, &c., whilst in progress of manufacture, or any machine or implement used therein, or forcibly entering any place to commit any of those offences. (7 & 8 Geo. IV. c. 30, ss. 3 and 27.)

4. Breaking down sea-banks, &c., whereby any land shall be in danger of being overflowed or damaged; or destroying works on navigable rivers or canals. (7 & 8 Geo IV. c. 30, ss. 12 and 27.)

5. Destroying, &c., public bridges. (7 & 8 Geo. IV. c. 30, ss. 13 and 27.)

XIII. *Transportation for life* or not less than seven years, or imprisonment not exceeding four years, with or without hard labour or solitary confinement, or with both.

1. Counterfeiting the queen's current gold or silver coin. (2 Wm. IV. c. 34, ss. 3 and 19.)

2. Gilding or silvering or colouring counterfeit coin, or any pieces of metal, with intent to make them pass for the queen's current gold or silver coin; or colouring or altering genuine coin, with intent to make it pass for a higher coin. (2 Wm. IV. c. 34, ss. 4 and 19.)

3. Buying, &c., or putting off, &c., at a lower value than the same by its denomination imports, or importing into the kingdom, counterfeit coin intended to pass for the queen's current gold or silver coin, knowing the same to be counterfeit. (2 Wm. IV. c. 34, ss. 6 and 19.)

4. Having been convicted of uttering counterfeit coin intended to pass for the queen's current gold or silver coin,* or having been convicted of uttering such coin, and being possessed at the time of such uttering of more such coin, or having, on the same day or within ten days afterwards, uttered more such coin,† afterwards committing any of such offences. (2 Wm. IV. c. 34, ss. 7 and 19.)

5. Having been convicted of having in possession three or more pieces of counterfeit coin intended to pass for the queen's current gold or silver coin, with intent to utter the same,* afterwards committing the like offence. (2 Wm. IV. c. 34, ss. 8 in part and 19.)

6. Without lawful authority, making, buying or selling, or having in possession, &c. any instrument adapted for counterfeiting the queen's current gold or silver coin. (2 Wm. IV. c. 34, ss. 10 and 19.)

7. Without lawful authority, conveying out of the Mint instruments of coining, or any coin, bullion, &c. (2 Wm. IV. c. 34, ss. 11 and 19.)

8. Persons employed under the Post Office stealing, embezzling, secreting, or destroying post letters containing money, &c. (7 Wm. IV. & 1 Vict. c. 36, ss. 26, 41, 42.)

9. Stealing money, &c., out of post letters. (7 Wm. IV. & 1 Vict. c. 36, ss. 27, 41, 42.)

10. Stealing post letter-bags, or post letters from post letter-bags or from post-offices, or from the officers of the post-office, or from mails; or stopping mails with intent to rob or search them. (7 Wm. IV. & 1 Vict. c. 36, ss. 28, 41, 42.)

11. Receiving letters or other property the stealing, &c. whereof is felony under the Post-office Acts, knowing the same to have been stolen, &c. (7 Wm. IV. & 1 Vict. c. 36, ss. 30, 41, 42.)

12. Forgery of the name or handwriting of the Receiver-General of the General Post-office, &c. to any draft &c. on the Bank. (7 Wm. IV. & 1 Vict. c. 36, ss. 33, 41, 42.)

XIV. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding four years, with or without hard labour.

1. Taking away or detaining, from motives of lucre, an heiress, &c. against her will, with intent to marry or defile her, &c. (9 Geo. IV. c. 31, s. 19.)

XV. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding four years, with or without hard labour; or such fine as the court shall award.

1. Manslaughter. (9 Geo. IV. c. 31, s. 9.)

XVI. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding four years.

1. Persons employed in the Public Record Office certifying as true false copies of records in the custody of the Master of the Rolls. (1 & 2 Vict. c. 94, s. 19 in part.)

2. Forgery of the signature of any Assistant Record Keeper, for the purpose of counterfeiting a certified copy of a record, or of the Seal of the Public Record Office. (1 & 2 Vict. c. 94, s. 19 in part.)

XVII. *Transportation for life* or not less than seven years, or imprisonment for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Breaking, entering and stealing in churches or chapels, or, having stolen therein, breaking out of the same. (7 & 8 Geo. IV. c. 29, s. 10; 5 & 6 Wm. IV. c. 81; 6 & 7 Wm. IV. c. 4.)

XVIII. *Transportation* for any term not exceeding *fifteen* nor less than ten years, or imprisonment for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Stealing in a dwelling-house† to the value of 5*l.* or more. (7 & 8 Geo. IV. c. 29, s. 12; 2 & 3 Wm. IV. c. 62; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 90, ss. 1 and 3.)

2. Breaking, entering, and stealing in a dwelling-house to any value. (7 & 8 Geo IV. c. 29, s. 12; 3 & 4 Wm. IV. c. 44, s. 2; 7 Wm. IV. & 1 Vict. c. 90, ss. 1 and 3.)

3. Cattle-stealing or killing-cattle, with intent to steal the carcass or skin or any part of the cattle so killed. (7 & 8 Geo. IV. c. 29, s. 25; 2 & 3 Wm. IV. c. 62; 3 & 4 Wm. IV. c. 44, s. 3; 7 Wm. IV. & 1 Vict. c. 90, ss. 1 and 3.)

4. Breaking, entering and stealing in buildings within the curtilage of a dwelling-house, but having no communication with the dwelling-house, either immediate or by means of a covered and inclosed passage leading from the one to the other. (7 & 8 Geo. IV. c. 29, ss. 13 and 14; 7 Wm. IV. & 1 Vict. c. 90, ss. 2 and 3.)

5. Breaking, entering and stealing in shops, warehouses or counting-houses. (7 & 8 Geo. IV. c. 29, s. 15; 7 Wm. IV. & 1 Vict. c. 90, ss. 2 and 3.)

* The punishment for uttering, in respect of a first offence, is imprisonment for any term not exceeding one year, with or without hard labour or solitary confinement, or with both.

† The punishment for uttering, accompanied by the aggravation above specified, is, for a first offence, imprisonment for any term not exceeding two years, with or without hard labour or solitary confinement, or with both.

* See below, the punishment for a first offence.

† For the purposes of this and the next offence no building, although within the curtilage of a dwelling-house, shall be deemed to be part of such dwelling-house, which would not be deemed to be so for the purpose of burglary; that is, no building between which and the dwelling-house there is not a communication, either immediate or by means of a covered and inclosed passage leading from the one to the other. See the 7 & 8 Geo. IV. c. 29, s. 13.

6. Stealing to the value of 10*s.* goods of silk, woollen, linen or cotton, &c., whilst exposed in any place during any stage of manufacture. (7 & 8 Geo. IV. c. 29 s. 16; 7 Wm. IV. & 1 Vict. c. 90, ss. 2 and 3.)

7. Stealing goods, from vessels, &c. in ports or upon navigable rivers or canals, &c., or from docks or quays, &c. adjacent thereto. (7 & 8 Geo. IV. c. 29, s. 17; 7 Wm. IV. & 1 Vict. c. 90, ss. 2 and 3.)

8. Maliciously killing, maiming or wounding cattle. (7 & 8 Geo. IV. c. 30, s. 16; 7 Wm. IV. & 1 Vict. c. 90 ss. 2 and 3.)

9. Maliciously destroying hop-binds growing on poles in hop plantations. (7 & 8 Geo. IV. c. 30, s. 18; 7 Wm. IV. & 1 Vict. c. 90, ss. 2 and 3.)

10. Stealing in a dwelling-house,* and by threats or menaces putting any inmate in bodily fear. (7 Wm. IV. & 1 Vict. c. 86, ss. 5 and 7.)

11. Robbery or stealing from the person. (7 Wm. IV. & 1 Vict. c. 87, ss. 5 and 10.)

12. Plundering vessels in distress, or wrecked, stranded, or cast on shore, or anything belonging to any such vessel. (7 Wm. IV. & 1 Vict. c. 87, ss. 8 and 10.)

13. Maliciously destroying any part of a vessel in distress, or wrecked, stranded or cast on shore, or anything belonging to such vessel. (7 Wm. IV. & 1 Vict. c. 89, ss. 8 and 12.)

XIX. *Transportation for fourteen* years.

1. Solemnizing matrimony at any other time than that prescribed by law, or without banns, unless by licence or under the provisions of the 6 & 7 Wm. IV. c. 85 (which allows marriages to take place before the Registrar of the district);† or pretending to be in holy orders and solemnizing matrimony according to the rites of the Church of England. (4 Geo. IV. c. 76, s. 21.)

2. Being possessed, &c. without lawful excuse, of forged bank-notes, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 12 and 28.)

3 Without the authority of the Bank, making or being possessed of instruments for making, &c. paper used by the Bank for bank-notes, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, s. 13.)

4. Without the authority of the Bank, engraving, making or being possessed of instruments for making, &c. bank-notes, &c., or any character or ornament resembling any part of a bank-note, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 15 and 16.)

XX. *Transportation* for any term not exceeding *fourteen* years.

1. Aiding prisoners to escape, or in attempting to escape from prison, whether an actual escape be made or not. (4 Geo. IV. c. 64, s. 43.)

2. Rescuing offenders sentenced to be transported or banished. (5 Geo. IV. c. 84, s. 22.)

3. Forging certificates given under the Income Tax Act. (5 & 6 Vict. c. 35, s. 181, continued by 8 & 9 Vict. c. 4.)

XXI. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or imprisonment not exceeding three years nor less than one year, with or without hard labour or solitary confinement, or with both.

1. Forgery of memorials or certificates of registry, &c. of lands in Yorkshire or Middlesex (2 & 3 Anne, c. 4, s. 19; 5 Anne, c. 18, s. 8; 6 Anne, c. 35, s. 26; 7 Anne, c. 20, s. 15; 8 Geo. II. c. 6, s. 31; 11 Geo. IV. & 1 Wm. IV. c. 66, ss. 23 and 26); or of extracts from registers of marriage, baptism, or burial, in order to sustain any claim to any allowance from the Compassionate Fund of the Navy, &c. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 87 in part and 88.)

2. Subscribing false petitions to the secretary of the Admiralty, or personating the representatives of deceased seamen or marines, in order to procure a certificate from the Inspector of Royal Marines, &c., thereby to obtain, without probate or letters of administration, any allowance from the Compassionate Fund of the Navy, &c. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 86 and 88; 2 Wm. IV. c. 40.)

3. Making false affidavits, &c. in order to procure any person to be admitted a pensioner as the widow of an officer of the royal navy, &c. (11 Geo. IV. & 1 Wm. IV. c. 20, ss. 87 in part and 88.)

* See the 7 & 8 Geo. IV. c. 29, s. 13, referred to in note* p. 169; it is doubtful, however, if the definition of the term "dwelling-house" there contained, apply to the above offence; though in all probability it would be held to do so, the above offence being contained in the one (see 7 & 8 Geo. IV. c. 29, s. 12) to which that definition was intended to apply.

† See below, the punishment for solemnizing marriages contrary to the provisions of 6 & 7 Wm. IV. c. 85.

4. Without authority, making or being possessed of instruments for making, &c. paper used by any other bank than the Bank of England. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 17 and 26.)

5. Without authority, engraving, making or being possessed of instruments for making, &c. the notes, &c. of any other bank than the Bank of England. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 18 and 26.)

6. Without authority, making or being possessed of instruments for making, &c. foreign bills, notes, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 19 and 26.)

XXII. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or imprisonment not exceeding three years nor less than one year.

1. Subscribing or publishing, &c. false petitions to the Inspector of seamen's wills in order to obtain a cheque or certificate in lieu of probate or letters of administration, in cases where deceased's assets do not exceed 32*l.* and 20*l.* respectively. (2 Wm. IV. c. 40, s. 33.)

XXIII. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or imprisonment not exceeding three years, with or without hard labour or solitary confinement, or with both; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment.

1. Stealing by clerks or servants. (7 & 8 Geo. IV. c. 29, ss. 4 and 46.)

2. Embezzlement by clerks or servants. (7 & 8 Geo. IV. c. 29, ss. 4 and 47.)

3. Receiving property, the stealing or taking whereof is felony, knowing the same to have been stolen, &c. (7 & 8 Geo. IV. c. 29, ss. 4 and 54.)

4. Boatmen and others concealing, &c. and not reporting according to law, or obliterating the marks, &c. on, anchors or other articles found by them on the coast, &c. (provided the stealing of such articles on shore would amount to felony). (1 & 2 Geo. IV. c. 75, s. 1; and c. 76.)

XXIV. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or imprisonment not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Impairing or lightening the queen's current gold or silver coin, with intent to make the same, when so impaired, &c., pass for the queen's current gold or silver coin. (2 Wm. IV. c. 34, ss. 5 and 19.)

2. Stealing post letter-bags from Post-office packets, or unlawfully taking letters out of or opening such bags. (7 Wm. IV. & 1 Vict. c. 36, ss. 29, 41 and 42.)

XXV. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or imprisonment not exceeding three years, with or without hard labour.

1. Embezzlement by public officers. (2 Wm. IV. c. 4, s. 1.)

2. Forgery, &c. of assay marks on gold or silver wares; or fraudulently using genuine dies provided for marking such wares. (7 & 8 Vict. c. 22, s. 2.)

XXVI. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or imprisonment not exceeding two years, with or without hard labour or solitary confinement, or with both.

1. Officer of the court certifying as true, &c. any false copy of a previous conviction, &c. of any offence relating to the coin, where a person shall be subsequently indicted for any such offence. (2 Wm. IV. c. 34, ss. 9 and 19.)

XXVII. *Transportation* for any term not exceeding *fourteen* years, or confinement not exceeding five nor less than three years, with hard labour.

1. Trading in slaves either directly or indirectly, or entering into contracts in connexion therewith; or forging certificates of valuation, sentences or decrees of condemnation or restitution, &c. (5 Geo. IV. c. 113, s. 10; 3 & 4 Wm. IV. c. 73.*)

XXVIII. *Transportation* for the term of *fourteen* years, or, in mitigation or commutation of such punishment, the offender to be publicly whipped, fined or imprisoned, or all or any one or more of them.

1. Obliterating, &c. the marks denoting her Majesty's property in any warlike or naval, ordnance or victualling, or other public stores, for the purpose of concealing her Majesty's property in such stores. (9 & 10 Wm. III. c. 41: 39 & 40 Geo. III. c. 89, ss. 4 and 7; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138.)

* See also 3 & 4 Vict. c. 111.

XXIX. *Transportation* for *seven* years.

1. Obstructing the execution of process, &c. within the hamlet of Wapping, Stepney, or any other place within the limits of the weekly bills of mortality, wherein persons shall unlawfully assemble and associate for the sheltering themselves from their debtors, of which complaint shall have been made by a presentment of the grand jury at a general or quarter sessions of the proper county. (11 Geo. I. c. 22, ss. 1 and 2.)

2. Aiding the escape from officers of justice of prisoners in their custody for the purpose of being carried to gaol by virtue of a warrant of commitment for treason or felony, or the escape of felons on their way for transportation. (16 Geo. II. c. 31, s. 3.*)

3. Riotously assembling, to the number of five or more, to rescue offenders against the Acts relating to spirituous liquors; or assaulting persons who have given, &c. evidence, &c. against such offenders, &c. (24 Geo. II. c. 40, s. 28.)

4. Prisoners for debt not delivering in under the Lords' Act a true account of all their estate and effects, &c.† (32 Geo. II. c. 28, s. 17; 33 Geo. III. c. 5; 39 Geo. III. c. 50.)

5. Damaging, &c. buoys, &c. fixed to the anchors or moorings of vessels in the Thames, with intent to steal the same. (2 Geo. III. c. 28, s. 13)

6. Being convicted a second time‡ of unlawfully stopping or attempting to stop, or of otherwise preventing the conveyance of grain to or from any city, market-town or place in the kingdom. (11 Geo. II. c. 22; 36 Geo. III. c. 9, ss. 2 and 6.)

7. With intent to prevent the removal of grain, pulling down or otherwise destroying granaries, &c. (36 Geo. III. c. 9, s. 2.)

8. Forgery of the declarations of the return of premiums on policies or contracts of insurance. (54 Geo. III. c. 133, s. 10; 54 Geo. III. c. 144, s. 11.)

9. Forcibly rescuing offenders or goods seized under 6 Geo. IV. c. 80 (for repealing the duties on spirits distilled in England, &c.), or otherwise forcibly opposing the execution of the powers of that Act. (6 Geo. IV. c. 80, s. 143.)

10. Being found in company with more than four persons with smuggled goods, or in company with only one person within five miles of the coast, &c. with such goods, and armed or disguised. (8 & 9 Vict. c. 87, s. 65.)

11. Forgery of the superscription of a post letter with intent to avoid the payment of postage.§ (7 Wm. IV. and 1 Vict. c. 36, s. 34.)

XXX. *Transportation* for any term not exceeding *seven* years.

1. Forgery of the seal, &c. of the British Society for extending the Fisheries and improving the Sea Coasts of the Kingdom. (26 Geo. III. c. 103, s. 26.)

2. Administering oaths intended to bind the person taking the same to engage in any seditious purpose, &c., or to be of any association or confederacy formed for any such purpose, &c. (37 Geo III. c. 123, s. 1.)

3. Counterfeiting foreign gold or silver coin, not permitted to be current within the realm. (37 Geo. III. c. 126, s. 2.)

4. Bringing any such coin into the realm with intent to utter the same. (37 Geo. III. c. 126, s. 3.)

5. Boatmen, &c. conveying anchors, &c. which they know to have been swept for or otherwise taken possession of without being reported according to law, to any foreign port, &c., and there disposing of the same. (1 & 2 Geo. IV. c. 75, s. 15.)

XXXI. *Transportation* for *seven* years, or imprisonment for any period not less than two years.

1. Without lawful excuse, making or being possessed of any instrument for making the paper used for permits by the Commissioners of Excise, or being possessed of any such paper, or engraving, &c. any plate, &c. for making or printing the paper used for permits, &c. (2 Wm. IV. c. 16, s. 3.)

2. Without lawful excuse, making or being possessed of instruments for making the paper to be used for postage covers, or being possessed of any such paper, or by any means imitating or causing to appear in any paper the marks or threads, &c. to be used in postage covers. (3 & 4 Vict. c. 96, s. 29.)

XXXII. *Transportation* for *seven* years, or imprisonment not exceeding four years.

1. Forgery of certificates or bills of exchange mentioned in 2 & 3 Wm. IV. c. 106 (An Act for enabling Officers, &c. in the Army to draw for their Half-pay and Allowances). (2 & 3 Wm. IV. c. 106, s. 3.)

XXXIII. *Transportation* for *seven* years, or imprisonment for any term not exceeding three years nor less than one year, with hard labour.

1. Forgery of the seals, stamps or signatures of such certificates, official or public documents, proceedings of corporations, or joint stock or other companies, or certified copies of such documents or proceedings, as are receivable in evidence in Parliament or in any judicial proceeding, or tendering in evidence such certificates, &c. with false or counterfeit seals &c. thereto; or

2. Forgery of the signature of any equity or common law judge of the Superior Courts at Westminster, to any judicial or official document, or tendering in evidence any such document with a false, &c. signature of any such judge thereto; or

3. Printing copies of private acts or of the journals of either House of Parliament, which copies shall falsely purport to have been printed by the printers to the Crown or either House of Parliament, or tendering in evidence any such copy, knowing that the same was not printed by the persons by whom it so purports to have been printed. (8 & 9 Vict. c. 113, s. 4.)

XXXIV. *Transportation* for *seven* years, or imprisonment for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Persons employed under the Post-Office stealing, embezzling, secreting or destroying post-letters. (7 Wm. IV. & 1 Vict. c. 36, ss. 26 and 42.)

XXXV. *Transportation* for *seven* years, or imprisonment for any term not exceeding two years nor less than one year, with or without hard labour or solitary confinement, or with both.

1. Forgery of the name or handwriting of witnesses attesting the execution of powers of attorney to transfer any public stock transferable at the Bank or South Sea House, or any capital stock of any body corporate, &c. established by charter or act of parliament, or to receive any dividend in respect thereof (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 8 and 26); or of copies of registers of baptisms, marriages,* or burials, directed by law to be transmitted to the registrar of the diocese; or making false entries in such copies, &c. (11 Geo. IV. & 1 Wm. IV. c. 66, ss. 22 and 26.)

2. Clerks, &c. of the Bank or South Sea House, with intent to defraud any person, making out dividend warrants for a greater or less amount than the persons on whose behalf they are made out are entitled to. (11 Geo. & Wm. IV. c. 66, ss. 9 and 26.)

XXXVI. *Transportation* for *seven* years, or imprisonment for any term not exceeding two years, with or without hard labour or solitary confinement, or with both; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment.

1. Forgery of the stamps or seals on hides or skins (9 Anne, c. 11; 10 Anne, c. 99; 5 Geo. I. c. 2, s. 9; 52 Geo. III. c. 143, s. 1; 7 & 8 Geo. IV. c. 28, ss. 8 and 9); of the stamps or seals used for stamping or sealing cambrics or lawns, in pursuance of 4 Geo. III. c. 37, An Act for the better establishing a manufactory of Cambrics and Lawns at Winchelsea, in the County of Sussex, &c. (4 Geo. III. c. 37, s. 26; 52 Geo. III. c. 143, s. 1; 7 & 8 Geo. IV. c. 28, ss. 8 and 9); of the stamps or seals on silk (13 Geo. III. c. 56, s. 5; 52 Geo. III. c. 143, s. 1; 7 & 8 Geo. IV. c. 28, ss. 8 and 9; 1 Wm. IV. c. 17, s. 1); of the name or handwriting of the registrar of the Court of Admiralty or High Court of Appeals of Prizes, &c., to any instrument relating to the money or effects of the suitors of those courts (53 Geo. III. c. 151, s. 12; 7 & 8

* See also 1 & 2 Geo. IV. c. 88, s. 1, which, under certain circumstances, inflicts transportation for seven years, or imprisonment not exceeding three years nor less than one year, upon persons rescuing or aiding in rescuing prisoners apprehended for felony, whilst in the personal custody of a constable or other person. The statute regards the offender in such case as an accessory after the fact, and therefore guilty of felony.

† This offence appears to be incidentally repealed by 1 & 2 Vict. c. 110, s. 119, which enacts that after the passing of that act, no prisoner for debt shall petition any court for his discharge under the provisions of 32 Geo. II. c. 28, nor shall any creditor of any prisoner petition any court for the exercise of the compulsory power given against debtors under the provisions of that act.

‡ The first offence is punishable, on summary conviction, with imprisonment and hard labour for any term not exceeding three months nor less than one month.

§ There are still some cases to which this enactment is applicable

* As regards copies of registers of marriages, it would appear that this offence can now, since the passing of 6 & 7 Wm. IV. c. 86 (for registering births, deaths, and marriages, in England), be committed with respect to such copies only as were transmitted before that Act came into operation. It is still in full force however, as regards registers of baptisms or burials. (See the 49th sect. of 6 & 7 Wm. IV. c. 86.)

Geo. IV. c. 28, ss. 8 and 9); of quarantine certificates (6 Geo. IV. c. 78, s. 25; 7 & 8 Geo. IV. c. 28, ss. 8 and 9); of the name or handwriting of her Majesty's Commissioners of Woods, Forests, Land Revenues, Works and Buildings, to any draft, &c. for any money in the Bank, &c. on account of such commissioners, &c. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 10 Geo. IV. c. 50, s. 124; 2 & 3 Wm. IV. c. 1, s. 1); or of the process of inferior courts for the recovery of debts and damages in personal actions (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 7 & 8 Vict. c. 19, s. 5 in part).

2. Obstructing the execution of process, &c. within Suffolk Place or the Mint, in the parish of St. George, in the county of Surrey. (9 Geo. I. c. 28, ss. 1 and 2; 7 & 8 Geo. IV. c. 28, ss. 8 and 9.)

3. Persons having preserved merchandise &c. belonging to vessels wrecked &c. within the jurisdiction of the Cinque Ports, selling or otherwise making away with the same, or in any manner altering the same with intent to prevent the discovery or identity thereof by the owners. (1 & 2 Geo. IV. c. 76, s. 8; 7 & 8 Geo. IV. c. 28, ss. 8 and 9.)

4. Quarantine officers deserting from their duty or permitting persons &c. to depart from lazarets &c., unless by permission under an order in council, &c.; or giving false certificates of vessels having duly performed quarantine. (6 Geo. IV. c. 78, s. 21; 7 & 8 Geo. IV. c. 28, ss. 8 and 9.)

5. Solemnizing marriages (except in the case of Quakers or Jews, or by special licence) in any other place than a church, chapel or registered office, or doing so in any such office in the absence of the registrar of the district, &c. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 6 & 7 Wm. IV. c. 85, s. 39.)

6. Superintendent registrars issuing certificates for marriage, or registering marriages, contrary to law; or registrars or superintendent registrars issuing licences for marriage, or solemnizing marriages, contrary to law. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 6 & 7 Wm. IV. c. 85, s. 40; 7 Wm. IV. & 1 Vict. c. 22, s. 3.)

7. Destroying, counterfeiting or inserting false entries in, the register-books directed to be provided by the act for registering births, deaths, and marriages in England; or forging the seal of the register-office. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 6 & 7 Wm. IV. c. 86, s. 43.)

8. Officer of the court uttering false certificates of indictments and convictions of a previous felony; or any other person signing &c., such certificates as such officer, &c. (7 & 8 Geo. IV. c. 28, ss. 9 and 11.)

9. Simple larceny. (7 & 8 Geo. IV. c. 29, ss. 3 and 4.)

10. Deer-stealing, &c., where the deer are kept in enclosed lands. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 26.)

11. Deer-stealing, &c. where the deer are kept in unenclosed lands (for a second offence*); or offending a second time in committing any other offence relating to deer for which a pecuniary penalty only is imposed, whether such second offence be of the same description as the first or not. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 26.)

12. Deer-stealers, &c. beating or wounding deer-keepers. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 29.)

13. Stealing oysters &c. from oyster-beds &c. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 36.)

14. Stealing or severing with intent to steal, ore, coal &c. from mines &c. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 37.)

15. Stealing or damaging with intent to steal, or maliciously destroying &c. trees, &c. growing in parks &c. or grounds belonging to dwelling-houses, if the value of the article stolen or the amount of injury done exceeds 1*l*., or growing elsewhere, if such value or amount exceeds 5*l*. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 38; and c. 30, ss. 19 and 27.)

16. Stealing, or damaging with intent to steal, or maliciously destroying &c. trees &c., wherever growing, if the stealing thereof, or the injury done is to the amount of a shilling at the least, and if the offender has been twice previously convicted.† (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 39; and c. 30, ss. 20 and 27.)

17. Stealing, or damaging with intent to steal, or maliciously destroying &c. plants, vegetable productions &c. growing in gardens, conservatories &c., if the offender has been previously convicted of any of such offences.* (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 42; and c. 30. ss. 21 and 27.)

18. Stealing, or breaking &c. with intent to steal, glass, fixtures &c. from buildings, or metal fences &c., belonging to dwelling-houses or fixed in any place dedicated to public use or ornament. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 44.)

19. Tenants or lodgers stealing chattels or fixtures let to be used with any house or lodging. (7 & 8 Geo. IV. c. 29, ss. 3, 4, and 45.)

20. Destroying &c. threshing-machines, or engines used in any other manufacture than those of silk, woollen, linen, or cotton goods, or of framework-knitted pieces, stockings, hose or lace. (7 & 8 Geo. IV. c. 30, ss. 4 and 27.)

21. Drowning mines, or obstructing airways, shafts &c. belonging to mines, with intent to damage or delay the working of them. (7 & 8 Geo. IV. c. 30, ss. 6 and 27.)

22. Destroying or damaging engines for working mines, or any buildings or erections used in conducting the business of mines. (7 & 8 Geo. IV. c. 30, ss. 7 and 27.)

23. Damaging vessels otherwise than by fire, with intent to render them useless. (7 & 8 Geo. IV. c. 30, ss. 10 and 27.)

24. Damaging sea-banks or the banks of rivers, canals or marshes, or injuring navigable rivers or canals, with intent and so as thereby to obstruct the navigation thereof. (7 & 8 Geo. IV. c. 30, ss. 12 and 27.)

25. Maliciously setting fire to crops of grain or pulse, plantations of trees, heath, fern, &c. (7 & 8 Geo. IV. c. 30, ss. 17 and 27.)

26. Offenders ordered to be confined in Parkhurst prison escaping or breaking prison, &c., after they have been already punished† for escaping therefrom, &c., or whilst in the custody of the person under whose charge they are confined. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 1 & 2 Vict. c. 82, s. 12.)

27. Rescuing offenders ordered to be confined in Parkhurst prison during their conveyance there or whilst in the custody of the person under whose charge they are confined. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 1 & 2 Vict. c. 82, s. 13.)

28. Persons having the custody of such offenders, allowing them to escape. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 1 & 2 Vict. c. 82, s. 13.)

29. Aiding in the escape of such offenders, or attempting to rescue them, although no rescue be made. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 1 & 2 Vict. c. 82, s. 13.)

30. Destroying, counterfeiting or making false entries in non-parochial registers of births, deaths, marriages, &c. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 3 & 4 Vict. c. 92, s. 8.)

31. Convicts confined in the Pentonville and Millbank prisons, being a second time‡ convicted of breaking prison or escaping during their conveyance to such prisons. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 5 & 6 Vict. c. 29, s. 24 in part; 6 & 7 Vict. c. 26, s. 22 in part.)

32. Rescuing or aiding in rescuing convicts during their conveyance to the Pentonville and Millbank prisons or during their imprisonment therein. (7 & 8 Geo. IV. c. 28, ss. 8 and 9; 5 & 6 Vict. c. 29, s. 25 in part; 6 & 7 Vict. c. 26, s. 23, in part.)

33. Persons having the custody of convicts in the Pentonville and Millbank prisons wilfully allowing them to escape: or any person aiding such convicts to escape, although no escape be made, or attempting to rescue such convicts, or aiding in any such attempt, though no rescue be made. (7 & 8 Geo. IV. c. 28, ss, 8 and 9; 5 & 6 Vict. c. 29, s. 25 in part; 6 & 7 Vict. c. 26, s. 23 in part.)

34. Acting as a bailiff of any inferior court for the recovery

* The first offence is punishable on summary conviction only, by fine not exceeding 50*l*. (See 7 & 8 Geo. IV. c. 29, s. 26.)

† The first two offences are punishable on summary conviction only; the first by fine not exceeding 5*l*. over and above the value of the trees, &c., or amount of injury done, and the second by imprisonment and hard labour not exceeding twelve calendar months. (See 7 & 8 Geo. IV. c. 29, s. 39; and c. 30, s. 20.)

* The first offence is punishable on summary conviction only, by imprisonment not exceeding six calendar months, with or without hard labour, or by fine not exceeding 20*l*. over and above the value of the plants &c., or the injury done. (See 7 & 8 Geo. IV. c. 29, s. 42; and c. 30, s. 2..)

† That is to say, by an addition, not exceeding two years, to the term of imprisonment for which they were subject to be confined at the time of their escape &c.; or if under sentence of transportation, in such manner as such persons escaping &c. are liable to be punished. (See sect. 12.) By the same section attempts to break prison or escape from Parkhurst prison are made punishable with imprisonment not exceeding twelve calendar months in addition to the punishment to which the offender was subject at the time of any such attempt.

‡ The punishment for a first escape or breach of prison is by an addition, not exceeding three years, to the term of their imprisonment. (5 & 6 Vict. c. 29, s. 24 in part; 6 & 7 Vict. c. 26, s. 22 in part.) By the same sections of those Acts attempts to break out of the Pentonville and Millbank prisons, or to escape therefrom, are punishable by an addition, not exceeding twelve calendar months, to the terms of the offenders' imprisonment. Also by sect. 21 of 5 & 6 Vict. c. 29, and sect. 19 of 6 & 7 Vict. c. 26, convicts in the Pentonville and Millbank prisons assaulting the governors or any of the officers or servants employed therein, are liable upon conviction to be imprisoned for any term not exceeding two years in addition to the term for which at the time of committing that offence they were subject to be confined, and, if males, may be ordered corporal punishment.

of debts or damages in personal actions, without lawful authority. (7 & 8 Geo. IV. c 28, ss. 8 and 9; 7 & 8 Vict. c. 19, s. 5 in part.)

35. Workmen in mines in Cornwall removing or concealing ore with intent to defraud the proprietors of such mines. (2 & 3 Vict. c. 58, s. 10.)

XXXVII. *Transportation* for *seven* years, or imprisonment for any term not exceeding two years, with or without hard labour; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment.

1. Child-stealing. (9 Geo. IV. c. 31, s. 21.)

XXXVIII. *Transportation* for *seven* years, or imprisonment for any term not exceeding two years, with or without hard labour.

1. Bigamy. (9 Geo. IV. c. 31, s. 22.)

XXXIX. *Transportation* for any term not exceeding *seven* years, or imprisonment for any number of years.

1. Cutting away or in any way injuring or concealing buoys, &c. belonging to vessels or attached to the anchors or cables of vessels, whether in distress or otherwise.* (1 & 2 Geo. IV. c. 75, s. 11.)

XL. *Transportation* for any term not exceeding *seven* years, or imprisonment not exceeding two years, with or without hard labour or solitary confinement, or with both.

1. Counterfeiting the queen's current copper coin; or, without lawful authority, making or being possessed of instruments for counterfeiting such coin; or buying or selling such coin at a lower value than it by its denomination imports. (2 Wm. IV. c. 34, ss. 12 and 19.)

XLI. *Transportation* for any term not exceeding *seven* years, or fine, imprisonment, and such corporal punishment by public or private whipping, as the court shall direct.

1. Slaughtering or flaying horses or other cattle without taking out the licence and giving the notice required by the Act for regulating slaughtering-houses, or doing so at any other time than within the hours limited by the Act, or not delaying to do so, when prohibited by the inspector. (26 Geo. III. c. 71, s. 8.)

IV. Misdemeanors.

Misdemeanors are punishable as follows, viz.: with

I. *Transportation* for *life*.

1. Being at large within the United Kingdom [after being sentenced to be banished under the provisions of the Roman Catholic Relief Act (10 Geo. IV. c. 7),] without some lawful excuse, after three calendar months from such sentence. (10 Geo. IV. c. 7, s. 36.)

II. *Banishment* for *life*.

1. Jesuits or members of Religious Orders or Societies of the Church of Rome, bound by monastic or religious vows, coming into the kingdom. (10 Geo. IV. c. 7, s. 29);† or

2. Having obtained the Secretary of State's licence to come, not departing within twenty days after the expiration of the time mentioned in such licence, &c. (10 Geo. IV. c. 7, s. 31.)

3. Within any part of the kingdom, becoming a Jesuit or member of any Society of the Church of Rome bound by monastic or religious vows. (10 Geo. IV. c. 7, s. 34.)

III. *Transportation* for the term of *fourteen* years, or, in mitigation or commutation of such punishment, the offender to be publicly whipped, fined or imprisoned, or all or any one or more of them.

1. Not being a contractor with the Commissioners of the Navy, Ordnance or Victualling Office for her Majesty's use, selling, receiving or being possessed of any warlike or naval, ordnance, victualling or other public stores, without being able to produce a certificate from the Commissioners of the Navy &c., expressing the occasion &c. of such stores being so in possession.‡ (9 & 10 Wm. III. c. 41; 9 Geo. I. c. 8, s. 3; 39 & 40 Geo. III. c. 89, ss. 1 and 7; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.)

2. Being a second time convicted (not being a contractor with the Commissioners of the Navy &c.) of being possessed of &c. certain of her Majesty's or other public stores, the being possessed &c. of which would not otherwise, as the first offence, subject a person to transportation. (9 & 10 Wm. III. c. 41; 39 & 40 Geo. III. c. 89, ss. 5 and 7; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.)

IV. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or fine or imprisonment, or both, such imprisonment to be with or without hard labour or solitary confinement, or with both.

1. Bankers, merchants &c. converting to their own use money or securities intrusted to them to be applied for a specified purpose. (7 & 8 Geo. IV. c. 29, ss. 4 and 49.)

2. Bankers, merchants &c. converting to their own use chattels, securities &c. intrusted to them for a special purpose, but without authority to sell or negotiate &c. the same. (7 & 8 Geo. IV. c. 29, ss. 4 and 49.)

3. Factors or agents pledging goods or merchandise intrusted to them for sale, as a security for money &c. borrowed &c. by them. (7 & 8 Geo. IV. c. 29, ss. 4 and 51.)

V. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or fine or imprisonment, or both.

1. Agents intrusted with goods making consignments &c. thereof, without the authority of their principals. (5 & 6 Vict. c. 39, s. 6.)

VI. *Transportation* for any term not exceeding *fourteen* nor less than seven years, or imprisonment with hard labour for any term not exceeding three years.

1. Being in any land, by night, to the number of three or more (any of them being armed), for the purpose of taking or destroying game* or rabbits. (9 Geo. IV. c. 69, s. 9.)

VII. *Transportation* for *seven* years.

1. Counterfeiting foreign copper or other coin of a less value than silver coin, not permitted to be current in this kingdom (for the second offence).† (43 Geo. III. c. 139, s. 3.)

VIII. *Transportation* for *seven* years, or fine or imprisonment, or both, such imprisonment to be with or without hard labour or solitary confinement, or with both.

1. Stealing, obliterating or destroying records or original documents belonging to Courts of Record, &c. (7 & 8 Geo. IV. c. 29, ss. 4 and 21.)

2. Stealing, destroying or concealing wills or other testamentary instruments, either during the life of the testator or after his death. (7 & 8 Geo. IV. c. 29, ss. 4 and 22.)

3. Stealing title-deeds. (7 & 8 Geo. IV. c. 29, ss. 4 and 23.)

4. Obtaining property by false pretences.‡ (7 & 8 Geo. IV. c. 29, ss. 4 and 53.)

IX. *Transportation* for *seven* years, or fine and imprisonment.

1. Forgery of permits, or knowingly accepting or receiving forged permits. (2 Wm. IV. c. 16, s. 4.)

X. *Transportation* for *seven* years, or the like punishment as for a misdemeanor at common law.§

1. Purchasing or receiving anchors &c. which have been swept for or otherwise taken possession of, whether the same have belonged to vessels in distress or otherwise, if such anchors &c. have not been reported &c. according to law. (1 & 2 Geo. IV. c. 75, s. 12; and c. 76, s. 10.)

XI. *Transportation* for *seven* years, or imprisonment with or without hard labour.

1. Assaulting officers on account of the exercise of their duty in the preservation of vessels in distress, &c. (9 Geo. IV. c. 31, s. 24.)

XII. *Fine of* 40*l*., or if the offender have not goods or chattels, lands or tenements to the value of 40*l*., then imprisonment by the space of one half-year;‖ and, besides the before-mentioned punishment, the offender may be imprisoned

* The 1 & 2 Geo. IV. c. 76, s. 6, contains a similar provision as regards buoys &c. within the jurisdiction of the Cinque Ports, but subjects the offender to transportation not exceeding fourteen years.

† This and the next two offences do not apply to members of Female Societies. (10 Geo. IV. c. 7, s. 37.)

‡ The mode in which the 39 & 40 Geo. III. c. 89, s. 1, imposes the above penalties in respect of these offences, is by enacting that persons who commit them shall be deemed *receivers of stolen goods*, knowing them to have been stolen, and shall, on being convicted thereof in due form of law, be transported beyond the seas, for the term of fourteen years, *in manner as other receivers of stolen goods are directed to be transported by the laws and statutes of this realm*; and then by sec. 7 empowers the court to mitigate or commute the punishment as above mentioned: the punishment of receivers has, however, been since altered by the 7 & 8 Geo. IV. c 29, ss. 54 and 55. It therefore becomes a question how far such alteration has modified the above punishment

* For the purposes of 9 Geo. IV. c. 69, the word "game" includes hares, pheasants, partridges, grouse, heath or moor game, black game, and bustards. (See sec. 13.)

† The punishment for a first offence is imprisonment not exceeding one year.

‡ See the 8 & 9 Vict. c. 109, s. 17, which declares that persons winning money, &c. by cheating at cards or other games, shall be guilty of obtaining such money, &c. by false pretences, and shall be punished accordingly.

§ The punishment for a misdemeanor at common law is fine and imprisonment.

‖ It is only when the offender is prosecuted under 5 Eliz. c. 9, that he is liable to this portion of these penalties. If prosecuted at common law he is punishable with fine and imprisonment; but may be sentenced to the other penalties stated above. The common law offence extends also to subornation of perjury in *any* judicial proceeding.

with hard labour for a term not exceeding seven years, or *transported* for a term not exceeding *seven* years; and, in addition to or in lieu of the before-mentioned punishments, may be imprisoned with hard labour for any term not exceeding the term for which he may be imprisoned as aforesaid; and the offender on conviction cannot thenceforth be received as a witness in any court of record, unless the judgment given against him be reversed.

1. Subornation of perjury in any of the Queen's Courts of Chancery or Courts of Record, or in any Leet, View of Frank-pledge, or Law-day, Ancient Demesne Court, Hundred Court, Court Baron, or in the Court or Courts of the Stannary in the counties of Devon and Cornwall; or suborning witnesses sworn to testify *in perpetuam rei memoriam*.* (5 Eliz. c. 9, ss. 3, 4, and 5; 29 Eliz. c. 5; 21 Jac. I. c. 28, s. 8; 2 Geo. II. c. 25, s. 2; 3 Geo. IV. c. 114; 7 Wm. IV. & 1 Vict. c. 23.)

XIII. *Fine of* 20*l.* and imprisonment for six months; † and besides the before-mentioned punishment the offender may be imprisoned with hard labour for a term not exceeding seven years, or *transported* for a term not exceeding *seven* years; and, in addition to or in lieu of the before-mentioned punishments, may be imprisoned with hard labour for any term not exceeding the term for which he may be imprisoned as aforesaid; and the offender on conviction cannot thenceforth be received as a witness in any Court of Record, unless the judgment given against him be reversed.

1. Perjury in any of the Courts mentioned above in the case of subornation of perjury, or by any person examined *ad perpetuam rei memoriam.* (5 Eliz. c. 9, ss. 6 and 7; 29 Eliz. c. 5; 21 Jac. I. c. 28, s. 8; 2 Geo. II. c. 25, s. 2; 3 Geo. IV. c. 114; 7 Wm. IV. & 1 Vict. c. 23.‡)

2. Seamen or marines attempting to obtain their pay by means of forged certificates of their discharge from the queen's ships, or from hospitals or sick-quarters. (11 Geo. IV. & 1 Wm. IV. c. 20, s. 89; 7 Wm. IV. & 1 Vict. c. 23.§)

3. Forgery of certificates of the Commissioners for executing the office of Lord High Admiral, of the purchase or sale of any naval or victualling stores. (2 Wm. IV. c. 40, s. 32; 7 Wm. IV. & 1 Vict. c. 23.)

4. Making false declarations or signing false notices for the purpose of procuring marriages; or

5. Forbidding the issue of any superintendent registrar's certificate, by falsely representing oneself to be a person whose consent to such marriage is required by law. (6 & 7 Wm. IV. c. 85, s. 38; 7 Wm. IV. & 1 Vict. c. 23; 3 & 4 Vict. c. 72, s. 4.)

6. Making false statements for the purpose of their being inserted in registers of births, deaths, or marriages. (6 & 7 Wm. IV. c. 86, s. 41; 7 Wm. IV. & 1 Vict. c. 23.)

XIV. *Transportation* for *seven* years, or imprisonment with hard labour for any term not exceeding three years.

1. Assaulting or obstructing persons duly employed for the prevention of smuggling. (8 & 9 Vict. c. 87, s. 66.)

XV. *Transportation* for *seven* years, or imprisonment with or without hard labour for any period not exceeding three years; and during such imprisonment the offender may be publicly or privately whipped ‖ as often and in such manner and form as the Court shall direct, not exceeding thrice.

1. Discharging or aiming fire or other arms, or discharging or attempting to discharge any explosive substance, at or near the person of the queen, or striking or attempting to strike at the person of the queen, or in any other manner throwing or attempting to throw anything at or upon her person, with intent to injure or alarm the queen or break the public peace, or whereby the public peace may be endangered; or having fire or other arms, or any explosive or dangerous matter or thing near the queen's person, with intent to use the same to injure or alarm her. (5 & 6 Vict. c. 51, s. 2.)

XVI. *Transportation* for *seven* years, or imprisonment for any term not exceeding two years, with or without hard labour or solitary confinement, or with both; and the offender, if a male, may be once, twice, or thrice publicly or privately whipped, in addition to such imprisonment.

1. Receiving property the stealing, taking, &c. whereof is made an indictable misdemeanor by 7 & 8 Geo. IV. c. 29, knowing the same to have been unlawfully stolen, taken, &c. (7 & 8 Geo. IV. c. 29, ss. 4 and 55.)

2. Boatmen and others concealing &c. and not reporting according to law, or obliterating the marks &c. on, articles found by them on the coast (provided the stealing of such articles on shore would be an indictable misdemeanor). (1 & 2 Geo. IV. c. 75, s. 1; and c. 76.)

3. Maliciously destroying the dams of fish-ponds or mill-ponds, or poisoning fish-ponds. (7 & 8 Geo. IV. c. 30, ss. 15 and 27.)

XVII. *Transportation* for *seven* years, or imprisonment with hard labour for any term not exceeding two years.

1. Taking or destroying game * or rabbits by night, in any land or on any public road, path &c., or at the openings, gates &c. from such land into such public road &c., or entering any such land, by night, with any instrument for that purpose (for the third offence).† (9 Geo. IV. c. 69, s. 1; 7 & 8 Vict. c. 29, s. 1.)

2. Assaults on gamekeepers by persons found committing any of the last-mentioned offences. (9 Geo. IV. c. 69, s. 2; 7 & 8 Vict. c. 29, s. 1.)

XVIII. *Transportation* for any term not exceeding *seven* years, or imprisonment not exceeding two years.

1. Being guilty of an unlawful combination or confederacy. (37 Geo. III. c. 123, s. 1; 39 Geo. III. c. 79, ss. 2 and 8; 52 Geo. III. c. 104, s. 1; 57 Geo. III. c. 19, s. 25.)

2. Being present at meetings for the purpose of drilling persons to the use of arms &c., such meetings being unauthorized by her Majesty or the lieutenant or two justices of the peace of the county or riding, by commission or otherwise; or drilling persons to the use of arms, &c. (60 Geo. III. & 1 Geo. IV. c. 1, s. 1.)

XIX. *Imprisonment* for *life*, loss of the offender's right hand, and forfeiture of his goods and chattels, and of the profits of his lands during life.

1. Assaulting any judge of the queen's courts of law or equity, or any justice of assize, oyer and terminer, or general gaol delivery, whilst acting in his official capacity; or striking any person in the presence of any such judge or justice.‡ (Hawk. *P. C.* b. i. c. 21, s. 3; *Seventh Report of the Criminal Law Commissioners*, pp. 49 and 160.)

XX. *Imprisonment* for *life* and forfeiture of the offender's goods and profits of his lands.

1. Rescuing prisoners being in the presence of any such judge whilst acting in his official capacity. (Hawk. *P. C.* b. i. c. 21, s. 5; *Seventh Report of the Criminal Law Commissioners*, pp. 49 and 160.)

XXI. *Imprisonment for life*, and forfeiture § of all goods and chattels real and personal.

1. Being a second time‖ convicted of publishing fond, fantastical or false prophecies, to the intent thereby to make any rebellion or other disturbance &c. within the queen's dominions.¶ (5 Eliz. c. 15, s. 3.)

XXII. *Imprisonment for life.*

1. Hearing and being present at any other form of common prayer &c. than is mentioned and set forth in the Book of Common Prayer, having been twice** previously convicted of the same. (5 & 6 Edw. VI. c. 1, s. 6; 13 & 14 Car. II. c. 4, s. 24.)

2. Clergymen of the Established Church using any other form of common prayer &c. than is set forth in the Book of Common Prayer, or speaking in derogation thereof, having been twice †† previously convicted of any such offence.‡‡ (1 Eliz. c. 2, s. 6; 13 & 14 Car. II. c. 4, s. 24.)

* See also 12 Geo. I. c. 29, s. 4 (made perpetual by 21 Geo. II. c. 3), as to subornation of perjury and perjury &c. by attorneys &c., for which the court may cause them, after an examination in a *summary way*, to be transported for seven years. The offence does not appear to be indictable.

† It is only when the offender is prosecuted under 5 Eliz. c. 9, that he is liable to this portion of these penalties. The punishment for the common-law offence is the same as for subornation of perjury; and perjury at common law may be in *any* judicial proceeding. Prosecutions are usually carried on for the offence as at common law, and not under the statute.

‡ There is a great number of public acts, besides those mentioned above, by which cases of false swearing are declared to be perjury, or to be punishable as perjury; but it would have occupied too much space to have inserted them here.

§ This and the next four offences subject the persons committing them to the penalties of perjury.

‖ It may be a question whether the 5 & 6 Vict. c. 51, s. 2, notwithstanding the provision of 1 Geo. IV. c. 57, quoted above, in the prefatory statement of provisions of general application, has not extended the punishment of whipping to the case of female offenders. (See *Seventh Report of Criminal Law Commissioners*, p. 46.) The above offence is a high misdemeanor.

* For the definition of game, see p. 173, note *.

† The two first offences are punishable on summary conviction.

‡ This and the next offence are punishable at common law.

§ This forfeiture, being by statute only, does not, as observed above, constitute the offence a felony.

‖ The punishment for the first offence is fine of 10*l.* and imprisonment for one year. (5 Eliz. c. 15, s. 2.)

¶ This offence may be considered to be virtually obsolete.

** The punishment for the first offence is imprisonment for six months, and for the second is one year.

†† The punishment for the first offence is imprisonment for six months, and for the second one year. (1 Eliz. c. 2, ss. 4 and 5.)

‡‡ Besides being imprisoned, the offender for the first offence forfeits the

3. Persons not having any spiritual promotion committing any such last-mentioned offence, after their first conviction.* (1 Eliz. c. 2, s. 8; 13 & 14 Car. II. c. 4, s. 24.)

4. In interludes, plays, &c. declaring or speaking anything in derogation &c. of the Book of Common Prayer, or compelling or causing any person or other minister to use any other form of common prayer &c. than is mentioned in the said book; or interrupting any person or other minister in saying common prayer &c. in the form mentioned in the said book, having been twice† previously convicted of any such offence.‡ (1 Eliz. c. 2, s. 11; 13 & 14 Car. II. c. 4, s. 24.)

XXIII. *Imprisonment* for any term not exceeding *twelve* nor less than six months, and the offender to be liable to such other punishment as may by law be inflicted in cases of high misdemeanors.§

1. Publishing in English newspapers anything tending to excite hatred of the queen, &c., as having been previously printed in some foreign paper which has not been so printed. (38 Geo. III. c. 78, s. 24.)

XXIV. *Fine* and *imprisonment*, with or without hard labour or solitary confinement, or with both.

1. Refusing to deliver up &c. post-letters which ought to have been delivered to any other person, or post-letters which shall have been found by the person so refusing, or any other person, &c. (7 Wm. IV. & 1 Vict. c. 36, ss. 31 and 42.)

XXV. *Fine* and *imprisonment*, and such corporal punishment by public or private whipping as the court shall direct.

1. Persons who keep or use slaughtering-houses or places, throwing into lime-pits, &c., or destroying or burying, the hides of cattle slaughtered, &c. by them; or,

2. Persons, generally, being guilty of any offence against the Act for regulating slaughtering-houses for which no punishment is expressly provided. (26 Geo. III. c. 71, s. 9.)

XXVI. *Fine*, *imprisonment*, or other corporal punishment.

1. Procuring or soliciting infants to grant annuities, &c. (53 Geo. III. c. 141, s. 8.)

XXVII. *Imprisonment* and *fine* and ransom‖ to the queen.

1. Being sufficient to travel, not being assistant to the justices, when warned to ride with them, in aid to resist riots, &c. (2 Hen. V. st. 1, c. 8.)

2. Contemning, despising or reviling the sacrament of the Lord's Supper. (1 Edw. VI. c. 1, s. 1; 1 Eliz. c. 1, s. 14.)

XXVIII. *Imprisonment* and *ransom* at the queen's will.¶

1. Forcible entry into lands and tenements. (5 Rich. II. st. 1, c. 8; 15 Rich. II. c. 2.)**

XXIX. *Imprisonment* and *fine* at the queen's will.††

1. Any of the clergy enacting or promulgating &c., any constitutions or ordinances, provincial or synodal, or any other canons, without the royal assent and licence. (25 Hen. VIII. c. 19, s. 1; 1 Eliz. c. 1, s. 6.)

XXX. *Fine* and *Imprisonment*,

1. Not assisting the justices to arrest persons holding lands &c. forcibly, after forcible entry made. (15 Rich. II. c. 2.)

2. Frauds by collectors or other officers intrusted with the receipt, custody or management of any part of the public revenues‡‡ (50 Geo. III. c. 59, s. 2); — of any part of the revenue of Excise. (7 & 8 Geo. IV. c. 53, s. 44.)

3. Persons concerned in the transmitting or delivery of writs for the election of members of parliament, wilfully neglecting or delaying to transmit or deliver any such writ &c. (53 Geo. III. c. 89, s. 6.)

4. Gaolers exacting fees from prisoners for or on account of the entrance, commitment or discharge of such prisoners, or detaining prisoners for non-payment of fees.* (55 Geo III. c. 50, s. 13.)

5. Furious driving, &c., by persons having charge of stage-coaches or public carriages, not being hackney-coaches drawn by two horses only, and not plying for hire as stage-coaches, whereby any person is injured. (1 Geo. IV. c. 4.)

6. Buying or selling offices, or keeping any place of business in any manner relating to the sale or purchase thereof.† (5 & 6 Edw. VI. c. 16; 40 Geo. III. c. 126, s. 3; 6 Geo. IV. c. 105, s. 10.)

7. Officers exacting fees from prisoners against whom no bill of indictment is found by the grand jury, or who are acquitted on their trial or discharged by proclamation for want of prosecution.‡ (55 Geo. III. c. 50, ss. 4 and 9.)

8. Officers of Customs or Excise by their misconduct causing waste, &c. in merchandise warehoused in warehouses under the Act for permitting goods imported to be secured in warehouses without payment of duty on first entry. (4 Geo. IV. c. 24, s. 72.)

9. By false certificates or representations endeavouring to obtain from Chelsea Hospital any pension, privilege or advantage.§ (7 Geo. IV. c. 16, s. 25.)

10. Setting spring-guns or man-traps, except within a dwelling-house, between sun-set and sun-rise, for the protection thereof. (7 & 8 Geo. IV. c. 18, ss. 1 and 4.)

11. Jesuits, or members of any religious order or society of the Church of Rome, bound by monastic or religious vows, within the United Kingdom, admitting any person to become a member of any such order or society.‖ (10 Geo. IV. c. 7, s. 23.)

12. Parish officers refusing to call meetings, &c. according to the provisions of the Act for the better Regulation of Vestries. (1 & 2 Wm. IV. c. 60, s. 11.)

13. Making false answers to any of the questions directed by the Reform Act to be put by the returning officer at elections of members of parliament, if required by any candidate, to any voter at the time of his tendering his vote. (2 & 3 Wm. IV. c. 45, s. 58.)

14. Refusing to attend, &c. the Poor Law Commissioners (4 & 5 Wm. IV. c. 76, s. 13); the Tithe Commissioners (6 & 7 Wm IV. c 71, s. 93); or the Copyhold Commissioners (4 & 5 Vict. c. 35, s. 94).

15. Forgery, &c. of protections from service in the navy. (5 & 6 Wm. IV. c. 24, s. 3.)

16. Making false declarations in cases where declarations are substituted for oaths by the Act for abolishing unnecessary Oaths. (5 & 6 Wm. IV. c. 62, s. 21.)

17. Executing &c. renewed ecclesiastical leases, knowing the recital required by law contained therein to be false. (6 & 7 Wm. IV. c. 20, s. 3.)

18. Making false statements in declarations required to be delivered to the Commissioners of Stamps and Taxes before being allowed to print and publish newspapers. (6 & 7 Wm. IV. c. 76, s. 6.)

19. Making, &c. false declaration of being qualified to be elected a member of the House of Commons. (1 & 2 Vict. c. 48, s. 7.)

20. Frauds in assignments of pensions for service in her Majesty's navy, royal marines or ordnance. (2 & 3 Vict. c. 51, s. 8.)

21. Making false declarations touching any of the matters contained in the Act for procuring Returns relative to Highways and Turnpikes.* (2 & 3 Vict. c. 40, s. 9.)

22. Officers of railways making false returns, under the

profits of all his spiritual benefices or promotions coming or arising in one whole year next after his conviction; and for his second and third offences, is to be deprived *ipso facto* of all his spiritual promotions. (1 Eliz. c. 2, ss. 4, 5, and 6.)

* The punishment for the first offence is imprisonment for one year. (1 Eliz. c. 2, s. 7.)

† The punishment for the first offence is forfeiture of 100 marks, or, if the offender do not pay the same within six weeks after his conviction, six months' imprisonment instead; and for the second offence is forfeiture of 400 marks, or, if the offender do not pay the same within six weeks after his conviction, twelve months' imprisonment instead. (1 Eliz. c. 2, ss. 9, 10, 12, and 13.)

‡ Besides being imprisoned for life, the person committing any of the above offences for the third time, forfeits all his goods and chattels; but this forfeiture, being by statute only, does not, as above observed, constitute the offence a felony.

§ The punishment for high misdemeanors at common law was fine, imprisonment, and infamous corporal punishment; but the punishment of the pillory has been wholly abolished.

‖ It would appear that where a person is to make fine and ransom, he is not to pay two different sums (Co.-Litt., 127 a); but, according to Dyer, p. 232, pl. 5, the ransom must be treble the fine at least.

¶ That is, the will of the queen as declared by her representatives, the judges, in her courts of justice.

** (See also 4 Hen. IV. c. 8; 8 Hen. VI. c. 9; 31 Eliz. c. 11; 21 Jac. I. c. 15.)

†† That is, as declared by the judges.

‡‡ The offender is also, on conviction, rendered for ever incapable of holding or enjoying any office under the crown.

* They are also, upon conviction, rendered incapable of holding their offices. The 55 Geo. III. c. 50, s. 13, did not extend to the Queen's Bench prison, the Fleet, or the Marshalsea and Palace Courts. But now, by 5 & 6 Vict. c. 22, s. 11, which consolidates the Queen's Bench, Fleet, and Marshalsea Prisons, and enacts that the Queen's Bench Prison shall, after the passing of that act, be called the Queen's Prison, all fees and gratuities payable by prisoners on their entrance or discharge &c. from the Queen's Prison (except such as shall be sanctioned by the Lords of the Treasury, for work and labour actually performed for such prisoners) are abolished, and any officer who exacts any such fees or gratuities, or detains any prisoner on account of the non-payment thereof, is rendered incapable of holding his office, and is guilty of a misdemeanor punishable by fine and imprisonment. See also the 8 & 9 Vict. c. 114, which explains and amends the 55 Geo. III. c. 50.

† The punishment for this and the next twenty-five offences (6 to 31 inclusive), is not assigned them by the statutes creating them: they are merely misdemeanors by the statutes, but as such the common law punishment of fine and imprisonment attaches.

‡ The offender, on conviction, is also rendered incapable of holding his office. See the 8 & 9 Vict. c. 114, which explains and amends the 55 Geo. III. c. 50.

§ The offender also forfeits all claim to pension or emolument on account of service, wounds, or disability.

‖ This offence does not apply to female societies. (10 Geo. IV. c. 7, s. 37.)

Act for regulating railways, to the committee of the Privy Council for Trade. (3 & 4 Vict. c. 97, s. 4.)

23. Making false returns of corn, under the Act regulating the importation of corn. (5 & 6 Vict. c. 14, s. 42.)

24. Making false entries in the Register Book of Copyrights. (5 & 6 Vict. c. 45, s. 12.)

25. Voters making false answers to returning officer at elections of members of parliament. (6 & 7 Vict. c. 18, s. 81.)

26. Actuaries or other persons holding appointments in savings' banks, receiving deposits and not paying the same over to the managers of such banks, &c. (7 & 8 Vict. c. 83, s. 4.)

27. The registrar of joint-stock companies or any person employed under him, demanding or receiving any gratuity or reward beyond the fees allowed by law. (7 & 8 Vict. c. 110, s. 22.)

28. Directors of joint-stock companies by whom certificates of shares are issued, making false statements on such certificates as to the date of the first complete registration of such companies. (7 & 8 Vict. c. 110, s. 26 in part.)

29. Persons knowing dogs or skins of dogs found in their possession, by virtue of a search warrant, to be stolen dogs, or the skins of stolen dogs (for the second offence*). (8 & 9 Vict. c. 47, s. 3 in part.)

30. Corruptly taking any reward for aiding persons to recover stolen &c. dogs. (8 & 9 Vict. c. 47, s. 6.)

31. Offences against the provisions of the 8 & 9 Vict. c. 100 (An Act for the regulation of the care and treatment of Lunatics), and the 8 & 9 Vict. c. 126 (An Act to amend the laws for the provision and regulation of Lunatic Asylums for counties and boroughs, and for the maintenance and care of Pauper Lunatics, in England), declared by those Acts to be misdemeanors.

32. Using contemptuous words or gestures of or against the queen.†

33. Unlawful assemblies.

34. Routs.

35. Riots.

36. Affrays.

37. Conspiracy.

38. Bribery.‡

39. Blasphemy.

40. Blasphemous or seditious libels.§

41. Unlawfully refusing to serve public offices.

42. Executing official duties before taking oath of office and giving security, where the same are required by law.

43. Wilfully disobeying any statute, by doing what it prohibits or omitting what it commands, whereby the public are or may be injured.

44. Wilfully disobeying any lawful warrant, order or command of her Majesty, or any court or person acting in a public capacity and duly authorized in that behalf, where no other penalty or mode of proceeding is expressly provided.

45. Obstructing officers in the execution of any public office or duty.

46. Excess or abuse of authority by public officers.

47. Extortion by public officers.

48. Fraudulent misapplication by public officers of property under their control as such officers.

49. Unlawfully, and contrary to oath of office, disclosing matter the knowledge of which has been acquired in an official capacity.

50. Assaulting &c. persons on account of anything done by them in connexion with any judicial proceeding.

51. Contempts of courts of justice or magistrates, by uttering insulting, opprobrious, or menacing words, or by acts or gestures expressed or done in the face of such courts or in the presence of such magistrates.

52. By force, or by violent or outrageous conduct, interrupting the proceedings of courts of justice.

53. The wilful omission by judicial officers to do their duty.

54. Oppression by judicial officers.

55. Judicial officers taking bribes.

56. Bribing or otherwise corruptly influencing judicial officers.

57. Persons procuring themselves to be returned as jurors, with intent to obtain a verdict or any undue advantage for any person interested in a trial.

58. Unlawfully preventing persons from serving as jurors.

59. Jurors determining their verdict by any mode of chance.

60. Witnesses refusing to be sworn or to give evidence in judicial proceedings.

61. Unlawfully preventing witnesses from giving evidence in judicial proceedings.

62. Endeavouring to procure the commission of perjury.

63. Publishing statements, pending suits or prosecutions, with intent to excite prejudice for or against any party to such suits or prosecutions.

64. Fabricating false evidence.

65. By disposing of dead bodies, without giving notice to the coroner, in cases where inquests ought to be taken, obstructing the taking of such inquests.

66. Gaolers and others, contrary to their duty, allowing dead bodies to remain unburied and to putrefy, without giving notice to the coroner, in cases where inquests ought to be taken.

67. Challenging or provoking to fight, or to commit a breach of the peace.

68. Open indecency in places of public resort or in view thereof.

69. Keeping gaming or other disorderly houses.*

70. Arresting or otherwise obstructing the burial of dead bodies.

71. Unlawfully disinterring dead bodies.

72. Buying or selling wives.

73. Selling unwholesome provisions.

74. Maliciously exposing persons labouring under contagious diseases in places of public resort.

75. Common nuisances.†

76. Corrupting wells or springs used by the public.

77. Innkeepers refusing to receive travellers, their inns not being fully occupied at the time, and a reasonable sum being tendered for accommodation.

78. Battery.

79. False imprisonment.

80. Assaults.

81. Persons maiming themselves, with intent to evade the discharge of any public duty.

82. Cheats.

83. Forgery, in cases where no punishment is provided by statute.

84. Concealing treasure-trove.

XXXI. *Forfeiture*, *fine* not exceeding 200*l.* and costs of suit, and also such further fine, and whipping and imprisonment, or any of them, in such manner and for such space of time as to the court shall seem meet.

1. Being possessed (not being a contractor with the Commissioners of the Navy, Ordnance or Victualling Office for her Majesty's use) of any of her majesty's stores called canvas, or bewper, otherwise called buntin, or of any cordage wrought with one or more worsted threads, or of any other public stores, the same not being charged to be new, or not more than one-third worn. (39 & 40 Geo. III. c. 89, s. 2; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.)

2. Making, being possessed of, or concealing (not being a contractor as last mentioned) any warlike or naval stores, with the marks used to her Majesty's warlike, naval, or ordnance stores, or any other public stores. (9 & 10 Wm. III. c. 41; 9 Geo. I. c. 8; 17 Geo. II. c. 40; 39 & 40 Geo. III. c. 89, s. 2; 54 Geo. III. c. 60; 55 Geo. III. c. 127; 56 Geo. III. c. 138, s. 2.)

XXXII. *Fine* not exceeding 500*l.*, or imprisonment for any term not exceeding two years, or both.

1. Aiding the escape of convicts from New South Wales or Van Diemen's Land. (9 Geo. IV. c. 83, s. 34.)

XXXIII. *Imprisonment*, with or without hard labour, for such term as the court shall award.

* The first offence is punishable on summary conviction before two or more justices by payment of such sum, not exceeding 20*l.*, as to the justices shall seem meet.

† This and the following fifty-two offences (29 to 84 inclusive) are misdemeanors at common law, and as such, punishable with fine and imprisonment. (See the Seventh Report of the Criminal Law Commissioners, and the authorities there cited.)

‡ See 5 & 6 Vict. c. 102, s. 20.

§ These offences, when committed for a second time, were made punishable as high misdemeanors or by banishment, by 60 Geo. III. & 1 Geo. IV. c. 8; but 11 Geo. IV. & 1 Wm. IV. c. 73, repealed the latter portion of the punishment.

* The court may order hard labour for these offences. (3 Geo. IV. c. 114.) See 21 Geo. III. c. 49, s. 1, by which persons keeping places opened or used for public entertainment or amusement, or for public debating on Sundays, and to which persons are admitted by payment of money or tickets sold for money, are made punishable as in cases of disorderly houses, and incur the penalty of 200*l.* for every Sunday that such places are kept opened, recoverable by action of debt, &c.

† See 9 & 10 Wm. III. c. 7, s. 1, which makes the manufacture of squibs or fireworks (except by order of the Board of Ordnance or by the Artillery Company), or the fireing thereof in any public street, &c., a common nuisance.

1. Unlawfully and carnally knowing girls above the age of ten and under the age of twelve years. (9 Geo. IV. c. 31, s. 17.)

XXXIV. *Fine* or *imprisonment*, or both, such imprisonment to be with or without hard labour or solitary confinement, or with both.

1. Unlawfully taking or killing hares or conies, in the night time, in warrens. (7 & 8 Geo. IV. c. 29, ss. 4 and 30.)

2. Unlawfully taking or destroying fish in waters running through or in lands adjoining or belonging to dwelling-houses.* (7 & 8 Geo. IV. c. 29, ss. 4 and 34.)

3. Unlawfully destroying turnpike or toll gates or houses, &c. (7 & 8 Geo. IV. c. 30, ss. 14 and 27.)

4. Officers of the Post-Office opening or detaining post letters† (7 Wm. IV. & 1 Vict. c. 36, ss. 25 and 42); or stealing, embezzling, or destroying printed votes or proceedings in parliament, or newspapers, or other printed papers sent by the post, without covers or in covers open at the sides. (7 Wm. IV. & 1 Vict. c. 36, ss. 32 and 42.)

XXXV. *Fine* or *imprisonment*, or both, such imprisonment to be with or without hard labour.

1. Forgery of hackney-carriage plates (1 & 2 Wm. IV. c. 22, s. 25); of stage-carriage plates (2 & 3 Wm. IV. c. 120, s. 32); or of the licences or tickets of drivers of hackney-carriages, drivers or conductors of stage-carriages, or watermen (1 & 2 Vict. c. 79, s. 12).

2. Frauds in applying for hackney-carriage or stage-carriage licences. (1 & 2 Wm. IV. c. 22, s. 33; 2 & 3 Wm. IV. c. 120, s. 10.)

XXXVI. *Fine* or *imprisonment*, or both.

1. Compounding offences,‡ or otherwise offending against the provisions of the 18 Eliz. c. 5 (An Act to redress disorders in common informers). (18 Eliz. c. 5, s. 4; 27 Eliz. c. 10; 56 Geo. III. c. 138, s. 2.)

2. Resisting the execution of any legal process, execution, or extent, taken out by persons having debts owing to them from persons residing within the Whitefriars, Savoy, Salisbury Court, Ram Alley, Mitre Court, Fuller's Rents, Baldwin's Gardens, Montague Close, or the Minories, Mint, Clink, or Deadman's Place. (8 & 9 Wm. III. c. 27, s. 15; 56 Geo. III. c. 138, s. 2.)

3. Illegal brokerage. (53 Geo. III. c. 141, s. 9.)

4. Persons having the custody of offenders ordered to be confined in Parkhurst Prison, or Pentonville or Millbank Prison, carelessly allowing such offenders to escape. (1 & 2 Vict. c. 82, s. 13; 5 & 6 Vict. c. 29, s. 25 in part; 6 & 7 Vict. c. 26, s. 23 in part.)

5. Offences against tho Foreign Enlistment Act. (59 Geo. III. c. 69, s. 2.)

6. Unlawfully taking unmarried girls under the age of 16 years out of the possession of those who have tho lawful charge of them. (9 Geo. IV. c. 31, s. 20.)

7. Arresting clergymen on civil process while employed about the performance of divine service. (9 Geo. IV. c. 31, s. 23.)

8. Frauds by Excise officers in the granting of permits, or in the performance of their duties in relation to the same.§ (2 Wm. IV. c. 16, s. 15.)

9. Altering, destroying, counterfeiting, or trafficking in the register-tickets with which merchant seamen are required to provide themselves. (7 & 8 Vict. c. 112, s. 21.)

10. Making false answers to questions by the registrar of seamen, &c. with reference to the granting of such tickets. (7 & 8 Vict. c. 112, s. 22.)

11. Masters of merchant ships, without the sanction of the consul, &c., discharging or abandoning abroad persons belonging to their ships or crews, or, in case any such person should desert abroad, neglecting to notify the same in writing to such consul, &c. (7 & 8 Vict. c. 112, s. 46.)

12. Masters, mates, or other officers of merchant ships, wrongfully forcing on shore, or leaving behind on shore or at sea, persons belonging to their ships or crews, before the completion of tho voyage for which such persons were engaged, or the return of their ships to the United Kingdom.* (7 & 8 Vict. c. 112, s. 47.)

13. Masters of merchant ships omitting, when required by the consul, &c., on the complaint of three or more of their crew, to provide proper provisions, water, or medicines, or the requisite quantity thereof, or using any provisions, &c. which the consul, &c. shall have signified to be unfit for use or inappropriate. (7 & 8 Vict. c. 112, s. 57.)

XXXVII. *Imprisonment* for three years, and fine at the queen's pleasure.†

1. Champerty. (3 Edw. I. c. 25; 13 Edw. I. st. 1, c. 49; 28 Edw. I. st. 3, c. 11; 33 Edw. I. st. 2; 33 Edw. I. st. 3; 4 Edw. III. c. 11; 20 Edw. III. c. 4 and c. 5; 7 Rich. II. c. 15; 32 Hen. VIII. c. 9.)

2. Maintenance. (3 Edw. I. c. 28 and c. 33; 33 Edw I. st. 3; 1 Edw. III. st. 2, c. 14; 4 Edw. III. c. 11; 20 Edw. III. c. 4 and c. 5; 1 Rich. II. c. 4 and c. 7; 7 Rich. II. c. c. 15; 32 Hen. VIII. c. 9.)

XXXVIII. *Great forfeiture.*

1. Disturbing any to make free election. (3 Edw. I. c. 5.)

XXXIX. *To be adjudged* incapable and disabled in law to have or enjoy any office or employment, ecclesiastical, civil or military, or any part in them, or any profit or advantage appertaining to them; and if the offender at the time of being convicted enjoy or possess any office, place or employment, the same is made void.

1. Having been educated in or professed Christianity within this realm, asserting that there are more Gods than one, or denying the Christian religion to be true, or the Scriptures to be of Divine authority.‡ (9 & 10 Wm. III. c. 32, s. 1; 55 Geo. III. c. 160, s. 2.)

XL. *Imprisonment* and hard labour for any period not exceeding three years.

1. Insolvent debtors or petitioners for protection from process, omitting in their schedules any property, or retaining or excepting out of such schedules, as necessaries, property of greater value than 20*l.* with intent to defraud their creditors. (1 & 2 Vict. c. 110, ss. 99 and 121; 7 & 8 Vict. c. 96, s. 39.)

XLI. *Imprisonment* for any term not exceeding three years, with or without hard labour or solitary confinement, or with both.

1. Being possessed of three or more pieces of counterfeit coin, intended to pass for the Queen's current gold or silver coin, knowing the same to be counterfeit and with intent to utter the same. (2 Wm. IV. c. 34, ss. 8 in part and 19.)

XLII. *Imprisonment* with hard labour for any term not exceeding three years, either in addition to or in lieu of any other punishment or penalty which may be inflicted upon the offender.

1. Being armed, assaulting Excise officers whilst searching for or seizing commodities forfeited under any Act relating to the Excise or Customs, or whilst endeavouring to arrest offenders. (7 & 8 Geo. IV. c. 53, ss. 40 and 43.)

XLIII. *Imprisonment* for any term not exceeding three years, with or without hard labour.

1. Bankrupts or members of incorporated commercial or trading companies which shall be adjudged bankrupt, falsifying or destroying their books, &c., with intent to defraud their creditors. (5 & 6 Vict. c. 122, s. 34; 7 & 8 Vict. c. 111, s. 30.)

2. Publishing or threatening to publish libels, &c. with intent to extort money, &c. (6 & 7 Vict. c. 96, s. 3.)

XLIV. *Imprisonment* for one year and grievous fine at the queen's pleasure; or if the offender have not whereof, imprisonment for three years.

1. Misprision of felony by sheriffs, coroners, or other bailiffs. (3 Edw. I. c. 9.)

XLV. *Imprisonment* for one year and grievous fine; or if the offender have not whereof, imprisonment for two years.

1. Bailiffs not being ready, on the huo and cry, to arrest felons. (3 Edw. I. c. 9.)

* This offence does not extend to angling in the day-time; but persons doing so unlawfully are liable, on summary conviction, to forfeit any sum not exceeding 5*l.*

† This offence does not extend to (amongst other exceptions contained in the Act) the opening or detaining of letters in obedience to an express warrant in writing under the hand of one of the principal secretaries of state.

‡ Besides the above punishment, the offender, upon conviction, is for ever disabled to pursue or be plaintiff or informer in any suit or information upon any statute, popular or penal, and also forfeits 10*l.*, recoverable by action of debt or information.

§ The offender, on conviction, is also rendered incapable of holding any office or place in or relating to any of the revenues of the United Kingdom.

* See also 9 Geo. IV. c. 31, s. 30, which makes it a misdemeanor, punishable with imprisonment for such term as the court shall award, for masters of merchant ships to force on shore or refuse to bring home all such of the men whom they carried out as are in a condition to return.

† That is, as declared by the judges. This punishment is taken from 33 Edw. I. st. 3 (Statute of Champerty); but see the other Acts referred to. The repeal of the offences of Champerty and Maintenance is recommended by the Criminal Law Commissioners. (See their Fifth Report.)

‡ For a first offence the above penalties may be relieved against by renunciation of such erroneous opinions in the same Court where the offender was convicted, within four months after such conviction. (s. 3.)

If a person be a second time convicted of any of the above offences, he is to be imprisoned for three years, and to be disabled to sue, &c. in any court of law or equity, or to be guardian of any child, or executor or administrator of any person, or capable of any legacy or deed of gift, or to bear any office, civil or military, or benefice ecclesiastical, for ever within the realm. (s. 1.)

XLVI. *Imprisonment* with or without hard labour for any term not exceeding two years, and fine if the court shall think fit; and the offender may be required to find sureties for keeping the peace.

1. Assaults with intent to commit felony, or on any peace or revenue officer, or with intent to resist the lawful apprehension or detainer of any person, or in pursuance of any conspiracy to raise the rate of wages (9 Geo. IV. c. 31, s. 25); or on special constables.* (9 Geo. IV. c. 31, s. 25; 1 & 2 Wm. IV. c. 41, s. 11.)

XLVII. *Fine* and imprisonment not exceeding two years.

1. Being present at meetings unauthorised by her Majesty, &c., for the purpose of being drilled to the use of arms, or, at any such meetings, being so drilled. (60 Geo. III. & 1 Geo. IV. c. 1, s. 1.)

2. Maliciously publishing defamatory libels, knowing them to be false. (6 & 7 Vict. c. 96, s. 4.)

XLVIII. *Imprisonment* for any term not exceeding two years, with or without hard labour or solitary confinement, or with both.

1. Soliciting the commission of any felony or misdemeanor punishable by the Post-Office Acts. (7 Wm. IV. & 1 Vict. c. 36, ss. 36 and 42.)

XLIX. *Imprisonment* with hard labour for any term not exceeding two years.

1. Personating voters at elections of members of Parliament. (6 & 7 Vict. c. 18, s. 83.)

L. *Imprisonment* with or without hard labour for any term not exceeding two years.

1. Women, by secret burying, &c., endeavouring to conceal the birth of children of which they have been delivered. (9 Geo. IV. c. 31, s. 14.)

2. Bankrupt, within three months next preceding his bankruptcy, obtaining goods on credit under the false pretence of dealing in the ordinary course of trade. (5 & 6 Vict. c. 122, s. 35.)

3. Drunkenness or other misconduct of servants of railway companies.† (3 & 4 Vict. c. 97, s. 13.)

LI. *Imprisonment* for a term not exceeding two years.

1. Embarking on board slavers in the capacity of petty officers, seamen, &c. (5 Geo. IV. c. 113, s. 11; 3 & 4 Wm. IV. c. 73.)

2. Doing any thing to obstruct carriages on railways or to endanger the safety of persons conveyed upon the same. (3 & 4 Vict. c. 97, s. 15.)

LII. *Imprisonment* for one year, and such further punishment by fine or imprisonment, or both, as to the court shall seem most proper, and the offender to give sureties for good behaviour and to be further imprisoned until they be given.

1. Witchcraft, fortune-telling, &c., or pretending to discover where property supposed to be stolen or lost may be found. (9 Geo. II. c. 5, s. 4; 56 Geo. III. c. 138, s. 2.)

LIII. *Fine*, or *Imprisonment* not exceeding eighteen months, or both, with or without hard labour.

1. Dog-stealing (for the second offence‡). (8 & 9 Vict. c. 47, s. 2 in part.)

LIV. *Forfeiture* of goods and chattels, real and personal,§ and if the offender have not goods and chattels to the value of 20*l*., then, in addition, imprisonment for one year.

1. Maintaining the authority, spiritual or ecclesiastical, of any foreign prince or state claimed within this realm or any of the dominions under the queen's obeisance before the passing of the 1 Eliz. c. 1.‖ (1 Eliz. c. 1, ss. 27 and 28; 7 & 8 Vict. c. 102.)

LV. *Imprisonment* for any term not exceeding one year, with or without hard labour or solitary confinement, or with both.

1. Uttering counterfeit coin intended to pass for the queen's current copper coin, or being possessed of three or more pieces of such coin with intent to utter the same. (2 Wm. IV. c. 34, ss. 12 and 19.)

* Assaults on special constables may also be punished on summary conviction before two justices. (See 1 & 2 Wm. IV. c. 41.)

† This offence may be punished on summary conviction, with imprisonment not exceeding two calendar months, or fine not exceeding 10*l*., if the justice before whom complaint is made shall think fit to decide upon it, instead of sending the offender for trial at the Quarter-Sessions.

‡ The first offence is punishable on summary conviction before two or more justices with imprisonment not exceeding six calendar months, with or without hard labour, or with forfeiture not exceeding 20*l*. over and above the value of the dog, as to the justices shall seem meet.

§ This forfeiture, being by statute, does not, as above observed, constitute the offence a felony.

‖ The repeal of this offence is recommended by the Commissioners for revising and consolidating the Criminal Law. (See their Report on penalties and disabilities in regard to religious opinions, dated 30th May, 1845.)

LVI. *Imprisonment* for any term not exceeding one year, or fine, or both.

1. Maliciously publishing defamatory libels. (6 & 7 Vict. c. 96, s. 5.)

LVII. *Solitary imprisonment* for a space not exceeding twelve nor less than three calendar months.*

1. Persons having hired stocking-frames, unlawfully disposing of them without the consent of the owners. (28 Geo. III. c. 55, s. 2.)

2. Knowingly receiving or purchasing such stocking-frames so unlawfully disposed of. (28 Geo. III. c. 55, s. 3.)

LVIII. *Fine* of 100*l*. or imprisonment with hard labour for any term not exceeding one year, at the discretion of the court.

1. Making signals between sunset and sunrise from the 21st of September to the 1st of April, and between 8 p.m. and 6 a.m. at any other time of the year, for the purpose of giving any notice to persons on board smuggling vessels, whether such persons be or be not within distance to notice such signals. (8 & 9 Vict. c. 87, s. 60.)

LIX. *Fine* of 500*l*., and the offender to be rendered incapable of holding any office or place under the crown.

1. Judges and other officers or persons demanding or taking any money or other thing of value for anything done or pretended to be done under any Act relating to bankrupts, beyond what is allowed by such Acts. (1 & 2 Wm. IV. c. 56, s. 58.)

2. Masters in Chancery, or persons holding offices in the Court of Chancery, or under any of the officers thereof, demanding or taking any emolument or other thing of value, other than is allowed to be taken for anything done or pretended to be done relating to their offices or employments.† (3 & 4 Wm. IV. c. 94, s. 41.)

LX. *Imprisonment* for six months.

1. Mayors, bailiffs, or other chief officers of towns corporate, designedly hindering the election of other mayors, &c. in the same towns corporate.‡ (11 Geo. I. c. 4, s. 6.)

2. Brokers, not being trading goldsmiths or refiners of silver, buying or selling bullion or molten silver. (6 & 7 Wm. III. c. 17, s. 7.)

3. Persons suspected of buying or selling unlawful bullion, in whose possession such bullion shall be found, not proving upon their trial for melting the current coin of the realm, by one witness at the least, that the same was lawful silver and not current coin, nor clippings thereof. (6 & 7 Wm. III. c. 17, s. 8 in part.)

LXI. *Half a year's* imprisonment, and ransom at the queen's will.§

1. Marshals of the Queen's Bench suffering prisoners indicted for felony, who have removed the same indictment before the queen, to wander out of prison by bail or without. (5 Edw. III. c. 8.)

LXII. *Imprisonment* for any period not exceeding six months, and the offender, if a male, may be put to hard labour, or be once, twice or thrice privately whipped, in such manner as the court shall direct.

1. Maliciously damaging anything kept for the purposes of art, science, or literature, or as an object of curiosity, in any museum or other repository, which is at all times or from time to time open to the public or any considerable number of persons, either by permission of the proprietor or by payment of money, or any picture, statue, monument or painted glass in any place of public worship, or any statue or monument exposed to public view. (8 & 9 Vict. c. 44, s. 1.)

LXIII. *Imprisonment* for any time not exceeding six calendar months.

1. Making false declarations under the provisions of the Act for regulating the manner of making surcharges of the duties of assessed taxes.‖ (50 Geo. III. c. 105, s. 9.)

LXIV. *Fine* not exceeding 100*l*. and three months' imprisonment.

1. Procuring the consent of more than twenty persons to any petition or other address to the queen or either house of

* But see 7 Wm. IV. & 1 Vict. c. 90, s. 5, which limits the time for which the court may order solitary confinement to a period not longer than one month at a time, or three months in a year. It may be a question whether the above punishment is affected by that enactment, being expressly directed by act of parliament, and the court having no discretion.

† In the case of officers of the Court of Chancery, the statute also provides that they are to be removed from their offices or employments.

‡ Such offenders are also disabled to hold any office belonging to the same corporations.

§ For the meaning of ransom and queen's will, see above, p. 175, col. 1, notes ‖ ††.

‖ Besides the above punishment, the offender is also to be fined any sum not exceeding treble the amount of duty for which he shall have been charged, as the court shall order. (sec. 9.)

parliament, for alteration of matters established by law in church or state, without the previous order of three or more justices, or the majority of the grand jury of the county, where the matter arises at the assizes or quarter-sessions, or, if arising in London, of the lord mayor, aldermen, and commons, in common council assembled; or, upon pretence of presenting any petition or other address, being accompanied with excessive number of people, or at any one time with above ten persons.* (13 Car. II. c. 5, s 2.)

LXV. *Fine* not exceeding 20*l.*, or imprisonment with or without hard labour or solitary confinement, or with both, for any term not exceeding three calendar months, or both.

1. Unlawfully dredging for oysters. (7 & 8 Geo. IV. c. 29, ss. 4 and 36.)

LXVI. *Imprisonment* for any term not exceeding three months, or fine not exceeding 50*l.*

1. Offending against the provisions of the Act for regulating schools of anatomy. (2 & 3 Wm. IV. c. 75, s. 18.)

LXVII. *Fine* not less than 20*l.*, and imprisonment with or without hard labour.

1. Neglecting or disobeying the orders of the Poor Law Commissioners or assistant commissioners, having been twice previously convicted of so doing.† (4 & 5 Wm. IV. c. 76, s. 98.)

LXVIII. *Imprisonment* until the offender brings into court him which was the first author of the tale, and, if he cannot find him, such punishment as the council shall advise.

1. Scandalum magnatum. (3 Edw. I. c. 34; 2 Rich. II. st. 1, c. 5; 12 Rich. II. c. 11.)

LXIX. *Forfeiture* of 100*l.*

1. Members of incorporated commercial or trading companies against which a fiat in bankruptcy has issued (not being the persons ordered to prepare the balance sheet), or any other person, wilfully concealing the estate of such companies.‡ (7 & 8 Vict. c. 111, s. 17.)

LXX. *Fine* of 40*l.*

1. Disturbing any religious assembly allowed by law. (1 Wm. & Mary, c. 18, s. 18; 31 Geo. III. c. 32, s. 10;§ 52 Geo. III. c. 155, s. 12.)

LXXI. *Fine* or imprisonment.

1. Embracery. (6 Geo. IV. c. 50, s. 61.)

LXXII. *Fine* according to the trespass.

1. Illegal distresses. (52 Henry III. cc. 1, 2, 3, 4; 3 Edw. I. c. 16.)

LXXIII. *Fine* and ransom at the queen's will and pleasure.‖

1. Judges or clerks rasing rolls, changing verdicts, &c. whereby ensueth disherison of any of the parties.¶ (8 Rich. II. c. 4.)

2. Frauds by persons holding commissions to compound for the payment of first-fruits.** (26 Hen. VIII. c. 3, s. 4; 1 Eliz. c. 4, s. 24.)

LXXIV. *Grievous fine* to the queen.

1. Not being ready and apparelled at the summons of sheriffs and the cry of the country, to arrest felons, when need is, as well within franchise as without.†† (3 Edw. I. c. 9.)

LXXV. *Grevious punishment.*

1. Justices' marshals taking money wrongfully from successful suitors or jurors, prisoners or others attached upon pleas of the crown.‡‡ (3 Edw. I. c. 30.)

LXXVI. *Punishment* at the queen's will.§§

1. Extortion by sheriffs and other queen's officers. (3 Edw. I. c. 26; 1 Hen. IV. c. 11.)

LXXVII. *Fine* not exceeding 100*l.*, at the discretion of the court.

1. Offences against the Act for abolishing the truck system in certain trades. (1 & 2 Wm. IV. c. 37, s. 9.)

LXXVIII. *To be* at the queen's will of body, lands, and goods, thereof to be done as shall please her.

1. Justices being found in default in any of the points contained in the oath required to be taken by them. (18 Edw. III. st. 4; 20 Edw. III. c. 1.)

LXXIX. *Forfeiture* of twenty shillings for every offence.

1. Drovers, horse coursers, waggoners, butchers, higglers, or their servants travelling or coming into their inns or lodgings upon the Lord's Day.* (29 Car. II. c. 7, s. 2.)

LXXX. *Forfeiture* of 5*s.*

1. Persons of the age of fourteen or upwards, doing or exercising any worldly labour, business, or work of their ordinary calling on the Lord's Day (works of necessity and charity only excepted).† (29 Car. II. c. 7, s. 1.‡)

Besides the misdemeanors above enumerated, there are several offences against the Established Church which are indictable, but the penalties for which may be relieved against by complying with the provisions of what are commonly called the Toleration Acts. These offences consist of

1. The forbearing to resort to one's parish church on Sundays or other holy days, without some lawful or reasonable excuse for being absent, which constitutes the offender on conviction a recusant convict, and renders him liable to forfeit 12*d.* for every such offence, to the use of the poor of the parish where the offence is committed (1 Eliz. c. 2, s. 14), and, in addition thereto, to pay into the Exchequer after the rate of 20*l.* for every month which shall be contained in the indictment upon which he is convicted; and also, having been once convicted, to forfeit without further indictment or conviction 20*l.* to the queen for every month of so forbearing (29 Eliz. c. 6, s. 4; 3 Jac. I. c. 4, s. 8). He also, previously to the passing of the 7 & 8 Vict. c. 102, which repealed the Acts imposing them, became liable to numerous disabilities, amounting in effect to outlawry. A Roman Catholic who so forbore to resort to his parish church, became on conviction a Popish recusant convict, and liable to additional penalties and disabilities beyond those which attached to recusants convict. The offence has, however, been repealed by the before-mentioned Act of the 7 & 8 Vict. c. 102, as regards Roman Catholics.

2. The relieving, harbouring, or keeping recusants in the house, the penalty for every month of doing which is 10*l.* (3 Jac. I. c. 4, ss. 32 and 33). The 7 & 8 Vict. c. 102, also repealed this offence so far as it is related to Popish recusants.

3. Schoolmasters teaching in private families without licence from their archbishop, &c., and before subscribing a declaration of their conformity to the Liturgy; for doing which they are liable, for the first offence, to suffer three months' imprisonment, and for every second and other offence the like imprisonment, and to forfeit 5*l.* to the queen. (13 & 14 Car. II. c. 4, ss. 11 and 12; 1 Wm. and Mary, sess. 1, c. 8, s. 11.)

4. Popish bishops, priests, or Jesuits, saying mass or exercising any other of their functions within the queen's dominions, or Papists keeping school or educating youth within the same, whereby, upon conviction, they become liable to perpetual imprisonment. (11 & 12 Wm. III. c. 4, s. 3.) Roman Catholics were also liable to many other severe penalties for promoting or exercising their religion, until these were repealed by 7 & 8 Vict. c. 102. It will be seen that the two former of the above offences no longer apply to Roman Catholics. The two latter are, however, still in force with respect to them as well as all other classes of the queen's subjects.

The offence of forbearing to resort to church is repealed by the Protestant Dissenters' Toleration Acts (1 Wm. & Mary, sess. 1, c. 18, ss. 13 and 16; and 52 Geo. III. c. 155, ss. 4 and 14) in favour of Dissenters who go to some congregation for religious worship of Protestants allowed by law. Quakers, however, must also, in addition, make the declaration of fidelity, as it is called, and subscribe a profession of their Christian belief. By the provisions of the same Acts, the offence of relieving, harbouring, or keeping recusants is

* Lord Mansfield declared it to be the unanimous opinion of the court, that neither the Bill of Rights (1 Wm. & Mary, sess. 2, c. 2) nor any other Act had repealed 13 Car. II. c. 5, and that it was in full force.—R. *v.* Lord G. Gordon, Dougl., 571.

† The first and second offences are punishable on summary conviction only.

‡ Such offenders also forfeit double the value of the estate concealed.

§ The punishment by 1 Wm. & Mary, c. 18, s. 18 (the Dissenters' Toleration Act), and 31 Geo. III. c. 32, s. 10 (the R. Catholic Toleration Act), was 20*l.* only. As regards the former there is no doubt that 52 Geo. III. c. 155, which was passed for the relief of Protestant Dissenters, has superseded it; but it may be a question whether, notwithstanding the generality of its terms, it has superseded the provision of 31 Geo. III. c. 32, s. 10.

‖ For the meaning of ransom and queen's will and pleasure, see p. 175, col. 1, notes ‖ ††.

¶ The offender must also satisfy the party.

** The offender also forfeits his office of deputation.

†† If default be found in the lord of the franchise, the queen may seize his franchise.

‡‡ Such offenders are also to pay to the complainants treble the value of what they so receive.

§§ For the meaning of queen's will, see p. 175, col. 1, note ††.

* The above offence does not apply to the drivers of fish-carriages, or of horses returning from drawing fish-carriages, used for the conveyance of fish under the provisions of 2 Geo. III. c. 15, an Act for the better supplying the cities of London and Westminster with fish. (See section 7 of that Act.)

Persons committing this and the next offence may be proceeded against either by indictment or in a summary way before a magistrate

† As to other exceptions see 29 Car. II. c. 7, s. 3; 10 & 11 Wm. III. c. 24, s. 14; 3 Geo IV. s. 106, s. 16; 6 & 7 Wm. IV. c. 37, s. 14; 7 & 8 Geo. IV. c. 75, ss. 42-50; 1 & 2 Wm. IV. c. 22, s. 37.

‡ By the same section of 29 Car. II. c. 7, persons also who publicly cry or expose to sale any wares or chattels on the Lord's Day, are to forfeit the same.

repealed in favour of Quakers who make the declaration and subscribe the profession before alluded to, and of all other Protestant Dissenters who resort to some congregation for religious worship of Protestants allowed by law, or take the oaths of allegiance and supremacy, or (since the passing of the 3 & 4 Wm. IV. cc. 49 and 82, in case such Dissenters be Moravians or Separatists) make an affirmation to the effect of such oaths. The penalties imposed upon schoolmasters teaching without licence from the archbishop, &c. are repealed in favour of Protestant Dissenters who take the oaths of allegiance and supremacy (or, if Moravians or Separatists, make a declaration to the effect thereof, or, if Quakers, make the declaration of fidelity and profession of their Christian belief before alluded to), and make a declaration that they are Protestants, and that they believe in the Scriptures as received among Protestant churches. (1 Wm. and Mary, sess. 1, c. 18, s. 13; 8 Geo. I. c. 6; 19 Geo. III. c. 44, s. 2; 10 Geo. IV. c. 7, s. 1; 3 & 4 Wm. IV. cc. 49 and 82.) Popish bishops, &c. saying mass, &c., and Papists keeping school or educating youth, are relieved from the penalties for so doing, provided they take the oath appointed by the Roman Catholic Relief Act (10 Geo. IV. c. 7). See the 31 Geo. III. c. 32. ss. 3, 4, and 13; and 10 Geo. IV. c. 7, ss. 2 and 23.

Persons committing any of the before-mentioned offences against the Established Church, may, also, in general, prevent the consequences of the commission of such offences by conforming themselves to the Church. Members of the Established Church are not within the Toleration Acts, and the only mode, therefore, in which they can escape the penalties for those offences is by conforming to the law. Neither do those Acts apply to Jews.

There are also two offences, having, however, much more of a political than of a religious character, which subject the persons committing them to be adjudged Popish recusants convict, and as such to forfeit and be proceeded against. These are, refusing to take the oaths of allegiance and abjuration, or to make the affirmations or declarations allowed by law in lieu thereof, when tendered by two justices of the peace or other authorized persons (1 Geo. I. st. 2, c. 13, s. 10; 8 Geo. I. c. 6; 6 Geo. III. c. 53; 3 & 4 Wm. IV. cc. 49 and 82; 1 & 2 Vict. c. 77); and peers or members of either House of Parliament, sitting or voting therein or coming into the queen's presence, before they have taken the oaths of allegiance and supremacy, or taken or made the oath, affirmations or declarations allowed by law in lieu thereof. (30 Car. II. st. 2, ss. 2, 5, and 6; 8 Geo. I. c. 6; 31 Geo. III. c. 32, s. 20; 10 Geo. IV. c. 7, ss. 2, 4, and 23; 3 & 4 Wm. IV. cc. 49 and 82; 1 & 2 Vict. c. 77.) Peers and Members of Parliament are also liable in respect of the latter offence to many disabilities, and to a fine of 500*l.* in addition to the penalties consequent on being adjudged Popish recusants convict. The repeal of the four first-mentioned offences relating to the Established Church, is recommended by the Commissioners for revising and consolidating the criminal law. (See their Report on Penalties and Disabilities in regard to Religious Opinions, dated 30th of May, 1845.) The Commissioners also recommend that persons committing the two last-mentioned offences should no longer be adjudged and suffer as Popish recusants convict, but should be punished in a more direct manner; and that one form of an oath, and one of an affirmation, should be substituted for the numerous forms of the oaths of allegiance, supremacy and abjuration, and the modifications thereof now existing, to be so framed that the same may be taken by all classes of her Majesty's subjects without objection on religious grounds.

The whole of the law, written as well as unwritten, relating to the definition and punishment of the above offences, that is, the whole Criminal Law of England as regards indictable crimes and their punishments, has been collected and reduced into one body by the Criminal Law Commissioners (see their 7th Report), and is thus for the first time rendered accessible to the public at large. Before this reduction the Criminal Law had to be sought for in an immense mass of statutes, reported decisions, records, antient and modern, and text-books; and, on that account, could be known but to the few, and those principally engaged in the the practice or administration of the law. The digest so prepared by the Commissioners, and called by them 'The Act of Crimes and Punishments,' is comprised in twenty-four chapters, under the following heads:—

1. Preliminary Declarations and Enactments.
2. Treason and other offences against the State.
3. Offences against Religion and the Established Church.
4. Offences against the Executive Power, generally.
5. Offences against the Administration of Justice.
6. Offences against the Public Peace.
7. Offences relating to the Coin, and to Bullion, and Gold and Silver Plate.
8. Offences relating to the Public Propery, Revenue and Funds.
9. Offences against the Law of Marriage.
10. Offences relating to Public Records and Registers.
11. Offences against Public Morals and Decency.
12. Offences against Public Health.
13. Common Nuisances.
14. Offences relating to Trade, Commerce, and Public Communication.
15. Homicide and other offences against the person.
16. Libel.
17. Offences against the Habitation.
18. Fraudulent Appropriations.
19. Piracy and Offences connected with the Slave Trade.
20. Malicious Injuries to Property.
21. Forgery and other offences connected therewith.
22. Illegal Solicitations, Conspiracies, Attempts and Repetitions of Offences.
23. Definitions of Terms and Explanations.
24. Chapter of Penalties.

Upon the subject of punishments, the Commissioners recommend the abolition of forfeiture as an incident to convictions for treason or felony; are inclined to reject whipping as a mode of punishment, except in the case of discharging or aiming fire-arms, &c. at the queen (5 & 6 Vict. c. 51, s. 2), in which it has lately been imposed by the legislature as constituting a signal mark of ignominy; propose that three, or at the utmost four, years should be the longest term of imprisonment to be inflicted for any offence, whether treason, felony, or misdemeanor, in cases where imprisonment forms the whole or part of the punishment; and suggest a scale of penalties, consisting of forty-five classes, to be substituted for the numerous punishments contained in the above statement. This scale might be much further reduced but for the special nature of some offences, and if the recommendations of the Commissioners should be adopted. At present it is extremely difficult in some instances to determine what punishment an offence is liable to.

It may be expected that at no distant period the 'Act of Crimes and Punishments,' subject to such omissions as are recommended by the Commissioners, will become the law of the land. A bill embodying its provisions was introduced, at the end of the session of 1844, in the House of Lords by Lord Brougham, was read a second time, and went into committee *pro formâ*; but was ultimately withdrawn at the instance of the Lord Chancellor, who undertook to issue a commission for the purpose of revising it, that duty being too laborious for any government to grapple with, and if their Report should be favourable to its adoption, to found one or more government measures upon it, as should be thought most expedient. A commission (the one whose Report on Penalties and Disabilities in regard to Religious Opinions has been several times alluded to in the foregoing statement) was accordingly appointed for this, amongst other purposes, on the 22nd of February of the year 1845. Since, the members of the old commission (who also form part of the new one) have made a Report containing a digest of the law of procedure as regards indictable offences (a most difficult and laborious undertaking), and this also is to be revised by the new commission, and if passed into a law would be a work of inestimable value.

Besides the 'Act of Crimes and Punishments' and the Digest of the Law of Procedure, several other most important Reports emanated from the original Criminal Law Commission. It was upon their recommendation that the Acts of the 1st year of her present Majesty's reign, repealing the punishment of death in the case of between thirty and forty crimes, were founded. It was a Report of theirs which mainly contributed to the alteration of that harsh and inconsistent rule of our law which denied a prisoner his full defence by counsel upon a charge of felony. They also made a very elaborate and valuable Report upon the Consolidation of the General Statute Law, and a Report upon the subject of Juvenile Offenders—in all, the number of Reports which issued from the Commission between the period of its first appointment in 1823 and its termination in the year 1845 was Eight.

Procedure.

Where any of the before-mentioned crimes has been or is suspected to have been committed, the ordinary mode of bringing the accused to justice is as follows:—Unless he surrender himself, he is, in the first place, to be summoned by some magistrate, having jurisdiction, to appear before him, or, as is more generally the case, a warrant for his apprehension is to be procured from some such magistrate. In order to the issuing of a summons or warrant there must be an information laid on oath: the former may be directed either to the accused himself, or to some other person who is to summon him to appear; the latter to any constable or other person whom the magistrate pleases, and must signify the party to be arrested and the offence which is the cause of his arrest. After a summons duly issued and served upon the accused, he is to appear according to its directions, or in default the magistrate may issue his warrant to apprehend him. After a warrant duly granted, whether a summons has been proviously issued or not, the person to whom it is directed is to proceed to arrest the accused (and if for treason, felony, or breach of the peace, may do so on any day, and at any time of the day or night), and to take him to gaol or before some magistrate having jurisdiction, according to the import of the warrant, and that without any unnecessary delay. It is also lawful for a constable or private person who sees a felony committed, or attempted to be committed, or a dangerous wound given, to arrest the offender, without warrant; also any person whom be reasonably suspects of having committed a felony which has actually been committed, and persons found committing thefts or malicious injuries to property and some other offences. A constable may also, without warrant, arrest on a reasonable charge made of a felony committed or dangerous wound given, although it afterwards appear that none such had been actually committed or given; also for a breach of the peace committed in his view; but (except in the case of one of the motropolitan police, who may under certain circumstances do so upon a charge made of an aggravated assault [see 2 & 3 Vict. c. 47], not for one committed out of bis view. Justices of the peace, sheriffs, coroners, and all other peace officers, have, it would appear, the like power to arrest as constables. Where a party is arrested without warrant, he must be taken before a magistrate within a reasonable time.

On surrendering bimself or appearing in obedience to a summons, or being brougbt before a justice of the peace under a warrant, the justice is to proceed to take the examination of the accused and the information on oath of those who know the facts and circumstances of the case, and is to put so much thereof as is material into writing. If a *primâ facie* case be made out, the justice is to commit him to prison (unless he be entitled to be discharged on bail). If it appear that no crime has been committed, or that, if committed, the accused is innocent, be is to discharge him. Unless it be prohibited by act of parliament, the accused ought to be admitted to bail in the case of all misdemeanors. Where the charge is one of felony, and the accused is brought before a single justice of the peace, if the evidence be neitber sufficient to raise a strong presumption of guilt, nor to warrant the dismissal of the charge, the accused is to be detained until the case be taken before two justices at the least, who in such case may admit him to bail (7 Geo. IV. c. 64, s. 1), and, if one of them has signed the warrant of commitment, may admit him to bail, although he confess the matter laid to bis charge, or such charge do not appear to be groundless, or the circumstances be such as to raise a presumption of gullt (5 & 6 Wm. IV. c 33, s. 3). If the accused be brought before two justices in the first instance, they have the like power to bail him. Where a party is committed or bailed for any offence, the justice may bind by recognizance all persons wbo know or declare anything material touching it, to appear and prosecute, or give evidence against him. When held to bail or committed to prison, the accused is entitled to have delivered to him, on demand, copies of the examinations of the witnesses upon whose depositions he is so bailed or committed, on payment of a reasonable sum not exceeding 1½*d.* for each folio of 90 words. If, however, such demand be not made before the day appointed for the commencement of the assizes or sessions at which the accused is to be tried, he is not entitled to such copies unless the court be of opinion that the same may be delivered without delay or inconvenience to the trial (6 & 7 Wm. IV. c. 114, s. 3).

Before a prisoner can be put upon his trial for any treason or felony, it is necessary that a bill of indictment should be found against bim by a grand jury duly returned before some court which bas jurisdiction to try parties for crimes by means of a petty jury; or in the case of murder or manslaughter, he may be tried upon the coroner's inquisition. Where the offence witb which he is charged is a misdemeanor, be may be tried either upon a bill of indictment found, as in the case of treason or felony, or upon a criminal information filed against him in the name of the queen. For a præmunire, he is to be first indicted as in other cases, or may be proceeded against in the peculiar manner pointed out by 16 Rich. II. c. 5, commonly called the Statute of Præmunire. This latter mode may, however, be regarded as obsolete.

A bill of indictment is an accusation at the suit of the Crown, and being for the public benefit and security, may generally be preferred by any person; but it is not usual for parties to interfere unless they are individually aggrieved by the offence, or fill some office which renders it peculiarly incumbent on them to bring the offender to justice. [INDICTMENT, P. C.] So soon as the grand jury have presented the bill of indictment in court, indorsed 'a true bill,' the indictment is complete. If the grand jury find no true bill, the accused, where in custody, is to be at once set at large, without the payment of any fees on account of such discharge (14 Geo. III. c. 20; 55 Geo. III. c. 50; 8 & 9 Vict. c. 114). An indictment may also be framed upon the presentment by a grand jury, of their own knowledge that an offence has been committed; but this mode of prosecution is seldom adopted. For further particulars relating to Grand Juries see JURY, P. C.

A criminal information in the name of the Queen is a suggestion filed on record by the attorney-general or by the queen's coroner or master of the Crown Office, in the court of Queen's Bench, that a misdemeanor has been committed by an alleged offender. The attorney-general, or, during vacancy in that office, the solicitor-genoral, may at his discretion file a criminal information. In all othor cases it is in the discretion of the Court of Queen's Bench to grant or refuse leave to file such informations, and such leave will only be granted on motion made, grounded on proper affidavits, and in respect of misdemeanors of such magnitude or under such circumstances as, in the opinion of the court, call for its interference. After an information is filed, all the subsequent proceedings are, in general, the same as after an indictment found for a misdemeanor.

Persons committed for treason or felony who move in open court the first week of the term, or first day of the sessions of oyer and terminer or gaol delivery, to be brougbt to trial, may, if not indicted some timo in the next term or session after their commitment, be bailed by the judges of the Queen's Bench, or justices of oyer and terminer or goal delivery, unless it appear that tbe witnesses for the crown could not be produced the same term or sessions; and if not indicted and tried the second term or sessions after their commitment, or if acquitted upon their trial, shall be discharged from imprisonment (31 Car. II. c. 2, s. 7). [HABEAS CORPUS ACT, P. C.]

When the indictment is found, in cases of felony, the accused is bound to plead and try *instanter*, and if in custody, is to be brought to the bar and arraigned (which is the legal term for calling on a prisoner to answer to a charge of an indictable offence) as soon as convenient after such indictment is found; but in all cases of treason, except where the overt act is tbe assassination of the queen, the endangering of her life or person, or any attempt to injure her person (39 & 40 Geo. III. c. 93; 5 & 6 Vict. c. 51), and except the forgery of the great and other royal seals (7 & 8 Wm. III. c. 3, s. 13), the accused is to have a true copy of the indictment delivered to him ten days at the least before he is arraigned, and, *at the same time*, a list of the witnesses to be produced against him, and if indicted in any other court than the Queen's Bench, a list of the petit jury; but if indicted in the Queen's Bench, the list of the petit jury may be delivered to him at any time after his arraignment, so as it be delivered ten days before the day of trial (7 & 8 Wm. III. c. 3, s. 1; 7 Anne, c. 21, s. 11; 6 Geo. IV. c. 50, s. 21). If the accused plead, however, without claiming or having had delivered to him such copy or lists, he will be considered to have waived any objection on account of such non-delivery. In cases of misdemeanor, the accused is not bound to plead and try at the session at wbich the indictment is found, unless he has been in custody or out on bail to appear to answer for the offence with which he is charged, twenty days at the least, before such session (60 Geo. III. & 1 Geo. IV. c. 4, s. 3), but may traverse the indictment, that is, postpone its determination to the next session. He must usually, however, before he will be allowed to do so, appear personally in court (except in the

Queen's Bench, where he may appear by attorney) and plead. A party indicted for a misdemeanor, not having been in custody nor out on bail, twenty days before the session at which he is so indicted, may also, at the subsequent session, traverse to the one following, unless he has been in custody or out on bail or has received notice of such indictment, twenty days before such subsequent session (60 Geo. III. & 1 Geo. IV. c. 4, s. 5). If the accused, whether in case of felony or misdemeanor, be not in custody nor on bail when the indictment is found, or, being on bail, make default, his appearance may be compelled by process or by a bench warrant; and he may be prosecuted to outlawry. [OUTLAWRY, P. C.] No fee is to be demanded or taken from persons charged with or indicted for felony or misdemeanor, or as an accessory to felony, for their appearance to the indictment or information, or for allowing them to plead, or for recording their appearance or plea, or for discharging any recognizance taken from such persons, or any sureties for them (8 & 9 Vict. c. 114, s. 1).

In cases of treason, the accused is entitled, on application to the court, to have two counsel assigned him, who may have free access to him at all seasonable hours (7 & 8 Wm. III. c. 3, s. 1). The court may also, if it think fit, upon the accused's making affidavit that he is not worth 5*l.* beyond his wearing apparel, allow him to defend *in formâ pauperis*; in which case neither the officers of the court, nor those who are assigned to conduct his cause, may take any fees.

The prisoner, upon being arraigned or charged with the indictment, in cases of felony or misdemeanor, may either confess the charge to be true, in which event such confession is to be recorded and judgment awarded according to law, or may plead to the indictment or demur. By pleading, he puts in issue the facts of the charge; by demurring, he admits the facts, but contends that they amount to no offence indictable by law; as if a man were indicted for feloniously stealing game, without alleging that it was tame or confined: in which case, upon demurrer, he must be discharged. After demurrer, in cases of felony, decided against the prisoner, he is at liberty to plead over 'Not Guilty;' but, in cases of misdemeanor, the judgment for the Crown is final, for it operates as if the prisoner had been convicted by a jury. In either case, if the demurrer be decided for the prisoner, the judgment is that he be dismissed and discharged.

The pleas which may be pleaded by a prisoner are either to the jurisdiction of the court, and these must be pleaded before any other plea, or in abatement (for the omission of his addition under the statute of additions, or for misnaming him) or in bar; and pleas in bar are either special pleas or the general issue. Special pleas may allege a previous acquittal, conviction, or attainder of the same offence, or a pardon [PARDON, P. C.]; and, in the case of prosecutions for the non-repair of highways or bridges, the liability, if denied by the defendant, of the party who is liable for the repair of the same.

The general issue, or 'Not Guilty,' which is the plea employed in the infinitely greatest number of cases, puts in issue the whole question of the accused's guilt or innocence of the charge in all its bearings; and not only casts on the prosecutor the burden of making out every part of his charge, but entitles the accused to give in evidence every possible ground of justification or excuse which can form an answer to the indictment.

No advantage can now be obtained by a plea in abatement, as by the 7 Geo. IV. c. 64, s. 19, the court may, upon such plea, immediately cause the indictment to be amended, and call upon the party to plead to it so amended, as if no such plea had been pleaded. In cases of felony, if a special plea be found for the Crown, the prisoner may plead over 'Not Guilty;' but in cases of misdemeanor, the judgment for the Crown is final. In either case, if it be found for the prisoner, he is to be dismissed.

If, instead of pleading, the prisoner stand mute of malice, or will not answer directly to the indictment, the court may order a plea of 'Not Guilty' to be entered on his behalf, and such plea will have the same effect as if it had been actually pleaded by him (7 & 8 Geo. IV. c. 28, s. 2). But if a doubt arise whether he be mute of malice or dumb, a jury is to be impannelled to try the fact, and, if the latter be found, the court will use means to make the prisoner understand what is required of him; but if this be impossible, will direct a plea of 'Not Guilty' to be entered, and the trial to proceed. Should he upon arraignment be found to be insane by a jury impannelled for the purpose under the provisions of the 39 & 40 Geo. III. c. 94, so that he cannot be tried, the court may order such finding to be recorded and the prisoner to be kept in strict custody until her Majesty's pleasure be known.

When, however, the plea of 'Not Guilty' has been pleaded, the trial is to be had before some court having jurisdiction, by twelve jurors, generally of the county where the fact is alleged in the indictment to have been committed, called a petit jury, by way of distinction from the grand jury. The ordinary courts having jurisdiction to try indictable offences are the Queen's Bench, Courts of Oyer and Terminer, Gaol Delivery, and Quarter-Sessions, Borough Courts and the superior Criminal Courts of the Counties Palatine; but Courts of Quarter-Sessions and Borough Courts have no jurisdiction with respect to treason or any felony punishable with death or transportation for life, and several other offences (see 5 & 6 Vict. c. 38, s. 1). The trial is generally to be had in the county or district in which the offence was committed.

Upon the trial being called on, the jurors are to be sworn as they appear, to the number of twelve, unless they be challenged. As to challenges, whether on the part of the Crown or the prisoner, and as to petit juries generally, see JURY, P. C. It may here be observed, however, that the right of peremptory challenge, *i. e.* of challenging at mere pleasure, without showing any cause, which exists in cases of treason and felony, is one of the peculiarities before alluded to, which distinguish those classes of crimes from misdemeanors; and that the power to challenge peremptorily to the number of thirty-five jurors in cases of treason, and to the number of twenty only in cases of felony, is a distinguishing feature between treasons and felonies. When twelve jurors are procured free from exception, and have been sworn, or, if Quakers, Moravians, or Separatists, or persons who have been Quakers or Moravians, have made their solemn affirmation, in case of treason or felony, well and truly to try and true deliverance make between the queen and the prisoner whom they have in charge, and, in cases of misdemeanor, well and truly to try the issues joined between the queen and the defendant, the case, where counsel is retained for the prosecution, is to be opened by him, or, if two or more counsel are retained, by the leading one, according to his instructions, unless the case is so plain as not to require any statement. The counsel for the prosecution ought, however, to confine himself, so far as possible, to a simple statement of the facts which he expects to prove, and to abstain from any appeal to the passions of the jury, more particularly in cases where the prisoner has no counsel. After the opening, or where no counsel is engaged for the prosecution, immediately after the swearing of the jury, the examination of the witnesses on behalf of the Crown commences. Before being examined an oath or affirmation is administered to each witness 'that he will true answer make to such questions as the court shall demand of him, and will tell the truth, the whole truth, and nothing but the truth.' Where there is counsel, he examines the witnesses; where there is none, that duty devolves on the court. In criminal cases a single witness, swearing to the actual offence or to such facts as necessarily lead to the inference that it has been committed, if believed by the jury, is generally sufficient to substantiate the charge. In treason, perjury, and the offences of tumultuously petitioning, affirming that parliament has a legislative authority without the Crown, or that any person is entitled to the crown contrary to the Act of Settlement, and Blasphemy under the provisions of 9 & 10 Wm. III. c. 32, however, there must be two witnesses. In all cases, also, the prisoner's confession, if made in consequence of a charge against him, and in a direct and positive manner, voluntarily and without promise or threat operating on his mind at the time of making it, is sufficient, even if there be no other proof that the crime with which he is charged has been committed, for the jury to convict upon, if they believe it to be true. And the single unsupported testimony of an accomplice is sufficient (except where two witnesses are required), if the jury believe his story; but it is usual in such cases for the court to direct the acquittal of the prisoner. If, however, the accomplice be corroborated by unsuspicious evidence as to such parts of his testimony as show that his story has not been fabricated, the court will not interfere.

There are four kinds of proof by which criminal charges may be sustained: 1st, *positive*, as by the direct testimony of a witness who saw the fact; 2ndly, *circumstantial*, when a number of facts are presented which are inconsistent with any other hypothesis than that of the prisoner's guilt; 3rdly, *presumptive*, as when the possession of a stolen article casts on the prisoner the burden of showing how he obtained it;

4thly, *confessional*, where the prisoner makes a voluntary admission of his guilt as already mentioned. The general rules of evidence in criminal proceedings are the same as those which are applicable in civil cases. [EVIDENCE, P. C.] A husband or wife, however, may be a witness for and against each other upon a charge of criminal violence done by either to the person of the other, contrary to the rule in civil cases, which excludes the testimony of husband and wife for or against each other. The prosecutor, also, notwithstanding his connexion with the proceedings against the prisoner, is a competent witness in support of the charge, for such proceedings are carried on in the name of the crown, and the prosecutor has, according to legal construction, no direct interest in the result.

After the examination of each witness, he may be cross-examined on behalf of the prisoner, who is entitled at the time of the trial to inspect, without fee or reward, all depositions, or copies thereof, which have been taken against him and returned into court. (6 & 7 Wm. IV. c. 114, s. 4.) When the cross-examination is finished, the counsel by whom the witness was called is entitled to re-examine him for the purpose of explaining any matters touched upon or referred to in the cross-examination, into which confusion may have been introduced by the questions on the prisoner's behalf. The court may also put any questions it thinks proper to the witnesses, and for this purpose may recall a witness at any stage of the inquiry.

When the case for the prosecution is closed, the prisoner or his counsel (who has, since the passing of the 6 & 7 Wm. IV. c. 114, the same right to address the jury on the merits of the case in felony as he previously had in treason and misdemeanor) is entitled to address the jury, and in so doing to comment on the entire case for the prosecution; and if he intends to adduce evidence, may open that evidence with any particulars he may think proper. After the prisoner or his counsel has finished his address, the witnesses for the defence are to be sworn, and their evidence gone into. The accused is always allowed to call witnesses to speak to his *general* character, as being inconsistent with the imputed offence, and it is for the jury to estimate the value of such evidence.

When the prisoner's evidence is closed, witnesses may be called on behalf of the prosecution to give specific contradictions to the denials by the prisoner's witnesses on cross-examination, and generally to give any evidence in reply which is strictly applicable to the defence and which could form no part of the original case. Where such evidence is given, the prisoner or his counsel has a right to address the jury on it before the general reply for the prosecution.

When the defence is ended, the counsel for the prosecution, in all cases where witnesses have been called on behalf of the accused, is entitled to reply on the entire case and on all the observations made by the other side during its progress. After the case on both sides is closed, the court sums up the evidence, and in so doing directs the attention of the jury to the precise issue they have to try, and applies the evidence to that issue. Upon the trial of a person for a non-capital felony committed after a previous conviction for felony, the jury is not to be charged to inquire concerning such previous conviction, until they have inquired concerning such subsequent felony and have found such person guilty of the same; and where such previous conviction is stated in the indictment, the reading of such conviction to the jury is to be deferred until after such finding. Where, however, such person gives evidence of good character, the prosecutor may in answer thereto give evidence of such previous conviction, before such finding, and the jury may inquire concerning such previous conviction at the same time that they inquire concerning the subsequent felony. (6 and 7 Wm. IV. c. 111.) The summing up being concluded, the jury proceed to consider of their verdict. If, on consultation in the jury-box, they are not able to agree within a convenient time, they retire, and a bailiff is sworn to keep them together without meat, drink, fire, or candle till they are agreed. This rule, however, has been relaxed in modern times. In cases of misdemeanor, where the trial lasts more than one day, the court will generally allow the jurors to return to their homes, the jury engaging to allow no one to speak to them on the subject of the trial. But in cases of treason or felony, the course has been to permit them to retire in a body to some tavern, where accommodation is provided for them by the sheriff and his officers, who are sworn to keep them together, and neither to speak to them themselves nor to suffer any other person to speak to them touching any matter relating to the trial.

When the jury have agreed upon their verdict, they signify that they are ready to deliver it; and on returning into court for that purpose, their names must be called over, and all twelve must be within hearing when it is given. The foreman of the jury is the person who is to deliver the verdict; and in cases of treason or felony, it can only be received in open court and in the presence of the prisoner: in cases of misdemeanor it may be otherwise. The verdict may be either 'Guilty' or 'Not Guilty,' or may be a special one; and may be 'Guilty' upon one count of an indictment, and 'Not Guilty' upon others; or may be 'Guilty' as to part of a count, and 'Not Guilty' as to the remainder, where an offence is charged which includes a lesser crime of the same degree, and the latter only is proved; as where murder is charged, and the proof is of manslaughter: and since the passing of 7 Wm. IV. & 1 Vict. c. 85, s. 11, before referred to, the jury may find guilty of an assault, where one is included in the felony charged, and acquit of the felony, although an assault is a misdemeanor only. A special verdict is the finding of all the facts specially, where the jury doubt whether they constitute the offence in the indictment, and leaves the court to give judgment according to the legal effect of the facts so found.

Where upon the trial evidence is given of insanity at the time of committing the offence charged, and the jury acquit, they are required to find specially whether the accused was insane at the time of the commission of the offence, and whether he was acquitted on that account; and if they find in the affirmative, the court is to order him to be detained till the queen's pleasure be known; and she may give such order for his safe custody during her pleasure as she may think fit. (39 & 40 Geo. III. c. 94, s. 1; 3 & 4 Vict. c. 54, s. 3.) On a verdict of acquittal, or where he is discharged by proclamation for want of prosecution, the prisoner is to be immediately set at large in open court, without the payment of any fines in respect of such discharge. (14 Geo. III. c. 20; 55 Geo. III. c. 50; 8 & 9 Vict. c. 114.)

When a verdict of guilty has been returned against a prisoner, the court, except in the case of prosecutions pending in the Queen's Bench, may proceed at once to pass sentence upon him, unless he allege some matter or thing sufficient in law to arrest or bar judgment. In prosecutions pending in the Queen's Bench, however, the prisoner is allowed four days for moving in arrest of judgment; or, in cases of misdemeanor, for a new trial or writ of *venire facias de novo*. Also where the trial at any sittings or assizes is upon a record of the Queen's Bench, the judge before whom the verdict is taken may, under 11 Geo. IV. & 1 Wm. IV. c. 70, s. 9 (except where the prosecution is by information filed by leave of the Queen's Bench, or such cases of information filed by the attorney-general wherein he prays that judgment may be postponed), pass sentence at once; but such sentence is not to have the force and effect of a judgment of that court, until after the expiration of six days after the commencement of the ensuing term, during which period the prisoner may move for a new trial, or to have the judgment amended. Except in the last-mentioned case of a trial at the sittings or assizes upon a record of the Queen's Bench, or where the offence of which the prisoner is convicted is a misdemeanor punishable by a simple fine, or where the Queen's Bench, after conviction for misdemeanor, thinks proper to dispense with his attendance, sentence cannot be pronounced against a prisoner unless he be present in court at the time.

Judgment may be arrested where the offender has received a pardon since his arraignment or after conviction becomes insane, or, having been out of custody since his conviction, denies that he is the person convicted (in which last case a jury is to be impannelled to try the fact), or for some defect apparent in any part of the record, as regards either the jurisdiction of the court, the statement of the offence or any of the proceedings thereon, but not for any of the mere technical defects specified in 7 Geo. IV. c. 64, ss. 20 and 21. If the judgment be arrested, all the proceedings against him are to be set aside, and judgment of acquittal is to be pronounced in his favour; but he may be prosecuted again for the offence of which he is so acquitted.

A new trial may be had on the application of the defendant in all cases of misdemeanor pending in the Queen's Bench, where it appears to the court that the awarding one is essential to justice; as, for instance, where the verdict is contrary to evidence or the directions of the judge, or evidence has been improperly received or rejected at the trial. The court of Queen's Bench will also in its discretion, where a party is acquitted of a misdemeanor on a prosecution pending in that court, allow a new trial, on the application of the prosecutor, if such acquittal has been obtained by any fraudulent means or practice, as where the party acquitted has kept back any of the prosecutor's witnesses, or neglected to give due notice of trial.

A writ of *venire facias de novo*, the effect of which is the same as granting a new trial, may be awarded where, by reason of misconduct on the part of the jury, or of some uncertainty or ambiguity or other imperfection in their verdict, or of any other irregularity or defect in the proceedings or trial, appearing on the record, the proper effect of the first *venire* has been frustrated, or the verdict has become void in law.

Neither new trials nor writs of *venire facias de novo* are grantable in cases of treason or felony.

Where a new trial or writ of *venire facias de novo* is awarded, the parties stand in the state in which they were immediately before the first trial: the whole case is to be reheard, and the first verdict cannot be used upon the new trial, or as evidence of any matter found by such verdict, or in argument.

After sentence pronounced against an offender, the judgment of the court may be falsified or reversed, either by plea without writ of error or by writ of error: by the former, for some matter not apparent upon the face of the record, as want of authority in the court by whom the judgment was pronounced; by the latter, for the same matters as are sufficient to arrest a judgment, and also for any material defect in the judgment itself. Where the judgment has been pronounced by a court of oyer and terminer, gaol delivery, or quarter-sessions of the peace or of a county palatine, the writ of error is to be brought in the court of Queen's Bench, and for that purpose the indictment and other proceedings thereon must be removed into that court by writ of *certiorari* [CERTIORARI, P. C. and P. C. S.]: where it has been pronounced in the Queen's Bench, it is to be brought in the Exchequer Chamber, before the justices of the Common Pleas and barons of the Exchequer, from whose judgment a writ of error lies to the House of Lords. In cases of treason and felony it is in the discretion of the crown to grant or refuse a writ of error: in all other cases the fiat of the attorney-general must be first obtained, and this he ought to grant upon probable cause of error shown. When issued, the writ of error stays the execution of the judgment, where it has not been carried into effect during the time that such writ is pending, except that in cases of treason or felony the offender is not entitled to be liberated on bail. In cases of misdemeanor, however, where he is imprisoned under execution, or any fine has been levied, either in whole or in part in pursuance of the judgment, he is entitled to be discharged from imprisonment and to receive back any money levied on account of such fine, until the final determination of the Writ of Error. (8 & 9 Vict. c. 68, s. 1.) If the judgment be falsified or reversed, such judgment and the execution thereupon, and all former proceedings, become thereby absolutely null and void; and the person the judgment against whom is so falsified or reversed, if living, and, if dead, his heir or executor, is restored to all things which such person may have lost by such judgment and other proceedings, and stands in every respect as if such person had never been charged with the offence in respect of which such judgment was pronounced against him. If, however, the execution only be erroneous, that only will be reversed; and if the judgment be reversed for some technical error merely, in the indictment or subsequent process, the party may be prosecuted again. If the judgment be confirmed, the prisoner is to be remanded to undergo the remainder of his sentence.

Where there is nothing to arrest or bar a judgment, the execution of it may be prevented by a pardon received after sentence pronounced; but, without express words of restitution, no property which the offender forfeited on his conviction or attainder, is thereby revested in him; nor, unless where the pardon is by act of parliament, is the corruption of his blood removed, except as regards those of his blood born after the granting of such pardon, nor are any of the consequences of such previous corruption prevented.

In capital cases the execution of a judgment may also be suspended by a reprieve, either at the discretion of the Crown, or, where substantial justice requires it, of the court. There are two instances however in which the court is bound to grant a reprieve, viz.: 1, where the offender, if a female, is pregnant; 2, where the offender becomes insane after judgment. If the offender allege that she is pregnant or the court have reason to suppose that she is so, a jury of twelve matrons is to be impannelled with all possible dispatch to try whether or not she be quick with child. In case they find in the affirmative, the court respites the offender from time to time until she be delivered of a child or it is no longer possible in the course of nature that she should be so. After her delivery or where such delivery is no longer possible as before mentioned, or if the jury find that she is not quick with child, the court, at the expiration of the period for which it has respited her, proceeds to award execution against her.

Where insanity is alleged, the court will reprieve the prisoner, if found to be insane by means of an *ex officio* inquiry, or if his insanity otherwise sufficiently appear.

Should the execution of a judgment be neither prevented nor suspended, or, having been suspended, should have ceased to be so, such judgment is to be executed according to law by the sheriff or other authorized person or his deputy. In capital cases, if the offender, after hanging, be taken down before he be dead, he is to be hanged again until he be dead.

As regards the manner in which the various judgments which may be pronounced against offenders are to be executed, the subject is too extensive to be further treated of in an article like the present.

With respect to the expenses of prosecutions for indictable offences, the general provisions on the subject are contained in 7 Geo. IV. c. 64. According to these the court before which any person is prosecuted for felony or the following misdemeanors, viz., assaults with intent to commit felony; attempts to commit felony; riots; receiving stolen property; assaults upon peace-officers in the execution of their duty, or upon persons acting in their aid; neglect or breach of duty by peace-officers; assaults in pursuance of conspiracies to raise the rate of wages; obtaining property by false pretences; indecent exposure of the person; perjury and subornation of perjury, may, at the request of the prosecutor or any other person appearing on recognizance or subpœna to prosecute or give evidence, order payment of the costs and expenses incurred by the prosecutor in preferring the indictment, and also the reasonable expenses of the prosecutor and witnesses for the prosecution in attending before the grand jury and otherwise carrying on the prosecution; and also, whether a bill of indictment be preferred or not, may order the reasonable expenses incurred by any person by reason of attending on any such recognizance or subpœna (such attendance, where no indictment is preferred, appearing to be in *bonâ fide* obedience to the recognizance or subpœna), and, except in cases of misdemeanor, by reason of attending before the examining magistrate, and also, except in respect of attendance before such magistrate in cases of misdemeanor, compensation for trouble and loss of time. Such payments are in general to be made out of the county rate.

It is difficult to discover upon what principle the selection of the cases of misdemeanor in respect of which the court is empowered to award costs has been made. Other cases might with justice be included; and it may be a question whether, under certain limitations, the power ought not even to be extended to the expenses of the prisoner's witnesses.

Offences punishable on Summary Conviction.

It would be inconsistent with the limits of the present article to give a detailed account of the various offences punishable on summary conviction, in number far exceeding those which are indictable. They relate, however, principally to ale and beer houses, apprentices, petty assaults, the Customs and Excise, distresses, drunkenness, friendly societies, game, hawkers and pedlars, highways, turnpike roads, petty thefts not amounting to larceny, malicious injuries to property, pawnbrokers, railways, stage and hackney carriages, servants, vagrants, weights and measures, and the numerous offences punishable under the Metropolitan Police Acts.

Summary proceedings, except in the case of contempts of the superior courts of justice (which those Courts have been immemorially used to punish by attachment), were wholly unknown to the common law. Their institution appears to have originated partly in the necessity for relieving the ordinary tribunals from the immense increase of labour which would otherwise have been cast upon them, owing to the multiplicity of new offences of a trivial kind which were yearly created for the protection of society as it advanced in population and civilization, and partly in the desire to do more speedy justice in the case of such trifling offences than would have been possible had they been made indictable. In the case of indictable offences a party cannot in general, as before observed, be put upon his trial until a true bill has been found against him by a grand jury, and cannot be convicted except by the verdict of a petit jury: to have made all these minute offences indictable would therefore have entailed upon the class of persons qualified to serve as jurors a frequency of attendance which would have been found to be most troublesome and harassing. Accordingly numerous acts of parliament have from time to time vested in one or more justices of the peace or other persons the power to try parties accused of trifling offences without the intervention of a jury. The extension, however, of this mode of proceeding has been always regarded with extreme jealousy.

Where an offence punishable on summary conviction before a justice of the peace has been committed, or is suspected to have been committed, the general course of proceeding is as follows:—An information (but which need not be in writing unless directed to be so by the statute which creates the offence) is to be laid before the justice authorized to take such information, who thereupon issues a summons to the party complained of, containing the substance of the charge, and giving him notice that at a certain time and place the hearing of the complaint against him will be proceeded with. If the party attend at the appointed time and place, and confess that he has committed the offence, the justice proceeds at once to convict him, and to impose the penalty assigned by the Act which creates the particular offence. If he attend, but deny that he has committed the offence, or if he fail to attend, evidence is to be gone into for the purpose of showing that he has committed it. In the latter case, however, it must be first ascertained that he has been duly summoned. It appears that the examination of witnesses in summary proceedings must in all cases be upon oath, notwithstanding the Act creating the offence may authorize conviction *on the examination of witnesses*, without stating that the same is to be upon oath. So also such examination must be in the presence of the party complained of, where he appears; and generally, all rules applicable to the trial of indictable crimes may be considered as applying to the trial of offences punishable on summary conviction, so far as such rules are compatible with that mode of proceeding. If, after hearing the evidence, the justice is of opinion that the charge is not substantiated, the party accused is to be acquitted. If, on the other hand, he thinks that it is, he is to convict the offender and to impose upon him the assigned penalty. Upon conviction the justice usually issues his warrant to apprehend the offender, in cases where corporal punishment is to be inflicted upon him, or else to levy the penalty incurred, by distress and sale of his goods. This is the general mode of proceeding, as well where the conviction is required to be before two or more justices, as where it may be before a single justice of the peace; but for particulars recourse must be had to the several statutes creating the offences or inflicting the punishment. In some cases a power of appealing to the quarter-sessions is given to the party convicted. [JUSTICE OF THE PEACE, P. C.]

For the method of proceeding with respect to offences punishable on summary conviction before the Commissioners of Excise or persons other than justices of the peace, reference must be made to the statutes on the subject.

The principal authorities besides the statutes of the realm which have been consulted in the preparation of this article, are Hawkins's *Pleas of the Crown*; Blackstone's *Commentaries*; Russell, *On Crimes and Misdemeanors*; Chitty's *Criminal Law*; Starkie's Treatises *On the Law of Evidence and On Criminal Pleading*; Dickenson's *Guide to the Quarter-Sessions*, by Talfourd; the 4th, 5th, 6th, 7th, and 8th Reports of the Criminal Law Commissioners; the Report of the Commissioners for revising and consolidating the Criminal Law, on the subject of Penalties and Disabilities in regard to Religious Opinions; and Hulton *On the Law of Convictions*.)

LEASE. A lease, or letting, is sometimes called a Demise (demissio). It is sometimes said that Lease is from the Latin 'locatio;' but as the verb which corresponds to the noun Lease is Let, it seems that the word Lease is the noun which corresponds to the verb Let. The verb Let is akin to the French 'laisser' and the German 'lassen.'

He who lets land is called the Lessor, and he to whom land is let is called the Lessee.

There are various legal definitions of a lease. A lease has been defined to be a conveyance of lands or tenements from lessor to lessee for life, for years, or at will, generally in consideration of a rent or other annual recompense to be paid by the lessee to the lessor. The reservation of a rent is not essential in a lease; but payment of rent is now the chief condition on which lands are let.

To constitute a lease, it is necessary that the lands must be let for a less time than the period for which the lessor has an interest in the lands demised. If a man parts with all his interest in the lands or tenements, the conveyance is an assignment [ASSIGNMENT, P. C.], and not a lease. The relation that is created by a lease between the lessor and the lessee is usually expressed by the phrase landlord and tenant. The lessor has a reversion in the lands which are demised, that is, after the expiration of the lease the land reverts to him. The lessor, by virtue of this reversion, seignory, or lord's title, has the power of distraining on the land for the rent which is agreed on, and for the services which may be due by the terms of the lease; and fealty is always due to the lessor. [FEALTY, P. C.] The ordinary lease is that for a term of years, by which lease a rent, generally payable in money, at stated times, is reserved to the lessor. These stated times are usually quarterly periods.

The words used in a lease for the purpose of conveying that interest in the lands which constitutes a term of years are 'demise, grant, and to farm let.' These words are derived from the law-Latin expressions 'demisi, concessi, et ad firmam tradidi.' The word 'firma,' farm, is said to signify originally 'provisions,' and 'to farm let' does not properly signify to let to be farmed, in the modern sense of the term, but to let on the condition of a certain rent being paid in farm, that is, in provisions. If this explanation is correct, a 'farmer' is one who had the use of lands on condition of paying a 'farm' or rent in provisions, such as corn and beasts But the word 'farm' now signifies the lands which a man hires to cultivate upon the payment of a rent.

The interest which a man acquires in land by a lease for years is a term of years, or an estate for years. [ESTATE, P. C.] The word lease is used in common language also to signify the estate or interest which the lessee acquires by the lease; but the word lease signifies properly the contract or conveyance by which the lessee acquires the interest in the lands.

The words 'demise,' &c. above mentioned, are the proper words to constitute a lease for years: but any words are sufficient, which clearly show 'the intent of the parties that the one shall divest himself of the possession (of the land), and the other come into it for a determinate time.' When the written contract is not intended to be a lease, but an agreement for a future lease, it is often difficult to determine whether the contract is not so expressed as to make it a lease.

At common law, it was necessary for the lessor to enter on the lands in order to make the lease complete, and no writing was necessary. But the Statute of Frauds (29 Car. II. c. 3, § 1) enacted, that all leases, estates, interests, of freehold or terms of years, created by livery and seisin [FEOFFMENT, P. C.] only, or by parol, and not put in writing and signed by the parties so making the same or their agents thereunto lawfully authorized by writing, shall have the force and effect of leases or estates at will only, except leases not exceeding the term of three years from the making thereof, upon which the rent reserved to the landlord during such term shall amount to two-thirds at the least of the full and improved value of the thing demised. A deed is not necessary to constitute the writing a lease, unless the tenement is an incorporeal hereditament or a reversion or remainder. But leases are generally made by deed, because covenants can be made only by deed. [DEED, P. C.]

The word 'lands,' which refers to the subject matter of a lease, comprehends what is upon the lands, as houses and other buildings, though houses and buildings are generally mentioned specifically in the lease.

The law of leases comprehends a great number of rules, which may be conveniently reduced to the following general heads:—

1. The things which may be subjects of leases.
2. The persons who may grant leases, and their powers to grant.
3. The form of leases, and the legal construction of the agreements contained in them.

The examination of these subjects belongs to treatises on Law. The article 'Leases and Terms of Years' in Bacon's 'Abridgment' is generally referred to as a good compendium of the law. A lease may contain any agreements that are lawful. The object of the present article is to consider what agreements Farming-leases should contain or should not contain, in order that the lease may be most beneficial to the landlord and the tenant, and by consequence to the public generally.

The chief subjects of leases are houses and buildings of all kinds, cultivable lands, and mines. Many persons who have not the complete ownership of houses and lands are enabled to grant leases under particular powers; and there are many statutes under which particular classes of persons are enabled or restrained as to the granting of leases, such as Bishops, Deans and Chapters, and others. [BENEFICE, P. C.]

The kind of leases of which we shall treat here are farming leases, which are granted by persons who have full power to grant them on such terms as they please. The particular form of such leases, as already intimated, is a matter that belongs to the subject of public economy, and it is almost beyond the province of direct legislation.

At present a great part of the land in England and Wales is held by large propriotors, and the number of land-owners who cultivate their own estates is comparatively small. In many parts of the kingdom the number of small land-owners who cultivate their own farms has certainly been decreasing for some centuries, and they are probably fewer now than in some former periods of our history. In England the great subdivision of land has been prevented by the form of government and the habits and feelings of those who have had the chief political power: and the great increase of wealth that has arisen out of the manufacturing and commercial industry of the country has tended to prevent the subdivision of land and not to increase it. Those who acquire great wealth in England by manufactures and commerce generally lay out a large part of it in the purchase of land; for the ownership of land is that which enables a man to found a family and to perpetuate it, to obtain social respect and consideration, and also political weight in the administration of public affairs. It facilitates his election to the House of Commons, and if he plays his part well, it may introduce him in due time to the House of Lords, and place him among the nobility of England.

Those who cannot acquire land enough to give them political weight, are still anxious to acquire land as a means of social distinction, and as a permanent investment which must continually rise in value. Thus there is a constant competition among the rich for the acquisition of land, which raises its price above its simple commercial value; and a man of moderate means does not find it easy to purchase land in small quantities and on such terms as will enable him to obtain a proper remuneration for the cultivation of it.

The great mass of the cultivators in England are now tenant farmers, who hold their land either by leases for years or by such agreements as amount to a tenancy from year to year only; and there is the like kind of competition among them to obtain land upon lease, that there is among the wealthy to obtain land by purchase. The consequence is that more rent is often paid for land than it is worth: a consequence of the limited amount of land and of the number of competitors for it. This circumstance however, combined with others, enables the landlord to impose conditions which are unfavourable to the tenant and to agriculture, and finally to himself.

Several things are essential to the good cultivation of land, whether it is held by lease or is the property of the cultivator. These essentials are, a knowledge of the best modes of husbandry, adequate capital, and a market in which the farmer may freely buy and sell all that he wants. Now, in the present state of agriculture in this country, not one of these three conditions exists in the degree which is necessary to ensure good cultivation. The greater part of the land in England, as already observed, is cultivated under leases or a tenancy from year to year; and the covenants in the leases are often such as to be an insuperable obstacle to good agriculture. The condition then of the tenant farmer, as determined by his lease, is that which we have to consider.

Many landholders have several objects in view in letting their lands besides the getting of rent. One of these objects is to maintain their political weight by commanding the votes of their tenantry; and this is mainly effected by not granting them leases of their lands for determinate periods, such as seven, fourteen, or twenty-one years; but by making them very nearly tenants at will, or liable to quit at six months' notice. He who depends for his subsistence on having a piece of land to cultivate, out of which he may be turned on a short notice, will not be an independent voter. Nor can the landlord expect to have a good tenant who will improve his land and a political tool at the same time. The uncertainty of the tenure will prevent a man of skill and capital from investing his money upon so uncertain a return. There may be many cases in which the personal character of the landlord is a sufficient guarantee to the tenant that he will not be disturbed in the possession of the land, even where he has no proper lease, so long as he cultivates it fairly and pays his rent.

But the most intelligent landlords themselves admit that the only proper tenure of the tenant is that of a lease for a determinate period; and it is on this condition alone as a general rule, that a landlord can get men of capital and skill to cultivate his land. It has been maintained by arguments which are unanswerable, that if lands were let to farmer tenants on leases for a determinate number of years, and on conditions which should not interfere with the land being cultivated in the best mode, there would be a great amount of fresh capital applied to the cultivation of the land, with all the improvements of modern husbandry. It is contrary to experience and to all reason to suppose that a good farmer will apply his skill and capital to improvement of another man's property, unless he has the security that he will be remunerated.

The improvements which would follow from a good system of leasing would be the abolition of the evils which now exist in consequence of uncertain tenure and of bad leases. It is affirmed by the best authorities that the amount of capital which is now applied to the cultivation of the land in England is very inadequate, that a large part of the farmers have not sufficient capital to improve their lands, nor the necessary skill and enterprise; and it is maintained that these evils are mainly owing to the want of a sufficient security of tenure or the want of a lease, or, where there is a lease, to the absurd restrictions with which many of them abound.

It has been said, and truly enough, that there is no advantage to the landlord in granting a lease to bad cultivators, and that there are many such. Such a lease would not indeed be any advantage to the farmer himself or the community in general; but he who has land to let, and will let it on terms that are mutually profitable to the landlord and the tenant, will be much more likely to get a tenant of competent skill and capital than he who gives the farmer an uncertain tenure or binds him in the fetters of a bad lease.

The preservation of the game and the enjoyment of the pleasures of the chase, or of the profits derived from the wild animals, is another object which some landlords secure by their lease with as much minuteness and strictness as they do their rent. [GAME LAWS, P. C. S.] Thus, in addition to getting a rent from his land, the landlord often wishes to command the votes of his tenant and secure his game. With reference to these objects and certain other imaginary advantages which he purposes to secure by directing the mode of cultivation, he has a lease drawn up with conditions, restrictions, penalties, and feudal services, which no care on the part of the farmer can prevent him from breaking in some particular, and which no man of capital, skill, and independent feeling would consent to sign. Specimens of such leases have been printed and circulated. One of them appeared in the 'Leicester Chronicle' for June 28, 1845. This lease prescribes a mode of cultivation which is absolutely inconsistent with good farming. The landlord in such a lease directs the tenant how he must cultivate the land. If the directions which the landlord gives comprehended the best modes of cultivation, they would be unnecessary if he had a good tenant, and they would not be observed by a bad one. A good tenant with sufficient capital will farm the land according to the system best adapted for the land, and he will be ready to avail himself of all improvements. A bad tenant, whether he has capital or not, will not farm well simply because he is prevented from doing some things and bound to do others; for farming, like other matters, consists not only in doing a thing, but in doing it well. These conditions and restrictions, if enforced at all, can only be enforced by constant supervision, and must be an endless source of trouble and dispute.

But these farming leases are often copies of old leases, made in other days, and are unsuited to the present state of agriculture. The things which they require not to be done and those which they require to be done, are often inconsistent with good agriculture, or, in other words, they prevent the land from yielding that amount of produce which it would yield under the best system, not only without thereby being impoverished, but with the certainty of permanent improvement. Ignorance on the side of the landlord of his true interest is one of the reasons why many of these absurd leases still exist.

There can be no principle in the letting of land, if the object is simply to secure the best rent to the landlord and the permanent improvement of the land, which makes it different from the letting of any other piece of property. The good farmer hires land to cultivate, with the hope of deriving profit from the application of his skill and capital. He does not want the advice and direction of another man: he trusts to himself. The first object of the landlord is to get as much rent as his land is worth, and to secure it against deterioration during the tenant's occupation. The terms of the lease, then, should simply be, the payment of the rent agreed on, and the observance of such conditions as are found by experience and known to practical agriculturists to be necessary to secure the permanent value of the landlord's land. It is admitted by all reasonable people that the landlord should have ample security by the lease for his land being given up to him at the end of the lease in as good condition as he gave it to the tenant. The tenant wants no directions from the landlord, and no conditions in his favour, beyond the simple condition of being allowed to cultivate the land in the best way that he can for his own profit during a period sufficiently long to secure him a return for his outlay; and he acknowledges that he must submit to all conditions in favour of the landlord which are not inconsistent with his free cultivation, and which shall secure the permanent value of the landlord's property. Perhaps many landlords who now grant hard leases would admit this general principle: but when they came to details, they would insist on many conditions as necessary to secure their permanent interest, which a good farmer would object to as not necessary for that purpose, and also as inconsistent with his profitable cultivation.

The framing of such a lease as we have described in general terms, must be the joint work of intelligent and liberal landlords and of good tenant farmers. It may require some time, some more experience, and suggestions from many quarters before such a lease is got into the best form. But it is an object worth the consideration of all persons interested in the cultivation of the land, and the attempt has been made already. We have received a copy of such a lease from the Vale of Evesham Agricultural Association, which has been circulated for the purpose of obtaining the suggestions of competent persons.

It has been said that some farmers do not care for having long leases; they are willing to go on as they have done. But can it be shown that there is a number of intelligent farmers with capital who prefer a yearly tenure to a lease of reasonable length? Besides, some of these agreements for a tenancy from year to year contain restrictions almost as numerous and absurd as those in leases for a term of years. If there are farmers who prefer dependence to the independence which is the result of a fair contract between farmer and landlord, these are not the men to improve our agriculture; these are the men with little capital, and less skill, who have no hopes of improving their condition, who rely on the easy temper or good-nature of an indulgent landlord, and are taught that they and their labour must be protected from foreign competition. The intelligent farmer with capital seeks no protection against the foreigner, and wants no indulgence from his landlord. He is ready to give, and he would be compelled by competition to give, to the landlord the full value for the use of his land, and he would ask for no more than the liberty of cultivating it in the best way.

Before, however, a good farmer could enter on the land with full confidence, he would have one favour to ask of his landlord; and that would be, not to protect him. If he wanted beans or oats to feed his cattle with, to increase his manure and so increase his crop of corn, he would ask the favour of buying them where he could get them cheapest, in order that he might have a greater return for his outlay, and so better pay his rent, or even an increased rent. Under the protective system [CORN LAWS, P. C.] a man who is protected, as it is termed, in one thing, is taxed in another: he may be protected in what he has to sell, but he must pay for that protection by being taxed in what he has to buy. The farmer in one part of the kingdom wants something that he does not produce: but it is produced in another part of the kingdom. Both parts are protected in what they produce, that each may be compelled to buy of the other; and each is taxed in what he buys in order that the other may be protected. Thus the legislature interfere with the prices of things. They do not impose a tax on foreign produce that comes into the kingdom simply with the view of getting revenue from it; they profess to interfere in order to keep up the prices of certain commodities that are produced in the kingdom. They profess to regulate within certain limits the prices for which the farmer must buy and sell his agricultural produce: they profess to do it; but everybody who knows the history of the corn laws knows that they cannot do it, and never have succeeded in the attempt. But they have succeeded in breeding up a race of farmers, and of landlords too, who believe that their true interests are best consulted by the government attempting to raise the prices of all agricultural produce, both that which a farmer buys and that which he sells. As matters stand now, it is thus:—We have a landlord who by his lease directs his tenant how to cultivate, and at the same time reserves the power of walking over his ground when he pleases to kill the game which the farmer must not kill, but which he must feed; a tenant with deficient capital and insufficient skill, and the shackles of a restrictive lease, or an agreement for a lease which constitutes a tenancy from year to year; and a legislature which interferes with prices and shuts out the farmer as well as others from buying in the cheapest market whatever agricultural produce he does not raise himself. Then there is a cry of agricultural distress, and when the ablest man in the House of Commons asks for a committee of inquiry into the cause of this distress, those who complain of the distress will not have the inquiry.

It has been shown [AGRICULTURE, P. C. S.] that all duties levied on agricultural produce that is brought into these kingdoms, are protective duties, however small they may be. He who disputes this proposition is inaccessible to the cogent power of reason. He who admits it, and contends for the system, must contend that on the whole it does more good than harm. But the system continues, and we still hear of agricultural distress, so that the system at least does not prevent agricultural distress. Those who have handled the subject best attempt to prove, and we believe that they have proved, that the system causes agricultural distress, and that it is the chief obstacle to improved cultivation of land, the granting of good leases, the employment of fresh capital in the cultivation of land, and the employment of agricultural labour. All these subjects were urged by Mr. Cobden, in the House of Commons (1845), in a speech, when he moved for a select committee to inquire into the extent and cause of the alleged existing agricultural distress, and into the effects of legislative protection upon the interests of landowners, farmers, and farm-labourers—a speech unequalled for perspicuity of statement, practical knowledge of the subject, clearness of expression, and sound argumentation; a speech which would place Mr. Cobden, if he had not already earned that distinction, among the very few men who have views at once comprehensive and sound enough to entitle them to the honour of directing the affairs of an industrious people.

The covenants contained in a lease, however few they may be, often occasion difficulty and dispute upon the expiration of the tenancy. The landlord may often claim more than his due, and the tenant may be disposed to do less. These difficulties are not peculiar to farm tenancies; they occur continually in the case of dwelling-houses let for a term of years upon the condition of keeping them in good repair. If such disputes cannot be settled amicably, or by reference to arbitration, the only way is by legal proceedings. It has been suggested that in the case of dwelling-houses in large towns like London, some easy mode of finally settling such disputes might be established. In such cases, the evidence of surveyors is the evidence on which a jury must give their verdict in case of legal proceedings; and it would be quite as satisfactory to all parties, if the evidence that is submitted to a jury, for their judgment, were submitted to a few competent persons to be chosen in some uniform manner, and whose decision should be final.

In 1845 an act was passed (8 & 9 Vict. c. 124) entitled 'An Act to facilitate the granting of certain Leases.' Its object is to substitute abbreviated forms for those now in use, and it is provided that in taxing any bill for preparing and executing any deed under the act, the taxing officer, in estimating the proper sum to be charged, is to consider 'not the length of such deed, but only the skill and labour employed, and the responsibility incurred in the preparation thereof.' It is enacted in section 4, 'That any deed or part of a deed which shall fail to take effect by virtue of this act shall nevertheless be as valid and effectual, and shall bind the parties thereto, so far as the rules of law and equity will permit, as if this act had not been made.' There are schedules to the act, one of which gives, in column 1, short forms of expression which may be used in place of the ordinary expressions in leases, which are contained in column 2; and it is enacted by section 1, 'That whenever any party to any deed made according to the forms set forth in the first schedule of this act, or to any other deed which shall be expressed to be made in pursuance of this act, shall employ in such deed respectively any of the forms of words contained in column 1 of the second schedule hereto annexed, and distinguished by any number therein, such deed shall be taken to have the same effect and be construed as if such party had inserted in such deed the form of words contained in column 2 of the same schedule, and distinguished by the same number as is annexed to the form of words employed by such party; but it shall not be necessary in any such deed to insert any such number.' This act does not extend to Scotland. The amount of words saved by this act is not sufficient to compensate for the difficulties that may arise from persons using the abbreviated forms in cases where they may not intend them to have the full meaning which this act gives to them. He who wishes to guard himself either as landlord or tenant by suitable covenants will do better to express his meaning at full length, without availing himself of the abbreviated forms which this act invites him to use.

Leases in general require either an ad valorem stamp or the common deed stamp, without which the instrument cannot be given in evidence. Leases for a term determinable on a life or lives not exceeding three, and the leases of all ecclesiastical corporations, whether aggregate or sole, for any term not exceeding twenty-one years, are exempted from the duty. There is also a stamp duty on agreements for leases. This is one of the many modes of taxation.

LEATHER. An account of the chemical processes by which the skins of animals are converted into leather is given under TANNING, P. C., p. 37; and under LEATHER, P. C., p. 379, are some statistical statements respecting the leather manufacture. The present article treats of the subject of currying and leather-dressing.

In an interesting lecture 'On Tanning and Leather-dressing,' read by Mr. Arthur Aikin before the Society of Arts in 1830, and published in the fiftieth volume of the Society's 'Transactions,' pp. 192-214, is a notice of the principal kinds of skin which are converted into leather, and of the chief uses to which each kind is applied. From this we may condense a few particulars illustrative of the wide range of the leather manufacture, from which it will be seen that the processes followed in its different departments must be exceedingly various. Commencing with the larger and thicker skins, Mr. Aikin observes that among those of *oxen*, technically known as *hides*, those supplied by bulls are thicker, stronger, and coarser in the grain than those of cows; while the hides of bullocks, or castrated oxen, are intermediate between those of the bull and the cow. He states that the thickest and most substantial leather now in use is that made from the hides of the half-wild cattle of South America. Such leather is employed for the soles of boots and shoes; for most parts of harness and saddlery; for making leather trunks, buckets, hose for fire-engines, and pump-valves; for the thick belts used in military accoutrements; and for the gloves of cavalry. The thick *buff-leather* formerly used as armour, and which was pistol-proof, and would resist the edge of a sword, was made from the hide of the urus or wild bull of Poland, Hungary, and the middle and southern provinces of Russia; the animal itself being called *buffe*, whence the common name of the leather made from its hide. The skins of *calves*, though thinner than those of cows, are thicker than most other kinds of skin which are converted into leather. They are *tawed* [TANNING, P. C., p. 40] for the use of bookbinders, and are tanned and curried for the upper leathers of boots and shoes. Aikin states that it was formerly customary, in the south-west of Ireland, to slaughter cows when in calf, and that the celebrated Limerick gloves were made of the exceedingly fine and delicate skins of the unborn calves. The practice is however, he adds, now almost discontinued, so that the superiority of the manufacture referred to must now depend rather upon peculiarities in the mode of preparing the skins than upon their original quality. *Sheep skins*, which are most commonly of home growth, although Aikin refers to a considerable supply as coming from the Cape of Good Hope, vary much in quality. 'A long fleece, observes our authority, 'always indicates a thin skin; much of the jelly laid up in that organ being, perhaps, the material from which the fleece is elaborated;' to which he adds the important practical remark that 'as soon as a sheep has been sheared the air comes in contact with the cuticle, checks the perspiration and expenditure of the skin, and allows the jelly to accumulate; which it does so rapidly that, if a parcel of sheep encumbered with long fleeces are driven up to London from the distance of a few days' journey, and if part of them are slaughtered immediately on their arrival, and the remainder are sheared and slaughtered two days afterwards, the skin of the latter will be twice as thick as that of the former.' When simply tanned, sheepskins are employed for inferior bookbinding, for leathering bellows, and for various other purposes for which a cheap leather is required. All the *whit-leather*, as it is termed, which is used for whip-lashes, bags, aprons, &c., is of sheepskin; as are also the cheaper kinds of *wash-leather*, of which brushes, gloves, under-waistcoats, and other articles of dress are made. Mock or imitation morocco, and most of the other coloured and dyed leathers used for women's and children's shoes, carriage-linings, and the covering of stools, chairs, sofas, writing-tables, &c. are also made of sheepskin. *Lamb-skins* are mostly dressed white or coloured for gloves; and those of *goats* and *kids* supply the best qualities of light leather, the former being the material of the best morocco, of all colours, while kid leather, both white and coloured, affords the finest material for gloves and ladies' shoes. Leather from goat-skins, ornamented and sometimes gilt, was formerly used as a hanging or covering for walls. [TAPESTRY, P. C., p. 43.] *Deer* and *antelope* skins, shamoyed or dressed in oil [TANNING, P. C., p. 40], are used chiefly for riding-breeches. Shamoyed leather breeches were formerly very much used, especially in the army, and as English shamoyed leather was in high repute, it was used not only in the clothing of our own army, but also by the cavalry of Prussia, Austria, and most of the other German states. During the Peninsular war it was discovered that the health of the British cavalry was seriously affected in wet weather by their leather breeches, which, fitting close to the skin, and being long in drying, chilled the men, and rendered them liable to rheumatism and other diseases. Woollen cloth was accordingly substituted for shamoyed leather in this article of dress, first in the British, and subsequently in the Austrian and Prussian armies, and this change has effected a great decline in this branch of the leather manufacture. *Horse-hides*, which, considering their size, are thin, are tanned and curried, and are used by the harness-maker, especially for collars; and occasionally, when pared thin, for the upper leathers of ladies' walking shoes. *Dog-skins* are thick and tough, and make excellent leather; but Aikin observes that as the supply is entirely of home growth, and has fallen off so much of late years as to be nearly extinct, dog-skin leather has been in a great measure superseded, as a material for dress shoes, by horse leather and by tanned rat-skins. *Seal-skins* produce a leather similar but inferior to that supplied by dog-skins; and *hog-skins* afford a thin but dense leather, which is used exclusively for covering the seats of saddles. 'It comes,' Aikin states, 'from Scotland and Yorkshire; for, though hogs are abundant in every part of the country, the general custom of cooking pork with the skin on greatly restricts the supply.'

Referring to TANNING, P. C., for an account of the processes by which hides and skins are converted into leather by tanning, tawing, or shamoying, we may here notice some important observations on the subject quoted by Dr. Ure, in the 'Supplement' to his 'Dictionary of Arts' (art. 'Leather,' p. 147), from a communication made by Mr. Lee to the Franklin Institute, in February, 1843. Mr. Lee expresses his belief 'that much of the original gelatine of the hides is never combined with the tannin, but is wasted; for he thinks that 100 lbs. of perfectly dry hide, when cleansed from extraneous matter, should, on chemical principles, afford at least 180 lbs. of leather.' He believes the usual mode of preparing the hides for actual tanning, called the liming and bating, or unhairing and cleansing, to be a wasteful process. As stated under TANNING (p. 37), this is usually done either by steeping the hides in a solution of lime, or by placing them in a close heated chamber until the epidermis is loosened by incipient putrefaction. Sometimes however the object is effected by a process termed sweating, which is employed in Germany, and consists in laying the hides in a pack or pile, covered with tan, to produce fermentative heat. All of these plans, but especially the two latter, are said to be injurious to the hides. 'The *bate*,' observes Dr. Ure, apparently in reference to a process analogous to that described in TANNING under the term *raising*, 'consists in steeping the haired hides in a solution of pigeon's dung, containing, Mr. Lee says, muriate of ammonia, muriate of soda, &c.; but most probably phosphates of ammonia and lime, with urate of ammonia, and very fermentable animal matter.' Dry hides are often softened by the operation of the fulling-stocks, which has the effect of opening the pores, before liming and bating; but when this is done, care must be taken that the fulling or beating be not too violent, in which case it would make the hide too limber and thin. Mr. Lee conceives that the liming process is injurious, by carrying off a portion of the gelatine and albumen of the skin; and it appears that leather which has been highly limed is loose in texture, weighs light, and wears out quickly. The subsequent fermentation in the bating process aggravates the evil ascribed to the liming. This evil however appears to be avoided in a process which has been adopted in New York, Maine, New Hampshire, and some parts of Philadelphia, which is called, somewhat incorrectly, *cold sweating*, and which consists in suspending the hides, previously soaked, in a subterranean vault with a temperature of about 50° Fahr., in which they are kept constantly damp by the trickling of cold spring water from points in the roof. After hanging thus for from six to twelve days, the hair is found to be well loosened by the mere softening effect of moisture, without fermentation. In quoting Mr. Lee's observations Dr. Ure makes no remark on the enormous amount of the increased weight to be gained in tanning, according to Mr. Lee's computation; or upon the circumstance that a great increase of weight by the addition of vegetable matter has been shown by himself [TANNING, P. C., p. 38] to be a disadvantage. In order to judge of the efficiency of any process of tanning by comparing the weight of the tanned with that of the untanned hide, the relative proportions of animal and vegetable matter in the finished leather must be known. In illustration of this very important point we may throw into a tabular form the results of an analysis of specimens of calf-leather tanned in various ways, as given by Dr. Ure in the 'Dictionary of Arts' (not the 'Supplement'), art. 'Leather,' p. 763:—

Mode of Tanning.	Parts in 100 by weight. Animal Matter.	Vegetable Matter.
Quickly, by an infusion of galls	61	39
,, by solution of catechu	80	20
,, by infusion of Leicester willow	74·5	25·5
,, by infusion of oak-bark	73·2	26·8
Slowly, by infusion of Leicester willow	87	13
,, by infusion of oak-bark	85	15

The time occupied in the first four cases of *quick* tanning is not stated, but in the *slow* process it appears to have been about three months. Dr. Ure adds that sole leather generally contains no less than 40 per cent. of vegetable matter. The inner white part of every astringent bark, or that which lies next to the alburnum, contains, according to this authority, the largest quantity of tannin, and the middle coloured part the largest quantity of extractive matter, while the outer surface or epidermis seldom furnishes either tannin or astringent matter; and as young trees abound most in the white cortical layers, it follows that they are more productive of tannin, in proportion to the comparative weight of the barks, than old trees. 'The different qualities of leather made with the same kind of skin,' Dr. Ure observes, 'seem to depend very much upon the different quantities of extractive matter it may have absorbed.' 'The leather made with infusion of galls,' he adds, 'is generally harder and more liable to crack than the leather obtained from infusions of barks; and it always contains a much larger proportion of tannin, and a smaller proportion of extractive matter.'

Currying is the general name given to the various operations of dressing leather after the tanning is completed, by which the requisite smoothness, lustre, colour, and suppleness is imparted, to adapt it to the various purposes of the shoemaker, the coach and harness maker, the upholsterer and others. The processes of the currier vary much according to the kind of leather on which he is employed, but Dr. Ure, who gives a description, illustrated by engravings, of the principal tools employed (*Dict of Arts*, art. 'Currying'), after stating that every kind of tanned leather not intended for soles, or such coarse purposes, is generally curried before being delivered to the workman who fashions it, divides the chief operations of the currier into four. Of these the first is styled dipping the leather. It consists in moistening it with water, and beating it well upon a strong hurdle of basket-twigs, or a kind of trellis-work of wooden spars, with a mallet, or with an instrument called a *mace*, which may be described as a large mallet with a cubical head, in two faces of which are inserted four egg-shaped pegs of hard wood, turned smooth and polished, that they may not tear the softened leather. After this beating, by which the stiffness of the hide or skin is destroyed, it is laid over an inclined board, and scraped and cleaned, and wherever it is too thick, pared or shaved down on the flesh side, by the careful application of various two-handled knives; and then thrown again into water, and well scoured by rubbing the grain or hair side with pumice-stone, or with a piece of slaty grit, by which means the *bloom*, a whitish matter which is found upon the surface in tanning, is removed. The second process, according to Dr. Ure's division, is the rubbing of the leather with a wooden instrument called the *pommel* (French, *paumelle*), which, he states, is so called because it clothes the palm of the hand, and performs its functions. It is a rectangular piece of hard wood, about twelve inches long and five broad, flat on the upper surface, which is provided with a leather strap, fastened at both ends, to secure it to the hand of the workman, and somewhat rounded or convex on the lower surface, which is covered with triangular grooves. The currier uses several of these instruments, with grooves of various degrees of fineness, and also, for some purposes, pommels of cork which are not grooved at all. In using the pommel, the object of which is to give grain and pliancy to the skins, the leather is first folded with the grain side inwards and rubbed strongly with it; and subsequently it is rubbed with the pommel upon the grain side, without being doubled or folded. Third in order he places the scraping of the leather with tools applied nearly perpendicular to its surface and worked forcibly with both hands, to reduce such parts as may yet be left too thick to a uniform substance; and he notices as the fourth operation the dressing of the leather with the *round knife* (French, *lunette*), a singular instrument shaped somewhat like a saucer, with a cutting edge, and with a hole in the centre for introducing the hands of the workman. It is usually from ten to twelve inches in diameter, with the central hole about four or five inches. This tool is applied with its concave side downwards, and with it, while the leather is stretched over a cylindrical wooden beam, the currier dexterously pares off the coarser fleshy parts of the skin. In addition to these operations, which cannot be minutely explained without entering too much into detail, the currier uses occasionally polishers of smooth wood or glass for rubbing the surface of the leather; and, when the leather is intended for the use of the shoemaker, he applies to it some kind of greasy composition called *dubbing* (daubing) or *stuffing*. This is frequently done before using the pommel, and Dr. Ure states that the oil used for the purpose is prepared by boiling sheep-skins or doe-skins in cod-oil. As, however, his account is less distinct than that of Hebert (*Engineer's and Mechanic's Encyclopædia*, vol. ii. p. 71), we shall follow the latter, premising that the description relates to the preparation of calf-leather for the uppers of boots or shoes. On receiving the calf-skins from the tanner, the currier first, according to this authority, removes the offal parts, such as the head, tail, and shanks, which operation is termed *rounding the skin*. It is then soaked, shaved, and scoured as above described, in the course of the second of which operations the currier frequently examines every part of the skin, testing its thickness by passing it double between his fingers. After being thoroughly cleansed, and distended while thus in a wet state, the skin is *stuffed*, Hebert states, 'with a mixture of two parts cod-oil and one part tallow, called *dubbing*, which is applied to both sides of the skin, but chiefly on the flesh side.' 'It is then,' he adds, 'hung up to dry, by which the moisture evaporates, and the oil, which cannot be dissipated by mere exposure, gradually takes the place of the moisture, and sinks deeply into the pores of the skin.' The use of the pommel follows this operation, and is succeeded by *whitening*, or lightly shaving the flesh side over again, by which it is thoroughly cleaned, and brought to a proper state to receive the colour used in waxing. Before waxing, however, it is boarded and rubbed with the pommel a second time, which brings it to the state of *finished russet*, in which state it can best be preserved until wanted for sale. In the operation termed *waxing*, a colour or blacking, composed of oil, lampblack, and tallow, is well rubbed into the flesh side with a hard brush, the grain side being carefully kept clean. A coat of strong size and tallow is then laid on with a soft brush, after which the surface is rubbed with a smoothing-glass The finishing gloss is given by a little thin size laid on with a sponge, after applying which 'the skin is laid up to dry and incorporate,' according to our authority, 'and a lump of hard tallow is rubbed lightly over the surface.' 'The skin is thus,' he adds, 'completely finished for the consumer; and leather so dressed is found superior in appearance and durability to any other method.'

Leather is occasionally dressed 'black on the grain,' or having the hair or grain instead of the flesh side coloured. The currying operations in such a case are similar to those above described, but the first blacking is applied to the wet skin immediately after scouring, by rubbing it with a solution of copperas. A brush dipped in stale urine is then passed over the surface, and an iron slicker is used to make the grain come out as fine as possible. It is then stuffed with oil, and, when dry, *seasoned*, or rubbed over with a brush dipped in copperas-water, on the grain, until it is perfectly black; after which it is slicked with a gritstone, to remove any wrinkles and smooth down the coarse grain. The grain is finally raised by repeatedly rubbing over the surface, in different directions, with the pommel or graining-board.

One of the most singular operations in the working of leather, which may be noticed here as an illustration of the peculiar properties of the material, and of the power of the currier over it, is the mode of covering the roofs and upper pannels of coach-bodies, of which an interesting description is given in No. 625 of the 'Penny Magazine,' in 'A Day at a Coach-factory.' In this operation, which is only performed upon the higher class of carriages, the whole of the roof and upper part of the front, back, and sides, is covered with a single hide, not cut into pieces, one for the roof, one for each side, and so on, but made to fit closely in every part to the woodwork without any joints or divisions, and without showing any folds or wrinkles. To accomplish this apparently impossible feat, the hide, which is very large, and of sound quality, is, to quote from the paper referred to, 'first thoroughly moistened throughout and thrown over the top of the coach, the edges hanging down on all sides. The currier then rubs or presses it down all over the roof, until it lies close and even in every part. He next proceeds to one of the sides, and in like manner rubs and scrapes the leather till all irregularities disappear. The leather is in that soft and pliable state that it will yield to the movement of the tools, and enable the workman to fit it to every part of the coach with perfect closeness.' 'A little consideration,' observes the writer, 'must show that a superfluous fold of leather will occur at each corner; yet by working it towards a central point at the back or front, the currier succeeds in crasing or pressing out all irregularities, and in producing a surface sufficiently flat and smooth for the subsequent operations of the painter.' The edge of the leather is cut or trimmed to the beading which divides the upper from the lower pannels. In many cases modern carriages have the roof only covered with leather, which is strained on wet, nailed, and left to shriuk.

Japanned leather of various kinds is used in coach-making, harness-making, and for various other purposes. Mr. Adams, in his treatise on 'English Pleasure-Carriages' (p. 69), states that what is ordinarily termed 'patent leather' is covered with a coat of elastic japan, which gives a surface like polished glass, impermeable to water; and that hides prepared in a more perfectly elastic mode of japanning, which will permit folding without cracking the surface, are called 'enamelled leather.' Such leather is usually made black, but may be produced of any required colours. 'All this japanned leather,' he observes, 'has the japan annealed, something in the same mode as glass: the hides are laid between blankets, and subjected to the heat of an oven at a particular temperature during several hours.' Boots and shoes are sometimes made of thin enamelled leather, and they possess the advantage of never requiring blacking, water being sufficient to remove any dirt which impairs their gloss.

Of the preparation of Morocco and some other kinds of leather which present peculiar features in their manufacture, a notice is given under TANNING, P. C.; we may here add an account of the manufacture of *Russia leather*, called by the Russians themselves *jucten*, which is usually dyed red with the aromatic saunders-wood, and is celebrated for being free from mould in damp situations, and not only being proof against insects, but repelling them by its odour, so as to preserve books in the binding of which it is used. The skins are freed from the hair or fleece by steeping them in an ash-lye, then rinced, fulled, and fermented in a proper steep, after having been washed in hot water, for a week or more, to *raise or open* their pores. They are then cleaned, by working them upon the horse, on both sides. They are then soaked for forty-eight hours in a bath composed of water mixed with a paste of rye-flour, in the proportion of 38 lbs. of flour to 200 skins, fermented with leaven. The skins, when taken out of the bath, are left in tubs for fifteen days, and then washed. Being thus prepared for the action of the astringent or tanning juices, they are immersed in a boiler containing a hot decoction (just sufficiently cooled to avoid injuring the animal fibres) of willow bark (that of the *salix cinerea* and *salix caprea*), in which they are handled and pressed for half an hour. This manipulation is repeated twice a day for a week, after which the tanning infusion is renewed, and the process is repeated on the same skins for another week, after which they are exposed to the air to dry, dyed, and curried with the empyreumatic oil of the bark of the birch-tree, for the preparation of which Dr. Ure, whose account we have followed, gives full directions (*Dict. of Arts*, p. 770). This oil, to which the leather is indebted for its peculiarities, is applied only to the flesh side, and care must be taken to prevent its passing through and staining the grain side. Chevreul, having investigated the odoriferous matter of this oil, has given it the name of *betuline*.

Shagreen, a peculiar kind of leather, or rather of prepared skin, formerly much used for the covers of watch-cases, mathematical-instrument cases, &c., is briefly noticed under that head in P. C., p. 335, but the accouut there given does not altogether agree with those of Aikin and some other authorities. From Aikin's lecture, referred to at the commencement of this article, and Hebert's 'Engineer's and Mechanic's Encyclopædia,' vol. ii. p. 75, it appears that the skin, after being soaked in water and scraped to remove the hair, is further scraped until it does not exceed a wetted hog's bladder in thickness. It is then, while wet and soft, stretched upon a frame, and the grain side is strewed with the hard round seeds of the alabuta, or goose-foot (*chenopodium album*). A felt being laid over these, they are trodden deeply into the soft yielding skin, after which the frames are so situated in the shade as to allow the skins to dry slowly, when the seeds may be shaken out without violence, leaving the skin in a hard horny state, covered with deep indentations. The surface is then rasped or rubbed down with iron tools, nearly to the bottom of the holes or indentations, the skin being, during this operation, laid upon a block covered with wool. The skins are then softened, first with water, and then with a warm alkaline ley, and are heaped, while warm and wet, upon each other; and by this softening the depressed parts of the skin rise to their former elevation, forming prominent points wherever depressions had been made by the seeds. The skins are then salted and dyed, after which, according to Hebert, they are finished with oil or suet. That writer states that 'the beautiful green dye is given by soaking the inner or flesh side of the skin with a saturated solution of sal-ammoniac, strewing it over with copper-filings, rolling it up with the flesh side inwards, and pressing each skin with a considerable weight for about twenty-four hours; in which time the sal-ammoniac dissolves enough of the copper to penetrate the skin with an agreeable sea-green colour: this is repeated a second time, in order to give the colour more body.' 'Blue shagreen,' he adds, 'is dyed with indigo, dissolved in an impure soda by means of lime and honey. Black shagreen is dyed with galls and vitriol.' Aikin, evidently referring to a more ornamental variety of shagreen, instead of giving the above directions for dyeing, says that the skin is stained superficially only, of a green colour, with copper-filings and sal-ammoniac, and then dried; and that it is finally rubbed down to a perfect level, when the points that were prominent, being deprived of their superficial colouring, appear as white dots scattered over, and gradually melting into a green ground. The shagreen thus prepared is susceptible of a high polish, and is both beautiful and durable.

Great difficulties present themselves in the way of any application of machinery to the dressing of leather, in consequence of the varying hardness, thickness, and texture, not only of different skins, but of different parts of the same skin; yet the great amount of time and manual labour involved in the polishing and graining of morocco and other ornamental leathers has led to some ingenious contrivances for this purpose. Hebert contrived what he describes as the earliest machine for the finishing of leather, for which he obtained a patent, and which had been in use about twenty-five years when he published his 'Engineer's and Mechanic's Encyclopædia,' in 1839. This machine consists essentially of a stiff circular frame or wheel, eight feet in diameter, revolving horizontally upon a vertical axis, and carrying, on the under side of its periphery, a series of circular polishers or grainers, which are capable of being changed according to the nature of the work to be performed. These, as the apparatus revolves, pass over a series of eight tables, circularly arranged, and mounted upon elastic bearings. The skins to be operated upon are laid upon these tables, each of which is attended by a man who lays the skin smoothly upon it, and moves it about from time to time, so as to bring every part in succession under the revolving tool; but as no elasticity of mounting could counteract the difficulties arising from the varying substance of the skins, each table is further supported by a lever, to one end of which is attached a treadle, on which the workman can place one or both feet. The effect of this arrangement is that while both hands are left at liberty to manage the skin, a greater or less pressure can be given at pleasure by the operator, while, by entirely removing his foot from the treadle, the table may be caused to fall just clear of the rubbers or polishers, so that the skin will not be touched at all by them. That portion of the surface of the table upon which the rubbers operate is formed of brass, and adjusted to a very perfect level by screws, and its edges are slightly bevelled off to prevent the rubbers from *striking* the skin injuriously as they come in contact with it. To obviate the comparatively trifling defect arising from the circular instead of rectilinear action of the rubbers, Mr. Joseph Ellis contrived a similar machine, which is also described by Hebert, in which the rubbers were attached to the periphery of a vertical wheel about thirty inches in diameter, and the skin was laid upon a concave table accurately fitted to the path of the rubbers; but the serious practical objections to such a contrivance are evident. Hebert did not know whether it had been brought to work with advantage or not.

Leather-splitting machines, by which even very thin skins may be divided into two thicknesses, each of which is capable of being dressed as a perfect skin, have called forth much ingenuity of contrivance. Illustrated descriptions of several such machines are given by Hebert, and of one, different to any mentioned by him, in Dr. Ure's 'Supplement.' Before such machines were introduced the reduction of thickness necessary to bring many of the finer kinds of leather to the requisite tenuity was effected solely, as it still is partially, by paring or shaving the flesh side with a knife worked by hand, an operation occupying much time, and requiring great nicety to prevent cutting through the skin. The part shaved off, also, being necessarily in small pieces, was only available for the making of glue. By the use of a machine the best portion of the leather, that with the grain side, is cut of a much more uniform thickness, and with less risk of injury; the removed portion is taken off in a more useful form; and the whole operation is conducted more rapidly. Hebert states that, to show the capabilities of a splitting-machine long used by the Messrs. Bevington, of Bermondsey, it has been made to split sheep-skins into three equal parts, one of which, that on the grain-side, might be used as leather, the middle portion converted into parchment, and the slice on the flesh side, being unequal in thickness, and therefore unfit for any better use, being used for glue-making. In this machine, which is also represented and described in No. 652 of the 'Penny Magazine,' the skin is drawn between two revolving rollers, and presented, as it emerges from their grasp, to the edge of a long and very sharp knife, which is kept continually moving a little backwards and forwards with great velocity. As a skin of unequal thickness could not be grasped in the proper manner between two perfectly true and rigid rollers, the upper roller, instead of being solid, is composed of a number of circular discs or rings of metal, about half an inch thick, slipped on to an axis rather smaller than the holes in their centres, but compelled to revolve with it by means of what may be termed a planetary axis, which is a rod passing loosely through holes in the whole series of discs between their centre and their circumference, and so connected with the axis by its ends as to be carried round with it. By this contrivance the upper roller is enabled to adapt its surface to that of the skin, which is everywhere pressed with an equal force, due to the weight of the discs of which the upper roller is composed. It is stated in the 'Penny Magazine,' that this machine will split a sheep-skin of the ordinary size in about two minutes, during which time the knife makes from two to three thousand vibratory motions to and fro. This machine, according to Hebert, is the invention of Lieutenant Parr. In the machine described by Dr. Ure, and in some others, the knife is stationary, and the cutting is occasioned by the application of a steady force by which the skin is drawn against its cutting edge; and in Duxbury's patent skin-splitting machine the knife consists of a series of plates of steel so attached to the periphery of a wheel or disc seventeen feet in diameter as to form a gigantic cutting-instrument resembling a crown or trepan saw, the compound blade projecting horizontally from the rim of the wheel, parallel to its axis. The skin to be split passes round the circumference of a horizontal drum, the axis of which is at right angles with that of the great disc, and lies very nearly in the same plane with its face, and which, instead of being perfectly cylindrical, has its sides so hollowed as to present a concavity perfectly tallying with the curvature of the periphery of the disc. As therefore the drum revolves, it brings the skin, which is confined closely to its concave surface by a contrivance somewhat resembling the upper roller in the machine above described, in contact with the edge of the revolving knife, which cuts by a continuous onward movement, instead of a sawing action backwards and forwards. The extreme nicety required to fix the concavity of the feeding-roller to the edge of the circular knife, and to keep the knife or cutter itself perfectly true in shape, appear to be the chief objections to this ingenious contrivance.

We may close this article by referring to some practical remarks on the choice or purchase of leather in the second part of Mr. Devlin's work entitled 'The Shoemaker,' in Knight's series of 'Guides to Trade,' premising that the subject of his complaint in reference to English leather is likely to be, if it be not already, materially affected by the very great reductions of duty upon foreign leather and leather manufactures under the tariff of 1842, and the still further reductions proposed in the government measure now (February, 1846) under discussion. After some remarks tending to prove a great deficiency of knowledge not only among shoemakers, but even among tanners and curriers themselves, respecting the qualities of leather, Mr. Devlin quotes from a pamphlet printed by himself for circulation among the London trade, on the 'Boot and Shoe Trade of France, as it affects the interests of the British Manufacturer,' the following remarks:—'If we look,' he says, 'to the nature of our leather, to almost every description of our leather, excepting that used for the soles, we shall find the article not so good—so intrinsically good—as that which the French boot and shoemaker can purchase; and what is more pertinent to the matter is, that formerly it was not so; when a greater time and a more honest consideration were paid by both tanner and currier to the production of the highest degree of wholesomeness, superadding beauty of grain, a perfect blackness and polish, as mere graces, rather than being the only necessary perfections.' 'But what,' he adds, 'cares the manufacturer? He gets his work done rapidly, and, in consequence, *cheaply*; and being, as he is, protected from the full effects of French and other competition, by the 30 per cent. importation duty, and likewise, through this circumstance, feeling himself secure of the commands of the home boot and shoemaker, he goes on in his cupidity, hurrying and driving through as much business as he can, safe in his own interests, and never pestered, hurt, and insulted by those complaints which the less fortunate and apparently more responsible shoemaker is every day or hour under the compulsion of submitting to from the consumer, about the leather breaking, tearing, or cracking, or of its pressing on the foot with the severe hardness of an uncomplying piece of wrought-iron.' After some remarks indicative of his confidence in the ability of British manufacturers to excel in ordinary boot and shoe leathers, as they confessedly do in some other kinds, he further observes that 'were the same substance of leather to be wrought generally into boots and shoes by the British manufacturer as is wrought into boots and shoes by the French manufacturer, the imperfection would be still more glaring; and hence we are often compelled into clumsiness, to make the coarse and unsightly that we may produce the serviceable, and so save the pocket at the expense of the taste and the wish for more pliant and pleasurable wear.' 'Our roans too,' he proceeds, 'with which we line our boots and shoes, can bear no comparison with the roans of our neighbours; they are in many cases so hard and stiff with the remains of the unextracted gelatine matter of the skin, and are so scoured on the grain with various chalks and pigments to produce the requisite surface, that the awl or needle in working is continually being thrust into many loose fibres, thus rendering the work not anything like so agreeable or so perfect as it ought to be. Add to which the quick manner in which such lining dirties and roughens in the keeping of the shop, and in the use of the customer.'

In purchasing dressed leather, Mr. Devlin recommends the shoemaker to take care that it be not of too large growth for its substance, and that, if waxed calf, it have 'a free easy grain,' and 'a fine flesh, not ruffling into hairs, but, when bent inwardly a little, discovering a series of diminutive ridges or curls,—a pretty correct token that such leather has not been taken down too deeply.' 'It should always,' he says, 'be silky and soft to the feel, not rank with grease, but yielding and smooth from the manner it has been wrought.' Skins freshly curried should not be bought for immediate use, 'all calf or other oil-dressed leather being the better to be laid by, skin over skin, for a month or two before they are cut; leather in this condition, as the phrase is, *fattening*, and thereby attaining a more durable character.' 'The qualities of sole leather,' which is generally better in England than in any other country, are, according to the same writer, 'defined by its closeness, weight, and, when cut, by the uniform healthiness of hue it offers to the sight; badly tanned hides being generally streaky, black, brown, grey, and green.'

Hebert describes two compositions which have been patented as *substitutes for leather*. Of these, Gunby's, patented in 1824, consists of an elastic coating or varnish of glue-size, boiled linseed oil, lampblack, white lead, and pipeclay, varying in proportions according to the degree of elasticity required, spread upon cotton, linen, or woollen cloth, or upon felt; while Hancock's consists of a felted fabric of flax, cotton, or other material, covered with several coats of liquid caoutchouc. Gunby's patent substitute is chiefly intended for the manufacture of patten ties, but is suitable also for covering coach-tops, and for some other purposes.

LECANO'RA. [Liverworts, P. C. S.]

LECTURES, COPYRIGHT IN. [Copyright, P. C. S.]

LEDUM, a genus of plants belonging to the natural order Ericaceae. It has a minute 4-toothed calyx, 5 spreading petals, from 5 to 10 stamens, anthers opening by two pores at the apex. The capsules are subovate, 5-celled, 5-valved, stalked, and dehiscent at the base. The seeds are furnished with a membranous wing at each extremity.

L. latifolium is a small evergreen shrub, with an irregularly branched stem. The branches and under surface of the leaves are woolly; the calyx is very minute; the corolla white, with obovate obtuse petals. It has been commended as a stomachic; but an infusion of the leaves in beer renders it unusually heady, and produces headache, nausea, and even delirium. Pallas however says that they have been used with advantage in tertian agues, dysentery, and diarrhoea. They have an aromatic bitter flavour. This species is a native of the swamps around Hudson's Bay, Labrador, Greenland, and various parts of the United States.

L. palustre has linear leaves, with revolute margins, clothed with rusty tomentum beneath; it has 10 stamens, longer than the corolla. It is a native of North America, in the swamps of Canada and New York, also the North of Europe, Denmark, Silesia, &c. *L. palustre* has somewhat similar properties to those ascribed to the former species. In Germany a kind of beer is made from its leaves, and it has also been recommended as a febrifuge. This species was formerly admitted into the catalogue of British plants; but Mr. Babington considers that it has no claim to appear there, and has omitted it accordingly.

L. Canadense has ovate petiolate leaves, white beneath; the flowers disposed in terminal large umbellate corymbs of a white hue. It is native of the swamps of Canada. A peat soil or a very sandy loam answers best for the cultivation of the species of Ledum, and they are readily propagated by layers or by seeds. The seeds should be sown, and the seedlings afterwards managed in the same manner as the Rhododendron.

LEEK. [Allium, P. C.]

LEFEBVRE, FRANÇOIS JOSEPH, Duke of Danzig, and Marshal of France, was born of humble parents, at Ruffach, in Upper Alsace, on the 25th October, 1755. He was designed for the ecclesiastical profession, but having lost his father, he enlisted, when eighteen years of age, as a private soldier in the regiment of French guards. He had attained the rank of sergeant-major when, on the breaking out of the French revolution, that regiment was dissolved. The changes which then took place in the government of France removed those obstacles which prevented the promotion of meritorious soldiers who were deprived of the advantage of noble birth. Lefebvre obtained the promotion which his talent and services deserved, and in 1792 he became a captain of his regiment. In that capacity he was enabled to render some valuable assistance to the unfortunate family of the dethroned King Louis XVI., and on two occasions he gallantly interposed in their behalf, and, at the peril of his life, rescued them from an infuriated populace. His subsequent rise in the army was without precedent rapid, even at that period: on the 3rd of September, 1793, he became adjutant-general; on the 2nd of December, in the same year, he was a general of brigade; and on the 10th of January, 1794, he rose to the rank of a general of division. While serving with the army of the Moselle, he distinguished himself at the combat of Lambach, and in the battle of Giesberg. During the whole of the campaign in Germany and the Netherlands, under Pichegru, Moreau, Hoche, and Jourdan, he made himself conspicuous for his skill and courage. In 1796, when the French army under General Kléber had passed the Rhine [Kleber, P. C. S.], the Austrians, finding themselves compelled to retire from Uckerath, had entrenched themselves, twenty thousand strong, on the heights which surround the small town of Altenkirchen. Their formidable position was attacked on the 4th of June by Kléber, who formed his army into two divisions, the first of which, the advanced-guard, he placed under Lefebvre. The brunt therefore of the assault fell on that division, which boldly charged the enemy at the point of the bayonet, and, in spite of a most vigorous resistance, compelled them to retire in disorder, leaving behind them four standards, twelve pieces of cannon, and about three thousand prisoners. On the 25th of March, 1799, was fought the memorable battle of Stockach, in which Lefebvre acquired fresh renown; with only eight thousand men he resisted, for many hours, the attack of thirty thousand Austrians. For these eminent services however Lefebvre appears to have been but poorly rewarded, and there is extant a letter from him to the Directory at Paris, in which are contained the following passages, sufficiently characteristic of the poverty of France at that period:—'The definitive conclusion of peace,' he says in it, 'will enable the country to dispense with my services. I petition you therefore to assign me a pension which may maintain me in comfort. I ask not for carriage or horses, but only for bread. My services must be well known to you, and I shall not enumerate my victories; as for defeats, I have none to reckon.'

At the time when Bonaparte was placing himself at the head of affairs, the Directory, who supposed Lefebvre devoted to their cause, appointed him to the command of the guards of the Legislative Assembly; but, on the morning of the 18th Brumaire (October 14th), he attended the meeting of officers at Bonaparte's private residence, and cordially co-operated in their proceedings. He was also instrumental in extricating Lucien Bonaparte from his dangerous position in the stormy meeting of the Council of Five Hundred at St. Cloud. [Bonaparte, P. C.; Bonaparte, Lucien, P. C. S.] These important services were rewarded by the command of the seventeenth military division, whose head-quarters were at Paris.

In the year 1804 he was raised to the dignity of a Marshal of the Empire. He accompanied Napoleon the following year in the Austrian campaign, and in 1806 took an active part at the battle of Jena, where, though at that time upwards of fifty years of age, he fought on foot at the head of the guards.

In 1807 he was sent with an army of sixteen thousand men to invest Danzig, which was garrisoned by twenty thousand troops, besides a numerous militia, and the investment was completed on the 14th of March. A body of twelve thousand Russians were advancing to the relief of the besieged, and Lefebvre was compelled to divide his force, and to detach a portion of them to oppose the Russians. On the 15th of May a severe action took place between them and the French, when the latter, seconded by the troops of Marshal Lannes and General Oudinot, who had been sent by the Emperor to their assistance, successfully repelled nine Russian regiments, and a part of the Prussian garrison by whom they had been joined. On the 21st of May, preparations having been made for a general assault, the Prussian commander General Kalkreuth offered to accept terms of capitulation; the long resistance which this fortress, among the strongest in Europe, was still able to make, rendered these terms as favourable as could be expected. The garrison were allowed to retire with the honours of war, and to take with them their munition and baggage, on the condition of giving their parole not to serve during the space of one year against the French or their allies. On this occasion Marshal Lefebvre generously desired the two generals, who lent him so powerful an assistance, to join him in the honour of signing the capitulation, but with a similar generosity, they declined to share with him a triumph which belonged to him by so just a title. A few days after these events, Napoleon, who was desirous of reviving the high nobility in France, and to give additional lustre and more munificent rewards to the twenty-four grand dignitaries whom he had lately created, made Lefebvre duke of Danzig. This marshal being highly esteemed by the army, and his eminent services during the wars of the Revolution having acquired for him the gratitude and respect of every Frenchman, he wisely selected him as the first person on whom to confer the ducal dignity. The siege of Danzig indeed was one of the most brilliant triumphs of the Prussian campaign. Eight hundred pieces of cannon and immense magazines fell into the hands of the conquerors, and the capture of this important fortress not only secured the left flank and rear of Napoleon's army, but left to Prussia only the stronghold of Pillau along the whole coast of the Baltic. [Danzig, P. C.]

In the year 1808 Lefebvre joined the Peninsular expedition, and was appointed to the command of the fifth corps of the French army. On leaving, the Emperor had given him directions to keep the Spaniards in check till his arrival; but when employed in the province of Biscay, finding that the enemy were seriously harassing the flanks of his army, he gave them battle, and on the 1st of November triumphantly entered the town of Bilbao. His conduct however on that occasion appears to have given displeasure to Napoleon, as it interfered with his plan of operations. He was afterwards present at the battle of Tudela, where he had the command of the cavalry. [Lannes, P. C. S.]

In the German campaign of 1809 he rendered himself conspicuous as a brave soldier and an excellent tactician, at the battles of Eckmühl and Wagram, and in the dangerous warfare among the passes of the Tyrol. He was also with Napoleon in the disastrous expedition to Russia, and had the command of the old guard, which was however seldom called into action; but during the retreat he showed considerable military skill, and, for the most part, accompanied his corps on foot, sharing every suffering and exposing himself to every danger in common with the private soldiers.

During the campaigns of 1813 and 1814 he appears faithfully to have adhered to the declining fortunes of his master; and after the battle of Leipzig, when the remnants of the French army were called to fight for the defence of their native country, by none of his lieutenants was Napoleon more ably seconded than by Lefebvre. At the battles of Champ-Aubert (February 10, 1814), at Arcis-sur-Aube (March 20), and at Mont-Mirail (April 14), he displayed the same gallantry as in the more renowned but not more glorious fields of Jena, Tudela, and Wagram. It is however stated that Lefebvre greatly influenced the abdication of Napoleon, and at the first restoration of Louis XVIII. he was created Chevalier of St. Louis and peer of France. But on the return of his former chief from Elba, we find him again adhering to his fortunes, and accepting a seat in his Chamber of Peers, where however he held himself aloof from all discussions. (*Journal des Débats* of the 10th April, 1814.) At the second restoration of the Bourbons, he was excluded from the Chamber of Peers, to which he was recalled in 1819, having been a few years previously reinstated in his rank of marshal. He died at Paris on the 14th of September, 1820.

The private qualities of this distinguished general are perhaps more to be admired than his public character; it being difficult to reconcile his conduct, during the latter years of his life, with genuine patriotism. His manners evinced the modest simplicity of a soldier, who had risen by merit alone; his disinterestedness, which was proverbial, was rendered manifest by his leaving a widow so destitute, that she was obliged to sell her jewels in order to defray the expenses of a monument, which she generously caused to be raised to the memory of her husband in the cemetery of Père-la-Chaise. The character of this excellent woman, who was of most humble origin, may be best judged by a trait which Las Cases presents to us in his 'Memorial of St. Helena' (vol. iii. 393).

There was another well known general of Napoleon, the Count Charles Lefebvre Desnouettes, whose name has sometimes been confounded with that of Marshal Lefebvre. He was condemned to death on the second restoration of the Bourbons, but he was enabled to take refuge in the United States. He perished in a shipwreck on the coast of Ireland, as he was returning to Europe, on the 22nd of April, 1822.

(*Biographie Universelle, deuxième partie; Biographie Moderne; Dict. Hist. des Batailles;* Tissot, *Précis des Guerres de la Révolution*, Paris, 1821; *Mémoires de la Duchesse d'Abrantes*, Las Cases, *Mémorial de St. Hélène; Court and Camp of Napoleon.*)

LEFORT, FRANÇOIS, was the son of Jacques Lefort, member of the Grand Council of Geneva, in which city he was born in 1656. After having served as a cadet in the Swiss Guards in the service of France, and subsequently in a regiment belonging to the Duke of Courland, in the pay of the Dutch, he was induced to try his fortune as a military man in Russia, and obtained a captain's commission from the Czar Feodor or Theodore Alexiwich, and greatly distinguished himself in the wars with the Turks and the Tartars. Having in 1678 married Mademoiselle Souhai, whose father, a native of France, held the rank of lieutenant-colonel in the Russian service, he revisited his native country in 1682, but, staying only for a few weeks, got back to Russia in time to be in readiness for the crisis which occurred on the death of Theodore (P. C., xviii. 23). His abilities being well known, he was appointed by the Prince Galitzin, who governed the country under the Princess Sophia, in the name of her two brothers Iwan and Peter, one of the captains of a new body of troops raised to counteract the domination of the Strelitzes, or old national militia. In this capacity he first attracted the attention of the young czar Peter, in the early part of the year 1683; and on the 29th of June in that year he was raised by him to the rank of major. When, in 1689, Peter took refuge in the Troitski convent, Lefort was one of those who joined him there, and on the overthrow of the usurpation of Sophia, which followed, he became the chief minister of the emancipated emperor. Many of Peter's greatest plans are believed to have been suggested by Lefort; all the Czar's measures for civilizing and elevating his country found in him, at least, the most able and zealous of seconders and promoters. Holding at once the rank of general and that of admiral, Lefort was always equally ready for service by land or by sea; and his active and versatile faculties shone as much in civil affairs as in military. At last Peter lost this inestimable servant by his death at Moscow on the 12th of March, 1699: his health had been for some time declining, and a fever following upon the breaking out of an old wound carried him off. Peter lamented him as if he had been a brother. Lefort's moral nature appears to have been as admirable as was his capacity; considerations of self-interest were always postponed by him to the public good and the glory of his sovereign, and a noble contempt of everything mean or mercenary marked the whole of his career. He left a son, but he died at an early age. There is a Life of Lefort, in French, by Bassville; and there is a long article about him in the 'Biographie Universelle,' by Catteau Calleville, who refers to other authorities, and from whose account the above outline has been abstracted. See also Voltaire's 'Life of Peter.'

LEGACY DUTIES. [Probate Duties, P. C. S.]

LEGION OF HONOUR, an order of merit in France, instituted by Napoleon during the year 1802, as a recompense for military and civil services. This order consists of five divisions: *chevaliers*, of whom the number is unlimited, *officers*, *commanders*, *grand officers*, and *grand crosses*. The members swear fidelity to the king, to the charter, and to the laws. The ordinary regulations require twenty-five years' service during peace, and half that period during war, in a civil or military capacity, to be admitted to the first grade. But, in time of war, a brilliant exploit, or a severe wound, are deemed sufficient to qualify for admission into this order. This honour however is frequently granted to any distinguished person at the pleasure of the king. But to rise to a superior rank, it is considered indispensable for natives of the country to have passed through the inferior grades. To obtain the rank of officer it is necessary to have served four years as a chevalier; an officer must serve two years to become commander; a commander three years to become a grand officer; and, finally, to obtain the highest grade, which is that of grand cross, he must have served five years as a grand officer.

When a promotion takes place the king determines the number of decorations of each grade, and a distribution is made by the chancellor of the order in the following proportion, 40 to 40:—

2	to the minister of		Justice and Religion.
1	,,	,,	Foreign Affairs.
5	,,	,,	Home Affairs.
2	,,	,,	Public Works.
2	,,	,,	Finances.
20	,,	,,	War.
5	,,	,,	Marine.
1	,,	,,	Public Instruction.
2	,,	,,	Grande Chancellerie.
40			

On all public occasions certain military honours are due to persons decorated with this order, and, at all times, a soldier on duty is bound to present arms on seeing the decoration.

The following salaries are attached to the different grades: chevalier, 250 francs; officer, 1000; commander, 2000; grand officer and grand cross, 5000.

In the formation of this order, as at first designed by Napoleon, though of a strictly military nature, the honour was not restricted to military men alone, but was intended to be the reward of civil, scientific, and literary services. He wished, moreover, that the name which he gave it should imply its object, which was to form a body of the most distinguished citizens, specially bound together by the ties of honour and devotion to their country. The legion, which was to be composed of fifteen cohorts, was to be governed by a supreme council, composed of seven members, the three consuls, and four grand officers—the first of whom was to be chosen by the senate, the second by the legislative body, the third by the tribunate, and the fourth by the council of state. He likewise enacted that all military men, who had previously received honourable distinctions for their services by the republican government, should be, of right, members of the new order.

The proposition of the first consul, when presented to the legislative body and to the tribunate, met with a violent though not unexpected opposition. The representatives of the French nation could see in it nothing but a powerful weapon of military despotism, to be sooner or later wielded by one whose projects of absolute rule were beginning to be discovered. His brother Lucien, moreover, to whom the motion had been entrusted, by his imprudent zeal in urging its adoption, raised in the minds of many the idea that he was enforcing the interests of his family rather than those of the nation. Even in the council of state, which, by the nature of its constitution, was especially under the influence of Napoleon, it was deemed by some to be a most dangerous experiment, calculated to reanimate aristocratical feelings, and gradually to introduce the ancient régime; while others, among whom was the general Mathieu Dumas, were desirous that the institution should be restricted to military men. Among the representatives of the people, the general expediency of the institution itself was still more strongly combated than it had been in the council of state. 'Crosses and ribbons,' said they, 'are the pillars of an hereditary throne; they were unknown to the Romans when they conquered the world.' The first consul's reply to these different objections contains many observations strikingly put and correct. 'Such ideas,' he remarked, 'might be well adapted to the feudal ages, when the knights were accustomed to combat together, man to man, and the bulk of the nation was reduced to a state of slavery. But when the military system changed, it was then not prowess in war, but science and skill, which decided the fate of nations. In all civilized states military force must of necessity yield precedence to civil qualities. Bayonets must lower before the priest who speaks in the name of heaven, or the man of science who has obtained an influence by the ascendancy of his knowledge. Think not that it is as a general that I govern France; but because the entire nation believes me possessed of that ability in the direction of civil affairs so necessary to a ruler; without it I could not, for an instant, keep my ground.'—'France,' he continued, 'contains thirty millions of men, united together by the ties of intelligence, property, and commerce; what are three or four hundred thousand soldiers in comparison to such a mass? and, moreover, not only does a commander preserve his influence and ascendancy over the soldiers of his army chiefly in virtue of his qualities as a civilian, but, when his command ceases, he returns to the rank and position of a private individual. The natural tendency of military men is to carry every thing by force; the enlightened and educated civilian, on the other hand, elevates his views to the perception of the general good, and follows an opposite course of conduct. I have no hesitation in asserting that, if a preference is to be awarded to the one rather than to the other, it belongs to the civilian. If you divide society into two orders, soldiers and citizens, you create disunion into what should be but one body.'

Influenced by these arguments, a majority of the council agreed that the proposed honours should be extended indiscriminately to civil and military men of distinction. At length, after many an angry discussion, the project was passed into a law on the 29th Floreal (May 19th, 1802), in the national assemblies; in each of them, however, but by a small majority.

The Legion of Honour, though it undoubtedly seemed a forerunner to that new nobility which Napoleon, in after years, collected around his imperial throne, soon became an institution in the highest degree important to his interests, and popular among the nation. On the 24th of July, 1804, Napoleon distributed to the principal civil and military dignitaries of France the higher order of decorations. The splendid church of the Hotel des Invalides was the place appropriately selected for the distribution. He had not as yet given the decorations of this order to foreign courts; as a prelude to doing so, he bestowed it upon the venerable Cardinal Caprera, who, in his capacity of legate, represented Pope Pius VII. at Paris, and, to enhance the value of the honour, he, on that occasion, detached from his own neck the ribbon of the order, and placed it affectionately around that of the aged representative of a church with which France, through his instrumentality, had been happily reconciled. (Thiers, *Hist. du Consulat*, &c., b. xx.) [BONAPARTE, P. C.]

But a more imposing spectacle took place at the head quarters of the vast army which Napoleon had assembled at Boulogne, preparatory to his intended invasion of England. On the 14th of August, 1804, the festival of his tutelar saint, nearly eighty thousand men were drawn up on the slopes of a large natural amphitheatre, on the western side of the hill, on which is situated the so-called tower of Cæsar. An elevated throne was raised in the centre of this theatre, and the soldiers were drawn up as rays of a circle emanating from this throne as their centre; beyond them was congregated a countless number of spectators. At mid-day the emperor ascended the throne, amidst the din of military salutes and the acclamations of the crowd; near him was placed the famed buckler of Francis the First, while the decorations of the order about to be distributed were contained in the helmet of the illustrious Chevalier Bayard. He was surrounded by his brothers, by the chief functionaries of the empire, by the marshals and generals of his army. Amidst this proud array were to be seen the ancient standards of the republic, the witnesses of the victories of Rivoli, Arcola, and Marengo. In presence of all the assembly, Napoleon took the oath of adherence to the laws of this order and of his country first himself, and afterwards administered it to those around him; then, raising his voice, and addressing the veterans of his army, he exclaimed: "You also, soldiers, swear to defend, at the hazard of your lives, the honour of the French name, your country, and your emperor." This animating appeal was responded to by the deafening shouts of the mighty multitude. The distribution of the various decorations then took place, and this imposing ceremony was concluded by a general review of the whole army, whose ranks defiled before the imperial throne. Napoleon estimated at twenty-five thousand the decorations he had distributed during the ten years of his reign. This remarkable institution has outlived the fortune of its founder. Its benefits were appreciated by the Bourbons, who soon discovered that it was the most powerful means they could employ of increasing their popularity, and giving stability to their precarious position. It has been wisely adopted, and its utility has been increased, under the pacific reign of the house of Orleans. By its means the present king of the French has been enabled, at a comparatively small expense to the state, to conciliate the esteem and to reward the merit of the most deserving citizens. It has been placed on the breast of an Arago, a Guizot, and a Thiers, with equal honour, and as much applause, as it had been on those of a Ney, a Masséna, and a Lannes. It is to the credit of the French nation that, while no other people are perhaps so much under the influence of military renown, it would be difficult to mention the name of any other country where men of science and literature are more generally esteemed and rewarded.

But the benefits which have accrued to the French from this institution may be best described in the eloquent words of one of their living historians, in his history of the consulate and the empire. 'The institution of this order,' he says, 'dates scarcely more than forty years' existence, and it is now consecrated in the memory of the people, as if it had passed through the lapse of many ages; so much has it become in these forty years the reward of heroism, and of talent and merit of every kind; so much has it been sought after by the great and principal personages of Europe, those even who pride themselves the most on the honours of their ancestry. Time then, the best criterion of all institutions, has declared in favour of its worth and utility. Leaving aside the abuse which has occasionally occurred in the distribution of its distinctions, under the various governments which have succeeded one another, an abuse inherent in all rewards bestowed by man upon his fellow men, let us gratefully recognize what there was novel in plan, profound in design, and beautiful in execution in an institution whose object it was to place on the breast of the common soldier, or on that of the unassuming man of science, the same decoration which was destined to confer distinction on the commander-in-chief of armies, on princes, and on kings; let us recognise, in the creation of these honorific rewards, the most brilliant triumph of true equality, that equality which raises instead of abasing the minds of men; let us recognize, in short, that if to the great in civil or military life it might become a mere gratification of vanity, it was to the common soldier, returned to his domestic hearth, at once the pledge of honourable ease and a visible proof of his former prowess.' (Thiers, *Histoire du Consulat et de l'Empire*, vol. iii.)

The following statistical table will show the increase that has taken place in the members of this order, and also how liberally its honours have been distributed by the present king of the French. We are indebted for the latter part of these details to the prompt and kind investigation of two distinguished members of the Legion of Honour—the general Ocher de Beaupré, of the French artillery, and his nephew, Monsieur Théophile Ballaud, sub-prefect of St. Quentin.

In the year 1815, on the second restoration of the Bourbons, the entire number of members of all the different divisions of this order were 30,747. We have stated above the number which Napoleon estimated that he had distributed during his reign.

The following detail will show the increase during the reign of Louis Philippe.

	1831.	1833.	Nov. 9th, 1844.	Oct. 1st, 1845.
Grand Crosses	99	106	81	85
Grand Officers	183	195	201	215
Commanders .	726	825	833	911
Officers . .	4,056	4,475	4,482	4,759
Chevaliers . .	37,828	43,659	44,117	45,340
Total	42,892	49,260	49,714	51,310

Thus it appears that there has been an increase during fourteen years of 8418 members; the diminution in the highest decorations has probably arisen from the deaths of many of the old marshals and generals of the empire. Of the members in the year 1844, 29,843 received no pension, and 19,851 drew the salaries attached to the order. The revenue during that year was 7,000,000 francs, about £280,000, and the expenditure 6,897,728 francs, about £275,509. Our information respecting that year is derived from the French newspaper 'le Courrier de l'Europe' published in London.

A full account of this order and of its most distinguished members may be found in a work entitled 'Fastes de la Légion d'Honneur,' 4 vols. Paris, 1842 and 1844.

LEGITIMATION. [BASTARD, P. C.]

LEGUMINOSITES, a genus of fossil fruits, from the Isle of Sheppey. (Bowerbank.)

LEICESTER, OF HOLKHAM, THOMAS WILLIAM COKE, EARL OF. Thomas Coke, Esq., of Holkham, in Norfolk, great-great-grandson of Sir Edward Coke, the chief-justice, was in 1728 created Baron Lovel, of Minster Lovel, in Oxfordshire; and in 1744 Viscount Coke of Holkham, and Earl of Leicester. On his death without heirs male, in 1759, the titles became extinct, and the estates went to his nephew, Wenman Roberts, Esq. (the son of his sister Anne and her husband, Colonel Philip Roberts), who thereupon assumed the surname and arms of Coke. The subject of the present notice was his son, by his wife Elizabeth, daughter of George Chamberlayne, afterwards Denton, Esq., and was born on the 4th of May, 1752.

His father, who had been returned to parliament as member for the county of Norfolk at the general election in 1774, having previously sat for Harwich, for Oakhampton, and for the town of Derby, died in 1776; upon which his son succeeded him in the representation of the county. In a speech which he made at a dinner given to him in 1833, he stated that when he came forward on this occasion he did so with great reluctance, being no orator or politician, having just returned from abroad, and being attached to other pursuits. They told him however that if he would not stand, a Tory would be sure to come in; and upon this, he said his blood chilled all over him from head to foot, and he resisted no longer. This horror of Toryism, or of what he imagined that term to mean, constituted nearly the whole of Mr. Coke's political system to the end of his life. He was returned again for Norfolk at the next general election in 1780; but after the dissolution in March, 1784, he was one of the numerous supporters of the late unpopular Coalition Ministry, who were thrown out, and who received the name of Fox's Martyrs. He recovered his seat however in 1790; and he was also rechosen without a contest in 1796 and in 1802. At the next general election, in 1806, he was returned by a majority of 4118 to 3772 over Mr. Windham, but was unseated by a Committee of the House; upon which he was elected for the town of Derby, and his younger brother, Mr. Edward Coke, who had vacated his seat for that borough, took his place as member for Norfolk. At the next general election, in 1807, Mr. Coke became again member for that county, which he continued to represent down to his retirement from the House of Commons in 1832.

Mr. Coke, though a keen and steady partisan, was not a frequent speaker in parliament. The two occasions on which he appeared most conspicuously were, on the 24th of March, 1783, when in a short speech he moved an address requesting that his majesty would be pleased to form an administration entitled to the confidence of the people, which, being assented to, was followed by the resignation of Lord Shelburne and the formation of the Coalition Ministry of Mr. Fox and Lord North; and on the 2nd and 3rd of February, 1784, when he carried two motions against the existing ministry of Mr. Pitt, which however had no effect. He also on subsequent years came forward on some occasions when measures affecting agriculture occupied the attention of the House. In all matters of general policy he voted with Mr. Fox, and after his death with Lord Grey and what was commonly called the Whig party.

His influence in the country arose from his large estates and the lead he took in agricultural improvement, together with his popular qualities as a landlord and a country gentleman. He is said to have raised the rental of his estate of Holkham, in the period of between sixty and seventy years during which it was in his possession, from little more than 2000*l.* to above 20,000*l.* From the death of Francis, duke of Bedford, in 1802, he was regarded as the chief of English agriculturists. His plantations were so extensive that the average value of the annual fall of timber on his property is stated to have amounted at his death to 2700*l.*, or considerably more than the entire rental of the land when it came into his hands. The annual sheep-shearing at Holkham, at which some hundreds of guests were entertained for several days, was probably the greatest agricultural festival in the world.

According to Mr. Coke's own account in the after-dinner speech of 1833 already quoted, he was twice offered a peerage in the very first session that he sat in parliament. More than sixty years after, namely, on the 21st of July, 1837, he was at last raised to the Upper House as Earl of Leicester, of Holkham. It is understood that the difficulty which had prevented his being sooner made a peer was that he would accept of nothing except this earldom of Leicester, which had been held by his maternal great-uncle, whose estates he inherited, but which had in the mean time been bestowed, in 1784, upon Lord Ferrers, afterwards Marquis Townshend, to whose heirs it of course descends. It was thought a very strong measure, when, to gratify the old man, the same title, with the slight and not very intelligible variation, 'Leicester of Holkham,' was bestowed upon a second person. It made of course no difference that the other Earl of Leicester had subsequently acquired a higher title; he was still notwithstanding as much Earl of Leicester as Marquis Townshend. The proceeding was precisely of the same nature as if Mr. Coke had been made Duke of Wellington, of Holkham.

The Earl of Leicester died at Longford Hall, Derbyshire, on the 30th of June, 1832, at the venerable age of ninety. He was twice married: first, in 1775, to Jane, daughter of James Lennox Dutton, Esq., who died in 1800, and by whom he had three daughters, and many grandchildren and great-grandchildren; secondly, on the 26th of February, 1822, to the Lady Anne Amelia Keppel, third daughter of the Earl of Albemarle, who was then not quite nineteen, and who brought him five sons and a daughter. The eldest son, born on Christmas-day, 1822, is now Earl of Leicester.

(*Memoir in the Gentleman's Magazine for Sept.*, 1842. See also in the number for December, 1842, a short notice of his will, in which he is said to state in that document that he had 'lately expended the sum of 500,000*l.* in the improvement of his estate.')

LEI'ODON, a genus of fossil reptiles. (Owen.) One species found in the chalk of Norfolk.

LEIPA (generally called Böhmisch-Leipa), is a town in the circle of Leitmeritz, in the kingdom of Bohemia, and in the lordship of Neuschoss, belonging to Prince Kaunitz. It is situated on the river Polza, and has about 6000 inhabitants, who have flourishing manufactures of woollen-cloth, cottons, calicoes, chintzes, and very beautiful earthenware and glass-works. There are a gymnasium and a high school in the town.

(Hörschelmann, *Handbuch*; Stein, *Lexicon*; Cannahich, *Lehrbuch*.)

LEMNA, a genus of plants belonging to the natural order Aroideæ, and the suborder Lemneæ. It has a 2-flowered membraneous urceolate spathe; the male flowers consist of two stamens; the fruit is reticular and indehiscent. The fronds are without distinction of stems or leaves. The flowers appear just below the margin of the frond. Several species have been described. They are all inhabitants of stagnant waters, and are known familiarly by the name of 'Duck-weeds.'

(Babington, *Manual of British Botany*.)

LEMOINE, FRANÇOIS, a celebrated French painter of the eighteenth century, was born at Paris in 1688. He was the pupil of Louis Galloche, early distinguished himself, and in 1718 was elected a member of the Royal Academy of Painting: his presentation-piece was an excellent picture of Hercules killing Cacus. He obtained a great reputation by his painting, in oil, of the Transfiguration of Christ on the ceiling of the choir of the church des Jacobins, Rue du Bacq. In 1724 Lemoine visited Italy, where he remained for a year; the artists whose works chiefly attracted his attention were Pietro da Cortona, Lanfranco, and Bernini. After his return to France he was made professor of painting in the Academy, and in a very few years his reputation surpassed that of all his Parisian contemporaries: Louis XV. appointed him in 1736 his principal painter, with a salary of 4100 francs, in the place of Louis de Boullougne, deceased. The first of Lemoine's great works was the cupola of the chapel of the Virgin in St. Sulpice, in fresco, which he commenced in 1729, a work of three years' labour. His master-piece however is the Apotheosis of Hercules, painted in oil on canvas pasted on the ceiling of the Salon d'Hercule at Versailles, commenced in 1732 and finished in 1736. It is a grand composition, containing one hundred and forty-two figures, and it is the most extensive and most magnificent monument of painting in France, though in a florid and superficial style, and, like the works of his model, Pietro da Cortona, belongs to the class of works called *pitture di macchina* by the Italians. The composition is arranged in nine groups, is vigorous and effective in arrangement, colour, and light, and especially in aerial perspective; but it is a purely decorative work, and is effective only as a whole: the parts have little individual merit, and the drawing wants correctness, expression, and distinctive character. Lemoine used on the ground of this picture, the blue vault of heaven, ultramarine to the value of 10,000 francs: it is sixty-four feet by fifty-four.

After the completion of this great work he was without a rival in France, but he never enjoyed his success. He was naturally of a melancholy temperament, a weakness which the loss of his wife, and the constant and intense application arising from an insatiable ambition, combined with vexation on account of the detraction of his less successful contemporaries, aggravated to that degree that it amounted to a chronic aberration of intellect, and he destroyed himself in one of these nervous fits, June 4, 1737, ten months after the termination of his great work at Versailles, and in the fiftieth year of his age.

Lemoine painted also many easel-pictures, both of large and of very small dimensions, and the latter have realized high prices at auctions: a Flight into Egypt is considered his best easel-piece. There is not a single picture by him in the Louvre at Paris. Many of his works have been engraved by some of the best French engravers, as L. Cars, N. Cochin, H. S. Thomassin, Silvestre, Larmessin, Et. Fessard, &c. Boucher, Natoire, and Nonotte, distinguished painters, were the pupils of Lemoine.

(D'Argenville, *Abrégé de la Vie des plus fameux Peintres*; Watelet et Levesque, *Dictionnaire des Arts*, &c.; Gault de Saint-Germain, *Trois Siècles de la Peinture en France*.)

LENCISCUS. The reference from BLEAK, P. C., to LENCISCUS was a misprint. [LEUCISCUS, P. C. S.]

LENFANT, JACQUES, was born at Bazoche in Beauce, a district of the ancient province of Orléannois in France, on the 13th of April, 1661, and was the son of Paul Lenfant, the Protestant minister of Châtillon-sur-Seine. Being destined to the same profession as his father, he was sent to prosecute his studies at Saumur; during his residence at that university he lived with the learned Jacques Cassel, the professor of Hebrew, with whom he formed a friendship which continued during their lives. He afterwards completed his theological education at Geneva and Heidelberg, in which latter town he was admitted into the ministry of the Protestant church during the month of August, 1684. Soon after his ordination he obtained the appointment of minister of the French church at Heidelberg, and chaplain to the Dowager Electress Palatine. The invasion of the Palatinate by the French troops, under Marshal Turenne [TURENNE, P. C.], compelled Lenfant to leave Heidelberg in 1688, and he settled at Berlin. The fear of meeting his countrymen arose from having rendered himself obnoxious to the Jesuits by two letters which he had written against that society, and which are appended to his work entitled 'A Preservative against a re-union with the Church of Rome.' Though the Protestant French church of that city had already a sufficient number of pastors attached to it, the reigning Elector of Brandenburg, Frederick, afterwards King of Prussia, who knew Lenfant by reputation, appointed him to that church, where for upwards of thirty-nine years he performed duty. In tho year 1705 he married Mademoiselle Gourgaud de Verones, a French lady from Poitou. In 1707 he visited England, and it is recorded that he was admitted to preach before Queen Anne, though we do not understand how he could have been permitted to do so without having received episcopal ordination; it is further stated that the Queen wished him to enter the Church of England, and offered him, in case he resolved to do so, to appoint him her chaplain. In 1710 he obtained the situation of chaplain to the King of Prussia, and councillor of the high consistory. He was also a corresponding member of the Society for the Propagation of the Gospel in Foreign Parts, which had a few years before been established in London. Lenfant was suddenly attacked with paralysis, while in the apparent enjoyment of perfect health, on the 29th of July, 1728, and he died on the 7th of August following.

His disposition is represented to have been amiable, and his manner simple and modest. Of a reflective turn of mind, he spoke but little, and that little well. Though a most voluminous writer, he was fond of society, and opened himself without reserve to the confidence of his friends. He is said to have had few personal enemies, which may be readily believed, for his character is universally described as remarkable for its disinterested charity, and for the exercise of the peaceable virtues of a Christian. As a preacher, his manner was pleasing and persuasive; the matter of his discourse was chiefly of a practical nature, and his eloquence was rather chaste than energetic. His varied talents and the depth of his learning may best be judged of by tho study of the numerous and valuable works which he has left, many of which are of indispensable utility to the theological student. The style of his writing is elegant, though never florid; it has less force than that of Jurieu [JURIEU, P. C. S.], and less eloquence than that of Saurin [SAURIN, P. C.], but the French is more pure, and the diction more chaste. In one respect especially he is far superior to any of the French Protestant writers of that period; his writings, particularly those of the latter years of his life, contain little asperity and few severe expressions of condemnation against those who differed with him in opinion. It is not certain whether he was the first to form the design of the 'Bibliothèque Germanique,' which was commenced in 1720, but it is well known he took a prominent part in its execution, and he is the acknowledged author of the preface.

Lenfant's first work, which appeared in 1683, was a review of one of Brueys, who, though a celebrated French dramatist, has written several theological works in defence of tho Roman Catholic faith. In 1688 be published a translation of a selection from the letters of St. Cyprian, in 1690, a defence of the Heidelberg catechism, which is generally annexed to his 'Preservative,' &c., a work wo have before alluded to; and in 1691, a Latin translation of the celebrated work of the Père Mallehranche on 'Research after Truth.' His history of the female Pope Joan, appeared in 1694; the arguments in it are drawn from the Latin dissertation on that suhjeet of Spanheim. It is said, however, that, in after life, Lenfant discovered and acknowledged the absurdity of this fiction. [JOAN, POPE, P. C.] In 1708 appeared his remarks on the Greek edition of the 'New Testament,' by Mill, which are in the 'Bibliothèque Choisio' of Le Clerc, vol. xvi. The following works afterwards appeared in succession: 1,'Réflexions et Remarques sur la Dispute du Père Martiany avec un Juif;' 2, 'Mémoire Historique touchant la Communion sur les deux Espèces;' 3, 'Critique des Remarques du Père Vavaseur; sur les Réflexions de Rapin touchant la Poëtique;' 4, 'Réponse de Mons. Lenfant à Mons. Dartis au sujet dn Socinianisme.' The above short works are to be found in the 'Nouvelle de la République des Lettres,' a review to which Lenfant was a frequent contributor.

In 1714 was published bis learned and interesting 'History of the Couneil of Constance,' 2 vols., Amsterdam. Two years after he wrote an apology for tbis work, whieh had been severely attacked in tbe 'Journal de Trévoux.' In 1718, in conjunction with Beausobre, he puhlished a translation of tbe New Testament, with explanatory notes, and a long and most learned introduction. It is hy this work, perhaps, that he is most known in England. [BEAUSOBRE, P. C.] We shall now hriefly mention the most important of his other productions: 1, 'Poggiana; or the Life, Cbaracter, and Maxims of the celebrated Florentine writer Poggio,' Amsterdam, 1720 [BRACCIOLINI, P. C.]; 2,'A Preventive against Reunion with the See of Rome, and Reasons for Separation from that See,' Amsterdam, 1723—a work whieh continues to enjoy great popularity among Protestants; 3, 'History of the Couneil of Nice, and of the most remarkahle Events during tho Interval hetwoen it and the Council of Constanee,' a learned and most accurate work, written with sufficient impartiality, 1724; 4, 'A Volume containing sixteen Sermons, on different Texts of Scripture,' 1728; 5, 'A General Preface to the Old and New Testaments,' whieh is appended to the French Bible in octavo, published at Hanover and Leipzig in 1728; 6, 'A small volumo of Remarks on Gishert's Treatise on Pulpit Eloquence.' The last work of Lenfant is one which has greatly added to his already high reputation, 'Tbe History of the Wars of tho Hussites, and of the Council of Basle,' 1728; hut the labour wbich the composition of it occasioned is said to have hastened his death; he had been many years collecting materials for this valuahle history, and had access, tbrough the influence of the King of Prussia, to the archives of tho corporation of Basle. The principal details of the life of Lenfant have been taken from a memoir annexed to the above work.

LENTIBULARIÆ. [LENTIBULACEÆ, P. C.]

LEONU'RUS (from λέων, 'a lion,' and οὐρά, 'a tail'), a genus of plants helonging to the natural order Lahiatæ. The anthers approximate in pairs, with parallel cells and naked valves. The upper lip of the corolla is nearly flat, the lower one trifid, with the middle lobe obcordate. Tbe calyx is tubular and 5-toothed; the nuts flatly truncate.

L. cardiaca, Mother-wort, is a bitter herh, with a pungent unpleasant smell. The stems rise from 2 to 3 feet in height; they are wand-like, downy, purplish, and quadrangular. The leaves are long-stalked, somewhat downy, and of a dark green colour. The lower leaves are the broadest, and deeply jagged, the upper ones 3-lohed, and tbose about the summit lanceolate and undivided. The corolla is of a purple colour, and externally hairy; the calyx rigid and pungent. It is found in hedges and waste places in Great Britain, all over Europe, and the middle of Asia. The reputed tonic powers of this herb as a remedy in palpitations of the heart and cardialgia, or heartburn, are now disregarded: from being used however in the last complaint it derives its name. It has been extolled by the Russians as an antidote to canine madness, and bees are fond of the honey contained in its flowers.

L. marrubiastrum has elongated pubescent branches, oblong ovate deeply-toothed leaves, the calyx nearly glahrous, and the corolla small, white or pale-red, and shorter than the calyeine teetn, wnich are suhulate, spiny, and diverging. It is found in waste plaees throughout Europe and Asiatic Russia. There are eight species of *Leonurus* described by botanists as growing chiefly in Europe and the North of Asia. None of them are very ornamental, and being biennial plants, the seeds only require to be sown in the open ground.

(Don, *Gardener's Dictionary*; Lindley, *Flora Medica*, Babington, *Manual of British Botany*.)

LEPADOGASTER. [DISCOBOLI, P. C. S.]

LEPI'DIUM (from λεπίς, a scale, in allusion to the form of the pods, which resemble little scales), a genus of plants belonging to the natural order Cruciferæ, and the tribe Lepidineæ. It has a roundish or ohlong pouch, either notched or entire, compressed valves, keeled or winged at the back. There is hut one seed in eaeb cell; the filaments are simple. The species consist of herbs or small shruhby herbs with small white flowers. This genus is divided into seven sections, the first of which, *Cardaria*, is so called from the heart-shaped form of the silicles. To this section belong:

L. Draba. It has ohlong leaves, entire or toothed, the lower ones narrowed into a foot-stalk, the stem-leaves sagittate and amplexicaule, the style as long as the dissepiment. It is native in the south of Europe from Spain to Tauria, and from Greece to Paris. It was introdueed into Great Britain probahly hy foreign seed, and is now found in the hedges of Kent.

L. sativum, common Garden Cress, belongs to the section *Cardamom* of this genus. It has orbicular pods, variously eut winged leaves, and smooth hranehes. It is native of Persia and the island of Cyprus in corn-fields. There are three varieties of the species: the broad-leaved eress, which is cultivated chiefly for rearing young turkeys; the eurled variety, which is sometimes used as a salad, hut is considered preferahle as a garnish; and the common plain-leaved cress, which forms one of our earliest spring salads, and has a peculiarly warm and grateful relish. All the varieties are raised from seed, of which one ounce will serve for a hed four feet square. Cress should be raised four or five times a month so as to have the crops delicately young in succession. When raised in the open garden it should be sown early in March, and if the weather be cold it should be covered either with matting or a frame during the night. Cress is often raised on porous earthenware vessels of a conical form, having small gutters on the sides for retaining the seeds. These are called pyramids: they are somewhat ornamental in winter, and afford repeated gatherings. This species is the λεπίδιον of Dioscorides, 2. 203.

L. campestris has downy leaves, the upper ones toothed, the lower ones oblong and narrowed into a foot-stalk, the stem leaves lanceolate, sagittate, and amplexicaule. It is distinguished from the other species by the pouch being ovate, rough, and covered with minute scales, notched and rounded at the end, the style scarcely longer than the notch. It grows on dry gravelly soil in Great Britain.

L. latifolium has ovate lanceolate leaves, serrated or entire; the pouch is oval and downy. It has numerous small flowers in compound leafy panicled clusters. It is a native of Europe, also of Algiers, and of several parts of England generally near the sea. It has a very hot biting taste, and has been used instead of horse-radish, occasionally as a salad; the poor people are in the habit of eating it as a condiment to their food, hence it has acquired the name of *Poor Man's Pepper*. An infusion of it acts as an emetic. Fraas believes this to be the κράμβη ἀγρία of Dioscorides, 2. 147, although it is usually referred to the Brassica eretica. It is also the Lepidium of Pliny, 20. 17. 19. δ.

The green-house species will thrive well in any kind of light soil, and are readily propagated hy cuttings planted under a hand-glass, or by seeds. The hardy perennial species, by dividing at the roots or hy seeds, will grow in any kind of soil. The hardy annual kinds only require to be sown in the open ground. None of the species are worth cultivating for ornament.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*; Fraas, *Synopsis Floræ Classicæ*; Burnett, *Outlines of Botany*.)

LEPIDOPUS. [TÆNIOIDES, P. C. S.]

LEPIDO'TUS, a genus of fossil ganoid fishes, abundant in the oolitic strata. (Agassiz.)

LEPISMA. [THYSANURA, P. C. S.]

LEPRA. [SKIN, DISEASES OF, P. C. S.]

LEPTACANTHUS, a genus of fossil placoid fishes, occurring in the carboniferous and oolitic strata. (Agassiz.)

LEPTÆNA, a subdivision of the great family of fossil

Brachiopoda, proposed by Dalman to include species which Mr. Sowerby named Producta. Its use is at present more restricted, and has become rather indefinite. Leptæna lata of the Silurian system may be regarded as a frequent type. The species are extinct, and are confined to palæozoic strata.

LEP'TIDES, Two-winged Flies (*Diptera*), of the division *Tanystoma* in Latreille's arrangement. They are remarkable for the habits of their larvæ, which excavate funnel-shaped cavities in the sand, and secreting themselves at the bottom, lie in wait for their prey. When an insect falls into the pit the larva of the *Leptis* suddenly rising seizes it, and clasping the body sucks out the juices, after which it flings away the carcass.

LEPTOCE'PHALUS, a remarkable fish of the Eel tribe, discovered on the British coast in Pennant's time, and since observed in the Mediterranean. The *Leptocephalus Morrisii* is a small, slender, and compressed animal, as thin as a piece of tape, and at first sight resembling a marine worm. The head is extremely small and short, the eyes large, the jaws furnished with numerous minute teeth; the pectoral fins and gill openings very small, and the anal and dorsal fins connected with the tail. The outline of the body resembles that of the Lancelet (*Branchiostoma*); but the organization of the *Leptocephalus* is that of a perfect fish. Mr. Yarrell describes the vertebræ as having no spinous processes. It lives among seaweed.

(Montagu in 2nd vol. of the *Wernerian Memoirs*; and Yarrell, *British Fishes*, vol. ii.)

LEPTO'LEPIS, a genus of fossil ganoid fishes, occurring in the liassic strata.

LESCOT, PIERRE, a French architect of the sixteenth century, of whom, however, nothing is distinctly known, but he is generally supposed to have designed and commenced, together with Jean Goujon, the present palace of the Louvre for Francis I. and Henry II.; the exact time is a matter of uncertainty. Lescot was born, according to some accounts, about 1510, and he lived to the age of sixty; other accounts give the dates 1518 and 1578 as the years of his birth and death. He erected the southern and western sides of the quadrangle, but all that now remains by Lescot is the western side, facing the Tuileries, known as the *Vieux Louvre*; it contains the antient Salle des Gardes, or Salle des Cent-Suisses, with the caryatides of Goujon, whence its modern name of Salle des Caryatides.

Lescot's style and services to architecture have been the subjects of various speculations; but they are all extremely vague, and amount to very little. By some he is supposed to have been the first to abandon the old irregular Gothic, and to have introduced the Italian style into France; but this was done by Italian artists themselves, several of whom were employed by Francis I. long before Lescot could have attained anything like mastery in his art, or even maturity of years. Fontainebleau is an instance, in which Serlio, Primaticcio, and others were employed by Francis I.

Lescot is said also to have designed the 'Fontaine des Innocents,' attributed by some to Goujon, the sculptor of the nymphs upon it. Lescot was Abbé of Cluny or Clugny, and a canon of the Cathedral of Notre Dame.

(Sauval, *Antiquités de Paris*; *Voyage Pittoresque de Paris*; Clarac, *Musée Royale des Antiques du Louvre*; Quatremère de Quincy, *Dictionnaire Historique d'Architecture*, &c. &c.)

L'ESPINASSE, MADEMOISELLE, the name of a lady much celebrated in the Parisian literary circles soon after the middle of last century, was born in 1732. She is supposed to have been the illegitimate daughter of people of rank. She was employed to read to and converse with Madame du Deffand in her blindness; but being ambitious, well-informed, and eloquent—endowed with much of what the French call l'esprit—she attracted the interest of the circle surrounding Madame du Deffand to an extent which greatly displeased that lady. She dismissed Mademoiselle, who had the boldness to plan, and the ability to execute, the collection of a brilliant literary circle round herself. In 1764, when D'Alembert fell ill she nursed him with zeal, and thenceforth he resided in her house. Marmontel, who in his Mémoires has given a very full account of this lady, states that she made divers attempts to accomplish a high matrimonial alliance, and in one instance induced the relations of a noble Spaniard on whom she had made an impression to allow him to return to France, by procuring a false medical certificate that it was necessary to his health. Morellet, the uncle-in-law of Marmontel, however, in his Mémoires throws doubt on this story. She died in 1776, to the great grief of D'Alembert, whom she had long mortified by not returning his affection. Three volumes of her love-letters, conspicuous for very ardent eloquence, were published in 1809.

LETTER OF CREDIT. [CREDIT, LETTER OF, P. C. S.]

LETTERS, THREATENING. [THREATS, P. C.]

LEUCISCUS, a genus of fishes of the family *Cyprinidæ*, distinguished by having short and soft anal dorsal fins, and a mouth unfurnished with barbules. There are many species, well-known inhabitants of the rivers of Europe. Those best known in Britain are the Roach (*Leuciscus rutilus*), the Dace (*Leuciscus vulgaris*), the Chub (*Leuciscus cephalus*), the Rudd (*Leuciscus erythropthalmus*), the Bleak (*Leuciscus alburnus*), and the Minnow (*Leuciscus phoxinus*). More rare are the Graining (*Leuciscus lancastriensis*) and Azurine (*Leuciscus coeruleus*), formerly supposed to be peculiar to the north of England, but stated by Agassiz to inhabit certain Swiss lakes. The Dobule (*Leuciscus dobula*), a native of the rivers of Western Germany, has been taken by Mr. Yarrell in the Thames, and the Ide (*Leuciscus idus*) is doubtfully recorded as a native of Scotland. Most of these fishes are sought after by anglers, either for the sport they afford or to be used as bait for pike. None of them are very excellent as food. The roach and chub have been known to attain a weight of five pounds.

The scales of several of these fishes have been used in the manufacture of artificial pearls. 'On the inner surface of roach, dace, bleak, whitebait, and other fishes,' writes Mr. Yarrell, 'is found a silvery pigment which gives the lustre those scales possess. Advantage has been taken of the colouring matter thus afforded to imitate, artificially, the oriental pearl. When this practice was most in fashion, the manufactured ornaments bore the name of patent pearl, and the use was universal in the bead-trade for necklaces, ear-drops, &c. At present it seems confined to ornaments attached to combs, or small beads arranged with flowers for head-dresses. So great was the demand formerly at particular times, that the price of a quart-measure of fish-scales has varied from one guinea to five. The Thames fishermen gave themselves no trouble beyond taking off the side scales, and throwing the fish into the river again; and it was the custom for hawkers, regularly, before selling any white-fish, as they were called, to supply the bead-makers with the scales. The method of obtaining and using the colouring matter was, first carrying off the slime and dirt from the scales by a run of water; then soaking them for a time, the pigment was found at the bottom of the vessel. When thus produced, small glass tubes were dipped in, and the pigment injected into thin hollow glass beads of various forms and sizes. These were then spread on sieves and dried in a current of air. If greater weight and firmness were required, a further injection of wax was necessary. Of this pigment, that obtained from the scales of roach and dace was the least valuable; that from the bleak was in much greater request; but the whitebait afforded the most delicate and beautiful silver, and obtained the highest price, partly from the prohibitory regulations affecting the capture of this little fish, the difficulty of transmission, and rapid decomposition.' (*History of British Fishes*, vol. i.)

LEVANT COMPANY. In 1581 Queen Elizabeth granted to a company the exclusive right of trading to Turkey. This was the origin of the Turkey or Levant Company. Its exclusive privileges of trade extended to the dominions of the Grand Seignor, whether in Europe, Asia, or Africa. Factories were established, and the company was at the cost of supporting an English ambassador at Constantinople, and consuls at Aleppo, Smyrna, and other places. Adam Smith speaks of the Turkey Company in his time, seventy or eighty years ago, as 'a strict and oppressive monopoly.' The Turkey Company surrendered its charter in 1825.

LEWIS, MATTHEW GREGORY, a writer of novels, poems, and dramatic pieces, was born at London on the 9th of July, 1775. His father was deputy secretary-at-war, and was connected with many families of rank and wealth. Lewis studied at Christ Church, Oxford, and afterwards lived for some time in Germany. There he became acquainted with Göthe and his followers, and imbibed the mysterious and tragic spirit of which his writings are full. Previously to his residence in Germany, when only sixteen years old, he wrote a successful comedy, called 'The East Indian.' The novel by which he is chiefly known, 'The Monk,' was published in 1794, when he was in his twentieth year. In the skilful employment of supernatural and mysterious agencies, and the display of horrors, it is, perhaps, unrivalled in the English language. A considerable portion of its details are devoted to the operations of the lustful passions on the character of a man violent and unscrupulous in his nature, but under the restraint of monastic vows. The young novellist drew the character broadly and offensively; and the singular lubricity of a performance, calculated by its genius and adaptation to the taste of novel readers to be extensively circulated, excited much indignation. It is understood that the Society for the Suppression of Vice applied to the Attorney-General to take legal steps against Lewis. These attacks only swelled the author's fame. At that time it was rather favourable to the success of a work of genius that its morality was not perfectly pure, and Lewis had the satisfaction of being a much courted and slightly abhorred man. His character, as represented in his published letters, is singularly at variance with that which might be derived from the study of his works. He appears to have been good-hearted, simple, affectionate, and not addicted to any vice. He had a very difficult part to maintain in his intercourse with his parents, his mother having, on account of her levities, long been separated from her husband. Although he could not vindicate her conduct, he gave her his kindest sympathies. It is a singular circumstance in his life, that, after having lived for some time on bad terms with his father, the latter dying in a temper which precluded the son from any hope of succession, yet left him, with slight exceptions, his whole fortune. This event made Lewis a rich West India proprietor. He was very kind to his slaves, and his occasional visits to his estates in Jamaica were welcomed as occasions of public rejoicing both among his own slaves and those in the neighbourhood of his estates. His poetical pieces, including 'Alonzo the Brave,' 'Bill Jones,' &c., are well known: they are distinguished by the fluency of their versification, and the distinctness and power with which they narrate horrible and tragical incidents. There is, however, in all his writings, a tone of barbarous and exaggerated taste. In 1812, he introduced to the stage the drama of 'Timour the Tartar,' which is said to have had much influence in creating the taste for gorgeous pageants, from which the British stage has for some years been struggling to relieve itself. Lewis died at sea, on the 14th May, 1818, when on the way home from a visit to his Jamaica estates.

(*Life and Correspondence of Matthew Gregory Lewis*, 8vo., London, 1839.)

LEYDEN, LUCAS VAN, a very celebrated old Dutch painter and engraver, was born at Leyden in 1494. He was first instructed in the arts by Hugh Jacobzc, his father; afterwards by Cornelis Engelbrechtsz; and he distinguished himself even as a boy by his engravings, and was a famous painter as early as his twelfth year. He painted in distemper a picture of St. Hubert, in 1506, for a citizen of Leyden of the name of Lokhorst, who was so astonished and gratified at the excellence of the work, that he paid him twelve gold pieces for it, one for each year of his age; at that time doubtless a very large sum for a picture. Some of Lucas's early engravings are highly prized by print-collectors, and accounted among the greatest rarities of their class: they owe their value, however, much more to their time and the peculiar circumstances of their origin, than to any intrinsic merit they may have. They are better as engravings than as works of art. Vasari speaks highly of the prints of Luca d'Ollanda, as he is called by the Italians. He excelled in aërial perspective, but he was far surpassed by his two contemporaries, Albert Dürer and Marcantonio—in correctness of drawing by the latter, and in execution and in drawing by the former. Albert Dürer visited Lucas at Antwerp in 1521, and he makes the following note in his journal: 'I was invited to dinner by master Lucas, who engraves in copper: he is a little man, and is a native of Leyden.' This visit was paid during a journey which Lucas made through Zealand, Flanders, and Brabant, for the sake of becoming acquainted with and seeing the works of their various painters. The entry above quoted from the pocket-book of Albert Dürer, fixes the date of this journey six years earlier than the account of Van Mander, who says that Lucas made it when he was about thirty-three years of age, which, according to his own date of Lucas's birth, 1494, would be in 1527.

Lucas, who was well to do in worldly matters, fitted up a small vessel or sloop expressly for this journey; and at Middelburg, where he entertained the painters of the place with a feast which cost him sixty florins, he persuaded Jan de Mabuse to join him, and they made the excursion together, both clad more like princes than artists. It was a succession of feasts, and Lucas repeated the entertainment of Middelburg at Ghent, at Antwerp, and at Mechlin. He, however, was not less energetic in his pleasures than at his work, and he indulged during this excursion in a round of dissipation which appears to have lastingly injured his constitution: he was never well afterwards. His own vanity led him to account for his illness by the supposition that some of his rivals whom he had entertained had endeavoured to poison him, and he added to his malady by indulgence and despondency. He allowed his mind to fall into such a morbid state that his physical strength left him, and he passed nearly the whole of the last few years of his life in bed, or at least in the sick-room, still, however, working at occasional intervals. He died in 1533, aged only thirty-nine.

Lucas's pictures are very scarce; they are in the old Flemish style, but are among the best works of that school. They are earnest, expressive, deeply coloured, and executed with great care; and are beautiful and highly interesting, notwithstanding their Gothic forms and arrangement: in the perspective of colour they are in advance of their time. The galleries of Vienna, Berlin, Dresden, and Munich possess a few good pictures by Lucas; his own portrait is in the Berlin Gallery. There is a very small curious picture by him in the collection of the Duke of Devonshire, at Devonshire House; it represents a man having a tooth drawn, while a woman is picking his pocket: there is a print of it, of the same size, by Lucas himself, dated 1523. There is a picture also by Lucas at Wilton House, and another at the Liverpool Institution. Mr. Rogers, the poet, possesses a pen-and-ink drawing of the portrait of the Emperor Maximilian I., of which the print by himself, is considered by some his best engraving. A picture of the 'Last Judgment,' one of his most remarkable works, is still in the town-house at Leyden. The print of Eulenspiegel, a notorious clown or jester of the fourteenth century, is the rarest engraving in existence: there are said to be not more than five or six of the original extant, but it has often been copied, and the first copy was made in 1644 by Hondius, when the price of the original, even at that early time, was fifty ducats; it is about six and a half inches high and rather better than five wide, and represents a man playing the bag-pipes, with two children on his back, followed by a woman who is also carrying a child, and is leading an ass burdened with two panniers in which are three other children; the whole family is preceded by a small figure dressed in a cowl, with a stick in one hand and a jug in the other, an owl on his shoulder, and a dog walking before him—this is Eulenspiegel; it was engraved in 1520. Bartsch, who published a distinct catalogue of the prints of Lucas van Leyden, describes 174 engravings by him; in all, including wood-cuts, his prints amount probably to about 200.

(Van Mander, *Het Leven der Schilders;* Bartsch, *Catalogue Raisonné de toutes les Etampes qui forment l'Œuvre de Lucas de Leyde*, and *Peintre Graveur*, vol. vii.; Huber, *Manuel des Amateurs*, &c.; Von Quandt, *Entwürfe zu einer Geschichte der Kupferstecher-kunst;* Van Eynden and Van der Willigen, *Geschiedenis der Vaterlantsche Schilder-kunst*, &c.)

LIBEL. [LIBEL, P. C.] The Act of 6 & 7 Vict. c. 96, entitled 'An Act to amend the law respecting defamatory words and libel,' has made some alterations in the law of defamation and libel. The Act commences with the preamble, 'For the better protection of private character, and for more effectually securing the liberty of the press, and for better preventing abuses in exercising the said liberty, be it enacted,' &c. The Act enacts—§ 1, That in any action for defamation it shall be lawful for the defendant, subject to a certain notice in writing therein described, to give in evidence in mitigation of damages, that he made or offered an apology to the plaintiff for such defamation at such time as in the said section is more particularly described.

§ 2 enacts, That in any action for a libel contained in any public newspaper or other periodical publication, it shall be competent to the defendant to plead that such libel was inserted without actual malice and without gross negligence, and that at such time as the section mentions he inserted in such newspaper or other periodical publication a full apology for the said libel, or made such other apology as in the said section is more particularly described.

§ 3 enacts, That if any person shall publish any libel upon any other person, or shall directly or indirectly threaten to print or publish, or shall directly or indirectly propose to abstain from printing or publishing, or shall directly or indirectly offer to prevent the printing or publishing of any matter or thing touching any other person, with intent to extort any money or security for money or any valuable thing from such or any other person, or with intent to induce any person to confer or procure for any person any appointment or office of profit or trust, such offender on conviction may be imprisoned for any term not exceeding three years. This enactment does not in any way affect any law as to the sending or delivery of threatening letters or writings. [THREATS AND THREATENING LETTERS, P. C.]

§ 4 enacts, That if any person shall maliciously publish any defamatory libel, knowing the same to be false, on conviction he shall be liable to two years' imprisonment, and to pay such fine as the court shall award.

§ 5 enacts, That if any person shall maliciously publish any defamatory libel, on conviction he shall be liable to fine or imprisonment, as the court may award, but the imprisonment is not to exceed one year.

§ 6 makes an important change. It enacts, That on the trial of any indictment or information for a defamatory libel, the defendant having pleaded such plea as in this section is afterwards mentioned, the truth of the matters charged may be inquired into, but shall not amount to a defence, unless it was for the public benefit that the said matters charged should be published. The defendant must in his plea to such indictment or information allege the truth of the matters charged in the manner that is required in pleading a justification to an action for defamation.

§ 7 enacts, That when on the trial of any indictment or information for the publication of a libel, under the plea of Not Guilty, evidence shall have been given which shall establish a presumptive case of publication against the defendant by the act of any other person by his authority, it shall be competent to the defendant to prove that such publication was made without his authority, consent, or knowledge, and that the said publication did not arise from want of due care or caution on his part.

§ 8 enacts, That in the case of any indictment or information by a private prosecutor for the publication of any defamatory libel, if judgment be given for the defendant, he shall be entitled to recover from the prosecutor the costs that he has sustained by reason of such indictment or information; and that upon a special plea of justification to such indictment or information, if the issue be found for the prosecutor, he shall be entitled to recover from the defendant the costs sustained by him by reason of such plea.

This act does not extend to Scotland, § 10. As it was doubted whether or not it did extend to Ireland, this act was extended to Ireland by 8 & 9 Vict. c. 75.

Defamation and libel were punished among the Romans. The oldest extant rule about defamation and libel is contained in the fragments of the 'Twelve Tables,' which punished both slanderous words and libellous writings. (Cicero, *De Repub.*, iv. 10.) The penalty was capital (in the Roman sense of that term), and it appears to have been death. Libellous writings were generally denominated 'famosa carmina' and 'mala carmina.' In course of time the Praetorian Edict modified the old law, or probably it fell into disuse. The praetor allowed an action for slander which was against 'boni mores' (*Dig.* 47, tit. 10, s. 15); and against 'boni mores' means, that which was disapproved of by the morality of the community, and tended to bring infamy or odium on the person against whom it was directed. The technical word for this kind of 'slander' was Convicium, which properly meant something said to a man's face that was injurious; but the commentators on the Edict laid it down that there might be Convicium even if the person against whom it was directed was not present. Convicium in fact was personal abuse which tended to damage a man, and was said with circumstances of great publicity. But the Praetor's Edict extended to other cases, and allowed an action wherever a man had done or said anything which injured a person's character. This general clause included libellous writings, and many other things, such as certain modes of soliciting women's chastity, and addressing them in obscene language. The penalty in all these cases was a sum of money assessed by Recuperatores as damages.

Under the imperial government the term 'liber famosus' often occurs: it signifies any writing in prose or verse which tended to injure a man's character (ad infamiam alicujus). The offence consisted in writing the libel, spreading it about or selling it, or in causing these things to be done maliciously (dolo malo); it made no difference whether the libel was anonymous or had a false name to it. The penalty was (according to some law, the name of which is not known), that the libeller, if convicted, became 'intestabilis,' that is, he could not make a will or be a witness to a will. (*Dig.* 28, tit. 1, s. 18.) A senatûs consultum extended the penalties of this lex to cases where there was no writing, but only marks which were of a like tendency; this must mean drawings and caricatures, such as are now published in London. Everything therefore which tended to the 'infamia' of a person, writings in prose or verse, and drawings, whether a man was mentioned or not mentioned, provided the person intended was clearly pointed at by such writings or drawings, were punishable offences; and writer, draftsman, and all concerned were liable to the legal penalty.

This legislation seems to belong to the Imperial period, though it was not intended to protect the emperor only. Augustus commenced this legislation (Sueton. *Octavian.*, 55), and probably his chief object was to protect himself. The Roman Cæsars, like other high personages in modern times, were the objects of pasquinades and various kinds of compositions which were intended to satirize them and make them ridiculous. The penalty of the law of Augustus is not certain; but in later times various Senatus consulta increased the penalty to Deportation or perhaps only relegation. If the author of a liber famosus had been punished in a criminal prosecution (judicium publicum), the injured person might still have his action, if he was mentioned by name in the libel. (*Dig.* 47, tit. 10, s. 6.) But if a man libelled a guilty person (nocens), it was considered equitable that he should not be subject to any legal penalty, 'because the bad deeds of evil-doers ought to be known, and it was expedient that they should be known.' Compare the 6 & 7 Vict. c. 96, § 6.

The 'libri famosi,' or 'libelli famosi,' of the Imperial period, signified anonymous writings, which contained a charge against some person, and were either sent to the Cæsar or to some magistrate, or put in some place where they might be found, for the purpose of causing injury to the person accused This is the only signification of the expression 'libelli famosi,' in the Theodosian and Justinian codes Constantine the Great declared that such charges should not prejudice any person who was mentioned in them, and that such writing should be burnt when the author was unknown. If the author was discovered, he was punishable even if he could prove the truth of the matter contained in the writing. Other constitutions on the same subject were made after the time of Constantine.

(Rein, *Das Criminalrecht der Römer*.)

LIBEL (Ecclesiastical Law). [ECCLESIASTICAL COURTS, P. C. S.]

LIBELLULA, the genus of insects which includes the well-known Dragon-Flies. It belongs to the order *Neuroptera* and to the section *Subulicornes* in the arrangement of Latreille. The dragon-flies have horny strong mandibles and maxillæ, covered by the labrum and labium; their tarsi are three-pointed; their wings are equal; the posterior extremity of the abdomen is furnished with hooks or peculiar appendages. The size, beauty, and habits of these insects have rendered them favourite objects of study with the entomologist. In the larva state they live entirely in the water, engaged in unceasing war with other insects, which by singular devices they entrap and devour. Their pupa state is also passed in water, and, contrary to the usual habit of insects, is a period of activity and locomotion. They are then furnished with an extraordinary mask formed out of that part of the head which replaces the lower lip, and by which they cover the jaws and the whole under part of the head. They use it to alarm and seize their prey, projecting it at will. When perfect insects, they become inhabitants of air, and are endowed with extraordinary power of flight and precision of movement, performing astonishing evolutions. Their habits continue as ferocious as they were before. When taken and imprisoned, they have been known to devour their own bodies! Several valuable monographs have been published on these interesting insects by De Geer, Roesel, Vander Linden, and Charpentier; but the most important and most recent is that of the distinguished Belgian zoologist M. de Sells Longchamps, entitled 'Monographie des Libellulidées d'Europe.' In this work 61 species are described, arranged under the genera *Libellula, Cordulia, Lindenia, Gomphus, Cordulegaster, Æshna, Anax, Calepteryx, Lestes, Sympecma*, and *Agrion*.

In the arrangement of Westwood ('Introduction to the modern Classification of Insects') the genera of *Libellulidæ* inhabiting Britain are grouped under two sub-families, *Libellulides* and *Agrionides*. The following table exhibits the chief characters of the British genera:—

Sub-fam. 1.—LIBELLULIDES.

A. Ocelli in a row . . .	*Anax* (1 species): anal angle of posterior pair of wings rounded. *Æshna* (7 species): anal angle of posterior pair of wings more or less angulated in the male. *Cordulegaster* (1 species): anal angle of posterior wings strongly angulated.
B. Ocelli in a line; eyes remote	*Gomphus* (2 species).
C. Ocelli in a triangle .	*Cordulia* (3 species): anal angle of posterior wings angulated in the male. *Libellula* (15 species): anal angle of posterior wings rounded in both sexes.

Sub-fam. 2.—AGRIONIDES.

A. Wings membranous	*Agrion* (13 species): stigma rhomboidal; areolets mostly quadrangular. *Lestes* (3 species): stigma oblongo-quadrate; areolets mostly pentagonal.
B. Wings coriaceo-membranous; stygma obsolete	*Calepteryx* (4 species).

LI'BERI, PIE'TRO, Cavaliere, was a celebrated painter of Padua, where he was born in 1605. He was the pupil of Padovanino, and is considered by some the best draftsman of the Venetian school of painters. He studied in Rome, at Parma, and in Venice, and his works are not distinguished by the peculiar characteristics of any particular school, but are equally conspicuous to a certain degree for the qualities of all. There are several great works by him, as the Slaughter of the Innocents, at Venice; Noah leaving the Ark, at Vicenza; and the Deluge, at Bergamo: he executed also many works in Germany. He was very fond of painting the nude, and particularly naked Venuses, which from their character acquired him the name of Libertino. Liberi had two manners; at one time he was bold and careless, and at another minute and laborious: this variety he explained to be intentional; he said that for the expert and intelligent he painted freely, but for the ignorant he finished highly. He died in 1687.

(Zanetti, *Della Pittura Veneziana;* Lanzi, *Storia Pittorica*, &c.)

LIBERTY. This word is the Latin *libertas*. The corresponding Teutonic word is *freiheit*, or, as it appears in English, *freedom*.

Liberty and freedom are familiar words with indefinite meanings. 'Liber,' the adjective which corresponds to the noun 'libertas,' is properly opposed to 'servus,' or slave; and libertas is the status of a freeman, as opposed to servitus, or the status of a slave. This division of freemen (liberi) and slaves (servi) was the fundamental division of persons in the Roman law (Gaius, i. 9). This word Liberty, then, in its origin indicates merely the personal status of a man as contrasted with the condition of servitude. In Greek the like opposition is expressed by two other words (δεσπότης, δοῦλος). But the word Libertas had also a political meaning among the Romans. When the Romans had ejected their last king, they considered that they had obtained their Liberty. (Livy, ii. 1.) The political meaning of libertas (liberty) was derived from the contrast of liberty and servitude in the person of individuals; and if the mass of a nation were subjected to the arbitrary rule of one man, that was considered a kind of servitude, and the deliverance from it was called libertas, a term which in this sense is clearly derived from the notion of liberty as obtained by him who was once a slave.

In the Greek writers the words (δεσπότης and δοῦλος), which respectively signify master and slave, were also applied in a political sense to signify monarch and subject. The Persian king was master (δεσπότης), and his subjects were slaves (δοῦλοι).

The political sense then of liberty and freedom, if traced to its source, is founded on the notions of personal liberty as contrasted with personal servitude. He who became free from being a slave in a republic became a member of the state, in which he formerly had no political existence. It is implied by the circumstance of his becoming free that he became a citizen, though positive law, as among the Romans, might limit the degree in which he thereby obtained citizenship. [CITIZEN, P.C. S.] Slavery may and did exist in many states of antiquity which were under monarchical or tyrannical rule; but he who was the slave of an individual in any such state, and obtained his freedom, did not thereby become a citizen, but was merely released from the duty that he owed to his master: he still owed together with others the duty of perfect obedience to an individual monarch or tyrant.

The words liberty and freedom, as political terms, have always been used to express a condition of a people in which they are to some degree at least secured against the arbitrary rule of an individual or of a small number of persons; and the word slavery, in its political sense, is applied to nations in which the mass of the people have not reasonable security for their lives and property against the capricious rule of one man or of a number of persons who form a small minority of the whole.

That which is really meant by political freedom and liberty is nothing more than a form of government which shall in some degree at least secure to the people the enjoyment of life and of their property against the tyranny of one man or of a few. Freedom and liberty then are terms which can only be applied to constitutional governments [CONSTITUTION, P. C.], and to republics, in the proper sense of that term. There is no political liberty or freedom under any other form of government, though under a monarchy, when the administration is good, there may be in many respects more personal freedom than there is in a pure democracy. But the essential quality by which political liberty or freedom is distinguished is simply this: the sovereign power is not in the hands of one or of a small minority, but it is either distributed among the whole community or a considerable part of it.

Political liberty does not exist in some civilized nations in Europe, in Prussia for instance. Political liberty does not exist in Russia. In some countries where it does not exist, it is the general opinion that its existence would be a benefit to the whole nation. In other countries the mass of the people are still in such a condition that political liberty could not exist, for political liberty, as already stated, means that the sovereign power must be in the hands of a large number, and they must possess intelligence enough to enable them to exercise and keep the power; but there are nations where the mass of the people are too ignorant to exercise or keep any political power.

The highest degree of political liberty is in a Democracy [DEMOCRACY, P. C.]; for it is that form of government which is furthest removed from a monarchy. The relationship of monarch and subject is the like relationship to master and slave.

A nation which strives for its liberty strives for a popular form of government, whether it be a constitutional kingly form or a democracy. But Liberty is a specious word, often ill understood; and many who have cried out for liberty have either not considered exactly what it is they want, or they have supposed that liberty would free them from many evils which they consider to be peculiar to a state of political slavery. It is now generally admitted, that in those states where a large part of the population have equal political knowledge with the few, who direct administration, the general interests are best served by this large number participating in the government. Political liberty then, to some extent or degree, is, in many countries, necessary for securing the advantages of good administration. But there are many evils incident to states, which are not due to the want of political liberty; and it is therefore a matter of importance for those who would make changes in government to consider whether the evils of which they complain are owing to the want of political liberty or to other causes.

The notion of political liberty has been based upon the analogy already pointed out between Political Liberty and Personal Liberty; which is a false analogy, though an historical one. Man, it has been assumed, is naturally free. No man is naturally or by nature another man's slave. As no man, it is said, is naturally a slave, so all mankind have naturally a right to political liberty, and just government, it is said, arises from the consent of the governed.

On these assumptions rests the American Declaration of Independence: 'We hold these truths to be self-evident: that all men are created equal; that they are endowed by their Creator with certain inalienable rights; that among these are life, liberty, and the pursuit of happiness; that to secure these rights governments are instituted among men, deriving their joint powers from the consent of the governed,' &c.

In this passage Liberty seems to mean the personal status, which is opposed to slavery; and it is on the assumption of the equality by birth and the endowment of all men with certain inalienable rights, that this instrument would found the American title to Political Liberty. It involves the doctrine of the social contract, and assumes, as an historical fact, an origin of governments by consent of the governed. It was also promulgated in a country in which a very large number of persons were then slaves and still are slaves.

If theories of government are to be tested by historical facts, it would be consistent with such facts to say, that men are not created equal; that they have not been endowed with liberty, for a large part of them have always been slaves; and that governments have been constituted without the consent of the governed. These are real facts: those assumptions are untruths.

Political liberty rests on no such sorry basis as the Declaration of Independence places it on. That nation which can obtain it and maintain it is in a better condition than if it were politically a slave, even to the wisest of masters; and when it is able to obtain and maintain that liberty, it is right, or in other words it is for the general interest, that a nation should, by force if necessary, alter that form of government which is political slavery.

That liberty promises to be most stable which is the growth of long time and the result of a perpetual struggle between a master and his slaves, in which the master has not ceased to be master all at once, but has always lost something in the contest.

That which is of sudden growth or is the offspring of Revolution, is often premature, and always insecure; for liberty so acquired may only be a step from a state of political slavery to a more wretched state; it may be a step from a state of slavery, mild and tolerable, to an anarchy, which of all things is most intolerable.

The words Liberty and Equality often go together, and each of them in so doubtful a sense that one hardly knows what to make of them. Liberty is often used, apparently without people considering what they really mean, in the sense of freedom from restraint. But this kind of Liberty is inconsistent with Political Liberty properly understood; and all men's liberty of action is and must be restrained by positive laws in every well-ordered community. Every law that forbids any act directly or by implication abridges Liberty, and such abridgment is always a universal benefit when the law which so abridges liberty only abridges it in cases where it is useful to all that it should be abridged, and where the law is so framed as to accomplish that object. Equality, in its unlimited sense, can no more exist in any state than perfect individual liberty; for if each man is left to exercise his industry in the best way that he can, without interfering directly with the industry of others, some will be richer, and happier, and wiser than others. The only Equality that can be approached to in a well-ordered state is that Equality which is the result of a good polity, which polity, so far as it is consistent with the universal good, secures alike to every individual in the State the free enjoyment of his industry, wealth, and talents, imposes restraint on all alike, and makes all alike bear the burden of taxation and of the services due to the State. Further, it gives to as large a number as it can, consistently with the universal interest, an equal share in the sovereign power; but no polity that has ever yet been framed has ever given an equal share in the sovereign power to all the members of a community: such an Equality is impossible.

The Declaration of Rights published by the French National Assembly in 1791 contains the words 'free,' 'equal,' 'rights,' 'liberty,' and many others, all of which are used in a manner as remote from precision as the most confused understanding could suggest. This strange sample of nonsense has been examined and dissected by Bentham in his 'Anarchical Fallacies' (Bentham's *Works*, part viii., Edinburgh, 1839).

The word Liberties is often used to express those particular constitutional principles or fundamental laws by which the political liberty of a nation is secured. If the British parliament should attempt to abolish the trial by Jury in all cases, or the Habeas Corpus, such an attempt would be called an attack on the liberties of Englishmen.

LICI'NIO. [PORDENONE, P. C.]

LIGAMENTS, in Anatomy, the organs by which the various articulations of the animal body are held together. [ARTICULATION, P. C.] They are generally very strong membranes, and in their structure and composition resemble tendons. [TENDON, P. C.] They are in most instances attached to two bones, and assist in the formation and strengthening of the joints. Ligaments are of various forms: some completely enclose the joint as in a case or capsule, and are then called capsular ligaments, as is seen in the knee, hip, and shoulder joint; others form straight bands passing from one bone to another; whilst others, again, are inserted into the heads and cavities of bones within the joints. For the composition and chemical characters of the tissue forming the ligaments see TISSUES, ANIMAL, P. C. S.

LIGHT, ABSORPTION OF. [ABSORPTION OF LIGHT, P. C. S.]

LIGHT-BALLS, for military purposes, are hollow cases, either spherical or in the form of cylinders, terminated at each extremity by a hemisphere: they are filled with a combustible composition, and being thrown, by night, in a burning state from mortars, or in some cases from the hand, they serve to discover the working-parties or troops of the enemy.

The spherical cases are made of canvas or cartridge-paper, cut into eight equal gores of a proper form and the edges sewn together, a hole being left for the introduction of the composition and the application of a fuze. The oblong cases consist, frequently, of two hollow hemispheres of iron, which are connected with each other by four slender bars of iron attached to their bases, in positions parallel to the axis of the case, and the whole is then covered with canvas: the entire length is about 1½ calibre of the piece of ordnance from which the ball is to be projected,—a mortar of one of the four different kinds, the calibre varying from 4⅖ inches to 10 inches.

The composition consists of pulverized saltpetre (6½ lbs.), pulverized rosin (1¾ lbs.), ground sulphur (2½ lbs.), and linseed oil (½ lb.). The dry materials, after having been passed through a sieve, are mixed with the oil while the latter is in a boiling state; and sometimes a small quantity of mealed gunpowder is added. The oblong balls are filled by passing the composition through a fuze-hole in one of the hemispheres, and are afterwards strengthened by cord wound about them. The fire is communicated to either kind of ball, at the time of being projected, by means of a piece of quick-match in the fuze.

Previously to besieging a fortified place, the works and the ground about them are reconnoitred, usually by night; the first trenches are also traced and formed during the hours of darkness, and therefore the defenders, at the commencement of the siege, prepare some mortars charged with light-balls: these balls being thrown beyond the glacis, enable them to discover the operations of the enemy, and direct a fire of shot against them. The assault of a breach is also frequently made by night; and in this case light-balls should be thrown by the defenders into the ditches of the place for like purposes. These may be made by merely filling granades with the composition above mentioned, and they may be thrown by hand.

Major-General Sir J. T. Jones states (*Journal of Sieges*), that the defenders of the towns which were besieged by the British army in Spain threw light-balls in order to discover the operations of the attack; and that two or three men of the engineers' brigade were kept in readiness to run up and extinguish them as they fell. That officer adds that the men generally succeeded, in a few seconds, in smothering them with filled sand-bags, or by shovelling earth over them. Some casualties are stated to have occurred among the men so employed, but the fire of the enemy being directed against them was thereby diverted from the working-party often employed at only a few yards' distance from the ball. On account of the great utility of such balls for illuminating the ground occupied by the enemy, Sir J. T. Jones recommended that grenades or other missiles should be connected with them by pieces of chain, in order that, through the risk of the explosion, men might be deterred from attempting to extinguish the light.

It may be added here that spherical cases of pasteboard or canvas filled with a composition which while burning emits a great quantity of smoke, are frequently discharged from mortars in order to conceal a movement of troops from the view of the enemy: they are also occasionally thrown from the hand either to suffocate the men employed in the galleries of military mines or to compel them to quit their work: these are called smoke-balls. The composition consists of mealed powder (5 lb.), pulverized saltpetre (1 lb.), pulverized seacoal (1½ lb.), pitch (2 lb.), and tallow (½ lb.): the pitch and tallow are melted together, and the dry materials, after being sifted, are mixed with the liquid.

LIGHTHOUSE. [SEA-LIGHTS, P. C. S.]

LIGHTS, ANTIENT. A Light is a right to the enjoyment of free access of light to a man's premises or buildings, which right must not be impaired by the building or erection of any object in such way as to obstruct the light. By the 2 & 3 Wm. IV. c. 71, § 3, an absolute right to light may now be acquired by twenty years' uninterrupted enjoyment, unless the use has been enjoyed by some consent or agreement made or given by deed or writing.

When a right to light has been established, he who occupies or owns the adjoining land cannot build in such manner as to obstruct the light. If such obstruction is built or erected, the person who is injured has an action on the case: and the Court of Chancery will in certain cases grant an injunction to restrain a person from making any erection or improvement which darkens or obstructs the usual lights or windows of an adjoining house. It will depend on the circumstances of the particular case, whether the new building or erection causes such a privation of light as to be an illegal act.

The right to the free enjoyment of Light belongs in the Roman law to the class of Servitutes (easements), among which were the Servitus altius non tollendi, ne luminibus officiatur, ne prospectui officiatur (Dig. 8, tit 2, s. 11, 12, 15-17). The general rule is thus expressed by Ulpian: 'He who shall attempt to obstruct his neighbour's lights, or to do anything else to damage them, must know that he ought to maintain the form and condition of the antient edifices. If you and your neighbour cannot agree about the height to which buildings may be raised which you have begun to erect, you will have the privilege of having an arbiter.'

It is said that according to the English law the stopping of a prospect is not a nuisance. The Roman law, as already observed, allowed a Servitus ne prospectui officiatur. The Roman rules of law as to easements in general are more precise than those of the English law.

LIGHTS, ARTIFICIAL. Within the last few years many new contrivances have been introduced for the illumination of apartments—by candles, by lamps, and by a sort of combination of both. The modes of illuminating large buildings have been explained in GAS, P. C.; BUDE LIGHT, P. C. S.; and DRUMMOND LIGHT, P. C. S.; while the articles ARGAND, P. C., and CANDLE, P. C., illustrated the common modes of domestic lighting. The recent inventions may be classed thus:—1, *Candles*; 2, *Candle-Lamps*; 3, *Oil-Lamps*; 4, *Spirit-Lamps*.

1. *Candles*.—Dr. Ure, in the Supplement to his 'Dictionary of Arts,' describes the mode adopted by Messrs. Hempel and Blundell, for making candles of palm-oil, margaric acid, and stearic acid or stearine. The palm-oil is melted in an iron pan, and then cooled gradually, by which it is separated into a liquid *oleine* or oil, and two solids, *stearine* and *margarine*. The oil being expelled by pressure, the solid fats are melted and mixed with quicklime; and the mixture is afterwards brought to a granulated state by the action of cold water. Muriate of lime and sulphuric acid are then employed to separate the quicklime from the solid fats; and the latter, after being washed, cooled, and crystallized, are pressed, whereby the stearine is separated from the margarine. The two are separately bleacbed; and the stearine goes through further refining processes, until it assumes the form of a pure and solid kind of palm-wax or hardened tallow, fit to make into candles in the usual way. The margarine, or margaric acid, obtained in this way, is mixed with common tallow to make another sort of candles.

Palmer's candles differ in many points from those in common use. In a patent obtained for them in 1842, one of the arrangements was intended to make the wick bend out of the flame, so as to come into contact with the atmosphere, and thereby render the troublesome process of 'snuffing' unnecessary; this consisted in impregnating one side of the wick with common paste or starch, which gave a greater stiffness and less combustibility to that side of the wick than to the other: this inequality of action gave a bending tendency to the wick. The same object is, however, now attained by having the wick in two halves, twisting spirally round each other; each half is bound round in a tolerably compact form; and the process of untwisting the spiral, by the gradual burning of the candle, causes the tops of the two wicks to spread out laterally beyond the boundary of the flame. The carbon or charred portion of the wick becomes then carried off or consumed, and the candle needs no snuffing. A particular mode of introducing the wick into candles, and a small apparatus for preventing the 'guttering' of candles, formed part of the patent of 1842.

The circumstance of palm-oil being in a solid state in our climate, coupled with an ascertained mode of separating it into three different substances, oleine, stearine, and margarine, has led to many suggested variations in the mode of making candles, by the mixture of one or more of these component elements with tallow or some kind of animal fat. There have also been patents taken out for new varieties of wick, and new forms given to the candle; but these do not involve any features which call for much notice.

2. *Candle-Lamps* or *Tallow-Lamps* is a designation under which may be grouped many recent contrivances, having for object the burning of solid tallow or fat instead of oil, but without having the tallow formed into a candle.

The *Soho* lamp, patented in 1840, is intended for burning solid tallow or some other kind of fat; although the lamp itself is very similar in shape to many of those used with oil. The tallow is brought to the form of a long cylinder like a candle without a wick, and is placed in the vertical stem of the lamp; there is a spiral spring beneath it, which presses it up close to a conical cap or cover at the top. A fixed tube passes up through the centre of the cylinder of tallow, from top to bottom; and in this tube is placed a cotton wick dipped in wax, the height of which above the top of the tallow can be regulated by a rack, pinion, and nut. The tallow or fat is made into a hollow cylinder in order to leave room for the central tube containing the wick. When the lamp is to be extinguished, the wick is drawn down below the top of the tube, and again raised before the tallow becomes cold.

The lamps or candlesticks now made for burning Palmer's candles, and which are indeed fitted for most kinds of candles, bear a good deal of resemblance to the above, in respect of having a conical cap to keep the candle within the tube, and a spiral spring in the lower part of the tube to press the candle upwards as it burns; but there is no necessity for the central wick tube, since the candles employed have wicks of their own. These candlesticks, and the candles belonging to them, offer the two conveniences of maintaining the light always at an equal height, and of dispensing with the aid of the snuffers. Some sort of shade or globe is necessary for realizing the latter of these two benefits fully; since the flame becomes very unsteady if the burning be effected as in a common candle.

One of the projects of this class consists in placing any kind of wax or tallow or fat into a receptacle, and having either hot water or hot metal beneath it, so as to keep it in a melted state, fitted to be used in the same manner as oil; but any method of keeping the water or the metal hot would seem likely to be a far greater inconvenience than any supposed good arising from the use of a solid food for the lamp. In another contrivance however, where the substance employed is either lard or tallow, there is a piece of metal which descends from the flame into the vessel containing the lard; and this metal, becoming heated by the flame, communicates this heat to the lard, and thus keeps it in a melted state. The inconvenience of such arrangements arises from the circumstance that the hot water or a heated piece of metal must be put into the lamp before lighting it, in order to melt the tallow. When this preliminary step is taken, the tallow is kept in a melted state by various means. One ingenious mode consists in having an air-tube within the wick, to carry air up to the flame, and two projections from this tube at the top, into the flame itself; so that the metal of which the tube is made, becoming heated at the upper end, speedily communicates heat to the contents of the lamp below.

There are many curious little pieces of mechanism, patented within the last few years, the object of which relates principally to the burning of common candles, or the mode of adjusting them into the candlesticks. One consists of a candle-shade constructed in a circular ring, which ring is suspended from a conical cap which rests on the top of the candle; as the candle burns, this cap sinks with it, and by that means the shade is kept at a constant height relatively to the level of the blaze, though not relatively to the level of the table on which the candlestick is placed. Another contrivance is intended to afford the means of adjusting any candle, large or small, to a large candlestick, by having a semicircular piece of brass, which is made to press against one side of the candle in the socket. A simpler contrivance for the same object consists of a pair of wedges, placed one on either side of the lower end of the candle. Another little piece of apparatus consists of a wire-frame for supporting a shade, and which is itself supported by having a sort of circular spring hoop, which clasps the candle.

3. *Oil-Lamps*.—One of the difficulties which have lessened

the usefulness of common oil-lamps is the tendency of the oil to thicken in cold weather; while another lies in the imperfection of the means for keeping the wick well moistened with oil up to the verge of the flame. Both of these matters have engaged attention within the last few years. Dr. Ure remarks (p. 134), 'The great cost of light from wax, spermaceti, and even stearic candles, as also the nuisance of the light from tallow ones, have led to the invention of an endless variety of lamps, of which the best hitherto known is undoubtedly the mechanical or Carcel lamp, so generally used by the opulent families in Paris. In this lamp the oil is raised through tubes by clockwork, so as continually to overflow at the bottom of the burning wick; thus keeping it thoroughly soaked, while the excess of the oil drops back into the cistern below.'

There is a lamp called the *Meteor* lamp, having some of the properties of the Carcel, but intended to burn rape-oil. The internal arrangements of this lamp are curious and complicated. The lower part of the pedestal consists of a reservoir for containing the oil; and in this reservoir is a kind of piston or plunger, worked up and down by a nut and screw from the outside; the rising of this piston occasions the pressure or tightening of a coiled spring, and this pressure causes the oil to be forced up a central tube towards the flame. The admission and regulation of the oil to the lamp, the adjustment of the wick, the arrangement of the air-holes for admitting draught, and of the gallery which supports the glass chimney, are all of an intricate kind, and, whatever may be their efficiency while in good order, would render the repair, in case of damage, a serious matter.

One of the modes adopted for maintaining the oil in a liquid state, is by the use of a lamp constructed by Mr. Parker, in which the oil is used in a hot state. At a small distance around the tube which contains the wick is another tube, and the space between the two tubes, of capacity sufficient to hold a pint, constitutes the reservoir for the oil. The oil is thus so near the flame, that it speedily becomes warm, by which its facility of burning is much increased. A slide-valve is opened to allow the oil to descend from the reservoir to the wick. The intensity of the flame is modified by raising or lowering a bell-mouthed glass chimney by means of rackwork mechanism. In a series of experiments on the illuminating powers of different kinds of lamps and candles, Dr. Ure found that the hot-oil lamp, with a given quantity of oil, gave a brighter light than any other form of lamp; or, the light being equal in intensity, the hot-oil lamp was the most economical. This corroborates, so far as it goes, the remarkable results obtained by the hot-blast in the iron manufacture.

Argand's principle of the mode of admitting air to act on the wick has been the one most generally followed since his time; and many of the subsequent inventions have had relation merely to some modification of this arrangement. The *Solar* lamp, one of the modern kinds, has a provision for sending up air through the interior of the wick, as in the Argand; but the action of the air on the exterior of the wick is made more decided. The wick passes through a hole in the centre of a cap or cone; and the air is admitted so as to act on the flame close to this hole, and in a horizontal direction, while the flame is yet small; so that the exposure of the gaseous products to the air is much more intimate than in the ordinary lamps, and the combustion more complete. Many improvements have been introduced from time to time; but the solar lamp remains in principle an Argand, with the addition of a cap or cone to deflect the external air more directly toward the flame. Many of the modern variations in lamps and in gas-burners have had relation to this circumstance of admitting the external air to act at the points and in the quantity found best for the maintenance of a clear flame.

4. *Spirit-Lamps.*—In chemical experiments the spirit-lamp has long been a valuable piece of apparatus; but the use of spirit instead of oil, as a food for lamps intended for domestic purposes, is a modern innovation, and has led to much mechanical ingenuity in the construction of the apparatus.

The term 'spirit' is rather a vague one, since there are many kinds of spirit which are inflammable enough to be used for this purpose; but the kind here alluded to is the *spirit of turpentine*, or that liquid which is distilled from common turpentine by being separated from the resin which is a component ingredient in the last-named substance. When brought to its purest state, this spirit is called by the French chemists '*camphine*;' and hence the name for some of the modern spirit-lamps. Turpentine being a very abundant produce of the American forests, camphine has been long in use in the United States for lighting shops and public buildings, and it seems to have been from that country that the practice was borrowed and introduced into England. When the import duty on turpentine was lowered two or three years ago, the price became reduced sufficiently to direct the attention of lampmakers to the practicability of using camphine as a substitute for oil. Many different forms of lamp have resulted from these inquiries; and different processes have also been adopted for freeing the turpentine from a small quantity of oxygen which it contains.

Young's 'Vesta' lamp is one of those varieties. In the specification of the patent it was stated that the lamp is constructed for burning rectified spirits of turpentine, or camphine; that, on account of the inflammability of this liquid, provision is made for keeping cool the reservoir where it is deposited; that no tube or metal conductor of any description is allowed to pass into or through the liquid from the burning part of the lamp; that a non-conductor of heat is placed between the burner and the liquid; that the cotton wick hangs down from the burner into the spirit, so as to supply spirit to the flame by capillary attraction, without the intervention of any metallic or conducting substance; that the admission of air to the interior of the wick is managed without the necessity of passing an air-tube through the liquid. All these features and a few others are rendered necessary in the camphine or spirit lamps, on account of the extreme inflammability of the liquid; an inflammability such that the arrangements for an oil-lamp would not be available for a camphine-lamp without much danger.

Whether these camphine-lamps receive the name of 'Vesta,' or 'Gem,' or 'Victoria,' or 'Paragon,' or 'Imperial,' or any other of the many which have been applied to them, they all present in common a reservoir, generally of glass, placed between the supporting pillar and the burner; the spirit is contained in this reservoir, and a cotton wick is seen to dip down into it. The chief points in which the several varieties of the lamp differ are in the arrangements for admitting air to the flame.

Of one of these lamps, the 'Vesta,' Dr. Ure states, that if 'burning with its utmost brilliancy, without smoke, it emits a light equal to very nearly twelve wax or sperm candles of three or four to the pound; and in so doing it consumes exactly one imperial pint of spirits of turpentine (value sixpence) in ten hours: hence the cost per hour for a light equal to ten such candles is one halfpenny.' Since that statement was written, the demand for camphine has raised its price, and the relative advantages in its favour are therefore smaller; but it still remains much cheaper than any form of candle or of oil-lamp, in relation to the quantity of light yielded. All lamp-oils contain some oxygen, which neutralizes a part of the hydrogen and carbon, and also some oxide or other substance which damps the brilliancy of the flame; whereas rectified camphine, being composed almost wholly of hydrogen and carbon, contains nothing but what is susceptible of combustion. Whether the lamp be so constructed as to admit of this perfect combustion, and also so as to avoid danger, are questions for the manufacturer; but in a scientific point of view, camphine seems better fitted for combustion than oil. It is not alone from turpentine that the spirit may be procured; for tar and naphtha also, if subjected to careful distillation and rectification, will yield a spirit or camphine differing but little from that yielded by turpentine.

A few words may here be added concerning two important features connected with lamps, viz. the comparative illuminating powers of different kinds, and the means of carrying off the products of combustion.

Pectet, Dr. Ure, and Dr. Fyfe have all instituted experiments bearing on the former of these two questions. Pectet experimented on candles only. He determined what would be the value of different kinds of candle, sufficient to produce a given intensity of light, as determined by Carcel's lamp as a standard. They rank in the following order, the first being the cheapest:—tallow candles, six to the pound; ditto, of eight to the pound; pressed tallow; stearine; spermaceti; wax. This relation was as to price only; the relative weights of material consumed followed a different order of arrangement, the spermaceti being the least, and the pressed tallow the greatest. In Dr. Ure's list ('Supplement to Dictionary of Arts') the relative quantities of light for a given price, or the relative cheapness of a given quantity of light, among several kinds of lamps and candles, are placed in the following order:

Hot-oil lamp, with southern whale-oil,
Carcel lamp, with sperm-oil,
Hot-oil lamp, with sperm-oil,
„ „ with common olive-oil,
„ „ with cocoanut-oil,

French lamp, with sperm-oil,
Mould tallow candles,
Palmer's spread-wick candles,
Stearic acid candles,
Cocoa-nut stearine,
Spermaceti candles,
Wax candles:

the first being, in point of economy, the cheapest, and the last the dearest.

Dr. Fyfe's experiments ('Transactions of the Royal Scottish Society of Arts') seem to have been of a more extensive character, embracing a larger number of sources of illumination. Assuming a given intensity of gas-light as a standard, he experimented on ten varieties of candles, and found their relative cheapness, in producing the given degree of light, to rank as follows:—tallow with single wick, cocoa, composite, palm, tallow with double wicks, wax, diaphane, margarine, spermaceti, and composition. In another table, comparing gas, oil, and candles together, he assumed an Argand gas-flame as a standard of intensity and price, and gives the following arrangement in respect to the ratios of relative cheapness, the intensity of light being uniform:—

Argand gas-flame	1·00
Solar lamp	2·00
Naphtha	2·00
Solar oil in Argand lamp	3·98
Whale-oil	5·00
Sperm-oil	8·00
Tallow candle (two wicks)	12·70
Cocoa candle	13·10
Tallow candle (one wick)	13·50
Composite	14·50
Palm	18·90
Wax	25·90
Diaphane	27·10
Margarine	28·40
Spermaceti	29·20
Composition	29·20

According to this table, composition candles are nearly thirty times as costly as gas for an equal intensity of light.

Dr. Faraday has introduced an important arrangement for carrying off the products of combustion in gas and oil lamps. This arose out of a complaint, on the part of the members of the Athenæum Club, that the air of their library was vitiated and the binding of the books injured by the lamps then used. Dr. Faraday investigated the subject, and shortly afterwards communicated to the Institute of Civil Engineers the mode which he proposed to adopt for remedying the evil. In a paper communicated to this body (Session 1843) he adduced striking proof of the magnitude of the product resulting from combustion. Oil and gas each contains carbon and hydrogen, and each requires the addition of oxygen to bring about combustion. The light is one of the indications of the intensity of this union; and the substances which result from it are mainly two—*water*, by a combination of some of the oxygen with the hydrogen; and *carbonic acid*, by the combination of more of the oxygen with the carbon. The quantity of these two substances produced, owing to the enormous absorption of oxygen during the combustion, would by many persons be deemed quite extraordinary. 'A pint of oil, when burned, produces a pint and a quarter of water, and a pound of gas more than two and a half pounds of water; the increase of weight being due to the absorption of oxygen from the atmosphere, one part of hydrogen taking eight parts (by weight) of oxygen to form water. A London Argand gas-lamp, in a closed shop-window, will produce in four hours two pints and a half of water; a pound of oil also produces nearly three pounds of carbonic acid, and a pound of gas two and a half pounds of carbonic acid. For every cubic foot of gas burned, rather more than a cubic foot of carbonic acid is produced.'

As the water produced deadens the effect of the flame, and as the carbonic acid is very deleterious to the lungs, Dr. Faraday contrived a mode of carrying both off without allowing them to mix with the air of the room. Air is admitted to feed the flame, nearly in the usual way; but when the products of combustion have arrived at the top of the glass chimney, their progress is arrested by a covering of talc, and they are compelled to pass down between the chimney and another larger glass chimney concentric with it. The open space between the two chimneys communicates with a pipe which is conducted in any convenient way into the open air; the carbonic acid, aqueous vapour, smoke, and other emanations from the flame have no means of escape except through this tube, and they are thus wholly cut off from contact with the air of the room. The mode of carrying out the arrangement may be varied in its details; but the general result is said to be that the light is brighter, the space around the lamp cooler, and the air of the room less vitiated than when common open burners are used.

LIGOZZI, JA'COPO, a distinguished Italian painter in fresco and in oil, was born at Verona, in 1543, and studied under Paolo Veronese. He established himself at Florence, where he had much influence upon the painters of his time, especially in colouring, for though not equal to Paolo Veronese, Ligozzi was an effective and powerful colourist, and at the same time that he added vigour to the colouring of the Florentines, he improved his own drawing. The Grand Duke Ferdinand II. appointed Ligozzi his principal painter, and superintendent of the Imperial Gallery. He died in 1627.

Ligozzi is the painter of several great works in oil, though they are what the Italians call *quadri di macchina* or machines, that is ornamental or decorative works, distinguished chiefly for their size and effect on the eye. The following works, however, are of a superior order of this class—San Raimondo resuscitating an infant, in Santa Maria Novella; the four crowned Saints,—SS. quattro Coronati—at Gli Scalzi, or the barefooted friars, at Imola; and the Martyrdom of Santa Dorotea, at the Conventual Friars, at Pescia. Ligozzi executed also many small highly finished easel pictures. Agostino Carracci engraved some of his works.

(Lanzi, *Storia Pittorica*, &c.)

LIGUSTRUM, a genus of plants belonging to the natural order Jasminaceæ. It has a fleshy fruit, the berry containing two membranous one-seeded nuts. The calyx is short, tubular, and four-toothed; the limb of the corolla 4-parted and spreading; stamens 2, with short filaments. The species are shrubs or low trees, natives of Europe and Asia.

L. vulgare, Common Privet, has elliptic lanceolate glabrous leaves; compound racemes; sweet-scented flowers, white at first, but soon changing to a reddish brown. The berries are dark purple, almost black. It is a bushy sub-evergreen shrub, growing in hedges and thickets in Great Britain, and native of the South-west of England. This plant was formerly called Prim, or Primwort, from its being used for verdant sculptures, or topiary-work, and for primly cut hedges. The common English name Privet seems to have been given to it from its being frequently planted to conceal private places. In German, Dutch, Danish, and Swedish it is called Ligster; in French, Troëne; in Italian, Ligustro; in Spanish, Alhena; and in Portuguese, Affena. It is probably the Σφίραια of Theophrastus, 'Hist. Plant.' 1, 14. In point of utility and ornament few shrubs exceed the privet. Its chief use is to form hedges either for shelter or ornament. It bears cutting well, and is not liable to be disfigured by insects; having fibrous roots, it robs the ground less than almost any other shrub. It is one of the few plants that will grow in the smoke of London; it also thrives under the dripping of other trees. The wood is hard and fit for timber. From the pulp of the berries a rose-coloured pigment may be prepared; with the addition of alum they dye wool and silk of a good durable green. The following varieties are those found chiefly in our gardens:—

L. v. leucocarpum, the white-berried privet.
L. v. xanthocarpum, the yellow-berried privet.
L. v. chlorocarpum, the green-berried privet.
L. v. sempervirens, the Italian or evergreen privet.
L. v. variegatum, the variegated-leaved privet.
L. v. angustifolium, the narrow-leaved privet.

L. Sinense has lanceolate tomentose leaves, white flowers, and very small brown berries. It is a native of China, near Canton.

L. Japonicum is a native of Japan, with oblong ovate grooved leaves, and white flowers growing to the height of six or eight feet.

L. spicatum has elliptic acute leaves, hairy beneath, as well as the branchlets. Flowers crowded, almost sessile, spicate, disposed in a thyrse, having the axis very hairy, and minute bracteas. It is an evergreen shrub, native of Nepaul, on mountains, growing from six to eight feet in height. All the species of Privet are of easy culture, and will grow in any kind of soil. Cuttings root without difficulty. *L. lucidum* requires some protection in the winter.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*; Frass, *Synopsis Floræ Classicæ*; Loudon, *Encyclopedia of Trees and Shrubs*.)

LILAC. [Syringa, P. C.]

LI'LIUM (the Latin *Lilium*, and Greek λείριον), a genus of plants the type of the natural order Liliaceæ. It has a perianth of six leaves spreading or reflexed, with a longitudinal nectariferous furrow at the base of each; an undivided style, capitate stigma, and flat seeds. The colour of the flowers is either white, yellow, or red.

L. candidum, common White Lily, has lanceolate scattered leaves attenuated at the base, a bell-shaped smooth corolla, the petals of a beautiful shining white on their inside, ridged and not quite so transparent or luminous on their outside. The flowers are large, white, and in a cluster at the top of the stem. It blossoms early in the summer, and has been cultivated in our gardens from time immemorial. Great doubts had existed respecting the native habitat of this species, till Mr. Hawkins, the friend and companion of Dr. Sibthorp, found it growing wild in that classical and celebrated spot the Vale of Tempe. It is the κρίνον of Theocritus (*Id.* 23) and of Dioscorides (3. 106). Both Pliny and Ovid have added their testimony to the general admiration in which this plant has been universally held. The flowers have a pleasant sweet smell, and were formerly used for medicinal purposes, particularly as an antiepileptic and anodyne. A water distilled from them had reputation as a cosmetic, but the odorous matter they contain is so exceedingly volatile that it is impossible to preserve it, as it is wholly carried off by evaporation. The roots only are found available in medicine, and they are frequently employed as emollient poultices, owing to the mucilaginous matter which they contain. It is however doubtful whether they are more efficacious than poultices formed of bread or farina. Gerard prescribes the lily root internally in dropsies, and for this purpose bread was made of barley-meal with the juice of the roots instead of water, and eaten for a considerable length of time. This species, as well as others, is cultivated in Siberia and eaten as the potato. The scent of the lily is exceedingly powerful, and peculiarly distressing in some cases. Murray mentions an instance of death ensuing from exposure to the odour of this plant.

L. bulbiferum, Bulb-bearing or Orange Lily, has linear-lanceolate scattered leaves, a bell-shaped erect corolla, glandular and rough on the inside, downy without. The flowers are large and handsome, of a beautiful red or orange colour, pale on the outside, and without any scent. The bulb is composed of numerous thick white loosely imbricated scales. This species and *L. chalcedonicum* is probably the κρίνον of Theophrastus, 'Hist. Plant.' 6, 6, and undoubtedly the ἡμεροκαλλίς of Dioscorides, 3. 127. It is a native of Italy, Austria, and North America.

L. superbum, Superb Martagon Lily, has a revolute corolla, the lower leaves whorled, the rest scattered. The flowers form a branched reflexed pyramid, and are large and handsome, one at the end of each branch, red or yellow with dark spots; their smell is disagreeable. The bulb is as white as ivory. It is a native of North America, whence it was imported by Mr. Peter Collinson in the year 1738.

L. Martagon, Turk's-cap Lily, has whorled elliptic lanceolate leaves, pubescent scabrous stem, nodding flowers, and a reflexed perianth. Though not a native of Great Britain, it is naturalised in copses in many places.

The species enumerated are those most commonly cultivated in our gardens, each of which has many varieties and sub-varieties. They are capable of being propagated by planting the offsets of the roots and by sowing seeds to obtain new varieties. Every year the roots produce many offsets, which, however, unless greatly wanted, are better left on for two or three years. The proper time for separating them is in summer and autumn, when the winter is past and the stalks decayed, either by taking them from the mother bulbs in the ground or removing the whole and dividing the offsets from the main bulb when uncovered; they should then be planted in beds a foot asunder and three inches deep, to remain a year or two; the large roots set again in the borders singly. The sowing of seed is chiefly practised to obtain new varieties of Martagons; it should be done in the autumn, soon after the seed is ripe, in pots or boxes of rich light sandy earth, with holes in the bottoms half an inch deep; the pots or boxes should be placed in a sheltered position during the winter and refreshed often at first with water; the plants will appear in the spring; in August they should be transplanted into nursery beds in flat drills an inch deep and three or four asunder. After having grown in this situation till the August or September following they should be again transplanted into another bed, and at greater distances; after which they may be finally removed into the pleasure-ground. The bulbs should be planted singly, as they soon increase by offsets into large bunches. All the species and varieties of *Lilium* are valuable as plants of ornament for the beauty of their flowers, which have a noble appearance. They are proper for the pleasure-ground, and if planted with judgment, succeed each other in blooming upwards of three months. The common white lily, the orange lily, and martagon will thrive under trees. The orange-lily also answers well for small gardens and confined situations in towns and cities.

(Babington, *Manual of Brit. Botany;* Fraas, *Synopsis Plantarum Floræ Classicæ;* Rees, *Encyclopædia.*)

LIMBURG, a town in the province of Liege, in the kingdom of Belgium, situated in 50° 40′ N. lat. and 6° E. long., on the Weze (Wesdre). It is a fortified town with two gates, on a mountain, at the foot of which is the suburb of Dalhem or Dolham. This suburb is larger than the town; both together have 3000 inhabitants, who manufacture a considerable quantity of fine linen. There are marble-quarries in the neighbourhood. The railroad from Brussels to Aix-la-Chapelle passes near Limburg.

(Hassel, *Handbuch;* Stein, *Lexicon.*)

LIMBURG ON THE LAHN, situated in 50° 20′ N. lat. and 8° 3′ E. long., is a town in the duchy of Nassau. It is the see of a Roman Catholic bishop. It lies on the river Lahn, over which there is a stone bridge. It has a mint and four churches, of which St. George's Church is deserving of notice. The inhabitants, 3000 in number, have a manufacture of earthenware, and carry on a considerable trade in the productions of the country.

(Cannabich, *Geography;* Stein, *Handbuch*, by Hörschelmann.)

LINA'RIA (from λίνον, flax, owing to a similarity in the leaves), a genus of plants belonging to the natural order Scrophulariaceæ. It has a 5-parted calyx, a personate spurred corolla, the lower lip 3-fid with a prominent palate closing the mouth. The capsules open by valves or teeth at the top. The species are annual or perennial plants, very rarely small shrubs, and the flowers of a beautiful appearance, racemose or spicately racemose at the tops of the branches.

L. Cymbalaria, ivy-leaved toad-flax, has roundish heart-shaped leaves, 5-lobed and glabrous; the stem is procumbent, slender, and rooting. The flowers are solitary, axillary upon long stalks, and of a pale blue colour. It is native of Europe, chiefly on old walls. It grows abundantly in Italy and Sicily, and is found in Great Britain. There are several varieties of this species.

L. Elatine, halbert-leaved toad-flax, has ovate hastate leaves, the lower ones ovate, the peduncles glabrous, stem procumbent, and the spur straight. The flowers are solitary, on long slender stalks, small, and of a yellow colour, with the upper lip purple. It is a native of Europe and Africa, and is found in chalky corn-fields in Great Britain.

L. spuria, spurious toad-flax, has roundish ovate entire leaves, the spur curved upwards, the peduncles hairy, and the stem procumbent. The appearance of this plant is similar to the last, but the flowers are larger, and the whole plant not so slender. It is native throughout Europe in corn-fields, and is found in Great Britain.

L. minor, smaller toad-flax, is distinguished by its linear lanceolate leaves, which are obtuse, glandular, pubescent, and mostly attenuate. The flowers are solitary and axillary, the peduncles three times as long as the calyx, and the seeds oblong sulcate. It is found in sandy corn-fields throughout Europe and Great Britain.

L. pelisseriana, is known by its racemose flowers, which are of a dark purple colour with darker veins. It is native of the south and middle of France and of Great Britain.

L. repens, is distinguished by its lanceolate sepals and angular seeds with transverse elevated lines. The flowers are of a bluish colour, the stem erect, branched, and leafy. The seeds are much smaller than either of the following species. It is found on calcareous soils, particularly near the sea, in Great Britain.

L. Italica has scattered linear lanceolate leaves, lanceolate oblong sepals, and orbicular scabrous seeds, with a membranous margin. The corollas are of a deep yellow colour. This species is found plentifully in the West of England and near Cork, in Ireland; it is also native of Switzerland, Italy, and Hungary.

L. vulgaris has ovate acute glabrous sepals, shorter than the capsules, and the spur. The flowers greatly resemble those of *L. Italica*, but are twice the size. In Worcestershire this plant is called 'Butter and Eggs.' Gerard names it wild-flax, toad-flax, and flax-weed. It abounds in an acrid oil which is almost empyreumatic. Taken inwardly, it induces nausea. It has been advised in dropsy, but Haller and others disapprove of it. When united with milk the juice is a poison to flies.

The whole of the species of Linaria have an elegant appearance, and are therefore suited for flower gardens. They grow well in common garden earth, but prefer a dry sandy soil. The seeds of the annual species require to be sown early in the open border where they are intended to remain. The perennial kinds may be propagated by division at the roots or by seeds.

(Don, *Gardener's Dictionary*; Babington, *Manual of British Botany*.)

LINCOLN, PORT. [SOUTH AUSTRALIA, P. C. S.]

LINDSAY, SIR DAVID, a Scottish poet, was born at Garmylton, in Haddingtonshire, about the end of the fifteenth century. He inherited from his father the estate of 'The Mount,' in Fifeshire, whence, to distinguish him from many others of the same name, he is usually called Sir David Lindsay of the Mount. In the year 1512, he was appointed servitor, or gentleman usher, to the young prince of Scotland, afterwards James V. His duties seem to have been of the most servile kind,—he had not only to attend the person of the infant prince, and see that he was properly attended to, but he seems to have himself exercised the craft of nursing. He says,

When thou was young, I bore thee in my arm
Full tenderly, till thou begouth to gang;
And in thy bed oft happit thee full warm,
With lute in hand syne softly to thee sang;
Some time in dancing fiercely I flang,
And sometimes playing farces on the floor,
And sometime on my office taking cure.

There is little doubt that his genius and good-humour must have made him a very animated and delightful companion to his charge. He seems never to have been entrusted with the education of the prince, which was placed in the hands of a much graver personage—Bishop Gavin Dunbar.

Lindsay's name is connected with a curious and poetical incident. He is the authority on which his kinsman, Lindsay of Pitscottie, in his 'Chronicles of Scotland,' describes a spectral apparition which, in 1513, appeared to James IV. in the church of Linlithgow, and warned him against that campaign which terminated so fatally in the battle of Flodden. Sir David professed to have seen the apparition approach and vanish, and described him as 'ane man clad in a blue gown, beltit about him with a roll of linen cloth, a pair of bootikins on his feet to the great of his legs, with all other clothes conform thereto.'

The 'Dreme,' supposed to be the earliest of his writings, appeared in 1528; it is a satire on the times, representing a vision of the punishment of the prevailing iniquities in the other world. His principal pieces are 'Complaint of the Papingo;' 'Complaint of John the Commonweil;' 'History of Squyer Meldrum;' 'The Monarchie;' and 'The Play, or Satire, on the Three Estates.' There is little sentiment or pathos in Lindsay's poetry—a fierce and unscrupulous tone of sarcasm is his principal quality. All that was powerful in the country came under his lash, and it is one of the most inexplicable circumstances in literary history that he should not have been the victim of his audacity. He particularly excelled in his attacks on the priesthood and the corruptions of the court; and after the Reformation his name was long popular as that of a Protestant champion. 'The Satire on the Three Estates' stands half way between the early 'Mysteries' and the dramas of the latter part of the sixteenth century. It was sometimes acted in the open air, and could not have failed strongly to excite popular feeling against the corruptions, civil and ecclesiastical, which it unsparingly exposed. 'It is a singular proof,' says Sir Walter Scott, 'of the liberty allowed to such representations at the period, that James V. and his queen repeatedly witnessed a piece in which the corruptions of the existing government and religion were treated with such satirical severity.' Another feature that makes the circumstance of Lindsay's performances having such an audience, seem strange at the present day, is their broad indecency. It is certainly beyond that of the other writers of the age, for 'Davie Lindsay,' as he was long called in Scotland, seems to have had an innate liking for what was impure. His 'Squyer Meldrum' is a sort of chivalric history of adventures, some of which exhibit a very loose and dangerous morality. Lindsay held the office of Lord Lyon King at Arms. In 1537 he had the task of preparing some masques or pageants to celebrate the arrival of Mary of Guise, queen of James V. The time of his death is not known, but he is said to have been alive in 1567.

(Lord Lindsay, *Lives of the Lindsays*; Irving, *Lives of Scottish Poets*.)

LINDSEY, REV. THEOPHILUS, was the youngest son, by a second marriage, of a respectable mercer and proprietor of salt-works, residing at Middlewich, in Cheshire, where he was born June 20, 1723, Old Style. His mother having some connection with the family, by whom she was much respected, Theophilus, Earl of Huntingdon, husband of Selina, Countess of Huntingdon, stood god-father for him, and gave him his baptismal name. Lindsey entered St. John's College, Cambridge, in 1741; and, after taking his degrees, he was elected fellow in 1747, about which time, in his twenty-third year, he commenced his clerical duties at an episcopal chapel in Spital Square, London. He then became domestic chaplain to Algernon, Duke of Somerset, and after his death, travelled for two years on the continent with his son, subsequently Duke of Northumberland. On his return, about 1753, he was presented to the living of Kirkby Wiske, in the North Riding of Yorkshire; and in 1756 he removed to that of Piddletown, in Dorsetshire. In 1760 he married a step-daughter of his intimate friend Archdeacon Blackburne, and in 1763, chiefly for the sake of enjoying his society, and that of other friends in Yorkshire, he exchanged the living of Piddletown for that of Catterick, which was of inferior value. Before this removal Lindsey, who had felt some scruples respecting subscription to the thirty-nine articles even while at Cambridge, began to entertain serious doubts concerning the Trinitarian doctrines of the offices of the Church of England, though, for reasons explained at some length by his principal biographer, on his own authority, he did not deem these a sufficient obstacle to the renewal of his assent to them on entering a new living. In 1769 his anti-Trinitarian opinions received additional strength from the commencement of an intimacy with the Rev. William Turner, a presbyterian minister at Wakefield, and Dr. Priestley, then a dissenting minister at Leeds, both of whom entertained similar views with himself. While contemplating the duty of resigning his living, Lindsey was induced to defer that step by an attempt which was made in 1771, by several clergymen and gentlemen of the learned professions, to obtain relief from parliament in the matter of subscription to the thirty-nine articles, and in which he joined heartily, travelling upwards of two thousand miles in the winter of that year to obtain signatures to the petition which was prepared. The petition was presented on the 6th of February, 1772, with nearly two hundred and fifty signatures, among which were those of many eminently pious and learned men; but, after a spirited debate, its reception was negatived by 217 to 71. It being intended to renew the application to parliament in the next session, Lindsey still deferred his resignation; but when the intention was abandoned he began to prepare for that important step, which involved not only severe pecuniary sacrifices, but also the breaking-off from many esteemed friends. Strengthening his mind for the trial by the example of the two thousand ejected ministers known as the Bartholomew divines, he drew up, in July, 1773, a copious and learned 'Apology' for the step he was about to take, which was subsequently published. In the following December, notwithstanding the attempts of his diocesan and others to dissuade him from the step, he formally resigned his connection with the Established Church, and, selling the greatest part of his library to meet his pecuniary exigencies, he proceeded to London. He and his wife reached London on the 10th of January, 1774, and they were soon reduced to such straits as to be compelled to sell their remaining plate for subsistence. On the 17th of April, after experiencing much difficulty in reference to its registration as a place of dissenting worship, he began to officiate in a room in Essex Street, Strand, which, by the help of friends, he had been enabled to convert into a temporary chapel. His desire being to deviate as little as possible from the mode of worship adopted in the Church of England, he used a liturgy very slightly altered from that modification of the national church-service which had been previously published by Dr. Samuel Clarke; which modified liturgy, as well as his opening sermon, Lindsey published. Being very successful in his efforts to raise a Unitarian congregation, he was able shortly afterwards to commence the erection of a more permanent chapel in Essex Street, which was opened in 1778, and which, together with an adjoining residence for the minister, was put in trust for the maintenance of Unitarian worship. His published 'Apology' having been attacked in print by Mr. Burgh, an Irish M.P., by Mr. Bingham, and by Dr. Randolph, Lindsey published a 'Sequel' to it in 1776, in which he answered those writers. In 1781 he published 'The Catechist, or an Inquiry into the Doctrine of the Scriptures concerning the only True God, and object of Religious Worship;' in 1783, 'An Historical View of the State of the Unitarian Doctrine and Worship from the Reformation to our own times; with some account of the obstructions it has met with at different periods;' an elaborate work, which had been several years in preparation; and in 1785, anonymously, 'An Examination of Mr. Robinson of Cambridge's Plea for the Divinity of our Lord Jesus Christ, by a late member of the University.' The work to which this was a reply had appeared several years before, but Lindsey, who disliked personal controversy, had not intended to answer it, though his friends at length prevailed on him to do so. In 1788 he published 'Vindiciæ Priestleianæ,' a defence of his friend Dr. Priestley, in the form of an address to the students of Oxford and Cambridge; and this was followed in 1790 by a 'Second Address to the Students of Oxford and Cambridge, relating to Jesus Christ, and the origin of the great errors concerning him.' In 1782 he invited Dr. Disney, who then left the Established Church on the same grounds as he had done himself, to become his colleague in the ministry at Essex Street, and in 1793, on account of age and growing infirmities, he resigned the pastorate entirely into his hands, publishing on the occasion a farewell discourse (which he felt himself unable to preach), and a revised edition, being the fourth, of his liturgy. He nevertheless continued to reside at the chapel-house, as did his wife after his death. In 1795 he reprinted, with an original preface, the 'Letters to a Philosophical Unbeliever,' which Dr. Priestley had recently published in America in reply to Paine's 'Age of Reason;' and in 1800 he republished in like way another of Priestley's works, on the knowledge which the Hebrews had of a future state. Lindsey's last work was published in 1802, entitled 'Conversations on the Divine Government; showing that everything is from God, and for good to all.' He died on the 3rd of November, 1808, in his eighty-sixth year, and was buried at Bunhill-fields. Copious biographical notices of Lindsey were published in the 'Monthly Repository' and 'Monthly Magazine' of December, 1808, the former being by Mrs. Catherine Cappe, with whom he had lived on intimate terms when in Yorkshire, and the latter by Mr. Joyce; and in 1812 the Rev. Thomas Belsham published a thick octavo volume of 'Memoirs,' in which he gives a full analysis of his works, and extracts from his correspondence, together with a list of his publications, which embrace, besides those above mentioned, several single sermons and tracts. Two volumes of his sermons were printed shortly after his death. The amusing autobiographical 'Memoirs' of Mrs. Cappe, printed in 1822, also contain many notices of Lindsey. A portrait of him accompanies Belsham's 'Memoirs.'

LINEAL DESCENT. [DESCENT, P. C.]

L'INGEGNO. [LUIGI, ANDREA DI, P. C. S.]

LI'PARIS. [DISCOBOLI, P. C. S.]

LIPPI, FRA FILIPPO, a celebrated Italian painter and one of the most distinguished of the *Quattrocentisti*, was born at Florence in the year 1412. He was the son of Tommaso Lippi, who died when Filippo was only two years of age; his grandfather's name was Guido Lippi. His mother died soon after he was born, and he was brought up by his father's sister Mona Lappaccia, until he was eight years old, when she placed him in the Carmelite convent Del Carmine, to commence his novitiate. Here he showed such a strong disinclination for study and so great a propensity for scribbling figures and other objects in his books, that the prior came to the wise conclusion of having him educated for a painter, then an occupation not in the least inconsistent with the assumption of a monastic life. Filippo was accordingly permitted daily to visit Masaccio, who was then employed in painting the chapel of the convent, and he took extreme delight in contemplating the works of Masaccio there. Filippo himself gave early evidence of his extraordinary ability, by a fresco of the papal confirmation of the rules of the order of the Carmelites, painted near a work by Masaccio, in the cloister of the convent, but both are now destroyed; he executed also several other works in various parts of the convent and in the church Del Carmine, each work superior to its preceding, and so like those of Masaccio that his spirit was said to have passed into Filippo. All these works however, or at least what remained of them, were destroyed in the conflagration of the church in 1771.

In 1430, or when only seventeen years of age, Filippo gave up the monastic life, left the convent Del Carmine, and went to Ancona. Here, while on an excursion of pleasure at sea with some other young men, he was captured by a pirate and carried in chains to Africa, and there sold as a slave. Eighteen months after the commencement of his captivity he amused himself one day with drawing, from memory, his master's portrait in chalk upon a white wall. The performance appeared to his master a sort of prodigy; he immediately released Filippo from his captivity, and after he had employed him to execute various pictures for him, sent him back safe to Italy. Filippo was landed in Naples, where he was, probably shortly after his arrival, employed by Alfonso Duke of Calabria, afterwards Alfonso I. of Naples, to paint a picture for the chapel of the Castell' Nuovo, then in his possession, which would fix the date at about 1435, or five years from the time that Filippo left his convent. He remained only a few months in Naples, and then returned to Florence; and one of the first works which he executed at this time was a small picture of the Adoration of the Madonna, for the wife of Cosmo de' Medici, which is now in the Imperial Gallery at Florence.

Fra Filippo executed many excellent works at Florence, Fiesole, Arezzo, and at Prato. While engaged in 1459 in the convent of Santa Margherita, in the last named place, he seduced and carried off Lucrezia, daughter of Francesco Buti, a young Florentine lady who was being educated at the convent; and he had a son by her called Filippino Lippi, who became likewise a celebrated painter, and died in 1505, aged only forty-five. The Death of San Bernardo, painted for the cathedral of Prato, is one of Lippi's finest works; it is in oil and on panel, and is still in the cathedral. The passages also from the lives of John the Baptist and St. Stephen, painted in fresco, in the choir of the same church, from 1456 to 1464, the figures of which are colossal, are among the best works of the fifteenth century: Vasari terms the martyrdom of St. Stephen his master-piece. Filippo has introduced his own portrait into this piece, and he has painted that of Lucrezia Buti as Herodias in one of the series from the life of the Baptist. These frescos were recently restored by a painter of Prato of the name of Marini.

Fra Filippo died at Spoleto in 1469, aged 57; this is no doubt the correct age of Filippo, though Vasari by his carelessness has done much to obscure the matter. In his first edition he states that Filippo died in 1438 aged 67, and in the second, in the same year aged 57; but 1438 is evidently a misprint for 1468; and, from Filippo's connection as a boy with Masaccio, he cannot have been 67 when he died, but may very well have been 57, which age accords with other facts mentioned in his Life: the year of his death, however, was 1469, as discovered by Baldinucci in the Necrology of the Carmelites. But Baldinucci and all other writers have overlooked the value of the evidence connected with Masaccio, and have assumed 1400 to be about the time of Filippo's birth, whereas Masaccio himself was born only in 1402. The pupilage of Filippo to Masaccio, or his works, which is the same, decides another fact, hitherto in doubt, namely, the time in which Masaccio executed the frescoes of the Carmine, supposing they were all painted at one period. Vasari says they were painted after Masaccio's return from Rome, and after the recall from exile of Cosmo de' Medici, which took place in 1434. But the 'Consecration of the Church of the Carmine,' in the cloister, was painted before Filippo left the convent, because Filippo painted his picture of the Confirmation of the rules of the Carmelites by the side of it, and, as said above, he left the convent when only seventeen years old; at the latest, therefore, in 1430, when Masaccio may have been twenty-eight years of age. The frescoes of the Brancacci chapel were executed after the 'Consecration,' and though some of those also may have been completed before 1430, as Masaccio died before they were all completed, it is probable that he was engaged in this convent at two distinct periods, with a considerable interval between them. The picture which Masaccio left incomplete is the resuscitation of a boy by St. Peter, which was completed by Filippo's son Filippino, many years afterwards. The works of Masaccio himself were a continuation of the history of St. Peter, commenced and left unfinished by his master Masolino da Panicale, who died aged only thirty-seven, but in what year is uncertain, yet probably not later than 1420, notwithstanding what Vasari says about Masaccio introducing the portrait of his former master Masolino into the picture of the 'Consecration,' which may have been done from memory or from some existing portrait, for Masolino was certainly dead before Masaccio commenced any work for the Carmine.

Fra Filippo is said to have been poisoned by the relations of Lucrezia Buti; Lanzi speaks of the fact as certain, but Vasari merely alludes to it as a vague report, which is the more probable version. The relations of Lucrezia could do her little service by poisoning Filippo, whom she evidently loved, for she would not return to her relations; and fifty-seven years is no a very short life for a man notoriously given to pleasure; his death also did not take place until eleven years after the abduction of Lucrezia, for Filippino was ten years old when his father died. Fra Filippo was buried at Spoleto, in the cathedral, which he was engaged in painting at the time of his death. His son was instructed in painting by Filippo's pupil and assistant Fra Diamante. He afterwards erected a marble monument, with a Latin inscription by Politian, to his father in the cathedral of Spoleto, by the order and at the expense of Lorenzo de' Medici.

Fra Filippo excelled in invention, in drawing, in colouring, and in chiaroscuro, and for his time was certainly a painter of extraordinary merit; he must, even without reference to time, be accounted among the greatest of the Italian painters from Masaccio to Raphael, both inclusive. Some of his easel pictures in oil are finished with extreme care and great taste; there are a few in the gallery of the Florentine Academy, of which the Coronation of the Virgin, formerly in the church of Sant' Ambrogio, is an admirable work. There are some chalk studies of hands by Filippo in the British Museum. Several of his works have been engraved by Lasinio.

Filippino, though not equal to his father in the higher qualities, surpassed him in others, especially in general accessaries, which he was perhaps the first to bestow great attention upon, and he had much more taste than most of his contemporaries; he understood better the rendering of mere appearances, one of the most essential, though not one of the highest qualities in pictorial art. He excelled in painting Madonnas; but his chief works are the frescoes of the Strozzi Chapel, in Santa Maria Novella, and of the Brancacci Chapel of the Carmine, where, besides others, he painted Peter and Paul before the Proconsul, which was long attributed to Masaccio, as in the 'Etruria Pittrice,' where it is engraved, and in many other works.

(Vasari, *Vite de' Pittori*, &c.; and the notes to the German Translation by Schorn; Baldanzi, *Delle Pitture di Fra Filippo Lippi nel Coro della Cattedrale di Prato*, &c.; Baldinucci, *Notizie dei Professori del Disegno*, &c.; Rumohr, *Italienische Forschungen*; Speth, *Kunst in Italien*; Gaye, *Carteggio inedito d'Artisti*, and *Kunstblatt*, 1836.)

LIQUIDITY is that condition of a material substance in which the particles have a perfect freedom of motion, without any sensible tendency to approach to or recede from one another, except by the action of some external power. Liquidity is therefore comprehended in the condition of fluidity, the latter term being applied as well to gases, and even to the principle of electricity, magnetism, &c., as to water, oil, &c., which are properly called liquids. [FLUID, FLUIDITY, P. C.]

The phænomena of capillary or molecular action show that the attractions which constitute what are called the affinities of substances extend to very small distances only from the particles; and hence, when the particles of a substance are situated beyond the limits of such attractive forces, the repulsive power, arising probably from the action of caloric, causes the particles to recede continually from one another, and induces the state of aeriform fluidity. Now the phænomena of crystallization seem to indicate that the attraction of affinity is exerted with greater or less intensity according as the like or unlike sides of the particles of a substance present themselves to one another in their mutual approaches; but it is probable that this modification of the attraction of affinity extends to less distances from the centres of gravity of the particles than the general attraction extends: hence, when the particles of a substance are, from any cause, brought so near one another that the attraction of affinity is in equilibrio with the repulsive force of the caloric, and at the same time the modification of that attraction caused by the various positions which the particles assume in approaching one another, entirely or nearly vanishes, it should follow that the particles become freely moveable in any direction about one another, whatever be their form; and thus may arise the condition of liquidity.

It may be added that, if the particles of a substance be, by the abstraction of caloric, made to approach still nearer to one another, the attraction of affinity will exceed the force of repulsion; and there will be constituted a solid body, which may be crystallized or not according as the particles approach one another gradually or otherwise: in the former case they may arrange themselves in such positions as to become connected together in one direction by the sides at which the attraction is the greatest; while, if the approach is rapid and is accompanied by agitation, the union of the particles may take place irregularly.

The particles of a liquid are held together with considerable force notwithstanding their freedom of motion, since a small quantity of a liquid has a tendency to take a spherical form when at a distance from any substance for which its particles have greater affinity than for one another: this is very evident in mercury, oil, and water, the first of which on being suffered to fall on a table immediately divides itself into globules, and the others take a like form when a small quantity of either is suspended from a pointed extremity of any object.

The dilatations of water and mercury by the application of heat, as well as the remarkable fact that the expansions of water are equal at temperatures which are at equal distances above and below about 39° (Fahrenheit's scale), have been noticed under THERMOMETER, P. C. But the expansions of any liquid, at different temperatures, for equal increments of caloric, are not equal to one another; and the following table of expansions, in volume, for an increment expressed by 1° (Fahr.), is abridged from that which is given by Dr. Young in his *Lectures on Natural Philosophy* (vol. ii. pp. 392, 393):—

Temperature.	Expansion.
Water (Sp. gr. = 1 at the maximum density).	
44 and 34°	·00002
48 and 30°	·00004
54	·00008
64	·00010
74	·00014
90	·00020
142	·00031
212	·00038
Highly rectified spirit of wine (Sp. gr. = 0·825).	
0°	·00047
12	·00050
32	·00054
52	·00057
72	·00061
92	·00065
132	·00074
172	·00083
Sulphuric acid (Sp. gr. = 1·84).	
55°	·00021
60	·00029
65	·00037
Muriatic acid (Sp. gr. = 1·185).	
50°	·00035
60	·00055
65	·00070

From the experiments of MM. Dulong and Petit, the mean expansion of mercury, in volume, for 1° (Fahr.) between the temperatures of freezing and boiling water, is expressed by ·000101; between the freezing-point of water and 392° (Fahr.), by ·000102; and between the freezing-point of water and the temperature at which mercury boils, by ·000105.

The expansions are expressed in parts of the original volumes of the liquids; and the corresponding linear expansions, in parts of the length of a column of the liquid, may be obtained with a sufficient approximation to the truth on dividing each of the above numbers by 3.

The phænomena of molecular action in liquids are mentioned under CAPILLARY ATTRACTION, P. C., and the state of our knowledge on that subject is noticed under THEORIES OF MOLECULARITY, P. C. For the specific heat of liquids, or their capacity for caloric, see SPECIFIC HEAT, P. C. S.

LIS PENDENS. [NOTICE, P. C.]

LITHOGRAPHIC PRESS. In the article LITHOGRAPHY, P. C., a reference was made to PRESS for an account of the press used in lithographic printing; but this account was accidentally omitted.

The mode of printing from a lithographic stone does not differ very materially from that adopted with copper and steel plates. A direct downward pressure, such as is used in type-printing, would not produce all the required effects: the action necessary being rather a kind of rolling than a direct pressure. In printing from a copper plate, the plate and the paper are passed between two rollers, the uppermost of which has an elasticity or softness given to it by layers of padding or felt; and the degree of closeness between the rollers is regulated according to the strength or blackness of the impression required.

In the lithographic process, the pressure is accompanied by a sort of scraping movement. Soon after the adoption of this branch of engraving, the press used in Paris consisted of a hollow table for holding the stone, covered with a tympanum or stretched parchment; the engraved stone was inked by rollers, the paper was laid down on it, the tympanum was brought down over the paper, and a bar of wood was pressed firmly on the tympanum; the stone, by the action of the levers, was made to traverse from side to side beneath this bar, so that every part of it in turn experienced the pressure of the bar.

All the parts of the apparatus have since undergone improvement and modification. Messrs. Taylor and Martineau's lithographic press has two cast-iron uprights rising from the bed or table; and there is a carriage for containing the stone, which carriage is supported on rollers moving along a miniature railway. The scraper or bar, instead of being pressed down by leverage, is governed by a spring, which keeps it closely in contact with the tympanum. A cylinder, worked by a handle, sets the carriage in motion, and the stone is thus brought in all its parts under the action of the scraper or pressing-bar. The different parts of the apparatus are adjusted to different requirements of the art by regulating screws.

Other machinists have improved the press in various ways; but the general principle of the apparatus may be inferred from these few details.

LITHORNIS. A fossil bird from the Isle of Sheppey is thus named by Owen.

LITHOSPERMUM (from λίθος, a stone, and σπέρμα, a seed; in reference to the hard seeds or nuts), a genus of plants belonging to the natural order Boragineæ. It has a deeply cut calyx in five segments, a funnel-shaped corolla, with a naked or minutely five-scaled throat. The filaments are very short; the stamens included in the tube. The nuts are smooth or tubercular, stony, and attached by their truncate flat base to the bottom of the calyx.

L. officinale, Gromwell, has an erect much-branched stem, lanceolate acute veined leaves with tubercles and adpressed bristles above, hairy beneath; the throat of the corolla has minute scales within, and is of a pale yellow or greenish colour. The nuts are white, shining, and very hard, two or three ripening in each calyx. They were esteemed in antient times as an infallible lithonthriptic; their virtues in this respect are, however, entirely imaginary. This species is native of Europe, Asia, and North America. It is found in dry and stony places in Great Britain, but sparingly.

L. purpureo-cæruleum has herbaceous stems, the barren ones prostrate and creeping, the others erect. The leaves are lanceolate, acute, and scabrous, of a dark green, with revolute margins. The flowers are showy and large, at first red, and afterwards of a bright blue. The nuts are white, highly polished, and hispid. This species has no scales in the throat of the corolla, but merely five longitudinal downy folds. It is native of middle and south Europe, of the Caucasus in woody mountain places, and of England and Wales in chalky soil.

L. arvense, Bastard Alkanet, has an erect branched stem, lanceolate leaves rather acute, hairy, and subciliated; the calyx a little shorter than the corolla; the nuts tubercular, wrinkled, polished, and of a pale brown. The throat of the corolla is destitute of scales, as in the former species. The flowers are white and small; the root of a bright red, communicating its colour to paper. It is native of Europe, Asia, Africa, and some parts of North America, and is found plentifully in the corn fields of Great Britain.

L. tinctorium has herbaceous procumbent stems, lanceolate obtuse leaves, hairy calyxes a little shorter than the tube of the corolla. The upper leaves are half-clasping, the lower ones on petioles. The flowers sessile in simple or conjugate leafy spikes; they are of a fine blue colour with a white throat. It is native of Spain, South of France, Italy, and Hungary, in sandy sterile places.

L. tenuiflorum has an herbaceous erect branched stem, lanceolate obtuse hairy scabrous leaves, the lower ones opposite; the calyx is shorter than the tube of the corolla, conniving when bearing fruit. It is native of Egypt and the island of Cyprus, and has the habit of *L. arvense*, but is much smaller. It is the Λιθόσπερμον of Dioscorides, 3. 148, and the Lithospermum of Pliny, 27. c. 74. *L. apulum* is the Σκορπιοειδὴς of Dioscorides, 4. 192.

All the species of Lithospermum are noted for the stony hardness of their pericarps, which have the brittleness and lustre of porcelain. This membrane when analyzed is found to contain nearly 60 per cent. of earthy matter, which is more than is known in any other organized substance. According to Spenner *L. officinale* is the only true Lithospermum, none of the other species having a crown of scales in the throat of the corolla. The perennial and herbaceous species are plants of very easy culture, requiring hardly any care. They are always propagated by seed, which may be sown in the open ground. The annual species should be treated as greenhouse plants, and the shrubby kinds may be grown on rockwork or on wall-tops, where they will maintain themselves if allowed to scatter their seeds. They do very well in pots among other alpine plants, and cuttings of them may be rooted under a hand-glass. In general they are however short-lived and apt to rot.

(Don, *Gardener's Dictionary*; Babington, *Manual Brit Bot.*; Burnett, *Outlines of Botany*.)

LIVERWORTS, or LICHENS, a family of plants belonging to the class Cryptogamia, of which a definition is given under LICHENS, P. C. The order consists of between fifty and sixty genera, which are divided by Fries into four sub-orders:—Hymenothalami, Gasterothalami, Idiothalami, and Coniothalami: to these some systematists add Byssaceæ. [BYSSOIDEÆ, P. C. S.] These are again subdivided into several tribes, each tribe comprising several genera.

The tribe *Usneaceæ* are characterised by having an open disk, and being destitute of an hypothallus. It embraces the genera *Usnea*, *Everina*, *Roccella*, *Ramalina*, and *Cetraria*. Several species of *Usnea* are known by the common names of Jupiter's-beard, Tree-beard, &c., on account of their hair-like appearance. They are amongst the most common of the Lichens which cover the trunks of aged trees, and give to them a picturesque appearance. *Usnea plicata* is a common species on old trees, park palings, &c., and has been recommended as a remedy in hooping-cough.

The species of the genus *Everina* are common in Great Britain. One of them, *E. prunastri*, has a peculiar power of imbibing and retaining odours, and on this account is in much request as an ingredient in perfumed cushions and sweet pots. It has been recommended as a remedy in pulmonary affections. It is frequently found on the oak and other trees. Evelyn says of it, 'This very moss of the oak that is white composes the choicest cypress-powder, which is esteemed good for the head; but impostors familiarly vend other mosses under that name, as they do the fungi for the true agaric (excellent for hæmorrhages and fluxes), to the great scandal of physic.' It is said that *E. vulpina* is poisonous to wolves, hence its name, but little is known of its real properties.

The genus *Ramalina* is found associated with the last two on the trunks and branches of trees, especially of the fir, the birch, the ash, the oak, the sloe, and the hawthorn. Lightfoot says that the *R. scopulorum* 'will dye a red colour, and promises in that intention to rival the famous Lichen roccella or argol which is brought from the Canary Islands.'

For the properties and uses of the species of Roccella and Cetraria see ORCHIL, P. C., and CETRARIA, P. C. S.

The tribe *Parmeliaceæ* is characterised by a horizontal thallus. To it belong the genera *Peltigera*, *Sticta*, *Borrera*, Parmelia, &c.

Two of the species of *Peltigera*, *P. canina* and *P. aphthosa*, have been used in medicine; the former as a remedy in hydrophobia; the latter is boiled in milk and administered in the thrush.

The species of *Parmelia* are exceedingly numerous; one of the most common throughout Europe is the *P. parietina*, yellow moss. The thallus and shields are both of a yellow colour; and Lightfoot says, 'It is affirmed to die a good yellow or orange colour if mixed with alum.' It has also a very bitter taste, which has caused it to be used as a tonic in medicine, and it has been recommended as a remedy in intermittent fever. *P. tartarea* yields the dye known by the name of Cudbear. [PARELLA, P. C.] *P. Parella* affords the substance known as Litmus, or Lacmus. [LITMUS, P. C.]

One of the species of the genus *Sticta*, *S. pulmonacea*, has been used as a substitute for the Iceland moss. [CETRARIA,

P. C. S.] It is used in Siberia for giving a bitter flavour to beer. It is a native of Great Britain, and is found on the trunks of trees in mountainous districts, almost entirely covering them with its large shaggy fronds.

A species of Borrera [BORRERA, P. C. S.], *B. furfuracea*, is reputed to be astringent and febrifuge. It is found on the trunks and branches of old trees, especially when decaying, and on old pales.

The tribe *Lecidinæ* embraces the important genus *Cladonia* [CLADONIA, P. C. S.], and also *Cenomyce* and *Scyphophorus*, which are often only regarded as subgenera of Cladonia. Tho *S. pyxidatus* and *S. cocciferus* are elegant lichens, having their apothecia elevated above the thallus in the form of little cups, those of the latter species being coloured scarlet. They have both been used in medicine as astringent and febrifuge.

The tribe *Sphærophoreæ* contains tho genera *Sphærophoron*, *Plocaria*, and *Isidium*. They are an exceedingly elegant group of Lichens, but the species have not been much used for economical purposes. *Isidium corallinum* is said to be rich in colouring matter.

The genera *Endocarpon* and *Porina* belong to the tribe Endocarpeæ. The species of the former genus are found on rocks and stones, whilst those of the latter are interesting as forming distinguishing marks between various kinds of barks used in medicine. Fée, in his 'Méthode Lichénographique,' has endeavoured to apply a knowledge of the various species of Lichens to the distinguishing not only between the bark of different species of Cinchona, &c., but also between good and bad barks of the same species.

Tho principal genus of the tribe *Verrucarinæ* is *Verrucaria*, of which the species are very numerous. [VERRUCARIA, P. C.]

The tribe *Graphideæ* is remarkable for the forms which the apothecia assume, bearing a resemblance to the letters of Eastern alphabets. This may be seen in Opegrapha scripta in *Fig.* 7 of the woodcuts illustrating the article LICHENS, P. C. As an indication of the value of the Lichens in distinguishing the various species of Cinchona bark, Fée states that the *Graphis interrupta* is only found on the bark of *Cinchona lancifolia*. Although the study of the Lichens on the officinal barks has not produced all the advantages anticipated by Fée, there can be no doubt of its value in many cases. Referring to this subject, Burnett observes, 'Until the publication of Fée's memoir on the cryptogamic epiphytes of the officinal barks, the study of the Opegraphas and their allies seemed to be one rather of speculative amusement than of practical utility. But now the case is wholly changed, since these graphic plants, these living letters, written by Nature's hand, are shown to constitute inscriptions legible by men. Always curious indeed, and admirable even to the least tutored eye, did the examination of these mimic characters appear; and as fancy traced the likeness to various Oriental signs, so were these little plants called Scripture-worts, some Hebrew (*Opegrapha Hebraica*), some Chinese (*Arthonia Sinensigraphia*), and so forth. But, like the hieroglyphics of the Egyptian fanes, their meaning was buried in obscurity, and so little guessed at, that it often was doubted whether they had any secrets to reveal. They were sources of wonder rather than wisdom, until the Young and the Champollion of the vegetable world arose, and by means of a natural Rosetta-stone deciphered these hitherto unknown manuscripts, and taught us to peruse this part of the sacred Scriptures of creation.'

(Burnett, *Outlines of Botany*; Lindley, *Natural System*; Lindley, *Flora Medica*; Fries, *Lichenographia Europæa reformata*.)

LIVERYMEN OF LONDON. [LONDON, P. C.]

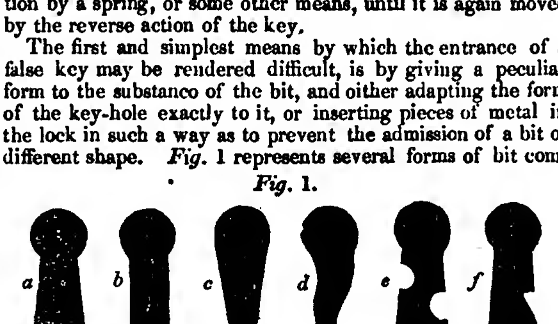
LOCK, a kind of secret fastening in which a moveable piece, termed a *bolt*, may be projected by the action of a separate instrument, called a *key*, introduced iuto the lock in such a manner that it cannot be returned to its nriginal position, so as to release the door, cover, or other article to which the lock is applied, excepting by another application of the key. While, however, the above appears to be the distinguishing characteristic of a lock, there are many locks in which the bolt is projected by the action of a spring, without the aid of the key, and in which it may be drawn back upon one side of the door to which it is applied by means of a handle, although it cannot be moved from the other side without the application of the key. Many such locks fall under the general denomination of *latches* or *latch-locks*. In other locks, again, there are two or more bolts, one of which only is under the control of the key, the others being moved by handles; while in another class of locks two or more bolts are shot or projected by the action of the key alone. In addition to such differences, the varieties in the form and size of locks, and in the arrangement of their parts, are almost infinite. In door and closet locks, which are sometimes attached to the surface of the door on the inner side, and sometimes inserted in the thickness of the woodwork, the bolt is usually projected into a fixed socket. In various kinds of box and cabinet locks the bolt is not under any circumstances projected beyond the casing of the lock, but is caused to shoot into or through a staple which drops into the lock to receive it. In desk-locks and some others the bolts project permanently, and are of a hooked shape, adapted to catch, by a lateral movement, into cavities or staples provided to receive them. *Padlocks* are a kind of detached lock in which a curved bar of iron, pivoted to the lock at one end, may be passed through a staple, and then so secured by shooting the bolt into a cavity in its free end, which is inserted into the lock for the purpose, that it cannot be removed from the staples or links through which it has been passed.

By far the greater part of the almost innumerable ingenious contrivances for rendering locks inviolable may be classed under one of two systems of security, the distinction between which was pointed out by Mr. Ainger iu a paper read before the Royal Institution in 1827 (an abstract of which was published in the first volume of the 'Quarterly Journal of Literature, Science, and Art'), and is further illustrated by the same gentleman in the article 'Lock,' in the seventh edition of the 'Encyclopædia Britannica.' Of these means of security, the first consists in the insertion in the lock of fixed obstacles, commonly called *wards*, which prevent the entrance or revolution of any instrument or key which is not formed with corresponding openings, so as to thread its way among them, and thus render the bolt inaccessible to any but the proper instrument; while the second consists in the use of moveable impediments, which in their most general form are called *tumblers* (a term which, for convenience, we may apply generically), to the motion of the bolt itself, the security arising from the difficulty of bringing these moveable impediments, by the use of any but the proper key, to the actual and relative positions necessary to allow free motion to the bolt. In many locks both of the above means of security aro used, but for convenience we shall here notice the peculiarities of each system independently of the othor. In dealing with the first system we may include under one general head all contrivances whatever by which the approach of the key to that part of the bolt by which it is capable of being shot backwards and forwards is impeded.

The key of an ordinary lock consists of a cylindrical shank with a loop-shaped handle at one end, and a piece called the *bit* projecting from it at a right angle at or near the other end. The bit end of the shank is, in the keys of locks which are to be entered by the key from one side only, made hollow or tubular, to fit on to a pin or axis fixed in the lock; but in locks which may have to be opened from either side, such as ordinary room-door locks, as no pin can be fixed in the lock, the shank is made solid, and is prolonged beyond the bit, so as to enter, and turn as in a socket within, the upper part of the key-hole of that plate of the lock which happens to be farthest from the person applying the key. The projecting bit, after being introduced into the body of the lock by a narrow opening (the key-hole), is turned round within tho lock by a rotatory motion imparted to the shank, until it comes in contact with a part of the bolt which is so shaped that the bit of the key cannot pass it, to complete its revolution, without shooting the bolt either backwards or forwards, as the case may be. When thus moved the bolt is retained in its position by a spring, or some other means, until it is again moved by the reverse action of the key.

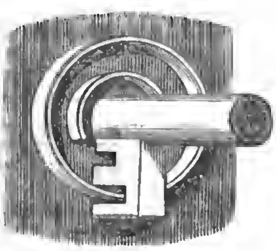
The first and simplest means by which the entrance of a false key may be rendered difficult, is by giving a peculiar form to the substance of the bit, and either adapting the form of the key-hole exactly to it, or inserting pieces of metal in the lock in such a way as to prevent the admission of a bit of different shape. *Fig.* 1 represents several forms of bit com-

Fig. 1.



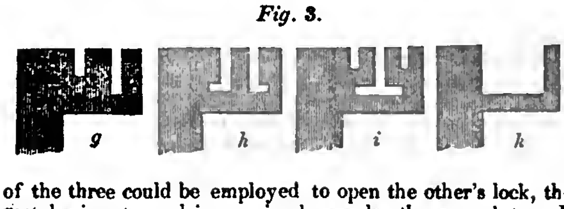
monly used, the keys, which are all represented as of the pipe or tubular make, being presented to the eye endways. Of these *a*, *b*, *c*, and *d* are adapted for key-holes of various corresponding forms, while *e* and *f*, though suitable for key-holes of the same general form as the bit *a*, admit of further security by forming projections upon the sides of the key-holes, which are cut through the plate of the lock, to fit the notches and grooves cut in the sides of the bit. The next and principal means of security of the first class mentioned above is the use of pieces of iron or brass of various forms, fixed within the lock in such a way that no key can be turned round within it unless corresponding notches or slits are cut in its projecting bit. *Fig.* 2, which represents a portion of the interior of a lock in isometrical projection, with the bit end of the key in its place, will illustrate this. The tinted surface in this cut represents part of the back-plate of a lock with a tubular key turning upon a central pin in the plate. Attached to this plate are two concentric prominent rings, of different degrees of elevation, one of which, for the sake of variety, is represented as complete or unbroken, while the other is cut away for a small space at the under side. These prominent rings are the *wards*, or, in technical language, *wheels*, which impede the introduction of a false key. It is obvious that no key could be put into a lock provided with them as in the cut, unless a slit or notch were made in its bit to correspond with the larger and more prominent of the two rings; and it is equally evident that, although it might be put into the lock, no key could be turned round without having also a notch to correspond with the smaller and less prominent circle, which, being cut off near the key-hole, could not be discovered by an inspection from the outside of the lock. In the commoner kind of locks the wards seldom form a complete circle, but their effect is the same if they occupy only a small segment of it. They are commonly made of thin sheet iron, riveted to the plates of the lock; but locks with similar wards of copper are made for use in cellars, and other places exposed to damp, where iron wards would become rusty. A thicker kind of ward, known as solid wards, formed by casting in brass, and finished in the lathe, is used in many superior locks. The above cut represents wards of the simplest possible shape, which require nothing but a simple straight notch in the key to fit them. Many wards, however, are of a more complicated character, such as what are termed L, T, or Z wards, from the resemblance of their sectional form to those letters respectively. The keys must, of course, be cut of a corresponding form, by which the difficulty of imitation is greatly increased.

Fig. 2.



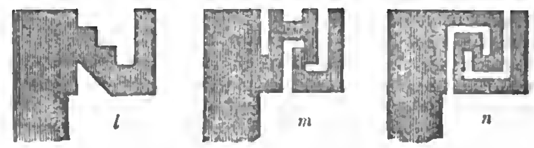
By referring to the various forms of key represented in *Figs.* 3, 4, 5, and 6, the peculiar advantages and defects of that principle of security which depends on the use of wards, may be readily comprehended. The first and greatest defect of the system arises from the circumstance that, in ordinary cases, it is not absolutely necessary that a surreptitious instrument should perfectly thread the mazes of the wards. Thus the form and arrangement of the wards in the three keys marked *g*, *h*, and *i*, *Fig.* 3, is so different, that none

Fig. 3.



of the three could be employed to open the other's lock, the first having two plain or simple wards, the second two L wards, and a third a T ward between two plain wards; but while these afford security against ordinary keys, they afford none whatever against a *pick* or *skeleton key* like *k*, *Fig.* 3, which would also open any other lock which is guarded merely by wards attached to the back-plate; the only part essential to the moving of the bolt being the extremity of the bit, which is retained in the skeleton key with nothing but a slender piece to connect it with the pipe or shank. The security may be greatly increased by the use of other wards, attached to the opposite plate of the lock, and requiring notches in that part of the bit of the key which is represented by the slender connecting piece in the skeleton *k*. Such is the case in all the keys represented in *Figs.* 4, 5, and 6. In *Fig.* 4, *l* represents

Fig. 4.



sents a key for a solid-warded lock, which might, however, be easily picked by a skeleton key resembling *r*, *Fig.* 6. The greater complication of the wards in *m*, *Fig.* 4, increases the difficulty of picking; while by the adoption of the arrangement shown at *n*, *Fig.* 4, the difficulty of introducing a false key is made perhaps as great as possible, since no instrument that does not thread all the intricacies of the wards could answer the purpose. This form, however, requires very accurate workmanship, and unavoidably weakens the key to such an extent that it is in danger of breaking in the lock. All the keys hitherto represented, as well as those in *Fig.* 6, are pipe-keys, adapted for such locks as have a fixed pin or axis, and can only be opened from one side. It is, therefore, of no consequence that the wards attached to the back and front plates of the lock should resemble each other. In ordinary door-locks, however, in which the key may have to be inserted from either side, it is essential that the wards attached to the two plates, if such be used, should either be precisely similar, or should bear such a relation to each other that notches may be cut in both sides, or rather edges of the bit, or, as it is sometimes called, the *web*, of the key to suit both sets of wards, it being a necessary condition that the two sides of the bit, marked *a* and *b* in the cut, *Fig.* 5, should be perfectly alike. In such locks there is, very commonly, an intermediate plate, which enters the opening marked *c* in the annexed figure, and which carries, on one or both of its sides, the principal wards; and in many cases the bit of a key divided by such an opening may be considered as constituting a double key, of which only one-half is used at one time, that half being either *a* or *b* according to the side through which the key is put into the lock. Such is in some measure, the case in the key from which *Fig.* 5 is drawn; although, as it is the key of a tumbler lock, both halves are brought into use at once, whatever may be the direction in which the key is applied, with this difference, that when the key is applied from the outer side of the door the part marked *a* moves the tumbler and *b* the bolt, while when the key is put into the lock from the inner side *a* moves the bolt and *b* the tumbler. Our remaining illustrations of warded keys are intended to explain the theory of *master-keys*, which was early understood by the ingenious locksmiths of Wolverhampton. In *Fig.* 6 the wards of the keys o, *p*, and *q* are so far different from each other that neither of those three keys

Fig. 5.

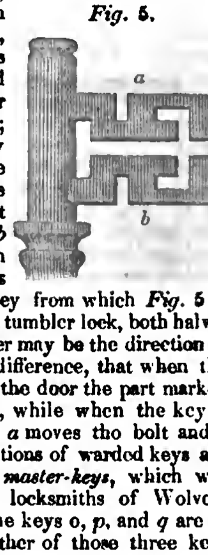


Fig. 6.

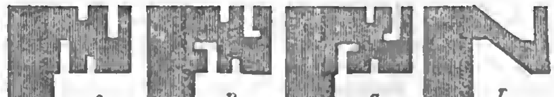

would open the lock designed for either of the other two, but a key formed like *r* would readily open any of the locks of the other three, or any other of a more extensive series, or *suit*, of locks constructed on the same principle.

One defect of the principle of security by wards is that, however complicated they may be, an ingenious picker will mostly be able to detect their form and position, by inserting a blank key with the bit covered with wax or tallow, so as to receive an impression of the concealed obstructions in the lock. It is well to observe that it is a very common practice to cut more notches in the key than there are wards in the lock, so that the complex appearance of a key is no certain proof of the secure construction of the lock to which it belongs. Indeed some of the commonest locks are manufactured without any wards at all, although the keys are invariably made as if wards were employed.

As above stated, some contrivance is necessary to keep the bolt steadily in the position in which it is left by the key; and in locks which depend upon wards for their security, this is usually effected by means of a spring, as illustrated by *Fig.* 7, which represents the interior of a small cupboard lock, with the bolt, *a b*, *half shot*, or in a position intermediate between locking and unlocking, and capable of being moved either backwards or forwards by the action of the bit of the key at *c* in a curved hollow formed in the lower edge of the bolt. The end *a* of the bolt is divided into two parts, shooting through separate holes in the rim of the lock; the top of the bolt carries a long elastic piece formed by nearly separating a stout lamina of metal from the body of the bolt, and giving it an inclination to diverge from the bolt at the end *b*; and the lower edge of the bolt, behind the curved part acted upon by the key, is indented with two deep notches, *b* and *d*, with a smooth convexity between them. The opening in the back rim of the lock through which the end *b* of the bolt passes, is so small as to compress the spring with considerable force. If, therefore, the key be so applied as to shoot the bolt forward, the re-action of the spring will cause the notch *b* to hold firmly on the edge of the rim, from which it cannot be disengaged without raising the bolt, and compressing the spring, so as to allow the convexity between *b* and *d* to pass over the edge of the rim, after which the notch *d* will hold on the rim in like manner. The necessary raising of the bolt and compression of the spring is properly effected by the action of the key, but as it may be effected by pressure upon the end of the bolt, the security of locks in which such an arrangement is adopted, which are called *back-spring* locks, is inferior to that of *tumbler* locks, which form the next branch of our subject, in the means of retaining the bolt in its position, as well as from the defects already explained as incident to the use of wards.

Fig. 7.

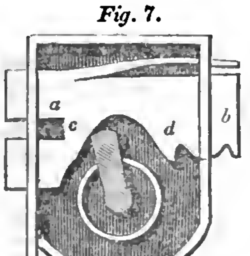

Fig. 8.

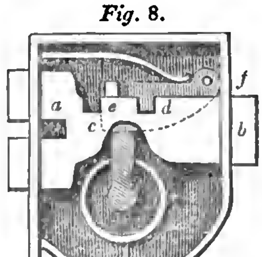
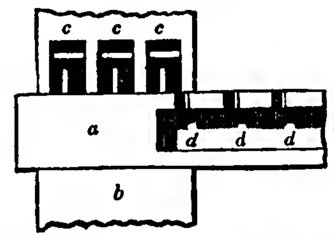


We pass naturally from the consideration of the back-spring as an essential feature in a lock protected by wards alone, to the explanation of one of the simplest modes of applying the second principle of security, that which consists in the use of moveable impediments to the motion of the bolt, and which may be applied, as an additional security, to locks in which the most ingenious arrangements of wards is employed to prevent the access of a false key to the bolt. *Fig.* 8 represents, side by side with our figure of a back-spring lock, a similar lock provided with a common tumbler. In this figure the bolt *a*, *b*, though shot backwards and forwards in the same manner as that of *Fig.* 7, has no spring, or notches to catch on the back rim of the lock, to hold it in any required position; but it is provided with two notches in its upper edge, at *c* and *d*. Behind the bolt is a piece of metal called the tumbler, pivoted to the plate of the lock at *f*, and continually forced downwards by a spring which presses upon its upper edge. The upper part of the tumbler, which is visible above the bolt, is distinguished in the cut by being covered with a light tint, while the shape of the lower part, which is concealed by the bolt, is indicated by dotted lines. At the angle *e* the tumbler carries a projecting stud, which, when the bolt is fully shot, falls into the notch *d*, and holds it firmly until, by the application of the key, the bit of which reaches the lower edge of the tumbler, the tumbler is lifted up to the position shown in the cut, by which the bolt is released, so that the further turning of the key shoots it back, when the stud of the tumbler falls into the notch *c*, and again secures the bolt. It is obvious that so long as the tumbler remains in its proper notch, the bolt cannot be moved backwards or forwards by any pressure upon its ends; and also that the lock cannot be opened by any pick or false key unless its bit be so formed as to reach the tumbler as well as the bolt. To render this more difficult the tumbler is often made to fall a little lower than the bolt, so as to be acted upon by a *step* formed on the bit of the key; while further complication and security may be obtained by the use of two or more tumblers, which may be acted upon by different steps on the key. The great exactness requisite in the length of the bit forms a strong recommendation of even the commonest tumbler locks; for if the bit be ever so little too short it will not lift the tumbler out of its notch, while if it be but a very little too long, it will not enter the curved portion of the bolt.

According to Mr. Ainger, the principle of security by tumblers, though of comparatively modern application in this country, has been known to the Egyptians from a very remote period. In the lock now commonly used in Egypt and Turkey, the bolt is secured by a number of pins, which, though contained at other times in holes or sockets in a solid piece through which the bolt slides, fall into holes in the bolt when it is shot. This contrivance is illustrated by the an-

Fig. 9.



nexed diagram, *Fig.* 9, in which *a* is a part of the bolt, capable of sliding through the solid piece *b*, in which are a number of hollows, *c*, *c*, *c*, each containing a moveable pin. As it is only by a sectional diagram that these pins can be represented, they are drawn as if all were in one straight line, which, however, is not the case in practice. In the present position of the bolt the pins rest upon its upper surface, and offer no impediment to its motion; but if the bolt be slid forward until the holes *d*, *d*, *d*, come under the pins *c*, *c*, *c*, the lower ends of the pins will drop into them, and the bolt will consequently be held fast. It can only be released by the application of a kind of key which has a series of fixed pins exactly corresponding with the holes in the bolt, and which, being introduced into the bolt by the hollow or cavity *e*, is pressed upwards in such a way as to lift the pins clear of the bolt. The security arises from the concealment of the obstacles to the motion of the bolt, and from the circumstance that, supposing a person to obtain a correct impression of the holes, it would be difficult to ascertain the exact length necessary for the pins of the key. If too short they would not raise the pins clear of the bolt, and if too long they would enter the holes in the solid part above the bolt, and so impede its motion. This kind of lock, Mr. Ainger observes in the 'Encyclopædia Britannica,' 'appears to be extensively, or rather universally, employed for gates of towns and of houses, as well as for the smallest articles of furniture. The evidence of its alleged antiquity is derived,' he adds, 'according to M. Denon (in whose magnificent work on Egypt it was published), from the circumstance of finding one sculptured among the bas-reliefs which decorate the great temple at Karnak, from which also it was ascertained that during forty centuries the lock had undergone no sensible change.'

Notwithstanding the high antiquity of the tumbler principle, its first important application in this country appears to have been made by Barron, in 1774, according to most authorities, or in 1778, according to the 'Encyclopædia Britannica.' In the simple form of the tumbler represented in *Fig.* 8, there is the disadvantage that, while it effectually prevents the removal of the bolt unless the tumbler be raised high enough, it presents no obstacle to its removal when, by the use of a false key, the tumbler is thrown up beyond the proper degree. This defect is remedied in Barron's lock, and in many more recent contrivances which are based upon it, by the use of several tumblers, each of which requires to be raised to a different degree, and any one of which, if lifted too high, will form as effectual a barrier to the motion of the bolt as if it were not lifted at all. To illustrate this, let *a*, *Fig.* 10, represent a tumbler pivoted at *b*, pressed downwards by the action of a spring, not shown in the cut, at *c*, but having its downward motion limited by the contact of the tail *d* with a fixed pin. Underneath, or behind the tumbler lies the bolt, a part of which only is shown in the cut, where it is distinguished by a dark tint, and at *e* an opening, somewhat resembling the letter H in shape, is cut through the tumbler, to allow a prominent square pin, or stud, which is attached to the bolt, and is shown in the cut by a light tint, to pass through it. It is obvious that the bolt secured by such a tumbler can only be shot when the tumbler

Fig. 10.

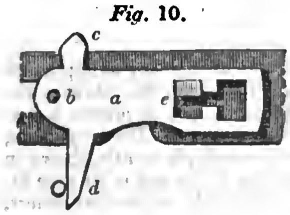


Fig. 11.

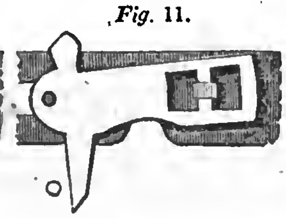
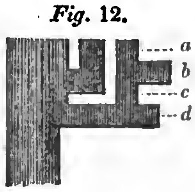


is raised precisely to such a degree as to bring the horizontal portion of the H-shaped aperture opposite to the stud, so that the stud, which fits it accurately, may slip through it. *Fig.* 11 shows the tumbler raised to this position, and the bolt half shot. When fully shot the tumbler again falls; the stud is secured in that division or notch of the H-shaped aperture which lies nearest the end of the tumbler; and an equal security is afforded against any attempt to return it to its first position by any key which does not lift it precisely to the proper height. Several such tumblers may be placed in one lock, the whole being mounted upon one pivot; and if the horizontal connecting portion of the H-shaped aperture be placed at a different elevation in each, each will require to be raised to a different degree to allow the stud of the bolt to pass. These different degrees of motion are provided for by variations in the curved portion of the lower edge of the tumblers, against which the bit of the key acts, and by dividing the end of the bit into a series of steps and notches, each acting upon a single tumbler. *Fig.* 12 represents the bit of such a key, adapted for a lock with three tumblers. As may be seen from the cut, the lock to which this key is adapted is guarded by two wards, of different forms, and the end of the bit is divided into four portions, of various degrees of projection, of which that marked *a* is employed for moving the bolt, while *b*, *c*, and *d* act upon the three tumblers.

Fig. 12.



In the event of such a key being lost, or it being suspected that an impression of it had fallen into wrong hands, the tumblers of the lock might be taken out and returned on to their common axis in a new order, so as to require a key in which the members *b*, *c*, and *d* would stand in a different relation to each other, by which means the old key would be rendered utterly useless.

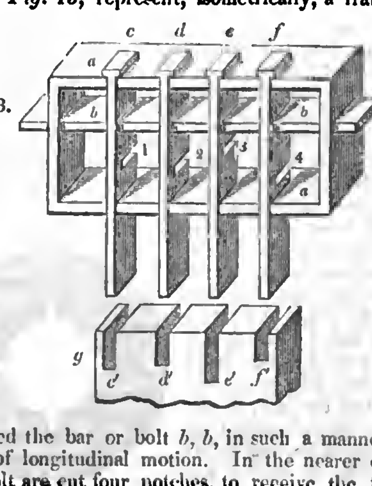
In many very ingenious locks of this character the same object is attained by the use of solid tumblers, carrying studs which pass through H-shaped openings in the bolt. As each stud requires a separate opening, this arrangement can hardly be adopted when more than two tumblers are used. The action of such a lock forms an excellent illustration of the principle, since it renders evident to the eye, when the lock is opened, the necessity of not only raising each tumbler to the requisite degree, and no more, but also of doing so in a certain preconcerted order of time, so that at the moment of shooting the bolt, they may be in the precise position for passing through their respective openings in the bolt, or rather for allowing those openings to pass over them, although the motion of the key before it begins to affect the bolt may cause them both to rise above and to fall below the required position. In a very well contrived lock of this description invented by Mr. Somerford, of which an account is given in the thirty-sixth volume of the 'Transactions of the Society of Arts,' one of the tumblers is drawn downwards by the key while the others are raised, thus introducing a new complication which greatly increases the difficulty of picking, without adding materially to the cost of the lock. In this case the tumbler, which is drawn downwards by the key, is placed on the opposite side of the bolt to the others. It may be observed of all such locks, that while the tumblers afford the main security, the judicious use of wards very greatly increases the difficulty of picking.

Chubb's detector lock, the original patent for which was obtained in 1818, though an important improvement upon it was secured by a second patent in 1824, is one of the most celebrated locks made on the principle above described. Its peculiar merits consists in the addition of a lever, called the *detector*, which is so fixed that, while it does not affect the bolt at all under ordinary circumstances, it cannot fail to move so as to drop a catch into the bolt if any one of the tumblers be lifted a little too high, as some of them must inevitably be by any attempt at picking the lock. By thus fixing the bolt immoveably, it not only renders useless any further attempt at picking the lock, but also gives notice of the attempt which has been made, when the proper key is next applied. By a very ingenious contrivance the proper key is enabled, after lifting all the tumblers to the proper degree for shooting the bolt, to release the detector by a peculiar movement, and thus to restore the lock to its usual state.

In Bramah's lock, which was invented and patented about 1784, the principle of tumblers or moveable obstacles is applied in a very different manner to that above described, and the use of wards is entirely abandoned. In a kind of prefatory record which was attached to his specification, and is quoted by Holland, Bramah alludes to the insufficiency, for the purpose of security, of all contrivances of the ward, or fixed obstacle character, not only on the grounds above noticed, but also because, according to Holland's abstract of his argument, 'the variations capable of being made in the disposition of such wheels or wards, and in the form of the key's bit, are not sufficient to produce the required number of locks, without having large quantities exactly alike, and their keys capable of opening one another reciprocally; in consequence of which they become a very imperfect security against violation, as any ill-disposed person might, by furnishing himself with a number of old keys, be enabled to open almost all the common locks in the kingdom with as little difficulty as if he had in his possession the key belonging to each lock.' In devising a remedy for these defects, Bramah contrived a method of applying moveable impediments very different to that adopted by Barron. Retaining the principle which required that every such impediment should require its own peculiar movement, he provided for restoring them, by the application of an elastic force, to such a position as should leave no trace of, and afford no possible clue to the discovery of, the extent of their motion under the pressure of the key, so that the opening of his lock without the true key is, to use his own expression, 'as difficult as it would be to determine what kind of impression had been made in any fluid, when the cause of such impression was wholly unknown; or to determine the separate magnitudes of any given number of unequal substances, without being permitted to see them; or to counterfeit the tally of a banker's cheque, without having either part in possession.'

To explain, more readily than could be done by a mere representation of the lock itself, the nature of the ingenious contrivance by which the above effect is produced, we may adopt, with some alteration, a diagram of a supposed apparatus illustrative of its principle, which is given by Holland from the original drawings attached to Bramah's specification. Let *a a*, *Fig.* 13, represent, isometrically, a frame in which

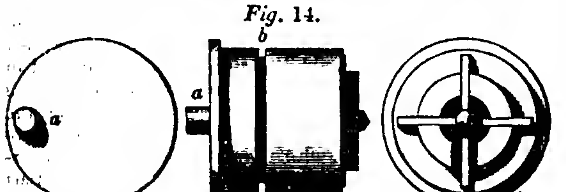
Fig. 13.



is mounted the bar or bolt *b*, *b*, in such a manner that it is capable of longitudinal motion. In the nearer edge of this bar or bolt are cut four notches, to receive the four vertical sliders, *c*, *d*, *e*, and *f*, which, when they are in the position represented in the cut, serve to hold it immoveable. In the further edge of each of these sliders, however, is cut a notch of such size and depth, that if it be brought to the same level as the bar *b b*, the bar will be capable of sliding through it. These notches in the sliders, shown by 1, 2, 3, and 4 in the diagram, are cut at various degrees of elevation, so that, in order to bring them all to tally with the bar at once, which is necessary to enable it to slide through them, each slider must be lifted up to a certain degree, different from the elevation of either of the others. As, however, the lower ends of the sliders, which pass through the bottom of the frame *a*, *a*, and which are the only parts of the apparatus intended to be visible, have a uniform degree of projection, it is impossible to tell how high each of them must be lifted in order to make its notch tally with the bar; and this can only be done by the application of an instrument resembling that marked *g* in the figure, in which are a series of slits, *c'*, *d'*, *e'*, and *f'*, corresponding with, and capable of fitting on to the lower ends of the sliders *c*, *d*, *e*, and *f*, and each slit being cut to exactly such a depth that when the instrument, or key, is put upon the ends of the sliders, and pushed up until its lower end comes in contact with the bottom of the frame, its corresponding slider will be raised to the degree necessary to make its notch tally with the bar *b b*. While the key, *g*, is held in this position, the bar *b b* may be slid backwards or forwards; but the instant it is returned to its original position, and the key is withdrawn, the sliders fall, by their own weight, into the position represented in the cut, and the bar is again held fast.

In order to explain how the principle of security illustrated by the above imaginary contrivance is applied in Bramah's lock, we must premise that the ordinary mode of shooting the bolt, by the action of the bit of the key, is entirely abandoned in it; the office of the end of the bit being performed by a stud attached to the end of a cylindrical barrel which is mounted in the lock, and which contains all its essential parts, or, rather, all the parts essential to its security. *Fig.* 14 represents this barrel, of the actual size, drawn from a street-door latch-lock, the central figure being a side view of the barrel, and the others representations of its back and front ends, respectively. In this cut *a*, in the side and back views, represents the stud by which, when the barrel is caused to revolve on its axis, the bolt is moved as by the bit of an ordinary key. This revolving motion is imparted to the barrel by the

Fig. 14.



insertion of the proper key, which is represented in *Fig.* 17, and which has a very small bit adapted to the square notch at the bottom of the key-hole shown in the front end of the barrel; but the barrel is prevented from revolving, excepting when the proper key is applied, by a contrivance similar to that represented in *Fig.* 13, but arranged, for convenience, in a circular form within the barrel. In this modification of the apparatus, the barrel, which contains four sliders radiating from its centre or axis, and having a motion in the direction of its length, represents the frame with its series of vertical sliders; the sliders, instead of being kept in their ordinary position by gravity, are continually pressed forward to the front or key-hole end of the barrel by a helical spring; and the bar *b b* is represented by a circular plate of steel, represented of the actual size in *Fig.* 15, which is cut into two halves by a division shown in the cut at top and bottom, and is inserted, by its inner edge, in the slit or opening *b b* in the barrel, *Fig.* 14. The four notches in the inner edge of the plate are thus placed upon the edges of the four sliders in the barrel; and as the plate is screwed by the holes shown at its two sides to an immoveable part of the lock, it follows that the barrel cannot be turned round unless the four sliders are so far pushed in by the key that their notches may all tally with the edge of the plate, *Fig.* 15. *Fig.* 16 is a longitudinal

*Fig.*15.

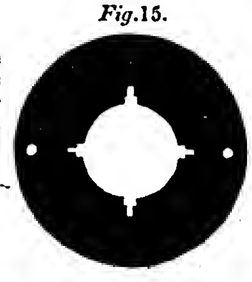


Fig. 16.

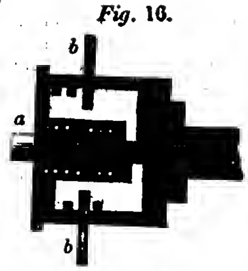

Fig. 17

section of the barrel with the end of the key as applied to bring the sliders into the required position for allowing the barrel to turn; and *Fig.* 17 represents, at *a* in profile, and at *b* in an end view, the key itself separately. The key, being tubular, is put upon the fixed central pin or axis, shown in *Fig.* 16, the four radiating notches in the end of its pipe fitting, at the same time, on to the ends of the four sliders, which are shown in *Fig.* 14. These sliders, two of which are shown white in the section, *Fig.* 16, are, in the absence of the key, kept pressed against the front of the barrel by means of a collar which slides upon the central pin or axis, and is pushed forward by a helical spring which surrounds the pin, and abuts upon the back plate of the barrel; but when the key is pushed into the lock it comes in contact with the sliding collar, compresses the spring, and thus allows each slide to be pushed forward to a degree exactly proportionate to the depth of that notch in the key which acts upon it. By this means the deepest of the three notches represented in the outer edge of each slider is brought to tally with the edge of the circular plate, which is represented detached in *Fig.* 15, and shown edgeways, at *b b* in *Fig.* 16, and thus all impediment to the rotation of the barrel is removed, and consequently, by moving the key, the barrel, with its stud *a*, may be caused to revolve, and to shoot the bolt just as an ordinary key would do. When the barrel is returned to its original position, the key is withdrawn, and the action of the spring restores the sliders to their ordinary situation, in which they lock into the notches of the circular steel-plate, and keep the barrel stationary.

In order to render the above description as simple as possible, we have omitted in it several minor points which tend to the security and efficiency of the lock. The whole of the apparatus above explained is securely enclosed in a turned brass box, so that even the ends of the sliders are only visible at the farther extremity of the deep and very small key-hole, the centre of which is occupied by the end of the pin or axis, which, projecting considerably beyond the sliders, greatly increases the difficulty of bringing any false instrument to act upon them. The small bit of the key, the main use of which is to cause the barrel to revolve whenever the key is turned, forms also a stop to prevent it from being pushed in too far, and to indicate when the sliders are brought to the proper position. To prevent the sliders from working too loose, or from dropping too far into the barrel, in advance of the key, when by the compression of the helical spring they are released from its influence, they are made of a thin piece of metal doubled, as shown at *c*, *Fig.* 17, so that their inner ends, having an inclination to spring open, press with sufficient force against the sides of the grooves in which they slide to keep them in whatever position the pressure of the key may place them, until such pressure is withdrawn, and they are exposed to the counter-pressure of the helical spring. The portability of the key constitutes a great advantage of this kind of lock, as a key which may always be carried in the waistcoat pocket, or even attached to a watch-chain, is less likely to be mislaid, or to fall into the hands of improper persons, than a large key. Again, both locks and keys, being made almost wholly by machinery, may be made with great accuracy at a moderate cost, while the production of a false key from an impression of the true key, or even from the key itself, would be no easy task to a person not possessed of the requisite machinery. The two additional small notches represented in the tumblers of *Fig.* 16 and 17, to which no allusion has yet been made, add greatly to the security of this kind of lock. For some time after its introduction it was deemed absolutely inviolable, but ingenuity at length overcame the difficulty of picking it. This was accomplished by what has been aptly termed the *tentative*, or *trying*, process. Force being applied to the barrel in such a way as to give it an inclination to revolve on its axis, the picker tried all the sliders in succession, to ascertain which of them, by the inevitable inaccuracy of workmanship, pressed with most force against the circular locking-plate. This slider he then gently pushed until, by the cessation of the resistance of the locking-plate, he found that its notch was in the required position, when, having secured it, he proceeded to adopt the same course with each of the other sliders in succession. Thus, by an extraordinary exercise of patience and delicacy of hand, a very skilful operator was able, in many instances, to accomplish the apparently impossible feat of picking a Bramah lock. No sooner, however, was this fact made public, than an efficient remedy was provided by a person named Russell, who was then in Bramah's establishment, by the simple device of cutting one, two, or more additional or false notches on each slider, and enlarging, as shown in *Fig.* 15, the inner portion of each notch in the locking-plate. The result is that it is utterly impossible for a picker to know whether he gets the true notch, or one of the false notches, on to the edge of the locking-plate, while, supposing him, against all probability, to find the right notch in a majority of the sliders, the fact of one only hanging on a false notch would be sufficient to prevent the barrel from turning, owing to the depth of such notch being insufficient to clear the plate. The enlargement of the notches in the locking-plate, which allows of a degree of motion far exceeding any which could arise from mere inaccuracy of workmanship, adds to the baffling effect of the false notches, by the use of which the Bramah lock may be fearlessly said to be rendered, so far as any mechanical contrivance can be, perfectly secure from picking. The same principle of picking, and the same kind of expedient for security against it, with variations of detail which need not be noticed here, have been applied to tumbler locks of the more ordinary construction.

The infinite variety attainable in the manufacture of locks on this principle forms one of its great recommendations. Our illustrations refer to one of its simplest forms, in which only four sliders are used; but even in this form the variety attainable, without any difference in the size of the key or the diameter of the central pin, is very great. By the use, however, of five, six, or seven sliders, the number of different locks, each of which may have the same external appearance, but can be opened only by its own proper key, is increased almost to infinity. Bramah himself showed that if twelve sliders were employed the number of changes which might be produced by simply varying their relative positions, would amount to 479,001,500; while by adding one more slider the number would be increased to 6,227,019,500; so that, as he observes, 'one lock, consisting of thirteen of the above-mentioned levers, sliders, or other moveable parts may (by changing their places only, without any difference in motion or size), be made to require the same immense number of keys. It may be observed that in the event of a key being lost, or the owner desiring, on any account, to have a lock altered, it is possible to change the relative positions of the sliders, so as to render the old key useless; and also that *master-keys* may be made, if required, by constructing a suit, or set, of locks alike in everything but the position of their notches, and then applying to each of them in succession the intended master-key, which must have notches different to any of the ordinary keys, and cutting new additional notches in the sliders to suit it. Such, indeed, is the principle upon which the notches of ordinary Bramah locks are cut, the key not being fitted to the lock, but made first, and having its notches cut by a machine which provides for a continual change in their order and depth. This done, each key is applied to a separate lock, with blank or uncut sliders, and the notches in the sliders are cut while they are thus held in the proper position by the key. By any other arrangement it would be almost impossible to secure the requisite accuracy.

Owing to the very small size of the protecting apparatus, the Bramah lock has been applied to many ingenious purposes for which other kinds of lock are less suitable, among which we may notice the locking of liquor-cocks. Mr. Russell's contrivance for thus applying it is referred to under Cock, P. C. S., p. 385; and we see no reason why, for small cocks, a more simple arrangement should not be adopted, in which the revolving barrel of the lock should be attached to, and indeed form the upper part of, the revolving plug of the cock itself, so that a single motion of the hand should be sufficient both to unlock and to open the cock. The proposed arrangement would have this advantage, that it would be impossible, by inadvertence, to leave the cock unlocked, since the act of turning off the liquor would both lock it and, by the force of the spring, so far eject the key that it could only be left in the lock by design. In the forty-eighth volume of the 'Transactions' of the Society of Arts (part i. p. 132) is a paper by Mr. S. Mordan, who has gained much celebrity by the manufacture of beautiful locks on the Bramah principle, on a curious application of this invention to what he calls a 'lock-protector,' which is, in fact, a scutcheon, or shield, adapted to cover the key-hole of a room door, and having in its centre a minute lock with seven sliders or guards. By applying this scutcheon to a key-hole on the outside of a door, and turning its key a quarter round, two lancet-shaped pieces of steel are projected from a little box at the back of the scutcheon, in such a manner as to dig into the wood on the opposite sides of the key-hole, and to hold the scutcheon so firmly in its place that nothing short of the application of violence can remove it, until, by a fresh application of the little key, the blades are withdrawn. The chief object of this contrivance is to enable travellers at inns to prevent their chamber doors from being opened in their absence, by closing up the key-hole.

A lock was invented by Mr. Kemp, of Cork, in 1816, in which the peculiarities of both Barron's and Bramah's locks are combined in such a way as to afford, in the inventor's opinion, greater security than can be attained by either alone. In this lock, which he calls the union lock, a number of pins or sliders, which detain the bolt much in the same way as the sliders of Bramah's lock detain the locking-plate, are acted upon by the ends of a series of tubes, of various lengths, which are placed within one another, inside the pipe or barrel of the key. This kind of key, its inventor justly pleads, must be far more difficult to imitate than either Barron's and Bramah's, so that it affords greater security against any attempt to make a false key in imitation of the true one. Hebert, in noticing this invention, observes, that until a complete remedy is provided against the possibility of copying or imitating keys, the art of lock-making is imperfect, and no locks are inviolable; and he adds 'that he had in his possession a lock the key of which *cannot be copied*—a locksmith possessing no tools by which an exactly similar one can be made.' The machine by which the original one was made, he adds, is so arranged as to be deprived of the power of producing another like it. The lock is very simple and strong, and might, he says, be manufactured cheaply; but as the inventor was waiting for an opportunity of bringing it before the public, Hebert gives no account of its construction.
