The colony of Natal is divided into the districts of Pietermaritzburg, D'Urban, Umvoti, Impafane, Tugala, and Umzinyate, and a tract in the south-west part of the territory. The principal town in the colony is *Pietermaritzburg*, founded by the Dutch boers in 1840, and containing about 3000 inhabitants. It is situated on an offset of the Drachenberg Mountains, in 29° 30′ S. lat., 30° 2′ E. long., about 50 miles W.N.W. from Port Natal. It contains a barrack, ordnance stores, and Dutch, Episcopal, and Methodist places of worship. It is well supplied with water. *D'Urban*, the only port of the colony, is situated on the east side of the inlet called *Port Natal*, which is a bay completely landlocked, and affording good anchorage. The entrance is narrow, and is impeded by a bar, on which there is sometimes not more than two fathoms of water. The cape at the entrance of Port Natal is in 29° 53′ S. lat., 31° 2′ E. long. Verulam, Windsor, and Western are the largest of the villages.

The white population of the colony is mostly composed of the original Dutch settlers who remained after the dispersion of the boers in 1842, and of the immigrants who have since arrived chiefly from Great Britain. The native population, consisting mostly of Tulas, are an intelligent and docile people, and make excellent servants. They are scattered in kraals along the banks of the rivers, and round the mission stations along the coast and western boundary. The British commissioner manages the affairs of the aborigines, and is regarded as their protector and chief. British, American, and Norwegian missionary societies have mission stations in the colony.

Natal has a lieutenant-governor, who is assisted by an attorney-general and an auditor-general, a collector of customs, a surveyor-general, a crown prosecutor, and a government secretary, who form a legislative and executive council. The revenue in 1854 amounted to 28,454*l* 13*s*.; the expenditure to 31,642*l*. 12*s*., the excess of expenditure over income having arisen chiefly from the construction of public buildings, roads, &c. The imports in 1854 amounted to 124,722*l*. 6*s*. 9*d*.; the exports of colonial produce to 37,039*l*. 15*s*., of which the wool exported was valued at 5141*l*. 15*s*. A bishopric of Natal was created in 1853. There are episcopal ministers at Pietermaritzburg and D'Urban.

The colony of Natal owes its origin to the Dutch boers (farmers), who in the year 1836 emigrated northward beyond the boundaries of the Cape Colony, and established themselves in small communities, with their families and cattle, in different parts of the unoccupied territory. These emigrants in 1838 employed their commandant, Pieter Retief, to enter into a treaty with Dingaan, the chief of the Zooloos. Retief crossed the Dracheuberg Mountains, accompanied by 70 or 80 farmers, and their families and attendants, who visited Dingaan at his place of residence, preparatory to forming their intended establishment in the vicinity of Port Natal. They were received by the Zooloo chief and his warriors with every demonstration of kindness, but were treacherously surrounded and slain in the midst of professedly friendly festivities. The farmers scattered over the territory were next attacked successively, and upwards of 600 men, women, and children were killed, besides those who had been previously massacred at Dingaan's residence. The great body of emigrants, who still remained behind the Drachenberg Mountains, sent off expedition after expedition against Dingaan, and at length, in February 1839, succeeded in putting him to flight. The greater part of the Dutch farmers then removed to Port Natal, where, in December 1839, they hoisted the tricolor flag, and proclaimed an independent republic, with Andries Wilhelm Pretorius for president. The British government refused to acknowledge their independence, and Sir George Napier, then governor of the Cape Colony, sent some troops to take possession of Port Natal. They entrenched themselves, and maintained their position till the arrival of reinforcements by sea, in June 1842, when the Dutch were compelled to submit. By a proclamation dated August 21, 1845, the colony of Natal was established by the British government.

NATURALIZATION. A simple and inexpensive method of obtaining naturalization has been provided by the statute 7 & 8 Vict., c. 66, which enables the Home Secretary to give a certificate entitling an alien, on his taking an oath of allegiance and fidelity, to all the capacities and rights of a British subject, except those of sitting in Parliament, or being a member of the Privy Council. These capacities and rights, when granted, are considered to confer on the alien a temporary character only as a subject; that is, the alien cannot, on returning to his own country, there claim the protection of the British flag, as if he were a natural-born subject. The same statute declares the right of every *alien amy* to hold every species of personal property, except chattels real; and every *resident alien amy* to hold lands or houses for residence, trade, business, or manufacture, for a term not exceeding twenty-one years; this occupation not, however, conferring any right to vote for a representative in Parliament.

The statute enables all persons born abroad of a *mother* who is a natural-born subject, to take any real or personal estate by devise, purchase, or succession; and it naturalizes *de facto* any alien woman who marries a British subject; in consequence of which, the notorious Mrs. Manning when indicted with her husband for murder, was held not entitled to a jury *de medietate linguæ*.

NAUVOO. [UTAH.]

NAVARRETE, MARTIN FERNANDEZ DE, a Spanish scientific naval officer and historical investigator, who had the good fortune to bring to light materials of unusual value. He was born at the town of Abalos in Old Castile on the 9th of November 1765; and his uncle, who was afterwards Grand Master of the Knights of Malta, being high in influence among them, he was received into the Order of St. John of Jerusalem on the 9th of August 1768, or three months before he was three years old. The Count of Peñaflorida, the patron of the school of Vergara, where he studied Latin and mathematics, took a fancy to send to Don Tomas Iriarte, the then fashionable poet, the verses in which some of the boys had celebrated his popular poem of 'Music' and Iriarte was so pleased with those of Navarrete that he began a literary correspondence with him, and invited the young scholar to visit him at his house at Madrid. Soon after, in 1780, Navarrete entered the naval service, and became a 'guardia marina,' or midshipman, at Ferrol. In the next year, on board of the Concepcion, he was one of the Spanish fleet under Cordova, which, during that part of the American war, cruised unassailed in the English Channel; and he was at the disastrous attack of the Spanish floating batteries on Gibraltar, in September 1782. After some cruises against the Moors and Algerines, Navarrete was, in 1789, obliged to quit active service for some time on account of the state of his health, and his character of a naval and literary man combined procured for him the commission from the new king, Charles IV., to examine the national archives to form a collection of documents relative to the naval history of the kingdom, and in particular that of the voyages of discovery which have conferred such immortal honour on Spain. This was the commencement of Navarrete's great work, the first volume of which did not appear till thirty-six years after. In 1793 the Spanish declaration of war against the French republic recalled him to sea, and in 1796 the declaration of war with England kept him there; but his health was still weak, and when in 1797 his friend Langara became minister of marine he provided Navarrete (now risen to the rank of captain in the navy) with a post in his office at Madrid. His life after this appears to have been as undisturbed by violent changes as a life in that country and time could possibly be. At the outset of the war of independence he refused to accept office under the French, and he removed to Seville, but he took no active share in the war. He was re-instated in office as soon as Ferdinand returned, and for many years continued to be the great naval authority of Spain, the moving power of the Admiralty, although the title he bore was that of chief of the Hydrographic department, to which he was appointed in 1823. In the midst of his official duties his zeal for literature never slackened: he left behind him two volumes of poems, though he never showed them to any but his most intimate friends. As a member of the Spanish Academy, he proposed, about 1815, the new system of orthography which was adopted for its Dictionary, and has been followed by many of the Spanish writers. As secretary of the Academy of San Fernando, which is that of the Fine Arts, he was always at his post, and to their 'Transactions,' and those of the Academy of History, he was a contributor of valuable papers. He was also the author of numerous works, some of which are of great importance from the information they contain. He held his offices and also a distinguished place in the literary society of Madrid through several revolutions; and in 1834, when the Estatuto Real established a chamber of peers on the French model, he was one of the first peers created. He died at Madrid, on the 8th of October 1844, at the age of seventy-eight.

The great work of Navarrete is the 'Coleccion de los Viages y Descubrimientos que hicieron por Mar los Españoles desde fines del siglo XV.' ('Collection of the voyages and maritime discoveries made by the Spaniards since the close of the 15th century'). The work was to consist of seven quarto volumes: the first and second were published in 1825, the third in 1829, the fourth and fifth in 1837, the sixth and seventh, chiefly consisting of documents relating to Columbus, have not yet appeared in print, but the materials for them were left by Navarrete at his death, arranged for publication and only awaiting the introductions and notes he intended to add to them. The book is described by Humboldt as "one of the most important historical monuments of modern times." Washington Irving, who went to Madrid expressly for the purpose of translating it, afterwards changed his intention, and wove the new matter which it supplied into the 'Life of Columbus,' in which in fact little belongs to Irving, except the style. This mode of dealing with the materials was perhaps the best that could have been adopted under the circumstances. A French translation of Navarrete's works which was commenced never advanced beyond a few volumes. Navarrete was a man who let no day go by without searching into something, who habitually read with a pen in his hand, who had an excellent memory for names and dates, and other small facts of all kinds, and a talent for combining their results; but he lacked the power of condensation; he was not the man to write a European classic; his prejudice as a Spaniard of the old school influenced not only his writings, but in its absolute theory interfered with his dignity as an historian. Perhaps he did himself an injury by the learning with which he loaded his volumes. In his 'Coleccion' the number of new documents brought forward in the first two volumes, is said to have been five hundred, and while the work is one which is absolutely indispensable in every large library, and necessary to be consulted by every inquirer into the subject of which it treats, it is little read and is mainly known as a mine for others to dig in. One of the most interesting volumes of the Hakluyt Society, Mr. Major's letters of Columbus, is for the most part taken from it; but there are few other documents in the collection of such surpassing interest as these.

The other great work with which Navarrete was connected was the 'Coleccion de Documentos Ineditos para la Historia de España,' or 'Collection of Unpublished Documents for the History of Spain,' commenced by him in 1842 in conjunction with Don Miguel Salvá and Don Pedro Sainz de Baranda. It was and is published in numbers, and one of the editors on bringing a number to Navarrete once remarked "Well, volume three is done at last;" "Three," the old man replied with vivacity, "I wish there were three hundred, and that I saw them on my shelves. Without such publications we shall never have a history of Spain." He died when it had reached the fifth volume, and the last numbers we have seen belong to the twenty-fifth, and were issued in 1855, by Don Miguel de Salvá and the Marquis de Pidal, the latter a member of the Spanish Cabinet, and also eminent as a man of letters. This collection is one of the most important now publishing in Europe, and is, like Navarrete's previous one, indispensable in every large library. It has been frequently laid under contribution by English and American writers; in particular by Mr. Helps, Mr. Prescott, and Mr. Stirling.

Among Navarrete's other works is the most copious life of Cervantes yet written, originally prefixed to a new edition of 'Don Quixote,' and afterwards separately published in 1819. It contains a very large number of new facts which he had unearthed by patient research. A work entitled 'The Life and Writings of Cervantes, by Thomas Roscoe,' which was published by Tegg in 1839 as a portion of Murray's 'Family Library,' appears to be entirely taken from Navarrete, without acknowledgment; at least in several passages that we have compared we have been unable to discover any difference. A history of the part that the Spaniards took in the Crusades, which was contributed by Navarrete to the 'Memoirs' of the Spanish Academy of History, and a translation of which was inserted by Michaud in his 'Histoire des Croisades,' was a portion of a general history of maritime affairs in Spain which he left behind him complete, and which is likely to be published by the Spanish Academy of History, in two or three volumes quarto. That academy issued in 1846 a 'Dissertation on the History of the Nautical and Mathematical Sciences in Spain,' which Navarrete had, it is said, been at work upon occasionally for fifty years. His next important work after that is a view of the discoveries of the Spaniards on the western coasts of North America, prefixed to a narrative of the 'Voyage of the Sutil and Mexican on the Coasts of California,' published in 1802. The book was frequently referred to in the disputes between the English and American governments respecting the Oregon territory.

A collection of the smaller works of Navarrete, 'Coleccion de Opusculos,' was commenced in 1848 by his sons, but has not been carried farther, we believe, than two volumes, though it was intended to consist of five or six, comprising a selection from his correspondence, and an extended account of his life and times. The two volumes mainly consist of short biographies of Spanish literary men and seamen, which had mostly been scattered in periodicals and transactions of academies.

NAVENBY. [LINCOLNSHIRE.]

NAVICULA. [DIATOMACEÆ, S. 2.]

NAVY BAY, a natural harbour lying between the Atlantic coast of New Granada and the island of Manzanilla. The island, which is a mile and a quarter long, a mile broad, and covered with luxuriant trees and shrubs, is separated from the mainland at its southern extremity by a channel of about 60 feet wide and about 10 feet in depth. A projecting reef stretching out from the mainland at the north-eastern extremity of the bay forms a natural breakwater. The harbour thus formed is accessible at all seasons; it is secure in every wind, with a depth of 6 to 7 fathoms in the middle, and 3 to 4 fathoms within 60 feet of the shore, and capable of containing 300 sail. Navy Bay is the Atlantic terminus of the Panama railway, which from hence to Gatun (7 miles) is carried over a swamp supported on piles. A lighthouse has been erected at the western point of the island.

Aspinwall city, founded in 1851, is situated on the island, the terminus of the railway, and is now the depôt of the eastern side of the isthmus, instead of Chagres, from which it is distant 7 miles, and which has been since nearly altogether abandoned.

NAYLAND. [SUFFOLK.]

NEANDER, JOHANN AUGUST WILHELM, Professor of Theology in the University of Berlin, and a member of the Consistory of the province of Brandenburg, was born of Jewish parents, at Göttingen, on the 15th of January 1789. His early youth was spent in Hamburg, where he was educated at the Gymnasium, and at the Johanneum, a college founded on the site of the old cathedral, in which is placed a large public library. While pursuing his studies here he became a sincere and zealous convert to the Christian faith, assuming the name of Neander ('a new man,' from the Greek) on his baptism. He then, in 1806, repaired to the University of Halle to study theology, and thence removed to that of Göttingen. After a short stay in Hamburg, in 1811, he transferred himself to the University of Heidelberg, where his remarkable theological attainments obtained him in 1812 the situation of Professor Extraordinary of Theology; and in the same year his reputation occasioned him to be called to a similar office in the University of Berlin. From that time his whole life was devoted to the advancement of Christianity by his writings, which have continued to gain an ever-extending influence, and to the interests of the university and of the students under his care. The earliest published work which established his reputation was 'The Emperor Julian and his Times,' which at once showed that in this branch of Church history he was a master of his art. This appeared in 1812; in 1813 was issued 'St. Bernard and his Times,' and others followed—on the principal Gnostic systems, on St. Chrysostom and the Eastern Church, on Tertullian and his writings, 'Memorable Occurrences from the History of Christianity and Christian Life,' between 1818 and 1826. These however were only the preparatory labours for his valuable work, 'Universal History of the Christian Religion and Church,' in 5 vols., issued successively between 1825 and 1845. The history, he says, is at once "a speaking proof of the Divine power of Christianity; a school of Christian experience; a voice sounding through centuries for the edification, the instruction, and the warning of all who are willing to hear." The development of the Christian Church and faith during the Apostolic times formed the subject of his next work, 'Geschichte der Pflanzung und Leitung der Kirche durch die Apostel,' in 2 vols., published in 1832-33. In these works he has with great ability combated the neologism and rationalism so prevalent in Germany, to which he was ever as active an opponent as Schleiermacher, Hengstenberg, or Tholuck. In 1835 he issued 'Das Leben Jesu in seinem geschichtligen zusammenhange' ('The Life of Jesus in its Historical Relations'), a work which was written in direct refutation of that of Strauss bearing a similar title, and which with his 'General History of the Church,' and the 'History of the Apostolic Church,' have had great influence in England, and been highly valued. His reputation as a lecturer was also great, and his lectures were numerously attended. After a short illness he died on July 14, 1850. His smaller occasional writings were collected by himself, and published in 1829 under the title of 'Kleinen Gelegenheitsschriften,' for the benefit of the Bible Society of Berlin, of which he was always an earnest supporter. The 'Life of Christ,' 'History of Christianity,' 'History of the Planting of Christianity and of the Apostolic Church,' and other of his works have been translated into English, and form a part of Bohn's 'Ecclesiastical Library.'

NEBRASKA, a Territory of the United States of North America, established by Act of Congress 1854, occupies the tract of unreclaimed country north of the Nebraska River up to 42° N. lat. It is bounded E. by the state of Iowa, from which it is divided by the Missouri River; N. by the North-West territory; W. by the Rocky Mountains, which divide it from the Oregon and Utah Territories; and S. by the Territory of Kansas. The area is 335,866 square miles. The population in 1856 was 10,716.

This country and Kansas have hitherto been usually spoken of together [KANSAS, *S.* 2], and the descriptions published have included both. Like Kansas, Nebraska has on the east, extending down to the valley of the Missouri, extensive tracts of prairie lands; on the west a broken and hilly country, rising into the mountainous tract of the Rocky Mountain range; while the centre is occupied by a broad apparently irreclaimable waste, forming the northern part of the Great American Desert, and the home of numerous wandering tribes of Indians. But Nebraska has a larger share than Kansas of this desert land, and in other parts it is believed a less fertile soil.

The Missouri, as we have said, forms its eastern boundary, and the only actual settlements, so far as we know, yet made in this territory are on its banks. The chief river belonging to the territory, and that which gives it its name, is the Nebraska, which is formed by the union, in 41° 5′ N. lat., 101° 21′ W. long., of two branches from the Rocky Mountains. The united stream flows in a generally eastern direction to the Missouri, into which it falls about 50 miles below Council Bluffs, and about 600 miles above the confluence of the Missouri with the Mississippi. It is a very rapid shallow stream, fordable, except during floods, in almost every part; and full of islands covered with cotton wood, willows, and shrubs, and of shifting sandy shoals: it is thought to be unavailable for navigation by steam-boats of light draught for more than 40 miles. At its confluence with the Missouri it is 600 yards wide. One of the two main routes for emigrants to Oregon and the Pacific lies along this river quite up to the Rocky Mountains. The chief affluents of the Nebraska belonging to this Territory are the Loup Fork, Elkhorn, and Wood rivers.

The chief settlement yet formed is Council Bluffs on the Missouri, which is within this Territory, though previous to its organisation assigned to IOWA, under which state it will be found noticed. It is of considerable local importance as the last civilised resting place of the emigrant to the 'far west,' who here makes his final arrangements and purchases, previous to entering upon what has hitherto been commonly known as the Indian country. Council Bluffs was established as a government Indian agency station. Bellevue, a little lower down the Missouri, is the only other civilised settlement in the Nebraska territory, with the exception of a military station for the surveillance of the Indians. The chief tribes of Indians in Nebraska are the Pawnees, Poncahs, Omahas, Ottoes, &c.; but we have no account of their numbers or condition.

The Act of Congress which erected Nebraska into a Territory, leaves it open to settlement by citizens of the United States, and to aliens who make the usual declaration of their intention to become citizens; and defers to the inhabitants themselves the power to determine whether slavery shall be permitted to exist within the territory.

NECKAR-KREIS (Circle of the Neckar), a province in the north-west of the kingdom of Würtemberg, is bounded N. and W. by the grand-duchy of Baden, E. by the circles of Jaxt and Danube, and S. by that of Schwarzwald. Its length from north to south is 55 miles; its breadth is about 36 miles; its area is 1278 square miles; and its population in 1852 was 501,034. The province is traversed by several ranges of moderately high forest-clad hills, which run in a western or north-western direction from the Rauhe Alb, or Alps of Suabia, in the east of the kingdom. It takes its name from the river Neckar, which, rising on the Baden frontier in the south of the Schwarzwald, runs in a general north-eastern direction to the centre of the kingdom of Würtemberg, whence it flows northerly past Heilbronn, below which it turns to the north-west, crosses the territory of Baden till it reaches that of Hesse-Darmstadt; of this it forms the boundary to its entrance into the Rhine at Mannheim, after a course of about 170 miles. The Neckar receives in this province the Enz, the Kocher, the Jaxt, and a great number of small streams. It is navigable for small craft from Cannstadt. There are several lakes and mineral springs in the province. The soil of the valley of the Neckar and of the other rivers is exceedingly rich and fertile. The chief products are wheat, hemp, wine, silk, and wood. Horned cattle, sheep, and horses of good breed are numerous. Railroads run from Stuttgardt to Heilbronn, and from Stuttgardt to Ulm and Frederikshaf on the Lake of Constance (from Ulm a line runs east to Augsburg). From the former line a branch is constructed to join the great trunk line along the right bank of the Rhine at the Bruchsal station, between Carlsruhe and Heidelberg.

Towns.—STUTTGARDT. CANNSTADT. ESSLINGEN. *Heilbronn*, 28 miles N. by railway from Stuttgardt, is situated on the right bank of the Neckar, which is here crossed by a wooden bridge. It is surrounded with high walls and a deep ditch, and contains some good buildings, the most interesting of which are the church of St. Kilian, the town-hall, and the house of the Teutonic Knights, now used as a barracks. Heilbronn has a gymnasium, a public library, and about 10,000 inhabitants, who are actively engaged in trade, and in the manufacture of silver ware, carpets, tobacco, white lead, chemical products, gunshot, paper, &c. The navigation of the Neckar below this town is much facilitated by the Wilhelm's Canal. *Ludwigsburg*, N. of Cannstadt, a mile from the left bank of the Neckar, is a well-built town, with 6208 inhabitants, exclusive of the garrison. The town, which, for its size, is one of the prettiest in Germany, has long wide streets, mostly lined with trees. The principal building is the former royal palace, one of the largest in Germany; it contains a great number of pictures of the old German and Flemish schools. The other remarkable objects are the military college, the lyceum, and the arsenal. Woollen cloth, linen, calico, jewellery, leather, nails, and cannon are amongst its industrial products.

NECROPHORUS, a genus of Coleopterous Insects belonging to the family *Silphidæ*. The antennæ are terminated by a nearly globular 4-jointed mass; the body is parallelopiped; and the maxillæ have no horny teeth. There are several species of this genus. They have obtained the name of Burying Beetles, from the peculiar instinct which they exhibit of burying the dead bodies of small animals, such as moles, mice, frogs, &c., as a receptacle for their eggs and larvæ. Their powers of perception are very strong, and it is surprising how soon they discover a dead body fitted for their purpose, round which they may be observed flying, with the elytra elevated, their dorsal surfaces being applied together. They soon creep beneath the body, and commence scratching up the earth from the sides and under the animal, which by degrees descends into the pit which is thus gradually deepened. When it has reached a sufficient depth the earth is thrown over it, and the insect deposits its eggs upon the carcass, so that the larva, when hatched, finds itself in the midst of a repast, disgusting enough, but suited to its taste. The larva is long, of a dirty-white colour, with the upper surface of the anterior segments armed with a scaly plate of a brown colour, and with small elevated points upon the hinder segments. They have also six scaly legs, and the jaws are robust. When they have attained their full size they bury themselves still deeper in the earth, where they construct an oval cell, the inner surface of which they coat with a gummy secretion. These insects, like many others which feed upon carrion, have a strong odour like musk. The habits of these insects have been especially studied by M. Gleditsch, and more recently by various persons in France, who have written upon the subject of destroying moles, and by whom various points in their economy have been elucidated.

There are a considerable number of species of this genus, some of the largest of which (*N. grandis*, Fabricius) have been observed in North America. There are seven British species, five of which are distinguished by the golden-coloured bands of the elytra. These species vary amongst themselves in the form of the thorax, the structure of the hind legs, the markings on the elytra, and the colour on the club of the antennæ. One of the most common species is the *Silpha Vespillo* (Linnæus), in which the posterior tibiæ are curved, and the trochanters furnished with a strong spine. The species vary also in length from half an inch to an inch and a third, which is the length of *N. germanicus*, the largest and rarest of the British species. (Westwood.)

NEUKOMM, THE CHEVALIER SIGISMUND, a celebrated German composer, was born at Salzburg in 1778. Being related to the family of Haydn, he received his early musical education from Michael Haydn, the elder brother of the author of 'The Creation.' From him Neukomm acquired that predilection for sacred music which distinguished him throughout his career. At the age of twenty he went to Vienna. Joseph Haydn received his young relative most kindly, and made him his pupil: and the friendship, thus begun, lasted without interruption during the whole of the great master's life. Neukomm's close and unbroken intercourse with Haydn, and admiration of his genius, had a sensible effect on the formation of his own style, which is marked not only with Haydn's regularity, symmetry, and clearness, but with many of Haydn's characteristic traits of musical phraseology.

After having gained a high reputation in Germany, Russia, and France, Neukomm came to England for the first time in 1829; and his reception by the public was such as to induce him to pass much time in this country. His residence in England was an active period of his life. It was here that his greatest works, the oratorios of 'Mount Sinai' and 'David' were produced. 'Mount Sinai,' originally composed to German words, was afterwards adapted by himself to an English version of the text, and performed for the first time at the Derby Musical Festival of 1831. 'David,' the poem of which was originally written in English, was composed expressly for the Birmingham Musical Festival, and performed in 1834. During the same period he gave the English public many vocal pieces, both sacred and secular, which obtained general popularity. Among these, his sacred cantatas, 'Miriam,' 'The Prophecy of Babylon,' and 'Absalom,' are remarkable for their grandeur, expression, and perfect adaptation of the music to the English poetry, for Neukomm was a perfect master of our language. 'The Sea' was for a long time the most popular song of the day; and though it has given places to newer favourites, it is still frequently heard, and always with pleasure. Neukomm's latest work was 'Twenty Psalms selected from the authorised English Version,' for the use of singing-schools, choral societies, churches, and chapels of every persuasion. It was written for the Association for the Revival of Sacred Music in Scotland, and published by that body at Edinburgh in 1853. It possesses great value. The most beautiful of the Psalms are selected, and the music, in a plain and simple style, has the grand and solemn beauty which characterises Neukomm's sacred works. A collection of Voluntaries for the Organ—an instrument on which Neukomm was one of the greatest performers in Europe—is among the most important works produced by him in England. There is scarcely a branch of his art which he left untouched. His instrumental compositions, symphonies, quartets, sonatas, &c., are very numerous and of much merit; but it is on his great sacred works that his permanent fame will rest.

In the course of his long life Neukomm received many of the honours due to the highest distinction in his art. He was invested with several orders of knighthood, in France, Portugal, and Prussia. He was a member of the Royal Academy of Arts in Prussia, and most of the principal musical institutions and societies in Europe and the United States. He was a Doctor of Music in the University of Dublin, and he was one of the jury of our great London Exhibition in 1851. For several years he was afflicted with an ophthalmic complaint, at one time almost amounting to deprivation of sight; but he partially recovered from it, and resided at Bonn, enjoying, till he was fourscore, a green old age and an honoured retirement. He died in April, 1858.

NEW GRANADA. [Granada, New.]

NEW GUINEA. [Papua.]

NEW JERSEY. [Jersey, New.]

NEW MEXICO, a Territory of the United States of North America, lying between 31° and 38° N. lat., 103° and 117° W. long. It is bounded S.E. and E. by the State of Texas, from which it is divided on the S. by the parallel of 32 N. lat., and on the E. by the meridian of 103° W. long; N. by the Territory of Utah; W. by the State of California; and S. by the Republic of Mexico. The area of New Mexico is estimated at 210,774 square miles. The white population was 61,525 in 1850. The Indian population was estimated by the Commissioner of Indian Affairs in 1853 at 45,000. The Territory of New Mexico was formed in 1850 out of the country ceded by Mexico to the United States, with the addition of a portion of that claimed by Texas.

Surface, Hydrography, &c.—The Territory of New Mexico, as at present constituted, consists of two distinct sections, which will probably at some future day be separated into two distinct territories or states: the one comprising the country occupied by the two great ranges into which the Rocky Mountains are in this part separated; the other the country west of those Mountains. The former, or New Mexico proper, is a rugged mountainous country, with a valley about

20 miles wide, formed by the Rio Grande del Norte, traversing it from north to south. The western range of the Rocky Mountains bears various names, as the Sierras de Anahuac, de los Mimbres, de los Grullas, Mogollon, Madre, &c.; but the name now most commonly given to the greater part of it is the Sierra Madre. Many of the most northern summits of this range are covered with perpetual snow, and may be from 9000 to 12,000 feet above the sea. The southern portion is probably from 6000 to 8000 feet above the sea. The eastern range, which runs nearly parallel to the other, is known in the northern part as the Sierra Obscura, and in the southern as the Sierra Sagramento, though the latter name is commonly applied to it throughout. These mountains rise very abruptly from the eastern plain into lofty peaks and knobs variously disposed, with fertile valleys between them. Some of the northern summits of this ridge are also covered with perpetual snow, and the altitude appears to be on the whole somewhat greater than that of the western ridge. Pines generally grow on the higher mountains, cedars and occasionally oaks on the lower ones. The narrow tract bordering the Sierra Sagramento on the east is very elevated, and forms the western boundary of the extensive plain north-west of Texas. The narrow valleys by which the mountain streams reach the plain are often heavily timbered, and the soil appears to be fertile; but the intervening spaces have an arid soil, which is only covered with vegetation in the early part of the year.

The great valley which lies between these mountain chains forms the district known as New Mexico while the country belonged to the Mexican republic. It is a very elevated tract, the northern part being more than 5000 feet, and the most southern, where it touches the Mexican boundary, 3800 feet above the sea. Through it as mentioned above flows the Rio Grande del Norte. The surface, especially in the upper part, is greatly broken, and the soil throughout is dry and sandy; but where irrigated is generally pretty fertile. Below Santa Fé about 36° 20′ N. lat. is the most fertile part, and there two crops are often obtained annually. This is the most populous and the only civilised part of the country, a large portion of it being occupied by the farms of the old settlers.

The country west of the Sierra Madre, forming nearly two fifths of the territory, is very much varied in surface. It is drained throughout by the Rio Colorado and its tributaries. The northern part is mountainous, and a large part of the eastern boundary is formed by rugged mountains. The interior is considerably diversified, well watered, and appears to be in many parts a fine agricultural country. The middle part is occupied by a great plain drained by the Rio Gila and its affluents, much of which is sandy and barren; but the land in the immediate vicinity of the streams is frequently fertile. The whole is occupied by Indian tribes: the Apaches inhabiting the east and south-east, the Navajoes the north-east, the Pah-Utahs the north-west, and the Pimos the west and south-west.

The Rio Grande del Norte, or, as it is more commonly called, the Rio Grande or Rio del Norte, rises in the Rocky Mountains, near 40° N. lat., not far from the sources of the Arkansas and Colorado. Its course before it reaches the boundary of New Mexico is generally south-east, but throughout this territory it is nearly south. Its direct length from its source to its mouth in the Gulf of Mexico is about 1400 miles, but its course following its windings is full 2000 miles. Throughout New Mexico it is a rapid shallow stream, and has numerous shoals and sand-bars. It appears to be scarcely navigable even by canoes, and though it is well fitted to supply mill-power, it is at present scarcely used except for irrigation. Its lower course is noticed under MEXICO. The Rio Puerco is its only tributary of any consequence in this territory; but this stream, though it runs for a considerable distance through a longitudinal valley west of the Rio Sagramento, has, owing to the arid nature of the soil, but little water. The Rio Colorado, which drains the western part of the territory, runs south by west from its source near that of the Rio Grande till it enters New Mexico, when it bears more to the west, and so continues till it quits the territory and opens into the Gulf of California. The Colorado is believed to be navigable for a great distance, but the country through which it flows has as yet been but little explored. Several of its tributaries are also believed to be navigable for considerable distances. The most important tributary in New Mexico is the Rio Gila, which drains the great plain noticed above. It rises in the most southern extremity of the western range of the Rocky Mountains, and after descending into the plain, where it is joined by the San Francisco, an affluent which rises much farther north, it flows through the plain nearly west-south-west to its confluence with the Colorado, about 32° 45′ N. lat. It receives several affluents on both its banks, but none appear to be of much consequence. The other more important tributaries of the Colorado in this state are the Nabajoa and the Yaquesila.

The mountains appear to be mainly composed of eruptive and metamorphic formations; the rocks enumerated consisting chiefly of granite, sienite, basalt, porphyry, &c., but Silurian and Carboniferous strata also seem to have been recognised. New Mexico appears to be rich in minerals, though its resources have been very imperfectly developed. Gold has been found in many places. In the Santa Fé district the peasantry have long been accustomed to employ a good deal of their time in washing the river-sands for gold, and some gold-mines are worked. The Spaniards wrought several silver-mines, but none are now in operation. Copper is said to abound throughout the mountain districts, though only one or two mines are now worked. Iron is also abundant. Coal is said to have been found near the village of James south-west of Santa Fé, and in other places. Gypsum occurs in various parts. On the high lands between the Rio Grande and Rio Pecos and in other places are extensive salt-lakes, or salinas, whence all the salt used in New Mexico is obtained.

The climate differs considerably, but is on the whole temperate; its great characteristic is its dryness. There is a rainy season, from July to October; but the rains are seldom heavy, and never of long continuance. The winters are long, especially in the north; but below Santa Fé the Colorado is seldom frozen firm enough to admit the passage of carriages. In the lower part of the valley of the Colorado the summer temperature occasionally rises to 100° Fahr., but the nights are generally cool. Epidemics are scarcely known.

The grain products are mostly confined to maize and wheat; mezquite is raised in the central valley; peas and beans, onions, red pepper, some fruit, and tobacco are also grown. Agriculture is everywhere in a most primitive state. Even in the central valley the chief dependence is on the raising of stock. Large numbers of horses, mules, cattle, and sheep are reared, there being everywhere extensive pastures; but comparatively little attention has been yet paid to the improvement of the breeds, which are generally small and inferior.

Almost the only manufactures are those for which the natives have long been celebrated—namely, those of coarse and fancy blankets, in great request for the favourite national garment called the 'serape;' and the chequered woollen-stuff called 'gerga,' used for carpets, as well as for clothing. Most of the imported articles are received by the Missouri overland route by caravans, by way of Independence to Santa Fé.

Of the 61,525 white inhabitants, above 58,000 are the descendants of the Spanish settlers, and all of them are Roman Catholics. The settlers from the older states and territories of the United States were only 761 in 1850. The natives appear to be an indolent but contented race, partaking more of the character of their Indian than their Spanish ancestors. The more laborious work is assigned to the females; not only the household work, and a good deal of the field labour, falls to their lot, but the spinning of the blankets and woollen wares is chiefly done by them. Of the ancient inhabitants of New Mexico the vestiges are still very numerous. They are chiefly what are called Aztec ruins, similar to those described under AMERICAN ANTIQUITIES, *S.* 1. Several are found along the banks of the Colorado and the Grande rivers and their tributaries. The most celebrated are those known as Las Casas Grandes, on the Gilas, noticed under AMERICAN ANTIQUITIES, *S.* 1, p. 98. Some of equal extent, called La Gran Quiviri, occur near the Salinas, between the Rio Grande and the Pecos, about 100 miles S.E. from Santa Fé, where, among other extensive remains, are said to be portions of an aqueduct 10 miles long.

Divisions, Towns, &c.—New Mexico is divided into seven counties. Santa Fé is the political capital, and though there are several other towns, they have necessarily so small a population as to be of little other than local consequence. *Albuquerque*, on the left bank of the Rio Grande, 76 miles S. from Santa Fé, is the only one which requires to be mentioned. It is said to have formerly contained 6000 inhabitants, but it has now little trade or population.

Santa Fé, the capital, is situated about 20 miles E. from the Rio Grande, in 35° 41′ N. lat., 106° 1′ W. long., on a wide plain surrounded by mountains, and at an elevation of 7047 feet above the level of the sea: population, 4846 in 1850. It is an old town, having been founded by the Spanish settlers in 1581, and consists of narrow irregular streets, with houses of a single story, built of adobe, square in form, and having a central area. It contains two Roman Catholic churches, but no other public buildings of any note. The inhabitants are still nearly all of Spanish and Indian descent, but there are a few Americans, who have established two newspapers, one published three times a week and the other weekly. Santa Fé is a place of great trade, being the centre and depôt of the overland route by way of Missouri. The climate is serene and little variable, and the town is said to be very healthy.

The government of New Mexico is based upon the Act of Congress of September 9th, 1850, which established the Territory, and provided that every free white male inhabitant then residing in New Mexico, and all free white citizens of the United States who should subsequently qualify by residence, should be entitled to vote in all elections. The legislative assembly consists of a Council of 13 members, elected for two years, and a House of Representatives of 26 members, elected annually. The governor, as in all the territories, is appointed by the president of the United States. A delegate to Congress is elected by the citizens.

NEWNHAM. [GLOUCESTERSHIRE.]

NEWPORT, GEORGE, distinguished as a comparative anatomist and physiologist, was born in the county of Kent in 1803. His parents were in humble circumstances, and with but little education he commenced following his father's business. He was indebted to a mechanics' institute at Canterbury for first exciting in him a taste for the study of natural history. He became so well known for these pursuits that, when a natural history museum was opened at Canterbury, he was at once appointed curator. Without any one to guide or direct him, he pursued the study of animals in his own way; and was particularly fond of dissecting any fresh specimen that came under his notice. His love of anatomy and natural history paved the way for his entering the medical profession; and after having served his apprenticeship, according to the requirements of the Apothecaries' Society, with Mr. Weeks of Sandwich in Kent, he finished his medical education at the London University, now University College. Here he attended the lectures of Professor Grant, and soon found that the work he had been pursuing in the country had qualified him for communicating the results of his labours to the world. His first paper was sent to the Royal Society, and was published in the 'Philosophical Transactions.' It was entitled, 'On the Nervous System of the Sphinx Ligustri, Linn.; and on the Changes which it undergoes during a Part of the Metamorphosis of the Insect.' This was speedily followed by other papers, which were read before the Royal Society, and published in the 'Philosophical Transactions.' The principal of these were entitled, 'On the Respiration of Insects;' 'On the Temperature of Insects, and its Connection with the Functions of Respiration and Circulation in this Class of Invertebrated Animals;' 'On the Organs of Reproduction and Development of the Myriapoda;' 'On the Structure, Relations, and Development of the Nervous and Circulating Systems, and on the Existence of a complete Circulation of the Blood in vessels, in Myriapoda and Macrourous Arachnida;' 'On the Reproduction of lost Parts in Myriapoda and Insecta.' He also published a series of papers on kindred subjects in the 'Transactions' of the Linnæan Society.

The labours of Newport, as a comparative anatomist, were chiefly confined to the insect tribes. Of all classes of animals they present the greatest variety of forms, and the largest number of adaptations of structure, to the circumstances in which they are placed. They hence afford a wide field for research to the comparative anatomist. It is however few who are endowed with the patience and delicate manipulative skill which the dissection of their delicate organisms demands. From his youth Newport had taken a delight in investigating the structure of insects, and his paper on the nervous system of the *Sphinx* was received with astonishment, on account of the skill and labour it displayed. In this paper he not only gave a minute account of the anatomy of the nervous system of this insect, but pointed out the relation which existed between the parts of the nervous system in insects and other animals. In the same philosophical spirit be pursued his researches in other departments of insect life. His papers on the respiration and temperature of insects, showed the relation between these two functions long before the chemical changes by which they are accompanied were understood. In his papers also on the reproduction of limbs in articulate animals, the structure of the blood-globule in insects, and the development of the ovum in the same class of animals, will be found a series of researches bearing on all the modern progress of physiology. A résumé of his own researches upon insect anatomy and physiology, with those of other comparative anatomists, will be found in his article 'Insecta,' in the 'Cyclopædia of Anatomy and Physiology.'

Whilst it is as an anatomist and physiologist that Newport takes a first position, his minor works and papers claim for him the highest merit as an entomologist. He was most diligent in his observations on the habits of insects, as is proved by his prize essay on the 'Habits and Economy of Athalia centifoliæ, the Sawfly of the Turnip.' Besides this paper he published many others on the habits of insects. In one of these he announced the discovery of a new genus of Parasites, and worked out their history in the most accurate and beautiful manner. This paper was published in the 'Transactions' of the Linnæan Society, and was entitled, 'The Anatomy and Development of certain Chalcididæ and Ichneumonidæ, compared with their special Economy and Instincts; with Descriptions of a new Genus and Species of Bee-Parasites.' As a systematic entomologist, he devoted his attention to the description and classification of the family *Myriapoda*. The specimens of these insects in the British Museum were arranged, and the catalogue descriptive of them published by the authorities of that institution was drawn up, by him.

Newport early joined the Entomological Society, and contributed many papers to its 'Transactions.' In 1844 he was elected president of this society, and in 1845 he was re-elected.

During the last few years of his life he had devoted great attention to the development of the ova in various kinds of animals. He published two series of papers on the development of the embryo in the ova of the *Amphibia*, and at the time of his death was engaged in drawing up a third. It was in consequence of pursuing this subject that he met with his death. In the spring of 1854, being desirous of obtaining some frogs for the purpose of pursuing his researches, he exposed himself to the malaria of the ponds which these creatures inhabit, and on the 6th of April sunk under a fever thus contracted.

Although Mr. Newport became a member of the College of Surgeons in 1835, and was made an honorary fellow in 1843, he was too devoted to his scientific pursuits to follow his profession. But England has no positions to offer her men of science, and during the latter years of his life he maintained himself on a pension of 100*l.* a year granted him by the government. Even the luxury of belonging to a scientific society has to be paid for, and out of his small pension Newport maintained his connection with the Royal and Linnæan societies, of which he was so distinguished a fellow, and to whose 'Transactions' he contributed so largely. He was twice rewarded with the royal medal of the Royal Society, and was a member of the councils of both the Linnæan and Royal Societies. His works were highly appreciated by Continental philosophers, and he was an honorary member of several foreign societies. He was an amiable, retiring man, little known beyond the limited sphere of men who cultivate the sciences of comparative anatomy and physiology; but his name will become more widely known as these sciences are more studied, and the true value of his researches be more widely appreciated.

NEWSPAPERS. In the 'Penny Cyclopædia,' vol. xvi., an account was given of newspapers down to 1838. Of the foreign newspapers little has to be added; the numbers in different countries may have varied somewhat, but their character remains unchanged, except that in France they have been brought still more under government control. In that country they are liable to an official warning for any infraction of prescribed rules, and after a third warning the publication is suspended.

In treating of the origin of the newspaper, we stated in our previous article that the claims of 'The English Mercuries,' of which three numbers are in the British Museum, purporting to be published at the time of the Armada, were suspected not to be genuine. The suspicion was well founded. In 1839 Mr. Thomas Watts, one of the librarians of the British Museum, published a 'Letter to Antonio Panizzi, Esq.,' in which he proved incontrovertibly that they were forgeries, and that the forgery was perpetrated about 1766. The three numbers, which are marked as 50, 51, and 54, purporting them to be part of a series, contain seven articles, three of which are in print, and four in manuscript. The type is of the date of 1766, but an old style of spelling is affected, while in the manuscript the spelling is modern, with a number of corrections in a different hand-writing; and the manuscript is written on a paper, with the watermark of the royal arms and initials of "G. R." In 1850 Mr. Watts made public the result of his further investigations, which showed that the manuscript was in the hand-writing of Philip Yorke, the second Earl of Hardwicke, and a few of the corrections in that of Dr. Birch. Mr. Watts also proves that the claims of France for the earliest newspaper, the 'Gazette of Paris,' in 1631, are also unfounded, and that the earliest specimen of this branch of literature belongs "to Italy or to Germany." The claim of Germany is strongest: at Augsburg and Vienna printed sheets containing news were published as early as 1524.

Since the publication of the previous article, the abolition of the advertisement duty in 1853 (16 & 17 Vict. cap. 63); the total removal of the stamp duty in 1855, or at least rendering it optional for the purpose of paying the penny postage, which gives the privilege of circulating by post for fifteen days (18 & 19 Vict. cap. 25); and the introduction of machinery, by which from 10,000 to 15,000 copies can be produced perfect in an hour; have united in giving a marked impetus to the extension of newspapers in the United Kingdom. In London there are now (April 1858) published 11 morning papers instead of six. The 'Times,' which usually consists of 16 pages, or two sheets, each containing a printed mass of upwards of 19½ square feet, price 4d.; the 'Morning Advertiser,' the 'Daily News,' the 'Morning Chronicle,' the 'Morning Herald,' the 'Morning Post,' and the 'Public Ledger,' each of 8 pages, and price 4d.; the 'Standard' and the 'Daily Telegraph,' each of 8 pages, the 'Morning Star' and the 'Morning News,' each of 4 pages, the last four published at 1d. each. As there is now no record of the numbers printed, it is impossible to give more than approximations; but it is known that the 'Times' publishes daily from 50,000 to 60,000 copies, and the 'Standard' has asserted that on one occasion it printed 100,000, the general sale nearly approaching that number. It is clear, indeed, that only a very large sale, with numerous advertisements, for which the wide circulation renders them a good medium, can enable these low-priced newspapers to maintain themselves, particularly as some of them, the 'Standard' for example, do not rely on the higher-priced morning papers for the more expensive articles of intelligence, such as the foreign and telegraphic communications, reports in parliament, &c. Of evening papers there are now eight, the 'Express,' the 'Globe,' the 'Evening Herald,' the 'Evening Star,' the 'Sun,' the 'Shipping and Mercantile Gazette,' the 'Shipping Advertiser,' and 'Lloyd's List.' The last two are entirely mercantile, as is the 'Public Ledger,' among the morning papers. Of the others, the 'Globe,' the 'Sun,' and the 'Shipping and Mercantile Gazette,' are papers of 4 pages, price 4d. The 'Express' and the 'Evening Herald' are branches of the 'Daily News' and the 'Morning Herald,' price 2d.; and the 'Evening Star,' price 1d., is an evening edition of the 'Morning Star.' The 'London Gazette' and the 'Patriot,' the organ of the Independent and Baptist dissenters, are published twice a week. The 'Evening Journal,' the 'Evening Mail,' the 'St. James's Chronicle,' the 'Monetary Times,' and the 'Record,' are published three times a week. Of weekly London papers there are altogether 111, but this includes literary papers, such as the 'Athenæum,' the 'Literary Gazette,' 'Punch,' 'Notes and Queries,' and many class publications, such as the 'Solicitor's Journal,' the 'Builder,' and the 'Pawnbroker's Gazette;' but they are all essentially newspapers, though not all political. One remarkable feature is the existence of a considerable number of local papers in London, the 'City Press,' the 'Clerkenwell News,' the 'Islington Gazette,' the 'Islington Times,' the 'Holborn Journal,' the 'Marylebone Mercury,' and several others. These are chiefly papers devoted to local affairs and advertisements, none of them exceeding a penny in price, and some being published at a halfpenny. Some of the other weekly papers are conducted with a large amount of literary and political talent, and are of a higher price, such as the 'Examiner,' the 'Spectator,' the 'Saturday Review,' the 'Press,' the 'Leader,' &c. Others appeal to cheapness and a variety of intelligence, and some of them reach a circulation of upwards of 200,000. Among those which reach a high number are some of the illustrated papers, such as the 'Illustrated London News,' the 'Illustrated Times,' &c. There are many other periodical publications, such as 'Household Words,' 'Chambers's Journal,' &c., which, as not containing *news*, are not included among newspapers. Of local newspapers published in England there are 411, and in Wales 22. Many of these are penny papers, which are mostly published in the smaller towns; but Birmingham has two daily papers and Liverpool one at that price. There are 131 newspapers published in Scotland, and the prices vary from a penny, of which price there are many and some of them daily, to sixpence. In Ireland there are 123 published, but only Belfast and Dublin have any papers so low in price as a penny. In the Isle of Man and the Channel Islands, there are published 13 newspapers, at prices varying from a penny to threepence. In all the preceding statements we have named the price independent of the stamp, which in all cases is charged for extra if a stamped paper is required. As we have already mentioned it is perfectly impossible even to guess at the total number printed, but in 1857 seventy-one millions passed through the post-office, of which about three-fourths bore the newspaper stamp, and the other fourth an affixed postage stamp.

By the Act 18 and 19 Vict., cap. 27, any periodical publication, published at intervals, not exceeding thirty-one days, of which the print does not exceed the prescribed superficies, may claim to be stamped as a newspaper; but in such case the title must be printed on the top of every page, with the date of publication; and, when posted, must be folded so as to show the stamp denoting the duty. Newspapers to be sent abroad by post may be registered at the General Post-office, for which an annual fee of *5s.* is charged, the year always terminating on the 30th of June. It is not absolutely necessary that the newspaper should be registered, but the English Post-office then charges *2d.* in addition to the foreign or colonial postage. Before a newspaper can be published a notice must be given at the Inland Revenue Office, Somerset House, or at the District Stamp-office, where the form of a "declaration" will be given, in which is to be stated—the title of the intended paper quoted literally; the place where it is to be printed, giving the number of the house, the name of the street and of the parish in which it is situated, and the name of the occupier if it forms part of a dwelling-house; and the like particulars respecting the place of publication if it differs from the place of printing; the Christian and surnames of the printers and publishers; the number of shares into which the property is divided whenever the number, exclusive of the printer and publisher, exceeds two; and the Christian and surnames, residences, and occupations of every proprietor, with the number of shares belonging to each when exceeding two, exclusive of the printer and publisher. This declaration must be made by the proprietor, or two proprietors, or by two of the largest shareholders where the number exceeds two, who must also furnish two respectable householders as sureties against the publication of seditions, blasphemous, or personal libels, to the amount of *400l.* in London and *300l.* elsewhere. A newspaper published before these securities are given subjects the proprietors to a penalty of *20l.* The paper when published must have across the bottom of the last page or the last column, the names and residences of the printer and publisher, the place of publication, the date, and the price, under a similar penalty for neglect. A supplement must not be issued without the paper itself; and a copy of the paper, which is paid for, must be transmitted to the Stamp-office on the day of publication or the day after in London, Edinburgh, or Dublin, and elsewhere within three days, under the like penalty of *20l.* for each offence; but the penalties can only be sued for by the Attorney-General or the Stamp-office.

The size and amount of stamp-duty for newspapers are defined as follows by the 16 and 17 Vict., cap. 63: Newspaper stamps are to be 1*d*. only, for a superficies of print, on one side of the paper, not exceeding 2295 inches, whether published as a supplement or not; any supplement that with the paper does not exceed that quantity is to be exempt; and any other supplement to a duly stamped newspaper not containing a superficies on one side of more than 1148 inches of print is to be subject to a stamp of one-halfpenny; and any two supplements not containing more than 2296 inches, to a duty of one halfpenny each, provided each be published on one sheet of paper only. Newspapers not stamped go by post at the book-post rate of a penny for 4 ounces, twopence for 8 ounces, and then ascending by twopence for every fraction of 8 ounces; and any number may be sent in one envelope open at the ends.

NEWT (*Lissotriton punctatus*). [SALAMANDRIÆ, p. 336.]

NEWTON. [LANCASHIRE.]

NEWTON ABBOT. [DEVONSHIRE.]

NEWTOWN-LIMAVADY. [LONDONDERRY.]

NEWTOWNARDS, County Down, Ireland, a market-town, and the seat of a Poor-Law Union, is situated near the head of Lough Strangford, in 54° 36′ N. lat., 5° 54′ W. long., 12½ miles E. from Belfast by the Belfast and County Down railway. The population in 1851 was 9567, besides 508 inmates of the workhouse. Newtownards Poor-Law Union comprises 16 electoral divisions, with an area of 93,851 acres, and a population in 1851 of 56,861. The town, pleasantly situated in the midst of hills, is neat, regular, and well built. In the Market-square and principal streets are many good houses. The parish church is a handsome building, erected in 1817. There are chapels for Roman Catholics, Presbyterians, and Methodists, and three National schools. The old parish church, erected in 1632, a large building with a handsome spire, is now used as a court-house. There are a market-house, a bridewell, and a Union workhouse. The weaving and embroidering of muslin afford a considerable amount of employment. Quarter and petty sessions are held. Fairs are held on the second Saturday of every month, and on January 23rd, May 14th, and September 23rd. Near the centre of the town is an octagonal structure, with canopied niches, forming the pedestal of a cross, erected in 1636. Newtownards was incorporated by James II., and returned two members to the Irish Parliament.

NGAMI, LAKE. [AFRICA, *S.* 2.]

NIAGARA. [CANADA, *S.* 2.]

NICÆA (*Nikaia*), an ancient ruined city in Bithynia, in the north-west of Asia Minor, the site of which is marked by the Turkish village of Is-nik. It stood on the eastern shore of the Lake Ascania, and was built or restored by Antigonus, son of Philip, after whom it was called Antigonela. The name was subsequently changed by Perdiccas in honour of his wife, Nicæa, daughter of Ptolomæus, king of Egypt. The city became early the seat of a Christian bishop. It was destroyed by an earthquake in the latter end of A.D. 325, but it was restored under the emperor Valens in 368. Aided by the Greek Nicephoras Melissenus, the Turks, under Solyman I., took the city (1080), which was made their head-quarters till 1097, when Godefroi de Bouillon, at the head of the Crusaders, took it after a siege of 35 days, and it was again united to the Greek empire. Two years after the establishment of the Latin empire in Constantinople (1204) Theodore Lascaris made Nicæa the Greek capital, which it continued to be till 1261, when in the reign of Michael Palæologus (who was crowned at Nicæa the year before), Constantinople was recovered by the Greeks. In 1333, after an obstinate and bloody siege, the Turks, under Orkan, again took Nicæa, which they made their capital. After the battle of Angora (June 30, 1402) it was taken and pillaged by the followers of Tamerlane. In 1422 it joined in a conspiracy to put Mustapha on the throne of his brother, Amurath II., whereupon the latter reduced the city to obedience, and had his brother and the chief conspirators strangled in his presence.

Sir Charles Fellows, who visited the site of Nicæa, says that the walls form a circuit of four miles. These walls are strengthened with towers. One part is built or repaired with materials of great elegance from an ancient temple; another part is built with Roman brick; a third with marbles of a late age, marked with the sign of a cross and ill-cut inscriptions, showing the repairs made in Christian times; the remaining parts are built of immense stones cut to fit into each other in the cyclopean style. Four large majestic gateways with arched entrances still exist in an almost perfect state, but the inscriptions that once covered them have been nearly altogether effaced. Among the existing remains are many inscribed stones, copies of which are given in Sir Charles Fellows's 'Asia Minor;' ancient bas-reliefs; a few statues; and ruins of an early Greek theatre, "of extremely good workmanship, and colossal, the stones being some nine and others fourteen feet in length." Ruins of mosques, baths, and houses are seen among the gardens and corn-fields which cover a great space within the ancient walls. In the village of Is-nik, which stands in the centre of the ruins, there is a small church, used by the Greeks for their worship, with Mosaic floor and ceiling of the Byzantine age. Every fence, trough, or paving-stone in the village and its neighbourhood is derived from this quarry of art, and many fragments of good sculpture are built into the houses. A Roman aqueduct still conveys water to the town from the neighbouring mountains. In the lake, the waters of which are of transparent clearness, are the remains of an ancient landing-place.

In the history of the church Nicæa is memorable as the place in which the first and seventh œcumenical or general councils were held. The first, held in 325 (June 19 to August 25), in presence of the emperor Constantine, and presided over by Osius, representative of Pope Sylvester, condemned the doctrines of Arius, maintained the divinity of Christ, and declared the consubstantiality of the Son of God with his Father to be an article of faith. The creed founded upon these decrees was drawn up by Osius; it is the Symbolum Nicænum, that is, Nicæne or Nicene Creed, still in use. This council also passed decrees for celebrating the festival of Easter on the same day throughout Christendom. A proposal forbidding priests who were married before receiving holy orders, to live with their wives, was rejected. The council was attended by 318 bishops from all parts of the Roman empire.

The seventh general council, held in 787 (September 24 to October 23), and attended by 377 bishops, condemned the Iconoclasts, and explained the worship of images.

(Fellows, *Asia Minor; Art de Vérifier les Dates*.)

NICARAGUA, Republic of, Central America, occupies the hilly and volcanic region extending from Salinas Bay to the Bay of Conchagua on the Pacific, and back to the Mosquito territory. It may be taken generally as lying between 10° 45′ and 14° 10′ N. lat., 84° and 87° 40′ W. long.; and as bounded E. by the Mosquito Territory; N. by the republic of Honduras; N.W. by that of Salvador; W. by the Pacific Ocean; and S. by the republic of Costa Rica: but the eastern boundary is really undefined, Nicaragua refusing to acknowledge the right of the King of Mosquito to the tract lying along the Caribbean Sea. The area, consequently, is not agreed upon: that really under the authority of the republic does not probably exceed 35,000 square miles, but that claimed is of course much greater. The population may be about 250,000: the chief part of whom are ladinos, or mulattoes, and native Indians.

The coast along the Pacific from Salinas Bay to the Gulf of Conchagua bears nearly north-west. It is throughout rocky, and has some harbours of much value. That which may just now be regarded as the most important, from its being the Pacific port for the Nicaragua route connecting the Atlantic and Pacific Oceans, is San Juan del Sur, north of Salinas Bay, which is formed by two promontories between 400 and 500 feet high, having an entrance above 3000 feet across. The harbour is small, but well sheltered, and affords anchorage in from 2 to 10 fathoms water. About a mile from it is the nearly similar harbour of Nacascolo. Port Realejo, towards the northern end of the state, is also a very good and much larger harbour, and is that which, prior to the opening of the Nicaragua transit route, received most of the foreign vessels trading with the republic. There is a very narrow tract of tolerably level land along a good part of the coast.

Along the western side of the republic, at a few miles from the coast, extends a ridge of low volcanic mountains, highest at the southern end, and generally decreasing in altitude as we proceed northward: though one or two of the isolated peaks in the northern part are among the most elevated. Several of these volcanoes appear to stand alone, or to have scarcely any connection with the main ridge, though standing in its general line of direction. The highest summits appear to be Omotepec, which forms an island in Lake Nicaragua (5100 feet above the sea); Momotomba, at the northern extremity of Lake Managua, about the same height; Mombacho, between Lake Nicaragua and the Pacific (4500 feet); Nindiri, between Managua and Masaga; Felica; El Viejo, and one or two others. Several of these are active volcanoes. Another mountain tract, a part of the mountain system of Honduras, extends along the northern part of the country. This part of Nicaragua is traversed by several ridges, some of whose summits attain a considerable altitude. Between the ridges extend many good-sized valleys, the principal being those of the Rio de Segovia, and the Rio Escondido. The remainder of the state belongs to the plain of Nicaragua, of which, however, the larger portion forms the Mosquito territory. This plain is but little elevated above the level of the sea; the Lake of Nicaragua which occupies a arge part of the Nicaragua section of it, being only 122 feet above the Caribbean Sea. Along the rivers it is wooded; the rest of the plain forms extensive savannahs, covered with a rich verdure, and presenting occasionally a clump of high trees. The climate being excessively hot and moist the white races have not formed any settlements on this plain, and it is only inhabited by independent aboriginal tribes.

The few rivers which in Nicaragua fall into the Pacific, are of short extent and little consequence. Those falling into the Atlantic are longer and more important. Two considerable streams rise, as already mentioned, in the northern part of the republic, the Segovia and the Escondido; the sources of some of their upper branches are not very distant, but their outlets are far apart—that of the Escondido being near the southern, and that of the Segovia towards the northern end of the Mosquito coast. The Segovia flows past the town of the same name, but both rivers belong more to Mosquito than to Nicaragua. The most important river of this republic is the *San Juan*, which forms the boundary between Nicaragua and Costa Rica, and falls into the Caribbean Sea, near 11° N. lat. It is by means of this river and the Lake of Nicaragua, that one of the two great lines of communication is proposed to be opened between the Atlantic and Pacific oceans. The river San Juan is the only channel by which the Lake of Nicaragua discharges its waters into the Atlantic. The Lake or Lagune of Nicaragua is an inland sea, of a lengthened form, being about 100 miles long and 40 miles broad where widest, without narrowing much at either end. It is the reservoir of a great extent of mountainous country, and is deep enough to be navigated by vessels of considerable size, having about 100 yards from the beach generally a depth of about 2 fathoms; and at a greater distance from 5 to 15 fathoms of water along the southern and western banks. It is only very shallow along the north-east shore for a mile and upwards into the lake. It contains several islands, among which that of Omotepec, near the south-western bank between Granada and Nicaragua, is remarkable for a high volcano, and for its fertility and population, being inhabited by a numerous and industrious tribe of Indians, who have a small town, Moyagalpa, possess cattle, and raise maize, rice, &c. The river issues from the south-eastern extremity of the lake; its breadth varies from 100 to 400 yards. About the middle of its course the San Juan receives from the south the Rio San Carlos, and lower down the Serapiqui. About 25 miles from its mouth the river divides into two arms, of which the southern and wider is called Rio Colorado; the other (the San Juan) enters the sea near the harbour of San Juan del Norte. The depth of water in the upper part of the course of the San Juan varies from 9 to 20 feet, but in some places it is so shallow that rapids are produced, and it contains numerous islands. The lower portion of the river, below its bifurcation, is generally shallow. The mouth of the San Juan has a bar with seldom four feet of water upon it. The winding course of the river is somewhat under 100 miles. On the Pacific side there are, however, greater obstacles to the communication between the two oceans than that presented by the channel of the San Juan. At the narrowest part the distance between the Lake and the Pacific is only about 15 miles, and on the coast there is here the good harbour of San Juan del Sur, but the hills upon it rise to between 400 and 500 feet, presenting a formidable barrier to the construction of a canal, while the difference of level between the lake and the sea is 129 feet, and therefore locks would be necessary. The hills might perhaps be in a measure avoided, but the canal would of course be longer. Whether such a canal will ever be formed it would be hard to predicate; especially since the completion of the railway across the Isthmus of Panama has provided so much more rapid a route. But even in the absence of the canal this route has been largely adopted. In 1850 the governments of England and the United States concluded a treaty by which they agreed to co-operate in the establishment of a secure and neutral line of communication between the two seas by way of the San Juan River and Lake Nicaragua, to be open on equal terms to all nations, with a free port at each end of the line. A company was formed for constructing a canal, improving the navigation of the San Juan, and working the communication by steam-boats. The Nicaragua Transit Company have been unable even to attempt to carry out the first and most arduous part of their task, but they have established steam-boats of light draught to navigate the river, and organised a line of carriages to convey the passengers and goods from Nicaragua to San Juan del Sur on the Pacific. During 1854 a very large number of passengers to and from California adopted this route, and it was asserted in some of the advertisements of the line published in New York, that not only was "the Nicaragua Transit route the shortest, safest, and by far the most comfortable and healthful," but that passengers by it had "to travel but 12 miles of land carriage over a good macadamised road." Long before the establishment of this route communication had been maintained between the Atlantic and the towns of Granada and Nicaragua, by the river San Juan and Lake Nicaragua, by means of flat-bottomed vessels called piraguas, of from 5 to 10 tons burden. The passage from Granada to San Juan, or Greytown, is usually made by the piraguas in about 8 days, whilst the return passage being against the stream, occupies from 12 to 15 days. It has been proposed by some as more advantageous to unite the Lake of Managua by a canal with the harbour of Realejo. The country between them is nearly level, and of a firm soil, without being rocky. Besides this, the canal would terminate in the port of Realejo, one of the best harbours on the west coast of America, while that near Nicaragua would end in the smaller harbour of San Juan del Sur. But this canal would be more than twice as long as the other; in addition to which, the Tepitapa, which unites the Lake of Nicaragua with that of Managua, must be rendered navigable. The lake of Managua is 35 miles long, and fifteen miles broad in its widest part. It is deep enough for vessels of considerable size; but the Rio Tepitapa, which brings down the water from the Lake of Nicaragua, and is about 25 miles long, has falls which, in the dry season, are from 6 to 8 feet high, and also several shoals. These obstacles could only be avoided by a canal cut through the level ground on the northern side of the Rio Tepitapa.

The climate of the Plain of Nicaragua, as stated above, is hot and moist, and so unhealthy as to have caused it to be left to the undisturbed occupation of the native races. The thickly wooded banks of the San Juan River are no exception to this observation. The shores of the Pacific, where the population is densest, are also very hot and somewhat humid, but do not appear to be particularly unhealthy, except in the vicinity of the Bay of Conchagua, where however there are comparatively few inhabitants. The hilly districts between the coast and the western banks of the lakes are much milder and more salubrious, as is also the mountainous country of the north. There are regular dry and rainy seasons, as in other parts of Central America, the only difference being that the rains last somewhat longer, and fall in larger quantities. In the hilly country west of the lakes occasional showers also occur out of the regular rainy season.

The soil throughout the occupied districts appears to be very fertile, but agriculture is in a rude state; the roads are almost everywhere insufficient, ill made, and ill kept, and oxen are almost the only animals of draught. Although therefore Nicaragua might with a peaceful and industrious people furnish vast quantities of agricultural produce for other countries as well as for the supply of a greatly increased population, it really affords little more than suffices for domestic consumption. Maize and frixoles are raised in considerable abundance, and form the staple food of the people. Some wheat is grown in the north, chiefly for use in the cities. Sugar, indigo, cotton, coffee, cocoa, and tobacco are all grown, but, except indigo, not to any great extent. A great variety of fruits, including several native kinds, with oranges, lemons, &c., ripen well; and garden vegetables flourish, but little attention is paid to them except by the Indians, who cultivate them for sale in the cities. Indigo, Nicaragua, and Brazil wood, and some other timber and dye-woods and hides are at present the chief articles exported. Cattle are among the principal sonrces of wealth, very large nnmbers of them heing kept on the plains along the eastern sides of the lakes. Fish are plentiful in the lakes, in which also crocodiles are common. Along the coast pearls used to be found. The mineral resources of Nicaragua have not been very diligently explored. Gold and silver have been fonnd and worked, bnt not extensively; copper has also been found.

The manufactnres are nearly confiued to the coarser goods required for home consumption. The chief articles made are coarse cotton and woollen cloths; the cotton heing dyed of a purple colour, ohtained from a shell-fish caught in the vicinity of San Juan del Snr, is in great reqnest among the Indians, who prefer it to any Europesn dyed goods on account of the greater durahility of the colour.

Nicaragua is divided into five departments, which are named after their respective capitals:—Segovia comprises the north-eastern part of the territory; Leon, the north and north-western; Managua, the district sonth of Leon; Granada, that south of Managua; and Nicaragua, the most sonthern part bordering on Costa Rica. Leon is the political capital. The following are the principal towns; the populations are merely a loose approximation:—

Leon, the capital of Nicaragua, contained not many years ago, a popnlation of 32,000 inhabitants, hut the civil contentions within the town have rednced it to half that numher, and destroyed a large proportion of its best hnildings. It is situated on the road which leads from the best-cultivated districts of the state to the harhour of Realejo, in 12° 26′ N. lat., 86° 52′ W. long. The city occnpies a considerahle area, and contains a cathedral, several chnrches, a university, Tridentine college, &c., but all in a very neglected condition.

Granada, on the north-western bank of the Lake of Nicaragua, population about 12,000, carries on some trade with Jamaica by means of the river and harbour of San Juan, contains several churches and convents; hut has no features requiring further notice.

Managua, on the south hank of Lake Managua, is a considerahle place containing 10,000 inhabitants. *Masaga*, some little distance S. of Managua, has a popnlation nearly eqnal to it, bnt almost all Indians, who are engaged in commerce with the adjacent populons country, and in the mannfactnre of the varions articles of domestic requirement in which they display mnch skill.

Nicaragua, ahont two miles from the west bank of Lake Nicaragua, contains, with the snburb of San George, some 15,000 inhabitants, and is surrounded by a district noted for its fertility, especially in cacao and grapes.

San Juan del Sur, on the Pacific, S.W. of the town of Nicaragua, contained hut few iuhahitants previous to its selection as the Pacific port for the Nicaragua line of communication between the two oceans. The harhonr, as already mentioned, is small but convenient, and possesses good anchorage.

Segovia, on the Rio de Segovia, is a small place, whose only claim to notice is that of heing the capital of the department of Segovia, the least populous section of the repuhlic. The country around is fertile and healthy, and its mineral wealth is helieved to be considerahle.

Nicaragua is nominally a Repuhlic with a senate and a chamber of depnties, hut the government is really vested in a dictator with the title of Snpreme Director. After the declaration of independeuce, and the formation in 1842 of the republic of Central America [GUATEMALA, *S.* 2; HONDURAS, *S.* 2], Nicaragua formed one of the federal states nntil the dissolution of the nnion, when, like the other states, it became an independent repuhlic; and, like them, all hopes of its progress have been since arrested by constant internal discord.

NICOLAS I., PAVLOVICH, Emperor of Rnssia (styled also Czar and Autocrat of all the Rnssias), was born in the city of St. Petershurg, Jnly 7, 1796 (June 25, Old Style). He was the third son of the Emperor Paul, Alexander I. having been the first son, and the Grand Duke Constantine the second son. His mother, Sophie Dorothea, a daughter of Friedrich Eugen, duke of Würtemherg, when she became the second wife of the Emperor Panl, became also a member of the Greek Chnrch, and, as is the usage, changed her names to those of Maria Feodorowna.

The Emperor Panl having been assassinated March 23, 1801, Nicolas was left entirely to the care of his mother, who appointed General Lamsdorf his governor, aud selected the Conntess Lieven and the German philologist Adeluug as his principal teachers in languages and literature, and Counsellor Storch as his instructor in general politics and other sciences and arts suitahle to his rank and station. He acquired the power of speaking the French and German languages with as much facility as the Russian, and early manifested that prefereuce for military display, military tactics, and the art of fortification, which distinguished him through life.

After the termination of the great Enropean war in 1814, Nicolas was sent to travel, and visited some of the principal battle-fields. In 1816 he came to England, where he met with a cordial reception. He afterwards made a tour in the chief provinces of the Russian empire. On the 13th of Jnly, 1817, he married Frederica-Louisa-Charlotte-Wilhelmina, eldest daughter of Frederic William III., king of Prussia, and sister of Frederic William IV., the present king. She was horn July 13, 1798, and her distinguishing name was Charlotte, hnt on her marriage and entering the Greek Church she assnmed the names of Alexandra Feodorowna.

The Emperor Alexander I. having no issue, his next brother Constantine was the legitimate heir to the throne; hut, hy a docnment signed August 28, 1823, Constantine renounced his right, reserving to himself the dignity of Viceroy of Poland; so that, when Alexander died at Taganrog, December 1, 1825, Nicolas immediately sncceeded him. He did not however hecome emperor without a struggle atteuded with much danger. An extensive conspiracy had been organised a considerable time before the death of Alexander among the officers of the Russian army and those of the nohility who were friendly to a constitutional government; and the soldiers aud people were taught to helieve that the abdication of the Grand Duke Constantine had heen ohtained hy forcihle means. When the troops were assemhled in the great square fronting the Imperial Winter Palace of St. Petersburg, in order to make a manifestation of their allegiance to the new emperor, the officers, jnst as the ceremony was ahout to commence, stepping forward out of the ranks, denonnced Nicolas as a usnrper, and proclaimed Constantine as their rightful czar. The soldiers followed their officers, with cries of "Constantine and the Constitntion!" Milardowich, governor of St. Petershurg, a veteran favourite of the army, and the archhishop, in his ecclesiastical robes, endeavonred to snppress the hostile demonstration, hut in vain, and the people showed signs of sympathising with the troops. At this critical moment Nicolas came forward, and, boldly confronting the officers and soldiers, called ont with a lond voice, "Retnrn to yonr ranks—obey—kneel!" The czar's majestic form and undannted bearing, his pale bnt calm and stern conntenance, and the reverence with which the Russians hahitually regard their sovereign, cansed most of the soldiers to kneel and gronnd their arms. The first outbreak was thns checked, hnt the conspiracy was not suppressed till artillery and mnsketry had poured freely their missiles of destruction among the gathering masses of the insurrectionists. Colonel Pestel and four other leaders of the conspiracy were execnted. Others were sent to the mines of Siberia, where Nicolas continued their punishments with nnappeasable severity. He was crowned at Moscow with great pomp and ceremony, September 3, 1826; and at Warsaw, May 24, 1829.

Soon after his corouatiou, in 1826, the Emperor Nicolas commenced a war with the Shah of Persia, which lasted till the victory over the Persians hy Field-Marshal Paskevich, February 28, 1828, led to the treaty of Turkmanchai, by which the Shah, hesides undertaking to pay about three millions sterling, ceded to Rnssia the provinces of Erivan and the conntries situated on the lower Konr and the Aras. A war between Rnssia and Turkey ensued in 1828, during which the Russian army crossed the Dannbe and took the fortresses of Braila aud Varna. In the campaign of 1829, General Diehitch took the fortress of Silistria, defeated the main army of the Tnrks at Shumla, crossed the Balkan, and advanced to Adrianople, where a treaty of peace was signed September 14, 1829. By this treaty, Nicolas ohtained for Russia, hesides a large sum as indemuification for the expenses of the war, liberty to trade in all parts of the Turkish empire, trading navigation on the Danube, free passage of the Dardanelles, the fortress and pashalic of Anapa on the eastern coast of the Black Sea, and other additions of territory as well as of political power.

On the 29th of Novemher 1830 an insurrection broke out in Poland. The Polish troops having joined the insurrectionists, the Grand-Duke Constantine, as commander-in-chief, was allowed to retire from Poland with 8000 Russians. In January 1831 the Polish Diet declared the throne vacant, organised a national government under Prince Adam Czartoryski, and prepared for a vigorous defence of their country. They assembled about 60,000 troops; but the Russian armies which advanced against them numbered about 130,000, and had about 400 pieces of artillery. The Poles fought bravely, and were successful in several actions, but sustained an enormous loss at the battle of Ostrolenka, May 26, 1831. The Prussian government prevented the Poles getting supplies of arms and ammunition across their frontier, while the Russians were allowed to have magazines within the Prussian territory. General Diebitch died suddenly on the 9th of June, and was succeeded by Paskevich. Warsaw was besieged on the 6th of September, and surrendered on the 8th. The failure of this insurrection was disastrous to the Poles. The Emperor Nicolas treated them with rigorous severity: several were sent to the mines of Siberia, and many to serve as soldiers in the Caucasus; the Polish constitution was formally abrogated; the chief universities were suppressed, and the libraries removed to St. Petersburg; and on the 17th of March, 1832, by a decree of the emperor, the kingdom of Poland was incorporated with the Russian empire.

In 1837 the Emperor Nicolas made a tour in his Trans-Caucasian provinces. He travelled with great rapidity, but remained at Tiflis from the 20th to the 24th of October, reviewed the troops, gave dinners and a grand ball, and held a levee, which was attended by all persons of distinction in the provinces. He paid a visit of inspection to the fortress of Gumri, since named Alexandropol, near the frontier of Turkish Armenia, and about 45 miles E. by N. from Kars. It was then in process of construction, and is now a fortified position of great strength either for defence or offence against the Turks in Asia Minor. A desultory conflict was at this period carried on between the Russians and the Circassians, but in 1839 war was formally declared by Russia against the Circassians, and has continued with little intermission ever since. In 1844 the Emperor Nicolas paid a second visit to England, and was entertained by Queen Victoria at Buckingham Palace and Windsor Castle from the 1st to the 9th of June. In 1849 he sent a Russian army into Hungary in aid of the Austrians, and the subjugation of that country was accomplished in the month of August of that year.

The last and most important event in the reign of the Emperor Nicolas was the recent war with Turkey and the Western Powers. It was the only unsuccessful and disastrous war in which he had engaged, and the reverses his army experienced probably occasioned a degree of excitement and irritation which shortened his life. It was commenced by the emperor's minister Menzikoff in March 1853 demanding a right of protectorate over those subjects of the sultan who belong to the Greek Church. The claim was refused, and a Russian army occupied Moldavia and Wallachia as a 'material guarantee' for enforcing it. In October the same year the Porte declared war against Russia, and applied to France and England for their promised aid. A Turkish army under Omar Pasha occupied Shumla and the fortresses on the Danube; in November he threw a body of troops across the river opposite Widin, and fortified a position at Oltenitza, on the left bank, which was retained till the termination of the war. The destruction of the Turkish fleet at Sinope in the same month was followed by the advance of the French and English fleets into the Black Sea. The English and French armies were next landed and encamped near Constantinople, whence they removed to the vicinity of Varna. In March 1854 the Russian army crossed the Danube, and besieged the fortress of Silistria, but after great efforts and an enormous loss of men was compelled to raise the siege on the 15th of June, and to retreat across the Danube. The Anglo-French army landed in the Crimea September 14, 1854; won the battle of the Alma; by a flank march seized a position on the south side of Sebastopol, and commenced the siege, which, after a severe struggle, the facts of which are well known, was terminated on the 8th and 9th of September 1855, by the capture of the town and all the forts on the southern side of the harbour of Sebastopol.

Meantime, before this great feat had been accomplished, the Emperor Nicolas died at St. Petersburg on the 2nd of March, 1855, and was succeeded by the present emperor Alexander II. The Empress Alexandra survives him, and he has left issue four sons and two daughters: Alexander, born April 29, 1818; Maria, born August 18, 1819; Olga, born September 11, 1822; Constantine, born September 21, 1827; Nicolas, born August 8, 1831; and Michael, born October 25, 1832.

The Emperor Nicolas was upwards of six feet in height, muscular and well-proportioned, with handsome features. In his personal habits he was simple, abstemious, and indefatigably industrious. He had a taste for the fine arts, and for music, and is stated to have composed some military airs; but his favourite pursuits were connected with the military sciences and military operations. In his political principles he was professedly despotic. He has been heard to say, "Despotism is the very essence of my government, and it suits the genius of my land." The great objects of his public life were the increase of the power of Russia and the extension of her territories to the east, west, and south, by unscrupulous diplomacy, and, when that failed, by war. His grand purpose is now known to have been the possession of Constantinople. By means of that unrivalled military and political position, he trusted to have superseded the Sultan in his empire, and to have become the dominant power in Europe and Asia.

NICOLAS, SIR NICHOLAS HARRIS, was born on March 10, 1799, the fourth son of John Harris Nicolas of Cornwall. He entered the navy early, and attained the rank of lieutenant on September 15, 1815, after having distinguished himself in the capture of several vessels on the coast of Calabria. As he ceased to be employed after the close of the war he turned his attention to antiquarian literature, and his first production was 'The Life of William Davison, Secretary of State and Privy Councillor to Queen Elizabeth,' published in 1823, occasioned probably by his having married in 1822 a daughter of John Davison, a descendant of the family of the secretary. He had entered himself at the Middle Temple, and in 1825 he was called to the bar, but his practice was almost entirely confined to claims of peerage before the House of Lords. About the same time he became a Fellow of the Society of Antiquaries, a member of the council, and a frequent contributor to the 'Archæologia,' but he soon disagreed with them, and wrote several pamphlets against the administration of the affairs of the society, and also pointing out defects in the proceedings of the Record Commission. His industry was extraordinary, and though many of the works he published were those of others, such as 'The Poetical Rhapsody, and other Poems by Francis Davison,' reprinted from the edition of 1608; 'The Literary Remains of Lady Jane Grey;' 'Journal of the Embassy of Thomas Beckington to France in 1442;' 'The Siege of Carlaverock;' 'The History of the Battle of Agincourt;' 'The Privy Purse Expenses of Henry VIII. from November 1529 to December 1552;' 'A Chronicle of London from 1089 to 1483,' from manuscripts in the British Museum; 'Memoirs of Lady Fanshaw, written by herself;' and others; they were all so enriched with memoirs of the persons mentioned, with annotations and other matters, as to assume the character of original works, and are all highly valuable to the historical student. In 1826 he became joint editor with Henry Southern of the new series of the 'Retrospective Review,' of which however only six numbers were published.

Among his most generally useful historical works are: 'Notitia Historica, containing Tables, Calendars, and Miscellaneous Information for the use of Historians, Antiquaries, and the Legal Profession,' 8vo, 1824; afterwards remodelled for 'Lardner's Cabinet Cyclopædia,' under the title of 'The Chronology of History; containing Tables, Calculations, and Statements indispensable for ascertaining the Dates of Historical Events, and of Public and Private Documents, from the earliest period to the present time,' 1835, a most valuable work, which has been more than once reprinted. In his 'Controversy between Sir Robert Grosvenor and Sir Richard Scrope in the Courts of Chivalry, A.D. 1385-1389,' a magnificent work in 2 vols. 8vo, but which was never completed, he had given a memoir of Geoffrey Chaucer; this he afterwards extended to a life, to accompany Pickering's Aldine edition of Chaucer's 'Works,' by far the best life which had hitherto appeared. For the same work he also furnished lives of the Earl of Surrey, Sir Thomas Wyatt, Collins, Cowper, Thomson, Burns, and Henry Kirke White. In 1844 he published 'The Despatches and Letters of Admiral Lord Viscount Nelson,' in 7 vols. 8vo. He had also commenced 'The History of the British Navy,' of which he only lived to complete two volnmes. Among his nnmerons other works were several on the statutes of various orders of knighthood, for which in 1831 he was made a knight of the Hanoverian Guelphic Order, and in 1832 chancellor of the Ionian Order of St. Michael and St. George. After a life of indefatigahle indnstry, spent in prodncing works nearly every one of which has great historical or professional merit, he died at Cape Cnré, near Boulogne, on Angust 3, 1848.

NICOPOLI, NIKOPOL, in Turkish *Tchingani-Kalé*, the ancient *Nicopolis ad Istrum*, a city in Bnlgaria, in Enropean Tnrkey, and the capital of a pashalic, is situated on the right hank of the Danube, 80 miles S.W. from Bukharest, 280 miles N.W. from Constantinople, and has ahout 10,000 inhabitants. The Osma on the Bulgarian side, and the Aluta on the Wallachian, join the Danube jnst above the town. The city, which occupies one of the finest sites in the world, consists of two parts. The fortress and Mnssulman town, crowned by many shining minarets, stand on the summit of a lofty limestone cliff above the Danuhe, several hundred feet high, and snrrounded hy a ravine. It is a place however of little real importance as a fortress, for it is commanded hy heights aronnd it. On the opposite or eastern slope the houses of Bulgarians, Wallachs, and Jews rise in white clusters one above another like an amphitheatre. The Turkish town is defended on every side hy batteries and hy a stout parapetted rampart, for the protection of infantry; it is further defended by a castle or citadel. There are some large well-built houses, several mosqnes and baths, but in general the town is ill built. The neighbonrhood of Nicopoli, especially on the eastern side, towards Sistova, is very heautiful; much of the ground about the town is laid out in gardens. Nicopoli gives title to a Greek archhishop and a Catholic bishop. Its situation on the Dannhe makes it a place of some trade.

Nicopoli was founded hy Trajan. Several patches of the ancient walls still remain. The snltan, Bajazet I., at the head of the Janissaries, defeated the Hungarians, commanded by their king, Sigismnnd, and aided by the choicest troops in Europe, under the walls of Nicopoli, Sept. 28, 1396. Sigismund had besieged the town for six days hefore the arrival of the Tnrks. The town has often suffered from the Russians.

NIDULARIACEÆ, a sub-order of Plants helonging to the order *Gasteromycetes*, the alliance *Fungales*, and the class *Thallogens*. It inclndes the genera *Nidularia*, *Cyathus*, *Crucibulum*, *Sphærobolus*, *Thelebolus*, and *Atractobolus*.

NINEVEH. [NINEVEH, *S.* 1.] Since M. Botta's first discoveries were made known to Enrope still greater additions to onr knowledge of Nineveh have been made hy Dr. Layard, who spent mnch time in making excavations in the great inclosure near the Tigris, before mentioned. Here, in the Mound of Nimroud, he discovered the ancient palace of the great Assyrian monarchs; brought to light those colossal hnman-headed bulls, the kings, warriors, priests, and winged messengers, which form subjects of astonishment to visitors of the British Mnseum; and gave to learned eyes to read from long cuneiform inscriptions the pompous bnt interesting catalogue of Assyrian triumphs in war or in architecture. In a word, the discoveries of Dr. Layard have shed light npon one of the darkest periods of history, and laid bare before ns the life, arts, and manners of a people of whom previously little more was known than the name. Colonel Rawlinson, Dr. Edward Hincks, and other distinguished British and Continental scholars have made great progress in interpreting the cuneiform inscriptions.

NIOBIUM. [CHEMISTRY, *S.* 1.]

NISI PRIUS. The *nisi prius* clause which gave rise to the use of this phrase in reference to the various matters mentioned nnder NISI PRIUS, p. 241 no longer exists, the writ of *venire facias* which was formerly issued in every case having been aholished by the Common Law Procedure Act 1852. That statute has substituted for the ancient jnry process a precept to be directed by the judges to the sheriff previous to each assize, commanding him generally to snmmon a sufficient number of jurors for the assizes, effecting in this way a considerable saving to the plaintiff.

NISSA, or NISCH, a town in European Turkey, the residence of a pasha, is situated in a fine open plain on the Nissava, a feeder of the Morava, near the frontier of Servia, 60 miles S.S.W. from Widden, and contains about 10,000 inhâbitants (4000 Mohammedans and 6000 Christians). Nissa occupies the site of Naïssos, the hirthplace of Constantine the Great; hnt nothing remains of its ancient glory. The town is modern, and by no means remarkable for its heauty. The principal huilding is the Konak, or palace of the pasha. The defensive works round the Turkish quarter on the right hank of the river, consist of well-built ramparts of great extent, with wattled parapets and a dry ditch. The hazaar on the left bank of the Nissava is surronnded hy a trench and palisades. The Christian qnarter, which is the largest part of the town, lies beyond the hazaar, and is open to the plain. Nissa is now the chief town of the pashalic of Sophia; it is called Nisch by the Tnrks. It is the residence of a Greek hishop, and has famous thermal springs. As it is the key to military communications hetween Thrace, Bulgaria, and Servia, the fortifications of the town are mounted with a considerahle numher of guns of large calibre, and in good order. The plain of Nissa lying between wooded slopes of the Tesovitch and the little Balkan, two ramifications of the Hæmus, is one of the most beautiful, fertile, and well-tilled districts in Bnlgaria. The town was taken hy the Turks nnder the Sultan Amurath I. in 1389, on the march to the battle of Kossova. A couple of miles above Nissa on the road to Sophia, the site of an action hetween the Turks and Serhs in the same year is marked by a tower of skulls, which is more terrihle in name than in reality. It was constructed of stone and lime, hnt externally heads were imbedded in the mortar. Very few skulls now remain, the Christians having in the course of time removed almost all of them for the purpose of interment, hnt their places are marked by rows of round holes. The tower is 10 feet square, 15 feet high, covered with a red-tiled roof, and has neither door nor window in it. The interior is said to he a favourite retreat of snakes and lizards. The Anstrians took Nissa in 1737.

NOCTILUCA, a genns of Animals nsually referred to the class *Acalephæ*. [ACALEPHÆ.] One species only of this genus has heen described *N. miliaris*. It occnrs occasionally in prodigions nnmbers aronnd the coasts of England, and is the most frequent canse in this part of the world of the phosphorescence of the ocean. It was first discovered hy M. Snriray in 1810.

According to M. Suriray the *Noctiluca* is a spherical gelatinons mass, provided with a long filiform tentacle or appendage, presenting a mouth, an œsophagus, one or many stomachs and ramified ovaries, and thns possessing a certain complexity of organisation. De Blainville confirmed Suriray's acconnt, and placed *Noctiluca*, without donbt most erroneonsly, among the *Diphydæ*. On the other hand, Van Beneden Verhaeghe and Doyère, denying the relation of *Noctiluca* with the *Acalephæ*—and conceiving its organisation to be of a mnch more elementary character—relegated it to the *Rhizopoda*.

To this doctrine M. de Quatrefages also attaches the weight of his authority in his valnahle essay 'Observations snr les Noctiluques,' published in the 'Annales des Sciences Nat.' for 1850. M. de Quatrefages does not admit the existence of any true month or intestinal canal, and considers that the so-called stomachs are nothing but 'vacuoles' similar to those observed in the *Rhizopoda* and *Infusoria*.

Krohn was the first to describe the long cilium which proceeds from the month of *Noctiluca*. Mr. Huxley has recently described this animal in the 'Quarterly Journal of Microscopical Science.' (Vol. iii.) He says—

"*Noctiluca miliaris* may he hest described as a gelatinous transparent hody, ahout 160th of an inch in diameter, and having very nearly the form of a peach—that is to say, one surface is a little excavated, and a groove or depression runs from one side of the excavation half way to the other pole (échancrure, Qnatrefages; Franenbusenähnliche Einbucht, Krohn). Where the stalk of the peach might be, a filiform tentacle, equal in length to about the diameter of the body, depends from it, and exhibits slow wavy motions when the creatnre is in fnll activity. I have even seen a *Noctiluca* appear to pnsh repeatedly against ohstacles with his tentacle.

"The body is composed of a structureless and somewhat dense external membrane, which is continued on to the tentacle. Beneath this is a layer of grannles, or rather a gelatinous membrane, through whose suhstance minute grannles are scattered without any very definite arrangement. From hence arises a network of very delicate fibrils, whose meshes are not more than 1-3000th of an inch in diameter, and these gradually pass internally—the reticulation becoming more and more open—into coarser fihres, which take a convergent direction towards the stomach and nucleus. All these fihres and fibrils are covered with minnte granules, which are usually larger towards the centre."

After describing minutely the structure of this creature, Mr. Huxley concludes—

"Not only does all I have observed lead me to believe that *Noctiluca* has a definite alimentary cavity, but I am inclined to think that this cavity has an excretory aperture distinct from the mouth. The funnel-shaped depression in the post-oral area in fact always appeared, when I could obtain a favourable view, to be connected with a special process of the stomach. On one occasion I observed the sides of this process to be surrounded by fusiform transversely striated fibres or folds; I could not determine which.

"Krohn states that he repeatedly saw the egesta voided 'in the neighbourhood of the groove of the body,' but he could not determine at what exact point, and he inclines to think it must have taken place through the mouth.

"I am equally unable to bring forward direct evidence on this point, and my belief in the existence of a distinct anus is founded simply on the structural appearances.

"In front of and above the gastric cavity is the nucleus, described by Verhaeghe and Krohn. This is a strongly refracting oval body of about 1-460th of an inch in length, which, by the action of acetic acid, assumes the appearance of a hollow vesicle. The anterior radiating fibres pass from it; the posterior from the alimentary canal.

"Quatrefages and Krohn consider that a process of fissiparous multiplication takes place in *Noctiluca;* both of these observers having found double individuals, though very rarely. According to the latter writer, division of the body is preceded by that of the nucleus. I have not had the good fortune to meet with any of these forms, and the only indication of a possible reproductive apparatus which I have seen consisted of a number of granular vesicular bodies, of about 1-2000th of an inch in diameter, scattered over the surface of the anterior and inferior part of the body.

"Such is what repeated examinations lead me to believe is the structure of *Noctiluca;* but if the preceding account be correct, it is obvious that the animal is no Rhizopod, but must be promoted from the lowest ranks of the *Protozoa* to the highest.

"The existence of a dental armature, and of a distinct anal aperture, are structural peculiarities which greatly increase the affinity to such forms. as *Colpoda* and *Paramæcium,* indicated by Krohn. *Noctiluca* might be regarded as a gigantic Infusorium with the grooved body of *Colpoda,* the long process of *Trachelius,* and the dental armature of *Nassula* united in one animal.

"On the other hand, the general absence of cilia over the body, and the wide differences in detail, would require the constitution of at least a distinct family for this singular creature."

In the same volume of the 'Microscopical Journal' is an account of this creature by Dr. Woodham Webb, of Lowestoft.

NOCTUA, a genus of Insects belonging to the Nocturnal *Lepidoptera,* to which the Red Under-Wing Moths belong.

NOLANACEÆ, a natural order of Plants, having erect or prostrate stems; alternate leaves without stipules. Flowers usually showy; calyx 5-parted, valvate in æstivation; corolla monopetalous, with a plaited æstivation usually thickened in the tube; stamens 5, equal, inserted into the tube, alternate with the segments of the corolla; anthers oblong, 2-celled, bursting longitudinally; pistil composed of several carpels, either distinct with a single style, or partially combined into several sets, with a single style seated on a succulent disc; stigma somewhat capitate. Fruit inclosed in the permanent calyx, constructed like the pistil; pericarp woody, often a little succulent: seeds ascending, solitary; embryo curved with either straight or double cotyledons in the midst of a small quantity of albumen; radicle next the hilum. This little order is remarkable for the various modes in which its carpels are disposed without ever being consolidated. In one genus there are but 5, and they are distinct; in another there are 20 combined in fours, in a third the combination is irregular though the number remains 20, and in others they are all wholly distinct. The species are all South American, and chiefly from Chili. Their uses are unknown. There are 6 genera and 35 species.

NONSUIT. The statute establishing the County Courts, 9 & 10 Vict., c. 95, has established one exception to the general rule that a plaintiff cannot be nonsuited against his will, by expressly authorising the judge to enter a judgment of nonsuit, an enactment for which none of the commentators on the Act have attempted to assign any reason.

The practice of giving judgment in the Supreme Courts, *as in case of a nonsuit,* has ceased since the passing of the Common Law Procedure Act, 1852, which provided a simple and more rational method of putting an end to the action. (See Kerr's 'Action at Law,' London, 1857.)

It may be added here that the Crown, being theoretically present in all our courts of justice, cannot be nonsuited; but the Attorney-General, or his representative, may always enter a *nolle prosequi,* which is in effect the same thing.

NORTH AUSTRALIA is at present the designation applied to all that part of Australia, comprising considerably more than one-half of the island, which lies north of the parallel of 26° S. lat. This parallel forms the northern boundary-line of the colonies of New South Wales and South Australia, that of Western Australia remaining unsettled. Coburg Peninsula projects west-north-west from the mainland, between Mount Norris Bay on the north-east and Van Diemen's Gulf on the south, and extends in that direction nearly 60 miles. The greatest breadth of the peninsula is 15 miles, and its narrowest part, where it is joined to the mainland by a neck of land of 5 miles in length, is 2½ miles. On the north side of Coburg Peninsula is the deep inlet named Port Essington, which lies between 11° 6′ and 11° 55′ S. lat., 132° 5′ and 132° 18′ E. long. The inlet, at its entrance, between Point Smith on the east and Vashon Head on the west, is 7 miles wide, and extends south by east about 18 miles; its average breadth is 5 miles. The depth of water varies between 5 and 12 fathoms, and at the southern end it forms three spacious harbours, each of which extends inwards 3 miles, with a width of about two miles; the depth of water is 5 fathoms, with a bottom of stiff mud and sand. These harbours are sheltered from every wind, and afford excellent and secure anchorage. The port forms one of the finest natural harbours in the world; it may be entered with safety both by night and day. Being within the range of the regular monsoon it is accessible to the Malay and Bugis trading proas, and to the junks from China.

The soil of the peninsula is in general indifferent, but in many places it is good, principally on the low flats and hollows, and near tracts which are swampy in wet weather. The vegetation is luxuriant, but suffers much during the dry season. The north-west monsoon, which brings the rainy season, begins about November. The rain during this monsoon falls in torrents, but seldom continues above two or three hours at a time. The general range of the thermometer at this season is from 80° to 95° Fahr. in the shade. The termination of the monsoon is indicated by squalls, and usually a tempest in the early part of April. In May the thermometer ranges between 75° and 95°, the midday heat being 89°. The average heat of the whole year is 83°, or about that of the equator.

With the expectation that, if there were an establishment on the north coast of Australia, it would be resorted to by the traders of the eastern portion of the Indian Archipelago for the sale of their produce and the purchase of European and Indian commodities, a settlement was made in 1824 in Apsley Strait, and called Fort Dundas, and another in 1827 on the Coburg Peninsula, and called Fort Wellington, but both settlements were abandoned in 1828. In 1838 another attempt was made, and the town of Victoria was founded on the western shores of Port Essington. In 1846 the population was stated to be about 60. The Malays did not settle there, as was expected: the climate is unsuitable to Europeans, and the settlement has been abandoned.

The coasts, inlets, and islands of North Australia have been surveyed and named, but of the interior hardly anything is yet known. Melville Island, on the northern coast, between 11° and 12° S. lat., 130° 20′ and 131° 34′ E. long., is one of the largest of the islands. The area is about 1800 square miles. It is separated from Bathurst Island, which lies west of it, by Apsley Strait, which is from 2 to 4 miles wide and 46 miles long. From Coburg Peninsula it is separated by Dundas Strait, which is 15 miles wide. The natives lead a wandering life, living in the dry season on kangaroos and other marsupial animals, and during the wet season on fish, turtles, crabs, and other shell-fish. Their vegetables are the cabbage-palm and the sago-palm.

NORTH LEACH. [GLOUCESTERSHIRE.]

NORTH-WEST PASSAGE. In the article NORTH-WEST PASSAGE an account is given of the series of voyages undertaken for the discovery of a passage westwards from the Atlantic Ocean to the Pacific, through the seas which surround the North Pole, and the narrative is there brought down to the year 1838. We now add an account of the subsequent voyages of exploration, and also of the expeditions sent out in search of Sir John Franklin and his associates.

In the year 1845 the British government sent out another expedition to the Arctic Seas for the purpose of discovery and survey, consisting of the Erebus and Terror, under the command of Sir John Franklin. They sailed from the Thames on the 23rd of May, and on the 26th of July were spoken by the Prince of Wales whaler at the entrance of Lancaster Sound. In consequence of the ships not having been afterwards seen or heard of, a series of searching expeditions were successively fitted out and sent to the Arctic Seas, all of which failed in the main object of finding the missing ships or their unfortunate crews, but one of which discovered the long-sought secret of a North-West Passage.

In 1848 the Enterprise and Investigator, under the command of Sir James Ross, were sent out, and reached Lancaster Sound on the 28th of August. They were not able to get farther west than Leopold Harbour, near the entrance of Prince Regent's Inlet, 73° 5′ N. lat., 90° 12′ W. long., where they wintered. After the ships were liberated from the ice, they were swept eastward by a mass of drift ice into Lancaster Sound, and Sir James Ross brought his ships back to England early in November 1849. In 1848 Sir John Richardson and Mr. Rae made a voyage in boats from the mouth of the Mackenzie River eastward, but without success.

Another searching expedition was fitted out by the British government at the end of 1849. Captain Collinson was appointed to the command of the Enterprise, and Captain M'Clure to that of the Investigator. The two ships left the Thames January 10, 1850, and sailed in company round Cape Horn. Captain M'Clure reached Point Barrow, at the north-eastern extremity of Behring's Strait, August 5, 1850, and then bore to the east, just keeping clear of the American coast. Captain Collinson having failed to force his way through the pack-ice of Behring's Strait, sailed for Hong-Kong, where he wintered. Captain M'Clure reached Cape Parry on the 6th of September. From this point high land was observed to the east-north-east, and named Baring Island, and two days afterwards, still farther to the east-north-east, more land was observed, and named Prince Albert Land. This land is continuous with Wollaston Land and Victoria Land, and extends northward to 73° 21′ N. lat. The Investigator was then navigated northward through a channel which separates Baring Island from Prince Albert Land, and which Captain M'Clure named Prince of Wales' Strait. In sailing up this strait the Investigator several times narrowly escaped destruction, but on the 8th of October was firmly frozen in near the northern extremity of the strait, and remained there during the winter. Parties were sent out to explore, by whom it was ascertained that Prince of Wales' Strait opens into Barrow Strait, and thus was made the first discovery of a North-West Passage.

On the 14th of July 1851 the Investigator was freed from the ice, when great exertions were made to pass out of Prince of Wales' Strait into Barrow Strait, but on the 10th of August, being then in 73° 14′ N. lat., 115° 32′ W. long., strong winds from the N.E. drove the masses of ice against the ship, and Captain M'Clure, thus baffled, resolved to sail southward back again down Prince of Wales' Strait. Having accomplished this, he sailed along the southern coast of Baring Island, and then northward along the western coast. At length, after incurring many risks and encountering difficulties which could only have been overcome by a rare combination of indomitable courage, admirable seamanship, and scientific resource, the Investigator, having rounded the whole island except a portion of the north shore, was got to the station which Captain M'Clure named Mercy Bay, September 24, 1851. This station is on the northern side of Baring Island, in 74° 6′ N. lat., 117° 54′ W. long., on the south side of Barrow Strait. Here then was the discovery of a second North-West Passage; and had there been open water to the east the whole voyage into Baffin's Bay might have been easily accomplished, but unfortunately the Investigator was frozen up in Mercy Bay on the very day when it was entered. The north side of Baring Island was ascertained to be the Banks' Land which Captain Parry saw from Melville Island in 1819.

Melville Island is distant about 60 miles N. from Mercy Bay, and in April 1852 Captain M'Clure sent a travelling party across the ice to it, who deposited a document there, giving an account of the proceedings of the expedition, and of the position of the Investigator. In April 1853, only a few days before Captain M'Clure had made arrangements for deserting his frozen-up ship, the document was discovered by Captain Kellett's officers, and Lieut. Pim, with a party of sailors carrying provisions, was sent from Melville Island to Mercy Bay. As nothing had been heard of the Investigator from the time of her rounding Barrow Point in August 1850, where Captain Kellett was then stationed with the Herald, and who made Captain M'Clure a signal of recall, till April 1853, when Captain Kellett sent his party to the relief of Captain M'Clure and his crew, the excitement of the meeting may be easily imagined. Captain M'Clure remained with his ship till the spring of 1854, when he and his crew were brought to England by the ships belonging to Sir Edward Belcher's expedition. The Investigator, as far as is known, still remains frozen-up in Mercy Bay.

Captain Collinson, after wintering at Hong Kong, passed through Behring's Strait in 1851, and followed very nearly the track of Captain M'Clure up Prince of Wales' Strait, whence he also was obliged to return. He wintered in 1851-2 in 71° 35′ N. lat., 117° 35′ W. long. The winter of 1852-3 was passed in Cambridge Bay, Wollaston Land, 69° N. lat., 105° 30′ W. long. Still struggling on, the winter of 1853-4 found the Enterprise in 70° 8′ N. lat., 145° 30′ W. long. On the 15th of July, 1854, the Enterprise was released from the ice, when Captain Collinson commenced his return voyage. He reached Point Barrow on the 9th of August, and Point Clarence on the 21st.

The other searching expeditions may be more briefly noticed. In 1850 Captain Kellett with the Herald and Plover reached 72° 51′ N. lat., 163° 48′ W. long. In the same year the Advance and Rescue, two small brigs, were fitted out at the expense of Mr. Grinnell, an American merchant, and placed under the command of Lieutenant de Haven. In August, 1850, Captain Ommanney and Captain Penny conducted travelling parties by order of Captain Austin, who commanded an expedition sent out by the British government. Captain Penny discovered that Sir John Franklin's expedition had passed the winter of 1845-6 at the mouth of the Wellington Channel, in a bay between Cape Riley and Beechey Island. Captain Penny also explored the Wellington Channel to a distance of 80 miles from the mouth, and discovered a strait bearing to the north-west, which he named Victoria Channel. Dr. Rae and Commander Pullen also conducted expeditions in 1850.

In May, 1851, the Prince Albert, a small vessel, was equipped at the expense of Lady Franklin, and placed under the command of Mr. William Kennedy. The Prince Albert passed through Lancaster Sound, and wintered in Batty Bay in Regent's Inlet, on the east side of North Somerset. In March, 1852, Mr. Kennedy, with M. Bellot, an enterprising young French naval officer, and six seamen, travelled southward along the east side of North Somerset till they reached Brentford Bay, which they ascertained to be a channel connecting Regent's Inlet with Victoria Strait, the northern part of which strait, called Peel Sound, enters Barrow Strait. They thus discovered a third North-West Passage, and proved that North Somerset is a large island, separated from Boothia Felix by the Brentford channel, which they named Bellot Strait, and found to be 15 miles long and 2 miles wide. They next travelled over the ice of Victoria Strait, then over Prince of Wales' Land due west as far as 100° W. long., then northward to the south-east angle of Ommanney Bay, then eastward to Browne's Bay in Peel Sound, whence, following the coast-line northward they arrived at Cape Walker. They reached the Prince Albert in Batty Bay, May 30th, after an absence of 96 days, and having travelled on foot and with sledges 1100 miles.

Captain Inglefield, in the small screw-steamer Isabel, sailed from the Thames July 6th, 1852. He proceeded along the east side of Baffin's Bay, and entering Whale Sound found that it contained two large openings to the north-eastward. He entered Smith's Sound at the head of Baffin's Bay, and on the 27th of August attained 78° 35′ N. lat., where he found himself in a great sea, only partially encumbered with ice. He was driven back by a violent gale, and afterwards entered Jones's Sound, which he penetrated to 84° W. long., the north coast there suddenly tending to the north-west, whilst the south shore continued its direction westward as far as the eye could reach. The Isabel returned to England in November, 1852.

A searching expedition under Sir Edward Belcher was sent out in 1852. He proceeded up the Wellington Channel, and wintered in 76° 52′ N. lat., 97° W. long. While here explorations with boats and sledges led to the discovery of various coasts and lands. The eastern side of Wellington Channel was named North Devon; the western side is Cornwallis Land, which is separated by a strait from Bathurst Land still farther west. A group of islands in 78° 10′ N. lat. was named Victoria Archipelago. On the 20th of May, 1853, Sir E. Belcher found the sea open in the latitude of Jones's Strait. His words are, "Polar Sea as far as the eye can reach." The gallant young Frenchman, Lieutenant Bellot, in attempting to convey the government despatches from Captain Inglefield to Sir E. Belcher, was blown from the top of a hummock of ice, and was drowned. Sir E. Belcher's ships were liberated from the ice July 14, 1853, and he returned to England the same year. In 1853-54, Dr. Kane, in the Advance, passed through Smith's Sound, and reached 78° 43′ N. lat.

In October, 1854, Dr. Rae returned suddenly to England from the vicinity of Boothia Felix, for the purpose of announcing to the British government that he had obtained some relics which had belonged to Sir John Franklin's companions. He stated that he had met with some Esquimaux in Pelly Bay, who were in possession of watches, silver spoons, telescopes, and other things, which had belonged to the officers and seamen of the Erebus and Terror. These he purchased, and brought with him to England; and he stated that the Esquimaux had informed him, that in the spring of 1850 about forty of the ships' crews were seen (but not by Dr. Rae's informants) near the north shore of King William's Land; that they were dragging a boat over the ice, looked worn and emaciated, and had purchased a seal of the natives. The two expeditions which it was stated the Admiralty intended to send out in November 1854 were not sent. Lady Franklin however, chiefly at her own expense, has sent out an expedition in the Fox, under the command of Captain M'Clintock, which sailed from Aberdeen on the 1st of July, 1857.

The result of all these searching expeditions—of which we have only noticed the most important—has been the discovery of three or four passages by which the Pacific Ocean may be entered from the Atlantic, or the Atlantic Ocean from the Pacific, namely, by the west coast of Baring Island, by the east coast of the same island, through Prince of Wales Strait, by Regent's Inlet through Bellot Strait into Victoria Strait, and probably also by Peel Strait into Victoria Strait. These passages, being all more or less encumbered with ice, may be of little or no commercial importance; but the long-sought North-West Passage has been discovered, many extensive lines of coast have also been traced, and large islands and countries have been found and partly examined. Besides the geographical discoveries which have been incidentally noticed in the course of this narrative, it has been ascertained, by the explorations of Dease and Simpson, Dr. Rae, and Captain M'Clure, that Wollaston Land and Victoria Land are continuous, forming the south coast of the largest of all the islands of the Arctic Seas, the western boundary being Prince of Wales' Strait, the eastern boundary Victoria Strait with its continuation Peel Strait, and the northern boundary Barrow Strait. The northern coast of this large island is deeply indented near the eastern end by Ommanney Bay and Osborne Bay, so named from the explorers. North Somerset is also, as has been stated, a large island, separated from Boothia Felix by Bellot Strait, previously called Brentford Bay; whilst Boothia Felix has been ascertained to be united to the American continent by an isthmus.

In many parts of these cold regions there is an extraordinary abundance of animal life, consisting of moose-deer, hares, ptarmigan, and other game. In 1851, Captain M'Clure says, "On the 1st of April we had 1000lbs. of venison hanging at the yard-arms;" and in 1853, he says, "A supply of game has been kept up during the winter, which has enabled us to issue a meal twice weekly." It seems also to have been ascertained, that north of Smith's Sound and the Wellington Channel there is an extensive Polar Sea, comparatively unencumbered with ice, which was seen by Dr. Kane as well as by Captain Inglefield.

NORTHERN SOVEREIGNTY. This name has been given, but perhaps not definitely, to an extensive tract of country which was annexed in 1848 to the British possessions in South Africa. It includes the whole of the territory west of the Drachenberg Mountains, between the two great branches of the Orange River, the Ky Gareep and the Nu Gareep, comprising a triangular area of about 50,000 square miles.

The Drachenberg Mountains, called also the Quathlamba Mountains, run parallel with the eastern coast of South Africa, at a distance varying from 60 to 90 miles from the shore. They rise to a height of from 6000 to 8000 feet, with towering peaks and rocky ridges, interrupted only by ravines and chasms, and thus form a barrier almost impassable between Kaffraria and Natal on the east, and the Northern Sovereignty on the west. A secondary range, called by the natives Malati, or the Peaks, runs parallel to the principal chain, at no great distance farther inland; and offsets, called the Wittebergen and Sneuwbergen, extend westward from the Drachenberg range, and close in the Northern Sovereignty on the south.

The country immediately west of the mountain ranges is from 5000 to 6000 feet above the level of the sea, and consists of a series of wide plateaus, which, sloping gradually downwards towards the lower course of the Vaal River, terminate in plains of vast extent, sometimes containing numerous isolated and rocky hills, but generally quite flat and without trees. These vast wastes are for the most part without a single human inhabitant, but afford abundant means of subsistence to countless herds of antelopes, quaggas, and other wild animals. All the rivers fall ultimately either into the Ky Gareep or the Nu Gareep. The Ky Gareep or Vaal River, rises between 26° and 27° S. lat., 29° and 30° E. long., about 200 miles W. from Delagoa Bay, in an interior range of mountains bounding the great plains of the north, and flows west, south, and south-west till it meets the Nu Gareep. The Nu Gareep, or Cradock River, rises in the Drachenberg Mountains, about 29° S. lat., 30° E. long. It flows south-west, west, and afterwards north-west, till it joins the Ky Gareep. Its principal affluent from the north is the Caledon; from the south it receives the Stormberg River, the Oorlogs, the Zeekoe River, and others of less importance.

This portion of the continent, being remote from the sea-coast, receives its rain in thunder-storms, chiefly during the summer months, of which December and January are the hottest; and there being no rain during the rest of the year, the climate and soil are then characterised by great dryness, though copious dews fall at night. The smaller rivers are dried up, and the ponds and lagoons are converted into swamps.

The White-Faced Antelope (*Antilope albifrons*), the Spring-Bok (*A. euchore*), the Gnu (*A. Gnu*), and the Quagga (*Equus Quagga*) seem to be in the greatest abundance. They are often seen in countless herds covering an immense extent of the plains, mixed with other species of the antelope, which are less numerous, and with buffaloes. Hyænas are abundant. Lions are very common. The hippopotamus is very common in the larger rivers. Ostriches appear on the great plains in considerable numbers. Timber grows on the slopes of the mountains, but not in the plains. There are salt-lagoons and salt-marshes, and some of the plains are covered with an incrustation of salt.

The white population is estimated to be about 5000, who are chiefly the residue of the Dutch farmers who, in 1836 and following years, emigrated from the Cape Colony, and are settled in villages and in small groups near the rivers. The native population are supposed to amount to about 150,000, who mostly inhabit the Malati Mountains. The Bushmen live among the isolated hills of the interior. The Griquas, who are a mixed breed, arising from the intercourse of Europeans with the natives, are in considerable numbers. They are mostly settled along the banks of the Nu Gareep and of the Orange rivers.

The colony has been distributed into four districts—Bloem Fontein, Caledon River, Winburg, and Vaal River. The principal town is *Bloem Fontein*, situated in 29° 8′ S. lat., 26° E. long., on the high road from the Cape Colony to Natal. It is about 380 miles N. from Graham's Town. It contains about 1000 inhabitants, has an Episcopal church, a Wesleyan Methodist chapel, and barracks. Smithfield, Winburgh, and one or two other villages, are inconsiderable places. There are three or four mission-stations belonging to the British, French, and Prussians.

The country appears to be well adapted for sheep pasturage and the production of wool. The climate seems to have a favourable influence on the fineness of the fleece. Small quantities of gold have been found in the neighbourhood of Smithfield.

When the Dutch inhabitants of the Cape Colony emigrated from it in 1836 and following years, they settled themselves at first in various parts of the territory which is now named the Northern Sovereignty. In 1838 a party of them went to Natal, where they were treacherously murdered by the warriors of the chief Dingaan. [NATAL, S. 2.] When the Dutch, who had conquered the natives and declared a republic, were obliged in their turn to submit to the English in 1842, the greater part of them fled into the Northern Sovereignty, where they founded the village called Winburg, and proclaimed a new Dutch republic. Little notice was taken of their proceedings till they began to expel from their farms the Dutch farmers who continued to acknowledge the British supremacy, and in 1845, under their leader Pretorius, prepared a large expedition to attack Adam Kok, a Griqua chief in alliance with the British. The chief applied to the colonial government, and two regiments were immediately sent to his assistance, who repulsed the revolutionary Dutch boers. On the 1st of February 1848, Sir Harry Smith, with the assent of the well-affected boers, erected the whole of the territory inclosed by the Ky Gareep and the Nu Gareep into a British colony. This led to another contest, in which Sir Harry Smith defeated Pretorius and his adherents on the 29th of August, 1848. Pretorius fled beyond the Vaal River, and the majority of the boers laid down their arms and submitted to the British government.

NORWOOD. [SURREY.]

NOSE, one of the external apertures of the respiratory system and the organ for the sense of smell. The portion of the nose by which odours are perceived, lies deep back in the cavity to which the external apertures of the nostrils lead; the portion which is prominent upon the face serves merely as the apparatus for inhaling the air which is impregnated with the odour. The most essential parts of the organ are the olfactory nerves, which come off from the olfactory bulbs of the brain [BRAIN], and passing through numerous holes in the ethmoid bone, which is situated between the orbits and above and behind the nostrils, ramify on the extended surfaces of that bone and the turbinated bones which form on each side the chambers of the nose. The sensitive terminations of the nerves are placed on the surface of a delicate and very vascular membrane which lines the whole cavity of the nose, and which is constantly kept moist by the secretion of a small quantity of mucus, in which the odoriferous particles are caught and for a time retained.

The sense of smell varies considerably, both in degree and in kind, in different animals. It is evidently possessed by insects and many others of the lower animals, but the organs by which they exercise it are unknown. In the higher animals its degree of acuteness is in general marked by the extent of surface of the ethmoid and turbinated bones, over which the olfactory nerves are distributed. In man this surface is proportionally smaller than in other animals, in most of which, besides occupying the greater part of the interior of the face, it is increased by peculiar branchings and convolutions of the thin layers of the bones. Each species has also a sense of smell in some degree peculiar to itself; thus herbivorous animals, though possessing the most delicate power of discerning the differences of vegetable odours, have no evident faculty of discriminating those of most animal substances; while the carnivora, on the other hand, can scarcely distinguish any others than the last. Each species has a fine sensibility for those substances which are of the greatest importance to its own existence, and thus obtains at once a knowledge of their presence in places concealed from all the other senses. Man possesses the sense of smell for a very large number of substances, but not in a very acute degree for any of them. The difference appears the greater between him and other animals in consequence of the neglect of the exercise of this sense which is common (except for particular purposes) in civilised society; but the American Indians and some of the northern Asiatic tribes, by their constant practice in hunting, are said to have acquired a power of scent scarcely inferior to that of the dog.

The olfactory nerve is appropriated exclusively to the sense of smell, and is incapable of perceiving pain or any other sensation. Of the peculiarities by which in different animals it is capable of perceiving only certain odours, we know no more than of the nature of those odours themselves, of whose existence we have no other evidence than that of the sense which they affect.

The sense of smell serves as an adjunct to that of taste, and is subservient in most instances to the same purpose, of providing proper and avoiding injurious food for the sustenance of the body. By it many animals seek out their food, and all select from that which they obtain; and much of that compound sensation which we regard as taste is really due to the smell, as for instance the sensation of the flavour of aromatic substances, which is completely lost by closing the nostrils while we are eating them.

For the full perception of odours it is necessary that the particles charged with them should be drawn with some force into the nose, and we may stand for some time in a very strongly smelling atmosphere without perceiving it if we breathe only through the mouth. The most acute sensation is obtained by the sudden inhalation of a large quantity, or by a succession of short and quick inspirations.

NOTONECTA, a genus of Insects belonging to the family *Hydrocorisæ*, of the order *Hemiptera*. *N. glauca*, the Water-Boatman, is one of our commonest insects. It is about half an inch long, and swims upon its back in order the better to seize its prey.

NUNEATON. [WARWICKSHIRE.]

NUSSIERITE. [MINERALOGY, S. 1.]

NUTRIMENT, NUTRITION. [FOOD, S. 2; TISSUES, ORGANIC, S. 1.]

NYCTAGINACEÆ, a small natural order of Hypogynous Exogenous Plants, belonging to Lindley's Chenopodal Alliance. They have a tubular often coloured calyx, which separates from its base, the latter becoming a hard spurious pericarp. The species are annuals or perennials often with fleshy roots, or shrubs or trees usually articulated at the tumid nodes. *Mirabilis dichotoma*, the Marvel of Peru of our gardens, may be taken as the type of the order. *M. Jalapa* was at one time supposed to be the plant yielding true jalap. This however is a mistake. [CONVOLVULACEÆ.] The roots of the plants of this order are generally purgative. They are natives of the warmer parts of the world in either hemisphere. They are tropical or subtropical. The order is related to *Polygonaceæ*, *Amarantaceæ*, and *Cannabinaceæ*. It contains 14 genera and about 100 species.

O

OAKINGHAM, or **WOKINGHAM**. [BERKSHIRE.]

OAT. [AVENA.]

OATH. The privilege long enjoyed by Quakers, Moravians, and Separatists, of giving their evidence upon solemn declaration, is by the Common Law Procedure Act, 1854, extended to all witnesses, who conscientiously object to be sworn. A wilfully false declaration in all these cases involves the party, by the provision of the statute, in the same penalty as wilful perjury.

OCCUPATIONS OF THE PEOPLE. The importance of obtaining as specific and complete an account as practicable of the pursuits and employments of the inhabitants of this country has long been recognised; and in each decennial census of the present century it has been attempted,—with constantly increasing efforts after greater fullness and precision,—to ascertain the number and proportion of the persons engaged in agriculture, commerce, the various trades, manufactures, and professions. In the enumerations of 1811 and 1821, inquiries were instituted as to how many *families* were employed in, or maintained by, agriculture; how many by trade or manufactures; and how many which could not be brought under either of these designations. The answers to these inquiries were given with tolerable fullness. In 1831, it was resolved to ascertain, so far as could be done, the occupation of every male adult twenty years of age or upwards. On that occasion a form, containing a list of one hundred different trades and handicrafts, being those most commonly carried on, was furnished to the overseers in each parish or place required to make a separate return, to be filled up with the number of males aged twenty and upwards; and the overseers were authorised to add to the list such additional trades as were not included in the printed form. But many anomalies and imperfections arose out of this plan; and it was therefore resolved, in 1841, that the enumerator, instead of using a prepared list of one hundred, or any other definite number of trades, should insert each man's description of himself opposite his name. This led to some curious results. In the more important manufactures, the subdivisions of labour entered in the schedules were so minute, that there were no less than 1225 distinct heads of employment (some of them, it is true, identical) in the cotton manufactures of Lancashire; in 1831 the enumerators had entered only 598 for the whole of the country. In like manner, the London occupations, given as 420 in 1831, were 757 in 1841; and the occupations of Great Britain became similarly increased from 598 to 877.

In 1851, to use the words of the Registrar-General, to whom the management of the census of that year was entrusted, "it was considered important to extend the inquiry, so as to show, as nearly as was practicable, the number of men, women, and children in every trade and profession;" and it was further held to be desirable, notwithstanding the great additional labour entailed in abstracting and tabulating the results, "not only to take out the number of persons of each sex in each occupation, but the numbers at each quinquennial period of age: for without this information the relative salubrity of the professions, and a great variety of important questions, cannot be determined." The results of the inquiries instituted are embodied in a bulky but very able report, drawn up by the Registrar-General, which examines the subject as a whole and in detail from various points of view, and in numerous elaborate tables presents the results as digested after a vast amount of labour and consideration.

We proceed to exhibit some of the results obtained, selecting such as will illustrate various industrial phases of British population.

In looking at the tables with regard to the more general results, there are many interesting particulars which become developed. Here is one. The total population for 1851, in Great Britain and the small adjacent islands, is set down at 20,959,477, of whom 10,223,558 are males, and 10,735,919 females. One-half of this total is 10,479,738. Now this is almost exactly identical with the number (10,418,989) of those set down under some domestic appellation, as wife, widow, daughter, grand-daughter, sister, niece, son, grandson, brother, nephew, child under tuition at home, child under tuition at school; that is, persons to whom no occupation whatever is attributed, but who are regarded as dependent on the head of the family for support. Regarded in this light, therefore, just one-half of the population have nothing and do nothing to earn a living; they are the home-members of a family; they may assist in domestic labours, but they do not work at money-getting employments. There are then left half the population, who either possess wealth already accumulated, or exercise their hands and heads in the acquisition of wealth; of this half, one moiety can, with a near approach to correctness, be divided into five equal parts, thus—

About 1,000,000 domestic servants.
" 1,000,000 employed in preparing the materials for dress.
" 1,000,000 employed in making dress.
" 1,000,000 ordinary agricultural labourers (males).
" 1,000,000 other persons, male and female, living by farm and field operations.

Most of these numbers are slightly over the million. If we suppose the two millions of farmers, graziers, gardeners, and in-door and out-door farm servants of every kind, to be all employed in raising food (and this is not such a wide departure from the truth as to vitiate such general results as we have now in view) it brings us to this conclusion: of the total population, about 21,000,000, there are—

Of family dependents, having no definite occupation	= about one-half.
Of persons supplying dress, food, or domestic service	= about one quarter.
Of persons employed in all other occupations	= about one-quarter.

When the Commissioners came to prepare their vast tables of the distribution of occupations in the respective divisions, counties, districts, and towns, they had to determine how many different occupations should be given in each table. If the whole 1057 occupations, presently to be adverted to, for males had been tabulated for each and all of the topographical sections, the volumes would have been numerous and bulky beyond all endurance, the labour and expense enormously great, and the practical value very questionable. The list was therefore weeded. Several occupations were omitted which are only very limited in their topographical distribution, and all were omitted in which the total number of persons is very small. Different degrees of minuteness were adopted, according to the nature of the tables. Thus, one table, for the whole of Great Britain, gives all the 1057 occupations in alphabetical order, distinguishing the workers who are above and those who are below 20 years of age, but not distinguishing the sexes. Another table gives the same occupations in classified instead of alphabetical order, distinguishing the ages to still greater minuteness, and also distinguishing the sexes. Another table, going as low down in classification as sub-classes, shows in respect to these the ratio or percentage of males under 20, males over 20, females under 20, and females over 20: this is done with a view of exhibiting, in a broad and general way, the extent of female labour and of juvenile labour in Great Britain. Lastly, a fourth table, or rather group of tables, gives the occupations of the people in all the 13 divisions of Great Britain, in all the counties, in all the 623 Registration Districts, and in 89 of the principal towns.

We proceed now to give some idea of the nature of the classification adopted.

The primary division, it must be understood, is into 17 groups or classes of persons having definite occupations, and these are again divided into 91 sub-classes, rather more than five to a class on an average. Thus:—

Classes and Sub-Classes of Occupation.

I. *Persons engaged in the general or local government of the country.*
1. National government.
2. Local government.
3. East India government.

II. *Persons engaged in the defence of the country.*
1. Army.
2. Navy.

III. *Persons in the learned professions,*

1. Clergymen and ministers.
2. Lawyers.
3. Physicians and surgeons.
4. Church officers.
5. Law clerks, court officers.
6. Chemists and surgical instrument makers.

IV. *Persons engaged in literature, fine arts, and science.*
1. Authors.
2. Artists.
3. Scientific persons.
4. Teachers.

V. *Persons returned only as children, or relations and scholars.*
1. Son, nephew, &c.
2. Scholars.

VI. *Persons engaged in entertaining, clothing, and performing personal offices for man.*
1. In boarding and lodging.
2. In attendance.
3. In providing dress.

VII. *Persons who buy or sell, keep, let, or lend money, houses, or goods of various kinds.*

VIII. *Persons engaged in the conveyance of men, animals, goods, and messages.*
1. On railways.
2. On roads.
3. On canals.
4. On seas and rivers.
5. Warehousemen.
6. Messengers.

IX. *Persons possessing or working the land, and engaged in growing grain, fruits, grasses, animals, and other products.*
1. In fields and pastures.
2. In woods.
3. In gardens.

X. *Persons engaged about animals.*

XI. *Persons engaged in art and mechanical productions.*
1. In books.
2. In plays.
3. In music.
4. In pictures.
5. In carving and figures.
6. In shows and games.
7. In plans and designs.
8. In medals and dies.
9. In watches and philosophical instruments.
10. In arms.
11. In machines.
12. In carriages.
13. In harness.
14. In ships.
15. In horses.
16. In implements.
17. In chemicals.

XII. *Persons working and dealing in animal substances.*
1. Animal food.
2. Bones, horns, &c.
3. Skins.
4. Feathers and quills.
5. Hair and fur.
6. Wool.
7. Silk.

XIII. *Persons working and dealing in vegetable substances.*
1. Vegetable food.
2. Drinks and stimulants.
3. Gums and resins.
4. Timber.
5. Bark.
6. Wood.
7. Wood furniture.
8. Wood utensils.
9. Wood tools.
10. Cane, rush, straw.
11 Hemp.
12. Flax, cotton.
13. Paper.

XIV. *Persons working and dealing in minerals.*
1. Coal.
2. Stone and clay.
3. Earthenware.
4. Glass.
5. Salt.
6. Slates.
7. Precious stones.
8. Gold and silver.
9. Copper.
10. Tin.
11. Zinc.
12. Lead.
13. Mixed metals.
14. Iron and steel.

XV. *Labourers and others—branch of labour undefined.*
1. Labourers.
2. Other persons.

XVI. *Persons of rank or property, not returned under an office or occupation.*

XVII. *Persons supported by the community, and of no specified occupation.*
1. Living on charity and rates.
2. Prisoners.
3. Vagrants.

The above, it must be remembered, are the 91 sub-classes of *male* occupations. The sub-classes of *female* occupations are not quite so numerous, and differ a little (but only a little) in designations.

The 17 classes, or 91 sub-classes are further subdivided into no less than 1057 occupations or employments, giving an average of about twelve to each sub-class, or sixty-two to each class. These are occupations for males only; but there is a separate classification for females, amounting to 746 employments. These are, of course, in some cases identical with those of men, in other cases nearly alike but differently named, while in others they are wholly distinct and feminine in their character.

Many of the *classes* cannot be rightly understood until the sub-classes into which they are divided have been examined; and even then, there are two or three against which grave doubts might be urged, as to the principle whereon the aggregation has been determined. Classes 4, 6, and 11 are those here adverted to. This, however, is a matter on which opinions will inevitably clash; for, where offices and employments differ one from another by imperceptible gradations, and where each one may be regarded under many aspects, no one can determine which is *the* classification: we can only adopt *a* classification, convenient according to the views of him who makes it. The commissioners, for instance, made class 6 to comprise "people who are principally engaged in lodging, entertaining, attending, or providing articles of dress, so as to be brought much into personal contact with those whom they serve." This reads well, in so far as it provides a chain of connection among employments which relate especially to the *person;* but the sub-classes give it an unsatisfactory effect; for we should hardly expect inn-keepers, coffee-house keepers, eating-house keepers, lodging-house keepers, domestic servants, inn-servants, undertakers, dress-makers, shoe-makers, umbrella-makers, rag-gatherers, and washer-women, to be all included in one class, as they here are. Again: class 4 comprises "the poet, the historian, the painter, the sculptor, the musician, the architect, and the natural philosopher, as well as the professors and teachers of literature and science;" while class 11 comprises "those engaged in the higher class of mechanical and chemical arts; they are intimately connected with artists and men of science, from whom they frequently, either directly or indirectly, derive materials, direction, or inspiration; they multiply copies of original works." Now this analysis has evidently been much studied and elaborated by the commissioners; but it leads to strange results when worked out in detail; for we find the music-master in one class and the musician in another, the painter in one and the engraver in another, the architect in one and the surveyor in another; while publishers, printers, actors, musicians, engravers, carvers, modellers, showmen, civil engineers, pattern-designers, die-sinkers, watch-makers, gunsmiths, machinists, coach-makers, saddlers, shipwrights, builders, wheelwrights, dyers, scourers, calenderers, and chemical manufacturers, are all thrown together in one class. The showman, the civil engineer, the publisher, the dyer—here is an odd grouping!

Taking the 1057 occupations for males, just as they stand in the classified tables, the highest numbers are the following, comprising those exceeding 40,000 persons in each employment:—

Agricultural labourers	1,006,728
Labourers (undefined)	367,472
Farmers	275,676
Shoemakers	243,052
Farm servants, indoor	235,943
Cotton spinners and weavers	222,612
Coal miners	216,366
Carpenters	182,546
Tailors	135,028
Blacksmiths	112,184
Masons	101,391
Porters and messengers	97,642
Merchant seamen	89,206
Woollen spinners and weavers	86,649
Domestic servants	79,615
Gardeners	78,462
Grocers	68,242
Butchers	65,912
Plumbers, painters, and glaziers	62,421
Carmen and drivers	56,252
Bakers	55,663
Worsted spinners and weavers	51,863
Engineers and machinists	48,050
Silk spinners and weavers	45,169
Clerks (commercial)	43,741

Among females, of 20 years of age and upwards, the highest numbers placed opposite definite occupations are the following:—

Domestic servants (general)	401,950
Milliners	202,437
Cotton spinners and weavers	143,212
Washerwomen and manglers	136,582
Farm servants, in-door	67,538
" out-door	56,067

These numbers, however, must not be used for any inferential purpose, without taking others belonging to employments collaterally connected with them. Thus, the 401,950 *general* servants do not include about 200,000 others who enter themselves under the more specific designations of housekeeper, housemaid, cook, nurse, and inn servant; the 202,437 milliners are irrespective of 140,000 seamstresses and needlewomen of other kinds; and so in other cases. It must also be borne in mind, in respect both of the male and the female lists, that the highest numbers are attached to designations which are rather degrees of relationship than occupations. For instance, we find

Wives (not otherwise specified)	2,631,380
Children and relations at home, ditto	4,745,217
Children who attend school, ditto	2,752,737

Here we have at once more than a third of the entire population entered under three headings, excluding everything like a business designation.

As a summary of results relating to occupations generally, without regard to age, sex, or topographical distribution, it may be profitable to give the annexed table, containing the Commissioners' own enumeration of the number of persons employed in 108 avocations in Great Britain, comprising all those for or in respect of which the numbers exceed 10,000: mere domestic relationship, such as 'wife,' 'widow,' &c. is not here taken into account; all are 'occupations,' in the usual meaning of that word—male or female, adult or juvenile.

Occupations in Great Britain, and Number of Persons engaged in them (arranged in the order of the Numbers), in 1851:—

Occupations.	*Persons.*	*Occupations.*	*Persons.*
Agricultural labourer, farm-servant, shepherd	1,460,896	Horsekeeper, groom (not domestic), jockey	29,408
Domestic servant	1,038,791	Nail manufacture	28,533
Cotton, calico, manufacture, printing and dyeing	501,465	Iron miner	28,088
Labourer (branch undefined)	376,551	Printer	26,024
Farmer, grazier	306,767	Nurse (not domestic servant)	25,518
Boot and shoe maker	274,451	Shipwright, shipbuilder	25,201
Milliner, dressmaker	267,791	Stone quarrier	23,489
Coal-miner	219,015	Lodging-house keeper	23,089
Carpenter, joiner	182,696	Lead miner	22,530
Army and navy	*178,773	Copper miner	22,386
Tailor	152,672	Straw hat and bonnet maker	21,902
Washerwoman, mangler, laundry-keeper	146,091	Cooper	20,245
Woollen cloth manufacture	137,814	Watch and clock maker	19,159
Silk manufacture	114.570	Brewer	18,620
Blacksmith	112,776	Clergymen of Established Church	18,587
Worsted manufacture	104,061	Protestant Dissenting minister	9,644
Mason, pavior	101,442	Dock labourer, dock and harbour service	18,462
Messenger, porter, errand-boy	101,425	Police	18,348
Linen, flax manufacture	96,860	Plasterer	17,980
Seaman (merchant service) on shore or in British ports	89,206	Warehouse-man, -woman	17,861
Grocer	85,913	Saddler, harness maker	17,583
Gardener	80,946	Hatter, hat manufacture	16,975
Iron manufacture, moulder, founder	80,032	Coachman (not domestic servant), guard, postboy	16,836
Innkeeper, licensed victualler, beershop-keeper	75,721	Law Clerk	16,626
Seamstress, shirtmaker	73,068	Coachmaker	16,590
Bricklayer	67,989	Cow-keeper, milk-seller	16,526
Butcher, meat-salesman	67,691	Ropemaker	15,966
Hose (stocking) manufacture	65,499	Druggist	15,643
School-master, mistress	65,376	Surgeon, apothecary	15,163
Lace manufacture	63,660	Tin miner	15,050
Plumber, painter, glazier	62,808	Paper manufacture	14,501
Baker	62,472	Coalheaver, coal labourer	14,426
Carman, carrier, carter, drayman	56,981	Greengrocer, fruiterer	14,320
Charwoman	55,423	Muslin manufacture	14,098
Draper (linen and woollen)	49,184	Confectioner	13,865
Engine and machine maker	48,082	Tinman, tinker, tin plate worker	13,770
Commercial clerk	43,760	Staymaker	13,699
Cabinet-maker, upholsterer	40,897	Solicitor, attorney, writer to the signet	13,256
Teacher (various), governess	40,575	Dyer, scourer, calenderer	12,964
Fisher-man, -woman	38,294	Currier	12,920
Boat, barge, man, woman	37.683	Builder	12,818
Miller	37,268	Farm bailiff	12,805
Earthenware manufacture	36,512	Hair-dresser, wig-maker	12,173
Sawyer	35,443	Coal merchant, dealer	12,092
Railway labourer	34,306	Glass manufacture	12,005
Straw-plait manufacture	32,062	Carpet and rug manufacture	11,457
Brick maker, dealer	31,168	Goldsmith, silversmith	11,242
Government civil service	30,963	Brass founder, moulder, manufacture	11,230
Hawker, pedlar	30,553	Maltster	11,150
Wheelwright	30,244	Bookbinder	10,953
Glover	29,882	Railway officer, clerk, station master	10,948
Shopkeeper (branch undefined)	29,800	Road labourer	10,923
		Wine and spirit merchant	10,467
		Fishmonger	10,439
		Merchant	10,256
		Ribbon manufacture	10,074

Leaving these general results, which apply for the most part to the whole of Great Britain, and to the whole circle of occupations, we proceed to notice a few of the results having a somewhat more special character. One of these has relation to the employment of the many by the few, and another relates to farms, farmers, and farm-labourers.

One of the valuable results of the Census of 1851, is the determination, to a certain degree of correctness, of the relative positions of employers and employed; a classification of masters and men in each occupation. Many of the schedules sent by the Commissioners were imperfectly filled up; but the general result approximates on the whole pretty nearly to accuracy. We may solve many interesting questions by means of the tables thus produced. For instance, let the question be this—How many occupations are there in which some of the masters employ 350 hands or more? They are the following:—shoemakers, glovemakers, stocking-weavers, engine and machine makers, builders, carpenters, manufacturing chemists, tanners, woollen manufacturers, worsted manufacturers, flannel manufacturers, woollen dyers, silk manufacturers, ribbon manufacturers, fancy goods' manufacturers, shawl manufacturers, brewers, cotton manufacturers, lace manufacturers, paper makers, stationers, coal-merchants, coal-miners, contractors, earthenware manufacturers, glass manufacturers, silversmiths, tin plate workers, white metal workers, button makers, iron manufacturers. Let the question be,—Which occupations contain the greatest number of firms employing 350 or more persons each? We find, in answer, 113 cotton manufacturers, 21 woollen manufacturers, 13 silk manufacturers, 12 worsted manufacturers, 14 engine and machine makers, 7 earthenware manufacturers, 5 iron manufacturers, 5 builders. Let the question be,—How many masters employ bodies of men not less than 100 in number? The answer, slightly classified, comes out as follows:—

390	masters	employ	from 100 to 150	men each.
236	"	"	150 to 200	"
135	"	"	200 to 250	"
88	"	"	250 to 300	"
65	"	"	300 to 350	"
228	"	"	350 and upwards,,	
1142	masters	each employ	100 men or upwards.	

It is in Lancashire chiefly that the factories are situated in which the largest number of persons are employed. This might be expected, knowing, as we do, on how gigantic a scale the cotton-mills of that county are conducted. No less than 106 of the Lancashire mills employ *more* than 350 hands each; how much more, is not stated in detail. There are also 10 engineers or machine makers, each of whom has at least 350 work-people.

In London the number of work-people employed by the respective masters differs, of course, from that observable in country lists, since the preponderant trades themselves differ. Taking 100 as a minimum, it may be asked,—Which are the London trades comprising the greatest number of masters who employ 100 men or more each? We find that there are altogether 80 of such masters—a smaller number than might at first perhaps have been supposed. Of these, there are 22 builders, 6 engineers, 5 shoemakers, 5 printers, 4 painters and glaziers, 3 pianoforte manufacturers, 2 each of bookbinders, gunsmiths, masons, tanners, silk manufacturers, drapers, tobacco-manufacturers, stationers, silversmiths, iron-manufacturers, mineral-workers, and 1 each of hatters, tailors, omnibus-proprietors, coach-makers, carpenters, dyers, brewers, sugar-refiners, coopers, brickmakers, gas-fitters, and cutlers. But there are several items which are very questionable. For instance, among shipbuilders in the metropolis, there is not one entered with so many as 50 men in his employ; among distillers and rectifiers, not one with so many as 20;—evidently there are great omissions here. Again, when we find that there are only 2 vinegar makers, 2 dye manufacturers, 1 law-stationer, entered as employing any persons at all, it is still more manifest that many of these returns were incomplete. The explanation is doubtless to be found in the statement prefixed to the Tables: "Many employers—in some trades more than one half of the whole number—omitted to attend to this instruction [directing that the master is to be distinguished from journeyman, and that the number of persons in the trade in the employ of the master is always to be inserted]. The present return, therefore," it is added, "is very incomplete; but the facts are sufficiently numerous to enable just deductions to be drawn as to the number of hands employed by masters in particular trades, as carried on in London." This may be so generally, but the instances to which we have directed attention, are sufficient to show that great caution is necessary in drawing deductions, as in some cases they would certainly be by no means just ones.

The small tradesmen in the metropolis are, in many respects, the most important of all, on account of their large number. The small chamber-masters, or small shopkeepers who employ each not more than two journeymen, or two apprentices, or one journeyman and one apprentice, are surprisingly numerous, showing to how great a degree master-

* This is the Army and Navy of the United Kingdom, exclusive of the Indian Army and Navy.

ship is diffused in the metropolis. We give the following table of chief trades followed by

Masters who employ 1 or not more than 2 Journeymen or Apprentices.

Bakers	842	Carpenters	360
Tailors	460	Cabinet-makers	255
Butchers	384	Painters and glaziers	251
Shoemakers	368	Grocers	242

The table is to be understood thus: that in the above eight occupations there are 3162 masters in the metropolis, who employ either one or two persons each. Of those, still lower in the social scale, who claim mastership only over their own individual labour, the numbers run in a somewhat different order, beginning with a shoemaker (the 'cobbler who lives in a stall,' perhaps), and going thence to the tailor, the butcher, the baker, the grocer, the carpenter. But these numbers include also those masters who made no definite returns at all.

In respect of agricultural pursuits, the Commissioners sought to obtain a return of the number of farms, the size of the farms, and the number of persons engaged in them. The following is a convenient general outline of the result:—

Size of Farms.	Number of Farms.			
Acres.	Great Britain.	England and Wales.	Scotland.	Islands in British Seas.
Total	283,378	223,271	56,150	3,957
Under 100	190,573	142,358	44,469	3,746
100	52,912	45,752	7,009	151
200	20,603	18,401	2,166	36
300	9,031	8,061	961	9
400	4,063	3,585	471	7
500	2,248	1,971	272	5
600	2,816	2,372	442	2
1,000 and upwards.	1,132	771	360	1

Besides the above, there were 2558 farms of which the sizes were not stated in the returns; making 285,936 farms or farm-holdings altogether. It is found that large farms prevail most in the North, and in Norfolk and Suffolk. The average size of all the farms is 102 acres; and, taken in the aggregate, they occupy just about one-half of the territory of Great Britain. Two-thirds of the farms are less than 100 acres each in extent. About 9000 small farmers seem to have no labourers except the members of their own families; about 170 farmers employ more than 60 labourers each; while all the rest have in their service a number varying from 1 to 60.

Professional avocations, as distinguished from trading and manufacturing, present a few interesting facts, which may be put together in the following form:—

	Males.	Females.
Persons engaged in the general or local government of the country—		
Civil service	38,849	1,487
Local service	29,851	1,113
East India (in England)	3,774	...
Persons engaged in the defence of the country—		
*Army, with pensioners, &c. at home	70,718	...
Navy " "	25,796	...
Persons engaged in religious duties—		
Clergymen of national churches	18,587	...
†Other ministers	9,614	...
Subordinate officers	6,371	879
Persons engaged in law and justice—		
Judges	85	...
Barristers, advocates, &c.	3,111	...
Solicitors, attorneys, &c.	13,582	...
Law students	1,659	...
Law clerks, &c.	19,149	...
Persons engaged in the medical profession—		
Physicians	2,328	...
Surgeons and apothecaries	15,163	...
Chemists and druggists	15,333	...
Students and assistants	3,655	...
Miscellaneous	2,012	571

* But the total of the Queen's forces, at home and abroad, naval and military, effectives and non-effectives, was 262,570.

† It is necessary to bear in mind that many dissenting ministers are, in the Census returns, entered under the occupations which they follow during the week.

	Males.	Females.
Persons engaged in literature, the fine arts, and sciences—		
Authors, editors, &c.	2,949	118
Artists, architects, &c.	8,609	536
Scientific persons	496	22
Professors and teachers	34,150	71,957

As before noticed, there is more confusion between Class 4 and Class 11. In the list here given, although artists are included, engravers are not; teachers of singing are, but not singers; dramatists are, but not actors. In order, therefore, to make our enumeration somewhat more complete, we must bring in a few items from Class 11, still comprising them among "persons engaged in literature, fine arts, and sciences."

	Males.	Females.
Actors and actresses, theatre servants	1,485	785
Musicians and vocalists	6,081	798
Engravers	5,507	77
Carvers and modellers	2,293	75
Pattern designers	2,161	43
Draughtsmen	597	...
Medallists and die-sinkers	439	14

Supposing that the above may be fairly reckoned as professional employments, it appears that, on Census-day in 1851, there were 344,464 males and 78,467 females thus occupied. These comprise 1 in 30 of all the males, 1 in 140 of all the females, and 1 in 50 of the whole population. If we omit the sailors and soldiers from the list of professional men, the ratio will become about 1 in 60.

Perhaps it will ultimately be found that the most valuable tables in the Census Reports are those which establish a comparison between different parts of the country. Large generalizations may be made from the tables which relate to the whole of Great Britain; but for comparison and analogy, the sectional tables will have a peculiar value of their own. In reference to a particular department of occupation, or a particular social relation, we may wish to know how far Wales differs from England, and Scotland from both; how far the 10 Divisions into which England is separated differ one from another in characteristics; in what way the 40 English Counties, 12 Welsh Counties, and 32 Scotch Counties exhibit peculiar characteristics; by what peculiarities the 623 registration districts or poor-law unions of England and Wales are distinguished; and so forth. The voluminous Census tables afford a store of information on all these local details.

Of course, when different districts or portions of the kingdom are treated separately, the metropolis comes in for the first notice; the following, then, is a rough outline of employments generally in the metropolis. Confining our attention, at present, to males, and to males only of 20 years and upwards, we find the following facts: That out of the 5,458,815 males of 20 years and upwards in Great Britain, 632,545 live in the metropolis; that the London shoemakers number 26,639, and the London tailors, 20,257; that there are no fewer than 25,708 domestic and inn servants; that the commercial establishments are so numerous and extensive as to employ 15,135 clerks and travellers; that the coachmen, drivers, carriers, waggoners, draymen, and others who drive vehicles through the London streets, number more than 17,000, besides 14,000 messengers and porters, in addition to railway, canal, and river servants; that there are, for house-work, 21,174 carpenters, 13,817 painters and glaziers, and 16,038 bricklayers and plasterers; that among those who supply us with food and drink, are 9841 bakers, 7428 butchers, 6843 publicans, 6475 grocers, 3372 milk-sellers, 3325 greengrocers, 2238 fishmongers, and 2156 cheesemongers; that the leather trades, chiefly in Bermondsey, employ 5391; that there are 13,206 persons employed in printing, binding, and selling books; that the wood-furniture makers and sellers number 13,574; and that there are more than 40,000 labourers whose branch of labour is undefined, but who must be distinguished from skilled artizans.

Let us next, still confining our attention to the metropolis, glance at the female occupations in a similar way. Among the 5,998,384 females, aged 20 years and upwards, living in Great Britain, 762,418 are in London. Of this number, 316,517 designate themselves simply as wives, and 26,627 simply as widows, and about 40,000 as daughters, without any other alleged employment. But of those who appear to earn their living by the labour of their own hands or brains, there are no fewer than 118,855 domestic servants of various kinds, 73,620 needlewomen of various kinds, and 45,754 charwomen, washerwomen, and manglers. These, with 25,652 annuitants, and gentlewomen of independent means, comprise all the large items among the female adult population of the metropolis; all the other items are, individually, very small. These facts are not without their instruction; for they show how limited is the range of female employments in London. They show, too, that, after deducting those who are dependent on relations for support, and those of independent means, there were 330,000 adult females in London in 1851 dependent on their own exertions for their daily bread; and they show also how large must be the number of families in comfortable circumstances in London, to give employment to nearly 120,000 female servants, and 45,000 laundry- and char-women.

But now let us compare one of the manufacturing counties of the North with London, to ascertain how far a different principle seems to determine the distribution of occupations. We take the cotton-spinning county of Lancashire. Here we have 539,075 males of 20 years of age or upwards, against 632,545 in the metropolis; that is, in the ratio of about 85 to 100. Different indeed, however, is the ratio in regard to employments. We have seen that the metropolis contains about 26,000 male adult servants, 31,000 drivers and porters, 27,000 shoemakers, 21,000 carpenters, 20,000 tailors, 16,000 bricklayers, 15,000 clerks, 14,000 painters; whereas, in Lancashire, these eight occupations exhibit the numbers, 4708, 9127, 15,443, 12,146, 11,346, 7658, 7643, 6336—all far below the ratio in respect to total inhabitants. In London there are 35,000 persons in the public service, receiving emoluments from the community at large; whereas in Lancashire there are only 11,000. In London there are 34,000 professional men, engaged in divinity, law, physic, science, and fine arts; in Lancashire the number is 11,000. In London there are 14,000 persons employed in writing, printing, binding, and selling books and periodicals; in Lancashire there are 2,000. All these numbers, it is evident at a glance, differ widely; London having far more than its ratio of 100 to 85 in each of these employments. But let us turn the tables, and see what are the employments wherein Lancashire takes precedence of the metropolis. Of course, in a county, farmers, graziers, shepherds, gardeners, agricultural labourers, and so forth, must be relatively more numerous than in a city; and thus we need not be surprised to find 56,000 of these in Lancashire, against 14,000 in the metropolis. And, considering the wonderful shipping activity of Liverpool, and the numerous canals which traverse Lancashire in every direction, we may be prepared to expect that this county and the metropolis are not far from equal in the numbers of persons connected with ships, boats, and barges in various capacities; in the metropolis, this number is about 21,000, in Lancashire 18,000—very nearly, indeed, in the ratio of 100 to 85. But it is in textile manufactures, and in minerals, that Lancashire most decidedly takes the lead before London. In Lancashire there are 104,000 persons (out of about 540,000) engaged in various departments of the cotton manufacture, against a few hundreds in London; 7000 in woollen manufactures, against a few hundreds; 21,000 coal miners and labourers, against 5000; 3000 quarrymen, against 500.

Here it must be borne in mind, that the numbers in the preceding paragraph are of males only, and males too who have reached their 20th year or upwards. A few parallel entries will suffice, relating to certain occupations for adult females: of domestic servants and nurses there are, 125,000 in London, and 55,000 in Lancashire; of silk-workers, 8000 in London, and 12,000 in Lancashire; of cotton-workers, 1000 in London, and 90,000 in Lancashire. Here we find that one-sixth of all the adult females in London are domestic servants or nurses, and that one-sixth of all the adult females in Lancashire are engaged in the cotton manufacture.

There are also striking differences in respect to juvenile labour:—The metropolis contains 474,013 males, and 493,260 females, under 20 years of age; the numbers in Lancashire are 469,749 and 474,735 respectively. Now in the metropolis, after deducting 770,000 young persons who are entered only in their domestic or family relations, without connection with any particular employments, there remain about 200,000 who are considered to have some occupation or other; whereas in Lancashire there are 270,000 having employment; and out of this number about 120,000 are employed in the cotton manufacture alone—that is, 120,000 young persons. In the metropolis, on the other hand, young seamstresses and young domestic servants chiefly fill the list.

We turn now to other phases of metropolitan employment. Of the whole 2,362,236 inhabitants, there are, in round numbers, 630,000 men, 760,000 women, and 970,000 persons of both sexes under 20 years of age. Of this latter number, nearly 300,000 are under 5 years of age, and therefore almost equally removed from schooling and occupation. In order to show, then, how far male employments are to be met with in London for young persons, we give the following table in relation to a few occupations:—

	Under 20.	20 and upwards.
Law clerks	1,530	5,401
Teachers	457	4,285
Messengers and porters	19,743	13,471
Printers, &c.	3,213	13,206
Silk manufacturers	1,435	8,388
Cabinet-makers	2,361	13,963
Gold and silver work	1,145	6,419
Brass work	1,066	5,358
Iron work	2,170	13,604
Building trades	6,931	59,451

It is probable that the greater part of the above young persons are apprentices, although the returns do not specify this fact in words. The 19,743 young messengers and porters are evidently the "errand boys," rather a formidable body in London. Taking female occupations instead of male, and noticing the difference of age in a similar manner, we find the following:—

	Under 20.	20 and upwards.
Teachers	1,314	11,185
Servants	46,524	138,262
Needlewomen	20,288	124,165
Silk-workers	2,373	8,847
Paper-workers	625	1,132

If we were to name the three most characteristic kinds of occupations in London for males under 20 years of age, therefore, they would be apprentices to mechanical trades, errand boys, and junior clerks; and for females under 20 years of age, they would be servants, needlewomen, and teachers.

The 36 districts of London exhibit many remarkable groupings in reference to employments. It is well known that the members of a particular trade are wont, in many cases, to congregate near each other; but the Census tables show this more exactly. Lawyers live in Kensington district in greater relative numbers than in any other district—a fact for which we do not feel very well able to account; but the law clerks, except those who live around Chancery-lane and the inns of court, are found in greater relative numbers at Islington. The authors, editors, artists, and architects, are found in small number south of the Thames, or in the eastern half of the metropolis; Marylebone, St. Pancras, and Kensington, are their chief districts. Domestic servants are found in greatest relative force in the districts of St. George's Hanover Square, St. James's Westminster, Marylebone, and Kensington—indeed overwhelmingly so. The tailors are strong in St. James's, Marylebone, and St. Pancras, but relatively more so in the Whitechapel and neighbouring districts, where much of the slop work is done. The chief districts for shoemakers are St. Pancras and Marylebone in the north, Lambeth and Newington in the south, Whitechapel and Bethnal Green in the east. The gardeners have Kensington and Wandsworth as their chief districts. Beyond all other districts, the City is the locality for publishers and booksellers, for it contains the regions of Paternoster Row, and the numberless courts around Fleet Street. Musical instrument makers congregate in decided preponderance in St. Pancras. There are two districts in which watchmakers appear in surprising force; these are, as may be supposed, Clerkenwell and St. Luke's. Coachmakers in Pancras and Marylebone; shipbuilders in Stepney and Poplar; dyers and calenderers in Shoreditch and Bethnal Green (where the silk manufacture is carried on); leather workers in Bermondsey (nearly as many as in all the other 35 districts combined); sugar refiners, nearly all in Stepney, Whitechapel, and St. George's in the East; cabinet and furniture makers, Pancras, and especially Shoreditch; coopers, in the districts nearest the various docks; rope and sail makers, Stepney and Bethnal Green; workers in gold, silver, and precious stones, Clerkenwell;—these are the chief associations between occupations and districts.

And so, in like manner, are there certain occupations for adult females, which seem to be carried on in some districts rather than others. Domestic servants and governesses are, relatively to the population, most numerous in the districts of Kensington, Marylebone, and St. George's Hanover Square; while schoolmistresses, as distinguished from governesses, are relatively as numerous in other districts. The charwomen are especially numerous in Marylebone. Those who assist in the hat manufacture, binding, and so forth, are in Southwark and Bermondsey, where most of the hat factories are situated. The women tailors, who make waistcoats and cheap goods for the slop shops, are chiefly in the three eastern districts of Stepney, Whitechapel, and St. George's in the East. The milliners, as distinguished from seamstresses, are in greatest number in Marylebone and Pancras; but the seamstresses, who are understood to occupy a lower grade among needlewomen, are in strongest force in Stepney and St. George's in the East. Staymakers are in Marylebone chiefly. The washerwomen and manglers take up their abode chiefly in the genteel districts. The women who work at shoemaking live principally in Shoreditch and Bethnal Green; while the umbrella makers are more generally to be found in Whitechapel and St. George's in the East. The hawkers and pedlars are chiefly in the four districts just named. Artificial flower-makers in St. Pancras; silk workers in Bethnal Green; upholstery workers in Marylebone; lace workers in the same district—these are other examples of predominance.

For reasons already sufficiently indicated, it will be impossible to give abstracts of the county and district tables here; so numerous are they, and to so great a length is the classification carried. But we may be able to select a few examples sufficient to illustrate broad general principles of industrial distribution. For instance, every one knows that certain towns have become celebrated for certain manufactures; Sheffield for cutlery, Birmingham for small metal works, Manchester for cotton, Leicester and Nottingham for hosiery, Leeds for woollens, Bradford for stuffs, and so on; but it may be useful and instructive to know more exactly the extent to which this localization is carried. Again, there may be certain districts containing no very large towns, but in which some particular manufacture is nevertheless carried on to a remarkable extent; such as straw-plait, pillow-lace, needles, and many others.

Passing in review the principal cities, boroughs, and towns, we can readily determine from the tables, even without the aid of any previous knowledge on the subject, the prevailing character of the industry in each town, and to some extent the degree in which female labour and juvenile labour are made use of. Let us take a few of the towns in succession.

Birmingham.—Here the males under 20 years of age are 52,640, and above 20 years 61,276; the females under 20 are 53,380, and above that age 65,545; or, placing the numbers in a compact table, we have the result thus:—

Males.		Females.		Total.	
52,640	+	53,380	=	106,020	under 20 years.
61,276	+	65,545	=	126,821	20 and upwards.
113,916	+	118,925	=	232,841	total population.

Now in respect to their population, we find that out of the various classes of occupations, classes 11 and 14 are those in which the Birmingham inhabitants are chiefly employed—viz., working in metal. 2000 men making guns, 1800 making machines and tools, 2400 working in gold and silver, 3000 brass founders, 1400 button makers, 1200 white and black smiths, 1400 iron manufacturers, 400 nail makers. These are among the men of 20 years and upwards; but of the males under this age there are no less than 7000 employed in the few metal trades above enumerated. In Birmingham, females are largely employed in the smaller kind of metal manufactures; for example—1,300 young females and 1,600 adult females in making buttons; 700 and 1,100 in miscellaneous works in mixed metal; 800 and 1,200 in miscellaneous iron and steel works.

Manchester and Salford.—In these cotton towns are—

Males.		Females.		Total.	
86,551	+	89,043	=	175,594	under 20 years.
104,906	+	120,821	=	225,727	20 and upwards.
191,457	+	209,864	=	401,321	total population.

These are within the Parliamentary limits, which exceed the municipal. Now passing over the tailors and shoemakers, the carpenters and painters, the bakers and butchers, who in all large towns must necessarily form a considerable part of the population, we turn to class 13 as likely to exhibit remarkable characteristics of the workers in Manchester and Salford. Here one single entry, cotton manufacture, comprises *enormous* numbers—13,257 men, 5692 boys, 14,503 women, 9051 girls, making a total of 42,503, in which the females exceed the males by 23,554 against 18,949. Putting the whole of the textile manufactures together—relating to cotton, flax, silk, and wool, they appear to employ about 25,000 men, 8000 boys, 20,000 women, and 12,000 girls, exhibiting the remarkably near equality of 33,000 males to 32,000 females—more than 1 in 7 of the entire population of Manchester and Salford employed in making the textile materials for dress, besides 12,000 tailors and seamstresses employed in making up textile materials into dress. We have in this paragraph, for brevity, applied the terms boys and girls to young persons under 20 years of age; and shall do so in those which follow.

Nottingham.—Here we enter a bobbin-net and cotton stocking town:—

Males.		Females.		Total.	
11,782	+	12,746	=	24,528	under 20 years.
14,805	+	18,074	=	32,879	20 and upwards.
26,587	+	30,820	=	57,407	total population.

Of course the numbers in any particular occupations here will appear much smaller than in Manchester, because the population is only one-seventh as large; but the following entries are well worthy of note:—stocking-makers, 2,469 men, 412 boys, 1,588 women, 474 girls, making nearly 5,000 persons, or more than one-twelfth of the whole of the inhabitants, employed in this one branch alone. The bobbin-net manufacture employs 1,376 men, 517 boys, 3,277 women, 1,902 girls, exhibiting a still more striking total of more than 7,000 persons. Of the aggregate 12,000, more than 7,000 are females. It is worthy of notice that the hose and lace workers bear a larger ratio to the population of Nottingham, than the whole of the textile workers bear to the population of Manchester.

Merthyr Tydvil.—We quit hosiery and lace, to turn to iron and coal:—

Males.		Females.		Total.	
14,357	+	13,628	=	27,985	under 20 years.
19,650	+	15,443	=	35,093	20 and upwards.
34,007	+	29,071	=	63,078	total population.

Now in this remarkable town we glance over the classes of occupation, one after another, without meeting with any numbers so large as to arrest the attention. At last, however, in class 14, we encounter them in surprising force. There are under the heading 'coal miners,' 1,671 boys and 4,302 men; and among iron workers are 2,038 boys and 6,915 men; making a total of about 15,000 workers in these two minerals alone; these, with 700 or 800 females similarly employed, comprise a quarter of the entire population. Considerably more than half the adult male population of Merthyr Tydvil are workers in iron and coal, employed chiefly in the four great establishments of Dowlais, Cyfarthfa, Pen-y-darren, and Plymouth works.

Bradford.—This busy Yorkshire town introduces us to a wholly different class of manufactures. The parliamentary borough is somewhat extensive, and includes some of the neighbouring villages, comprising a population of—

Males.		Females.		Total.	
22,934	+	24,399	=	47,333	under 20 years.
27,032	+	29,413	=	56,445	20 and upwards.
49,966	+	53,812	=	103,778	total population.

After making allowance for the large number of tailors, shoemakers, carpenters, masons, and similar handicraftsmen for supplying the wants of so large a population, we find that class 12 contains the employments characteristic of Bradford. Here are entered, under worsted and stuff manufacture, 5381 boys, 10,759 men, 7936 girls, and 8780 women—a powerful body of about 33,000 persons (nearly a third of the whole population) employed in worsted and stuff manufactures alone. The woollen cloth, the silk, and the cotton manufactures, occupy perhaps 1000 altogether, showing how insignificant they are at Bradford.

Leeds.—The borough contains—

Males.		Females.		Total.	
38,468	+	38,987	=	77,455	nnder 20 years.
45,246	+	49,569	=	94,815	20 and upwards.
83,714	+	88,556	=	172,270	total popnlation.

We devote a short paragraph to Leeds, for the purpose of showing how remarkable a contrast may be presented in the indnstry of two towns situated only abont ten miles apart. Bradford and Leeds both work np wool largely; bnt Bradford prepares it for stnff or worsted fabrics, while Leeds prepares it for woollen cloth. Leeds has 2920 boys, 7640 men, 1710 girls, and 2624 women employed in making woollen cloth: while the stnff and worsted mannfactures barely employ 1000. Leeds, however, is a large manufacturing town in other respects; for it employs about 9000 persons in the flax mannfacture, and 3000 in making engines and machines. Relatively to the population, Hnddersfield is perhaps more peculiarly associated than Leeds with the woollen cloth manufacture.

Macclesfield.—Having given an idea of the distribntion of occnpations in the towns which may be regarded as the chief seats of the cotton, woollen, and stnff manufactnres, let us do the same in reference to the silk-workers of Macclesfield borough:—

Males.		Females.		Total.	
8,299	+	8,735	=	17,034	nnder 20 years.
10,242	+	11,772	=	22,014	20 and npwards.
18,541	+	20,507	=	39,048	total population.

There are 2462 boys 4772 men, 2979 girls, and 4339 women employed in the silk manufactnre, making an aggregate of about 14,500 persons, considerably more than one-third of the entire population. The males and females are employed in almost exactly eqnal nnmbers, 7234 to 7318.

Sheffield.—In this cntlery borough there are—

Males.		Females.		Total.	
31,108	+	31,112	=	62,220	under 20 years.
36,392	+	36,698	=	73,090	20 and upwards.
67,500	+	67,810	=	135,310	total popnlation.

In the classes relating to the supply of food, clothing, and dwellings, Sheffield contains a nnmber fairly proportionate to its popnlation; but it is only in class 14 that the industrial characteristics make their appearance. The works in gold, silver, steel, iron, and mixed metals employ abont 20,000 men and boys at Sheffield. Females are very little employed in the metal trades, thereby presenting a striking contrast to the arrangements at Birmingham. No fewer than 2461 boys and 7044 men are employed in making and grinding cntlery and files alone.

Glasgow.—There are two or three Scotch towns which present remarkable characteristics. Glasgow has—

Males.		Females.		Total.	
71,474	+	73,593	=	145,067	nnder 20 years.
83,455	+	100,574	=	184,029	20 and upwards.
154,929	+	174,167	=	329,096	total population.

This bnsy city is worthy of note for the degree in which it combines cotton working and iron working, two departments of industry which certainly do not seem to have any very necessary bond of connection. There are 3449 boys, 11,371 men, 9692 girls, and 16,442 women—abont 15,000 males and 26,000 females—employed in various branches of the cotton mannfactnre. Of all the females in Glasgow, in every age and condition, one in seven are employed in this manufactnre. There are, in respect to metal trades, 2600 machine and tool makers, 4800 miners and manufactnrers, and 5400 other workers in metal—almost wholly males.

Dundee.—This is the great centre of the flax and linen manufacture of Scotland. Dnndee contains—

Males.		Females.		Total.	
17,444	+	17,999	=	35,443	nnder 20 years.
18,420	+	25,068	=	43,488	20 and upwards.
35,864	+	43,067	=	78,931	total population.

Of these nnmbers there are 2713 boys, 6161 men, 4300 girls, and 6568 women, employed in flax and linen mannfactures, being almost exactly one-fonrth of the whole popnlation—a ratio which certainly appears surprisingly large. Aberdeen is also engaged in these trades, but in a very mnch smaller ratio than Dnndee.

These few examples would perhaps snffice to illnstrate the distribution of particular branches of manufacture in the principal towns; bnt, adopting a still more compressed form, we will give a few additional instances in the following way:—

At *Portsmouth*, ont of about 35,000 men and boys in the borongh, abont 9000 are in the pnblic service, and receive pay from the commnnity; while there are abont 2000 privately employed as seamen or as shipwrights. At *Leicester*, ont of 60,000 persons, nearly 9000 are employed in making worsted stockings, and similar articles. At *Northampton*, ont of 13,000 men and boys, more than 4000 are employed in making boots and shoes, the staple industry of the place; and at *Stafford* the men and boys similarly employed are in the ratio of one to fonr of the whole male population. At *Worcester*, ont of 15,080 women and girls, 2133 are employed in making gloves. Of the 25,705 men and boys in *Wolverhampton*, abont 7500 are employed npon metals or npon coal; no less than 1400 make locks alone. In *Dudley* the ratio is abont as high, abont 6000 out of 19,093. *Coventry* is remarkable for two trades, abont as diverse as any two can be, ribbon-making and watch-making: out of a popnlation of 36,612, nearly 10,000 persons (of whom 6500 are females) are employed upon silks and ribbons; while 1700 men and boys are making watches. At *Stockport*, 17,000 persons are employed in cotton mannfactures, ont of a total popnlation of 53,835—nearly one in three; at *Blackburn*, 16,000 ont of 46,536—more than one in three; at *Bolton*, 14,500 ont of 61,171; at *Oldham*, 20,000 ont of 72,357; at *Preston*, 18,000 ont of 69,542. Thns, in these five cotton spinning and weaving towns, containing an aggregate of about 300,000 inhabitants, abont 34,000 males and 42,000 females—considerably more than one-fourth of all the inhabitants—are engaged in this mannfactnre. Looking at the distribntion of workers in reference to age, we find that there are abont 33,000 children and young persons nnder 20, and 43,000 adnlts of 20 and npwards. In *Paisley*, ont of abont 31,000 inhabitants, nearly 9000 are employed in varions kinds of textile mannfacture, of which the principal is shawls.

Hitherto, in the above paragraphs, we have spoken of distinct towns, each with defined limits and defined nnmber of inhabitants. Bnt a few remarkable manufactures are centred rather in districts than in large towns.

In *Staffordshire*, the registration connty (which often differs slightly both in limits and in population from the real county), contains 320,903 males and 309,641 females. Now it is plain, on a little examination, that the main departments of industry whereby these are snpported have relation to mineral mannfactures; and it is further observable, on comparing the several districts in Poor Law Unions, that while the southern exhibit the metallic and colliery operations, the northern are associated with earthenware manufactnres. In short, we have the Wolverhampton region of the sonth, and the pottery region of the north. There are 27,000 males and 1000 females engaged in various departments of the coal trade; 45,000 males and 7000 females in metallic manufactnres; 16,000 males and 9000 females in pottery and earthenware mannfactnres. It is worthy of note that in the two districts or Poor Law Unions of Stoke-npon-Trent and Wolstanton, containing the pottery towns of Stoke, Hanley, Lane End, Delph, Etruria, Shelton, Burslem, &c., ont of a popnlation of 51,000 adult males and females, more than 13,000 are engaged in the earthenware mannfactnre. And in respect to Sonth Staffordshire, it would perhaps scarcely be expected that 5000 women are engaged in nail-making.

Bedfordshire, containing 62,539 males and 67,266 females, is not a county likely to contain large mannfactnring establishments of any kind; bnt there are, nevertheless, two or three entries in the tables which deserve attention. There are, we find, 2300 males and more than 10,000 females engaged in the straw-plait manufacture; together with nearly 6000 females occupied in hand-lace making. One fonrth of all the females in the connty, of all ages and conditions, are employed in one or other of these two occnpations. In *Buckinghamshire*, containing 70,928 males and 72,727 females, the straw-plait trade is smaller, employing only abont 3000 females; bnt the lace-trade is about as extensive as in Bedfordshire, employing nearly 11,000 females. In *Hertford-*

shire we almost entirely lose the lace-trade; but the straw-plait employs about 9000 females out of 87,497. In *Cambridgeshire* there is a little done in these two trades, but only a little; and in *Huntingdonshire* there are about 1000 females out of 30,295 engaged in the lace-trade. In these two departments of cottage industry, the females employed are of all ages from 5 to 90, chiefly between 10 and 20.

Worcestershire, for some reason which it is difficult to explain, is the centre of the needle manufacture. At Redditch in this county nearly all the inhabitants are supported, directly or indirectly, by this manufacture; although the steel for making the needles, and all the coal for heating the steam-engines, must be brought from other quarters.

Cornwall is rich in metals, but has no coals. It has 172,193 males in the (registration) county. Among these are 3000 seamen and 2600 fishermen; but when we come to class 14, mineral working, we find about 16,000 copper-miners, more than 10,000 tin-miners, 2500 lead-miners, and about 6000 employed in other ways on metals and minerals; none, however, in coals. There are also about 6000 females engaged at the 'above-ground' works of the copper and tin mines.

Let us contrast this with a county containing much coal but little metal. *Durham* (registration) county contains 207,088 males, and 204,591 females, a departure from the general rule; for here we find more males than females. Now, here are 10,000 men and boys engaged in sea and river navigation; a very large number out of such a population, and evidently due principally to the navigation of colliery vessels. The number of 4500 ship and boat builders is also large, and points to the busy trade of Sunderland. But a much larger item is that of 29,000 men and boys employed in coal-mining and working, about one-seventh of the male population. In *Northumberland*, as might be expected, a somewhat parallel state of things presents itself. There are here 149,515 males; and, of these, about 6000 are engaged in navigating ships and boats, 1400 in building ships and boats, and 11,000 coal-miners; the parallelism, it will be observed, is in the nature of the prevalent occupation, and not in their extent, for Durham greatly takes the lead in this respect. Five of the coal-miners of Northumberland are entered as being upwards of 90 years of age; but it is satisfactory to find that, consequent on recent legislation, scarcely any boys under 10 years of age, or females of any age, are included among the coal-miners or labourers.

There are two counties in the western part of the kingdom which we may similarly notice, in respect partly to the iron manufacture, but still more decidedly to coal-mining. These are Monmouthshire and Glamorganshire. *Monmouthshire* contains 92,301 males and 82,849 females—another example, in a mining county, of the males outnumbering the females. The iron trades occupy 12,000 males, and the coal trade also 12,000—in round numbers: together more than one-fourth of the entire male population. Females are not much employed in these trades in this county. *Glamorganshire*, containing the remarkable towns of Merthyr and Aberdare and their vicinity, has a population of 125,087 males and 115,000 females. Of these males, no less a number than 15,500 are engaged in the coal trade, and 14,000 in the iron trades. In another Welsh county, *Caermarthen*, copper manufactures are, in respect to the population, if not as remarkable as iron manufactures in Glamorganshire, at least worthy of note as the staple industry of portions of the country. The explanation of this is, that nearly all the copper ores of Cornwall and Devon are sold on the spot to copper-smelters, who have their works at Swansea or Neath, or some other town in Caermarthenshire. But besides the copper workers there are, among the 125,087 males in this county, 14,000 workers in iron, and 15,000 coal-miners.

Something has been said, in former paragraphs, of the remarkable distribution of employments in the cotton and woollen towns of the north; and a comparison, in relation to certain items, has been made between Lancashire and the metropolis. In order, however, to illustrate more definitely the centralisation of certain manufactures in the two great counties of Lancashire and Yorkshire (West Riding), we will present, in the following form certain numbers and ratios. In *Lancashire*, out of 1,008,824 males of all ages, there are 160,000 engaged in the various departments of the cotton manufacture; and out of 1,058,477 females, about 158,000 similarly engaged; and of this large total of 318,000, not less than 118,000 are under 20 years of age. In the West Riding of *Yorkshire*, out of 666,912 males of all ages, there are about 120,000 engaged in various departments of wool and worsted manufactures; and out of 673,139 females, about 80,000 similarly engaged; and of this total of 200,000, about 15,000 are under 20 years of age. In comparing the above numbers, we observe the following results:—that the male workers in wool bear a larger ratio to the whole male population in the West Riding, than the male workers in cotton bear to the whole male population of Lancashire; that in respect of female workers, the ratio lies in the other direction; that the ratio of juvenile workers to adult workers is about the same in both departments of industry; and that while 1 in 6 of the Lancashire population is engaged in cotton manufactures, about 1 in 6½ of the West Riding population is engaged in the wool manufactures.

Such are a few of the most striking results obtained by the Census of 1851, relating to the occupations of the people. The entire Report is worthy of the careful study of every person who desires to know something more of the condition of the people, in this hard-working country, than can be derived from vague generalizations and partial inquiries.

OCEANIA, a name given by Balbi and other French geographers to a fifth division of the earth. They make it extend from about 93° E. to 105° W. long.; the northern boundary being the Indian Ocean, Malacca Strait, the Chinese Sea, and the Pacific along the parallel of 35° N.; the southern boundary being the 56th parallel of south latitude. The name is thus made to comprise the Andaman Isles, all the islands of the Indian Archipelago, Sumatra, Java, Borneo, Celebes, the Moluccas, the Philippines, Formosa, Australia, New Guinea, New Zealand, and the countless groups of islands in the Pacific within the limits above stated to the islets of Sala-y-Gomez, the most eastern of the whole.

O'CONNELL, DANIEL, the eldest son of Morgan O'Connell, was born at his father's residence, near Cahirciveen, Kerry, August 6, 1775. The family of Connell, or O'Connell, is of antiquity in the south of Ireland, but the circumstances of the father of Daniel O'Connell were much straitened. Still he did not neglect the education of his son, according to his means, for he sent him at an early age to a "poor old hedge-schoolmaster," named David Mahoney, who first taught the Irish agitator his letters. At the age of thirteen Daniel O'Connell was removed to a school at Redington, near Cove, county Cork, kept by the Rev. Mr. Harrington, a Roman Catholic priest: this school is said to have been the first publicly opened in Ireland after the repeal of the persecuting laws which made it penal for a Roman Catholic to educate his children. In 1790 Daniel, then just fifteen years of age, was removed from Redington with the intention of being sent to Liège; but on reaching that place he was found to be too old for admission, and accordingly was entered at St. Omer's. There he remained till 1792, when he was transferred for a time to the English college of the Benedictines at Douai. Returning after a few months to St. Omer's, he rose speedily to the head of the college; and so arrested the attention of the then president, Dr. Stapylton, that he prophesied that he would hereafter make a remarkable figure in the world. The first outbreak of the French revolution scattered the scholars of the Roman Catholic colleges at Douai and St. Omer's. Daniel O'Connell succeeded in reaching Calais safely, and, embarking on board the English packet-boat, he landed on the shores of England, "half a Tory at heart"—so deep and keen was the impression left upon his mind by the excesses of the revolution in France.

The legal profession having been recently thrown open to members of his faith, he in 1794 entered himself a student at Lincoln's Inn; and four years afterwards was called to the bar, having taken no ordinary pains to qualify himself. His first public speech was against the proposed union between the English and Irish legislatures. It was delivered at a meeting of the Roman Catholics of Dublin, assembled at the Royal Exchange in that city, for the purpose of petitioning against that measure; but the meeting was broken up by the intervention of the military. In 1802 Mr. O'Connell, while his professional prospects were brighter than its realities, was married privately to his cousin Mary, the daughter of Dr. O'Connell of Tralee. The calamitous occurrences however connected with the Irish outbreak of 1803, known by the name of Emmett's rebellion, found Mr. O'Connell already in possession of a moderate practice. He was now becoming gradually absorbed in the arena of political contention. Emmett's trial was the starting point of a new era in the history of Irish agitation: the cruelty inflicted by the citizen-soldiery made an impression as deep and lasting as it was general, and the 'Catholic Question,' as it was called, rose daily in importance. From this time forward Mr. O'Connell took the leading part in the prosecution of the Roman Catholic claims. "For more than twenty years," he writes to the late Lord Shrewsbury, "before the passing of the Emancipation Bill, the burden of the cause was thrown upon me. I had to arrange the meetings, to prepare resolutions, to furnish replies to the correspondence, to examine the case of each person complaining of practical grievances, to rouse the torpid, to animate the lukewarm, to control the violent and inflammatory, to avoid the shoals and breakers of the law, to guard against multiplied treachery, and at all times to oppose at every peril the powerful and multitudinous enemies of the cause." Day and night he devoted himself with surprising energy to the work, without receiving pay or fee. In 1804 the 'Catholic Board' was dissolved by a proclamation from government, but it was immediately revived under the name of the 'Catholic Committee.' It met in the Exhibition House in William-street, and its debates were reported from January 1808.

In 1815 Mr. O'Connell fought a duel with Mr. d'Esterre, a member of the Dublin corporation, and had the misfortune to inflict upon his adversary a wound which ultimately proved fatal: it is but just to add that for this result he ever afterwards felt and expressed the most painful remorse. Mr. O'Connell's public life henceforth offers very little material for remark, until we come to the very eve of the time at which the Roman Catholic Emancipation Bill was carried. In the summer of 1828, when the fever and excitement on the subject then in suspense was at its height, Mr. O'Connell and his friends judged that the time was come for bringing the question to a final decision. In the June of that year a vacancy occured in the representation of Clare county, and Mr. O'Connell, though a Roman Catholic, was proposed as a candidate against Mr. (afterwards Lord) Fitzgerald. He was returned to Parliament by a large majority, and proceeded to Westminster for the purpose of taking his seat in St. Stephen's. As a Roman Catholic, he of course refused to take the oaths drawn expressly against the doctrines of the Roman Catholic Church. Discussions in the house, and arguments at the bar ensued; and though the session closed without any practical result, yet the agitation in Ireland began to assume a formidable appearance, and to threaten another outbreak. Alarmed at the probable consequences of further opposition to claims which a large majority of educated Protestants had come to regard as just and equitable, the Duke of Wellington and Sir Robert Peel gave way, and early in the following year brought into parliament a bill for the repeal of the last civil disabilities under which the Roman Catholic body laboured. Mr. O'Connell accordingly was re-elected, and took his seat as member of parliament in May 1829. In the following year, at the general election consequent upon the death of George IV., Mr. O'Connell exchanged the representation of Clare for that of his native county of Kerry. He represented Dublin from 1832 to June 1835, when he was unseated on petition, but was immediately afterwards returned for Kilkenny. In 1837 he was once more returned for Dublin, and in 1841 for the county of Cork. To carry on more effectively the agitation, Mr. O'Connell had relinquished his professional practice, and as a compensation for his loss of income, an annual subscription was organised, which afterwards came to be known as the 'Rent.'

The year 1841 witnessed the return of Sir R. Peel and the Conservative party to power, and this was the signal for renewed agitation in Ireland. In the following year, Mr. O'Connell commenced his movement in favour of a repeal of the Union, which met with general sympathy from the violent and the ignorant throughout Ireland.

In 1842 and 1843 monster meetings were collected on the royal hill of Tara, on the Curragh of Kildare, the rath of Mullaghmast, and other localities renowned in tradition and song. A monster meeting announced as to be held at Clontarf on Oct. 8th in the latter year, was forbidden by government authority, and a state prosecution for high treason was commenced against Mr. O'Connell and the other ringleaders. Mr. O'Connell was convicted of sedition, sentenced to be imprisoned for a year, and to pay a fine of 2000*l.* The judgment was reversed on appeal to the House of Lords; but the prosecution answered its intended end; the prestige and magic influence of the great 'Liberator,' as he was called, was destroyed; he himself henceforth spoke in more measured language, and the funds of the Repeal Association were nearly exhausted in the contest.

The return of the Whigs to power in 1846, and the adherence which Mr. O'Connell gave to their party, introduced dissensions and differences among his immediate followers and supporters, over whom for forty years he had exercised an all-powerful influence. His health began to fail, and he became soured by opposition, as well as depressed in spirits by the evident approach of famine in Ireland. Early in 1847 he went abroad with the intention of spending some months in Italy, and of paying a devotional visit to Rome. He had not however proceeded further on his way than Genoa, when he suddenly sunk and expired on the 15th of May. His heart was embalmed and carried to Rome in compliance with his last wishes; and his body was conveyed to Ireland for interment. Besides three daughters, Mr. O'Connell left four sons, all of whom at one time or other have had seats in Parliament. His eldest son Maurice, many years M.P. for Tralee, died in 1853; and his second son, John, after representing several Irish constituencies, was appointed in 1856 to the Clerkship of the Hanaper Office in Dublin.

(*Life and Times of Daniel O'Connell, by his son, John O'Connell.*)

OCTODON. [MURIDÆ.]

OCTOPUS. [PAPER NAUTILUS.]

ODIHAM. [HAMPSHIRE.]

ODONTOPTERIS. [COAL PLANTS.]

OEHLENSCHLÄGER, ADAM GOTTLOB, the greatest poet of Scandinavia and one of the greatest European poets of the 19th century, was born on the 14th of November 1779, at Vesterbro, a suburb of Copenhagen. The whole of his early life was recorded by himself with singular minuteness, first in an autobiography written to be prefixed to a German edition of his works and afterwards in a series of 'Erindringer' or 'Recollections' which were published immediately after his death by his eldest son. The reader is informed in the 'Erindringer' of the boy's first inclination to swear, and how his mother checked it, of his strong propensity to pull off the bed-clothes, and a variety of similar particulars, the whole of which put together supply a varied picture of the life of a Danish boy at the close of the 18th century.

The name of Oehlenschläger is German; his father was from Krusendorf, a village in Sleswig, where the family had produced a long succession of schoolmasters and organists; and his mother Martha Maria Hansen was of German parentage by the father's side, of Danish by the mother's. "Thus," says Oehlenschläger, "I am descended from both Danes and Germans, and it seems as if Fate had determined I should belong to both nations." His father had fallen much below the respectability of his ancestry by becoming a servant to Count Adam Gottlob Moltke, after whom the poet was named; but on his marriage with the countess's lady's-maid he obtained by the count's patronage the post of organist at Frederiksberg, and afterwards of some subordinate position at the castle of that name, where he finally rose to be steward. Frederiksberg, one of the numerous palaces of the king of Denmark, a building which is said by some to have been erected from the plans of Inigo Jones, stands about two English miles from the western gates of Copenhagen, and is a favourite Sunday resort of the inhabitants of the capital. Here the early life of young Adam was passed amid scenes of great variety. In the summer Frederiksberg was often occupied by the court, and he heard the royal band of music play on Sundays, and saw the royal company at dinner. In the autumn the place of the court was supplied by a legion of workpeople, busy with repairs; and in the winter the building was left in charge of the Oehlenschläger family, with, in addition, two watchmen and two watchdogs. "The whole palace," says Oehlenschläger, "then belonged to us, and I went about in the royal rooms, looking at the paintings and building castles in the air."

The chief amusement of Oehlenschläger in the winter was reading novels, which he got from a circulating library in Copenhagen, and of which he tells us that before he was twelve years old he had got through more than three hundred volumes. All that he read was Danish—a circumstance to which he partly attributes the mastery he obtained over his native tongue. His parents, though German was their native language, never used it to their children, and only to each other when they did not wish the children to understand them.

Up to the age of twelve, yonng Adam had been very unfortunate in the article of schools; he was then taken notice of by Edward Storm, a Norwegian poet, who offered to his father to procure him gratuitous admission to a public school in Copenhagen, if his father would be at the charge of his board. Young Adam soon began to write not only verses but even plays, which were acted by himself, his sister, and some play-fellows, on Sundays, in one of the rooms at Frederiksberg. Storm, who was superintendent of the school to which the boy had been admitted, laughed at his attempts; and Dichmann, another Norwegian, who was one of the masters, told him, to his great mortification, that he was no genius—he wonld never be another Edward Storm. The education he received was intended to qualify him for a mercantile life; but when he left the school at the age of sixteen, he was glad of an accident which prevented his being placed in a connting-house, and readily persuaded his indulgent father, who was now in much better circumstances than he had heen, to allow him to study. In a year however he was tired of Greek and Latin, and having for some months spent all his spare time and money at the theatre, was seized with a desire to appear on the stage. Theatrical matters are generally looked upon in a more serious light in a foreign city than in an English one, and at Copenhagen the management of the drama was treated with unusual solemnity. In Rahbek's Lectnres on the Drama, delivered to the actors, the stage is regarded as a moral engine hardly secondary in importance to the pulpit. With the exception of the comedies of Holberg, the Danish Molière [Holberg], the plays that were performed were then chiefly translations. "Of English pieces," says Oehlenschläger, "the 'School for Scandal' pleased me mnch, in which Rosing was an excellent Sir Joseph [Joseph Surface?], and 'She Stoops to Conquer,' in which Gielstrup was an incomparable Tony Lnmpkin." He soon found however that he was not likely to rise to a much higher position than that of a walking gentleman, and the acquaintance of two young stndents, who had taken lodgings with the same landlady as himself, led him into a different line. They were the two brothers Oersted, afterwards so well known. Of the three young men who occupied together for some years those obscure lodgings, one, Oehlenschläger, became the greatest poet of Denmark; another, Hans Oersted, became its greatest natnral philosopher, and the discoverer of electro-magnetism; the third, Anders Oersted, who married Oehlenschläger's sister, became its greatest lawyer, and for a time the prime-minister of the kingdom. Oehlenschläger infected the future lawyer with a love of poetry, and the lawyer infected him with a taste for jurisprudence. With the consent of his father he relinquished the stage, and entered himself at the University of Copenhagen as a student of law, his friend promising his assistance to help him on a little more rapidly than usual. Literature however soon won the victory over law. The university offered in 1800 a prize for an essay on the subject 'Would it be an advantage for Northern literatnre if the Scandinavian mythology were made use of in it, instead of the Grecian?' It was the very idea which was taking possession of Oehlenschläger, and was destined to occnpy him for life; but when he drew np an essay he had the mortification to see the prize carried off by another—receiving himself however the honour of being declared the second best.

On the famous 2nd of April 1801 when Nelson attacked the Danish fleet off Copenhagen, Oehlenschläger saw the fight at a short distance, from the balcony of the Sea-Cadets' Academy, and he afterwards held the post of ensign in a volnnteer regiment of students. He also pnblished a small dramatic piece, 'The Second of April;' but it was of no great merit. "That battle," he wrote, several years afterwards, "inspired the Danes with a taste for poetry, as the battles of Marathon and Salamis did the Greeks, and the destrnction of the Spanish Armada the English in the time of Elizabeth. Some great development of power is reqnisite to drive the mean, the petty, and parochial out of a nation's mind, and hring it in tnne for the great and beautiful." In 1803 he issned a volume of poems, containing among other works, the play of 'The Eve of Saint John,' and at once took rank as a writer of some note. The play, or rather dramatic tale, of 'Aladdin,' which followed, fonnded on the well-known story in the 'Arabian Nights,' captivated the pnblic, in spite of some very obvious faults, hy the general vivacity of its tone, and raised his name very high in the list of the living Danish poets, if it did not place him at their head. He used often to say afterwards that in writing 'Aladdin' he had discovered his own 'wonderful lamp,' the vein of poetry which was to give him fame and fortune. He received in 1805 the usnal mark of success for a Danish author—a travelling stipend from the government, procured for him by Connt Schimmelmann, and set out on a tour to Germany, to make the acquaintance of the band of literary men who at that time invested Germany with a halo. The second volume of his autobiography is chiefly occupied with an account of his travels, and of his intercourse with Göthe, Wieland, Tieck, Hegel, Voss, and other poets and philosophers. Up to his twenty-fourth year he had never written a line of German, but he was now so anxious to impart to his new and illnstrious friends some notion of his poetical capacity that he translated his new compositions into German as fast as he wrote them, and somewhat unnecessarily occupied the time of many of them by availing himself of the permission to read his productions to them in manuscript, and take their opinion not only on the merits or defects of the structure and the poetry, but on the correctness or incorrectness of the language. It is not a little singular that prodnctions so thoroughly Scandinavian in their tone and spirit as the earliest of the long line of Oehlenschläger's northern tragedies should have been written in a foreign land and partly composed in a foreign tongue. 'Hakon Jarl' was written at Halle. It is a tragedy in five acts, on the fortunes of Hakon Jarl, the last pagan sovereign of Norway, and the struggle between the two religions, Christianity and the belief in Odin. Nothing can well be more different than a tragedy of the old French school and such a tragedy as 'Hakon Jarl.' As the reader of 'Ivanhoe' finds himself, before be has arrived at the end of the narrative, not only interested in the fortunes of Wilfrid and Rowena, but also well-informed and perhaps not less interested in the whole framework of the country around them, cognisant of the relative position of the Normans and Saxons, of the enmity between the king and the Templars, of the ceremonies of a tournament and an ordeal, of the condition of serfs and Jews, so the reader of 'Hakon Jarl' sees pass before him the old tyrant superstitiously clinging to the wild religion of Valhalla, the young champion eager for the triumph of the Cross, the rude but independent Norwegian boor, the crouching northern slave, the ambitious serf who carelessly espouses the new faith because it promises him a better career. An unceasing vivacity pervades the whole, and there is not only pathos but hnmour; nothing can be further removed from the unvarying solemnity and systematic monotony which have by some been thought essential to the character of a tragic drama.

Oehlenschläger, before qnitting Germany, was accidentally present at Weimar on the day of the double battle of Auerstadt and Jena, and was in some danger when the victorious French entered the town. From Germany he went to Paris, where he composed what is by some regarded as his finest tragedy, 'Palnatoke,' and also 'Axel and Valborg,' the former a sort of companion pictnre to 'Hakon Jarl,' in which Odinism is shown in a more favourable point of view, and the latter a love tale of the middle ages. At Paris he was welcomed by Baggesen, who had before his own rise occupied the highest position in the Danish Parnassus; and when Oehlenschläger read to him the 'Palnatoke' the impetuous poet flnng himself at his feet in transports of admiration.

From France he went to Italy, and at Rome, while in daily intercourse with Thorvaldsen, composed his 'Correggio,' which, reversing his usual practice of writing his plays first in Danish and then in German, he wrote originally in the German language. This is of a different kind from any of his previons works,—it is the embodiment of the feelings of the great painter who, labouring in obscurity and not conscious of his own value, is subjected to all the emotions of which artistic genins is capable, by a series of ingeniously contrived incidents skilfully gronped on the known facts of Correggio's biography. The introdnction of Michel Angelo and Julio Romano, as two of the persons of the drama, affords the dramatist an opportnnity of painting more than one variety of the artistic character. Few of Oehlenschläger's works have met with greater variety of judgments than this. Treated with disdain by Göthe, it was afterwards caustically criticised hy Tieck, and Cotta the publisher of Tühingen, after purchasing the German copyright, kept the play hy him for years unpublished. Meanwhile the writer, after staying some time in Italy, beginning to feel home sickness, returned to Denmark after an absence of nearly five years, and read this production in manuscript to many of the most select circles of the capital, among others to the king and queen of Denmark, in presence of the leading members of the court, in the queen's apartments. The play, when produced in Germany, became one of the most popular on the stage, and had a run of success which caused it to be one of the most frequently acted for thirty years; and it also became a favourite in Denmark. A translation of it into English, by Theodore Martin, published in 1854, has met, we believe, with a general welcome, and all English critics regard 'Correggio' as one of Oehlenschläger's principal titles to fame.

Oehlenschläger had left Denmark in 1805, an eminent rising poet. His reputation had risen higher and higher during every year of his absence, and on his return in 1810 he was without a rival. Before he set out on his travels he had engaged the hand of Christiana Heger, the sister of Camma Rahbek, the wife of Rahbek the theatrical writer, whose house on the hill (Bakkehuus), a short distance outside the city walls, had been since 1800, and continued till 1830, the resort of the choicest literary society of Copenhagen. Rahbek himself had in a fit of vexation just thrown up the post of professor of æsthetics at the university, and Oehlenschläger obtained it, with the privilege from the king of being absent if he pleased during the summer terms, which was a privilege he did not neglect to make use of. Being thus provided with an income, he celebrated his wedding in an unusual way, but precisely in the style that Rogers, the English poet, was accustomed to say would have been his, if he had ever ceased to be a bachelor. "On the 17th of May, 1810," says the Dane's 'Erindringer,' "I dined with Christiana at her father's at Copenhagen, afterwards she and I drove by ourselves to Gientofte, where Pastor Högh, after I had shown him the necessary papers, went with us to the church and married us. We got into the vehicle again, man and wife, and drove off to the beautiful Christiausholm, to Sölyst, which Count Schimmelmann had had the kindness to offer us for a summer residence." The newly married lady had a notion that her husband had lost much by his dealings with the booksellers, and under her advice he began to issue his new plays and poems at his own risk, but soon convinced himself that he understood nothing of the publishing business, and his wife no more; a conviction which he says, however, that his wife could never be persuaded to share.

During the next five years he wrote a number of plays of various merit, but none that were equal to those he had composed abroad, and his peace was disturbed by a singular literary feud. Baggesen, already mentioned as formerly the head of the Danish Parnassus, had left Denmark a little before Oehlenschläger, with the deliberate intention, although in receipt of a poetical pension from the government, of never returning to the country, and of never writing another line of Danish. He now changed his mind, came back, and, unable to see with patience the throne of poetry occupied by another, though one whom he had himself applauded, commenced a series of critical onslaughts on Oehlenschläger, in which the animus was painfully apparent. The public became disgusted, Baggesen found himself in general disfavour, again expatriated himself, and finally died abroad. It must however be owned, that Oehlenschläger stood in need of a little criticism not too indulgent, and that he wrote better after these attacks than he did at the time they commenced. In 1816 he made a second foreign tour to Germany and to France, still using his pen when he halted, but was driven home by severe sickness after a twelvemonth. A long series of plays and poems followed, among which, the most conspicuous was 'Nordens Guder,' the 'Gods of the North' (published in 1819), an attempt to combine into one convenient whole all the scattered legends of the Eddas. The attempt has been pronounced successful; a translation of the work into English verse of very considerable merit by W. E. Frye was published at Paris in 1845, and the poem supplies much of the material for Pigot's 'Manual of Northern Mythology;' a novel, 'The Island in the South Sea,' written originally in German, was, on the contrary, of an unmistakeably inferior character. Oehlenschläger, who at the age of seven-and-thirty took lessons in English from Andersen Feldborg, a Dane long settled in Edinburgh, and well known to Walter Scott, entered into correspondence with Sir Walter to express his warm admiration of his novels; and, on being encouraged, sent the manuscript of his own novel to England to be translated by Mr. Gillies, but in spite of the zealous exertions of Sir Walter, the affair fell through from his inability to find a publisher who would pay 100*l.* to the author and translator for copyright. The failure was a fortunate one for the fame of Oehlenschläger, which would have suffered much in England from a work so unworthy of him.

In 1829, when at the age of fifty, he lost his father. "He was vain of his son," says the poet in the 'Erindringer' "but, like a sensible father, he never allowed me to see it; only sometimes I detected the feeling when he had been reading my poems. It amused him to get into conversation with strangers, and particularly with students on the bench at the hill at Frederiksberg, and lead the conversation to bear on me; when, if they said anything in my praise, it tickled him much, as he used to think he remained incognito. Many good-natured people were aware of this, and often afforded this innocent pleasure to the old man."

The death of his father, and the death of Camma Rahbek and her husband about the same time, threw a gloom over Oehlenschläger's spirits, but they were soon afterwards relieved by a singularly pleasing incident. He took for the first time in his life, in 1829, a trip across the Sound to the coast of Scania, thinking, as the steamer approached the Swedish shore, how strange it was that, though it had always greeted his sight over the waves from his earliest childhood at Frederiksberg, he had lived half a century, and been to Rome, without ever passing the straits. A brilliant reception awaited him from all ranks in Sweden: addresses were presented to him; the students at the University of Lund met him in a body in the high road with a professor at their head. He attended the ceremony of the inauguration of a rector of the university at the cathedral of Lund in company with Tegner, the Bishop of Wexio, who was acknowledged by all as the first poet of Sweden, and was by many considered to have surpassed in his 'Frithiof' any single work of Oehlenschläger's. Tegner, in the course of the delivery of a poetical address in hexameters, suddenly pronounced the lines—

> "Skaldernas Adam är här, den Nordiske Sångarekungen
> Thronarfvingen i Diktningens verld ty Thronen är Goethes;"
>
> (The Adam of poets is here, the northern monarch of minstrels,
> Heir of the sceptre of Song, for now the sceptre is Goethe's;)

and in the presence of the crowd that filled the cathedral, among whom were Oehlenschläger's wife and children, placed a laurel crown on his head, amidst a burst of music and the roar of cannon. The event, from all its circumstances, assumed almost a national significance. Tegner and some other eminent Swedes returned the visit by coming to Copenhagen. A few days after the King of Sweden sent the Order of the North Star to Oehlenschläger.

Honours continued to shower on him after this; one of them, the gift of free lodging by the king, seems however to have been obtained only by a sort of stratagem. "King Christian VIII.," he tells us, "granted me permission to live for one summer in the house of the castle steward at Frederiksberg," (the house which had been the official residence of his father). "I wished very much to get the permission extended to more summers than one. When I thanked the king for his kindness, he asked me if there was not a garden belonging to the house, and if I was not fond of gardening. This gave me an excellent opportunity of bringing in my petition. I answered that I should like very much to garden if I could hope to gather some of the fruit afterwards. The king said that if it was practicable I should have permission to live there; and I then told him, in the lively tone in which he liked to hear me speak, 'For your Majesty a good deal is practicable.' He then gave me permission to keep the house." Soon after, the poet tells us, he changed it for a better.

In 1844, on another visit to Paris, Oehlenschläger was repeatedly invited to court by Louis-Philippe, and presented on one occasion to a gentleman, whom he afterwards found to be King Leopold, who told him he had read all his works in German, and invited him to Brussels. A visit which he paid to Norway, and another in 1847 to Sweden, were like the triumphal progresses of a sovereign in literature. On his sixty-seventh birth day his play of 'Amleth,' on the same story as Shakspere's 'Hamlet,' was produced at Copenhagen. It was completely successful, and the King of Denmark wrote him a letter to congratulate him on his triumph. On his seventieth birthday, the 14th of November, 1849, a grand festival was given in his honour in the great saloon of the Royal Shooting-Gallery. All the leading poets of Denmark were present, and many of them wrote a song for the occasion. Oehlenschläger recited a poetical address of thanks, in which he alluded to his being near the termination of his career, but said—

> "I quaff a goblet with you as a guest;
> The feast I share is not my funeral feast . . .
> Close to us stands the house where I was born,
> And from it to the churchyard's quiet meads
> Beautiful is the avenue that leads."

In little more than two months he was destined to be borne along the avenue to which he had thus symbolically alluded. An illness which did not at first seem serious soon became so, and about eight o'clock in the evening on Sunday the 20th of January 1850 he felt the approach of death. At half past nine he called to his eldest son and told him, "At the theatre on the occasion of my funeral I wish them to act my own tragedy of 'Socrates.' Read to me now that part of the scene in the fifth act between Socrates and Cebes, in which Socrates speaks of death, it is so unspeakably beautiful." The son read the passage—

> "How then can Death affright thee!
> It only can be one of two things, Cebes—
> It must be something or it must be nothing," &c.

ending with

> "Think what a joy then that must be
> E'en with the gods themselves to live,—to speak
> With Hesiod, with Orpheus and with Homer,
> And all the great men who have been before us."

He heard this passage read with the greatest emotion, looking round him with a smile of pleasure. When it was concluded he put an end to the reading and took leave of his family who were standing around the bed. As the clock struck eleven he expired.

The funeral of Oehlenschläger was a national solemnity, like that of Thorvaldsen a few years before. The funeral procession consisted of about 3000 persons, including representatives of the king and queen, the heir of the throne in person, the foreign ambassadors, the professors of the university, the clergy of the capital, and all that was most distinguished. As it emerged from the western gate of Copenhagen it passed the house in which the deceased was born, and halted while the musical societies executed a solemn 'Farewell,' composed for music by Andersen. The procession closed at the church of Frederiksberg, where lies the poet. Grundtvig and Bishop Mynster spoke over the poet's grave. It is the church where his father was organist, and where the boy had first attended divine service.

The estimation in which Oehlenschläger is held by his countrymen is best shown by the commencement of the life of him in Flamand's 'Galleri af berömte Danske Mœnd og Qvinder.' "Small as Denmark is, it must be counted among the great powers in the world of art and poetry, since it has a sculptor to show like Thorvaldsen, whom only the great masters of antiquity can be considered to rival, and a poet like Oehlenschläger, who can worthily take the fourth seat by the side of the three heroes of poetry, Shakspere, Byron, and Göthe." Foersan the translator of Shakspere into Danish sent a copy to Oehlenschläger inscribed "To William Shakspere's Twin-brother." The English writer however to whom Oehlenschläger bears by far the most resemblance is Walter Scott. Though the great Danish writer was unfortunate in pure fiction and the great Scottish writer in the drama, the series of the Scotch novels of the one may be most aptly paralleled by the series of Danish tragedies of the other. In both there is an exuberance of life, a careless felicity, an apparent ease of production, a wonderful 'breadth of effect.'

Oehlenschläger's tragedies are twenty-four in number, and nineteen are on Scandinavian subjects. They are arranged in the last edition in chronological order, and touch upon almost everything of any great interest or importance in Scandinavian history or tradition. Besides those that have been already mentioned there are—'Knud den Store' ('Canute the Great'); 'Væringerne i Miklagord' ('The Varingers in Constantinople'), the hero of which is one of the northern body-guards of the Byzantine monarchs, who were taken as a subject after Oehlenschläger by Sir Walter Scott in 'Count Robert of Paris;' 'Landet fundet og forsvundet' ('Land Found and Lost'), in which are dramatised the incidents of the early discovery of America by the Northmen, latterly brought so prominently before the public by the 'Autiquitates Americanæ;' 'Dina,' a very interesting play founded on the extraordinary story of the Danish Alcibiades, Corfitz Ulfeld; 'Tordenskiold,' the 'Danish Nelson,' on one of whose adventures Oehlenschläger also composed an opera, was published in 1849. These tragedies are the true monument of the fame of Oehlenschläger. If to the ten octavo volumes which contain them, in the fine edition of his works commenced in 1849, be added his 'Aladdin,' his 'Fisherman and his Daughter,' his 'Twin Brothers of Damascus,' and perhaps his 'Robinson Crusoe in England' (a play on the story of Defoe and Alexander Selkirk), his 'Ludlam's Hole,' his 'Garrick in France,' and a few other operas and comedies, a series of dramatic works will be shown which, for extent and value, no other author of the 19th century can rival.

Oehlenschläger's poems, which are sometimes spirited, are for the most part common-place; and his prose works are seldom of a character to claim much attention. His 'Poetical Works,' as they are called, comprising all of his imaginative works, whether in prose or verse, except the tragedies, occupy in the collected edition twenty-seven volumes. If to these be added the 'Erindringer,' four volumes of the same size, the whole series of his Danish works will be found to amount to forty-one volumes. The last edition of his German works reaches to twenty-one. In these sixty-two volumes are not included many translations which flowed from his ever-active pen:—Otway's 'Orphan,' the 'Midsummer Night's Dream,' Beskav's Swedish dramas into Danish, and the whole of Holberg's 'Danish Theatre' into German. In mentioning the 'Midsummer Night's Dream,' it may not be uninteresting to add that Oehlenschläger, though a warm, was not an unconditional admirer of Shakspere. He professed to belong to the old school, who saw great faults as well as great beauties in the bard of Avon. It may be suspected however that his acquaintance with his works was not perfect—his acquaintance with his biography was singularly defective. In a ballad entitled 'William Shakspere,' which is entirely devoid of merit, he speaks of him as being born at Warwick, never apparently having heard of Stratford, and of his gaining his fame at "Drury Lane."

In the general character of Oehlenschläger, as shown in his life, it may be seen that a high estimation of himself was a prominent feature; but this in his case, as in many others, was grounded on real merit. The tone of his 'Autobiography,' not unfrequently reminds the English reader of that of Hogg, the Ettrick Shepherd. Neither of the two was inclined to overlook or undervalue his own claims to attention. It is a more singular circumstance that the merits of the poet were through the course of a long life generously appreciated and rewarded by his countrymen, who by their conduct did no less honour to themselves than to him.

ŒNANTHIC ACID. [Chemistry, *S.* 2.]

ŒNANTHYLE. [Chemistry, *S.* 2.]

OERSTED (ÖRSTED), HANS CHRISTIAN, celebrated as the originator of the science of electro-magnetism, from which sprung the electric telegraph, Professor of Natural Philosophy, and Director of the Polytechnic School of Copenhagen, was born on the 14th of August 1777 at Rudkjöbing, in the Danish island of Langeland, where his father was an apothecary. He studied in the University of Copenhagen, and was made a Doctor of Philosophy in that university in 1800. At this time he studied the subject of galvanism, and discovered that the power of the opposite poles of the galvanic battery to give off acids and alkalies depended on circumstances, and showed that this power was relative. From 1801 to 1803 he studied in Holland and France, returning to Copenhagen, where he was made Professor of Physics in 1806. In 1812 he went to Germany, and whilst there he wrote his essay on the identity of chemical and electrical forces, thus laying the foundation for the subsequent identification of the forces of magnetism, electricity, and galvanism. In 1819 he made the announcement of his great discovery of the intimate relation existing between magnetism and electricity. This announcement was made in an essay entitled, 'Experimenta circa efficaciam conflictus electrici in acum magneticam.' By defining the nature of the influence exerted by the galvanic current on the magnetic needle, he laid the foundations of the science of electro-magnetism, and led the way to its practical application in the production of the electric telegraph. Previous to this time the identity of the forces of magnetism and electricity had only been suspected. He now demonstrated "that there is always a magnetic circulation round the electric conductor, and that the electric current, in accordance with a certain law, always exercises determined and similar impressions on the direction of the magnetic needle, even when it does not pass through the needle, but near it." For this discovery he received the Copley medal of the Royal Society of London, and the French Institute presented him with one of its mathematical class prizes worth 3000 francs.

In 1809 he wrote a 'Manual of Mechanical Physics,' a second edition of which was published in 1844. The re-writing this work led him to make many original researches in many departments of natural philosophy, scarcely any of which have not been enriched by his experiments. He made many important experiments on the compression of water, and invented an instrument by which liquids might be compressed with more certainty. He was the first to demonstrate the existence of the metal aluminium in alumina, and made other chemical discoveries. In 1822-23 he again visited Germany and France, and also visited England. On his return to Denmark he founded the Society for the Distribution of Natural Science, one object of which was to send forth a body of popular lecturers to deliver courses of instruction in the most important towns of the country. He took an active part in the Scandinavian Society of Naturalists, which, like our own British Association for the Advancement of Science, assembles annually in different parts of the country. He again visited England in 1846, during the meeting of the British Association at Southampton.

As he increased in years honours increased upon him. He was made secretary to the Royal Society of Copenhagen; a corresponding member of the Academy of Sciences in the French Institute; and Director of the Polytechnic School at Copenhagen, which he had himself founded. In 1837 he was made Knight of the Legion of Honour, and in 1842 Knight of the Prussian Order for the Reward of Merit in the Arts and Sciences. In early life Oersted was associated with the poet Oehlenschläger, whose sister was married to his younger brother, and although devoted to experimental science he took a deep interest in the progress and development of Danish literature. He was a constant writer for the newspapers and magazines. Acting upon the deep conviction that science should be the handmaid of religion, he did all that lay in his power to make the popular mind of his country acquainted with the facts of natural science. He wrote a lyrical and didactic poem called 'The Balloon,' which was translated into German. He was also one of the most popular lecturers of his day. He not only lectured in the university to young students and senior students, but out of the university to citizens and classes of ladies. A variety of Oersted's papers and lectures of a popular kind have been translated into the English language by the Misses Horner, under the title of 'The Soul in Nature, with Supplementary Contributions.'

On the 9th of November 1850 a jubilee was held in honour of the fiftieth anniversary of his services at the University of Copenhagen. On this occasion people of all ranks and opinions assembled round the noble old philosopher. The king of Denmark presented him on the occasion with a country residence at Frederiksberg, near Copenhagen. He lectured through the winter, but the following March he took a severe cold, which terminated in inflammation of the lungs, of which he died on the 9th of March 1851. A biographical sketch of Oersted, to which we are indebted for some of the materials of this notice, was published by P. L. Möller, a translation of which is published with the English translation mentioned above.

OERSTEDTITE. [MINERALOGY, *S.* 1.]

ŒSTRUS. [BOTS; ŒSTRIDÆ.]

OFFENCES AND PUNISHMENTS. The punishments under the criminal law had been greatly mitigated previous to 1840. In consequence of this, and perhaps still more from the establishment of an effective police in the metropolis by Sir R. Peel's Act, the 10 Geo. 4, cap. 44, which has been gradually extended to the whole of Great Britain and Ireland, though the number of executions has declined, the number of commitments and the proportion of convictions has increased. In 1831 the number of commitments had been 19,647, of whom 3047 were females. Of these 13,830 had been convicted, and 1601 sentenced to capital punishments. Of these only 52 were executed, 12 being for murder. Up to 1834 there had been no classification of offences. From that year and subsequently they have been classed under the following heads, from which it will be seen that the increase of offences has been, in England and Scotland, chiefly in offences against property without violence: Class 1, offences against the person; 2, offences against property, committed with violence; 3, offences against property, committed without violence; 4, malicious offences against property; 5, forgery and offences against the currency; 6, other offences, not included in the foregoing classes. In 1835 there were 20,731 commitments, of which 2016 was under class 1, 1354 under class 2, 15,478 under class 3, 156 under class 4, 368 under class 5, and 1359 under class 6. Of the total 14,729 were convicted, of whom 523 were sentenced to capital punishment, and 34 executed, of whom 21 were for murder. In 1840 there were 27,187 commitments, of which 21,484 were under class 3, and 19,927 convictions; of these 77 were sentenced to capital punishments, 9 of whom were executed, all for murder. In 1845 there were 24,303 commitments, of which 19,506 were under class 3, and 17,402 convictions; of these 49 were sentenced to capital punishments, and 12 executed, all for murder. In 1850, in England there were 26,813 commitments, of which 1886 were under class 1, 2014 under class 2, 21,353 under class 3, 236 under class 4, 680 under class 5, and 744 under class 6. Of the total there were 20,539 convicted, of whom 49 were sentenced to capital punishment, and 9 executed. In Ireland there were 31,326 commitments, of which 4202 were under class 1, 2224 under class 2, 16,737 under class 3, 462 under class 4, 250 under class 5, and 7451 under class 6. Of the total only 17,108 were convicted, of whom 17 were sentenced to capital punishment, and 8 executed. In Scotland there were 4468 commitments, of which 1192 were under class 1, 676 under class 2, 2150 under class 3, 49 under class 4, 170 under class 5, and 231 under class 6. Of the total, 3633 were convicted, of whom 3 were sentenced to capital punishment, and 2 executed. In 1856, the latest returns we have, there were in England 19,437 persons committed for trial, of whom 15,425 were males and 4012 females; of these, 4672 were acquitted or discharged and 31 were found insane; of the number convicted, 1264 were for offences against the person, 1787 for offences against property with violence, 10,487 for offences against property without violence, 94 for malicious offences against property, 757 for forgery and offences against the currency, and 345 for offences not included in the preceding classes and including misdemeanors; 69 were sentenced to death, of whom 16 were executed; 57 were transported for life, and 216 for terms exceeding ten years; 2158 were sentenced to penal imprisonment for terms varying from four years to life; 11,865 were sentenced to various imprisonments from one month and under to not exceeding four years; and in this class, in the terms betwixt six months and one month or less, the numbers show a remarkable decrease from previous years; in 1856 the numbers were 7800, against 13,447 in 1855, and 16,509 in 1854; indeed it is by far the smallest amount in any year from 1847; 222 were ordered to be detained in reformatory schools, and 127 were whipped, fined, or discharged on sureties. The great decrease in the number of commitments is probably to be attributed in a considerable degree to the extended provisions of the Summary Convictions Acts. On summary proceedings, the number of cases under the Criminal Justice Act, was 11,272, and under the Juvenile Offenders' Act, 2031. Altogether there were 132,869 persons committed to prison, 99,336 of whom were males and 33,363 females. The commitments were—19,278 for trial, 77,712 on summary convictions, 2794 for want of sureties, 13,952 remanded and discharged, 11,406 debtors on civil process, and 7557 under the Mutiny Act. The total shows an increase of nearly 4000 commitments over those for 1855; but there is a decrease of 7000 in the number of summary convictions. Of the committals, omitting debtors and military prisoners, which reduce the number to 113,736, 1990 were of children under 12 years of age; 11,991 of persons between 12 and 16; 24,868 between 16 and 21; 33,400 between 21 and 30; 20,973 between 30 and 40; 11,343 between 40 and 50; 5519 between 50 and 60; 2732 above 60; and 920 of whom the age was not ascertained. Of the whole, 37,686 could neither read nor write, 61,253 could read or read and write imperfectly, 6108 could read and write well, 318 had received superior instruction, and of 8371 the instruction was not ascertained. The county and borough prisons are stated to be constructed to contain 26,447 prisoners; the daily average of prisoners is 17,754, and the greatest nnmber at one time was 22,035: bnt, thongh on the average there may be room enongh, some prisons are terribly overcrowded.

In Ireland in 1856 the total nnmber of persons committed or held to bail for trial was 7009, of whom 3075 were either acquitted or discharged. Of the nnmber committed, 2063 were for offences against the person, 556 for offences against property with violence, 2884 for offences against property withont violence, 78 for malicions offences against property, 75 for forgery and offences against the currency, and 1143 for other miscellaneous offences. Of those convicted only 8 were sentenced to death, and 3 only execnted; 14 sentenced to transportation for life, and 372 to other periods of transportation or penal servitude; 2798 to various terms of imprisonment; and 832 were whipped or fined, or discharged on surety, or pardoned. In the same year there were 25,461 cases heard at petty sessions or before magistrates, and 9526 persons were imprisoned for drunkenness.

In Scotland in 1856 the total number of offenders committed for trial was 3713. Of these 1046 were for offences against the person, 380 for offences against property committed with violence, 1942 for offences against property without violeuce, 79 for malicious offences against property, 85 for forgery and offences against the cnrrency, and 181 other offences not included in the preceding classes. Of the total nnmber committed, 2723 were convicted, of whom 3 were sentenced to death and executed, 274 sentenced to varions periods of transportation and penal servitnde, 2170 to varions periods of imprisonment, and 276 to he whipped, fined, or discharged on sureties. Of those not convicted, 35 were outlawed, 7 were fonnd insane, 55 were fonnd not guilty, and 179 not proven; the remainder were discharged withont trial.

OIDIUM, a genns of Plants belonging to the order of *Fungi*, some of the species of which are fonnd npon the human body and others attack plants. It is known by possessing a simple or branched mycelium, which is very minute and pellucid, aggregated into floccnlent masses slightly interwoven and articulated. The sporidia are simple and pellucid, and arise from the joint of the mycelinm.

O. albicans, the Thrush-Fungus, is fonnd in the mncons memhrane of the mouth, fauces, and œsophagus of sncking children, and also occasionally in grown-np persons in a state of extreme exhanstion. The nlcerations, amidst the discharge of which this fungus is fonnd, are usually called thrush. Although constantly present in this disease the fungus does not appear to produce the disease, but to be the resnlt of the changes produced in the mucous membrane. It has been ohserved that the mucous memhrane in this state constantly affords an acid re-action, and this acidity seems necessary to the growth of the fungus. The best account of this fnngus will be found in Robin's 'Histoire des Végétaux Parasites.' Several other species of *Oidium* have been described. The fungus fonnd in connection with the recent grape-vine disease is an *Oidium*. [ENTOPHYTA, S. 2; FUNGI.]

OIL-PALM. [ELÆIS.]

OIL-TREE. [BASSIA.]

OILS. The *Fixed Oils* are mostly prodncts of animal organization, in the fat and adipose tissue; but are fonnd also in plants, generally in the seeds, but in some cases in the fruit, as in the olive. They are composed of carhon, hydrogen, and oxygen, and are liquid or solid according to the manner in which these elements are disposed, most of them consisting of two compounds, a liquid called Olein, and a solid called Margarin, or another solid called Stearin. The *Volatile Oils* are mostly products of vegetable organization, and are so called on account of the ready manner in which they are volatilized by heat. Plants owe their peculiar odours to the volatile oils. They are divided by chemists into three gronps: those which consist of only carbon and hydrogen, as oil of turpentine; those which contain also oxygen, as oil of cloves; and those which contain sulphur, as oil of garlic. [OILS.]

OKEN, LORENZ, a celebrated Swiss naturalist, was born at Offenberg on the 2nd of August 1779. He studied mediciue and natural history at Göttingen, and held the position of privat-docens in that university. In 1807 he became extraordinary professor of medicine in the university of Jena; thence he removed to Zürich, where he held the post of professor of natnral history till his death. At the time he began to stndy natural science, the writings of Kant, Fichte, and Schelling were producing a deep impression on the minds of the students of natural history. Schelling, who had studied medicine, had applied the principles of the transcendental philosophy to the facts of the natnral world, and had by a process of thought endeavonred to give an explanation to the phenomena of natnre. It was in this school that Oken stndied, and the principles of the transcendental philosophy more or less guided his researches as a natnralist throughont his long life. His first work was pnblished in 1802, and was entitled 'Elements of Natural Philosophy, the Theory of the Senses, and the Classification of Animals founded thereon.' This was followed by a work 'On Generation' in 1805. In these works he endeavoured to apply a general theory of nature to the facts presented by the forms and the development of animals. In his classification he took for his basis the presence of the senses, making each class of animals to represent an organ of sense. In his work 'On Generation' he first suggested that all animals are bnilt up of vesicles or cells. In 1806 he pnhlished his 'Contributions to Comparative Anatomy and Physiology,' and pointed ont the origin of the intestines in the nmbilical vesicle. In this year he made an excursion to the Harz Mountains, which resulted in an important thought. This may be described in his own language: "In August 1806," he says, "I made a journey over the Harz. I slid down through the wood on the south side; and straight before me, at my feet, lay a most beantiful bleached skull of a hind. I picked it np, turned it round, regarded it intensely: the thing was done. 'It is a vertehral colnmn!' struck me, as a flash of lightning, to the marrow and bone; and since that time the skull has been regarded as a vertebral column." This discovery was published in an essay on the 'Signification of the Bones of the Skull.' This essay, althongh it attracted little attention at first, laid the foundation of those inquiries which in the hands of Carus, Géoffroy St.-Hilaire, and Owen, have led to the estahlishment of those laws of homology in the vertehrate skeleton that are now a universally received hranch of anatomical science. It was by the persevering nse of the idea that flashed across his mind in the Harz, that Oken has earned for himself the title of "the father of morphological science."

Whilst still a young man and deeply convinced of the importance of an ideal philosophy in explaining the phenomena of the external world, he wrote his 'Lehrhuch der Natur-Philosophie.' This work was published in 1809, and having gone through three editions, it was translated into English by Mr. Faulke, and published in 1847, by the Ray Society, with the title 'Elements of Physio-Philosophy.' In this work the author takes the widest possible view of natural science, and classifies the mineral, vegetable, and animal kingdoms according to his philosophical views. The trausceudental philosophy has never been popular in England, and its language is entirely foreign to that adopted by the generality of writers on natural history in this country, so that this work has been freqnently regarded as the offspring of a diseased imagination rather than the cool decisions of a philosopher. Nevertheless, the author was pleased at its translation, and wrote a preface to the English edition. Of however little value this work may he as an introduction to modern science, it is interesting as a docnment in the history of a great mental movement, and contains the germs of those principles which are now regarded as the secure generalisation of well-observed facts.

From the date of the publication of this work to the day of his death, Oken unceasingly contribnted to the literature of natural history. In the year 1817, he started a natural history jonrnal, named 'Isis,' which he conducted for thirty years, and which contains a large series of his papers on every department of natnral history. Thongh a transcendentalist in philosophy, he was an energetic and acute observer, and has contributed largely to the individual history of the animal kingdom.

He was greatly respected throughont Germany, and it was at his suggestion that the first meeting of natural philosophers took place in 1822. The German Association which thus came into existence, has assembled every year in one of the large towns of Germany, whilst every country in Europe has imitated this example with great and increasing success. Oken died full of years and honour, at Zürich, in August 1847.

OKENITE. [MINERALOGY, S. 1.]

OLD RED-SANDSTONE. The following table and account of the Old Red-Sandstone Formation is given by Professor Ansted in his 'Elementary Geology':—

Old Red-Sandstone Series.

Herefordshire.	Scotland.
Old Red Conglomerate . .	Quartzose Yellow Sandstone.
	Impure Limestone.
	Gritty Red-Sandstone.
Cornstone	Grey Fissile Sandstone.
Cornstone and Marl . .	Red and Variagated Sandstone.
	Bituminous Schist.
	Coarse Gritty Sandstone.
	Great Conglomerate.

Devonian Series.

Devonshire.	Belgium.
Calcareous Grit and Impure Limestone . . .	Indurated Shale and Psammite.
	Calcareous Shale.
Red Flagstone . . .	Lower Limestone of Belgium.
Calcareous Slate and Plymouth Limestone . .	Hard Siliceous Beds and Conglomerates.

The fossils of this period include many species of corals, encrinites, and shells. There are also a number of remains of fishes, some of very great interest from the remarkable peculiarities of form and structure which they present. Many of these are small, but others of gigantic proportions.

The Old Red-Sandstone of England and Wales consists of various strata of limestone, marl, and sandstone, alternating with great thicknesses of conglomerate, which often pass upwards into overlying sandstones; and the series is expanded over a considerable portion of our island, rising into lofty mountains, occupying extensive plains, and developed to an enormous thickness.

In North Wales, although the Old Red-Sandstone retains its general character, we find it inferior in thickness and importance to its development in Herefordshire and South Wales. It again increases, however, as we advance still farther northward into Westmoreland and Cumberland, where it appears as an irregular conglomerate. In this part of England its largest development is near the foot of Ullswater, and it rises into a succession of round-topped hills several hundred feet high, the beds being of great thickness. No true passage is there discernible into the overlying limestones.

The loftiest points occupied by this deposit are the Vans of Caermarthen and Brecon, the former 2590 and the latter 2500 feet above the level of the sea. These hills are made up of a conglomerate composed of white quartz pebbles embedded in a red matrix; and it is this quartzose conglomerate which gives its name to the uppermost group of the formation.

The highest beds of the series do not however always consist of conglomerates, but are more frequently composed of beds of sandstone, hard and finely grained, and alternating with a few imperfectly exhibited mottled marls. The lower portion capping the escarpment of the Cornstone in Herefordshire furnishes thick beds of valuable building material, and is occasionally quarried for tiles. The upper beds are for the most part less compact, and commencing as a fine conglomerate they afterwards become coarser, and alternate with bands of red and green argillaceous marl. Fine examples of the conglomerate beds (attaining near Abergavenny a thickness of 200 feet) may be seen on the banks of the Wye between Ross and Monmouth, and again on the right bank of that beautiful river to the north of Tintern Abbey.

The Cornstone consists of a number of argillaceous marly beds, sometimes alternating with sandstone and sometimes with impure limestone, affording by decomposition the soil of the richest tracts of Herefordshire and Monmouthshire. The lower part of this rock very often contains flaggy beds, some of which are extensively quarried near Downton Hall, the stone being of a greenish colour and highly micaceous, and usually more or less intermixed with party-coloured marls or soft argillaceous sandstones, not so compact as the rock which incloses them. The surface of the sandstone is frequently worn into irregular holes and patches.

But the subdivisions of the sandstones are too entirely local to allow of any lithological character being given which can apply to more than a very limited district. Generally speaking, the impure concretionary limestone, which is more especially denominated Cornstone, appears at intervals in irregular lenticular masses throughout the district, contracting and expanding in the most capricious manner; sometimes replaced by finer and more crystalline limestone, and sometimes alternating with hard flaggy sandstones. Nearly the whole of the central and northern parts of Herefordshire, and the contiguous parts of Shropshire and Worcestershire, are occupied by this formation; and its vast thickness is well displayed in the hills crossed by the new road from Leominster to Hereford. In the northern portion of the range, and near the mouth of the Towey in Caermarthenshire, the limestones are most fully developed, becoming much thicker and almost more crystalline than in other parts.

In Scotland the uppermost beds are highly arenaceous, and often consist of sandstone conglomerates. The intermediate calcareous band is barren of fossils, and is of somewhat singular composition, yielding unequally to the weather, and exhibiting a brecciated aspect. It contains masses of chert exceedingly hard, and these, from the manner in which they are incorporated with the rock, appear to have been of contemporaneous origin. The bed is several yards in thickness, and is very persistent, being found both in Moray and in Fife, localities 120 miles apart.

The middle group of the Old Red-Sandstone of Scotland, corresponding to the Cornstone of England, is developed in Forfarshire, in Morayshire, and in the Gray-Sandstone of Balruddery, where the lower beds are absent. It is represented as consisting, for the most part, of rocks of a bluish-gray colour, sometimes, as at Balruddery, resembling the silurian mudstones, at others forming a hard fissile flagstone exported as a paving-stone, and occasionally appearing in beds of friable stratified clay, easily washed away by the sea. The colour however throughout is gray, and in this respect differs essentially from the English contemporaneous beds, which are chiefly red and green marls.

The base of the whole system is represented by Mr. Miller as consisting of an extensive and thick conglomerate rising into a lofty mountain-chain in the county of Caithness, and attaining an elevation of 3500 feet in the hill called Morrheim, but a great thickness of arenaceous strata, containing conglomerates of various magnitude, intervenes between these and the middle beds.

The Devonian Beds present a series so distinct that no relations of mineral or mechanical condition can be traced between them and the Old Red-Sandstones. The upper beds on which the culms of Devonshire repose, consist of coarse red flags and slates, sometimes alternating with or overlaid by other slates and limestones, while the lower beds are to be sought for among the calcareous slates of Cornwall and South Devon. The calcareous slates are occasionally fossiliferous, and are based upon an impure limestone. The Plymouth limestone in the south, and a group of coarse arenaceous beds in the north of Devon, together with the general series of Cornish rocks, are all included among these calcareous slates. Throughout the whole series fossils occur, but they are very unequally distributed, being locally abundant, although owing to the metamorphic character of many of the beds they are sometimes much altered, and frequently obliterated. (Ansted.)

The Old Red-Sandstone is largely developed in Ireland, and is peculiarly interesting as presenting all those parts of the series which are found in different parts of England.

This formation is well represented in Belgium by a series of beds consisting of 1500 feet of strata. They are principally composed of a yellowish-sandstone alternating with shale and calcareous beds.

The Devonian or Old Red-Sandstones of Russia occupy a tract nearly as large as the whole of the British Islands. They rest conformably upon low plateaux of silurian rocks, and attain a height of from 500 to 900 feet above the sea level.

This formation is repeated with nearly the same mineral characters and organic remains in America. It is found in both North and South America.

The following are the genera of the Invertebrate Fossils found in the Devonian Group, as given by Mr. Tennant in his 'Stratigraphical List of British Fossils':—

Amorphozoa.

Manon cribrosum, Goldf.
Scyphia turbinata, Goldf.

Zoophyta.

Amplexus tortuosus, Phil.
Astrea, Blainv., 3 species.
Aulopora conglomerata, Goldf.
Caunopora ramosa, Phil.
Coscinopora placenta, Goldf.
Cyathophyllum, 2 species.
Cystiphyllum, 2 species.
Favosites, 4 species.
Fenestella, 5 species.
Glauconome bipinnata, Phil.
Gorgonia ripisteria, Goldf.
Hemitrypa oculata, Phil.
Millepora gracilis, Phil.
Millepora similis, Phil.
Petraia, 4 species.
Porites pyriformis, Ehrenb.
Stromatopora, 2 species.
Strombodes, 2 species.
Syringopora catenata, Mart.

Echinodermata.

Adelocrinus hystrix, Phil.
Cyathocrinus, 8 species.
Pentatrematites ovalis, Goldf.
Platycrinus, 2 species.
Taxocrinus macrodactylus, Phil.

Crustacea.

Brontes flabellifer, Goldf.
Calymene Sternbergii, Munst.
Harpes macrocephalus, Goldf.
Olenus punctatus, Stein.
Phacops, 3 species.

Conchifera Dimyaria.

Corbula Hennahii, Sow.
Cucullæa, 7 species.
Cypricardia, 2 species.
Megalodon, 2 species.
Modiola, 3 species.
Mytilus Damnoniensis, Phil.
Nucula, 3 species.
Pleurorhyncus, 2 species.
Pullastra, 3 species.
Sanguinolaria, 3 species.

Conchifera Monomyaria.

Avicula, 9 species.
Pecten, 8 species.
Posidonomya, 2 species.
Pterinea, 3 species.

Brachiopoda.

Atrypa, 19 species.
Calceola sandalina, Lam.
Chonetes, 3 species.
Leptæna, 7 species.
Orthis, 16 species.
Productus, 6 species.
Spirifer, 33 species.
Strigocephalus, 3 species.
Terebratula, 31 species.

Gasteropoda.

Acroculia sigmoidalis, Phil.
Buccinum, 4 species.
Euomphalus, 3 species.
Loxonema, 8 species.
Macrocheilus, 3 species.
Murchisonia, 6 species.
Murex harpula, Sow.
Natica, 2 species.
Nerita, 2 species.
Platyceras vetustum, Sow.
Pleurotomaria, 8 species.
Schizostoma, 2 species.
Trochus Boueii, Stein.
Turbo, 3 species.

Heteropoda.

Bellerophon, 8 species.
Porcellia Woodwardii, Sow.

Pteropoda.

Creseis dimidiatum (*Orthoceras*, *sp.* Sow.)

Cephalopoda.

Clymenia, 7 species.
Cyrtoceras, 12 species.
Goniatites, 11 species.
Nautilus, 2 species.
Orthoceras, 12 species.

OLDBURY, Worcestershire, a town in the parish of Hales Owen, is situated near the junction of Staffordshire, Shropshire, and Worcestershire, in 52° 30′ N. lat., 2° W. long., distant 29 miles N.N.E. from Worcester, and 120 miles N.W. from London. The population of the town of Oldbury is given in the Returns of the Census of 1851 as 5114, but this does not include the whole of the town. The entire population in 1851 was 11,641.

The town of Oldbury has very much increased of late years, owing to the extension of the iron trade. The parochial chapel of Christchurch is a commodious brick edifice with a square tower. There are chapels for Wesleyan, Primitive, and New Connexion Methodists, Baptists, Independents, Christian Brethren, Roman Catholics, and Unitarians; and National, Free, and other schools. Besides numerous iron and coal mines in the vicinity, there are manufactures of iron and steel, of locomotive engines, malt-mills, edge-tools, hollow iron ware, bricks, earthen draining tubes, and of alkali. Boat-building is carried on, and there are corn-mills and breweries. Oldbury is nearly surrounded by the Birmingham Canal; the river Tame runs through the town, turning several mills in its course; and the Stour Valley railway passes close to it. A customary market is held weekly on Saturday. A county court is held in the town.

OLDCASTLE. [Meath.]
OLEANDER. [Nerium, *S.* 1.]
OLEGON SPAR. [Mineralogy, *S.* 1.]
OLEIN. [Tissues, Organic, *S.* 1.]
OLIGOCLASE. [Mineralogy, *S.* 1.]
OLIVENITE. [Mineralogy, *S.* 1.]
OLLERTON. [Nottinghamshire.]
OLNEY. [Buckinghamshire.]
OMAGH. [Tyrone.]
OMALISUS. [Lampyridæ.]

OMMASTREPHES, a genus of Cuttle-Fishes belonging to the family *Teuthidæ*. Body fleshy, firm, cylindrical, elongated, flanked near its posterior extremity by two triangular fins. Locomotive apparatus formed of "conical perpendicular pits, each communicating by a narrow groove with a small horizontal pit, surrounded by a prominent margin, the whole describing a rather prominent triangle, placed at the base of the locomotive tube; and, besides, of a tubercle prolonged into its upper part into a decreasing nose-shaped crest; and lastly, of little horizontal inferior crests placed on the inner margin of the body." Eyes very large, opening widely exteriorly, and provided with a lachrymal sinus; arms 10, like those of *Loligo;* pen corneous, flexible, elongated, as long as the body, terminating at its lower extremity in a hollow simple cup.

The Cuttle-Fishes of this genus closely resemble those belonging to *Loligo*. Besides the character just given, they may generally be distinguished by the short rhomboidal termination of the body, formed by the fins, combined with the hinder extremity.

The species are mostly pelagic, and some of them are gregarious. They seem to be distributed all over the world. They are called Flying Squids by Fishermen. (Forbes and Hanley.)

The following species have been taken on the British coasts:—

O. sagittatus (*Sepia Loligo*, Linnæus), with an elongated body; peduncles of tentacular arms without suckers; extremities of their clubs covered with closely set rows of numerous minute suckers. This species is very rare on the British coast, but Messrs. Forbes and Hanley record two instances of its recent capture. M. d'Orbigny regards the *Loligo Piscatorum*, *L. Harpago*, *L. illecebrosa*, and *L. Coindetii* as founded on this species.

O. todarus (*Loligo sagittata*, Lam.), Delle Chiaje. It has an elongated body, and the peduncles of the tentacula provided with suckers throughout their length. This squid is often called in British catalogues *Loligo sagittata*. It is frequently found on the coasts of Great Britain. It has been made the subject of an elaborate memoir on the anatomy of its nervous system by Mr. Albany Hancock.

O. Eblana (Ball), has a short body; suckers confined to the clubs of the tentacles, minute, and 4-ranked at their extremities. It has been found in Dublin Bay, and was first described by Dr. R. Ball of Dublin.

(Forbes and Hanley, *History of British Mollusca.*)

OMPHALEA, a genus of Plants belonging to the natural order *Euphorbiaceæ*. The seeds of one of the species are said to be eatable when the embryo is extracted, but if this is not done, they are too cathartic for food. On the authority of Mr. W. M'Leay, Dr. Lindley says this nut is most delicious and wholesome, and that it is known by the name of Cob-Nut or Hog-Nut in Jamaica. Other euphorbiaceous seeds have the same properties.

O. triandra is a Guyana plant with a white juice, which turns black on drying, and is then used as ink.

ONYX. [Agate.]

OOLITE. [Geology; Oolite.] At one time it was supposed that the little round masses which are so characteristic of the Oolitic Formation were portions of limestone which had gathered round various forms of minute fossil animals. It was suggested that these organisms were probably *Foraminifera*. Recent microscopic investigations have however shown that these little round bodies are purely inorganic, and that they are formed in the same manner as the larger nodules of the magnesian limestone.

The oolitic deposits are divided naturally in England into three parts, the Upper Oolite resting on the Kimmeridge Clay, the Middle Oolite representing the Oxford Clay covered by the Coral Rag, while the Lower Oolite is more varied, being composed of numerous bands of clay, sand, and limestone.

The *Upper Oolites*, called on the Continent the Portlandian Group, are, so far as the British Islands are concerned, almost entirely confined in their development to the south of England, only that stratum of clay which usually forms the base of the group being exhibited in Yorkshire, in the vale of Pickering.

The group of strata containing the Portland stone, and exhibited in Portland Island, includes several layers of coarse earthy limestone, which rest on a bed of siliceous sand, mixed with green particles. This is called the Portland Sand, and sometimes attains a thickness of as much as 80 feet in the west of the island, and forms a complete passage into the underlying clay.

Above the coarse limestones of the lower part, which usually consist of alternate hard and soft layers to a thickness of 50 or 60 feet, there are three beds of serviceable stone, interstratified with clayey or siliceous bands. Fossils occur in all these strata; but they are rare in those beds of the stone which are worked to advantage for economical purposes.

In the upper part of the Portland series there occurs a very interesting bed, about a foot in thickness, of a dark-brown substance, containing much earthy lignite. This bed, called the Dirt-Bed, seems to be made up of black loam, which at some distant period nourished the roots of trees, fragments of whose stems are now found fossilised around it. Wherever the dirt-bed is laid open to extract the subjacent building-stone these remains of trees occur, and they are placed at such distances from one another as trees growing in a modern forest.

It results from the circumstances of this deposit, that the surface of the Portland stone, at the termination of the Oolitic period, must have been for some time dry land, and covered with a forest; and we have a kind of measure even of the duration of this period in the thickness of the dirt-bed, which has accumulated more than a foot of black earth, loaded with the wreck of its former vegetation. "The regular and uniform preservation also of this thin bed over a distance of so many miles, shows that the change from dry land to the state of a fresh-water lake or æstuary (which the nature of the overlying rock proves to have succeeded the period of dry land) was not accompanied by any violent denudation or rush of water, since the loose earth, together with the trees which lay prostrate on its surface, must inevitably have been swept away had any such violent catastrophe then taken place."

The *Kimmeridge Clay* is of a blue, slaty, or grayish-yellow colour. It frequently contains a considerable quantity of silenite, or crystallised sulphate of lime. It usually effervesces with acids, and exhibits in tolerable abundance both vegetable and animal impressions, although its fossils are rarely in such good condition as to be preservable in a collection. It is a bed of great thickness; horizontal, or nearly so, in its stratification; extremely persistent in its peculiar mineral and fossil characters, but not very extensively developed either in England or on the Continent. The name, Kimmeridge Clay, has been applied to it because it is well exhibited at Kimmeridge Bay, and near the village bearing the same name in the Isle of Purbeck.

At this spot there are also found, alternating with the clay, certain beds of highly bituminous shale, occasionally used for fuel, and locally known as the Kimmeridge Coal. There are many beds of lignite found in the Oolites, but these are perhaps the most remarkable, next to those of the lowest Oolitic deposits of Yorkshire and North America.

Among the foreign rocks of this part of the oolitic period are—1st, the Calcaire de Blangy, on the coast of Normandy; 2nd, the upper beds of the Jura, in Switzerland; and 3rd, the Solenhofen beds.

On the banks of the Donetz, in Southern Russia, there are beds of Oolitic Limestone of light-yellow colour, which appear to belong to this division of the secondary series.

The *Middle Oolites* consist for the most part of a thick bed of clay, called the *Oxford Clay*, widely expanded throughout England, and met with also in the same form on the Continent, and a series of overlying limestones, chiefly remarkable for the abundant remains of coral found in them.

The upper beds of the middle Oolitic Series are partly calcareous and partly sandy, the former consisting chiefly of a very interesting group of corals known under the name of Coral-Rag, and the latter, the sandy beds, or calcareous grits, often more or less intermixed with calcareous matter, and containing thin laminæ of clay sometimes passing into irregular bands of hard and tough marly rock. This calcareous matter seems entirely due to the presence of crushed and decomposed organic remains.

It is chiefly in Wiltshire, near the towns of Calne and Steeple Ashton, and in the surrounding neighbourhood, that the corals of the Coral-Rag are found in greater abundance and perfection; and this part of our island, at the time of the deposit, has clearly existed in the condition of a coral island in an open sea. The thickness of the bed is about 40 feet; large portions of it are frequently made up of the remains of a single species, and an earthy calcareous freestone, sometimes used as a building-stone, and full of fragments of shells, rests immediately upon it, and is surmounted by a fine-grained ferruginous sandstone, slightly oolitic in structure, and containing a few fossils, marking the close of the Middle Oolitic period.

In the north of England the contemporaneous bed is a calcareous deposit, also containing corals, but (as at Malton, in Yorkshire), including a considerable proportion of the fossil remains of shells, both bivalves and univalves. The bed never loses its coralline character, and may perhaps represent an imperfect coral reef, once extending from the south-west of England to what is now the right bank of the Humber.

The *Oxford Clay* is a very important member of the oolitic series, attaining a thickness of not less than 500 feet, and spreading over a great part of England—more especially occupying the fen-districts in the counties of Cambridge and Lincoln, which appear to be partly caused by the union of this bed with the Kimmeridge Clay, producing a wide expanse of flat and undrained country. The same deposits are well seen at Weymouth; and they cover an important part of the East Riding of Yorkshire. The stratification throughout is nearly horizontal and undisturbed, being conformable with that of the formations immediately above and below it.

The appearance of the Oxford Clay is that of a stiff pale-blue argillaceous bed, containing a large proportion of calcareous matter, and a more or less abundant mixture of iron pyrites. Numerous organic remains are found in it, which are sometimes preserved in the clay itself, but more frequently form a nucleus, about which iron pyrites have aggregated. Those preserved in the clay have been generally found in a very rotten condition.

The *Lower Oolites* admit of considerable subdivision in the British Islands, but the details seem to be rather of local than general interest; and though partially extending to Normandy, are by no means universal in other parts of Europe.

1. The Cornbrash (the uppermost bed) consists of a variable thickness of clays and sandstones, which ultimately pass into a thin rubbly stone, tough and occasionally crystalline.

2. The Forest Marble, which consists of carbonate of lime.

3. The Great Oolite, consisting of a variable series of coarse shelly limestones.

4. The Bradford Clay, consisting of a pale-greenish clay, containing a small proportion of calcareous matter, and inclosing thin slabs of tough brownish limestone.

5. The Great Oolite is separated from the next bed, containing amongst them the clay used in the manufacture of cloth under the name of Fuller's Earth, and also a thin calcareous flag-stone known as the Stonesfield Slate. The latter is remarkable for containing the remains of Marsupiate Animals. [MARSUPIALIA.]

6. The Inferior Oolite is the last of the series of oolitic limestones. It is employed to a great extent as a building material. Its representative in France is the Caen Limestone.

The oolitic system embraces also the formation called Lias. In England it consists of a series of strata in which an argillaceous character predominates throughout; it also contains limestone mixed with clay. It seems to form four principal members, which are thus described by Professor Ansted.

"The Upper Lias, or Alum-Shale, is best seen at Whitby, and on the Yorkshire coast, and it attains there a considerable thickness. It consists of three distinct parts: the lowest division including soft shales, extremely fossiliferous, which are separated from the uppermost series, also composed of incoherent slaty beds, by an intermediate stratum of hard shale, about 30 feet thick, containing a quantity of the mineral called jet, and also occasionally large fragments of the bituminised wood of coniferous trees. The jet itself is but a peculiar form of carbon, and there can be little doubt that it is of organic origin. It is in the upper shales of the lias, both on the coast of Yorkshire and at Lyme Regis, that there have been found the most remarkable and interesting of those fossil remains of extinct animals, for which the formation is so celebrated. The presence of alternate bands of tolerably hard limestone and soft shale is usually characteristic of the lias in the different parts of England where it is most developed. The dark bluish-gray colour, united with the singular riband-like structure, is more particularly remarkable in the upper beds of the formation, and is well seen at Lyme Regis, Whitby, and Barrow-upon-Soar, in Leicestershire.

"The principal locality of the middle beds of the lias is the neighbourhood of Cheltenham, where the marlstone of Dumbleton Hill is crowded with interesting organic remains. It is made up of alternating layers of coloured clays and sands, which are occasionally calcareous, and of beds of impure limestone.

"This part of the series is also represented in the north of England, where it has an average thickness of about 130 feet, and consists of sandy shales, of which the upper portions are distinguished by the presence of several bands of argillaceous irony nodules.

"Lower Lias Shale.—The great mass of the lower division of the Lias is found in the middle of England, and consists of thick beds of dark-coloured and finely laminated shale, in which are calcareous bands and concretions. These form the base of the series, and graduate downwards into a whitish sandstone, belonging to the uppermost beds of the New Red-Sandstone system. The transition is different again in the south of England; and at Lyme Regis marls of a light-bluish colour represent the upper beds of the New Red-Sandstone and pass into the Lias Limestone by a succession of dark slaty marls, which are overlaid by a number of gray calcareous beds, and these again by other slaty marls of the upper series. The Marlstone and Upper Lias Shales are not present in this part of the deposit in their ordinary form.

"The lowest portion of the Liassic System occasionally consists of a very thin bed, in some places entirely made up of the fragments of fossil bodies (chiefly the remains of fish), but sometimes passing into a white micaceous sandstone, still recognisable as the same bed. This bed was first observed underlying a small patch of Lias, near the town of Aust (situated on the left bank of the Severn, nearly opposite the mouth of the Wye); but it has since been recognised at Axmouth, in Devonshire, and in other parts of England farther north, having a total range of upwards of 100 miles. It is rarely more than 2 or 3 inches in thickness, but invariably occupies the same geological position, and is for the most part so exclusively composed of organic remains, that a long period must have been required for its formation. In some parts of the country, and especially in Gloucestershire and Worcestershire, the passage of the Lias into the underlying beds of New Red-Sandstone is marked by the presence of calcareous flagstones, called Lower Lias Limestones; and these usually alternate with laminated shales, the whole in that case forming together the lowest deposits of Lias.

"On the Continent the Lias is frequently found, and the upper beds resemble those developed in England; the middle however are usually more calcareous, and the lower more sandy, and these latter sometimes, as in Belgium, pass insensibly into the upper New Red-Sandstone. The town of Luxemburg is built upon a hard sandstone of this kind, and these beds pass into the rock called Arkose, a peculiar and often metalliferous metamorphosed deposit, occurring where the Lias sands come in contact with crystalline rocks. Fossils have been found in South America, and also in Northern India, attributed to the period we are now considering.

"The Lias is a formation exceedingly rich in fossils; and amongst them are representatives of all the principal natural groups. Corals however are exceedingly rare, and of small size. Encrinites are numerous and abundant, especially the Pentacrinite, which attached itself to floating wood. Radiated animals of other kinds characterise parts of the deposits, and of these the *Diadema* is an example. Insects and Crustaceans have been frequently found. Star-Fishes are common in the marlstone.

"Both univalve and bivalve shells of various kinds are characteristic either of the whole deposit or of different beds. The *Spirifer* is one of the latter species of a genus represented far more abundantly in more ancient deposits, while the *Plicatula* and *Plagiostoma* are among the ancient representatives of more recent forms. The *Pecten* is an example of a similar kind; and the *Ammonite* and *Belemnite*, are eminently characteristic cephalopodous shells, infinitely abundant during the Lias, and scarcely less so for a great part of the oolitic period. Above 170 species of *Mollusca* have been described from the British localities only, of which as many as 70 are Ammonites.

"Fishes' remains are common in some parts of the Lias, and as many as 60 species in all have been described; of these many resemble the shark, but none seem to have attained very gigantic proportions. This however was not the case with the Reptiles, which during the period in question were equally remarkable for their large size, voracious habits, and incredible abundance. Many species belonging to natural orders of these animals long since lost, were then widely dispersed; and many other species existed of genera now common in distant parts of the world. The Flying Reptile is a striking instance of anomalous structure. The swimming and indeed strictly marine monsters named *Ichthyosaurus* and *Plesiosaurus*, are other examples." [PTERODACTYLE; ICHTHYOSAURUS; PLESIOSAURUS.]

The following is a list of the Fossil Genera found in the Oolitic Beds:—

Plantæ.

Alethopteris, 2 species.
Araucarites peregrinus, Presl.
Bensonia ovata, Buck.
Brachyphyllum mammillare, Lindl.
Bucklandia squamosa, Brong.
Carpolithes, 3 species.
Cyclopteris, 2 species.
Dictyophyllum rugosum, Lindl.
Equisetites, 2 species.
Lilia lanceolata, Buckm.
Lycopodites, 2 species.
Naiadea, 2 species.
Neuropteris recentior, Lindl.
Otopteris, 2 species.
Pachypteris, 2 species.
Pecopteris, 11 species.
Peuce, 2 species.
Phlebopteris, 2 species.
Polypodites, 2 species.
Polystichites Murrayana, Presl.
Pterophyllum, 4 species.
Salicites longifolius, Buckm.
Solenites, 2 species.
Sphæreda paradoxa, Lindl.
Sphænopteris, 6 species.
Spherococcites, 2 species.
Stricklandia acuminata, Buckm.
Strobilites elongata, Lindl.
Tæniopteris, 3 species.
Thuytes, 4 species.
Tympanophora, 2 species.
Zamites, 6 species.

Amorphozoa.

Spongia, 7 species.

Zoophyta.

Alecto dichotoma, Lamx.
Aspendesia cristata, Lamx.
Agaricia lobata, Goldf.
Astrea, 5 species.
Caryophyllia, 2 species.
Ceriopora clavata, Goldf.
Chrysaora, 2 species.
Cricopora, 2 species.
Diastopora, 3 species.
Eunomia radiata, Lamx.
Fungia orbulites, Lamx.
Heteropora, 2 species.
Idmonea triquetra, Lamx.
Intricaria Bajocensis, Bronn.
Lithodendron elegans, Goldf.
Madrepora limbata, Goldf.
Meandrina Soemmeringii, Goldf.
Millepora, 2 species.
Montlivaltia caryophyllata, Lam.
Terebellaria ramosissima, Lamx.
Theonoa clathrata, Lamx.
Turbinolia dispar, Phil.

Echinodermata. [ECHINODERMATA.]

Annelida.

Serpula, 17 species.
Vermilia sulcata, Sow.
Vermicularia, 5 species.

Cirripedia.

Pollicipes, 3 species.

Insecta. [INSECTA, FOSSIL, *S.* 1.]

Crustacea.

Astacus, 4 species.

Conchifera Monomyaria.

Amphidesma, 3 species.
Anatina undulata, Sow. sp.
Arca, 9 species.
Astarte, 16 species.
Cardinia, 12 species.
Cardium, 12 species.
Corbis, 3 species.
Corbula, 4 species.
Cucullæa, 14 species.
Cypricardia solida, Lycett.
Cytherea, 2 species.
Gastrochæna tortuosa, Sow.
Gresslya Anglica, Ag.
Hippopodium ponderosum, Sow.
Lutraria, 5 species.
Isocardia, 11 species.
Lysianassa, 4 species.
Lucina, 4 species.
Mactromya Cardioides, Phil. sp.
Modiola, 17 species.
Mya, 3 species.
Myoconcha crassa, Sow.
Mytilus, 4 species.
Nucula, 11 species.
Opis, 2 species.
Panopæa, 3 species.
Pectunculus, 2 species.
Pholadomya, 19 species.
Pholas, 2 species.
Pinna, 8 species.
Psammobia lævigata, Phil.
Pullastra (?) 4 species.
Sanguinolaria, 8 species.
Sphæra Madridi (*Cardium*), Arch.
Tellina ampliata, Phil.
Thracia depressa, Sow. sp.

Thetis varicosa (*Venus*), Sow.
Thracia depressa, Sow. sp.
Trigonia, 13 species.
Unio distortus, Bean.
Venus Nuculæformis, Roemer.

Monomyaria.

Anomia, 2 species.
Avicula, 16 species.
Crenatula, 2 species.
Gervillia, 10 species.
Gryphæa, 14 species.
Inoceramus, 3 species.
Lima, 6 species.
Limea duplicata, Goldf.
Monotis decussata, Munst.
Ostrea, 19 species.
Pecten, 31 species.
Perna, 2 species.
Plagiostoma, 16 species.
Plicatula, 3 species.
Spondylus comptus, Goldf.

Brachiopoda.

Crania antiquior, Jelly.
Lingula Beani, Phil.
Orbicula, 4 species.
Spirifer, 5 species.
Terebratula, 43 species.

Gasteropoda.

Actæon, 2 species.
Buccinum, 4 species.
Bulla (?), 3 species.
Cirrus, 5 species.
Dentalium, 3 species.
Delphinula coronata, Flem.
Emarginula, 2 species.
Littorina, 4 species.
Murex Haccanensis, Phil.
Natica, 10 species.
Nerinæa, 6 species.
Nerita, 5 species.
Patella, 5 species.
Phasianella cincta, Phil.
Pileolus, 2 species.
Pleurotomaria, 11 species.
Rimula clathrata, Sow. sp.
Rissoa, 4 species.
Rostellaria, 3 species.
Rotella, 4 species.
Solarium calyx, Phil.
Terebra, 8 species.
Trochotoma sulcata, Lycett.
Trochus, 10 species.
Turbo, 4 species.
Turritella, 2 species.

Cephalopoda.

The Fossil Cephalopoda are multitudinous, and in the bygone ages of the world appear to have been powerful instruments for keeping down the other tribes of ancient Testaceans, Crustaceans, and even Fishes; for many of them—certain *Orthocerata* and *Ammonites* for example—afford evidence of gigantic dimensions. In the periods prior to the Chalk Formation, and at the time of its deposit, they were the agents employed for this purpose, and were succeeded in the Tertiary period by the Fossil Trachelipods, which are either entirely absent or very scarce in the Secondary and Transition series, while the Fossil Cephalopods occur but rarely in the Tertiary beds. The extinct Ammonite, Baculite, Belemnite, Hamite, Orthoceratite, Turrilite, and Scaphite, will readily occur to the fossil zoologist as some of the ancient class. The *Foraminifera*, formerly placed by D'Orbigny in this class, are now no longer regarded even as *Mollusca*. [FORAMINIFERA, *S.* 2.]

Pisces. [FISHES, FOSSIL, *S.* 1.]

(Ansted, *Elementary Geology;* Tennant, *Stratigraphical List of British Fossils.*)

OPHIOCE'PHALUS (from ὄφις, a snake, and κεφαλή, head), a genus of Fishes belonging to the division of *Acanthopterygii*, characterised by having labyrinthiform pharyngeals, and capable of living for a long time out of the water. The species inhabit India and China. [ANABAS, *S.* 1.]

OPHIOCOMA, a genus of Animals belonging to the order *Echinodermata*, to the family *Ophiuridæ*, and to the tribe *Ophiuræ*. The rays are simple, squamose, not prolonged into the disc superiorly, and separated at their origins beneath by small pentangular plates. The species are called Brittle-Stars on account of their fragility. They are very difficult to preserve. Professor E. Forbes recommends their being placed in fresh-water as soon as caught, which quickly destroys them; and after they have been in it an hour or so, to dip them rapidly in boiling water. They are then to be dried in the sun, or in a current of air. The following are the British species of this genus recorded by Mr. Forbes in his 'History of British Star-Fishes:'—

O. neglecta, Gray Brittle-Star. Disc round, flat, imbricated with small smooth scales; two oblong parallel touching plates opposite the origin of each ray; upper ray-scales square; lateral ray-plates bearing four or five spines each, which are equal in length to the breadth of the ray. This species is not uncommon on all parts of the British coast.

O. Ballii, Ball's Brittle-Star, was first discovered in Ireland by Dr. Ball.

O. punctata (Forbes), Dotted Brittle-Star. This species, first described by Edward Forbes, was found by Henry Goodsir in the stomach of a cod.

O. filiformis, Thread-Rayed Brittle-Star. The rays are very long and filiform. It is a rare species in Great Britain.

O. brachiata, the Long-Armed Brittle-Star. This also is a rare species.

O. granulata, Granulated Brittle-Star. The rays are covered over with minute spines.

O. Bellis, Daisy Brittle-Star. It is not uncommon on many parts of our coast, and is to be found under stones at low tide.

O. Goodsiri, named after Dr. Goodsir, who took it from a cod's stomach taken off Anstruther in Fifeshire.

O. rosula, Common Brittle-Star. Disc rounded, convex, covered with spines of various lengths; two large triangular parallel plates opposite the origin of each ray; upper ray-scales triangular, carinated, imbricated; lateral ray-plates bearing five spines each, which are much longer than the breadth of the ray. This is the most common of our British Brittle-Stars.

O. minuta, Sand Brittle-Star. This is smaller than the last, and is found buried in the sand.

(E. Forbes, *A History of British Star-Fishes.*)

OPHIOGLOSSACEÆ, *Adders' Tongues*, a natural order of Acrogenous Plants, belonging to the alliance Filicales. They have an erect or pendulous stem, with a cavity in the middle instead of pith, and two or three woody bundles placed round it in a ring; the stalks of the leaves and the stem become blended together below; the leaves have netted veins; the spore-cases are collected into a spike formed out of the sides of a contracted leaf, 2-valved, without any trace of an elastic ring; spores resembling fine powder.

These plants are a transition from Ferns to *Lycopodiaceæ*. The species are most abundant in the islands of tropical Asia. They occur however in the West Indies and in the tropical parts of Africa, at the Cape, and in Tasmania. They are of little or no known use. The following genera with about 25 species belong to this order:—*Ophioglossum*, *Ophiodema*, *Helminthostachys*, *Botrychium*.

OPIAMMON. [CHEMISTRY, *S.* 1.]

OPIANIC ACID. [CHEMISTRY, *S.* 1.]

OPIANINE. [CHEMISTRY, *S.* 2.]

OPIANYLE. [CHEMISTRY, *S.* 2.]

OPIE, AMELIA, the wife of John Opie, was the daughter and only child of Dr. James Alderson, a physician of Norwich, where she was born on November 12, 1769. Her mother, a woman of considerable talent, attended to the care of her daughter's education, but she died in 1784, and the daughter assumed the position of mistress in her father's house, and became his companion. Handsome and lively, possessing musical talents, her company was much sought, and she enjoyed society thoroughly, but it did not tend to solidify her mind. Very early in life also she took a fancy to attend the trials in the assize courts, which she continued to frequent even at an advanced age. Her father was an admirer of the principles advocated in the early stages of the French revolution. These principles his daughter adopted, and she was present at the trial of Horne Tooke and his associates for high treason, of which she wrote home an account. In this whirl of social life, law, and politics, she had the judgment to form her friendships among persons distinguished for their virtues and talents, and she gave some of her leisure to literature, writing one or two tragedies, which however were never published, some poetry, and a novel, called 'The Dangers of Coquetry,' which was published anonymously, and attracted no attention. In 1798 she married Mr. Opie, and, encouraged by her husband, in 1801 appeared before the world as an author, with "a simple moral tale," as she herself styled it, entitled 'Father and Daughter.' It was very popular at the time, and furnished the plot of the opera of 'Agnese,' by Paer; yet it has little power, even of pathos, but is told in an easy unpretending style, while its chief merit is now that it details, though with no conviction of its impropriety, the harshness with which lunatics were then treated, and the instinctive kindness which led her to show by the fictitious example the possibility of governing them by kindness. In 1802 she published 'Poems,' a volume in which, without striking poetic genius, there is much natural grace and sweetness. In the autumn of 1802 she and her husband visited France, and of this, her first journey, she published an account in

'Tait's Magazine' in 1831. In 1804 she published the novel of 'Adeline Mowbray; or Mother and Daughter,' in 3 vols., which added considerably to her reputation, and some passages of which are highly pathetic; but still she wanted art in grouping and developing her characters, and in combining her incidents. In 1805 'Simple Tales,' in 4 vols. were issued. With virtuous principles and good feelings, an artlessness that steals into the heart, and language easy and simple though not always strictly accurate, there is still the same want of logical coherence; the tales want reality. The characters are ill-defined and often extravagant, yet the 'Ruffian Boy' and 'Murder will out' will always produce an interest. In 1807 after the death of her husband, she returned to the home of her father. In 1808 she published 'The Warrior's Return and other Poems,' and in the following year her husband's 'Lectures on Painting,' to which she prefixed a memoir. In 1812 appeared 'Temper,' a tale in which she introduced many of her impressions of France; and in 1813 'Tales of Real Life,' which however are not more real than her former tales. In 1816 'Valentine's Eve,' a novel in 3 vols. was published, developing some of her religious views, now becoming more decided. In 1818 'Tales of the Heart,' and in 1822 'Madeline,' neither of them rising above the average of the preceding. Her next work, 'Illustrations of Lying,' appeared in 1825, and was dedicated to her father; they consist of short tales, made for her avowed purpose, with dissertations, and show more decidedly than any the great defect in her reasoning powers, though all evince the most praiseworthy intentions.

Early in life Mrs. Opie had been intimate with the Quaker family of the Frys, particularly with Mrs. Fry, and through them with the Gurneys. In 1814 a letter from J. J. Gurney appears to have made much impression on her mind, she commenced attending the Quaker meetings, and in 1825, with her father's consent, she formally joined their society. In 1825 her father died, but she continued to make Norwich her abiding place, varied by frequent visits to her friends, to Scotland, and the Continent. She had adopted the style and dress of the society she had joined, but did not give up her literary pursuits. She still wrote occasional poems, and in 1828 'Detraction Displayed' was published. In 1829 she visited Paris, and her old political feelings seem to have revived. She wrote some verses on the tricolor, addressed to Lafayette, in which she says that at the sight of it, "I seem to feel youth's hours return." In 1830, on the expulsion of Charles X., she again went to Paris, and has given a lively account of what she saw. In 1833, 'Lays for the Dead,' a volume of poems, was published. In 1835 she made a tour to Belgium and Switzerland, of which she gave an account in 'Tait's Magazine,' in 1840. She continued active and beneficent for some years, contributing occasionally, as she had done through previous years, to various periodical works, and after an illness of some duration, she died at Norwich, Dec. 2, 1853. Her Life has been written with much care by an attached friend, Miss C. L. Brightwell, and was published in 1854.

ORANGE, the Principality of, included the town and neighbourhood of Orange in the south of France. Réné de Nassau, nephew and successor of Philibert de Challon, prince of Orange, was killed at the siege of St.-Dizier in 1544, and left his heritage to his cousin William of Nassau, the founder of the republic of the Dutch United Provinces. After the death of William III., king of England, the principality passed to Frederick, king of Prussia, William's eldest sister's son, whose successor, Frederick-William, ceded it to Louis XIV. at the peace of Utrecht. [NASSAU, HOUSE OF.] The principality then merged in the province of Dauphiné, and is now included in the Department of Vaucluse.

ORANGE TRIBE. [AURANTIACEÆ; CITRUS.]

ORCHIS, a genus of Plants the type of the natural order *Orchidaceæ*, and belonging to the tribe *Ophrydineæ*. The old Linnæan genus *Orchis* is now divided into many genera [ORCHIDACEÆ], but a large number of species are still retained under this designation. The tribe *Ophrydineæ* is distinguished by the pollen masses being divisible into lobes, which are waxy and definite in number. The anthers are wholly adnate. The genus *Orchis* belongs to a section of this tribe, in which the cells of the anther have a rostellate process between their bases. In *Orchis* the perianth is ringent and hooded; the lip 3-lobed, spurred; the glands of the stalks of the pollen-masses are in a common pouch. The following is an arrangement of the British species according to Babington:—

* Glands of the pollen-masses separate; lip erect in æstivation.

† Bracts mostly 1-nerved; root-knobs undivided.

‡ Lip, 3-lobed; lobes broad and short.

Orchis Morio, Green-Winged Meadow-Orchis. *O. mascula*, Early Purple Orchis.

‡‡ Lip 3-lobed; middle lobe dilated, bifid, and often with an intermediate tooth.

O. fusca. *O. militaris.* *O. Simia.* *O. ustulata.*

†† Bracts with three or more nerves; root-knobs undivided.

O. laxiflora.

††† Bracts with three or more nerves; root-knobs palmate.

O. maculata, Spotted Palmate-Orchis. *O. latifolia*, Marsh-Orchis.

** Glands of the pollen-masses united; root-knobs undivided.

† Lip erect in æstivation.

O. pyramidalis, Pyramidal-Orchis.

†† Lip spiral in æstivation.

O. hircina, Lizard-Orchis.

(Babington, *Manual of British Botany*.)

ORDERS, a group of objects in natural history classifications, subordinate to a Class, or sub-Class. It is, however, like many other general terms, used very loosely, especially by zoologists. In botany it is more definitely applied, and is used synonymously with Family and Tribe. In zoology Family and Tribe are frequently employed to denote groups subordinate to Orders. [FAMILIES OF PLANTS, *S.* 1.]

OREGON, a Territory of the United States of North America, lies between 42° and 46° N. lat., 110° and 125° W. long. It is bounded E. by the Rocky Mountains, which separate it from the Territory of Nebraska; N. by the Territory of Washington; W. by the Pacific Ocean; and S. by the State of California and the Territory of Utah. At the census of 1850 the Territory of Oregon included the country since separated from it and formed into the Territory of Washington, and comprised altogether an area of 341,463 square miles. The area of Oregon Territory is 185,030 square miles. The estimated population, in 1857, was 43,000.

Surface and Hydrography.—The Territory of Oregon is traversed from south to north by the ranges of the Cascade and Blue Mountains, while a third range, that of the Rocky Mountains, forms its eastern boundary. The Cascade, or Coast, or as it is sometimes called, President's Range, is a continuous and very lofty range rising at a distance of 100 to 150 miles from the coast; and almost entirely cutting off direct communication between those portions of the Territory which lie east and west of it. Except where the Columbia, which forms here the northern boundary of the state, breaks through the range, the few passes which exist are so difficult as to be of little use to the traveller. The high peaks are from 12,000 to 14,000 feet above the level of the sea. The country west of this range is a good deal broken by spurs from the main chain. The greater part of this broken country is thickly timbered, in many parts there being dense forests of fir, pine, spruce, oak, ash, and other valuable trees, with close undergrowths of hazel, &c. The valleys and plains afford much excellent farming land, the soil consisting in some places of a black vegetable loam, in others of clays and gravel. The uplands form good pastures. The harbours along the coast are, with the exception of that formed by the mouth of the Columbia, of little value; most of the other rivers have bars at their mouths, over which only vessels of little draught can pass. The coast itself is formed by steep sandy cliffs and beaches and is broken by projecting headlands which rise precipitously from the sea; the principal of these are named Cape Orford, Cape Gregory, Cape Perpetua, and Cape Look-Out, but they afford little shelter, and have mostly numerous rocks scattered about them, while everywhere a heavy surf sets in upon the beach.

The Blue Mountains, which traverse the middle of the Territory, are more broken and irregular than the Cascade and Rocky ranges. On the south-west the Blue Mountains are united with the Cascade Mountains by offsets which form the valleys of the Clamet and Umqua rivers, while the main chain forms the valley of the Willamette. Other offsets, diverging eastward, connect this range with the Rocky Mountains. This middle section of the state differs considerably from that west of the Cascade range. The hills are barren, but in the valleys of the Columbia, Willamette, and Saptin rivers the soil is generally fertile, and in some places extremely rich. Much of the country in the vicinity of the Columbia and Saptin rivers consists of rolling prairie land, and affords good pasturage. The southern portion of this middle section is for the most part broken and desert, with scarcely a tree or vegetable. The general elevation of the section is about 1000 feet above the sea.

The Rocky Mountains have been noticed elsewhere. [ROCKY MOUNTAINS.] They are of great altitude, and only one practicable pass has been discovered over them along this Territory. This, known as the Great South Pass, occurs at the south-eastern extremity of Oregon, and is that crossed by the great stream of overland emigration to Utah and California. The country immediately west of the Rocky Mountains is everywhere broken by great spurs from the main chain, and though in some places partially timbered, is for by far the greater part rocky, barren, extremely variable in climate, and incapable of permanent settlement

The principal river of Oregon is the Columbia, which forms for a considerable distance the boundary between this Territory and Washington, and is not only common to both Territories, but receives all the rivers of both which rise east of the Cascade Mountains. [COLUMBIA RIVER.] The Saptin, Snake, or Lewis River, sometimes called the Southern Fork of the Columbia, is formed by the union of many small branches which rise in the Rocky Mountains between 42° and 43° N. lat., and flows first west and then south through Oregon, passing into Washington near 117° W. long., after a very serpentine course of nearly 800 miles. The Saptin in its course through Oregon receives numerous affluents, all or nearly all of which belong entirely to this Territory. Of these the principal are the Waptiacoos, Fayette, and Sickly, on the right, and the Malheur on the left. Most of these rivers are very rapid, and run in deep channels, but are of little value for navigation. The Willamette, which rises on the west side of the Blue Mountains near 43° 30′ N. lat., is one of the most important tributaries of the Columbia; it has a generally northern course and enters that river nearly opposite to Fort Vancouver, considerably below where it becomes navigable; is itself navigable by small vessels for a considerable distance; and drains one of the most fertile valleys in the Territory. The rivers which rise west of the Cascade Mountains have mostly a short course and are of little service for navigation. The principal are the Umqua and the Clamet. The Umqua, which after the union of its two head branches, flows nearly west to the Pacific, into which it falls by Cape Gregory, about 43° 54′ N. lat., is in its lower course a wide but comparatively shallow stream, and like all the other rivers of Oregon which fall into the Pacific, has its mouth obstructed by a sand bar. The Clamet, the most southern river of Oregon, is also the longest south of the Columbia; but there are few settlements along its banks, and its navigable capabilities are very limited.

Geology.—Of the geological features of Oregon only very partial examinations have been made. The mountain ranges belong generally to the igneous and palæozoic formations. Granite, trap, basalt, hornblende, and other eruptive and metamorphic rocks occur very widely, with slates, limestone, sandstone, &c. Gold is found in the sands of several of the rivers which flow from the Cascade Mountains to the Pacific; and it is said to have been also found in various places east of that range. Other minerals, especially iron, lead, and tin are also said to occur, but none of them have, we believe, been worked. We have not heard that coal has been found, though it is known to exist in Washington. Saline springs occur in the middle section of the Territory, and near its south-eastern corner occur several soda and magnesia springs.

Climate, Productions, &c.—The climate is very varied in the different sections of the Territory. Along the Pacific, and generally west of the Cascade range, it is mild and genial during the entire year. The winter is very short and far from severe, and snow seldom lies long on the ground. In the middle section the changes of temperature are much greater, and the winter much colder; but the air is more bracing, and the climate appears to be generally healthy. It is said that no dew falls in this section. In the vicinity of the Rocky Mountains the changes of temperature are extremely great and rapid. In the south-eastern part of the territory along the line of the great emigration route, the climate is very variable, but rain seldom falls, and there is little snow.

Wheat is the principal grain crop; but a considerable quantity of oats is also grown. Maize is cultivated, but not to any great extent. The other grains are scarcely cultivated at all. Peas and beans, potatoes, and a few other vegetables are raised. Small quantities of tobacco, flax, &c., are grown. Most of the European fruits flourish in the valleys of the Columbia, Willamette, &c. At present however the chief dependence of the settlers is perhaps upon the rearing of stock, which with scarce any attention thrive abundantly on the excellent pasture. Horses, horned cattle, sheep, and swine are already very numerous; and butter, cheese, and wool receive much attention from the agriculturists.

Oregon was formerly exceedingly rich in fur-bearing animals, but their numbers are rapidly diminishing; beavers, musk-rats, and martins are the chief which are left. Their collection is still carried on almost exclusively by the officers of the Hudson's Bay company. In the forests bears, wolves, foxes, deer, elks, antelopes, and other game are still very abundant. Vast quantities of aquatic birds frequent the rivers in the spring and autumn. Along the coast whales are found; and edible fish are extremely abundant both along the coast and in the rivers: the Columbia especially swarms with fish, which form the chief food of the Indians. The principal fish taken are salmon, sturgeon, cod, ray, carp, smelt, and innumerable other small fish, with crabs, oysters, mussels, and other shell-fish.

At present manufacturing industry is chiefly confined to the production of the articles required in a very thinly peopled agricultural country, and those connected with the shipping trade. The commerce of Oregon is not unimportant, a considerable coasting trade being carried on with California; the exports consist of large quantities of lumber, boards, flour, and provisions generally. There is also a good deal of trade carried on with New York, Boston, &c. The direct foreign trade is of little consequence.

Divisions, Towns, &c.—The Territory of Oregon is divided into ten counties. Salem is the political capital. All the towns are as yet but small: we notice some of the principal places; the population is that of 1850:—

Salem, the capital, stands on the right bank of the Willamette; it has a small population, and little trade, but contains the state buildings, &c.

Astoria, on the Columbia, 8 miles from its mouth, population 252, is one of the oldest American trading places in Oregon, having been founded by Mr. J. Astor in 1811, but its present increase is very slow. *Milton City*, Washington county, population 692, is one of the rising towns of Oregon. *Oregon City*, on the right bank of the Willamette River, 35 miles N.E. from Salem, population 692, is the chief town of the Willamette Valley, the best settled and most flourishing district in Oregon. The city possesses a great amount of water power, and appears likely to become a place of considerable importance. *Portland*, on the left bank of the Willamette, above its confluence with the Columbia, 47 miles N. by E. from Salem, population 821, is also a busy and flourishing place, being the port of entry of an extensive and rich country.

The constitution was enacted by Congress in 1848; by it the right of voting is vested in every white male inhabitant of Oregon, 21 years of age, and a citizen of the United States, or who shall in the usual manner declare his desire to become one. The legislature consists of a council of 9 members, elected for three years; and a house of representatives of not less than 18 nor more than 30 members elected for one year. All laws passed by this legislature must be submitted to Congress for approval. The governor is appointed for four years.

The coast of Oregon was visited both by the English and Spaniards in the 16th century, and it has been much disputed to the mariners of which country the honour of the discovery is to be ascribed. Spanish writers claim its discovery for Ferrelo, the pilot of Cabrillo, who they assert reached 43° N. lat. in 1543; while those who claim for England the honour of the discovery, show that Drake in 1579 attained to 48° N. lat. The mouth of the Columbia, although Heceta in 1775 and Vancouver early in 1792, suspected the existence of an important river from the general appearance of the bay into which it empties itself, was not actually discovered until later in 1792, when a Captain Baker of the English merchant service and a Captain Gray, the master of an American merchant vessel, entered the æstuary of the river. On the priority of Gray's entry the United States government some years later founded its claim to the territory drained by the river and its tributaries; but the river was actually ascended for the first time by Lieutenant Broughton, R.N., who a few months after Captain Gray had entered its mouth went up it for above 100 miles, and formally took possession of the country in the name of his sovereign George III. The sovereignty of Oregon was in 1789-90 a matter of grave dispute between the governments of England and Spain, but the question was terminated in 1790 by the Convention of Madrid, by which the right of exclusive possession was relinquished by both countries. The Americans subsequently formed a trading settlement at Astoria, which, during the war in 1814, was taken possession of by the English, but given up at the close of the war. After the treaty with Spain in 1819 the United States government first set up a claim, founded on the right of discovery, and also on their having by the treaty succeeded to the Spanish right of occupancy, to the exclusive possession of Oregon; and the claim involved the English and American governments on more than one occasion in very serious disputes. The question was not finally settled till 1846, when a treaty was concluded between the two powers, giving to the United States the entire country up to the parallel of 49° N. lat., including therefore the whole tract since formed into the territories of Oregon and Washington, but reserving to England the free navigation of the Columbia River as a line of communication with the Hudson's Bay Territory. Oregon was constituted a Territory by Act of Congress, August 14th, 1848.

(*Statistical Gazetteer of the United States; American Almanac; Seventh Census of the United States;* Wilkes, *Narrative of the United States Exploring Expedition;* Greenhow; Falconer; Wallace; Twiss; Nicolay, &c.)

ORFILA, P., an eminent French physician and toxicologist, was born at Mahon, in the island of Minorca, on the 24th of April, 1787. He was sent to Paris to study medicine, and was naturalised in France in the year 1815. He early displayed a love for the science of chemistry, and in the application of this science to the investigation of poisons and their treatment became the most distinguished man in Europe. He was professor of medical chemistry in the Faculty of Medicine at Paris, and was subsequently for many years dean of that faculty. He was a correspondent of the Institute and a member of the Council of Hospitals. He wrote many works on the subject of toxicology, as well as on medical jurisprudence generally. His first published work was produced in 1817, and was entitled 'Elements of Chemistry applied to Medicine and the Arts.' This work was many times republished. From time to time he published lectures on various departments of legal medicine. In 1821 he commenced the publication of a course of 'Lectures on Legal Medicine,' which was completed in 1823. Another series of lectures on the treatment of persons poisoned or asphyxiated, was published in 1818. In 1830, conjointly with M. Leseur, he published a work 'On the Appearances presented by Dead Bodies after Exhumation, Drowning, Suffocation in Cesspools, or by Gases.' He was also one of the editors of the 'Nouveau Dictionnaire des Termes de Médecine, Chirurgie, Pharmacie, Physique, Chimie, Histoire Naturelle,' &c.

His greatest work on medical jurisprudence was his 'Traité de Médecine Légale,' in 4 vols., and published from 1835 to 1847. His special papers on poisoning are very numerous, and those on the absorption of lead, corrosive sublimate, silver, arsenic, and other metals, are most valuable contributions to toxicology. He devoted much attention to the subject of public health, and wrote a little work entitled 'Hygienic Precepts for the Use of Children in Primary Schools' (1845). One of his last papers was 'On the Pernicious Effects of Tobacco, and the Danger of Smoking Havannah Cigars." He died in the month of March 1853.

ORO CITY. [CALIFORNIA, *S.* 2.]

ORONTIACEÆ, a natural order of Endogenous Plants, under which Lindley, in his 'Vegetable Kingdom,' includes the *Acorinæ* of Link and other authors. This order embraces the genera *Calla, Orontium,* and *Acorus,* which are the types of three separate tribes. They are related to *Juncaceæ, Liliaceæ, Piperaceæ,* and *Araceæ.* It contains 13 genera and 70 species. Some of the species are used by man. *Symplocarpus fœtidus,* the Skunk Cabbage, yields a fœtid volatile oil. The Rootstocks of *Calla palustris* are eatable.

ORTHAGORISCUS, a genus of Plectognathous Fishes, belonging to the family *Gymnodontidæ.* On account of their round form the species are called Sun-Fishes. The genus has the following characters:—Jaws undivided, forming a cutting edge; body compressed, deep for its length, short, truncated, without spines; tail short and very high vertically; rays of the dorsal and anal fins long and pointed, both united at the caudal fin at the base. Two species of this curious genus have been taken on the British coasts.

O. mola, the Short Sun-Fish, the Molebut, although only occasionally seen, has been taken around all the shores of Great Britain. When observed in our seas they have generally appeared as though they were dead or dying, and floating along on one side, presenting the broad surface of the other side to view. This seems to be a natural position.

O. oblongus, the Oblong Sun-Fish, Oblong Tetrodon, Truncated Sun-Fish. This fish is larger, longer, and rarer than the last.

(Yarrell, *British Fishes.*)

OSCILLATORIA. [ALGÆ.]

OSMERUS. [SALMONIDÆ.]

OSSEOUS TISSUE. [TISSUES, ORGANIC, *S.* 1.]

OTAGO. [ZEALAND, NEW, *S.* 2.]

OTLEY. [YORKSHIRE.]

OTTAWA, a city of Canada, previously called Bytown. [BYTOWN, *S.* 2, to which the present notice, founded on more recent information, is subsidiary.] The original name was derived from Colonel By, an officer of the Royal Engineers, whom the British government in 1827 commissioned to superintend the construction of the Rideau Canal. Bytown in 1854 was constituted a city, and the name was changed to Ottawa. A disagreement having arisen between the inhabitants of Canada West and Canada East respecting the seat of the Provincial Government, the matter was referred to the decision of Queen Victoria, who is stated to have chosen Ottawa as the future capital of the United Provinces of Canada. The situation is central for the whole of Canada, and has communication by river, canal, or railway, eastwards with Montreal and Quebec, and westwards with the Detroit River, through Kingston, Toronto, Hamilton, and Chatham. [CANADA, *S.* 2.]

Ottawa is situated at the entrance of the Rideau River into the Ottawa, 87 miles W. from the confluence of the Ottawa with the St. Lawrence. At the western extremity of the city are the celebrated Chaudière Falls, unsurpassed in America except by the Falls of Niagara. The city is in Canada West, but a suspension bridge erected by the Provincial Government just below the Chaudière Falls spans the foaming mass of water, and unites Canada West with Canada East: it is called the Union Bridge. The Rideau Canal divides the city into Upper Town and Lower Town, entering the Ottawa by eight magnificent stone locks: and a massive bridge of cut stone, erected by the Royal Sappers and Miners, crosses the Rideau Canal. At the north-east end of the city are two other falls, by which the Rideau River pours itself into the Ottawa. The water-power for driving mills or machinery is immense on both sides of the Ottawa, and manufactories of various kinds have already been established.

The city is well laid out, the streets wide and regular, the houses mostly of stone, and the principal quarters are lighted with gas. There are already several good hotels. The population now exceeds 10,000. The principal commerce consists of lumber (timber in logs and squared), of which from 16 to 18 millions of cubic feet are annually brought down the Ottawa and its tributary rivers. The Hull iron-mines, about seven miles from the city, are worked successfully. The value of assessed property in 1856 was 3,300,000 dollars. Ottawa returns one member to the Legislative Assembly. It has communication daily by steamers with Montreal and Kingston, and by railway twice a day with Prescott, on the left bank of St. Lawrence (54 miles), where a connection is formed with the Grand Trunk Railway. Ottawa is distant 296 miles W.S.W. from Quebec, 126 miles W. from Montreal, 95 miles N.N.E. from Kingston, and 233 miles N.E. from Toronto.

OTTRELITE. [MINERALOGY, *S.* 1.]

OUDE, a kingdom of Hindustan, is bounded S. by Allahabad, N. by Nepaul, E. by Bahar, and W. by Delhi. Its greatest length south-south-east to north-north-west is about 200 miles; its greatest breadth east by north to west by south is about 130 miles. The area is estimated at 25,000 square miles. The population is estimated at 5,000,000.

Oude was formerly a soubah, or subordinate government, of the Mogul's dominions. By various treaties between successive viziers and the East India Company, Oude became one of those dependent states over which the British government have supreme political control. In 1819 the reigning prince renounced his nominal allegiance to the Mogul, and assumed the title of King. On the 7th of February, 1856, the Marquis of Dalhousie, governor-general, announced by proclamation the deposition of the King of Onde, and the annexation of the kingdom of Oude to the British possessions in India. The King of Oude was granted an annual pension of twelve lacks of rupees (120,000*l.*). Oude forms a portion of the plain of the Ganges. The general character of the country, and the capital city, Lucknow, are noticed under HINDUSTAN.

OUDINOT, CHARLES NICOLAS, DUKE OF REGGIO, Marshal of France, and Grand Officer of the Legion of Honour, was born on the 2nd (some biographers state the 25th) of April, 1767, at Bar-sur-Ornain. Having chosen the career of a soldier, in opposition to his father's wishes, he joined the regiment of Medoc in 1783; but parental influence induced him to withdraw from the army four years after. The general call to arms at the outbreak of the revolution revived his martial spirit, and on offering himself as a volunteer in 1791, his former service at once procured him a battalion. In September 1792 Oudinot defended the fort of Bitsch against the Prussians, whom he repulsed with great loss. After this, the government of the Girondists promoted him to the command of the regiment of Picardy, left vacant by its former colonel, whom the Jacobin excesses of the day had induced to emigrate. At daybreak on the 2nd of June, 1794, being stationed at a distant outpost, the Austrians fell in great numbers upon his regiment; but he held his ground for ten hours against a corps estimated at 10,000 strong. Surrounded by the enemy's entire cavalry, he formed his men into a square, repulsed every charge of their cuirassiers, till at length, having opened a passage through them with fixed bayonets, he effected his junction with the main army, his lines never once having been broken. Instantly raised to a brigade for this intrepid conduct, he was sent to besiege Trèves, and on the 7th of August 1794 captured the town by a skilful manœuvre. He next received orders to join the army of the Rhin-et-Moselle, which he did on the 14th of September. During a desperate night-attack, October 14, 1795, he was disabled by five sabre-cuts; and having fainted from the loss of blood, was taken prisoner by the Austrians. Released by exchange a few months later, he joined Morean's army in 1796, distinguished himself at the battles of Nordlingen and Donanwerth, captured several fortresses on the Danube, and was again most severely wounded at Ingolstadt. On the 19th of March, 1797, he attacked the emigrant army of Coudé before Constance, and penetrated into the town, in spite of a second corps of Austrians by which it was defended.

Oudinot was created a general of division, April 12, 1799; and on the 4th of June contributed effectually to the great victory of Zurich. Being subsequently appointed head of the staff in Massena's army, he shared with that commander the dangers and sufferings of the seige of Genoa. Twice during the siege he succeeded in passing through the English blockading fleet, bearing with him Massena's despatches to Suchet. In 1800, as head of the staff under Brune, he obtained fresh honours at the battle of Pozzolo and the passage of the Mincio. The First Consul was so highly satisfied with Oudinot's conduct on these occasions that he presented him with a sword of honour, to which he added one of the pieces of cannon captured from the enemy by Oudinot himself. At the opening of the campaign of 1805 Napoleon formed a picked corps of grenadiers, the command of which he intrusted to Oudinot, presenting him at the same time with the grand cordon of the Legion of Honour. At the head of his grenadiers he was the first to enter Vienna; he crossed the bridge over the Danube, though undermined and defended with 180 pieces of cannon. General Oudinot was likewise present at Austerlitz.

The following year he took possession of the counties of Neufchâtel and Valengen, relinquished by Prussia; and during his government conciliated the inhabitants by his liberality and disinterestedness. Before he left his office, the burghers of Neufchâtel evinced their esteem by a public address and the present of a sword. After the battle of Jena, October 14, 1806, he marched into Poland, and gained the victory of Ostrolenka, February 6, 1807. The Emperor Napoleon now made him a count, to which he annexed a dotation of a million of francs. But the 14th of June 1807, the morning of Friedland, was the most signal of his life. On that famous ground, with his single corps, he checked for many hours the advance of the whole Russian army; and after the sacrifice of half his men, enabled Napoleon to come up in time to win one of his greatest battles. Meeting the general after the action, Napoleon said to him, with unusual emotion, "General, you have done wonders; but wherever you are my only fear is for yourself." This incident has since afforded a subject for one of Horace Vernet's best pictures.

In the memorable campaign of 1809 the reputation of Oudinot was fully sustained; for after the death of Marshal Lannes, at Essling, the second corps, formerly commanded by him, was conferred upon Oudinot in these flattering terms:—"Given to you, as a general, tried in a hundred fights, in which equal skill and intrepidity have been displayed." After the battle of Wagram, Oudinot received the marshal's bâton, with the title of Duke of Reggio, and a pension of 100,000 francs. In 1810, Louis Bonaparte, tired of submitting to the dictation of his imperial brother, threw off the ensigns of royalty, and clandestinely left Holland. Upon this defection Marshal Oudinot was ordered to take military possession of the country; he fixed his headquarters accordingly at Amsterdam. In this government he continued nearly two years, exhibiting great capacity and justice, and winning the good report of the Dutch people by his integrity and conciliatory behaviour.

Throughout the whole of the subsequent campaigns of 1812, 1813, and 1814, the name of Marshal Oudinot reappears with undiminished honour, as one of the best-trained and most efficient of the imperial band of generals. After the first abdication he submitted to the restored Bourbons, stedfastly adhered to their cause during the Hundred Days, and was loaded with favours by Louis XVIII. and Charles X. In 1823 he accompanied the Duke of Angoulême in his expedition for the re-establishment of the King of Spain. He was appointed governor of the Invalides in 1842, and died at Paris, September 27, 1847, in his eighty-first year, having been upwards of sixty-four years in the French army.

The marshal's eldest son, Nicholas-Charles-Victor, the present Duke of Reggio, commanded the French army sent in 1849 to support the authority of the present pope in the Roman states. His younger son, an officer of great promise, fell into an ambush in the late wars in Africa, and was killed by the Arabs, June 26, 1835.

OUTLAWRY. Outlawry, in civil suits, was of two kinds, that on *mesne* process, and that on *final* process. The object of the former was to compel the appearance of a defendant who could not be served with a writ, and it was consequently always reversed on application to the Court, and the defendant appearing to the action. A simple method of proceeding against a defendant, or rather of enabling a plaintiff to obtain judgment by default when the defendant does not appear, having been provided by the Common Law Procedure Act, 1852, outlawry on *mesne* process is by that statute abolished. Outlawry on *final* process may still be obtained against a judgment debtor, but there are so many other means of stripping him of all his property, that this mode of proceeding is rarely resorted to in practice.

OVEÆ (Gray), a sub-tribe of the tribe *Bovina* and family *Bovidæ*. It includes the common Sheep and allied species. The following is Dr. J. E. Gray's definition of this family:—Forehead flat or concave. The horns are more or less spiral, wider than deep at the base, and slightly annulated in front. The females are often hornless. The skull has a more or less deep rounded suborbital pit, without any fissure; the masseteric ridge ascending high before the orbit; the auditory bulla small; the basioccipital flat, more or less expanded anteriorily by the extension of the anterior pair of tubercles, the posterior ones small; the cutting-teeth are nearly equal-sized and shelving; and there are no supplemental lobes to the grinders. The hoofs are triangular, and being shallow behind, they have distinct interdigital fossæ. Males emitting no stench.

The genera included in this family are—

1. OVIS. Crumen distinct. Tail elongated. Skin covered with wool or adpressed hair.

2. Caprovis. Crumen distinct. Tail very short. Skin covered with thick hair, covering the wool.
3. Pseudovis. Crumen none. Tail rather elongated. Forehead convex. Skin covered with thick hair.
4. Ammotragus. Crumen none. Tail rather elongated. Forehead concave. Skin covered with short hair, and elongated tuft of hair.

Ovis Aries, the Common Sheep, is subject to great variety, and many of its forms have been raised to the rank of species. Dr. Gray, in the 'British Museum Catalogue,' ennmerates no less than 33 varieties of this species.

In the article Sheep the subject is treated chiefly with reference to farming and grazing. We here present a few of the varieties which are more interesting to the zoologist. The Sheep is one of those animals which man has domesticated, and which, like the horse, dog, cat, pig, and ox, is subject to the greatest possible variety. These varieties have been often described as species; but the most distinguished zoologists of the present day regard all the forms of *Ovis* as belonging to the species *O. Aries*.

The following is a list of the varieties from the 'British Musenm Catalogue':—

1. The Spanish Sheep. It is the *Ovis Hispanicus* of Linn.; called also the Merino Sheep and the British Middle-Wooled Sheep.

2. The Common Sheep (*Ovis rusticus*, Linn.; *O. Gallica*, Desm.; *O. brachyurus*, Pallas; *O. leptura*, Schreb.): the Hornless Sheep (*O. Anglicana*, Linn.). Of this variety there are numerons forms, such as the Muggs Sheep and Shetland Sheep, the Sonthdown Sheep, the Old Lincoln Sheep, the Romney Marsh Sheep, the Cobwold Sheep, the New Leicester Sheep, the Cheviot Sheep, the Old Teeswater Sheep, the Improved Teeswater Sheep, the Dnnky Sheep, the Zetland and Orkney Sheep, the Welsh Mountain Sheep, the Soft-Wooled Sheep of Wales, the Wicklow Mountain Sheep, the Kerry Sheep, the Exmoor Sheep, the Black-Faced Sheep, the Black-Faced Heath-Sheep, and the Rass or Roosh (*Ovis Polii*, Blyth).

3. The Barwall Sheep, *Ovis (Aries) Bârwâl*, Hodgson; *Ovis Barual*, Hodgson; *O. Ammonoides*, var. 1, Gray. It inhabits Nepaul.

4. The Huniah Sheep (*Ovis Hunia*, Hodgs.); The Hoonia, or Black-Faced Sheep of Tibet. Also a native of Nepaul.

5. The Cago (*Ovis Cagia*, Hodgs.); the Kago, or Tame Sheep of Cabnl region; the Cago Sheep of Gray. A native of Nepaul.

6. The Seling. A native of Nepaul.
7. The Curumbar Sheep of Mysore.
8. The Sheep called Gârăr in India.
9. The Dukhun (Deccan) Sheep.
10. The West-Indian Sheep.
11. The Brazilian Sheep.
12. The Demerara Sheep.
13. The South American Sheep (*Ovis Aries*, Renger).
14. The Smooth-Haired Sheep (*O. Africanus*, Ray; *O. Æthiopica*, Charlet; *O. Africana*, Sloane).
15. The African Sheep, (*O. Guineensis; A. longipes*, Desm.; *Caper Mambrinus*); the Sheep of Sahara.
16. The Guinea Sheep (Belier et Brebis des Indes, Buffon; *O. A. Guineensis*, Schreb.).
17. The Morvant de la Chine, Buffon.
18. The Shaymbliar Sheep of Mysore.
19. The Sheep of Zeyla, of Buckingham.
20. The Fezzan Sheep, of Bennett, from Tripoli.
21. The St. Helena Sheep.
22. The Marocco Sheep (*O. A. Numidæ*, H. Smith).
23. The Congo Sheep (*O. A. Congensis*, H. Smith).
24. The Angola Sheep (*O. A. Angolensis*, H. Smith).
25. The Zenu or Goitred Sheep (*O. A. Steatinion*, H. Smith).
26. The Ixalns (*Ixalus probaton*, Ogilby; *O. Ixalon*, Sundevall).
27. The Cretan Sheep (*O. Strepsiceros*, Ray; *O. A. Strepsiceros*, Schreb.; *O. Cretensis*, Jonst.; *Capra Cretensis*, Brisson; *Strepsiceros Cretica*, Besch.; Belier et Brebis de Valachie, Buffon; Zackl of the Austrians; Wallachian Sheep of Bewick).
28. The Long-Tailed Sheep of Russia (*O. longicaudatus*, Brisson; *O. Dolichura seu Tscherkessica*, Pallas).
29. The Broad-Tailed Sheep (*O laticaudatus*, Erxl., Geoff., 'Mem. Egypt,'; Lesson, 'Comp. Buffon,' x. 312; *O. laticauda platyceros s. Arabica*, Linn.; *O. Turcica*, Charlet; *O. cauda obesa*, Ludolf). It is a native of Barbary. There are several forms of this variety, of which the following are most prominent:—The Fat-Rumped Sheep (*O. Steatopyga*, Pallas; the Tartarian Sheep of Bewick); the Persian Sheep (*O. A. ecaudatus*, Geoff.); the Fat-Tailed Sheep (*O. A. macrocercus*, Schreb.); the Aora Fiyel, or Abyssinian Sheep; the Bucharian Sheep (*O. Bucharica*, Pallas); the Tibetan Sheep (*O. Thibetanus*, Fischer); the Cape Sheep (*O. Capensis*, Erxleb.); the Sheep of Belkah.

Fat-Tailed Sheep *Ovis Aries macrocercus*.

30. The Many-Horned Sheep (*O. polyceratus*, Linn.). It is also called the Four-Horned Ram, and the Dumba Sheep. It is a native of Nepanl.
31. The Puchia, or Hindustan Dumba (*O. puchia*, Hodgson).
32. The Sbort-Tailed Sheep (*O. brachyura borealis*, Pallas). It is a native of Northern Russia.
33. The Sheep of Tartary. They are said to eat bones like a dog.

The genns *Caprovis* embraces the following species:—

C. Vignei, the Sha, or Koch. It is the Monntain Sheep of the north of India, and is found in Tibet.

C. orientalis, the Armenian Sheep. It is the *Ægoceros Musimon* of Pallas; the *Ovis Musimon* of Brandt. It is a native of Armenia.

C. Musimon, the Mouflon. This animal has a mnltitude of synonyms. It is the *Capra Ammon* of Linnæus, and the *Ovis Musimon* and *O. Musmon* of other authors. It is the Wild Sheep and Siberian Goat of Pennant. It is found in Cyprus, Candia, and Corsica. For figure of Mouflon, see Sheep, p. 355.

C. Ammotragus, A. Tragelaphus, the Aondad of the Moors of Barbary and the Kebsch of the Arabians, is a native of North Africa. For figure, see Goat, where it is named Jaal Goat.

C. Canadensis, the Taye or Big Horn. It is the *Ovis montanus* of Geoffroy; and a variety, the *O. Californiana* of Douglas. Dr. Gray says it is probably the same as the Ammon of Northern Siberia.

There is only one species of *Pseudois*, the *P. Nahoor*, the Nahoor Nervate or Sna. It is a native of Nepaul.

C. Argalis, the Argali. It is the *Ægoceras Argali* of Pallas, and often confounded with the former. It is a native of Siberia. Dr. Gray says of this species—

"The Nyens or Bambheras, or Wild Sheep, seldom or never cross the Hemachal, the Indian side of which range is the special habitat of the Nahoors, while to the north and west beyond Thibet our animal is replaced by other species, so that Thibet may be considered as the special habitat of one species (*Ovis Ammonides*), and the plateaux north of Thibet as far as the Altai of another (*Ovis Ammon*), cited as types of the true ovine form; and it may be added, that the six sorts of tame sheep of Thibet and the Sub-Himalayas all without exception exhibit the essential characters of that form.

"There are several species that may be confounded under this head: the Siberian Argali is found in the most northern part of that country, and it is probably different from the Himalayan animal; but I have not been able to discover any difference between the specimen received from Mr. Hodgson and those which were sent from Siberia by the Russian naturalist."

OVER. [CHESHIRE.]

OVERSEER. The duties of overseers have by recent statutes been extended and modified in varions matters of detail; but the outline of their duties given under OVERSEER, vol. xvii., p. 70, is still sufficiently accurate, no alterations being of sufficient moment to call for comment.

OVERTON. [FLINTSHIRE.]

OVERWEG, DR. ADOLF, was born July 24, 1822, in the city of Hamburg. He was educated at the University of Bonn, and afterwards at the University of Berlin, where he took his degree. His favourite stndy was geology, which he pnrsued for some years. In 1849, when Mr. Richardson, at the expense of the British government, was preparing to undertake a journey to Lake Tchad, in Central Africa, Dr. Overweg and Dr. Heinrich Barth were selected to accompany him, in order to make scientific observations. An account of this expedition is given nnder AFRICA, *S.* 2. Dr. Overweg died of an attack of fever, Sept. 20, 1852, at Maduari, about ten miles east from Kuka, and near the western shore of Lake Tchad.

OXYCOCCUS, a genus of Plants belonging to the natural order *Ericaceæ*.

O. palustris, the English Cranberry, is found wild abundantly in the fens of Norfolk, Lincolnshire, and many other parts of England, always by the side of little rills, and not among stagnant water; it has slender trailing thread-like shrubby shoots, clothed with tiny linear leaves, and has a 5-parted pink corolla with the segments sharp-pointed and turned back. The fruit is a round austere red berry, which makes excellent tarts and one of the many kinds of marmalade. The Russian cranberries of the shops are borne by this species. They are not gathered till after the disappearance of winter. Near St. Petersburg the cranberry plant is so common, that the snow is stained crimson by the berries crushed to pieces by the passage of sledges over them.

O. macrocarpus, the American Cranberry, is very like the other, but its leaves, flowers, and fruit are larger; and the latter has a more medicinal taste. It is imported from the United States in hogsheads, in considerable quantity, and used for the same pnrposes as the other; bnt it is considered of inferior quality.

PAINSHAW. [DURHAM.]

PAIXHANS, HENRI-JOSEPH, General of Artillery in the French army, was born January 22, 1783, at Metz, in the French department of Moselle. He received instruction in the Ecole Polytechnique, and having entered the artillery, rose by successive gradations to the rank of Colonel, and ultimately of General. He was also elected a member of the French Chamber of Deputies, and spoke occasionally on snbjects connected with the army and navy. Several of his speeches in the chamber have been published, as well as the valuable works qnoted hereafter. General Paixhans died Angust 19, 1854, on his domain of Jouy-anx-Arches, near Metz.

General Paixhans made important improvements in the construction of heavy ordnance, and also in the projectiles, in the carriages, and in the mode of working the guns. The Paixhans-guns are especially adapted for the projection of shells and hollow shot, and were first adopted in France about the year 1824. Similar pieces of ordnance have since been introduced into the British service. They are suitable either for ships of war, or for fortresses which defend coasts. The original Paixhans-gun was 9 feet 4 inches long, and weighed nearly 74 cwts. The bore was 22 centimètres ($8\frac{2}{3}$ inches nearly). By judicious distribntion of the metal it was so mnch strengthened abont the cbamber, or place of charge, that it conld bear firing with solid shot weighing from 86 to 88 lbs., or with hollow shot weighing abont 60 lbs. The charge varied from 10 lbs. 12 oz. to 18 lbs. of powder. General Paixhans was one of the first to recommend cylindro-conical projectiles, as having the advantage of encountering less resistance from the air than round balls, having a more direct flight, and striking the object aimed at with much greater force, when discharged from a piece of eqnal calibre, whether musket or great gun.. As large ships of war, particnlarly three-decked ships, offer a mark which can hardly be missed, even at considerable distances, and as their wooden walls are so thick and strong that a shell projected horizontally could not pass through them, an explosion taking place would prodnce the destructive effects of springing a mine, and far exceeding those of a shell projected vertically, and acting by concussion or percussion. In accordance with these views, General Paixhans recommended the use of smaller ships carrying heavier guns suitable for projecting shells and hollow shot; and advised his government to avoid the construction of large ships, and the equipment of any ship for shell-firing to such an extent as to expose her to the great risk of being blown up by her own masses of ammunition. Paixhans-guns were used in the Russian ships of war which attacked the Turkish fleet in the roadstead of Sinope, and their powerful effects were made manifest by the ntter destruction of the Turkish forts as well as the ships.

General Paixhans suggested several other improvements in the French army as well as in the navy, as is shown by the following list of his principal works:—Considérations sur l'État Actuel de l'Artillerie des Places, et sur les Améliorations dont elle parait susceptible,' 4to, 1815; 'Nouvelle Force Maritime, ou Exposé des Moyens d'annnler la Force des Marines Actuelles de Haut-Bord, et de donner à des Navires très petits assez de Puissance pour détruire les plus grands Vaisseaux de Guerre,' 8vo, Paris, 1821, forming the First Book of the next work, 'Nouvelle Force Maritime, on Application de cette Force à qnelques Parties du Service de l'Armée de Terre: ou, Essai sur l'État Actuel des Moyens de la Force Maritime; sur une Espèce Nouvelle d'Artillerie de Mer qui détruirait promptement les Vaisseaux de Haut-Bord; sur la construction des Navires à Voile à Vapeur de Grandeur moderée, qui, armés de cette Artillerie, donneraient une Marine moins coûtouse et plus puissante que celles existantes; et sur la Force que la Système de Bonches à Feu proposé offrirait à Terre, pour les Batteries de Siège, de Côtes, et de Campagne,' 8vo, Paris, 1822; 'Expériences faites par le Marine Française sur une Arme Nouvelle; Changemens qui paraissent devoir résulter dans le Système Naval, et Examen des Questions relatives à la Marine, à l'Artillerie, à l'Attaque, et à la Défense des Côtes et des Places,' 8vo, Paris, 1828; 'Force et Faiblesse Militaire de la France: Essai sur la Question Générale de la Défense des Etats, et sur la Guerre Défensive, en prenant pour Example les Frontères Actuelles et l'Armée de la France,' 8vo, Paris, 1830; 'Fortifications de Paris, on Examen de ces Questions —Paris, doit-il être fortifié? les Systèmes presentés peuvent-ils être admis?' &c., 8vo, Paris, 1834; 'Constitntion Militaire de la France: Etude sur les Modifications à apporter an Système de nos Forces de Terre et de Mer, tant pour opérer les Progrès devenus nécessaires que pour diminuer les Défenses, sans que la Puissance Nationale en soit altérée,' 8vo, Paris, 1849.

PALM-TREE WINE. [BORASSUS.]

PALMBLAD, VILHELM FREDRIK, a Swedish writer of considerable note, was born on the 16th of December 1788, at Liljestad, near Söderköping, the 11th child of a military commissary, who had procured the situation of Kronofogde, or collector of taxes. The property of the family must have been considerable, as young Palmblad, when a student at Upsal, and before attaining his majority, bought, in conjunction with another student, the university printing-office, and forthwith commenced a series of publications, which had for their object to effect a revolution in Swedish literature. The first number of 'Phosphoros,' a new periodical by Atterbom and Palmblad, appeared in July 1810, within a month of his taking possession of the printing-office; at Christmas of the next year appeared the first number of the 'Poetisk Kalender,' the earliest Swedish annual, and in the beginning of 1813 the first of the 'Svensk Litteratur Tidning,' or 'Swedish Literary Gazette.'

The 'Tidning,' which lasted for eleven years—up to 1824—was the most long-lived Swedish literary periodical on record; while the Danes could, in 1824, boast of one that had outlived a century. Its circulation, we are told by Palmblad, was never upwards of 200, and averaged about 150: yet it had a great influence on the cultivation of Swedish literature. It excited the astonishment of the public by the audacity of its attacks upon the old school in literature, which at that time was entirely French in its models and its opinions; and on one occasion the Rector of the University of Upsal summoned Palmblad, as the university printer, before him to inform him that, if his periodical contained any more unfavourable criticisms upon the Swedish Academy, his privilege would be withdrawn. The Swedish Academy had been founded in imitation of the French Academy by Gustavus III., who was accustomed to declare that there were two things he held in utter abomination—the German language and tobacco. One of the chief objects of the new school—which from the title of its first periodical, the 'Phosphoros,' became known by the name of the 'Phosphorists'—was to introduce the Swedish public to some knowledge of the masterpieces of Göthe and Schiller; and in spite of the efforts of the Academy, which in the first instance looked upon the Phosphorists as a body of contumacious rebels, the result was general though not local success. Atterbom, the chief leader of the party, was indeed too fantastic in the character of his own writings to become unconditionally popular; but before the close of his career he was elected a member of the Academy of which he had been the assailant. Tegnér and Geijer, who had censured some of the proceedings of the new party as violent and intolerant, were themselves much more averse to the principles of the old; and, finally, an almost complete revolution took place in the aspect of Swedish literature.

Palmblad, who was active both with the pen and the press, continued to contribute to the periodicals that successively arose on the ruins of each other, the 'Journal of the Swedish Literary Union,' 'Svea,' 'Skandia,' 'Mimer Frey,' &c., and also pursued an academical career. In 1822 he became 'Docent' or tutor of Swedish history at the university, in 1827 assistant professor of geography and history, and in 1835 professor of Greek. Many of his numerous works are on the subjects which occupied him as professor: his 'Handbook of Physical and Political Geography' (5 vols., Upsal 1826-37) is of high reputation, and has been translated from Swedish into German. His poetical translations of Sophocles (1841) and of Æschylus (1845) are of some note. When professor of Greek however he often felt an inclination to return to an early amusement of writing novels, and his 'Falkensvärd Family,' (2 vols., Örebro, 1844-45), and 'Aurora Königsmark' (6 vols., Örebro, 1846-51), met with much success, and were translated into German. The work however which is certain to perpetuate his name is the great 'Biographical Dictionary of Celebrated Swedes,' which he left incomplete at his death, on the 2nd of September 1852.

This dictionary, 'Biographiskt Lexicon öfver namnkunnige Svenska Män,' commenced in 1835, was interrupted at Professor Palmblad's death, but is now again in progress. The last volume we have seen is the twenty-second, which brings it as far in the alphabet as the end of the letter W. It embraces the names of the living as well as the dead, and a considerable portion of the information it contains is derived from private communications or from personal observation, and embodied for the first time in its pages. It aspires to give an account of every Swedish name of note, and a list of the works of every Swedish author. The only other biographical dictionary of the same kind that the Swedes possess, is that of Gezelius in three volumes, and a supplement commenced in 1778. But the new work is on a much larger scale in every way than the somewhat meagre compilation of Gezelius. Many of the lives are given at considerable length, several are autobiographies, as the account of Palmblad himself. On the other hand, some of the lives of living persons are little more than a string of dates, with a record of promotions; but such inequalities are of course unavoidable in a work of the kind. The book is generally known as 'Palmblad's Biographical Dictionary,' but does not bear his name in the title, and in his life he speaks of himself as only one of the editors, and the author of a considerable number of the lives. It is one of the most indispensable books in a Swedish library, and will, as it comes to be more generally known, do much to spread abroad the knowledge of the illustrious names of Sweden.

PALMIPES, a genus of Star-Fishes belonging to the tribe *Goniasteriæ* and the family *Asteriadeæ*. The body is thin, flat, and pentagonal, and covered above and beneath with fasciculated spines; avenues bordered by longitudinal fasciculi of spines; suckers visceral. The species of this genus are not numerous.

P. membranaceus, the Bird's-Foot-Sea-Star, is a British species. It has broad ample sub-acute lobes. Colour white, with red rays and border. It is the thinnest and flattest of all its class. It ranges from the Arctic seas to the Mediterranean.

(Forbes, *History of British Star-Fishes.*)

PANARIA. [LIPARI ISLANDS.]

PANGIACEÆ, a natural order of Diclinous Exogenous Plants. This order embraces three genera, the species of which are trees with alternate stalked entire leaves, polypetalous axillary monœcious flowers, with scales in the throat of those bearing pistils. The stamens are five, the seeds large and oily. Dr. Lindley says, "What the distinction is between these plants and Papayads, except that the last are monopetalous, and have no faucial side scales in the ♀ flowers, it is hard to say.

The species are found in the hotter parts of India. They are all poisonous. The natives of India employ extensively in medicine the seeds of *Gynocardia odorata*, which are known by the name of Chaulmoogra and Petarkura. The genus *Hydnocarpus*, formerly referred to *Flacourtiaceæ*, belongs to this order.

PARIETINE. [CHEMISTRY, *S.* 2.]

PARIS, JOHN AYRTON, a distinguished physician, was born at Cambridge, on the 7th of August, 1785. He received his early education at the Grammar school at Linton. At the age of fourteen he commenced the study of medicine, and for this purpose became a pupil of Dr. Bradley of London, who was physician to Westminster Hospital. Here he made great progress in his classical studies, and made acquaintance with the sciences of chemistry and botany. In 1803 he matriculated at Caius College, Cambridge, where he became distinguished for the extent and elegance of his classical knowledge, and pursued the natural sciences as far as the university studies permitted him. He subsequently graduated as M.D. at Cambridge, after having previously studied at Edinburgh. He obtained the Tancred studentship in physic at Cambridge in 1804, and made the Tancred speech in 1808. He first commenced the practice of his profession in London, where he made the acquaintance and gained the patronage of Dr. Maton, whom he succeeded when only in his twenty-third year as physician to the Westminster Hospital. He had not, however, been long in London when he was induced to settle at Penzance in Cornwall, as successor to Dr. Borlase. Here he met with great success in practice, and turned his attention to the study of natural history. He founded the Royal Geological Society of Cornwall, one of the earliest geological societies in the kingdom. He wrote a 'Guide to Mount's Bay and Land's End,' which contained an account of the geology and objects of natural interest in that part of Cornwall. He also studied agriculture in relation to chemistry, and wrote a paper 'On the Soils of Cornwall, with a View to form a Rational System of Improvement by the Judicious Application of Mineral Manure.' He anticipated here the discoveries of modern times, and suggested a practice which is but now beginning to bear its fruits. Whilst at Penzance he also wrote 'Memoirs of the Life and Scientific Labours of the late Rev. W. Gregor.' In the Preface to this work, which was published in 1817, he took leave of his friends in Cornwall, and once more returned to London.

He now commenced a course of lectures on the materia medica, at the Windmill-street School of Medicine. He also gave a course of lectures on the philosophy of medicine, at the Royal College of Physicians. The matter of these lectures he afterwards worked into the Introduction to his celebrated 'Pharmacologia.' This work, which was originally published in 1819, went through many editions, and is at the present day regarded as one of the useful text-books on the subject of materia medica. He also published a 'Treatise on Diet,' which comprehended all that was known on the subject at the time he wrote. It was a work much needed in the profession, and brought Dr. Paris more than any of his other publications as a practical physician before the public.

As a Cambridge graduate all the positions at the London College of Physicians became opened to him. He was made a censor in 1817, an elect in 1839, and delivered the Harveian oration in 1843. On the death of Sir Henry Halford in 1844, as one of the elects, of whom there are seven, he was eligible for the post of president of the College, and was selected by the fraternity of elects to that position. During his presidency he was opposed to all reform in the College, whose charter, granted in the time of Henry VIII., is ill adapted to the requirements of the profession in the present century. He retained his position as president till his death, on the 24th of December, 1856, and was succeeded by Dr. Thomas Mayo.

Dr. Paris devoted much attention to the study of the physical sciences, especially chemistry. When in Cornwall he conferred a great benefit on the mining population by suggesting that the bar used for moving portions of rock, should be covered with copper, which prevented the iron of which it was composed from striking fire against the rock, and which by igniting the gunpowder used in blasting, often produced the most serious ill consequences. In London he became an early member of the Royal Institution, and was the friend and biographer of Sir Humphry Davy. His 'Life' of the great chemist is an unusually elegant piece of biography. He wrote anonymously a little work of great merit, and which has gone through many editions, entitled 'Philosophy in Sport made Science in Earnest.' He was a Fellow of the Royal Society, and a Doctor of Civil Law of the University of Oxford.

PARLIAMENT, IMPERIAL. The alterations which have been made in the law relating to the election of members of Parliament, and the constitution and powers of election committees, have been mentioned under ELECTIONS, *S.* 2.

PARONYCHIACEÆ, Meisner's name for the family of Plants called by Lindley *Knotworts*. Brown named this tribe, after *Illecebrum*, *Illecebreæ*, which is now most commonly adopted. [ILLECEBRACEÆ.]

PARRY, SIR WILLIAM EDWARD, KNIGHT., Rear-Admiral of the White, was born December 19, 1790, at Bath, in Somersetshire. His father was Caleb Hillier Parry, M.D., a physician of some celebrity. His mother was the daughter of John Rigby, Esq., of Lancaster.

Edward Parry, as he was always called when a boy (and generally known afterwards as Sir Edward Parry), was educated in the grammar-school of the city of Bath, where he attained a knowledge by no means contemptible of the Latin and Greek languages. His parents intended him for the medical profession, but in 1803 Miss Cornwallis, a near relative of Admiral the Hon. William Cornwallis, then in command of the Channel fleet off Brest, induced them to change their purpose. She thought he had the qualities suitable for a naval officer, and that her influence would suffice to float him off comfortably. As he had no objection to make trial of a sailor's life, in June 1803, through the kindness of Admiral Cornwallis, he was appointed a first-class volunteer on board the Ville-de-Paris, 110 guns, then about to go out as flag-ship to the Channel fleet. Young Parry took a liking to his profession, and studied French and mathematics under the chaplain of the Ville-de-Paris, which continued to cruise in the Channel, off Brest and Ushant. In the early part of 1806 he left the Ville-de-Paris to go on board the Tribune frigate, as a midshipman. The Tribune was employed about two years in cruising off the French coast; but in the spring of 1808 Captain Baker was promoted from the Tribune to the Vanguard, 74, which belonged to the Baltic fleet, and Parry went with him. The Vanguard returned to the Downs in December 1809, and Parry obtained his commission as lieutenant, January 6, 1810. Early in February the same year he proceeded to Sheerness to join the Alexandria frigate, which was about to sail on service in the Baltic, and was afterwards employed in the northern seas in protecting the Spitzbergen whale-fishery. During that period Lieutenant Parry was a good deal employed in making astronomical observations, and in improving the Admiralty charts of those seas. In January 1813 he left the Alexandria, and proceeded to Halifax in Nova Scotia, to join the La Hogue, 74. Great Britain was then at war with the United States, and Lieutenant Parry having joined the La Hogue in the summer of 1813, in the spring of 1814 was engaged in a successful boat-expedition, which ascended the river Connecticut as far as Pettipague Point, and destroyed several privateers and other vessels, in all 27, valued at 50,000*l.*, with the loss of only two men killed.

After the peace of 1814 the La Hogue returned to England, but Lieutenant Parry, in hopes of preferment, remained on the North American station in the Maidstone frigate, and afterwards in the Ardent, 64, the Carron, 20, and the Niger, 36. He continued on the North American station without preferment till March 1817, when he was summoned home in consequence of his father having suffered a severe attack of paralysis. While on the North American station in the La Hogue he drew up a little work for the use of the junior officers of the fleet on that station, and distributed it in manuscript. It was afterwards printed, under the title of 'Nautical Astronomy by Night, comprehending Practical Directions for knowing and observing the Principal Fixed Stars of the Northern Hemisphere; to which is prefixed a Short Account of the most interesting Phenomena in the Science of Astronomy; the whole illustrated by several Engravings,' 4to.

Lieutenant Parry was desirous of joining the expedition to the river Congo in Africa, but owing to his having been detained at the Bermudas, he did not reach England till the end of 1817, when it was too late. Meantime, in consequence of a report that the Arctic seas were then much less encumbered with ice than usual, the Admiralty had fitted out two expeditions for those seas, one under Captain Buchan and Lieutenant Franklin, to proceed by Spitzbergen to the North Pole; the other under Commander John Ross for the purpose of exploring Baffin's Bay, and ascertaining the probabilities of a North-West Passage from the Atlantic to the Pacific. Parry having heard of these expeditions, wrote to request employment, observing that he was "ready for hot or cold, Africa or the Arctic regions." When he arrived in London, he was introduced to Mr. Barrow, secretary to the Admiralty, who soon afterwards appointed him to the command of the Alexander, under the orders of Captain Ross in the Isabella. The Isabella, followed by the Alexander, left the Thames at the end of April 1818. On the 19th of August the two ships were off Smith's Sound at the northern extremity of Baffin's Bay. They then turned southwards, sailing along the western coast, passed the mouth of Jones's Sound, and on the 30th reached the wide opening of Lancaster Sound. The water was deep and free from ice, and on the following day both ships under a press of sail were steering westwards up Lancaster Sound. Parry was full of expectation, as were all the crew on board the Alexander, when suddenly the Isabella tacked, turned her head eastwards, and rejoined the Alexander. Both vessels then retraced their course, and Lancaster Sound was left behind. Commander Ross had imagined that he saw high land, which he named the Croker Mountains, barring the passage to the westward. The two vessels entered the Thames on their return in November of the same year.

Lieutenant Parry's opinion that there was an open passage up Lancaster Sound, and that the Croker Mountains were a mistake, though privately expressed, was soon known at the Admiralty. He had interviews with Mr. Barrow, and was introduced to Lord Melville; and a second expedition for the discovery of a North-West Passage having been resolved upon, the Hecla and Griper were taken into dock at Deptford to be repaired and strengthened for service in the Arctic seas. Parry was appointed to the command of the Hecla and of the expedition, Lieutenant Liddon being placed under his orders in the Griper. The expedition left the Thames on the 11th of May 1819, and having sailed up the eastern side of Davis's Strait and Baffin's Bay, on the 21st of July they were in 73° N. lat., nearly opposite to the entrance of Lancaster Sound, but with extensive masses of ice to the west interrupting their passage to it. Through these masses however, with excessive labour and frequently exposed to great danger of being crushed, the ships forced their way; and on the 29th of July reached open water on the western side of the ice, having passed through eighty miles of it. They entered Lancaster Sound, and sailing westward through the imaginary Croker Mountains, on the 4th of September crossed the meridian of 110° W. long. in 74° 44′ 20″ N. lat., by which they became entitled to a reward of 5000*l.*, offered by an order in council to such of his Majesty's subjects as might succeed in penetrating thus far to the westward, within the Arctic Circle. Parry gave the name of Barrow's Strait to the continuation of Lancaster Sound; discovered Melville island, on its northern side, and from its vicinity descried the high coast on the southern side, which he named Banks' Land, but which Sir Robert M'Clure has since ascertained to be the northern side of Baring Island. Parry also discovered Prince Regent's Inlet and the Wellington Channel, and penetrated as far as 113° 54′ 43″ W. long. On the 26th of September, after three days of arduous labour in cutting a channel, with the thermometer nearly at zero, both ships were got safely into their station at Winter Harbour, on the south shore of Melville Island. There the ships remained frozen up, with the sun entirely below the horizon from the 11th of November to the 7th of February, and were not released from the ice till the beginning of August 1820. After making several attempts to advance farther westward, they were compelled to return to England, and entered the Thames in November 1820. On the 4th of the same month Lieutenant Parry was promoted to the rank of commander; and several other rewards and honours, F.R.S., &c., were bestowed upon him. His 'Journal of a Voyage for the Discovery of a North-West Passage,' 4to, 1821, with maps and engravings, was published by authority of the Lords Commissioners of the Admiralty.

Arrangements were soon afterwards made for another expedition. Captain Parry received a commission, dated December 30, 1820, for the Fury, with Captain G. F. Lyon under his orders in command of the Hecla. This expedition was much less fortunate than the former. It sailed from the Nore on the 8th of May 1821, and having entered Hudson's Strait, on the 8th of October the ships were frozen in at Winter Island, where they remained till the 2nd of July 1822. They were then released, and sailed northward up Fox Channel. Having discovered the Fury and Hecla Strait, the ships were again frozen in on the 31st of October at the island of Igloolik, at the eastern end of Fury and Hecla Strait. There they remained till the middle of August 1823, when they commenced their voyage homewards, and entered the Thames in October. During his absence Captain Parry had been promoted to the rank of post-captain, November 8, 1821. His 'Journal of a Second Voyage for the Discovery of a North-West Passage, from the Atlantic to the Pacific, performed in the Years 1821-22-23,' 4to, 1824, was published by authority of the Lords of the Admiralty. On the 1st of December 1823 Captain Parry was appointed Acting Hydrographer to the Admiralty.

The Hecla and Fury were soon afterwards refitted for another Arctic voyage, the Hecla commanded by Captain Parry and the Fury by Captain H. P. Hoppner. They sailed from the Thames on the 8th of May 1824, passed the following winter at Port Bowen in Prince Regent's Inlet, and remained there frozen up from the 28th of September till the 20th of July, 1825. The Fury was shortly afterwards wrecked, and the Hecla reached England, with a double ship's company, in the following October. Parry's 'Journal of a Third Voyage for the Discovery of a North-West Passage' was similarly published, in 4to, in 1826.

After his return Captain Parry was appointed Hydrographer to the Admiralty, and continued to perform the duties of the office till the 10th of November 1826. Having then proposed a plan for reaching the North Pole, and obtained sanction for it, he was again appointed to the command of the Hecla for that purpose, and sailed from the Thames on the 3rd of April 1827. The Hecla was secured in Trenrenberg Bay, on the north coast of Spitzbergen, on the 21st of June; and on the 22nd two flat-bottomed boats, which had been prepared for the enterprise, left the ship, and proceeded northward. One boat, with twelve men, was commanded by Captain Parry; the other, with the same number of men, by Lieutenant James C. Ross. The remainder of the crew, under Lieutenant Foster, remained in charge of the Hecla. With excessive labour the boats were paddled through the water and dragged over the ice till they attained the latitude of 82° 45′, which is the nearest point to the North Pole ever yet reached. Finding then that a current was taking them southward as fast or faster than they could advance northward, they commenced their return, and reached the Hecla on the 21st of August, after an absence of sixty-one days. The Hecla began her return voyage on the 28th of August, and Captain Parry reached London at the end of September. This expedition terminated Parry's arduous labours in the Arctic regions. His 'Narrative of an Attempt to reach the North Pole in Boats fitted for the Purpose, and attached to his Majesty's Ship Hecla, in the Year 1827,' 4to, was published by authority of the Duke of Clarence, then Lord High Admiral.

Captain Parry resumed his situation as hydrographer; but, as his health suffered considerably from close attention to the duties of his sedentary occupation, he accepted the office of Commissioner of the Australian Agricultural Company in New South Wales. Previously however to his departure from England, he received the honour of knighthood from George IV., together with Sir John Franklin, April 29, 1829; and he and Franklin had, also together, the degree of D.C.L. conferred on them by the University of Oxford. Sir Edward Parry sailed from the Thames for Australia on the 20th of July, and reached Sydney on the 13th of December. His residence as commissioner was at Port Stephens, about 90 miles north from Sydney. He entered the Thames on his return, with his wife and family, in November 1834.

In March 1835 Sir Edward Parry was appointed an Assistant Poor-Law Commissioner in the county of Norfolk; but his health giving way under the pressure of work, he resigned the office within a year. In 1837 he was appointed to organise the packet-service between Liverpool and Ireland. From the 19th of April 1837 to the 2nd of December 1846 he was Comptroller of Steam Machinery for the Royal Navy. He then retired from active service, receiving the appointment of Captain-Superintendent of the Royal Clarence Yard and of the Naval Hospital at Haslar, near Portsmouth. On the 4th of June 1852 he attained the rank of Rear-Admiral of the White. At the end of 1853 he received the appointment of Lieutenant-Governor of Greenwich Hospital, a situation which he retained till his death, which took place on the 7th of July 1855, at Ems in Germany, where he had been residing for the benefit of his health. His body was brought to England, and interred in the cemetery at Greenwich.

Sir Edward Parry married, October 23, 1826, Isabella Louisa, fourth daughter of the first Lord Stanley of Alderley. She died May 13, 1839. On the 29th of June 1841 he married the daughter of the Rev. Robert Hankinson, of Walpole in Norfolk, and widow of Samuel Hoare, jun., Esq. By his first wife he had two sons and two daughters, and by his second wife, who survives him, two daughters.

A life of Sir Edward Parry, has been published recently, 'Memoirs of Rear-Admiral Sir W. Edward Parry, Knt., F.R.S., &c., late Lieutenant-Governor of Greenwich Hospital, by his Son, the Rev. Edward Parry, M.A., of Balliol College, Oxford, and late Tutor in the University of Durham,' cr. 8vo, London, 1857.

PARSONSTOWN. [Birr.]

PARTNERSHIP. [Joint-Stock Companies, *S.* 2.]

PASENG. [Goat.]

PASKEVICH, IVAN FEDOROVICH, a Russian field-marshal, Prince of Warsaw, and Viceroy of Poland, was descended from a family of the Greek religion, bearing the name of Paskiewicz, which was driven from Poland in the 17th century by the persecution of the Jesuits. He was born on the 19th of May (new style) 1782, at Pultowa or Pultava, famous for the battle which decided the ascendancy of Russia over Sweden. After receiving his education at St. Petersburg, he held the appointment first of page and afterwards of aide-de-camp to the Emperor Paul, and subsequently to the Emperor Alexander. He first saw service at the great battle of Austerlitz in 1805. In 1806 he was sent with the Russian ultimatum to the Porte, and in those days of Turkish barbarism owed to his own determination and activity his escape from Constantinople with his life. Not long afterwards he was taken up for dead from the ditch of Brailov, where he had mounted to the assault: he was promoted as a reward to the rank of colonel, and from that time his advancement was rapid. In the great campaign against the French in 1812 he fought at Borodino, and afterwards being put in command of a division, which at first amounted to only 4000 men, but subsequently rose to 30,000, took an active share in the triumphant campaign in Germany, and was one of the captors of Paris. After the peace he accompanied the Grand Duke Michael on a three years' tour through Europe. On the accession of the Emperor Nicolas in 1825 he was named successor to Yermolov, in command on the Persian frontier, at the time of the outbreak of the war with Persia. So high had the name of Yermolov risen, that it was doubted by the Russians, probably for the first time in Russian history, if a subject would yield obedience to the emperor's orders, and it even occasioned some surprise that 'the King of the Caucasus' allowed himself to be dethroned so easily. Paskevich, on the 25th of September 1826, defeated the Persians under Abbas-Mirza at Elizavethpol; later in the same year he crossed the Araxes; early in the next he conquered all Persian Armenia, and on the 13th of October he took by assault Erivan, and thenceforth by the emperor's order bore the name of Paskevich-Erivansky to commemorate the exploit. The peace with Persia, established by the treaty of Turkmanchai (22nd of February 1828), was almost immediately followed by war with Turkey. In 1828 Paskevich took Kars, and in the following year Erzerum, receiving in reward the title of field-marshal. A year of desultory warfare against the Circassians in 1830 was followed in 1831 by the campaign against the Poles, to whom the name of Paskevich sounded as that of a countryman. He took the command of the Russian army after the death of Diebitsch, and, more fortunate than his predecessor, was soon able to announce the fall of Warsaw. Raised to the rank of Prince of Warsaw, and made Governor-general of Poland, he promulgated the organic statute of the 26th of February, 1832, which unites Poland to Russia, and for the next sixteen years carried out his plan of subjecting the country, one of the main points of which was the conversion of Warsaw into a strong fortress against its own inhabitants not less than against an invading army. He succeeded so well, that 1848 passed over Russian Poland without a revolt, and in 1849 the Emperor Nicolas could spare him to crush the Hungarians. As on former occasions, his plans did not meet the approbation of military critics, but with his usual good fortune he was enabled to commence a despatch to the emperor in August with the words, "Hungary is at your feet." In 1850 the jubilee of his fiftieth anniversary in the service was celebrated with great rejoicings at Warsaw, and on this occasion the Emperor of Austria and the King of Prussia nominated him a field-marshal in their respective armies. This was the culminating point of Paskevich's long career. When the recent war broke out between Russia and Turkey, the veteran was again summoned to the field, much, it is said, against his will. He planned the campaign against the Turks, which terminated disastrously for the Russians in the repulse of their attack on Silistria, and in that repulse Paskevich himself, then past his seventieth year, received a severe contusion. From this time he seems never to have thoroughly rallied, and after a long and tedious illness he expired at Warsaw on the 29th of January 1856.

Marshal Paskevich was married to a lady who was a relative of the poet Griboyedov, his companion in some of his Persian campaigns, and had by her four children, one of whom, a son, Fedor, is a colonel of the Russian guards, and has also made his appearance as an author. A separate life of the marshal in French was published by Tolstoy at Paris in 1835.

PASSER. [Sparrow.]

PASSIFLORACEÆ, *Passion-Flowers*, a natural order of Hypogynous Exogenous Plants. This order is included by Lindley in his alliance *Violales*. It is characterised by possessing polypetalous or apetalous coronetted flowers; perigynous imbricated petals; stamens on the stalk of the ovary; simple terminal styles; arillated seeds; and stipulate leaves. The species are herbaceous plants or shrubs, usually climbing, very seldom erect.

Considerable difference of opinion exists among botanists as to the real nature of the floral envelopes of this remarkable order. Jussieu and De Candolle, regarding the parts called petals as a second row of sepals, have made the order apetalous; whilst Lindley and others have regarded the second row of floral envelopes as petals, and made it polypetalous. Lindley makes the affinities of this order with *Samydaceæ*, *Capparidaceæ*, *Malesherbiaceæ*, and *Papayaceæ*.

Most of the useful properties of this order are included in the genus *Passiflora*. [Passiflora.] *Murucuja ocellata*, a West Indian Climber, is said to be anthelmintic and diaphoretic. Besides the fruit of several species of *Passiflora*, the fruit of *Tacsonia mollissima*, *T. tripartita*, *T. speciosa*, and *Paropsia edulis* are all of them edible. The species are principally found in South America. There are 10 genera and about 216 species.

PASSION-FLOWERS. [Passifloraceæ, *S.* 2.]

PATELEY-BRIDGE. [Yorkshire.]

PATENT. The Law with respect to Patents has been greatly simplified and improved by the statute 15 & 16 Vict. c. 83, the fees payable for a patent have been reduced, and the payment of them spread over several years. One patent now suffices for the United Kingdom; and is no longer void as formerly from trifling inaccuracies in the specification, as these may now be disclaimed. A Register of Patents has likewise been provided, in which disclaimers, assignments, and licences must be recorded.

PATRINGTON. [Yorkshire.]

PAULUS, HEINRICH EBERHARD GOTTLOB, was born on September 1, 1761, at Leonberg, near Stuttgart. He first proposed devoting himself to the study of medicine; but becoming attached to the sect of Pietists, he soon turned his attention to theology, and proceeded to Tübingen, where he pursued his studies. By the liberality of the Baron von Palm he was shortly enabled to travel in Franconia and Saxony, in order to examine the state of education. He afterwards studied the Oriental languages at Göttingen, and then again assisted by Palm, proceeded to London and Oxford to prosecute his studies. On his return to Germany he was appointed in 1789 professor of the Oriental languages in the University of Jena. Here he occupied himself in illustrating and explaining the Old and New Testaments in a philological-historical manner, which he first developed to the world in his 'Clavis über die Psalmen,' 1791, and 'Clavis über den Jésaias,' 1793, with others. To these succeeded his 'Philologisch-kritischer und historischer Commentar über das Neue Testament,' which was given to the world in 4 volumes from 1800 to 1804, which made a great impression, and added much to his reputation. In 1793, on Döderlein's death, he was created professor of theology, but on account of his health, he removed in 1803 to Würzburg in a similar capacity, where he became also a counsellor of the consistory and government. On the abolition of the Protestant theological professorship at Würzburg, he was sent to inspect the state of the schools and churches, in 1808 to Bamberg, in 1809 to Nürnberg, and in 1811 to Ansbach. In this year a call to the chair of exegesis and church history in the University of Heidelberg restored him to his academical life, and to his literary activity. In 1814 the endeavours then being made to give a constitution to his native state of Würtemberg excited his attention, and in 1819 he commenced writing in a periodical work called 'Sophronizon,' in which his essays upon passing important subjects, such as proselytising, upon the influence of the Papist government on the national Roman Catholic Church of Germany, and others, gained great applause. In this he continued to write till 1829. As a theological writer he was anxious to warn his readers equally against a one-sided nationality and a speculative deviation from the original doctrines of Christianity, as from mysticism and Jesuitism. With these ideas he began in 1825 a theological year-book, called 'Der Denkgläubige,' published from 1825 to 1829, and another journal called 'Kirchenbeleuchtungen,' published in 1827. Among his other numerous writings we may mention 'Memorabilien,' published in parts from 1791 to 1796; 'Sammlung der Merkwürdigsten Reisen in dem Orient,' in 7 vols., published from 1792 to 1803; 'Leben Jesu, als Grundlage einer reinen Geschichte des Urchristenthums,' 2 vols. 1828; 'Aufklärende Beiträge zur Dogmen- Kirchen- und Religions-Geschichte,' 1830; 'Exegetisches Handbuch über die drei ersten Evangelien,' 3 vols., 1830 to 1833; 'Skizzen aus seiner Bildungs- und Lebens-Geschichte, zum Andenken an sein fünfzigjahriges Jubiläum,' 1839; and the 'Vorlesungen Schelling's über die Offenbarung,' accompanied with critical remarks. Few men have had a wider influence upon religious opinions in Germany than Paulus, though many of his views have been contested as too rationalistic. In 1844 on account of his great age he was allowed to retire from his situation on a pension, and he died on August 9, 1850, aged ninety.

PAUPERISM. [POOR-LAWS, *S.* 2.]

PECULIAR. The jurisdiction of all Royal and other Peculiars in the probate of Wills and the grant of Administrations has been transferred to the new Court of Probate. [PROBATE, COURT OF, *S*, 2.]

PEDICELLARIA, the name given by Müller to little pincer-shaped bodies found on the surface of many species of star-fishes and sea-urchins. When seen on the surface of the dried specimens they appear like little cleft spines. In *Uraster rubens*, according to Dr. Sharpey, they cover the surface generally, and are more numerous round the spines. Each one of these little bodies consists of a soft stem, which bears on its summit a little forceps of calcareous matter. If anything is introduced between the blades of these forceps when the animal is alive, it is instantly grasped with considerable force. Those on the body and upper spines differ in shape from those on the spines immediately bordering the avenues. When the star-fish is living the blades of the forceps are in continual activity, but when cut off they seem to lose that power. These bodies have been observed by Sars in *Echinus sphæra*, and he describes three species—*P. tridens*, *P. triphylla*, and *P. globifera*.

The question of the nature of these bodies has been often agitated. Whilst Müller and others have considered them to be parasitic animals, Oken, Sharpey, and Sars regard them as organs of the animal. Sars assigns the following reasons for his belief:—

1. The *Pedicellariæ* are found in the same species of *Echinodermata* under all circumstances, which would not be the case if they were parasitical animals.

2. The structure of the calcareous forceps and stems to which they are attached, bear structurally a greater resemblance to the spines of the *Echinodermata* than to other structures.

3. The *Pedicellariæ* have a vital connection with the skin and shell of the *Echinus*. The stem of the *Pedicellaria* is attached to a knob of the shell of the *Echinus*, on which it moves.

4. Sars states that when a single *Pedicellaria* is irritated, the rest are inclined towards it.

Although Professor E. Forbes states that he was not able to confirm Sars's observation on the two last points, he was nevertheless inclined to adopt the opinion that they were peculiar organs of the *Echinodermata*, rather than parasitic animals.

(E. Forbes, *British Star-Fishes*.)

PEDILANTHUS, a genus of Plants belonging to the natural order *Euphorbiaceæ*. It has a common slipper-shaped involucre. The male flowers several in the circumference. Pedicels bracteolate, each articulated with a naked anther. Female flowers one in the centre. Calyx wanting; style 1; stigmas 3; capsules 3-coccus.

P. tithymaloides, Jew-Bush, is found in various parts of the West Indies in stony bushy places, near the coast. It is a shrub throwing out runners, erect, about six feet high, abounding in white bitter milk. The stems are numerous, weak, soft, as thick as the finger; when old cinereous, when young green. The leaves are ovate, obtuse, or acute; coriaceous, entire, alternate, stalked, distichous, when young downy on each side, and wavy at the edges, becoming at last quite smooth and flat. Peduncles 1-flowered, short, clustered about the extremities of the branches. Involucre slipper-shaped, bright-red with a green back. The practitioners of Curaçoa give a decoction of the whole plant, especially of the stem, as the ordinary beverage, and in large doses in some diseases. The root is emetic.

PEEL, SIR ROBERT, the second baronet of the name, was born on the 5th of February, 1788, near Bury in Lancashire, the eldest son and third child of the first Sir Robert Peel. He was educated first at Harrow school, where he had Lord Byron for his class-fellow, and afterwards at Christ Church, Oxford, where he graduated B.A. in 1808. Both at school and at the university he was distinguished by his talents, his studiousness, and the solid perseverance of his character; and, on quitting the university he took what was then (the modern examination system having been but recently introduced) the unprecedented honour of a double first-class—i. e. of paramount excellence both in classics and in mathematics. He had scarcely left college when, in 1809, at the age of twenty-one he was returned to the House of Commons as member for Cashel. His father had destined him for a political career, and from the time of his first entrance into Parliament he was placed in a position of absolute independence by an allowance out of his father's income equal in amount to the fortune of many a nobleman.

On entering Parliament Mr. Peel attached himself to the Tory party, to which his father already belonged. Perceval was then prime minister, and Canning and Castlereagh were his most powerful coadjutors; while on the Whig benches sat Sheridan, Tierney, Whitbread, Horner, Brougham, Romilly, and Sir Frances Burdett. The elder Peel had made no secret of the great expectations he entertained of his son's success in Parliament; and the young man's first steps in the walk of life for which he had been confessedly trained, were looked at with much interest and with some jealousy. But Mr. Peel was prudent, and was in no haste to measure himself against the established orators of the House. His first speech of any length was in January, 1810, when he seconded the address at the opening of the session. His subsequent votes and speeches gained him the reputation of a steady and able young man, from whom much might be expected; and this, coupled with the weight which he possessed as the son of a man of so much commercial influence, led to his appointment, in 1811, to the office of under-secretary for the colonies. It was the time of the Peninsular War, and of the great struggle with Napoleon, of which that war formed a part; and as purely colonial questions were of comparatively small importance in the midst of events of so engrossing a nature, Mr. Peel had not many opportunities of displaying his powers in his first office, whether as an administrator or as a parliamentary speaker. Whatever he did however brought him a clear accession of parliamentary reputation.

The assassination of Mr. Perceval on the 11th of May, 1812, occasioned the formation of a new Tory ministry.

The Earl of Liverpool became premier with Lord Castlereagh as foreign secretary, Lord Sidmouth as home secretary, Lord Eldon as chancellor, and others of the seniors of the same party in other places of the cabinet; while among the ministers out of the cabinet were Viscount Palmerston as secretary at war, the Duke of Richmond as lord-lieutenant of Ireland, and Mr. Peel as chief secretary for Ireland. The post accepted by Mr. Peel in this ministry, stationing him as it did in the midst of the tempestuous sea of Irish politics, was no very enviable one. The Irish agitation connected with the union of 1800 had not yet subsided; the agitation for Catholic emancipation was fiercer than ever; and Mr. O'Connell had just become the leader of the Irish people, and was singling out objects against which to direct the full force of the popular wrath. The young secretary for Ireland was identified with the anti-Catholic policy of the existing ministry; he was nick-named 'Orange-Peel;' and Mr. O'Connell seemed from the first to conceive an implacable hatred to him personally. After various manifestations of this animosity, Mr. O'Connell in May, 1815, attacked him in one of his public speeches in terms so directly insulting that a challenge was the consequence. Some delay however having occurred in settling the preliminaries, the duel was prevented by the interference of the police. It became more evident afterwards than it was at that time that, though Mr. Peel opposed the claims of Roman Catholic emancipation, and backed the ministry with which he was connected in their resistance to those claims, his notions with respect to the government of Ireland were by no means those of the extreme Orange party. "From his first entrance," says one of his biographers, "upon the tumultuous arena of Irish politics to the end of his life, he would, if he could, have quenched the fiercer polemics that consumed the country amid their fires, in the cooler element of practical and secular education; but this was far beyond his power. His encouragement of schools, where the strife of religious proselytism might be merged in the soberer pursuits of ordinary mental culture, was only attributed to lukewarmness by one party and to infidelity by the other; and by the diligence alone with which he sought to remedy the multiform abuses and total want of order which existed in the details of his own office, did he gain credit in Ireland with either party. In all else, for his own party he was too temporising, for the emancipationists too exacting." To all intents and purposes however he acted consistently with his position as Irish secretary under the Liverpool administration. Not only did he oppose Mr. Grattan's motion for a committee to consider the Roman Catholic claims in February, 1813, and again Sir Henry Parnell's motion on the same subject in 1815, but his speeches on both these occasions were the ablest that he had yet delivered, and among the most telling on that side of the debate. They scarcely grappled with the question on the ground of essential principle, but strongly and skilfully laid hold of the points of real practical difficulty. The truth is that a mind so thoroughly cool, English, and moderate as that of Peel, must have felt itself out of its element when charged, in a subordinate capacity, with the management of Irish affairs at a time of such heat and frenzy. Accordingly, as soon as an opportunity offered, he vacated the Irish secretaryship. The war with Napoleon I. was at an end; Waterloo had brought peace; Europe had been re-arranged by the Treaty of Vienna; and the Liverpool-Castlereagh ministry, with gradually increasing unpopularity, was addressing itself to the home-questions the discussion of which forms the chief part of the history of the Regency. Such was the state of affairs when Mr. Abbott, the Speaker of the House of Commons, having retired into the Upper House as Lord Colchester, and a vacancy having in consequence occurred in the representation of the University of Oxford, Mr. Peel was elected his successor (1818). Mr. Canning aspired to the honour; but the influence of Lord Eldon, and the conviction entertained by the university of the orthodoxy of Mr. Peel's views on the Roman Catholic question, determined the choice. Mr. Peel then, greatly to the regret and not a little to the damage of the government, already far from firm, resigned his post without accepting another.

From 1818 till 1822 Mr. Peel had no official connection with the Liverpool-Castlereagh ministry. He continued, however, to give it his extra-official support in all measures of consequence. It was during this period, too, that by the leading part he took in the pressing currency questions of the day, he laid the foundation of his subsequent fame as a financier. He had already shown his sympathy with the views of what was then called the Economist party, of which Mr. Horner during his life had been the head, and to which the House about this time received a powerful accession in Mr. David Ricardo; and on the appointment of a Bank-Committee in February 1819, to consider the question of a resumption of cash payments and other allied questions, rendered necessary by the commercial distresses attending the transition from a state of war to one of peace, Mr. Peel, then only thirty-one years of age, was appointed chairman, having among his colleagues Canning, Castlereagh, Vansittart, Tierney, Huskisson, Frederick Robinson, and Sir James Mackintosh. In the proceedings of this committee and the debates which arose out of them, Mr. Peel displayed his ability both as a speaker and as a man of business; and it was in May 1819 that, in moving resolutions involving a resumption of cash-payments, he constituted himself the champion, to use his own words, of "the old, the vulgar doctrine, as some called it, that the true standard of value consisted in a definite quantity of gold bullion." "Every sound writer on the subject," he said, "came to the same conclusion, that a certain weight of gold bullion, with an impression on it denoting it to be of that certain weight, and of a certain fineness, constituted the only true, intelligible, and adequate standard of value." Though these views were carried into effect by parliament, there were not wanting members who demurred to them; and among these was Mr. Peel's father, Sir Robert. Besides this currency question, the further history of which we need not trace, Mr. Peel in the same year took part with the Liverpool government in their opposition to the then revived agitation for Parliamentary Reform. He approved of the famous 'Six Acts;' and—what was long afterwards remembered by the other party to his discredit—he defended, with a vigour all the more remarkable that he was not called upon to exhibit it by any official connection with government, the conduct of the magistracy in the so-called 'Manchester massacre' of August 1819. He kept aloof however, with studious caution, from the ministerial proceedings in the case of Queen Caroline, which followed the demise of George III. and the accession of George IV. to the throne (January 29, 1820), and which were terminated by the queen's death in August, 1821. It was in the midst of this storm of matrimonial politics that Mr. Peel himself married. His wife was Julia, the youngest daughter of General Sir John Floyd, Bart. The marriage took place on the 8th of June, 1820.

George IV. having retained the Liverpool ministry in office, Mr. Peel was induced again to become a member of it. In January, 1822, he took office as secretary of state for the home department. A further modification of the ministry was caused by the suicide, in August, of Lord Castlereagh, whom Mr. Canning succeeded in the foreign secretaryship. Till the fatal illness of Lord Liverpool (April, 1827) broke up this ministry, Mr. Canning and Mr. Peel continued to be the most prominent and active members of it—agreeing sufficiently to co-operate, but having at the same time certain differences. While Mr. Canning was liberalising the foreign policy of the country, Mr. Peel was busy with new forms of the currency-question peculiar to a time of unusual commercial distress and panic. While Mr. Canning was favourable to a consideration of the Roman Catholic claims, Mr. Peel, as before, opposed them, though with a growing conviction that the opposition could not be long continued. Both remained opposed to parliamentary reform. Prior to the time of Lord Liverpool's resignation his ministry was broken into two parties—the Old Tory or Eldon-Peel party who stood opposed to the Roman Catholic claims, and of whom Mr. Peel was the active leader; and the more liberal party, who, with Canning as their leader, were approximating to the Whigs. The question, on Lord Liverpool's retirement, was whether by the appointment of a nobleman of high rank and influence, such as the Duke of Wellington, to succeed him, the two parties could be held together, or whether a new ministry should be formed of which Canning should be the head. The second was the alternative which actually came to pass. The king, though personally hostile to the Roman Catholic claims, empowered Mr. Canning to form a ministry in which the Roman Catholic question should be an open one, but which should be pledged to resist parliamentary reform or any repeal of the Test and Corporation Act. In this ministry, the formation of which was regarded as a new epoch in the political history of the country, and was accordingly welcomed by many of the leading Whigs, Mr. Canning held the Chancellorship of the Exchequer together with the premier's usual office of First Lord of the Treasury; and the blanks in the administration caused by the secession of Lord Eldon, Mr. Peel, the Duke of Wellington, Lord Melville, and others, were filled up by the selection of men willing to act along with Mr. Canning—among whom was Mr. Robinson (now created Lord Goderich) as Colonial Secretary, and Sir John Copley (now Lord Lyndhurst) as Lord Chancellor (April 1827). [CANNING, GEORGE.]

On Mr. Canning's death (Aug. 8, 1827), his anomalous ministry, so delicately poised between the Tories and the Whigs, was continued for a few months by Lord Goderich; but on his resignation, in January 1828, a new ministry was formed of the old Tory construction, with the important and significant exception, that Lord Eldon was not re-instated in the chancellorship, but Lord Lyndhurst continued in it. The following was the composition of the cabinet of this memorable administration, which, from the names of its two chiefs, is now usually called the Wellington-Peel Administration:—First Lord of the Treasury, the Duke of Wellington; Chancellor of the Exchequer, Mr. Goulburn; Lord Chancellor, Lord Lyndhurst; President of the Council, Earl Bathurst; Lord Privy Seal, Lord Ellenborough; Foreign Secretary, Lord Dudley and Ward; Colonial Secretary, Mr. Huskisson; Home Secretary, Mr. Peel; Master of the Mint, Mr. Herries; President of the India Board, Lord Melville; President of the Board of Trade, Mr. Grant; Secretary at War, Lord Palmerston. The ministry was afterwards modified by the secession of Mr. Huskisson. Its great act was the passing of the Roman Catholic Relief Bill—a measure the eventual necessity of which Mr. Peel had been prepared for; which was now pressed to an issue by the overwhelming influence of the Catholic Association in Ireland, as shown in the election of Mr. O'Connell to the House of Commons for the county of Clare, and which the ministry determined on as soon as the king had given his reluctant consent. On the 5th of March 1829, Mr. Peel—who had in the meantime been rejected by the University of Oxford in favour of Sir Harry Inglis, whose anti-Roman-Catholic principles recommended him—brought forward the Relief Bill in the Commons, as member for the close borough of Westbury. His speech on this occasion was not only powerful at the time, but is interesting now as revealing what may be called the cardinal principle of Mr. Peel's career as a statesman. "We are placed," he said, "in a position in which we cannot remain. We cannot continue stationary. There is an evil in divided cabinets and distracted councils which cannot be longer tolerated. . . . . Supposing this to be established, and supposing it to be conceded that a united government must be formed, in the next place I say that government must choose one of two courses. They must advance or they must recede. They must grant further political privileges to the Roman Catholics, or they must retract those already given. . . . . I am asked what new light has broken in upon me? Why I see a necessity for concession now which was not evident before? The same events, I am told, have happened before, and therefore the same consequences ought to follow! Is this the fact? Are events in politics like equal quantities in numbers or mathematics, always the same? Are they, like the great abstract truths of morality, eternal and invariable in their application? May not the recurrence—the continued recurrence—of the very same event totally alter its character, at least its practical results?" Mr. Peel on this occasion spoke out, as a statesman, the general sense of the nation; and the Emancipation Act, after running the gauntlet of the Upper House, became law. Besides this great measure, Mr. Peel, as Home Secretary, introduced other measures, including the New Metropolitan Police Act, which provided London with its efficient body of 'Peelers,' subject to the Home Office, in lieu of the old 'Charlies.' Questions of currency also occupied him during this administration.

Though the Wellington-Peel government had yielded on the Roman Catholic Relief question, they were not prepared to yield on the great constitutional question of Parliamentary Reform. When in February 1830, Lord John Russell moved the question of disfranchising one or two corrupt small boroughs, and transferring the representation to some of the large commercial towns then unrepresented, Mr. Peel opposed the motion, "because it introduced a principle into the system of representation—that of mere numbers—which he said was the ultra-democratic principle, and with which the aristocratic and monarchical principle could not long co-exist." The death of George IV. however (June 26, 1830), and the accession of William IV., followed as it was by an immediate dissolution of Parliament, and a general election (not to speak of the concurrent influence of the French Revolution of July), rendered the continued refusal of Parliamentary Reform impossible. After the re-assembling of Parliament on the 2nd of November 1830, the Duke again repudiated reform absolutely; but Mr. Peel's language, though also negative, was more guarded. Amidst violent excitement, the ministers resigned; and a Reform ministry—the first Whig ministry since 1807—was constituted the same month under the premiership of Earl Grey. Lord Brougham became Lord Chancellor; Lord Palmerston, Foreign Secretary; the Marquis of Lansdowne, President of the Council; Lord John Russell, Paymaster of the Forces; Lord Althorp, Chancellor of the Exchequer; and Mr. Peel was succeeded in the Home secretaryship by Lord Melbourne. It was at this juncture that the death of Mr. Peel's father raised him to the baronetcy and the estates.

For the first time in his life Sir Robert Peel was now in open opposition. He opposed with great determination the Whig schemes of reform, but in such a manner as to indicate his private conviction, from an observation of public opinion, that *some* change in the representative system was inevitable. His conduct in fact, during the whole of the Reform Bill crisis, had an important influence on the result. He declined at the last moment to join with the Duke of Wellington in the attempt to form a ministry to supersede that of Earl Grey. The Duke of Wellington withdrew his opposition: on the 4th of June 1832 the Reform Bill passed the Lords, and three days afterwards it was law. In January 1833 the first reformed Parliament met. Sir Robert Peel was returned for Tamworth, which he continued to represent during the rest of his life.

Acquiescing in the new state of things, and abandoning all idea of abrogating the constitutional change which had occurred, it was now Sir Robert's aim to organise, what he called a 'Conservative' party, as distinct either from that of the Whigs, or that of the inveterate Tories. Supported in this aim by the Duke of Wellington and others, whose views took the same shape, he acted as a vigilant, but not factious, critic of the various important measures introduced by the Whigs into the Reformed Parliament; first, under the premiership of Earl Grey; and, next, under that of Lord Melbourne. He gave his support to the Irish Coercion Bill; he advocated the abolition of negro slavery in the colonies, but advised great caution in the practical steps for carrying it into effect; and he acted a cautious part in the debates on the Poor Law Amendment Act of 1834, but, on the whole, approved of that momentous change. These measures were carried while Earl Grey was still premier; but before the prorogation of Parliament in August, 1834, Lord Grey had been succeeded by Lord Melbourne, with Lord Althorp as his Chancellor of the Exchequer. The death of Lord Althorp's father, Earl Spencer, in November 1834, having raised him to the Upper House, the king, to the surprise of all, availed himself of the ministerial difficulty thus occasioned to dismiss the Whig Ministers altogether, and call the Duke of Wellington to his councils. Sir Robert Peel, who had not expected any such event, was then at Rome with his family. Being sent for, however, he hastened back to London, where he arrived on the 9th of December; the Duke, who had, in the mean time, acted provisionally as minister, immediately consulted with him, and a Conservative Ministry was arranged as follows:—First Lord of the Treasury and Chancellor of the Exchequer, Sir Robert Peel; Lord Chancellor, Lord Lyndhurst; President of the Council, Lord Rosslyn; Privy Seal, Lord Wharncliffe; Foreign Secretary, the Duke of Wellington; Home Secretary, Mr. Goulburn; Colonial Secretary, Lord Aberdeen; First Lord of the Admiralty, Earl de Grey; Master of the Ordnance, Sir George Murray; President of the Board of Trade and Master of the Mint, Mr. Alexander Baring; President of the India Board, Lord Ellenborough; Paymaster of the Forces, Sir E. Knatchbull; Secretary at War, Mr. Herries; Secretary for Ireland, Sir Henry Hardinge.

Sir Robert Peel's first premiership was but short. It began in December, 1834, and in April 1835 it was at an end. On assuming office, Sir Robert, in a letter to the electors of Tamworth, had made a manifesto of the intended policy of his Conservative ministry. "With regard to the Reform Bill," he said, "I will now repeat the declaration which I made when I entered the House of Commons as a member of the Reformed Parliament, that I consider the Reform Bill a final and irrevocable settlement of a great constitutional question—a settlement which no friend to the peace and welfare of this country would attempt to disturb, either by indirect or insidious means." Proceeding on this as a fixed principle, the new ministry was to govern the country in a Conservative spirit, but with a readiness to carry into effect certain minor domestic reforms which were indicated. This policy, however, while perhaps it was not satisfactory to the remnant of the old Tories, was certainly not satisfactory to the country at large. The Reform Bill had not, indeed, produced all the results that the more eager had anticipated; the Whigs had not, in all respects, come up to the mark of popular expectation, and the disappointment had begun to show itself among the Radical party, who criticised the Whigs severely and were bent on carrying farther constitutional changes. Still, the re-action against Whig rule was not such that Sir Robert Peel's "Conservative" ministry could stand its ground. This was shown by the result of the elections which followed the dissolution of Parliament—a dissolution thought necessary by Sir Robert himself. As soon as the new Parliament met, government was defeated by a majority of 316 votes to 306 on the election of a speaker—Mr. Abercromby, the nominee of the Whigs (now Lord Dunfermline), being chosen instead of the former speaker, Sir Charles Sutton. This was on the 19th of February 1835; and on the 25th of the same month government was again beaten in the Commons by a majority of seven, on a motion by Lord Morpeth for an amendment on the address. Sir Robert's speech on this occasion was extremely able. Singling out the fact that the strength of the opposition to him arose from the co-operation of Mr. O'Connell and the Irish members with the Whigs, he animadverted in cutting terms on this conjunction, seeing that in point of fact the Irish party and the Radicals had been far more unfriendly to the defunct Whig ministry than he and the Conservatives had been, and seeing also that even now the Whigs did not pledge themselves, any more than he did, to the Ballot, the exclusion of bishops from the House of Lords, the repeal of the Corn Laws, or any other of those measures upon which the Radicals had split with the Whigs. The gist of his argument was, that a Whig ministry could not really be a whit more innovative than his own would be. The answer to this given at the time, says Mr. Doubleday, was "that the Whigs would be more 'squeezable' than the Conservatives;" and, accordingly, though Sir Robert remained in office, showing wonderful patience and wonderful practical talent, till April, he was then defeated by so considerable a majority, in a skilfully framed series of motions of Lord John Russell's, relative to the temporalities of the Irish Church, that he had no option but to resign (April 8, 1835). Lord Melbourne was again placed at the head of a Whig administration, consisting of nearly the same men who had been in office four months before, the chief exception being that in the interim the famous rupture had taken place between the Whigs and Lord Brougham, so that the chancellorship was given not to him but to Lord Cottenham. Lord John Russell became home secretary.

The second Melbourne administration lasted throughout the rest of the reign of William IV. (who died June 20, 1837) and during nearly four years of the reign of Queen Victoria. During those six years (1835-1841) though many questions were agitated, their chief success was in the Municipal Reform Bill, passed during the first year. From 1836 to 1839 they were able to do little, and, robbed of their strength as they were by the growth of the more extreme party and of the party who desired a repeal of the Corn Laws, they were becoming more and more unpopular. At last Sir Robert Peel, whose popularity had been in proportion increasing, and who had in the meantime been acting as a critic of their measures, and husbanding his own strength, opposed their bill for suspending the constitution of the Colony of Jamaica; and the majority for ministers was so small, the numbers being 294 against 289, that the Whigs resigned on the following day (May 7, 1839), and Sir Robert was called upon to form a new ministry. In this he failed, owing to the refusal of the queen to consent to the removal of some ladies of her household, whose connection with the Whig party Sir Robert deemed inconsistent with their holding official place under a Conservative government. The Whigs accordingly resumed office, and kept it for more than two years longer—weakened, as before, by the pressure upon them of Mr. O'Connell's party, and the Anti-Corn Law League on the one hand, and of Sir Robert Peel and his well-drilled Conservatives on the other. A general election in 1841, instead of giving them fresh strength, so increased the force of the Conservatives, that, immediately on the opening of the new parliament Sir Robert had a majority of 360 against 269 in the Commons on a motion for an amendment to the address so framed as to involve a vote of want of confidence in the policy of ministers, more especially their financial policy and their conduct in reference to the Corn Laws (Aug. 27, 1841). Three days afterwards Lord Melbourne and his colleagues resigned, and Sir Robert Peel was once more premier.

The new Conservative cabinet consisted of the following members:—First Lord of the Treasury, Sir Robert Peel; Lord Chancellor, Lord Lyndhurst; President of the Council, Lord Wharncliffe; First Lord of the Admiralty, Lord Haddington; Lord Privy Seal, the Duke of Buckingham; Home Secretary, Sir James Graham; Foreign Secretary, the Earl of Aberdeen; Colonial Secretary, Lord Stanley; President of the India Board, Lord Ellenborough; Secretary at War, Sir Henry Hardinge; President of the Board of Trade, the Earl of Ripon; Chancellor of the Exchequer, Mr. Goulburn; Paymaster-General, Sir Edward Knatchbull. Among the ministers not in the cabinet, was Mr. W. E. Gladstone, as Vice-President of the Board of Trade. At the head of this ministry, and with the command of a working majority of about a hundred in the House of Commons, Sir Robert entered on the greatest period of his political career. The history of his ministry from August 1841 to July 1846 is full of interest. Having committed himself to no definite line of policy, except in his preference for a sliding-scale of corn duties over a fixed duty, and such other general avowals, the country, on his accession to office, was left to form its own auguries and anticipations. Nor during the remainder of the session of 1841 would he bring forward any explicit statement of intended measures—resolved as he was to mature them during the prorogation. On the re-assembling of parliament in February 1842, he was prepared with his measures. They were of a bold and comprehensive character. First, in the matter of the Corn Laws, he proposed his famous sliding-scale (Feb. 9, 1842), according to which the duty on foreign corn, commencing in the case of wheat at *20s.* per quarter when wheat was at *50s.*, should gradually diminish, as the price rose,—becoming, for example, *17s.* when wheat was at *55s.*, *12s.* when wheat was at *60s.*, *8s.* when wheat was at *65s.*, *5s.* when wheat was at *70s.*, and only *1s.* when wheat should be at *73s.* or upwards. There was a corresponding scale for oats and another for barley. The measure, displeasing as it was on various grounds to various parties—to the Whigs, because they had declared for a fixed duty, to the Anti-Corn Law League, because they desired a total repeal, and to many of the landed proprietors, because they disliked any relaxation of protection—roused much discussion; but after several motions against it on different principles had been rejected, it became law. Next came the important question of the means of repairing the deficit which had been going on in the revenue, at such a rate that the total for the five years ending April 5, 1842, was 7,502,638*l.*, while for the year 1842-43, it was calculated by anticipation at 2,570,000*l.* On this head, says Mr. Doubleday, Sir Robert argued "that the maximum of indirect taxation was then reached, and that to accumulate the already unbearable load of imposts upon the necessaries or even the luxuries of life would be ruinous as well as futile. The conclusion, therefore, was that nothing but a direct tax upon income could be relied upon to fill up the hiatus in the exchequer." Accordingly it was proposed to levy for three years an income-tax of sevenpence in the pound, or nearly three per cent. This also, in spite of opposition, was carried. Then came the reversion of the tariff, by which the premier abandoned the duties on a great variety of minor foreign commodities, such as drugs and dye-woods; and diminished the prohibitory duties on cattle, sheep, pigs, salted meat, butter, eggs, cheese, and lard. Though the new tariff was also carried, it caused dissension between Sir Robert and many of his Protectionist supporters; the more so that, in the course of the debates upon it, it distinctly appeared that he was a convert to the theory of free-trade. "I believe," he said in his speech on the tariff, "that on the general principle of free-trade, there is now no great difference of opinion, and that all agree in the general rule that 'we should purchase in the cheapest market and sell in the dearest.'" This statement drew rapturous cheers from the economists and opposition generally; and though Sir Robert went on to say, that he deemed corn and sugar exceptional cases, the ulterior tendency was evident. With the exception of some debates on the poor-law, and some on foreign policy in reference to France, Spain, America, and China, the foregoing measures of taxation and finance engrossed the parliament of 1842. The most important events of 1843 were extra-parliamentary. The permission of the disruption of the Scottish established Church in May 1843 has been accounted by some a strange oversight of a ministry constructed on the principles of conservatism, and has been attributed to false or insufficient information on the part of government. The contest with Mr. O'Connell, who was then agitating Ireland to the verge of revolution by monster-meetings and the organised action of an association which had 'repeal' for its motto, occupied a greater share of the energies of the government. For a time Sir Robert, confident, as it afterwards appeared, that Mr. O'Connell himself did not mean to go beyond a certain length, allowed him to proceed without check; but at length (October 1844) the government took their measures, the Clontarf meeting was forbidden, and Mr. O'Connell, his son John, and seven of their associates, were arrested on charges of conspiracy and sedition, and, being tried, were sentenced to fine and imprisonment. From that moment, although the sentence was reversed on appeal to the House of Lords, Mr. O'Connell was virtually crushed; he was never able again to be what he had been.

The year 1844, with its Banking Act, and its extraordinary activity in railways, had passed away; and 1845 opened with every outward show of prosperity. The parliamentary session of that year was comparatively easy; the renewal of the income-tax for three years longer, the augmentation of the Maynooth grant, and the proposal for erecting six new Irish colleges, open to all sects, were carried by government; and though the Anti-Corn-Law League, represented in the House by Messrs. Cobden and Bright, were making way, and were gaining over the Whigs, the stability of the existing administration was not materially affected. But the events of the long recess of 1845 were of a kind to disturb all existing arrangements and all ordinary calculations. The potato rot, followed as it was by a dreadful famine in Ireland, rendered it absolutely necessary to come to some conclusion on the great question which the Anti-Corn Law League had been maturing. Lord John Russell announced this in his famous letter of the 22nd of November, written from Edinburgh, to the electors of London. Sir Robert Peel lost no time in declaring to his colleagues that the Corn Laws must be totally repealed. In this Lord Stanley and others would not go along with him; and on the 6th of December, Sir Robert advised the queen to send for Lord John Russell. As Earl Grey refused to join with Lord John in attempting to form a cabinet, Sir Robert was recalled after a few days, and re-accepted office at the head of his ministry (Lord Stanley seceding) with the avowed intention of repealing the Corn Laws. Accordingly, a few days after the meeting of parliament (Jan. 27, 1846), he brought out a new tariff, and with it his proposition to modify the action of the sliding-scale for the next three years, and after that period to abolish all duties on corn, except the nominal one of a shilling per quarter. Vehement debates followed, in which Lord Stanley, Lord George Bentinck, and Mr. Disraeli, as the heads of a new Protectionist party, attacked Sir Robert with every weapon of sarcasm and argument. The Duke of Wellington however, and other Conservatives of great weight, remained firm to their leader; and the repeal was carried. Defeated on the Irish Coercion Bill, only a few hours after the Tariff Bill had passed the Lords, Sir Robert resigned office (June 29, 1846). Before doing so he made a magnanimous declaration to the effect that the merit of the repeal of the Corn Laws was more due to Mr. Cobden than to himself, or to any other man in the House. Never perhaps was a minister followed into his retirement with such general applauses as followed Sir Robert Peel.

Sir Robert's popularity continued unabated during the next four years. During two of these he lent a general and cordial support to the Whig government of Lord John Russell—voting with them on the question of the Navigation Laws, and also for the removal of Jewish disabilities. The European revolutionary movements of 1848-49 however, brought in a new set of questions, and Sir Robert disagreed seriously with the foreign policy of Lord Palmerston. Anticipations were general of his speedy return to power when, riding up Constitution-hill on the 29th of June 1850 he was thrown from his horse, and injured so severely that he died on the 2nd of July.

This is not the place for any attempt to appreciate Sir Robert's character as a man and a statesman. Many reviews of his career, some in the form of elaborate biographies, have been published since his death—among which may be mentioned 'The Political Life of Sir Robert Peel, by Thomas Doubleday,' 2 vols., 1856; and M. Guizot's more recent biographical tribute. Memoirs of Sir Robert from his own papers, referring particularly to his conduct in the Roman Catholic Emancipation movement, and in the Corn Law Repeal movement, have also been published by his literary executors. Almost all who have written about him have agreed in their general estimate of him as a man of high conscientiousness, and of a species of ability peculiarly English and peculiarly fitting him for the work which fell to him—ability not of the speculative or philosophical, but of the practical, deliberate, and considerate order. His political genius consisted in perceiving when the necessity for carrying a great social change arose, and in devising the parliamentary means for carrying it. As the leader of a party, and as a master of the art of parliamentary management, he was probably unrivalled; the House of Commons was his element; and though there have been greater orators there, there have been few speakers combining such dignity, tact and courtesy, with fine powers of eloquence. Apart from his parliamentary duties, his chief pleasure seemed to be in art. He was a noted collector of pictures, and left valuable collections both in his town mansion and at Drayton manor. He was generous in his patronage of artists, and many kind and munificent actions done by him privately have come to light. His tastes in literature, though he did not himself practise authorship except in connection with practical politics, were high and scholarly, and more wide in their range than might have been supposed.

Sir Robert left five sons—the present baronet, Sir Robert (born May 4, 1822), formerly secretary of legation in Switzerland, and in 1857 a junior lord of the Admiralty, and who has represented Tamworth in parliament ever since his father's death; Frederick (born 1823) who also sat in parliament for some years, and was under-secretary of the colonies from 1851 to 1857, with a short interruption; William (born 1824) a captain in the Royal Navy, who has greatly distinguished himself in the Crimean war and in India; John Floyd (born 1827) an officer in the Scots Fusilier Guards; Arthur Wellesley (born 1829). Of two daughters, one married (1841) Viscount Villiers, eldest son of Earl Jersey; the other married (1855) the Honourable Mr. Stonor.

PEERS OF THE REALM. In the case of Lord Wensleydale, to whom a barony had been granted *for the term of his natural life*, it was held (in the Session of 1855-56), that such a grant did not constitute the grantee a lord of Parliament; in other words, that *hereditary* peerage alone entitled the holders to a seat in the House of Lords.

PEGU. This province of the Birman Empire was annexed to the British possessions in India, by proclamation of the Governor-General of India, dated June 20, 1853.

It includes the following districts:—

	Square Miles.	Population.
Rangoon	9,800	137,130
Bassein	8,900	128,189
Prome	5,500	100,600
Henzadu	2,200	103,775
Toungoo	3,950	34,957
Tharawaddy	1,950	66,129
Total	32,300	570,180

PEKTOLITE. [MINERALOGY, *S.* 1.]

PELARGONIC ACID. [CHEMISTRY, *S.* 2.]

PELLICO, SILVIO, was born in 1789, at Saluzzo, in Piedmont. His father was Onorato Pellico, of a respectable family, and in good circumstances. His mother was a native of Chambery in Savoy, who, retaining her maiden name in addition to that of her husband, was called La Signora Pellico-Tournier. They had six children. Luigi and Gioseffina were the two eldest; Silvio and Rosina, twins, followed; Francesco and Marietta were next in succession. Luigi and Silvio were educated at home under the care of their parents. Onorato Pellico, while his children were yet young, having established a manufactory for winding silk at Pinerolo, resided there some time; but removed to Turin, where he was appointed to a situation under the government. There Luigi and Silvio were instructed in Latin and Greek, and other branches of education, by Don Manavella, a clergyman. Onorato Pellico, who had a taste for poetry and the drama, wrote scenes and short plays, which were performed by his children and others of a similar age, on a small stage constructed in his house. Luigi afterwards became a dramatic writer as well as Silvio.

Silvio Pellico's twin-sister Rosina, who is described as having been extremely beautiful, was married at the age of eighteen to a cousin by the mother's side, who was prosperously established in business at Lyon in France; and Signora Pellico-Tournier, with her son Silvio, accompanied the bride to the residence of her husband. The mother after a short stay returned home, but Silvio continued to reside with his sister's husband during four years. While at Lyon in 1807 Ugo Foscolo's poem 'I Sepolcri' ('The Tombs') was published, and was sent to him by his brother Luigi. The reading of it excited him greatly, and stimulated him to the prosecution of his poetical studies. Meantime his father had obtained a situation under the minister of war at Milan, and had removed to that city with his family. His brother Luigi was secretary to the Marquis Caprara, grand equerry of the kingdom of Italy.

Silvio Pellico returned from France in 1810, and went to Milan, where he became a teacher of French in the Collegio degli Orfani Militari, an occupation which required two or three hours of the day. The rest of his time was devoted to his poetical studies and to the acquisition of the German and English languages. He became acquainted with Ugo Foscolo and Monti, who were then at Milan, and occasionally saw Pindemonte, who resided at Verona. He was for a time tutor to the son of Count Briche, and afterwards to the two sons of Count Luigi Porro Lamberteughi, in whose mansion he became a resident, and at whose assemblies he associated with the most intellectual men of Italy, and with many distinguished foreigners, among whom he himself mentions Madame de Staël, Schlegel, Davy, Byron, Hobhouse, and Brougham. After the fall of Napoleon I., Onorato Pellico returned with the rest of his family to Turin, where he had again an office under the government. Silvio Pellico continued to reside at Milan with Count Porro.

Silvio Pellico's first dramatic production was the tragedy of 'Laodamia,' which was followed by his tragedy of 'Francesca da Rimini,' founded on a well-known passage in the 5th canto of the 'Inferno' of Dante. This tragedy was much admired, was acted with great applause in the principal cities of Italy, and established his reputation as a dramatic poet. Byron translated it into English verse, but did not publish it, and Pellico translated Byron's 'Manfred' into Italian prose. He was desirous of publishing his next tragedy, 'Eufemio da Messina;' but so many passages were objected to by the censorship that he sent it to Turin, where it was published by his father. It was afterwards published at Milan, but was not allowed to be acted. In 1818 Silvio Pellico was the chief agent in establishing a periodical entitled 'Il Conciliatore,' of which he became the secretary. It was mainly of a literary character, and Silvio Pellico, Manzoni, and similar literary men, were the chief contributors; but it was of too liberal a tendency to be endured by the Austrian government, and was suppressed.

On the 13th of October 1820 Silvio Pellico was arrested, and was confined in the prison of Santa Margherita at Milan. He seems to have become a member of the revolutionary society called Carbonari, but does not say so. He was transferred thence to a prison on the island of San Michele, near Venice; and while there was tried at Venice, found guilty, and condemned to death. That sentence however was commuted to fifteen years of 'carcere duro.' In April 1822 he was removed to the prison of Spielberg, near the city of Brünn, in Moravia. Some of those sent to this prison are condemned to the 'carcere duro' (severe imprisonment), and some to 'carcere durissimo' (very severe imprisonment). Silvio Pellico says:—"Those condemned to 'carcere duro' are obliged to labour, to wear chains on their feet, to sleep on bare boards, and to eat the poorest food. Those condemned to 'carcere durissimo' are chained more heavily, and with a band of iron round the waist, the chain being fastened in the wall, so that they can walk only just by the side of the boards which serve them for a bed. Their food is the same, though the law says only bread and water." In the earlier part of his imprisonment, during about eighteen months, he was treated with indulgence by his jailer, and read the Bible, Homer in Greek, Dante, Petrarch, Shakspere, Byron, Scott, Schiller, Göthe, and other writers, and was allowed some paper, and pen and ink. His friendly jailer having been removed to another situation, during the whole of the years 1824-25-26-27 his imprisonment was excessively severe, and his health was much injured. His imprisonment was afterwards less stringent, and on the 1st of August 1830 he received the announcement that he was to be set at liberty. This promise was soon afterwards performed, and he returned to his parents at Turin. In 1831 he published the account of his imprisonments, entitled 'Le Mie Prigioni,' which has had a very large circulation, and has been translated into the principal languages of Europe. It is written in a style of great simplicity, with much apparent truthfulness, and is very interesting. In 1832 he published at Turin 'Tre Nove Tragedie,' which were 'Gismonda da Mandrisio,' 'Leoniero da Dertona,' and 'Erodiade;' and in the same year his tragedy of 'Tommaso Moro.' His mother died in 1837, his father in 1838, and his brother Luigi in 1841. In 1837 appeared his 'Opere Inedite,' 2 vols. One of his latest works was a treatise in prose, 'Dei Doveri degli Uomini' ('On the Duties of Men'). During his later years Silvio Pellico was secretary to the Marchesa Barola, and he died at her villa of Moncaglieri, near Turin, January 1, 1854.

PENÆACEÆ, a small natural order of Perigynous Exogenous Plants. These plants are shrubs with opposite imbricated exstipulated leaves. The flowers are apetalous, the ovary composed of four carpels, the calyx tubular. Lindley places this order in his Rhamnal alliance, and points out its relations with *Proteaceæ* and *Bruniaceæ*. The species are mostly natives of the Cape of Good Hope. A viscid sweetish nauseous gum-resin, called Sarcocol, is produced by various species. This substance contains a peculiar principle called Sarcocollin, which is converted into oxalic acid by the addition of nitric acid. Although Dr. Lindley has named these plants Sarcocollads, he is inclined to doubt, with Endlicher, if this order really produces Sarcocol at all; and suggests that it is produced, as Sagapenum and Galbanum, by a species of the order *Umbelliferæ*. The genera are *Panæa*, *Sarcocolla*, and *Geisoloma*. There are 21 species.

PENISTONE. [YORKSHIRE.]

PENNINE, a Mineral belonging to the Hydrous Silicate of Magnesia series. It is near Chlorite, and occurs in hexagonal tables. It is found in the Pennine Alps.

PENTACTÆ, a sub-family of *Holothuriadæ*, a family of *Echinodermata*. It includes the genera *Psolinus*, *Cucumaria*, and *Ocnus*.

Psolinus (Forbes) has an irregular ovate body, arcuated with five rows of distant suckers, those below being always bent; tentacula ten; dental apparatus short, truncate; no gizzard.

P. brevis, of Forbes and Goodsir, is the only species. It was discovered in the Shetland seas, adhering to the stems of *Laminariæ*. It links the family of *Psolidæ* with *Pentactæ*. It is about half an inch in length, of an ovate form, with both its extremities bent upwards. The body is pinkish-white, with minute papillæ. The tentacula are long, pedicled, and digitate at the extremity. It is sluggish in its movements, but moves its tentacula freely.

Cucumaria has the body regular, more or less pentangular, with five longitudinal rows of approximate suckers; ten tentacula; dental apparatus composed of nearly square plates.

The species are called Sea-Cucumbers. They are the most typical of the *Holothuriadæ*, and their popular name is very expressive of their usual form. They have all of them the power of changing their shape, so that sometimes they are very long, and others are oval or round. They usually live among sea-weeds or in mud, and are supposed to seize their prey by their large tentacula. They are found very generally throughout the seas of the globe. The following are the British species described by Professor E. Forbes in his 'History of British Star-Fishes':—

C. frondosa (*Holothuria frondosa*, Gunner), the Great Sea-Cucumber. It has been principally found off the coasts of Scotland.

C. pentactes (*Holothuria pentactes*, Müller), the Angular Sea-Cucumber. It has been taken on the coasts of Devonshire and Dorsetshire, and is found in the seas of France and Norway.

C. communis, Common Sea-Cucumber. Great numbers of these animals have been observed off the coast of Fifeshire, and been dredged in the north and south of Ireland, by Mr. W. Thompson and Dr. Ball.

C. fusiformis, the Long Sea-Cucumber. This is the longest of all the species in proportion to its thickness.

C. hyalina, the Glassy Sea-Cucumber. It is remarkable for its hyaline glassy appearance. It inhabits the Shetland seas.

C. Drummondii. This species was named after Dr. Drummond, who discovered it in Belfast Bay.

C. Hyndmanni is named after Mr. Hyndman, who dredged it in Belfast Bay. It has been since taken in large numbers off the western coast of Ireland.

C. fucicola, the Tangle Sea-Cucumber. It has been found in the Shetland seas.

Ocnus (Forbes and Goodsir) has the body regular, cylindrical, pentagonal, with five rows of distant suckers on the angles; tentacula ten; dental apparatus very short.

Professor E. Forbes describes two species of this genus, which he calls, on account of its size as compared with the Sea-Cucumber, the Sea-Girkin. The two British species are *O. branneus* and *O. lactea*, distinguished by their colour, the latter being milk-white, the former brown.

PEPSIN, a substance found in the gastric acid of man and the lower animals. If the glandular portion of the stomach is treated with extremely dilute acids a substance is thrown down from the fluid by corrosive sublimate, which Schwann first called Pepsin. Wasmann afterwards obtained pepsin in a purer form. He proceeded in the following manner:—The glandular layer in the stomach of the pig, which extends chiefly from the greater curvature towards the cardia, was carefully detached and washed, without being cut up, then digested with distilled water at a temperature of from 30° to 35°. After some hours the fluid was poured away, the membrane was again washed in cold water, and then digested in the cold with about six ounces of distilled water, and repeatedly washed, till a putrid odour began to be developed. The filtered fluid was transparent, viscid, and without any reaction; it was now precipitated with acetate of lead or corrosive sublimate; the precipitate was carefully washed and decomposed with sulphuretted hydrogen; the pepsin was then precipitated by alcohol from the watery solution in white flocks.

The pepsin thus obtained, forms, when dry, a yellow, gummy, slightly hygroscopic mass; in its moist state it is white and bulky; it dissolves readily in water, and always retains a little free acid so as to redden litmus; it is precipitated by alcohol from its watery solution; mineral acids induce a turbidity in a solution of neutralised pepsin, which disappears on the addition of a small excess of the acid; but if there be a considerable excess of the acid, there is a flocculent deposit. It is only imperfectly precipitated by metallic salts, and not at all by ferrocyanide of potassium. It has been asserted that pepsin is coagulated by boiling, but Frierichs has shown that the coagulation is merely dependent on its admixture with albumen. This substance possesses the converting power so strong that, according to Wasmann, a solution containing only 1-60,000th part of this substance dissolved albumen in six or eight hours. Similar experiments have been made by Pappenheim, Valentin, and Elsasser.

C. Schmidt has proposed a new view with regard to the nature of the digestive principle. He regards it as a conjugated acid, whose negative constituent is hydrochloric acid, with Wasmann's non-acid or coagulated pepsin, as an adjunct; and assumes that it possesses the property of entering into soluble combinations with albumen, glutin, chondrin, &c. According to him, it more nearly resembles lignosulphuric acid than any other conjugated acid, and as this becomes disintegrated into dextrin and sulphuric acid, so the pepsin-hydrochloric-acid becomes separated at 100° into Wasmann's coagulated pepsin and hydrochloric acid, and in either case it is equally impossible to reproduce the conjugated acid from its proximate elements after their separation. On bringing the complex acid in contact with an alkali, the adjunct—the substance which has been in combination with the hydrochloric acid—is precipitated. Schmidt believes that he has ascertained that an artificial digestive mixture which has expended its solvent and digestive powers, regains them on the addition of free acid; and that when hydrochloric acid is added, the pepsin-hydrochloric-acid is expelled from its combination with albumen, &c., and thus regains its former properties, while the newly added hydrochloric acid enters into its well-known soluble combinations with albumen, &c. By the repeated addition of hydrochloric acid, a digestive fluid or this pepsin-hydrochloric-acid might preserve its digesting power for ever, unless the fluid became saturated with the dissolved substances, or the conjugated acid underwent decomposition.

(Lehmann, *Physiological Chemistry*, translated for the Cavendish Society.)

PEPYS, WILLIAM HASELDINE, F.R.S., was born in the year 1775, in the city of London, where his father conducted in the Poultry a superior business as a cutler and maker of certain classes of surgical instruments. His early history is connected in a remarkable manner with that of the progress of chemistry, and of some other branches of science in this country, as well as with that of the various institutions formed for their advancement. In March 1796 the Askesian Society (from ἄσκησις, exercise), was established by the association of a number of young men for their mutual improvement by the discussion of philosophical subjects. Of these Mr. Pepys was one. He became a member of the Committee for Apparatus appointed by the society, and took an active part in the experimental elucidation to the members of facts generally understood, and in the repetition and examination of new discoveries. Mr. Pepys also contributed papers to the same body, which, from the residence or occupation of its members in the city of London, eventually led to the foundation of the London Institution, and, through the British Mineralogical Society, in part also to the establishment of the Geological Society of London, of all which Mr. Pepys was an early member and office-bearer. His skill and ingenuity in the construction of apparatus proved most important auxiliaries in the progress of chemical and electro-chemical science in England for a period exceeding thirty years. His researches on respiration, prosecuted in conjunction with Mr. Allen [ALLEN, WILLIAM, *S.* 1], and published in the 'Philosophical Transactions,' may be said to have established the foundation of our exact knowledge of the chemical changes produced in air by that process; while their preliminary experiments on carbon and carbonic acid, recorded in papers contained in the same collection, confirmed several points in the chemical history of those bodies, which had remained in doubt or been insufficiently examined. In 1808 Mr. Pepys was elected a Fellow of the Royal Society, in the proceedings of which he took an active part for many years.

As just intimated, he was one of the earliest promoters of the London Institution for the Advancement of Literature and the Diffusion of Useful Knowledge, which was founded in 1805 and 1806, with the intention of supplying for the City of London advantages corresponding to those derived in the west of the metropolis from the establishment of the Royal Institution, a few years before. He is named as one of the managers of the London Institution in the Charter of Incorporation, dated January 21st, 1807, and for many years continued to be an active member of the Board. The arrangements for the laboratory, the collection of chemical and philosophical apparatus, and subsequently for the lectures, were mainly carried out by him, and from 1821 to 1824 he was honorary secretary. After an interval of some years he was again elected a manager, and afterwards a vice-president, which office he continued to hold during the remainder of his life. Under his direction a voltaic battery of 2000 double plates of zinc and copper was constructed for the laboratory, with which many of Sir Humphrey Davy's experiments on the magnetic phenomena produced by electricity were made, with the personal assistance of Mr. Pepys and other friends. In the 'Philosophical Transactions' for 1823 is described another voltaic battery devised by Mr. Pepys, for the performance of electro-magnetic experiments, and constructed for the London Institution, consisting of two plates only, one of copper, the other of zinc, but those each fifty feet in length and two in width, coiled around each other. A remarkable experiment repeated by Sir H. Davy with this apparatus is described in a paper by him in the same volume. A similar apparatus was produced, about the same time, but quite independently, by the late Dr. Seebeck, of Berlin.

For some years prior to his decease, the progress of age and infirmity withdrew Mr. Pepys in a great degree from scientific society, but he retained to the last his interest in the progress of science, together with a vivid recollection of the part which he and his friends and fellow-labourers had taken in the production of the English school of Chemistry, among the contemporaries of Davy and Wollaston. He died at his house in Earl's Terrace, Kensington, London, on the 17th of August 1856, at the age of eighty-one.

PERCH. [PERCIDÆ; FISH.]

PERCOIDES. [PERCIDÆ.]

PEREIRA, JONATHAN, an eminent physician and pharmacologist, was born in the parish of Shoreditch, London, on the 22nd of May 1804. He received his early education in his native parish, and was distinguished at school for his knowledge of classics. At the age of fourteen he was apprenticed to Mr. Latham of the City-road, who practised as a surgeon and apothecary. His master having died, he commenced attending on the practice of the Aldersgate-street Dispensary in 1821. At this time this dispensary was recognised by the Apothecaries' Society as one of the institutions, the attendance on the practice of which qualified medical students as candidates for the Apothecaries' licence. The physicians and surgeons of the dispensary gave lectures, which were also recognised by the Society of Apothecaries. In 1822 Pereira became a pupil of St. Bartholomew's Hospital, and in March 1823 obtained his licence to practise from the examiners of the Society of Apothecaries. He was not nineteen years old, and the facility with which he obtained his licence, indicates very plainly how small an amount of education was required for the medical man at this time. He was shortly after appointed apothecary to the Aldersgate-street Dispensary, and thenceforward his name was connected with the falling fortunes of this at one time somewhat celebrated school of medicine.

On his appointment young Pereira at once established himself as a private tutor or 'grinder' as teachers of this class are technically called. In this capacity he was very efficient, and his early publications all had reference to the wants of medical students about to present themselves for examination. He published an English translation of the Latin Pharmacopœia of the London College of Physicians. He also published a collection of Latin prescriptions entitled 'Selecta e Prescriptis,' a large number of which have been printed. He devoted much time to chemistry and published 'A general Table of Atomic Numbers.' In 1825 he became a member of the Royal College of Surgeons. In 1826 he was appointed lecturer in chemistry in the Aldersgate-street School of Medicine, and subsequently he delivered the course of lectures on Materia Medica. These lectures were the foundation of his great work on Materia Medica and his reputation as a pharmacologist. The lectures were first published in the Medical Gazette, and the matter was subsequently re-arranged and published in two volumes in 1839, under the title 'Elements of Materia Medica and Therapeutics.' Dr. Pereira's mind was eminently discursive. Even while lecturing on Chemistry and Materia Medica in Aldersgate-street he undertook to lecture on chemistry and botany at the London Hospital. This fitted him for working successfully at the Materia Medica, and he produced a work more scientific and practical than any which had before been devoted to the prolific subject of medicines and their actions. Up to this time he had practised as a general practitioner; but his position as lecturer at the London Hospital School of Medicine, prepared the way for his appointment as physician to that institution. He accordingly in 1840 obtained the degree of doctor of medicine from the University of Erlangen, and was appointed in the same year assistant physician to the London Hospital. He subsequently submitted to the examination of the College of Physicians, and became a London licentiate of that body. He was elected a fellow of the College in 1845. In connection with Materia Medica, Dr. Pereira devoted himself to the Materia Dietetica, and in 1842 he published a treatise on 'Food and Diet,' which, like his work on Materia Medica, was by far the best that had been published on that subject.

His works brought Dr. Pereira into considerable note as a physician, and increasing practice compelled him to give up his various lectureships. In 1851 he was appointed full physician to the London Hospital. His great knowledge of Materia Medica pointed him out as the most fitting person to fill the post of examiner at the London University, an office which he held till his death.

Although Dr. Pereira occupied himself more with compiling and arranging the information obtained from others than with original observations, he nevertheless displayed considerable ability in chemical and physiological research. He published a series of 'Lectures on Polarised Light,' and many original papers and observations in the Pharmaceutical and Medical Journals. He took an interest in the formation of the Pharmaceutical Society, and delivered several courses of lectures on Materia Medica in connection with that Society. He was a fellow of the Royal Society and also of the Linnæan Society. His death, which occurred in 1853, was sudden, and was thus described:—"A few weeks previous to this occurrence he had been to consult Professor Quekett (of the College of Surgeons, London) on a scientific question, and whilst descending a staircase leading to the Hunterian Museum, made a false step, fell, and ruptured the rectus femoris muscle of both legs. In all probability at the same time some internal injury was sustained by the heart or larger vessels; but as only local inconvenience was experienced, no danger was apprehended; but whilst getting into bed on the 20th of January he felt a violent throb in the region of the heart, when he became fully aware that a speedy termination of his life was at hand, and this impression was verified within twenty minutes after." A bust was erected to his memory in the London Hospital by his friends.

PERIANTH. [FLOWER, S. 2.]

PERICLASE, a Mineral, occurring crystallised in regular octohedrons. Primary form a cube. Cleavage in three directions parallel to the faces of the cube. Colour obscure green. Hardness equal to felspar. Lustre vitreous. Translucent. Specific gravity 3·78. It is found in the lava of Vesuvius. Its analysis by Damour gives:—

Magnesia	92·57
Oxide of Iron	6·91
Insoluble Matter	0·86
	——100·34

PERISTEDION, a genus of Fishes belonging to the *Acanthopterygii* with hard cheeks. The body is covered with bony plates, forming a defensive armature. The nasal bone is divided into two points. The mouth has no teeth.

P. Malarmat, the Mailed Gurnard, was taken, according to Mr. Yarrell, off Plymouth in 1836. It is also a native of the Mediterranean. It is easily known from the other gurnards by its elongated and bifurcated nasal bones. It frequents deep water over rocky ground, approaching the shallows only at the period of spawning. It swims with great rapidity, occasionally breaking its nose against the rocks. It is fished in the Mediterranean, and as an article of food is in greatest estimation during Lent.

PERIWINKLE, a Plant. [VINCA.]

PERJURY. A summary power of committing persons guilty of perjury is vested in all the courts of the country by the statute 14 and 15 Vict., c. 100. One object of the statute is to give the prosecutor his costs, when the prosecution is directed by the court. It was passed to meet an expected increase of crimes of this nature, from the parties being allowed to give evidence in their own causes.

PEROVSKITE. [MINERALOGY, S. 1.]

PERTH. [CANADA, S. 2.]

PERTHES, CHRISTOPHER FRIEDRICH, one of the most distinguished booksellers of Germany, was born April 21, 1772, at Rudolfstadt, the capital of the petty German principality of Schwarzburg, where his father was secretary of the exchequer, who, dying in 1777, left his widow and son unprovided for, except by a pension of twenty-one florins to the widow. The widow sought to maintain herself by going to service as a nurse, while young Perthes was confided to the care of his grandmother. On her death in 1779 he was transferred to his maternal uncle, Friedrich Heubel, also a state official of the Prince of Schwarzburg, who as far as he was able instructed the young Perthes, instilled good principles into him, but little of literature. At the age of twelve he was sent to the gymnasium of Rudolfstadt, but his previous deficiencies rendered him unable to profit much by the instruction here afforded, a loss which he continued to lament in later life, and which he then made great efforts to repair. While at this seminary however he took great delight in reading travels, and they appear to have had much influence in developing a feeling of self-dependence on his own exertions; and another relation, Lieutenant-Colonel Heubel, the superintendent of public buildings, by taking young Perthes in his occasional visitations, gave him a liking for natural scenery. A brother of his father's was a bookseller at Gotha, and this seems to have led to the idea of dedicating Perthes to that trade. In 1786, therefore, he was taken to the great bookselling mart at Leipzic, as to a statute fair, to find a master for him. He was rejected by one because he could not construe *amo*, and by another as too delicate; but one, Böhme, agreed to accept him as an apprentice at the end of another year. On September 11, 1787, he entered upon his new occupation. His master was not unkind, but strict; he was employed in the lower and more irksome duties of his trade: particularly as a collector; his feet were frost-bitten in the winter; he was confined to his room for nine weeks, during which his master's daughter, Frederika, then only twelve years old, attended him, and read to him a translation of Muratori's 'History of Italy.' He recovered and became fondly attached to his nurse. While serving his apprenticeship his desire for acquiring knowledge was great, but his means were so restricted that he had little opportunity of doing so beyond his own unaided exertions. His mother's pension (about 2*l.* a-year), a few occasional presents from his uncle Henbel, and two dollars yearly from his master, formed the extent of his funds, and with these he had to supply himself with shoes and clothes. After he had been apprenticed some time, a new apprentice, named Nessig, was introduced. This associate became a candidate for the affections of Frederika. The rivalship revealed to Perthes that he was in love, and like a true German, he made a confidant of his rival. They agreed to each attempt to gain her, and that the unsuccessful suitor was to submit uncomplainingly to his fate. In 1792, when the French revolution broke out, both uncle and nephew took a great interest in its progress; but Perthes saw and expressed in his letters to his uncle reasons for apprehending danger. His manners appear to have been all his life peculiarly attractive, modest yet firm; and while with Böhme he became acquainted with Göthe, Herder, and Schiller. At the Easter fair of 1793, Hoffmann, a large publisher in Hamburg, having expressed a wish to hire him as an assistant, his master released him from his apprenticeship, which had yet a year to run, and he departed with Hoffmann to Hamburg. While here, though he sedulously attended to his business, he did not forget his first attachment, and corresponded with his rival, Nessig, who undertook to give a faithful account of Frederika, and the state of her affections. His notions of bookselling appear to have far exceeded those of either of his masters. In 1794 he writes: "Where will you find a body of men so deficient in the requisite information, and so negligent of the duties of their calling, as the booksellers? Germany is deluged with wretched and abominable publications, and will be delivered from this plague only when the booksellers shall care more for honour than for gold." After a residence of about three years with Hoffmann, during which he had won the esteem of many eminent literary men, and made great efforts to repair his defective education by study and by intercourse with the numerous French emigrants then in Hamburg, and having received a promise of the reversion of his uncle's business in Gotha, for which he was not inclined to wait, he determined to begin business for himself. This he effected on borrowed capital, and in partnership with his old fellow-apprentice, Nessig. As soon as this was effected, they both offered themselves to Frederika Böhme, who declined to marry either, though she owned that she loved both—a good reason, perhaps, for her resolution. Perthes was in despair. He writes, "my whole life-plan is ruined—ruined by her." But he immersed himself in business, in hopes of thus overcoming his apprehended ruin—and succeeded. The partnership with Nessig did not last long, as it was found that, though not unsuccessful, the profits were not enough for two; and he now proceeded on his own account. His acquaintance with literary men extended. Fred. H. Jacobi, the Stolbergs, Voss, and Count Reventlow were among them. By Jacobi he was introduced to Claudius, the editor of the 'Wandsbecker Bote' (Messenger), whose daughter Caroline he married, after a short courtship, on August 2nd of that year. She was a delicate retiring woman, possessed of strong religious feelings, and an ardent love for her husband; but his active bustling habits gave her occasional uneasiness, and she would have preferred his being more calm and less worldly. To her gentle remonstrances he replied, "I am persuaded that I am a man born to turn my own wheel, and that of others, with energy." In 1799, with an addition of capital, also borrowed, he entered into partnership with Besser, who, from his integrity, activity, and great literary knowledge, was of most essential service in the business. This went on happily and successfully till 1803, when the French occupied Hanover, placed Hamburg in a state of blockade, and in 1806 occupied the town itself; and though for a short time released by the peace of Tilsit, it was incorporated in 1810 with the French empire. Still the firm went on, though embarrassed by the Milan and Berlin Decrees, and the censorship to which the press was subjected. Perthes had, in his correspondence, lamented the apathy of Germany under the French yoke, and when the French retired before the Russians in 1813, he took an active part in restoring the old constitution, and became a member of the burgher guard. But the French under Davoust and Vandamme almost immediately returned, regained possession of Hamburg, levied enormous contributions, and devastated the town. Perthes had sent his wife and family to Wandsbeck, but he was a marked man, and one of those exempted from the general pardon which was proclaimed. He was forced to fly, the shop was plundered, and sealed up as sequestrated. It was now that the calm heroism and devoted attachment of his wife displayed itself. She thanked him from her heart "that your name stands among the ten enemies of the tyrant;" and subsequently, though suffering extreme deprivation, with one of her children dying, she exhorts him to persist in fulfilling his duty. In 1814 they were enabled to return to Hamburg, where, by the exertions of Besser, they met all their trade obligations, and the business again proceeded prosperously. In 1821 his excellent wife died, soon after which he resigned the Hamburg business to his partner, and in 1822 removed to Gotha, where he adventured more largely as a publisher, the works he chiefly produced being on theology and history. In theology he published for Neander, Ullman, Tholuck, Bunsen, and many others, who were opponents of the rationalistic opinions: and in history he published the 'General History of the State of Europe,' edited by Heeren and Ukert, to which many of the most eminent writers of Germany contributed. He was also the publisher of the well-known 'Almanach de Gotha.' In all these undertakings he was not only publisher, but a most efficient adviser, and his opinions were highly valued, not only by the contributors, but by men like Niebuhr and Schlegel. In 1825 he married a second time, and his choice was almost as fortunate as his first. Charlotte Becker, a widow, was an excellent mother to his children, and an attentive and affectionate wife to himself. Some few years before his death he resigned the business to his son Justus, by whom it is now carried on, and of which an establishment for printing maps on a large scale forms a part. He retired to the village of Friedrichroda, a few miles from Gotha, where, with a cheerful and tolerant piety which had always distinguished him, he awaited his dissolution, which took place on May 18, 1843.

Perthes' correspondence was very extensive, and was both instructive and entertaining. Excellent specimens of it are given in 'F. Perthes Leben. Nach dessen schriftlichen und mündlichen aufgezeichnet,' in 3 vols. 8vo, published 1848-55, by his son, Clemens Theodor, who is professor of law in the University of Bonn. Besides these, some of his correspondence was published in 1819 in 'Etwas über den Deutschen Adel, in Briefen,' a correspondence between Perthes, Fouqué, Moser, and others; and in 'Beiträge zur Geschichte Deutschlands in den Jahren 1805-1809, aus brieflichen Mittheilungen,' letters between Perthes, Johann von Müller, and others, issued in 1803. His son Clemens, besides the Memoirs of his father, is the author of 'Der Deutsche Staatsleben vor der Revolution. Eine Vorarbeit zum deutschen Staatsrecht,' 1845; and 'Einverleibung Krakaus, und die Schlussacte des Wiener Congresses,' 1846. The Memoirs have been translated with some condensation, in 2 vols. 8vo, published in 1856.

PESTALOZZI, JOHANN HEINRICH, was born January 12, 1746, at Zürich, in Switzerland. His father, who was a medical practitioner, died when Pestalozzi was about six years old; but his mother, with the assistance of some relatives, procured him a good education. He studied divinity and afterwards law, but instead of adopting either the clerical or legal profession, turned to farming as a means of support. At the age of twenty-three he married the daughter of a merchant of Zürich, purchased a small landed property which he named Neuhof, and went to reside upon it and cultivate it. The reading of Rousseau's 'Emile' had drawn his attention to the subject of education, and he began in 1775 to carry out his views by turning his farm into a farm-school for instructing the children of the poorer classes of the vicinity in industrial pursuits as well as in reading and writing. In this, however, he was little more successful than he had been in his agricultural operations: at the end of two years his school was broken up, and he became involved in debt. In order to relieve himself from his incumbrances, and to procure the means of subsistence, he produced his popular novel of 'Leinhardt und Gertrud,' 4 vols., Basel, 1781; in which, under the guise of depicting actual peasant life, he sought to show the neglected condition of the peasantry, and how by better teaching they might be improved both morally and physically. It was read with general interest, and the Agricultural Society of Bern awarded him for it a gold medal, which however his necessities compelled him at once to sell. It was followed by 'Christoph und Else,' Zürich, 1782. During 1782-83 he edited a periodical entitled 'Das Schweizer-Blatt für das Volk' ('Swiss-Journal for the People'), which was collected in 2 vols. 'Nachforschungen über den Gang der Natur in der Entwickelung des Menchengeschlechts' ('Investigations into the Process of Nature in the Improvement of the Human Race'), appeared at Zürich in 1797; and he wrote also other works of less importance.

In 1798, with the assistance of the Swiss Directory, he established a school for orphan children in a convent which had belonged to the Ursuline nuns at Stanz, in the canton of Unterwalden. Stanz had been sacked by a French army, and the children were such as were left without protectors to wander about the country. In the bare and deserted convent he had, without assistance and without books, to teach about eighty children of from four to ten years of age. He was thus driven by necessity to set the elder and better-taught children to teach the younger and more ignorant; and thus struck out the monitorial or mutual-instruction system of teaching, which, just about the same time, Lancaster was under somewhat similar circumstances led to adopt in England. [LANCASTER, JOSEPH.] In less than a year Pestalozzi's benevolent labours were suddenly interrupted by the Austrians, who converted his orphan-house into a military hospital. He then removed to Burgdorf, eleven miles northeast from Bern, where he founded another school of a higher class, and produced his educational works, 'Wie Gertrud ihre Kinder lehrt' ('How Gertrude teaches her Children'), Bern, 1801; 'Buch der Mütter' ('Mothers' Book'), Bern, 1803; and some others. During this period of political excitement he joined the popular party, and in a considerable degree incurred the disapproval of the upper class. In 1802 the people of the canton of Bern sent him as their deputy to an educational conference summoned by Bonaparte, then First Consul, at Paris. His establishment at Burgdorf was prosperous, became celebrated, and was resorted to from all parts of Europe by persons interested in education, some for instruction and others for inspection. In 1804 he removed his establishment to München-Buchsee, near Hofwyl, in order to operate in conjunction with Fellenberg, who had a similar establishment at the latter place; but the two educational reformers disagreed, and in the same year Pestalozzi removed to Yverdun, in the canton of Vand, where the government appropriated to his use an unoccupied castle. This establishment became even more prosperous and more celebrated than the one at Burgdorf, and had a still greater number of pupils and of visitors. Unfortunately dissensions arose among the teachers, in which Pestalozzi himself became implicated, and which embittered the latter years of his life. The number of pupils rapidly diminished, the establishment became a losing concern, and Pestalozzi was again involved in debt, which the proceeds of the complete edition of his works ('Pestalozzi's Sämmtliche Werke,' 15 vols., Stuttgart and Tübingen, 1819-26) hardly sufficed to liquidate. This edition was the result of a subscription got up in 1818 for the publication of his works, the names of the Emperor of Russia, the King of Prussia, and the King of Bavaria standing at the head of the list.

In 1825 Pestalozzi retired from his laborious duties to Neuhof, where his grandson resided. Here he wrote his 'Schwanengesang' ('Song of the [Dying] Swan'), 1826; and 'Meine Lebensschicksale als Vorsteher meiner Erziehungsanstalten in Burgdorf und Iferten.' ('My Life's Fortunes as Superintendent of my Educational Establishments at Burgdorf and Yverdun'), 1826. He died February 17, 1827, at Brugg, in the canton of Aargau.

PETERBOROUGH. [CANADA, *S.* 2.]

PETERHEAD. [ABERDEENSHIRE, *S.* 1.]

PETHERTON. [SOMERSETSHIRE.]

PETIVERIACEÆ, a small natural order of Exogenous Plants, of which the principal genus is *Petiveria*. [PETIVERIA, *S.* 1.] There are 2 other genera and 10 species.

PETÖFI, SANDOR or ALEXANDER, an eminent poet, and more especially an eminent song-writer, who may be called the Burns of Hungary, was born at Félegyhaz, in the district of Little Kumania, in the county of Pesth, on the 1st of January 1823. His father, who had migrated from the mountains of the north of Hungary to the plains, bore then, and till his death the name of Petrovics, equivalent to 'Peterson,' which showed that he was of Slavonic descent; the son changed the name to Petöfi, which has the same meaning in the Magyar or Hungarian language. The fact is worthy of note, as showing, in conjunction with some similar instances, that in a country where the rivalry of different nationalities has been pushed to a disastrous extreme, the most vehement defenders of one nationality may be recruited from the ranks of another. Petöfi's father was a butcher, who, having succeeded in trade, was anxious to see his son in a profession of some kind, and seems to have been indifferent whether in divinity, law, or medicine. The youth was wild and unruly, and extravagantly stage-struck, and was expelled from the school at Selmecz, to which his father had sent him, for engaging in some theatrical performances. Not daring or not wishing to return home, he went to Pesth, where at the age of fourteen he gained a precarious livelihood by assisting as a scene-shifter at the theatre, but spent most of his time in the streets. His father came to Pesth in search of him, took him home by force, and kept him as a sort of prisoner for about two years, after which he again sent him to school at Oedenburg.

The first thing that Petöfi did on arriving there was to go the barracks and enlist as a soldier in an Austrian regiment, which he understood was to be quartered in the Tyrol, when he intended to desert, and enjoy a free life among the mountains. The regiment was sent instead to Croatia, and his disappointment was so great that he fell ill, and continued seriously affected so long that the regimental doctor in 1841 recommended his discharge. Being now of the age of eighteen he resumed his studies at the college of Pápa, near Raab, and became acquainted with two young men who have since attained to some eminence—Orlay as a painter, and Jokai as a novelist. At that time Orlay was ambitious of becoming a poet, Jokai a painter, and Petöfi an actor, and all three failed in their respective ambitions. Petöfi, who soon left college to commence his career as a strolling player, seems never to have met with even the most moderate degree of success, and was soon plunged in the most abject poverty. He had long been in the habit of composing songs for his own amusement, and on a visit to Pesth in 1843 he called with some of them on Bajza, the editor of the 'Athenæum,' a popular periodical, mentioning to him that they were the composition of one Petöfi, but not mentioning that Petöfi was himself. The poems awakened the attention of Vörösmarty, at that time the leading poet of Hungary, who predicted that the author would soon stand high, and began to exert himself to bring him into notice. Some other friends procured him literary employment to translate into Hungarian a novel of G. P. R. James's, entitled 'Forest Days,' and with the money thus obtained he set off for Debreczin, to gratify his theatrical aspirations, by appearing as the Prince of Morocco in a translation of the 'Merchant of Venice.' He found his way back to Pesth on foot, and Vachot, the editor of the 'Divatlap,' or 'Journal of Fashion,' engaged him as a regular contributor of poetry to its pages. At this period he suddenly burst into fame, and became in a few weeks the most popular poet in Hungary. Two or three of his short poems appeared every week, and they were at once on the lips of the nation. The ease and fluency of his language recommended him even to the lowest classes, while he counted some of his warmest admirers among the highest. The sudden tide of success seems to have carried him off his feet, and even his eulogists speak of him as having become perhaps the proudest man in Hungary. His triumphs however were not unmingled; a novel which he wrote at the suggestion of Eötvös, entitled 'A' Hohér Kötele' ('The Hangman's Rope'), dropped still-born, and when, in 1845, he offered a play to the managing committee of Pesth, it was unhesitatingly rejected. Though in the same year he was allowed to make an appearance on the stage at Pesth, in the character of 'the Deserter,' the result was what is called 'a dead failure,' and he then finally took the hint and withdrew from the stage. For some time afterwards he continued in the enjoyment of a wide-spread popularity; a larger poem under the title of 'A'Vitez Janos' ('the Hero John'), was received with unbounded applause, and he had a train of imitators, even in the particular of costume in which he was somewhat eccentric. He was at the height of his fame at the outbreak of the revolution of 1848, which found in him one of its most ardent admirers and supporters. He had always been an uncompromising advocate of the independence of Hungary, and distinguished for hostility to the aristocracy, as well as by a warm feeling of personal independence.

On the 15th of March, it was Petöfi who incited the students of the university to action by reading aloud in the yard of the university his poem of 'Talpra Magyar' ('Hungarians, up!') which was received with shouts of applause; the poem was the same day issued in innumerable copies, being the first poem printed in Hungary without passing the censorship; and at the theatre that evening, after the great events of the day, it was sung again and again, the whole audience joining in the chorus. His other poems, 'Most vagy soha' ('Now or Never'), and 'Csatadal' ('Battle-Song'), had a great influence on the popular mind. He failed however as a candidate for a seat in the National Assembly for Little Kumania, but seized every opportunity of demonstrating his adhesion to the principles of Kossuth. When on the 21st of August 1848, the two parties of the Moderate and the Extreme Liberals in the National Assembly came to a conflict on the question, if the words of command to the Hungarian army should be given in Hungarian, or as they had always been before, in German, Vörösmarty, who was one of the deputies, gave his vote on the side of the Moderates, who, on that occasion, were first brought into a minority by the party of Kossuth. Petöfi, who, only a few months before had dedicated the collected edition of his poems to Vörösmarty, "as a sign of love and esteem," on this occasion wrote a poetical address to him renouncing his friendship, each stanza concluding with the lines,

"I do not tear the laurel from thy brow,
'Tis thy own hand has torn it now;"

and in spite of the remonstrances of mutual friends, gave it to the public in the 'Életkepek' ('Pictures of Life'), a periodical he was then publishing in conjunction with Jokai. Soon after he exchanged the pen for the sword, and joined the division of the army under the command of General Bem, who appointed him his aide-de-camp. A dispute with General Mészaros, who found fault with the poet's inattention to discipline, induced him to throw up the appointment in May 1849, and quit the service, his enemies remarking that the quarrel was between a butcher (the meaning of Mészaros in Hungarian) and a butcher's boy. The approach of the Russians led him to take up arms anew; he again became aide-de-camp to Bem, and he shared the last terrible campaign of that general in Transylvania. After one of the most desperate fights of that period he was seen no more, and it was universally believed that he was one of the slain. His body however was never found, and in 1852 a report was in circulation among the Hungarian refugees in London and elsewhere, that Petöfi was still alive and in concealment. Six additional years have now elapsed without any tidings being heard of him; his wife has been long re-married, and there seems little probability that he is still among the living. In the last poem of the first collection of his works beginning 'Egy gondolat bánt engemet,' he expresses a horror of dying in bed, and puts up an ardent prayer for death on the battle-field.

There is a collected edition of the poems of Petöfi up to 1846, in two small volumes, of which a first edition was published at Pesth in 1847, and a second in 1848. Two additional volumes, containing his subsequent works, were seized and suppressed by the Austrian government after the defeat of the revolution of Hungary. Many of them are to be found in a volume entitled 'Hangok á multbol' ('Sounds from the Past'), published at Leipzig in 1851, of which a German translation by Vasfi and Benkö, with interesting notes, was issued at Brunswick in 1852, under the title of 'Nationallieder der Magyaren.' As the wonderfully idiomatic elegance of the language is always spoken of as one of the principal charms of the poems of Petöfi, the foreign reader can hardly expect to appreciate them with any approach to the relish of a native; but there is a lightness and airiness about the songs which make it easy to believe in the effect they are said to produce on the sympathies of an Hungarian reader.

It may be remarked, that though Petöfi has often been spoken of as a wild son of nature, he had, as has been shown, enjoyed ample opportunities of education; and he was in reality well acquainted with the German, French, and English languages and literature. Gyulai, from whose biographical article in the 'Uj Magyar Muzeum' our information is chiefly taken, informs us that in English his favourite authors were Shakspere, Byron, Moore, and Dickens; and that he was accustomed to call Dickens, from the kindliness which his writings tend to inculcate, a "benefactor of mankind." Characteristically enough in a song-writer, he regarded Béranger as "the world's greatest poet." His own long poems are very inferior to his short ones; and in prose he can only be considered to have succeeded in some short tales and articles in the 'Életkenek.'

PEVENSEY. [Sussex.]

PHARMACOSIDERITE. [Mineralogy, *S.* 1.]

PHASMIDÆ, a tribe of Orthopterous Insects, embracing a number of exotic forms which have been often included in the *Mantidæ*, from which they are distinguished by the fore-legs being of the ordinary size, and fitted like the rest for walking rather than running. From the other *Orthoptera* they are distinguished by the hind legs not being saltatorial.

The body is generally long and slender. The head is of moderate size, of an oval subdepressed form, porrected, with large globular eyes, in front of which the antennæ are placed, which are variable in form, but ordinarily long, slender, and composed of a great number of articulations. The ocelli are rudimentary or obsolete. The labrum is deeply notched in front; the jaws are strong and horny. The dorsal surface in both sexes consists of nine segments, but only seven are distinct in the females. All the legs are alike, being long and slender, often armed with short spurs along the edges. The fore wings are of small size, and attached at the posterior part of the mesothorax. The true wings are very large and attached to the anterior part of the metathorax. "As they far exceed the wing-covers in size, it is essential that provision should be made for their defence. This is effected not as in the earwig, by the transverse folding of the wing so as to enable it to be folded beneath the small wing-cover, but by the front margin of the hind wing being greatly thickened, serving as a flat plate, beneath which the other part of the wing is folded longitudinally, the latter part being often differently coloured. Thus in some species the short wing-covers and the front margin of the wing are pale-green, whilst the other part of the wing is pink. Many species however remain throughout their lives without ever acquiring wings or wing-covers." (Westwood, 'History of Insects.')

The odd appearance of these insects have got for them the name of Walking-Sticks, Straws, Leaves, Spectres, &c., and certainly nothing can be imagined more curious than the forms they assume. In many instances they might be mistaken for a portion of the branch of the trees on which they rest.

PHENAKITE. [Mineralogy, *S.* 1.]

PHENYLE. [Chemistry, *S.* 2.]

PHILLIPS, RICHARD, F.R.S., some time President of the Chemical Society of London, first Curator and Chemist of the Museum of Practical Geology, an eminent mineralogical and pharmaceutical chemist, was a younger son of James Phillips, a member of the Society of Friends, who carried on the business of a printer and bookseller in George Yard, Lombard Street, London. Richard was born in the year 1778. He was educated as a chemist and druggist, under William Allen, at the well-known pharmaceutical establishment, Plough-court, Lombard-street, London; but he received his first instructions in chemistry from Dr. George Fordyce. Richard Phillips and his elder brother William, the mineralogist, William Allen, Luke Howard, and several other members of the Society of Friends, and three young men who were not Quakers, were among the founders, eight in number, of the Askesian Society, already noticed in a preceding article on Mr. Pepys, who was one of those three. To Richard Phillips, says Dr. Daubeny, in his anniversary address as president of the Chemical Society in 1852, "we are indebted for the first correct analyses of the Bath waters, in the course of which investigation he discovered the cause of the apparent uncertainty in the indications afforded by the common tests for iron, caused by the variations that occur in their effects, according as carbonate of lime is present or not." The elaborate paper stating the process and results of these analyses, was first communicated to the Askesian Society, and published in the 'Philosophical Magazine.'

His labours in mineralogical chemistry were characterised by great neatness and precision, so that they may indeed be appealed to at the present time as models of skilful and exact research. The analyses of the Bath waters were succeeded by examinations of other celebrated mineral springs, and of several rare minerals. In 1823 he discovered that the mineral called uranite was not the hydrated oxide of uranium, as it had been previously supposed to be, but a hydrated double phosphate of that metal and copper. The presence of phosphoric acid in uranite had escaped the scrutiny of Berzelius, who was thus as much outdone in this particular respect by the subject of this notice, as Davy had been by him when he detected the presence of the same acid in wavellite, which the great English chemist had overlooked.

The late Dr. Thomas Thomson, Regius Professor of Chemistry in the University of Glasgow, the author of the celebrated 'System' of the science, in his 'History of Chemistry,' forming part of the 'National Library,' published in 1831, when reviewing the progress of analytical chemistry in Great Britain, bore the following honourable testimony to the merits of Mr. R. Phillips—a testimony involving also considerations relative to the social position of the cultivators of science in this country, which thinking men of all ranks perceive to be of daily augmenting importance to the community:—"Of modern British analytical chemists," says Dr. Thomson, "undoubtedly the first is Mr. Richard Phillips, to whom we are indebted for not a few analyses, conducted with great chemical skill, and performed with great accuracy. Unfortunately of late years he has done little, having been withdrawn from science by the necessity of providing for a large family, which can hardly be done in this country except by turning one's attention to trade or manufactures."

It was however in the pharmaceutical branch of practical chemistry that Mr. R. Phillips's services were most conspicuous, as might be expected from one of his peculiar acuteness of mind, after a training in the establishment in Plough-court, of which the chemical reputation ranked justly so high. Indeed, the perfect familiarity he possessed with the processes in use, enabled him to detect the errors into which the framers of the London Pharmacopœia had fallen; whilst the keenness of his reviews gave currency to his censures, of which even those who smarted under their severity, could scarcely help acknowledging the justice. Accordingly, at a subsequent period he was especially consulted on the drawing up of two of the editions of the 'London Pharmacopœia' by the College of Physicians itself, whose previous labours in that department he had so severely criticised, and thus led the way to many of the much needed corrections in the processes since introduced. Indeed, during the latter part of his life, he was appealed to as perhaps the highest living authority in this branch of chemistry; and his translation of the London Pharmacopœia, the last edition of which he was engaged at the time of his death in superintending, was looked upon as the best book of reference on all chemical questions involved in the preparation of medicines.

From the year 1821 Mr. R. Phillips conducted the 'Annals of Philosophy,' with the assistance of Mr. E. W. Brayley, jun. (now F.R.S., and Librarian to the London Institution), and when that periodical was incorporated with the 'Philosophical Magazine' in 1827, his services were secured as one of its editors, a post he held till his death. The principal articles on subjects of chemistry and mineralogy in the 'Penny Cyclopædia,' were contributed by him.

Mr. Phillips was successively lecturer on chemistry at the London Hospital, at the Government Military College at Sandhurst, at Mr. Grainger's School of Medicine in Southwark, and at St. Thomas's Hospital. In 1839 Mr. (afterwards Sir Henry) De la Beche, knowing that in the first instance chemical investigations of mineral products would be those chiefly appreciated by the government and the public, wisely selected him for the appointment of curator and chemist of the Museum of Economic Geology, now the Museum of Practical Geology in Jermyn-street, an office which he continued to hold till his death, which occurred May 11, 1851, in his seventy-third year, after a very short illness, having been absent from the museum for three or four days only. On the following day, Monday, May 12, the formal opening of the Museum took place, under the auspices of H. R. H. Prince Albert.

On the institution of the Chemical Society of London, in the year 1841, its founders had offered Mr. R. Phillips the honourable position of the first president, deeming it due alike to his seniority among English chemists and his distinguished reputation; and although he declined the office then, he became the president in 1849 and 1850. He had been elected a Fellow of the Royal Society in 1822.

"He might indeed be regarded," remarks Dr. Daubeny, "during the latter part of his life, as a connecting link between the chemists of the last generation and of the present, having been the contemporary of Davy and Wollaston no less than of Faraday and Graham; and in his death we have lost one of the last of that distinguished band of philosophers, who, before chemical science had so enlarged its boundaries as to include within its domain and to comprehend within the operation of its laws the products of animal and of vegetable life, occupied themselves almost exclusively in the investigation of the combinations of which mineral bodies are susceptible."

PHILLIPS, SAMUEL, LL.D., was born in 1815. His father, who was of the Jewish faith, and a tradesman in Regent-street, London, struck by the boy's liveliness of manner and skill in mimicry, conceived that he would make a successful actor. He accordingly trained him for the stage, and in June 1829, "Master Phillips, a young gentleman only fourteen years of age," was announced to appear at the Haymarket Theatre in the character of Richard III. Fortunately some powerful friends—the late Duke of Sussex being one—thought that the boy's cleverness deserved a better culture than it would find in such a school, and they induced his father to send him, in 1832, to the London University, whence he proceeded in the following year to the University of Göttingen. Having changed his religious views, he afterwards went to Sidney-Sussex College, Cambridge, with the intention of ultimately taking holy orders. His father's death, and the necessity there appeared of continuing the business for the support of his mother and family, changed his plans, and he returned, after a single term, to carry on in conjunction with his brother, the Regent-street shop. In this the brothers were unsuccessful, though they were highly commended for their honourable conduct.

He now (1841) turned to literature as a profession. His first work was the novel of 'Caleb Stukeley,' which originally appeared in 'Blackwood's Magazine,' but has since been two or three times reprinted in a separate form. He afterwards wrote other tales in the pages of that and other periodicals, but none of them we believe were published with his name. For a brief space—during the summer months of 1844—he resided at the seat of the Marquis of Ailesbury in Wiltshire, in order to read with Lord F. Bruce; and whilst there he was thrown from a horse and seriously hurt. He had perhaps always had a tendency to consumption; it was developed by the hurt, and during his remaining days he worked with the weight of that terrible malady pressing upon him. But he worked steadily on, and was able to secure himself a handsome income, and an honourable position among his literary compeers. Writing exclusively in newspapers and periodicals, it was only in the last year or two of his life that Mr. Phillips was at all known by name to the general public, yet he probably exercised a much more considerable influence on public opinion and public taste than many much better known men. For some time he wrote political leaders in the 'Morning Herald;' but he afterwards became one of the chiefs of the literary staff of the 'Times,' and during some years his brilliant criticisms on current literature afforded an agreeable relief among the news and politics of that powerful journal. In the 'Times' his pen was entirely confined to literary criticism,—at any rate he never wrote 'leaders'—and he continued to write its more important reviews down to his death. Two volumes of 'Essays from the Times,' by him, were published, though still without his name, in 1852 and 1854. Lucid, picturesque, often eloquent, and sometimes bitterly keen, yet discriminating, and with all the appearance of being scrupulously fair, they will no doubt keep their place as a permanent addition to our store of that class of essays: and some that were attributed to him, but which appeared after the publication of these volumes, are of at least equal merit. Besides his papers in the 'Times,' Mr. Phillips wrote reviews in the 'Literary Gazette,' &c. He also purchased, and for about a year edited, the 'John Bull' newspaper, but without much pecuniary success. In the formation of the Crystal Palace Company he took an active part; and for a time acted as secretary, and subsequently as 'literary director' to the company, and many of the arrangements are said to have been suggested by him. He wrote likewise the general 'Guide to the Crystal Palace and Park,' and the 'Portrait Gallery of the Crystal Palace.' He died at Brighton, where he had gone on account of his health, on the 14th of October, 1854, from the rupture of a large vessel on the lungs. He left a widow and five children, for whom he had been enabled to make a comfortable provision. In 1852 the University of Göttingen conferred on him the honorary degree of LL.D.

PHILLYRINE. [Chemistry, *S.* 2.]

PHLEGM, a common name for Mucus. [Mucus.]

PHLORIDZIN. [Chemistry, *S.* 2.]

PHOLARITE. [Mineralogy, *S.* 1.]

PHOSPHATITE, a name proposed for the native Phosphate of Lime derived from organic sources, and usually called *Coprolites*. The latter term conveys an impression which is evidently wrong, with regard to large quantities of the phosphate of lime now obtained for agricultural purposes. In that which is obtained from the Red Crag fragments of bones of large size are constantly present, and it is questionable if any portion of this phosphate has ever been excrementitious matter. Hence the impropriety of the term coprolite. The more probable origin of these masses seems to be that they are the debris of a huge sepulchre of *Cetacea*, sharks, and other animals, which was formed previously to the existence of the beds in which these remains are now found. After deposition in this sepulchre, the animal matter of the bones was gradually washed away, and the large quantities of phosphate of lime found in the water-worn nodules of the Red Crag are thus accounted for. [Coprolites, *S.* 2.]

PHOTOGRAPHY is both an *art* and a *science*. As an art it enables us to draw, depict, or write by means of light. As a science it teaches us how to observe and further to investigate the effects produced by light upon all natural bodies, whether animate or inanimate, mineral, vegetable, or animal. Its full study is of comparatively recent date, but it has already occupied the liveliest attention of nearly all the most eminent investigators in modern science. The names of Davy, Wedgwood, Thomas Young, Wollaston, and the two Herschels in this country—of Scheele, Ritter, Seebeck, Berthollet, and Becquerel on the Continent—testify to this effect. Photography is worthy of special attention from the fact that it requires for its rational and thoroughly successful pursuit a knowledge of chemistry, optics, and physics generally, together with an amount of artistic taste and manual dexterity such as must be useful not only for purposes of mental training, but under a variety of circumstances in actual life. The variety of its parts and aims gives it a special charm for those who like to have a pursuit admitting of both activity of mind and body; its processes are as much carried on out of doors as in close laboratories. Further it has this charm, that while it furnishes problems of the greatest interest and intricacy for the most advanced philosopher in optics or chemistry, it has its practical processes, which may be readily apprehended, and exercised for purposes of utility or recreation by those who are but little skilled in physical manipulations.

The history of photography has been so fully treated of by Mr. Robert Hunt, in his 'Researches on Light,' and in his 'Treatise on Photography,' and also by the Abbé Moigno, in his 'Repertoire d'Optique Moderne,' that we need not do here more than recapitulate in a brief manner the points of chief interest which they have given at greater length.

It may be well to say at the outset, that it was not till the year 1839 that Protography acquired for itself "a local habitation and a name," through the investigations of Fox Talbot and Daguerre, which resulted in the introduction of the two processes known as the Calotype or Talbotype, and Daguerreotype. As usual in the history of art and science, approximations had been attained to by earlier experimentalists. It is interesting to inquire into the labours of some of these. Proceeding historically, we shall find that observations relating to the science of photography precede the first attempts at establishing the principles of the art.

In 1722 Petit noticed that solutions of nitrate of potash and muriate of ammonia crystallised more readily in the light than they did in darkness. In 1777 the illustrious Scheele writes, "It is well known that the solution of silver in acid of nitre, poured on a piece of chalk and exposed to the beams of the sun, grows black. The light of the sun reflected from a white wall has the same effect, but more slowly, heat without light being without effect." Again, "Fix a glass prism at the window, and let the refracted sunbeams fall on the floor. In this coloured light put a paper strewed with *luna cornua* (chloride of silver), and you will observe that this horn silver grows sooner black in the violet ray than in any of the other rays."

Senebier repeated these experiments, and also experimented on the influence of light in the bleaching of wax.

In 1798 Count Rumford sent to the 'Philosophical Transactions' a memoir entitled 'An Inquiry concerning the Chemical Properties that have been attributed to Light.' In this paper the Count attempts to prove that all the effects produced upon metallic solutions by bright sunshine are due to heat. In 1802 Mr. Harrup refuted this view, and showed that several salts of mercury were reduced by light alone, and not by heat.

In 1801 Ritter proved the existence of rays in the solar spectrum, which are to be found beyond its visible limits, and these rays have the power of darkening chloride of silver. These researches having excited attention, M. Berard, Seebeck, Berthollet, Sir W. Herschel, Sir H. Englefield, Wollaston, Davy, and others, made various experiments which tended still further to confirm the proof that light had a special influence over bodies beyond that exercised through its heat; and that the colour of the light was in some way related to this newly observed action of the sunbeam.

Before proceeding to notice the early efforts of those who laid the foundation of the *art* of photography, with which we are now to be chiefly engaged, we may observe that Priestley, Senebier, Ingenhousz, De Candolle, Saussure, and Ritter, directed attention to the influence of light upon plants —an interesting and important subject. Others followed in a similar track, still, however, leaving the matter in a comparatively obscure condition. The action of light on the human frame, and on animal life generally, has not yet been fairly investigated. That some special action will be detected there can be no doubt. We have long thought that light will come to be considered as important an element to health as fresh air and wholesome food. It may possibly be that much mental or bodily labour, exercised in the absence of the stimulus of daylight, is directly injurious to animal life.

But let us proceed to trace rapidly the *art* of photography to its source. In the Journals of the Royal Institution of Great Britain for 1802 will be found a paper by "Thomas Wedgwood and Humphry Davy"—the first a brother of the famous porcelain manufacturer, the second the Sir H. Davy of a later period. Their joint paper was entitled 'An Account of a Method of Copying Paintings upon Glass and of making Profiles by the Agency of Light upon Nitrate of Silver; with Observations by H. Davy.' This paper contains the complete germs of the photographic art, namely, the application of an optical instrument to imprint upon a sensitive chemical surface the images of all natural objects illuminated by the sunbeam, or other source of light. The instruments used by these observers were the *camera obscura* and the solar microscope: but let us first see how this important invention took shape in the mind of Wedgwood.

According to Davy, Wedgwood first commenced his researches with a view to copy the images of the *camera obscura;* and for this purpose, says Davy, "he first used nitrate of silver, which was mentioned to him by a friend as a substance very sensible to the influence of light." This nitrate of silver was applied in solution to surfaces of white paper and leather. "White paper or white leather," to quote the words of the memoir of 1802, "moistened with solution of nitrate of silver, undergoes no change when kept in a dark place; but on being exposed to the daylight, it speedily changes colour, and, after passing through different shades of grey and brown, becomes at length nearly black. The alterations of colour take place more speedily in proportion as the light is more intense. In the direct beam of the sun two or three minutes are sufficient to produce the full effect; in the shade several hours are required; and light transmitted through different-coloured glasses acts upon it with different degrees of intensity." . . . . "When the shadow of any figure is thrown upon the prepared surface, the part concealed by it remains white, and the other parts speedily become dark. For copying paintings on glass the solution should be applied on leather, and in this case it is more readily acted on than when paper is used. After the colour has been once fixed on the leather or paper, it cannot be removed by the application of water, or water and soap; and it is in a high degree permanent. The copy of a painting, or the profile, immediately after being taken must be kept in an obscure place; it may, indeed, be examined in the shade, but in this case the exposure should be only for a few minutes: by the light of candles or lamps, as commonly employed, it is not sensibly affected." No means were found to fix permanently the impressions thus produced. And, as regards the primary end of Wedgwood's researches, we are told that "The images formed by means of a camera obscura have been found to be too faint to produce in any moderate time an effect upon the nitrate of silver." Davy adds, "In following these processes, I have found that the images of small objects produced by means of the solar microscope, may be copied without difficulty on prepared paper. This will probably be a useful application of the method: that it may be employed successfully, however, it is necessary that the paper be placed at but a small distance from the lens."

The muriate (chloride) of silver was found to be more sensitive to light than the nitrate. "Even in the twilight, the colour of the moist muriate of silver spread upon paper slowly changed from white to faint violet; though under similar circumstances no immediate alteration was produced upon the nitrate." Davy concludes with these remarkable words: "Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the day, is wanting to render this process as useful as it is elegant."

From this time the art in England slumbered until 1834, when Mr. Fox Talbot, without knowing what had been done, commenced experiments with the same end in view.

But we must now turn to a neighbouring country, France. In 1813 M. Niépce, of Chalons on the Soane, was engaged in a task identical in conception with that of Wedgwood. He was endeavouring by means of bituminous varnishes and metal plates to fix permanently the images of the camera, and he succeeded to a remarkable extent. His experiments were carried on until 1827, in which year he presented a memoir with specimens to the Royal Society of London; but as he kept his processes secret no notice was taken of his labours. Niépce returned to France dispirited. He there however continued his experiments, making pictures on a surface of bitumen laid upon a metal plate, which he afterwards engraved by ordinary engraver's acid. The rationale of his process is this: Light is capable of hardening a bituminous surface in such a way that the usual solvents of bitumen no longer act readily upon the altered part of the surface, and therefore only the shaded portions of a partially illuminated plate would yield to such solvents as the mineral naphthas, for example, furnish. But when a metal plate had been partially laid bare by the removal of the bitumen in the shadows, nothing was easier than to etch such a plate by aqua fortis, and this was what Niépce did. A plate thus made and prints from it are now in the possession of Mr. Robert Brown, of the Bristish Museum. It is to be hoped that they will be placed in the Museum itself. M. Niépce named his art *Heliography*.

In 1829 M. Niépce became acquainted with a M. Daguerre, who was noted for his dioramic paintings, and who was, it is alleged, also engaged upon methods for fixing the images of the camera. A deed of partnership was executed between the two experimentalists, and they jointly pursued their labours until the death of Niépce, in July 1833. A new arrangement was then made between his son M. Isidore Niépce and Daguerre.

At length came the memorable year 1839, when the whole scientific and artistic world was startled at the announcement that objects could be made to draw their own pictures with an accuracy and minuteness quite unattainable by hand. In January 1839 the first specimens by Daguerre were shown, but the process was withheld until the month of July. This enabled Mr. Fox Talbot to secure to himself the merit of priority of publication of a method by which sun-drawn pictures could be successfully produced. He on the 13th of January communicated to the Royal Society a paper, entitled 'Some Account of the Art of Photogenic Drawing, or the Process by which Natural Objects may be made to delineate themselves without the Aid of the Artist's Pencil.' And on the 21st of February in the same year, he gave another communication on the method of preparing sensitive paper and of fixing the images obtained. That the two experimentalists, Talbot and Daguerre, were independent discoverers is evident from the dissimilarity of their processes; the light and camera obscura being the only means strictly in common.

Mr. Talbot's method consisted in washing letter-paper over repeatedly with alternate solutions of salt and nitrate of silver; at a certain stage a surface was obtained which gave images under the influence of the camera, and these images were fixed by immersion in a strong solution of salt and water, in which the unaltered parts of the chloride of silver were soluble. This process was not very sensitive, and was therefore set aside by Mr. Talbot's later discoveries of 1840.

Let us now examine the nature of Daguerre's process called the Daguerreotype. A plate of silvered copper is highly polished, and then exposed to the vapour of the chemical element iodine, which imparts to the plate a series of colours, depending on the quantity of iodine absorbed. The exposure to the vapour was carried on until the plate assumed a rosy tint, or simply a deep orange-yellow, bordering on red. The plate was now sensitive, and had only to be exposed at the focus of the camera obscura in order to obtain a picture of any strongly illuminated object. Some minutes were necessary even in full sunshine. The plate was then withdrawn into the darkened room in which it had been prepared, and there it was exposed to the vapour of heated mercury, which has the wonderful property of attaching itself only to those parts of the iodised plate which have been exposed to light: and this deposit takes place in proportion to the original intensity of light of the image. Thus a picture was produced which represented in shades of black and white the original optical image seen on the ground-glass screen of the camera.

A solution of the hyposulphite of soda was used to fix the image by removing the compound of iodine and silver which still veiled in some degree the shadows on the plate. Subsequently M. Fizeau improved the appearance of daguerreotypes by imparting to them a warm tinge by a thin film of gold which was thrown down upon the image by a spontaneous electro-chemical action.

The original Daguerreotype process was not sufficiently sensitive to be used in portraiture. To Mr. Goddard we owe the great improvement of the introduction of a second chemical agent which now enables us to make pictures in a second of time. In 1840 Mr. Goddard combined bromine with iodine, and at once published the result. In the dull weather of November of that year, he obtained portraits in a few seconds; Daguerre's process requiring many minutes, even in a strong light.

One of the best modes of procedure now adopted is the following: Take a plate of silvered copper and polish it by means of tripoli powder and oil of lavender or rosemary, applied by cotton velvet; finishing the polish by *clean* cotton velvet alone. Then expose the silver to a mixture of iodine and pure sand in such a manner that the vapour of the iodine shall act equally upon the surface of the silver plate, to which it imparts a coating which is seen to be coloured when examined by light reflected from any white surface, a piece of paper for example. As soon as the plate has assumed an orange-yellow colour it is removed, and then exposed to the vapour issuing from a peculiar red compound of bromine with lime, called 'bromide of lime.' Over this it absorbs bromine, and assumes a rose tint, and as soon as this shade of colour has been obtained, the plate must be removed and again exposed to the iodine vessel until the rose colour has deepened into a plum tint. The plate is then ready for exposure in the camera obscura. No time can be stated for these various exposures as temperature influences the results. A few seconds in each case suffice. The plate must be prepared in a room which can be darkened, the light of a candle, or that obtained through yellow glass being alone used at the last iodizing, and in some of the subsequent operations. After exposure in the camera the plate is exposed to the vapour of mercury for a few minutes, the mercury being at a temperature of about 180° Fahr. Here the picture is developed by the action of the mercury upon the bromo-iodized surface, the mercury being, it is believed by some, deposited upon the plate in proportion to the amount of light which fell upon its surface during its exposure in the camera. On its removal from the mercury box the plate is partially fixed by washing its surface with a strong solution of hyposulphite of soda. The final fixation is effected by boiling upon the plate a solution of a double salt, called hyposulphite of soda and gold. The image is now fixed upon the plate, and may be coloured by brushing over it colours in very fine powder. The image should be kept so as to exclude the vapours of an impure atmosphere such as is usually found in large towns. Sulphuretted vapours will at once darken the light part of the image. The film of stain may, however, generally be removed by a solution of cyanide of potassium.

Having given an account of the daguerreotype, we might proceed to relate the history of Mr. Fox Talbot's researches, which led to the invention of the first successful process in photography on paper; but as these will be found detailed in Mr. Talbot's work 'The Pencil of Nature,' and in the Specifications of his Patents, we prefer to pass at once to consider a process which has now almost superseded all others, and which certainly sprang out of Mr. Fox Talbot's discoveries. Mr. Talbot nsed iodide of silver with nitrate of silver in excess, upon paper, for the purpose of procuring an image which remained latent until developed by a solution of gallic acid. The process now used, and called the Collodion Process, of Mr. Scott Archer, consists in the use of a film, on glass, of collodion, containing also iodide of silver with an excess of nitrate, the development being accomplished by pyro-gallic acid in the place of gallic acid. The analogy is complete, but the latter materials improve very much the ultimate results.

Collodion is made by dissolving in ether and alcohol cotton-wool which has been altered in its properties by treatment with strong acids. The following is a good mode of proceeding, and is due mainly to the researches of Mr. Hadow: Take of pure nitrate of potash in fine powder 510 grains, of oil of vitriol (specific gravity 1·833 about) 15½ drachms, of water 1½ drachms; stir together, and when at a temperature of from 150 to 155° Fahr., add, bit by bit, 15 grains of cotton-wool to each ounce of the acid mixture. Allow the cotton to soak for four or five minntes, and then wash it many times in water until it is quite free from acid. Then, to make the collodion, take 9 grains of the dry cotton, and add 6 drachms of pure ether (sp. gr. ·725 to ·730), and 2 drachms of pure alcohol (sp. gr. ·818 to ·820). The cotton should at once dissolve. In another bottle prepare what is called the 'iodizing solution' by taking alcohol (sp. gr. ·818 to ·820) one ounce, iodide of potassium 12 grains, iodide of cadmium 4 grains; dissolve the salts in the alcohol, and keep the solution for use. To make 'iodized collodion,' mix six drachms of collodion with two drachms of the iodizing solution; this mixture changes by keeping, and should therefore be made only in moderate quantities. Having prepared the iodized collodion, a plate of glass is covered with it by pouring a quantity on the centre of the plate, and then allowing the liquid to flow to the corners in such a way that the glass shall be uniformly covered; the excess is then run off at one corner into a bottle set apart for the purpose. After a few seconds the film of iodized collodion is sufficiently firm to be fit for immersion—in the dark—in what is called the 'nitrate bath.' This bath is made by dissolving 30 grains of nitrate of silver in one ounce of distilled water. The nitrate of silver should be pure, and free from excess of nitric acid, and it should be saturated, when in solntion, with iodide of silver; a little acetic acid, too, may be added. The plate is immersed in this bath for a few minntes, drained, and then exposed in the camera obscura. To develope the image, a solution of pyrogallic acid containing one grain of the salt to one ounce of water acidulated by 20 drops, or minims, of glacial acetic acid is poured npon the plate. If the image is not intense enough, a little weak solution of nitrate of silver must be added. The image obtained is fixed by a strong solution of hyposulphite of soda, in which it is immersed, or, instead, a weak solntion of cyanide of potassium may be poured upon the plate, and left there until the yellow film of iodide of silver disappears. The plate is then washed and dried, and protected hy a film of varnish: amber in chloroform being usually preferred for this purpose.

The picture thus obtained is, as in the calotype or Talbotype process of Mr. Fox Talbot, a *negative* one, that is to say, a picture having its light and shade reversed; though by modifying the collodion process *direct* positives may be at once obtained; a good negative, however, is a more valuable acquisition. In order to obtain copies correct in light and shade and position, a *positive* has to be made. There are many processes by which this can be done; but we will here give only one, which answers perfectly. Take the white of an egg and beat up, with every fluid ounce of it 12 grains of common salt: remove the froth thus obtained, and continue beating until all has become froth. Leave this froth to itself, and the greater part of the white of egg will become again liquid. Pour this liquid into a flat shallow dish, and upon it place carefully, so as to exclude bubbles of air, a sheet of thin paper, French paper is usually chosen; leave the paper for two or three minutes floating, so as to coat only one side with the 'salted albumen,' as the white of egg mixture is now called. Then carefully remove the sheet, and pin it up by a corner to dry. This operation can be carried on in daylight. To make this paper sensitive, it is floated upon a solution of nitrate of silver containing 60 grains of nitrate to one ounce of water. Here it is left for two or three minutes, and then removed and suspended to dry. This last operation must be performed in a room dimly lighted, as in the case of the daguerreotype and collodion final preparation. Upon the dry paper the negative picture is placed face to face, and the whole exposed in a proper 'pressure-frame' to the sun or to daylight. After a few minutes the picture is found printed, and must next be fixed by immersion in a solution of hyposulphite of soda, one part of the salt in from 6 to 10 parts of water. Ten or fifteen minutes' immersion would suffice to fix the picture; but in order to produce an agreeable tint of colour, a longer immersion is had recourse to, with the addition to the 'fixing bath' of a few grains of a neutral solution of chloride of gold. After several hours' immersion in this bath, the pictnre is removed, and washed repeatedly with plenty of water; hot distilled water heing used at last. This fixing bath is made fresh for each day's work. The pictures, when washed and dried, may be mounted on cardboard by means of starch, gum, or gelatine: paste is supposed to injure the picture under some circumstances. Exposure of the finished picture to impure atmospheric vapours, and to damp, is to he avoided. Mr. Malone has advised that the picture should be heated in a solution of caustic potash in order to secure its greater permanency. He also insists on the injurious action of sulphur in certain forms npon the print.

There is another branch of photography which is worthy of the attention of the student, but which has not yet come into practical operation in a perfectly satisfactory manner. It is that of photographic engraving. The labours of Niépce, Grove, Fizeau, Talbot, Pretsch of Poitevin, and others have done much to forward this art, hnt at present all is too uncertain to justify our extending this article by a description of the processes.

Stimulated by the experiments of Sir John Herschel, M. Ed. Becquerel and others, M. Niépce de St. Victor commenced a series of beautiful experiments upon coloured flames and their photographic images. He laid before the Academy of Sciences, Paris, a detailed memoir npon the subject on the 4th of March, 1851. This was followed by others on June 2, 1851; Feb. 9, 1852; and November 6, 1852. By the method described in these papers, M. Niépce succeeded in obtaining upon silver plates which had been rendered sensitive by a chloride of copper, images which faithfully reproduced the colours in coloured engravings, flowers both artificial and natural, lay-figures dressed in stuffs and gold and silver lace, precious stones, &c. These were obtained both by the process of photographic printing and in the camera; the light and brilliant colours being obtained with comparative ease, but the darker and more sombre colours more slowly. The colours he rendered more vivid and at the same time more lasting by the action of ammonia. But beautiful as were the results, and much more nearly as they seemed to approach the solution of the problem of photographing the colours of nature, they proved to be only comparatively permanent. The colours soon began to fade, and eventually disappeared altogether. This method (mainly due to M. Ed. Becquerel) M. Niépce named Heliochrome. M. Ed. Becquerel, by the use of silver plates, coated with a dark compound of chlorine and silver, obtained hy the voltaic decomposition of hydrochloric acid, has succeeded in obtaining coloured images of the solar spectrum, but no method of fixing them permanently has been discovered.

In scientific photography much remains to be done. We know but little of the properties of light in its influence on vegetation and animal life. Mr. Robert Hunt and others have, however, established some interesting facts in the former direction, and lately some experiments made upon the eggs of insects seem to show that light of various colours and intensities acts differently according to its colour and other peculiar qualities. There is no branch of science which will better repay the philosophical experimentalist for his investigations than that of photography. The most marvellous and nnexpected results have heen constantly obtained. As an instance let ns take the recent discovery of M. Niépce de St. Victor, which seems to prove that bodies acted upon by the sun absorb its powers in such a manner that they can emit photographically the same kind of influence which they have originally received from the sun. A bottling up of light—so to speak—has thus been arrived at.

Those who would pursue photography further should consult Hunt's 'Researches on Light,' the Abbé Moigno's 'Repertoire d'Optique Moderne,' and Mr. Hardwich's 'Treatise on Photographic Chemistry.' There are many papers also of interest to be found in the 'Comptes Rendus' of the Paris Academy of Sciences, in our own Royal Society's 'Transactions,' and above all in the journals of the various Photographic Societies.

PHYCIS, a genus of fishes belonging to the family *Gadidæ*. It has an elongated body; two dorsal fins, the first short, the second long; ventral fins with a single ray only at the base, afterwards divided; chin with one barbule.

P. furcatus, the Forked Hake, the Hake-Dame, the Common Fork Beard, is a rare fish on the British coasts. It has been taken most frequently in Cornwall. It is about two feet in length, but not very good eating.

PHYLLOSTOMA. [Cheiroptera.]

PHYSIC, PRACTICE OF. The more common diseases of the human system are treated of in the 'Penny Cyclopædia,' either under the head of the particular disease, or the organs or system of organs disordered. In the First Supplement, under the article Nosology, a classification of diseases will be found. In the present article, some forms of disease are noticed which have either been recently described or on which new light has been thrown by recent research. The subjects have been arranged for the convenience of reference in an alphabetical form.

Acclimation is a term applied to that change in the human system produced by residence in a place whose climate is different from that to which it has been accustomed, and which enables it to resist those causes of disease which readily act upon it before such change has taken place. A person is thus rendered similar in constitution to the natives of the country which he has adopted. This subject is one of great importance, and has not yet received the attention it demands. As far as present evidence goes, it appears that the white races attain their highest physical and intellectual development, the greatest amount of health, and reach the greatest age, above 40° in the western and 45° in the eastern hemispheres. Whenever they pass below these latitudes they begin to deteriorate and exhibit unmistakeable symptoms of decadence in both health and strength. The same law holds good with the dark races of the tropical parts of the earth. The negro who lives in the interior of Africa, is killed by cold. The limits of his health and strength are found at 40° north or south. If he proceeds to higher latitudes, he deteriorates and becomes exterminated. In the northern states of America the mortality of the black population is double that of the white.

"The laws of climate show that each race of mankind has its prescribed salubrious limits. All of them seem to possess a certain degree of constitutional pliability by which they are able to bear, to a certain extent, great changes of temperature and latitude; and those races that are indigenous to temperate climates support best the extremes of other latitudes. The inhabitants of the arctic regions, as also of the tropics, have a certain pliancy of constitution; and while the inhabitants of the middle latitudes may emigrate 30° south or 30° north with comparative impunity, the Esquimaux in the one extreme, or the Negro, Hindoo, or Malay, in the other, have no power to withstand the vicissitudes of climate encountered in traversing the 70° of latitude between Greenland and the equator. The fair races of northern Europe below the arctic zone find Jamaica, Louisiana, and India, to be extreme climates; and they and their descendants are no longer to be recognised after a prolonged residence there. When an Englishman is placed in the most beautiful part of Bengal or Jamaica, where malaria does not exist, and although he may be subjected to no attack of acute diseases, but may live with a tolerable degree of health his threescore years and ten, he nevertheless ceases to be the same healthy individual he once was; and, moreover, his descendants degenerate. He complains bitterly of the heat, and becomes tanned; his plump plethoric frame becomes attenuated; his blood loses fibrine and red globules; both mind and body become sluggish; gray hairs and other marks show that age has come on prematurely—the man of forty looks fifty years old; the average duration of life is shortened (as shown in life insurance tables); and the race in time would be exterminated if cut off from fresh supplies of emigrants from the home country. Our army medical historians tell us that our troops do not become acclimatised in India. Length of residence in a distant land affords no immunity from the diseases of its climate, which act with redoubled energy on the stranger from the temperate zones. On the contrary, the mortality among officers and troops is greatest among those who remain longest in those climates." (Johnson, Martin, Tulloch, Macpherson, Boudin.) Dr. Macpherson also makes the significant remark, that the small mortality among officers compared with soldiers, in India, is due to the greater facilities they enjoy of obtaining change of climate when they fall sick. Although the constitution of the man may be so modified that comparative health may be retained, yet there is a morbid degradation of the physical and intellectual constitution. If, however, he or his descendants are taken back to their native climate, they may yet revert to the healthful standard of their original types. The good effects of limiting the period of service of our troops abroad to three years, has shown this in sustaining for a greater period the strength of the regiments; a protracted residence of the European regiments in India having been followed by the most disastrous results. "European regiments in India have melted away like the spectres of a dream. A thousand strong men form this year a regiment: a year passes, and one hundred and twenty-five new recruits are required to fill up the broken column; and eight years having come and gone, not a man of the original thousand remains in the dissolving corps."

"With regard to the Bombay Fusilier European regiment, for instance, Dr. Arnot has shown that its losses average 104 per 1000 per annum; a loss equivalent to the entire absorption of the regiment in nine years and seven months. In Bengal also it is an ascertained fact, that a British regiment of 1,000 men dissolves entirely away in 11 years, even in favourable times, and with all the improved conditions of the service. Dr. Arnot's statistics show that the Bengal army loses annually 9 per cent. of its numbers, giving a total loss in eight years of upwards of 14,005 men out of an army of 156,130 men." (Aitken's 'Handbook of Medicine.')

In the island of Ceylon the rate of mortality has been recorded amongst five different races of which the British troops are composed. The following table gives the result:—

	Annual death in 1000 men
Native troops of Bengal and Madras	12
Troops recruited on the coast of Ceylon	23
Malays	24
Negro troops	50
English troops	69

Although from these facts it would appear there is an insuperable barrier to the prolonged occupation of tropical countries by white races, yet much may be done by attention to the laws of health and disease. One cause of the great amount of mortality amongst Europeans in the tropics is that they continue the habits they had acquired in cold countries when they arrive in the hotter parts of the world. An attention to diet, clothing, and residence, would do much to remove many of the causes of disease. It would appear also that many of the races that now inhabit cold climates made their way from warmer countries, and that changes gradually produced in the constitution, as by the slow advance of peoples north or south, may overcome that tendency to succumb which is so evident in the rapid removals to which the above data refer. The question of the permanent occupation of tropical countries has become one of vital importance to the two great European governments of England and France. How this can be done at the least expense of human life can only be ascertained by the study of the laws which regulate acclimation.

Addison's Disease. The name of Dr. Addison, physician to Guy's Hospital, has been connected with a diseased condition of the system, which is made apparent by a discoloration of the skin. Hence this disease is also called 'Bronzed Skin.' The existence of this discoloured skin has long been known as a symptom of certain cachectic states of the system; but Dr. Addison was the first to point out that this state of the skin always existed in connection with a diseased condition of the supra-renal capsules. These bodies belong to the class of ductless glands, and till the time of Dr. Addison's researches upon bronzed skin appeared, little was known of their uses and functions in the human body. The following conclusions with regard to these bodies have been arrived at by Dr. Harley as the result of his experiments:—

1. The supra-renal capsules are not solely fœtal organs.
2. They are not absolutely essential to life.
3. The removal of the right is generally more fatal than the left.

4. That convulsions do not necessarily follow their removal.

5. The absence of their function is attended neither by great emaciation nor debility.

6. If death follows an experiment, it occurs as the result of injuring neighbouring parts.

7. Absence of the supra-renal bodies is not proved to have any special effect in arresting the transformation of hæmatin or in increasing the formation of blood-crystals.

8. The suppression of the supra-renal capsular function is not attended by an increased deposit of pigment in the skin or its appendages.

9. The problem of the connection of the bronzed skin and supra-renal capsular disease is more likely to be solved in the dead-house than in the physiological laboratory.

These conclusions were chiefly arrived at by experiments on rats, but they would seem to indicate that the connection between the bronzed skin and supra-renal capsules is not clearly made out.

The distinguishing features of the disease to which the name bronzed skin has been given, are general languor and debility, great feebleness of the heart's action, irritability of the stomach, a peculiar change of colour of the skin, and these symptoms usually occurring in connection with a diseased condition of the supra-renal capsules. The general symptoms are in fact those of anæmia, or cases in which the blood is imperfectly developed. Dr. Addison says of this discoloration of the skin, that it usually increases with the advance of the disease. "The anæmia, languor, failure of appetite, and feebleness of the heart become aggravated; a darkish streak usually appears upon the commissure of the lips; the body wastes, but without the extreme emaciation and dry harsh condition of the surface so commonly observed in ordinary malignant diseases; the pulse becomes smaller and weaker, and without any special complaint of pain or uneasiness, the patient at length gradually sinks and expires. In one case, which may be said to have been acute in its development as well as rapid in its course, and in which both capsules were found universally diseased after death, the mottled or checkered discoloration was very manifest, the anæmic condition strongly marked, and the sickness and vomiting urgent; but the pulse, instead of being small and feeble as usual, was large, soft, extremely compressible, and jerking on the slightest exertion or emotion, and the patient speedily died." (Addison.)

Although the connection between the state of the skin and the disease of the capsules was exhibited in all Dr. Addison's original cases, many exceptions have been recorded. Cases have occurred in which extensive disease of the supra-renal capsules has occurred without any bronzed skin, and cases of bronzed skin have been seen where no disease of the supra-renal capsules could be detected after death.

Dr. Harley, in the paper before referred to, concludes:—

1. That bronzed skin may exist without the supra-renal capsules being diseased.

2. That complete degeneration or total absence of the supra-renal capsules may occur without any bronzing of the skin.

3. That bronzed skin may be associated with a variety of differently-marked conditions of the system, among which a prominent one is disease of the supra-renal capsules.

4. That bronzed skin may be present without any derangement of the other functions of the body being observed. ('British and Foreign Medico-Chirurgical Review,' No. 42, 1848.) Dr. Harley is of opinion that the general symptoms in this disease are produced by a "diseased state of the solar plexus *per se*, or by irritation of the ganglionic system of nerves, caused by the close proximity and intimate connection of diseased supra-renal capsules."

The blood has been examined by the microscope in some of these cases, and found to present an increased quantity of the white blood cells, as observed in the disease known as Leucocythemia. [Blood, Diseases of.]

The microscopic character of the skin has been carefully examined in this disease, and it has been found to present the same appearance as observed in the skin of the black man. The pigmentary matter of the skin was found to be increased, and existed in larger quantities in the under than in the upper layers of the epidermis.

The treatment of this disease is not affected by our knowledge of its supposed cause. The remedies which would be applicable to bloodless and depressed conditions of the system should be used here. Tonics, nutritious diet, fresh air, and the means resorted to for restoring health in anæmia and leucocythemia may be had recourse to here.

The prognosis in this disease is unfavourable, although cases are reported in which recovery has taken place.

Anæmia, a diseased condition of the human body, in which is implied either a morbid condition of the blood, or a relative diminution of some of its most important constituents. This disease is also called *oligonæmia* and *spanæmia*, terms which, like anæmia, express a deficiency or paucity of the constituents of the blood. This state of the system is generally indicated by the excessive paleness of the face and the whole surface of the body. The lips are pale. The conjunctiva is of an unnatural white, having a pearly lustre. The veins on the surface are small, blue, and collapsed. These general symptoms are frequently attended with derangements of the nervous system. There is frequently violent pain in the head, and not unfrequently disordered sensations, as singing in the ears and flashings before the eyes. The whole surface of the body is frequently preternaturally tender, the slightest touch causing the patient to start. The course of the spine is frequently excessively tender, leading to the supposition that there is spinal irritation. The circulating system is deranged; palpitations of the heart come on after slight exertion. The pulse is mostly small, feeble, and quick, excited to rapid action on slight exertions. The breathing is quickened by exertion, and there is generally lassitude and inability to take much exercise. This disease is accompanied with disturbances of the circulating system, which may be detected by means of the stethoscope. These are heard in the heart, arteries, and veins. The sound heard in the heart is a 'bellows' murmur of varying intensity, and is heard most distinctly at the apex. This sound is not present in all cases of anæmia, nor is its occurrence diagnostic of anæmia; but it is very important to know that it may be entirely dependent on the anæmic condition, and removed with it. The arterial murmurs are not frequently heard; they are synchronous with the beat of the pulse, and when present may even be recognised by the character of the pulse. The venous murmurs are much more common. They are continuous, and produce various buzzing, humming, musical, and singing murmurs. "They are most frequently heard on the right side of the neck, at the junction of the external and internal jugular vein." (Aitken.)

The venous murmurs are seldom absent to a greater or less extent in anæmia.

When the blood of anæmic persons is examined under the microscope a deficiency of blood globules is observed. Andral records a case in which there were but 30 parts of blood globules in 1000 of blood. The other constituents of the blood, as far as observations at present go, seem to suffer little alteration.

The *causes* of anæmia are anything acting on the system by which the quantity of blood is diminished or the healthy development of the blood cells prevented. Thus, amongst the causes of this disease we may reckon: 1. Want of food. 2. Want of proper food. 3. Indigestion or imperfect nutrition, from whatever cause. 4. Derangement of the liver, spleen, &c. 5. Hæmorrhages, as from hæmorrhoids, the stomach, lungs, wounds, &c. 6. All extensive discharges from wounds, ulcers, or mucous surfaces.

A knowledge of the causes of anæmia at once suggests its treatment. Where it depends on a want of food altogether, or of proper food, then food of a proper kind must be supplied. Where improper food, as alcohol, produces imperfect assimilation, it must be withdrawn. Deficient nutritionary changes often come on as the result of impure air, and change from an impure to a pure air often acts most beneficially. In certain cases dependent on imperfect blood-cell formation great benefit results from the administration of iron. Cases are recorded in which, under an iron treatment, the blood-cells have increased from 32 to 95 in a 1000. Other tonics may also be administered with advantage. In cases of anæmia in marshy districts quinine is of great service.

Bright's Disease. An affection of the kidneys, having very definite symptoms, and exhibiting uniformity of structural change, was first pointed out by Dr. Bright, of Guy's Hospital, and is generally called after him. This disease is also called *Albuminuria* and *granular disease of the kidney*; the first on account of its diagnostic symptom, albumen in the urine, the second on account of the morbid condition presented by the kidney. This formidable disease presents several stages or varieties, and some discussion has taken place as to whether the symptom of albumen in the urine may not occur in several distinct morbid conditions of the kidney. There is no doubt that albumen may be found in the urine in even functional derangements of the kidney; but the term Bright's Disease is very conveniently applied to all those forms of structural change in the kidney which are accompanied with albuminous urine.

The general symptoms accompanying this disease vary according to the intensity of the disease and the condition of the patient. One of the first symptoms to which the physician's attention is usually drawn, is the presence of dropsy. This may occur in the skin or in any of the cavities of the body. It is frequently noticed in the face; and in all varieties of this disease an effusion of fluid is observed underneath the conjunctiva, producing the appearance of a watery eye. In addition to dropsical effusions, inflammatory affections of the mucous and serous membranes are very common accompaniments of Bright's disease. The heart also is frequently affected, and pericarditis and endocarditis are observed. Affections of the brain are also not unfrequently present, especially in the more severe cases arising from the poisoned condition of the blood.

In all cases of this disease, the urine contains albumen. This is easily detected either by coagulating the albumen by heat or nitric acid. The specific gravity of the urine is also decreased, being sometimes as low as 1·010, whilst healthy urine has a specific gravity of 1·020. It contains less urea than healthy urine. Under the microscope it also presents appearances indicative of the nature of the disease. These appearances consist of casts of the minute tubes of the kidneys, formed by substances produced in various stages of the disease. They are thus classified by Dr. Bennett:—

1. *Exudative casts*, consisting of the coagulated exudation or fibrine which is poured into the tube during the inflammatory stage.

2. *Desquamative casts*, consisting of masses of the epithelium lining the tubes, and occurring in all stages of the disease.

3. *Fatty casts*, consisting of patches of epithelium as in the last, but which have undergone a fatty transformation by the accumulation of a greater or less number of fatty granules in its cells.

4. *Waxy casts*, presenting an exceedingly diaphanous and structureless substance. They are frequently associated with the two last.

Dr. Bright originally described three stages of this disease, but later observers have recognised six.

1. The catarrhal form, in which the kidneys are enlarged, and contain an increased quantity of blood. In this stage only a small quantity of urine is passed containing the exudative and desquamative casts.

2. In this stage the kidney is enlarged to nearly double its size, and is white and granular in its appearance. The tubes of the kidney are obliterated by the inflammatory deposit. The urine is very albuminous, and of light specific gravity.

3. The kidney presents a mottled appearance. It is probably a transition from the first to the second stage.

4. In this stage the kidney is large, dense, and white. The tissues of the kidney have become charged. The urine is scanty, of low specific gravity, and defective in urea and other excretory matters.

5. In this stage the kidney is hard, granular, and contracted. The kidney is smaller than in health, the surface is uneven and puckered, the tunic adherent. There is no deposit in the tubes, but fibrous matter has been deposited in the tissues of the kidney, and the tubes are strangulated. The urine may not contain albumen. Its specific gravity is sometimes as low as 1·005.

6. This stage has been called the 'coarse kidney.' The organ is large and dark. The specific gravity of the urine is high, and it is loaded with urates.

The presence of fatty matter in the casts of the kidneys may occur in any of these stages, and does not appear to exist as a separate form of the disease.

The cause of this disease is anything which will unduly excite the action of the kidney. Thus it comes on as the result of spirit drinking, which powerfully excites the action of the kidneys. Exposure to cold and diminution of the action of the skin will also produce it. It comes on frequently after scarlatina, when the skin is highly susceptible of any diminution of temperature.

The treatment must be active in the early stages. Purgatives may be given and blood abstracted locally, and the febrile symptoms treated accordingly. Mercury is not found beneficial. When chronic, diaphoretics and diuretics are both admissible. Amongst the former, Dover's powder and warm baths, and the latter, bitartrate of potash and digitalis. The patient should be protected from cold; a warm climate is serviceable; and a nutritious but not stimulating diet, with fresh air and exercise, are desirable.

Blood, Diseases of. A large number of diseases are now referred to disordered conditions of the blood. Amongst these are the following:—Anæmia, Diabetes, Continued Fevers, Eruptive Fevers, Syphilis, Mercurial Poisoning, Rheumatism, Gout, Scorbutics, Obesity, Leucocythemia, and Pyæmia. With the exception of the two last, these diseases have been treated of in the 'Penny Cyclopædia.'

Leucocythemia, as a distinct disease, was first pointed out by Dr. Bennett, of Edinburgh, in 1845. The name is derived from the fact, that in these cases the white or colourless corpuscles of the blood are increased in number. This state appears to be brought about by loss of blood, chronic diseases, more especially affections of the lymphatic glands and spleen. It is accompanied by debility, wasting, cough or diarrhœa, and a generally unhealthy condition of the system. The increase of the white corpuscles of the blood, which are easily detected, does not appear to occur of itself, but is generally dependent on some morbid condition which has preceded. The most frequent complication is enlargement of the spleen. Vogel states that in nineteen cases this complication existed in sixteen. Occasionally the liver is found enlarged, and in some cases the lymphatic glands are the organs most extensively affected. The occurrence of this disease has led to highly interesting inquiries as to the origin and nature of the white cells of the blood, which are increased so largely in these cases. Dr. Bennett, in his work on the 'Principles and Practice of Medicine,' (1858), gives the following conclusions as to the result of his own elaborate and carefully conducted inquiries:—

"1. That the blood-corpuscles of vertebrate animals are originally formed in the lymphatic glandular system, and that the great majority of them, on joining the circulation, become coloured in a manner as yet unexplained. Hence the blood may be considered as a secretion from the lymphatic glands, although in the higher animals that secretion only becomes fully formed after it has received colour by exposure to oxygen in the lungs.

"2. That in mammalia, the lymphatic glandular system is composed of the spleen, thymus, thyroid, supra-renal, pituitary, pineal, and lymphatic glands.

"3. That in fishes, reptiles, and birds, the coloured blood-corpuscles are nucleated cells, originating in those glands; but that in mammals they are free nuclei, sometimes derived as such from the glands, at others developed within colourless cells.

"4. That in certain hypertrophies of the lymphatic glands in man, their cell-elements are multiplied to an unusual extent, and under such circumstances find their way into the blood, and constitute an increase in the number of its colourless cells. A corresponding diminution in the formation of free nuclei, and consequently of coloured corpuscles, must also occur. This is leucocythemia."

The treatment of this disease must be directed to the removal of those affections by which it is preceded and accompanied. Unfortunately, these are mostly of such a nature as to resist all treatment after the white cells have been discovered in the blood.

Pyæmia. Pus in the blood. By this term is understood a peculiar and dangerous disturbance of the system, supposed to be produced by the admixture of pus with the blood. In the cases in which this disease occurs, the pus is supposed to gain access to the blood from a suppurating surface in which the veins are opened, or by the production of pus on the interior surfaces of the vein, as in suppurating phlebitis. Many cases, however, of this disease have been recorded in which no open suppurating wound of the body could be discovered.

This disease usually sets in with more or less violent shivering fits. When suppurating surfaces exist they dry up, or the discharge becomes greyish and fetid, the surfaces of the wound assume a withered, flabby aspect. The patient becomes exceedingly languid and exhausted, and is sometimes plunged into a deep stupor, or has occasional delirium; the inspirations increase, the breath exhales a purulent odour, the lungs are congested, the skin becomes daily more yellowish, articular pains with swelling, and intra-synovial effusion occur successively in several of the joints. The tongue is dry, and coated with a brown fur; the teeth and lips are covered with sores, the abdomen is tender and frequently tympanitic, the pulse is quick and becomes tremulous and rapid, the eye becomes dull, partial paralyses present themselves, the voice is lost, and the patient sinks from the fourth to the tenth day.

After death abscesses are found in the lungs, liver, spleen, brain, kidneys, heart, pleura, joints, muscles, and the subcutaneous connective tissue.

In many cases pus-cells, or an increase of the white corpuscles, have been found in the blood. This increase is not, however, a diagnostic symptom, as many cases have occurred in which no increase in the white cells (which are not easily distinguished in the blood from the pus-cells, and have been supposed to be identical) has been observed.

The pathology of this disease has excited much discussion. Whilst some have regarded it as entirely dependent on the introduction of pus into the blood, others maintain that it depends on the introduction of a peculiar poison into the blood. Dr. Bennett injected pus into the blood of an ass without producing ill effects, and the above symptoms come on without any introduction of pus from without. It is more probable therefore that the disease arises from a peculiar state of the blood, either arising from vital changes in itself, or produced by the introduction of an external poison.

This disease is most frequently fatal, and no one plan of treatment can be laid down. Where suppurating surfaces are present these must be attended to, and accumulations of pus in abscesses should be removed by free incisions. The system must be supported by stimulants. Large doses of quinine have been recommended.

Under the head of FEVER, 'Penny Cyclopædia,' an account is given of the principal forms assumed by continued fever. Recent researches have led some pathologists to the conclusion that, under the name of continued fever, several distinct diseases resembling each other have been included. Dr. Jenner has given the following summary of the various forms of fever now recognised as follows:—

"*Febricula.*—A disease attended by chilliness, alternating with a sense of heat, headache, white tongue, confined bowels, high-coloured scanty urine, hot and dry skin, and frequent pulse, terminating in from two to seven days, and having for its cause excess, exposure, over-fatigue, &c.—(*i. e.*) the cause of febricula is not specific.

"*Relapsing Fever.*—A disease arising from a specific cause, attended by rigors and chilliness, headache, vomiting, white tongue, epigastric tenderness, confined bowels, enlarged liver and spleen, high-coloured urine, frequent pulse, hot skin, and occasionally by jaundice, and terminating in apparent convalescence in from five to eight days; in a week a relapse—(*i. e.*) a repetition of the symptoms present during the primary attack. After death, spleen and liver are found considerably enlarged; absence of marked congestion of internal organs.

"*Typhoid Fever.*—A disease arising from a specific cause, attended by rigors, chilliness, headache, successive crops of rose spots, frequent pulse, sonorous râle, diarrhœa, fulness, resonance, and tenderness of the abdomen, gurgling in the right iliac fossa, increased splenic dulness, delirium, dry and brown tongue, and prostration, and terminating by the 30th day. After death enlargement of the mesenteric glands, disease of Peyer's patches, enlargement of the spleen, disseminated ulcerations, disseminated inflammations.

"*Typhus Fever.*—A disease arising from a specific cause, attended by rigors, chilliness, headache, mulberry rash, frequent pulse, delirium, dry brown tongue, and prostration, and terminating by the twenty-first day. After death, disseminated and extreme congestions; in young persons, enlargement of the spleen." ('Medical Times,' 20th Paper.)

On the other hand, Dr. Duncan of Liverpool maintains, that not only are there no specific differences between the various kinds of continued fever, but that there are none between this and intermittent or remittent fevers. All these, he maintains, belong to one form of disease, and are curable by one remedy, and that is quinine. He prescribes ten grains of the sulphate of quinine every two hours until five or six doses are taken, and states that it cuts short all forms of fever in the same way as it does intermittent fever or ague. This practice has been followed by many medical men with favourable results, but with others it has entirely failed. Dr. Bennett of Edinburgh tried this remedy in nineteen cases, which he has related in his "chemical lectures," but the result of these cases was not favourable to the use of this remedy.

DENGUE (*Scarlatina Rheumatica*) is a peculiar febrile disease, conjoined with sudden severe pains in the small joints, which are usually swollen. It is accompanied by heat of skin, intense pain of the head and eyeballs, and the appearance of a cutaneous eruption on the third or fourth day. It is an infectious disease, and has a tendency to develope itself epidemically. The chief peculiarity of this disease is the combination of the symptoms of an exanthematous fever with rheumatic or neuralgic affections of the joints.

This disease has not been observed in Great Britain. "It has been chiefly prevalent in Rangoon, Calcutta, Berhampore, Benares, Chunaighur, in the East Indies; the island of St. Thomas in the West Indies; the Southern States of America; the ports on the Gulf of Mexico; the towns of New Orleans, Savannah, Charleston, Philadelphia, and New York. It was epidemic in 1824—28, and nothing appears to have been heard of it again till 1849 and 1850, when it again visited the Southern States of America." (Aitken.)

The general course of the disease is that the patient is attacked with headache, intolerance of light, chilliness, and pains in the back and joints. The small joints swell, the skin becomes hot, the pulse frequent, and the face flushed. The tongue is red. Sometimes an eruption appears at this stage. This state lasts from twelve hours to three or four days, after which it subsides, leaving the patient very feeble. This remission is, however, only temporary. In the course of two or three days there is a return of the fever and pains, with a thickly coated tongue, nausea, and tenderness of the epigastrium. On the sixth or seventh day a scarlet rash appears on the hands, which rapidly spreads over the whole of the body, and gives relief to the febrile irritation. The eruption is very irregular, sometimes being smooth, but at others being papular, vesicular, pustular, or even furunculous. The symptoms gradually subside, leaving the patient with some rheumatic stiffness, and feelings of weakness and mental depression. During the last epidemic at Calcutta the throat was sore, and the articular symptoms were less obvious.

The treatment of this disease consists simply in the palliation of the symptoms. When the nervous irritability and pain are considerable, then opium has been found of essential service. The disease might at first sight be regarded as a mild form of Scarlatina. Some of the symptoms, however, are sufficiently characteristic.

DIPHTHERITE or DIPHTHERITES (from διφθέρα, a skin or membrane) a term applied by M. Bretonneau and other French writers to a peculiar inflammation of the mucous membrane of the throat or pharynx, which is accompanied by the production of a false membrane. This disease first attracted attention at Tours in France, where it prevailed as an epidemic in 1818. It subsequently appeared in other towns of France, and alarmed the inhabitants of Boulogne in 1856. It has also been seen in India since its discovery and description by Bretonneau. No cases seem to have been accurately observed in this country till 1857. But during this year and the beginning of the present (1858) this disease has prevailed in Essex and many other counties of England. It has also been recorded as a cause of death in London, and the Registrar-General has assigned a place for it in his list of diseases accompanying the bills of mortality. When this disease was first described, it was regarded by some writers in this country as a variety of croup, and by others as a form of scarlet fever. Now that it has appeared, few observers could be found who would not agree that it is a disease *sui generis*. The invasion of this disease has been looked on with greater anxiety, as there seems to be little doubt of its belonging to the contagious or communicable class. It is also very fatal, and already a large amount of mortality has been caused by it in this country.

The distinguishing feature of this disease is the formation of a false membrane upon the surface of the mucous membrane of the fauces. This membrane is of a whitish or ash-gray colour, and frequently extends forwards from the pharynx and tonsils to the soft palate and into the nostrils, and backwards into the œsophagus. It is seldom found in the larynx and the trachea, and in this respect it differs from croup, and may be easily distinguished from it. When the membrane is found in the larynx or trachea, it is always subsequent to its appearance in the fauces. At the commencement of the disease, the membrane is seen in the form of a white spot on the pharynx or tonsils, from which it gradually extends all around. As it goes on, the membrane comes away in spots or presents fissures, through which the mucous membrane may be seen of a deep red or even of a purplish and claret colour. During the progress of the disease the cervical and submaxillary glands become swollen, and there is a fetid discharge from the nose and mouth. As the sloughs separate from the fauces, hæmorrhage frequently occurs.

The general symptoms are those of low fever. The disease sets in with shivering and intense depression, there is dryness and tingling of the throat and ears, difficulty of swallowing, and very frequently headache. The tongue is loaded, the pulse is frequent and feeble. In the early stages it might be taken for scarlet fever. But there is no active fever, no eruption of the skin, no redness of the papillæ of the tongue, and when the patient recovers, no desquamation of the cuticle as is constantly the case in that disease.

The prognosis in these cases is unfavourable. This disease generally terminates life by extending to the air passages and producing effusion in the glottis, which speedily terminates life.

This disease is from the beginning attended with a great depression of the vital powers, and its treatment demands that the vital processes should be sustained. A purgative may be given at the onset, but in most cases wine may be administered from the commencement of the attack. Many writers also speak highly of the chlorate of potash administered in the same way as in scarlet fever. To this may be added the preparations of ammonia. Quinine has also been highly commended, with the mineral acids. The throat also requires local treatment. Two remedies have been generally employed, nitrate of silver and chlorine. The nitrate of silver is applied in the proportion of one drachm to an ounce of water on a sponge several times in the course of the day. Dr. Watson recommends injecting the nares with a solution of chlorine in water. This relieves the fetid smell which is very disagreeable to the patient and those around.

This disease occurring in districts, and attacking in succession the members of a family, has led to the conviction that it is contagious. As it is so dangerous a disease, it is well to act on the doubt, and to take those measures which would be adopted in the case of contagious diseases, as smallpox and scarlet fever.

Glanders or Farcy is a name given by veterinary surgeons to a disease affecting horses and other cattle. It appears in the form of a suppurative disease of the mucous membrane of the nose and of a pustular eruption. The former is sometimes called glanders and the latter farcy, but the two often occur together, and the pus discharged by the one will produce the other. In 1821, Mr. Muscroft drew attention to the fact that this disease could be communicated from the horse to the human system. In the same year cases occurred in Germany, and since then it has been demonstrated by a large number of cases that this disease often spreads from the horse to man. When it attacks man it is characterised by vascular injection of the nasal mucous membrane, on which chancre-like sores are formed, extending to the frontal sinus and neighbouring mucous surfaces, from which a profuse and offensive discharge flows. At the same time a tubercular or pustular eruption appears upon the skin, followed by suppurating bloody or gangrenous ulceration in various parts. These symptoms may be either *acute* or *chronic*. In the acute cases a primary fever is followed by the local disease. In chronic cases the local affection alone presents itself. The acute disease is ushered in by rigors, pains in the back and limbs. These symptoms are followed by phlegmonous tumours in various parts of the body, which are accompanied with pain and tenderness, and terminate in abscesses or boils. At the same time a discharge takes place from the nostrils of a matter more or less purulent, viscid, and mixed with blood. The eyelids frequently become tumefied, and discharge a thick viscid matter like that from the nose. About the twelfth day of the disease an eruption breaks out on the face, trunk, and limbs. It is preceded and accompanied by profuse and fetid sweats. The eruption is scattered, and resembles, according to circumstances, the vesicles of cow-pox or the pustules of small-pox or ecthyma. These are sometimes accompanied with large vesicles (bullæ), which become black and discharging leave gangrenous sores. At first the pulse is full and quick; but it becomes rapid, small, irregular, and intermittent. The tongue is at first loaded with white fur, which afterwards becomes brown or black. Diarrhœa and tympanitis often come on in the course of the disease. This disease is generally fatal from the seventeenth to the twenty-first day. In the chronic cases the febrile symptoms are not so prominent. The local symptoms are much the same, but they progress more slowly. The abscesses are attended with a large amount of subcutaneous inflammation. In this state patients may recover, but they die from a fortnight to a month. A twelvemonth has been known to elapse before a patient has recovered or died.

There is no doubt that these symptoms are the result of a poison introduced into the system of man from the horse. In all cases contact with glandered horses has been ascertained to have taken place before the breaking out of the disease. Matter has been taken from the ulcers and membranes in men and horses have been inoculated, and the disease has been produced. The disease has also been produced by compelling animals to swallow the poisoned matter in their food. There can, therefore, be no doubt that the poison can be absorbed both from mucous and cutaneous surfaces. This being ascertained, it becomes more than ever necessary to prevent contact with glandered horses. Such horses have been known to give the disease to persons riding behind them or passing near them by snorting the matter from their nostrils into the air. All glandered horses ought to be destroyed. In Germany the conviction of the danger of this disease is so strong, that all horses proved to have come in contact with glandered horses are ordered to be destroyed. Not only can this disease be communicated from horse to horse, and from the horse to man, but cases have occurred in which those attending glandered individuals have become affected. The poison of glanders soon manifests itself. Mr. Turner inoculated two young donkeys, and in one the maxillary glands became tender on the second day, and the discharge took place from the nose on the third day, whilst in the second the glands became swollen on the third day, and the discharge took place on the sixth. Cases have been recorded in which the incubation of the poison must have taken at least three months. In the human being the poison has remained latent from two to eight days after exposure.

This disease in its acute form is very fatal. Of fifteen cases recorded by Rayer only one recovered. Of the treatment, therefore, little can be said as a matter of experience. The general symptoms in the latter stages are those of low malignant fever, and a stimulant plan of treatment is indicated. Cases have been bled, and the blood was buffed and cupped, but there is no reason to believe that the bleeding did any good. In the chronic forms of the disease recovery is more frequent. The symptoms indicate the necessity of a generous diet.

Microscopic Diagnosis. The recent improvements in the construction of the microscope have not only rendered this instrument necessary in physiological and pathological investigations, but essential as a means of diagnosis in many diseased conditions of the human system. The very general demand for this instrument as an important aid to the eye in examining minute structures and objects, has led to the construction of various forms adapted for the use of the medical man. The description of this instrument will be found in the article Microscope, and an account of the methods of using it under Microscope, Uses of, in the second supplement of the 'Penny Cyclopædia.' In the present article the application of this instrument to the diagnosis of disease will alone be referred to, and the subject may be divided under the two heads of Diseased Structures and Diseased Secretions.

Diseased Structures.—1. *Cancer.* The distinction between cancer and other forms of diseased structure in the human body, is one of the most important departments of diagnosis, as upon this depends a just estimate of the action of any particular system of treatment, and the solution of the question of the curability of cancer. There can be no doubt that many ulcers have been called cancerous, which have no claim to be regarded as such; whilst others, with a true cancerous character, have been overlooked. Although the microscope cannot in all cases decide the character of a questionable ulceration, it has nevertheless thrown great light on the true nature of cancerous growths, and is a most important aid in their determination. Cancerous exudation generally presents three forms, which, however, are constantly found running one into the other. These have been named *schirrhus, encephaloma*, and *colloid cancer*. In all these forms certain cells are discovered by the aid of the microscope, which have been called *cancer-cells*. These cells may be round, oval, caudate, spindle-shaped, oblong, square, heart-shaped, or of other indescribable forms. In size they vary from $\frac{1}{1200}$th to the $\frac{1}{1200}$th of an inch in diameter. The cell-wall when young is smooth and distended, but when old it becomes flaccid and more or less corrugated. These cells contain in their interior always one nucleus, often two, and sometimes a larger number. These nuclei vary in size. Besides the nuclei the cells contain a colourless fluid, which is at first clear, but afterwards becomes opalescent from the presence of molecules and granules. On the addition of water the cells become enlarged by its absorption into their interior. On adding to them acetic acid, the young cells become absorbed, whilst the older cells are rendered more transparent, and the nuclei remain unaffected, or become thicker from contraction.

In *schirrhus* these cells are found either in distinct cysts or isolated amongst a mass of filaments which vary in size, and run in different directions, sometimes forming waved bands, and at others an inextricable plexus. In *encephaloma* the same fibrous structure is observed, but it is looser. In the softer parts no traces of fibres are observed, and the cancer-cells abound. When blood is extravasated in this structure, it constitutes the form of cancer known by the name of *fungus hæmatodes*. The *colloid cancer* is found also to consist of a fibrous structure, but which is so arranged as to form areolæ or loculi, which are filled with a gray or amber-coloured glutinous matter. This matter is sometimes quite structureless, but at other times it presents the nucleated cells characteristic of cancer.

Sometimes the cancerous matter is found mixed with oil globules, and crystals of cholesterin and margarine. At other times it becomes hardened by the deposit of calcareous substances. Thus indicating the tendency of cancer to assume the forms of fatty and mineral degeneration. (Bennett, 'Principles and Practice of Medicine.')

2. *Tubercle*. This form of diseased structure is found in the lungs of persons labouring under phthisis. It generally presents a yellowish or dirty white colour, and has a consistence varying from that of cream to a substance resembling tough cheese. "A small portion squeezed between glasses and examined under the microscope presents a number of irregular-shaped bodies approaching a round, oval, or triangular form, varying in their longest diameters from the $\frac{1}{3000}$th to the $\frac{1}{1200}$th of an inch. These bodies contain from one to seven granules, are unaffected by water, but rendered very transparent by acetic acid." (Bennett.) These bodies are called tubercle-corpuscles, and are mingled with molecules and granules, in a greater or less number, according to the consistence of the tubercle. When the tubercle becomes hardened by calcareous deposits, few of these bodies are seen, the mass consisting of irregular particles of phosphate of lime, and crystals of cholesterin. In the earlier stages of tuberculous deposit of the lungs, the system is found to contain small portions of the disintegrated tissue of the lungs, and in some cases this appearance has been observed when no physical or other decided indications of tubercle existed.

3. *Blood*. In some forms of the disease the blood-cells exhibit a changed character, which can alone be detected by the microscope. This is seen most remarkably in a disease recently discovered by Dr. Bennett, of Edinburgh, called "Leucocythemia," in which the white corpuscles of the blood, which are much fewer than the red in healthy blood are found to be greatly increased in number. [Blood, Diseases of.]

In many diseases the blood presents an unusual degree of thickness. In this condition the red corpuscles easily lose under pressure their rounded margin, and assume a caudate or flask form. They do not aggregate together in the usual form of rolls, but present masses of an irregular shape.

In blood produced by internal hæmorrhage the red cells readily break down and are partly dissolved. The liquor sanguinis in which they float is also found to contain a large number of granules. In these conditions also the blood-cells frequently present nuclei in their interior.

In cholera the blood has been observed to undergo a remarkable change. Dr. Bennett states, that in blood he examined the red corpuscles were paler than usual, the colourless ones were normal, and mingled with these were others which varied both in shape and size. The latter were generally circular, but some were oval and a few caudate. Their long diameter varied from the $\frac{1}{1200}$th to the $\frac{1}{3000}$th of an inch, and their transverse diameter $\frac{1}{3000}$th to the $\frac{1}{4000}$th of an inch.

In certain cases the serum of the blood presents a milky appearance, and on being allowed to rest a creamy pellicle is formed on its surface. On placing this under the microscope it is found to be composed of minute particles of oil, which resemble the smaller molecules found in milk and the chyle.

The blood has been observed to undergo other changes, observable by the microscope, in conditions of plethora, fever, jaundice, dropsy, cholera, and other diseases; these have not however been sufficiently accurately described to be relied on at present as a means of diagnosis.

4. *Pus*. It becomes sometimes a matter of considerable diagnostic importance to detect the presence of pus-globules in discharges from the human body, as when present they indicate the occurrence of suppuration, sometimes in parts of the body which cannot be observed. Normal or good pus, as it is called, consists of numerous corpuscles floating in a clear liquid. The corpuscles are globular in form, with a smooth margin and a finely granular surface. They are exceedingly like the white blood-corpuscles in their general appearance. They vary in size from the $\frac{1}{1200}$th to the $\frac{1}{3000}$th of an inch in diameter. They generally contain in their interior a round or oval nucleus, which becomes very distinct on the addition of water, and the rough surface of the cell also becomes smooth. The nuclei are liberated from their cells by the addition of acetic acid, in the form of two, three, four, or rarely five granules, each having a central nucleolus. Occasionally the pus-corpuscles are surrounded by a second membrane. At other times they are not perfectly globular, presenting a greater or less irregularity of their margins, and accompanied with granules and molecules. This occurs in pus from scrofulous ulcers and other kinds of what is called *unhealthy pus*.

5. *Vomited Matters*. It is frequently of importance to examine the matters thrown up from the stomach by vomiting. One of the most interesting results of the application of the microscope to these matters has been the discovery of a plant which has been called *Sarcina Ventriculi*. Occasionally other forms of plants have been found in the vomited matters, although these have probably been introduced from without. In cases where poisons have been taken which produce vomiting, the application of the microscope will detect the kind of poison. In this way the husks of the ripe fruit of the Deadly Nightshade, the seeds and leaves of *Lobelia inflata*, and other poisonous substances, have been discovered. It is also a matter of importance sometimes to ascertain the nature of the food taken by children or insensible persons who can give no account of themselves, and this can be done by the examination of the vomited matters by the microscope. When the mucous surfaces of the stomach are affected with inflammation or ulceration, the discharges from the stomach will afford indications of the nature of the disease.

6. *Fæces*. The contents of the bowels, when examined by the microscope, often afford important diagnostic indications. They contain naturally the matters secreted by the mucous membranes of the intestines and the remains of the food. They will also contain various morbid products. Amongst these latter may be mentioned plants and animals. Confervæ and fungi have been found in the fæces, and various organic bodies, now known to be introduced from without, were at one time regarded as the cause of cholera. The presence of pus- and blood-corpuscles may also indicate diseased conditions of the membranes of the intestines. In cholera the rice-water evacuations consist of mucus and the remains of epithelial cells. The nature of food of an injurious character may frequently be discovered, by the aid of the microscope, in the feculent matters.

7. *Plants*. The lower forms of plants, belonging to the orders *Confervæ* and *Fungi*, frequently accompany diseases of the body. These are mentioned in the article Entophyta, *S.* 2.

8. *Animals*.—Several microscopic forms of animals are found to accompany diseased conditions. Some forms of *Infusoria* have been found in the mucous discharges from the mouth and other parts of the body. The cystic conditions of annuloid worms can only be made out by the microscope, as in the case of the *Trichina spiralis* which is probably the larval condition of the *Trichocephalus dispar*. The

scolex heads of *Echinococcus* and *Cysticercus* can only be distinguished by the microscope, and are diagnostic of the nature of the cysts in which they are found. Amongst the articulate animals producing disease, and only to be detected by the microscope are the *Sarcoptes Scabiei*, producing the itch, and the *Demodex folliculorum* which inhabits the follicles of the skin.

9. *Degenerated Tissues.*—The tissues of the body are liable to have their normal constituents replaced by substances which are morbid. The nature of these degenerations can only be definitely made out by the aid of the microscope. Thus the muscular tissue is liable to have its sarcous elements replaced by fatty matter, causing fatty degeneration. When this occurs in the heart, it becomes one of the most serious lesions to which this organ is subject, and is a frequent cause of fatal results. It has also been recently shown by Virchow and others, that starch is present in the tissues of the body, and to this form of degeneration the term amyloid has been applied.

Diseased Secretions. 1. *Urine.*—This fluid contains various salts and histological elements which can only be detected by the microscope. Many of these are very characteristic of diseased conditions. [BRIGHT'S DISEASE, *S.* 2; MICROSCOPE, USES OF, *S.* 2.]

2. *Saliva.*—This secretion may present various alterations dependent on disease of the mucous membrane of the mouth and tongue. The epithelial scales naturally found in the saliva are altered in their character. They become opaque and granular. Sometimes confervoid growths are attached to them. In thrush the ulcers are now known to be covered with a fungus called *oidium albicans*, which seems to be the cause of this disease. The filaments of this fungus may frequently be detected in the saliva and the discharge from the mouth. The characteristic appearances of the fur on the tongue, under the microscope, is yet a desideratum in the practice of medicine.

3. *Mucus.*—This secretion is found on all healthy mucous membranes. When the membranes become diseased, this secretion is changed in its characters, and various conditions indicative of the nature of the change may be observed under the microscope. In inflammatory affections, the so called mucus-corpuscles, which resemble pus-corpuscles, are increased in number. The mucus contains also epithelial cells, which may be changed in their character from morbid conditions. These corpuscles and cells are contained in a viscous fluid, which contain a very readily coagulable albumen. This substance is seen to be diminished in quantity in morbid conditions of the mucous membrane.

4. *Milk.*—Diseased conditions of the milk can be determined by the microscope. In a healthy state it contains oil-globules, which are from the $\frac{1}{5000}$th to the $\frac{1}{2000}$th of an inch in diameter. These globules are enclosed in a membranous envelope. In healthy milk they are of a perfectly globular form, and roll freely over each other. In unhealthy milk the globules are of various sizes, and when acid they run together in masses. For a few days after the birth of the young, these globules are mixed with others of a larger size and more variable. They give the milk a yellow colour, and it is then called *colostrum*. They should disappear in the human milk the fifth or sixth day after parturition. If they remain longer, the milk must be considered unhealthy. Milk can be obtained from the mammæ during the early months of pregnancy, and its peculiar characteristics are easily distinguished by the microscope. Under such circumstances it is a most important indication of pregnancy.

WORMS.—The researches of Siebold, Küchemeister, Leuckart, Rainey, and others have recently thrown much light on the history and development of these parasites of the human body. The following is a classification of the various forms of worms found inhabiting the human body as given in Dr. Lankester's translation of Küchenmeister's work 'on the Animal and Vegetable Parasites attacking the Human Body.'

Division ANNULOSA.
Sub-division ANNULOIDA.
Order SCOLECIDÆ.
Section PLATYELMIA—Flat worms.
Family TÆNIADÆ=CESTODÆ.
A. Mature States:
Bothriocephalus latus—Broad Tape-worm.
Tænia solium—Common Tape-worm.
Tænia mediocanellata.
Tænia nana.
Tænia ? (Cape of Good Hope).
B. Immature States:
Cysticercus cellulosæ.
Cysticercus tenuicollis.
Echinococcus scolicipariens (*E. veterinorum*).
Echinococcus altricipariens (*E. hominis*).
Acephalocysts.
Family TREMATODA.
Distoma hepaticum—Fluke.
Distoma lanceolatum.
Distoma Buskii—Busk's Fluke.
Distoma heterophyes.
Distoma hæmatobium.
Distoma ophthalmobium.
Monostoma lentis.
Posystoma pinguicola.
Section NEMATELMIA—Round Worms.
Family GORDIACEÆ.
Filaria Medinensis—Guinea-worm.
Filaria oculi humani.
Family NEMATOIDEA.
Ascaris lumbricoides—Round Worm.
Oxyuris vermicularis—Thread Worm.
Trichocephalus dispar (Mature Stage).
Trichina spiralis (Immature Stage).
Strongylus gigas.
Strongylus longivaginatus (*Filaria bronchialis*).
Spiroptera hominis.
Ancylostomum duodenale.
Dactylius aculeatus.

The most important point made out in the history of these creatures is the fact, that during their development they pass from one animal body to another, and that the whole group of what are Cystic worms are but immature stages of the more perfectly formed worms. The history of the common tape-worm (*Tænia solium*) of the human body may be taken as a type of the whole. The eggs of this worm are contained in the segments of the mature worm, which are called *proglottides.* These eggs, in order to their future growth and development, must be swallowed and submitted to a process of digestion by some other animal before they reach maturity. This process may occur in many species of animals, but that in which it takes place most commonly is the pig. In the intestines of the pig the egg becomes an embryo, which is supplied with six hooks, by means of which it penetrates the tissues of the intestines, and entering the blood-vessels is carried by the current of the blood to the various organs of the body. This embryo having reached a place of rest, is developed into the cystic worm known by the name of *Cysticercus cellulosæ*. This form of the worm is well known, and produces in the flesh of the pig that appearance which is called in the markets "measly pork." Here it remains and dies, unless the flesh containing it is eaten by some other animal. When eaten by man and submitted to the process of digestion, the cystic worm is further developed. In the cyst there is a head called the "Scolex head," supplied with suckers and hooks, adapted to laying hold of the mucous membrane of the intestines, which, when effected, results in the growth of those segments which are known as the characteristic of the tape-worm. The scolex head is now the head of the tape-worm, and the segments are the proglottides which continue to increase, and eventually each segment is developed into a sexual being, containing both the male and female organs of generation, and the eggs are produced. These facts have been well established by experiments made by both Von Siebold and Küchemeister. Man is also subject to the attack of cystic worms, *Echinococcus*, &c., which attain their mature development in other animals. The tape-worms of the lower animals have the same origin, and their history has now been traced in a large number of animals. Other forms of worms have been found to undergo similar changes in their larval conditions. The common fluke, which is sometimes found in the liver of sheep, commences its existence as a *Cercaria*, and being swallowed by fresh water mollusca undergoes a further development before it enters the stomach of the sheep, and becomes developed into the fluke in its liver. The *Trichina spiralis*, a little worm found in the muscles of man, is now believed to be the early stage of the growth of the *Tricocephalus dispar*, a very frequent inhabitant of the intestines of man. The mature and immature forms of these worms found in man and some of the lower animals, are exhibited in the following diagram:—

List of Mature and Immature Worms and their Habitats.

Immature State.	Habitat.	Mature state.	Habitat.
		TENIADÆ.	
Cysticercus cellulosæ	Pig	*Tænia solium*	Man
C. fasciolaris	Rat, mouse	*T. crassicollis*	Cat
C. pisiformis	Rabbit	*T. serrata vera*	Dog
C. tenuicollis	Sheep, horse, monkey, man	*T. ex cysticerco tenuicolli*	Dog
C. innominatus Hyperdæi	Mole, field-mouse	*T. tenuicollis*	Marten, weasel
C. longicollis Hyperdæi	——	*T. crassiceps*	Dog
Cœnurus cerebralis	Sheep, ox	*T. cœnurus*	Dog
Echinococcus veterinorum (*E. scoliciparions* Küch.)	Man, ruminantia	*T. echinococcus sc.*	Dog
E. hominis (*E. altriciparions* Küch.)	Man, domestic an.	*T. echinococcus alt.*	
		TREMATODA.	
Cercaria	Fresh water mussel	*Distoma hepaticum*	Sheep, man
		NEMATOIDEA.	
Trichina spiralis	Man	*Trichocephalus dispar*	Man

The practical conclusion to which these researches lead, is the necessity of preventing the introduction into the system of the eggs and immature forms of these worms. The eggs of the various forms of tape-worms which produce the cystic states of the worm, are introduced into the stomach by water, salads, and all kinds of uncleanly food. The cystic worms themselves are introduced through the medium of raw or partially cooked flesh, especially pork, which should be carefully avoided.

PLATA, LA, STATES OF. The historical notice of the *Argentine Confederation* has been brought down to 1836 [PLATA, LA], when Rosas had been created governor, or captain-general, with almost dictatorial power. By this arrangement the provincial government of Buenos Ayres was invested with extraordinary powers, and temporarily charged with the transaction of all matters appertaining to the common interests of the confederation, and the carrying out of its business with foreign nations. Rosas had previously served as governor and captain-general of Buenos Ayres for the usual term of three years, and had obtained unrivalled influence in that province, chiefly through his military powers, as displayed against the Indians. His decision and energy secured for a while internal peace, and the provinces began to recover from the effects of the long prevalent anarchy. But cruelty and despotism marked his sway at home, and his ambition, which continually prompted him to endeavour to extend his power over the whole country watered by the Plata and the Paraná, led him into disputes with foreign powers: and these ultimately brought about his downfall. His commercial policy had for its object to secure to Buenos Ayres the monopoly of the trade of the Plata, his political policy to obtain a like territorial superiority. On the death of Francia, dictator of Paraguay, he refused to acknowledge the independence of that power, insisting that it should join the Argentine Confederation, at the same time he refused to allow the navigation of the Paraná by vessels bound to Paraguay. Lopez, the new dictator of Paraguay, therefore entered into alliance with the Banda Oriental, now called Uruguay, with which Rosas was at war. These powers applied for assistance to Brazil. The war was prolonged until the whole country on both sides of the Plata and the Paraná was in a state of confusion. On the earnest appeal of the merchants and others interested, Great Britain volunteered her mediation, but it was rejected by Rosas who marched his troops within a few miles of Monte Video, which his fleet at the same time blockaded. The emperor of Brazil now interfered, and sent a special mission to request the interposition of the courts of London and Paris. The British and French governments in February, 1845, decided on sending plenipotentiaries to the Plata to offer their mediation, and to announce their intention to enforce a cessation of hostilities if needful, by an armed intervention. The offer was rejected by Rosas, but readily accepted by his opponents. The united fleet of England and France at once commenced operations by seizing the fleet of Rosas which was blockading Monte Video, and the island of Martin Garcia which commands the entrances of the Paraná and the Uruguay. The harbour of Buenos Ayres was at the same time declared under blockade, and the combined fleet prepared to open the Paraná and convoy as far as Corrientes any merchant vessels that might desire to ascend that river. Rosas on his part made hasty preparations to intercept the fleet by planting batteries with parks of heavy artillery at Point Obligado; and placing three strong chains across the river, supported by 24 vessels and 10 fire-ships. On the 19th of November, 1845, the combined fleet consisting of eight sailing and three steam vessels forced the passage with trifling loss to itself, but entirely destroying the batteries, and considerably injuring the army of Rosas. On the return of the fleet, with a convoy of 110 vessels, it was encountered at San Lorenzo by a very powerful battery which Rosas had erected in an admirable position, in the full expectation of destroying a large number of the merchant vessels, and of crippling the naval force. The battery commanded the river, and was difficult of attack by the steamers, but it was speedily silenced by a rocket-brigade, which had been the previous night secretly landed on a small island in the river. The combined fleet escaped with trifling loss, the rocket-brigade lost not a man; but four of the merchant vessels which, through unskilful pilotage, ran ashore, were burnt to prevent them falling into the hands of Rosas. The loss to the Argentine army was very great. Again plenipotentiaries were sent out by the combined powers, but Rosas refused to yield; and England withdrew from the blockade in July, 1848. It was however continued by France until January, 1849. On the final withdrawal of the two great powers in 1850, Brazil determined on active interference. The power of Rosas, essentially despotic, and devoted to the maintenance of the supremacy of Buenos Ayres, had moreover become intolerable to the provinces which desired a federal and equal union. Accordingly, towards the close of 1850, Brazil, Uruguay, and Paraguay entered into a treaty, to which Corrientes and Entre Rios, as represented by General Urquiza, became parties, by which they bound themselves to continue hostilities until they had effected the deposition of Rosas, "whose power and tyranny" they declared to be "incompatible with the peace and happiness of this part of the world." Early in the spring of 1851 a Brazilian fleet blockaded Buenos Ayres, and soon after an Argentine force commanded by Urquiza crossed the Uruguay. The struggle was now virtually terminated. General Oribe who commanded the army of Rosas in Monte Video, made a show of resistance, but it was merely to gain time in order to complete his arrangements with Urquiza, and he soon after capitulated. His soldiers for the most part joined the army of Urquiza, who at the head of a force amounting it is said to 70,000 men, crossed into Buenos Ayres. A general engagement was fought on the plains of Moron, February, 2, 1851, when the army of Rosas was entirely defeated. Rosas, who had commanded in person, succeeded in escaping from the field; and, in the dress of a peasant, he reached in safety the house of the British minister at Buenos Ayres. From thence, with his daughter, he proceeded on board H. M.'s steamer Locust, and on the 10th of February sailed in the Conflict steamer for England.

But the fall of the tyrant did not bring peace to the unhappy country. Urquiza, by the governors of the provinces assembled at San Nicolas, was invested with the chief power, and appointed Provisional Director of the Argentine Confederation. The Chamber of Representatives of Buenos Ayres, however, declared against him, and protested against the proceedings of the convention, on the ground of the superior privileges of Buenos Ayres being menaced. Urquiza dissolved the Chamber, and insurrection broke out. Civil war, with all its aggravated evils, continued during 1853; but on the 20th of December, 1854, the separation of Buenos Ayres from the other states of the Argentine Confederation was settled by treaty; and it has since been acknowledged as an independent state by the principal governments of America and Europe. The republic of Buenos Ayres is briefly described under PLATA, LA, as one of the provinces of the Argentine Confederation. The capital city is described under BUENOS AYRES. *San Nicolas de los Arroyos*, the city next in size and importance, stands on high ground on the right bank of the Paraná, about 190 miles N.W. from Buenos Ayres, and has a population of about 8000. The other towns are comparatively small.

PLATANACEÆ, *Planes*, a natural order of Exogenous Plants. The species are amentiferous trees or shrubs, with alternate deciduous palmate or toothed stipulate leaves, and unisexual naked flowers in globose catkins. The barren flowers with stamens single, mixed with scales. Fertile flowers with ovary 1-celled, style thick and subulate. Ovules 1-2, orthotropal; suspended. Nuts clavate, with a persistent style. Seeds usually solitary and albuminous; radicle inferior. They are natives of the Levant and North America chiefly. They are fine trees, but their timber is not durable.

There is but one genus (*Platanus*) in the order and six species. [PLANE.] The family resembles *Artocarpaceæ* and *Altingiaceæ*.

PLATYSTERNON. [TORTOISES.]

PLEADING, AT LAW and IN EQUITY. Although modern Statutes have made several alterations in the procedure of the Superior Courts both of Law and Equity, the outline of the system of pleading in use in these Courts, which is given under PLEADING, vol. xviii., p. 245, *et seq.*, is still substantially accurate. The more important changes effected in the procedure of the Common Law Courts have been mentioned under ABATEMENT [*S.* 2], INJUNCTION [*S.* 2], and MANDAMUS [*S.* 2]; those in the Court of Chancery under EQUITY [*S.* 2]. It may be added here that the system of pleading devised for the new Courts of Probate and Divorce, is of the nature of that now in use in the Courts of Common Law.

PLOCARIA, a genus of Plants belonging to the alliance *Algales*, the order *Ceramiaceæ*, and the sub-order *Sphærococceæ*. One of the species, *P. Helminthocorton*, is called Corsican Moss, and has a considerable reputation as a vermifuge. It is a native of the Mediterranean.

PLUMBO-CALCITE. [MINERALOGY, *S.* 1.]

PLUNKETT, WILLIAM CONYNGHAM, FIRST LORD PLUNKETT, of Newton, County Cork, was the second son of the Rev. Thomas Plunkett, a Presbyterian minister at Enniskillen, in which town his son William was born in July 1764. Having some scruples as to the received doctrine of the Trinity, the elder Plunkett removed to Dublin, where he became minister of the Strand-street chapel. His eldest son practised for many years as a physician in that metropolis, and bequeathed to his brother a large library and a considerable fortune. William was still a boy when his father died, leaving the care of his family to the piety and zeal of his congregation. His dying request was not in vain, and the sons received by their assistance a good education. William was sent to Trinity College, Dublin, where he obtained a scholarship and a degree, and where he was the friend and contemporary of the late Dr. Magee, archbishop of Dublin. Mr. Plunkett was called to the bar in 1787. He had already gained some reputation by his speeches delivered in the debating club of the university, then known as the Historical Society; and the late Earl of Charlemont soon afterwards introduced him into the Irish Parliament, as member for the borough from which he derived his title.

Mr. Plunkett commenced his public career by bold and sarcastic oratory, reserving himself almost entirely for great occasions. Hence his name is but little associated with the every day business of legislation; the fame which he acquired in the Irish House of Commons is principally connected with the zeal with which he opposed the legislative Union in 1800. The vehement oratory with which he denounced the ministry on this occasion, proved the means of increasing his professional engagements in the Irish courts of law. His income now rose rapidly, and with its proceeds he repaid, with liberal interest, the contributions of his father's congregation which had been the means of enabling him to get a start in life. About the same time he married Catharine, only daughter of John M'Causland, Esq., who had represented the county of Donegal in four successive parliaments. When the rebellion of 1798 broke out, Mr. Plunkett gave the aid of his professional talents to its victims, and indeed was at one time so intimate with Robert Emmett and his associates, that he was more than once publicly accused of being concerned in their unhappy proceedings. The accusation however was shown to be unfounded.

In 1803 he was appointed solicitor-general for Ireland, from which post he was promoted in 1805 to that of attorney-general. In the following year the Whigs, with Lord Grenville at their head, came into office, and he determined to throw in his lot with them. Accordingly he retained the attorney-generalship under their administration, whose well-known views offered an opportunity for the Catholic Association to press upon their notice the importance of granting Roman Catholic emancipation. Of this subject, Mr. Plunkett was always an able and energetic advocate. The death of Mr. Fox having broken up the Grenville administration in 1807, Mr. Plunkett retired, and applied himself to the pursuit of chancery practice with such success, that for several years he was engaged as leading counsel in almost every important Irish chancery suit, and rapidly accumulated a large fortune.

Mr. Plunkett first entered the British House of Commons in 1807 as member for Midhurst. In 1812 he was elected to represent the University of Dublin, which at that time returned only a single member; and he was re-elected in 1818. Of his first speech in the House of Commons, which at once secured for him a high reputation, Mr. Canning affirmed, that it brought back the days of Burke and Pitt, of Fox and Sheridan. In 1822 a number of ministerial changes took place on the death of the Marquis of Londonderry, and among others Mr. Plunkett was re-appointed attorney-general for Ireland, the late Marquis of Wellesley being lord-lieutenant, and in that capacity he was engaged to prosecute on behalf of the crown a large number of the Dublin Orangemen, and of the insurgents in the south of Ireland. Early in 1827 Mr. Canning proposed to appoint Mr. Plunkett master of the rolls in England, but the intention was ultimately abandoned. In the following June however he was elevated to the post of lord chief-justice of the common pleas in Ireland, and created a peer of the United Kingdom. He held the chief-justiceship for three years, and resigned it at the downfall of the Wellington administration. His judicial career was not marked by any great brilliancy or success, which indeed there were no remarkable or stirring events to call forth. But it was otherwise in the English House of Lords, where he sat by the Duke of Wellington, at his Grace's especial request, to advise with him at every step of the Roman Catholic Emancipation Bill, of which he 'took charge' in its passage through the Upper House.

With the passing of this measure the political career of Lord Plunkett may be said to have closed, though he was appointed Lord Chancellor of Ireland by the ministry of Earl Grey at the close of 1830. This post he occupied for eleven years, with the brief interval of a few months in 1834-35, during which the seals were held by Sir Edward Sugden (now Lord St. Leonards). He ultimately only resigned the chancellorship a few months before the removal of the Liberal administration of Lord Melbourne from office in 1841, when he was induced to resign in order to make way for Lord Campbell. During his later years Lord Plunkett had almost wholly retired from political life, and indeed for several years before his death he had not come over to England to take his seat in the House of Lords, but spent his declining days in the enjoyment of the society of his family and private friends, at his country villa near Bray, where he died on the 4th of January 1854. His eldest son, now second Lord Plunkett, is also Bishop of Tuam.

On the whole, nature was bountiful to Lord Plunkett, and accident favoured him at almost every step of his long and brilliant career. He was sixty-six years of age when he took his seat in the Irish Court of Chancery, and it could scarcely be expected that as chancellor he could add much to his previous fame. His reputation shot upwards from a narrow ground-work. His speeches were at once few and famous;

they excited the unqualified applause of his contemporaries, and his name is still foremost among the orators of the 19th century. But the great principles of legislation, which men seek and find in the speeches of Pitt and Burke, are seldom met with in the startling orations of Lord Plunkett. He could hardly be called a statesman—scarcely even a sound or experienced practical politician; and there were abler judges and more learned men than himself among his brethren on the Irish bench, though probably there were none of equal powers of native eloquence.

POE, EDGAR ALLAN, was born at Baltimore, in the United States, in January 1811. He was descended of a good family, but his father and mother, who had become strolling players, having died when he was quite a child, he was adopted by a Mr. John Allan, a wealthy merchant, who had known his father, and having no children of his own, treated him as his son. In 1816 Mr. and Mrs. Allan brought him to England, where he was put to school at Stoke Newington. He returned to America in 1822, was first placed in an academy at Richmond, in Virginia, and thence sent to the university of Charlottesville in the same state. At all these places of instruction his progress was rapid, and he held a high rank as a scholar, but his extravagance was so great, and his conduct so licentious, that he was expelled from the university. He returned home, and on Mr. Allan refusing to honour some of his drafts for gambling debts incurred at the university, he wrote a satirical and abusive letter to his benefactor, left the house, and set off to Greece to help to free that land from the tyranny of the Turks. He never reached Greece, but after wandering about Europe for nearly a year, he arrived at St. Petersburg, fell into the hands of the police for a drunken riot, was rescued by the intervention of the minister of the United States, and by him sent back to America. His old patron welcomed him home, and as he now expressed a desire to adopt the military profession, he procured him the appointment of a cadet in the Military Academy at Westpoint in New York. Here, after a short period of assiduous application, his old habits returned, and within a twelvemonth he was cashiered for insubordination and drunkenness. He returned to Mr. Allan at Richmond, who again received him with kindness, but that gentleman having married a second wife, Poe satirised both him and his wife so severely that he was forced to quit that place of refuge, nor would Mr. Allan ever see him again or assist him any further. He had by this time published a small volume of poems, and from the favourable reception they had met with, he thought he might support himself by his pen. He failed, and enlisted as a private soldier. From this situation he was rescued by some military friends he had made at Westpoint, who procured his release. He again had recourse to his pen, and this time with more success. He became connected with various magazines and other periodical works, with some as contributor, and with others as editor; but his irregular habits constantly prevented the engagements being permanent. He followed this course at Baltimore, Virginia, Philadelphia, and New York, where he arrived in 1844. His undoubted talent unfailingly procured him employment, while his intemperate and immoral habits as necessarily occasioned his dismissal. In 1848 he gave a series of lectures in New York on the universe, which were afterwards embodied in a work entitled 'Eureka, a Prose Poem.' In the autumn of 1848 he joined a temperance society, but this could not save him. He went in 1849 to Virginia to deliver lectures, and on the 4th of October he set out on his return to New York. At Baltimore he met with some acquaintances, who invited him to drink; he forgot his pledge, became so utterly intoxicated that he was picked up in the street, carried to a hospital, and died the following day, October 7th, 1849. His works, as may be supposed from the previous sketch, consist wholly of short pieces. He wanted the steadiness and perseverance to produce anything worthy of his genius; but they exhibit in a remarkable degree the possession of faculties of a high order. In his tales there is magnificence of imagination and description; a remarkable display of analytical power, though wasted upon trivial subjects; a love and an acute observation of nature, and an admiration of the beautiful, which it is remarkable in such a man never descends into the sensuous; considerable humour, and a ghastly and mystical sublimity in some of his fictions that is deeply impressive. In his poetry he is tender and melodious, with great command of language: and in conversation he is described as having been highly eloquent, but irritable and sarcastic. There are few more striking instances of perverted talent, and personal advantages thrown away, than that of Edgar Poe. Two small volumes of tales and one of poetry, besides the 'Eureka' already mentioned, are all that remain of him.

POLAND. The Emperor of Russia, by a ukase, dated August 21, 1844, divided Poland into five governments, exclusive of the city of Warsaw, which are governed in the same manner as the other provinces of the empire, each having a military and a civil governor. The following table shows the area and population of the present divisions according to the official returns for the year 1851:—

Governments.	Old Provinces.	Square Miles.	Population in 1851.
Warsaw . .	Mazovia . . / Kalisz . . .	14,219	1,544,790
Radom . . .	Kielce, or Cracow / Sandomir . .	9,289	939,344

Plock . . .	. . . . .	6,411	548,413
Augustovo . .	. . . .	7,237	626,594
Warsaw City . .	. . . . .	—	164,115
Total . .	. . . .	49,090	4,851,639

POLAR COUNTRIES AND SEAS. The countries and seas which lie between the northern coasts of America and the North Pole are noticed in the article NORTH-WEST PASSAGE, *S.* 2; those which are situated on the other sides of the North Pole are described under their respective names. [GREENLAND; ICELAND; SPITZBERGEN; NOVA ZEMBLA; SIBERIA.] It only remains to notice certain conditions of the countries and seas which surround the North Pole. The discoveries which have been made in the seas surrounding the South Pole are narrated in the article SOUTH POLAR COUNTRIES.

The seas which surround the North and South Poles are named the Arctic Ocean or North Polar Sea, and the Antarctic Ocean, or South Polar Sea. The two oceans are bounded by two imaginary circles which surround the globe at about 66° 30′ N. lat. and 66° 30′ S. lat. At the Poles themselves there is only one day of six months, during which the sun never sets, and one night of six months, when the sun never rises. In the spaces comprised between the Polar Circles and the Poles the quantities of continuous day and continuous night vary according to the distances from the Poles. Thus, at the north point of Nova Zembla, 75° N. lat., there is uninterrupted light from May 1st to August 12th, and uninterrupted darkness from November 8th to February 9th. At the Arctic Circle the greatest length of continuous light is 24 hours at the summer solstice, or Midsummer's-Day, whilst, at the same time, at the Antarctic Circle, the sun is 24 hours below the horizon; and the reverse at the opposite seasons of the year. The general coldness of the Polar Regions arises from the sun's rays striking the earth obliquely, as at the equator the heat is produced by the sun's rays falling upon the earth vertically.

The two great continents of the Northern Hemisphere terminate towards the North Pole near 70° N. lat., which parallel may therefore be considered as the general boundary-line of the North Polar Sea. The lands comprised within this polar basin, besides the northern shores of Europe, Asia, and America, include the northern parts of Greenland and Nova Zembla, the islands of Spitzbergen, the Liakhov Islands, and the great mass of islands which lie opposite to the northern coasts of British America. The North Polar Sea has only one entrance from the Pacific Ocean, by Behring's Strait, the narrowest part of which, between East Cape and Prince of Wales Cape, is only about 18 miles across. From the Atlantic Ocean, besides the great entrance by the Spitzbergen Seas, it is now known that there are entrances by Smith's Sound from Baffin's Bay, and by the Wellington Channel from Barrow's Strait.

A large portion of the Arctic Ocean is constantly filled with extensive fields and moving masses of thick and impenetrable ice. This portion seems to extend round the Pole at variable distances from the shores of Siberia, Russian America, and British America. In an easterly direction it extends from the north point of Nova Zembla to the western side of Melville Island. Here the navigation westward up Barrow's Strait ceases, the 'pack-ice,' as it is called, presenting an impassable barrier. On entering the Arctic Ocean from the Pacific through Behring's Strait, the most daring and skilful navigators have not been able to penetrate much farther in a northern direction than 70° N. lat. Captain Cook, in his last voyage, after passing through Behring's Strait, sailed as far westward as North Cape, 180° W. long.; bnt here the masses of ice prevented any farther advance. If the navigator, after passing through Behring's Strait, turns eastward, he finds, in summer, between the American shores and the pack-ice, a narrow passage mnch encumbered with broken ice, and may thus with some difficulty reach the most north-eastern point of the American continent; or, having reached Baring Island, may turn northward and try to accomplish the North-West Passage by following either of the tracks of Captain M'Clure.

The great entrance to the Arctic Ocean by the Spitzbergen Seas is not attended with mnch difficulty. Ships sail every year from the shores of the Atlantic Ocean to Archangel, and must necessarily pass round North Cape, 71° 10′ N. lat.; other vessels proceed annually to fish for whales, which they never expect to take sonth of about 78° N. lat.; and others much smaller go every year from Hammerfest and other places to fish for walruses along the western shores of Spitzbergen. Barentz, the Dutch navigator, in 1594 and 1596, traced the western shores of Nova Zembla as far as North Cape, 75° N. lat.; and the Russian navigator Ziwolka, who in 1836 surveyed the island of Nova Zemhla, found no difficulty in tracing the western coast to Cape Nassau, and even the eastern coast to 61° E. long.; but impenetrable masses of ice prevented his advance farther to the east.

The greater or less severity of cold in the Arctic Seas seems to depend more on circumstances of locality than on the degrees of latitude. Thns, on the European side of the Polar Basin, the navigatiou, as has been shown, is open as far as 80° N. lat.; on the Asiatic side it is generally closed by masses of ice; on the American side the cold is very severe, and the navigation everywhere difficult and in many parts dangerous. At North Cape, iu Europe, 71° 10′ N. lat., the mean temperature of the year is 32° Fahr.; at Bear Island (Cherry Island), between North Cape and Spitzbergen, 70° 30′ N. lat., the mildness of the climate is extraordinary; bnt opposite the coasts of Siberia, farther to the east, the floating masses of ice render the navigation so dangerous that some portions of the coast-line have not been surveyed. This tract includes the most northern point of Siberia, Cape Severo (Severo Vostochinii Noss). In this part of the Polar Basin are the Liakehov Islands, the largest of which are named Kotelnoï Fadeifskoï, New Siberia, and Liakehov. They are situated between 73° and 76° N. lat. On these islands the snow does not entirely melt even in summer, and there is no vegetation whatever. Along these coasts of Siberia it has been ascertained that in winter the large body of the sea is free from ice at certain distances from the shore. North of New Siberia and Kotelnoï the distance is less than 20 miles. Farther east it approaches nearer to the coast. Near 165° E. long. it is about 170 miles distant; but between 175° and 180° E. long., opposite Cape Yacan, it is only about 4 miles distant. At Ustyansk, in Siberia, near the mouth of the river Yana, 70° 55′ N. lat., the mean temperature of the year is only 4° Fahr. At Wiuter Island, on the north-eastern coast of America, in 66° 11′ N. lat., 83° 30′ W. long., the mean annual temperature is not more than 7° Fahr., while on the south shore of Melville Island, about 74° N. lat., the mercury of the thermometer is frozen every winter during four or five months.

That there is a great sea comparatively unincumbered with ice in the vicinity of the North Pole, and perhaps flowing over it, seems to have been rendered probable by many facts and circumstances. Barentz, in 1594, remarked, "as soon as we made from the land [Nova Zembla] and put more iuto the sea, although it was much farther northward, presently we felt more warmth." Captain Parry, in his attempt to reach the North Pole in 1827, leaviug his ship, the Hecla, moored in a bay on the north-east coast of Spitzbergen, proceeded with his party over the ice, dragging the boats and sledges which had been constructed for the purpose. On July 27th they reached 82° 45′ N. lat., 19° 25′ E. loug., when, the season being far advanced, and finding that the ice over which they were travelling northward was itself drifting southward, they relinquished their attempt, and commenced their return-journey. On August 12th they reached Little Table Island, or rather a rock north of it, which Captain Parry named Ross's Islet, and which is the farthest land known in the northern hemisphere; it is in 80° 47′ 30″ N. lat., 20° 24′ E. long. Captain Parry and his party were absent from the Hecla 61 days, the distauce traversed being 654 miles. On July 15th, being then in 82° 17′ N. lat., it rained incessantly for 21 hours. On July 16th the temperature was 37½° Fahr. in the shade. "In the evening it was so warm in the sun, though the temperatnre in the shade was only 35°, that the tar was running out of the seams of the boats." They found the ice everywhere broken, but most so when they were farthest north. After the middle of July no ice entered the bay where the Hecla was moored, and for some weeks afterwards not a piece was seen in the vicinity.

In further confirmation of there being a great sea in the vicinity of the North Pole, it may be stated that Sir Edward Belcher saw an extensive sea with little ice north of the Wellington Channel, as did also Captain Penny north-west of the Victoria Channel: that Captain Inglefield saw a great sea north-east of Whale Sound, near the head of Baffin's Bay, and also north of Smith's Sound, which is an outlet into the Polar Basin from the head of Baffin's Bay. The same extensive open sea was seen by Dr. Kane from a position still further north of Smith's Sound than that which was attained by Captain Inglefield.

The difference of temperature between the north-western shores of Europe and the north-eastern shores of America seems to be owing to two main causes—the Gulf-Stream, and the drifting of the ice-masses from the shores of Siberia. The Gulf-Stream is a great warm current many miles in width, which flows in a north-eastern direction from the Gulf of Mexico across the Atlantic, and passing by the British Islands and along the coast of Norway, penetrates the Polar Sea as far as the northern shores of Spitzbergen and Nova Zembla. Here in the spring it meets the powerful current caused by the breaking-np of the ice in the great rivers of Siberia. As this vast body of water and broken ice advances towards the shores of Nova Zembla and Spitzbergen the Gulf-Stream opposes its farther progress south and gives it a direction westward, so that it passes by East Greenland and Iceland, and reaches the shores of America aud Newfoundland, where the masses of floating ice (sometimes miles in length and of great thickness) descend in the spring as low as 40° N. lat. On the coast of Norway, on the contrary, as far as 71° N. lat., not a piece of drift-ico is ever seen.

The countries which surround the North Pole generally afford an abundant supply of animal food, consisting of the walrus, the polar bear, the moose-deer, the rein-deer, the wolf, the polar hare, and the seal. The number of aquatic birds is very large, and various kinds of fish are in great abundance.

POLEVOY, NIKOLAY ALEXIEVICH, one of the few distinguished authors whom Siberia has yet produced, was born on the 22nd of June (old style) 1796, at Irkutsk. His father, who was descended from an adventurous family of merchants, settled for some generations at Kursk, where the names of Polevoy and Golikov are excessively common, had been left an orphan at the age of thirteen, and sent to Tobolsk in the employ of a relation of the name of Golikov. Most of the elder Polevoy's life was spent in commercial enterprises in Siberia, and at one time he had the prospect of making a fortune by establishing a new company for commerce with Russian America, but the nnion of the two old companies crushed the plan. In 1805 he set np a manufactory of earthenware at Irkutsk, and "he used," says his son, "to pronounce with enthusiasm the name of Wedgwood." In assisting in the business of this manufactory, and of a brandy distillery with which his father was also connected, the early years of Polevoy were passed. He never apparently received any schooling; he learned to read from an elder sister at six years old; at eight he used to read aloud to his mother novels, and to his father the Bible, and the 'Moscow News,' and at ten he assisted his father in the counting-house, and amused himself by composing a manuscript newspaper (in imitation of the 'Moscow News' ('Moskovskiya Viedomosti'), which he called the 'Asiatic News' ('Aziyatskiya Viedomosti'). The father was in the habit of boasting of his relation the historian Golikov, who had written a history of Peter the Great in thirty volumes, and the boy formed the singular project of writing additions to a work already so voluminous. He also tried his hand at composing plays, and produced a drama, 'The Marriage of the Tzar Alexis Mikhailovich,' and a tragedy, entitled 'Blanche of

Bourbon.' "At last," says Polevoy in the autobiography prefixed to his 'Ocherki Russkoy Litteraturui,' published in 1839, "I became my father's walking dictionary in geography and history, for my memory at that time was such as I have never met with in anybody else. To learn by heart a whole tragedy cost me nothing. In a word, if I must describe my mental progress up to the year 1811, it was this: I had read about a thousand volumes of all kinds and sorts, and remembered all that I read from the verses of Karamzin, and the articles in the 'Courier of Europe' (a Russian Magazine), to the Chronological Tables and the Bible, from which I could repeat whole chapters by heart. I was known in the town of Irkutsk as 'the wonderful boy,' with whom the governor himself used to converse, and the director of the grammar-school to dispute as with a learned man." In 1811 his father resolved to leave Siberia and establish himself in Moscow; the son, who was sent on before him, then on the first occasion of his quitting Irkutsk, passed through all Siberia, saw a play for the first time at the theatre of the great fair of Makariev, and on his arrival at Moscow spent much of his time at the theatre and the bookshops, wrote tragedies and romances, and was unwillingly recalled to business and the brandy distillery by the arrival of his father. This took place in June 1812, and both business and pleasure were soon at an end in the devoted city, where the conflagration was witnessed by father and son as fugitives from before the army of Napoleon I. For a few years afterwards Polevoy was almost in constant movement from St. Petersburg to Irkutsk, and from Irkutsk to Kursk, and his literary ardour, deadened by the reproaches of his father, who now wished him to become a 'man of business,' appears to have been all but extinguished. It suddenly revived when he was about eighteen, a clerk at Kursk; but the main cause of its renewal, according to his own account, was his discontent with his then situation and its limited prospects, and his conviction that in Russia there was no other way to consideration for a person in his position but through learning and literary success. Himself and his younger brother, Xenophont, began to study French and German in secret, devoting many hours of the night to their books; and the knowledge of foreign languages led him into a new world of reading. In 1817, when the Emperor Alexander paid a visit to Kursk, Polevoy sent to the 'Russian Courier' an article describing the event, and had the pleasure of seeing for the first time his name in print. Other contributions followed, and the name became known; on a visit to St. Petersburg he was introduced to Zhukovsky, Griboyedov, Grech, and Bulgarin; and in 1825 he commenced at Moscow the publication of a magazine entitled the 'Moscow Telegraph.'

For the twenty-one years that followed, Polevoy was in incessant literary activity. The 'Moscow Telegraph' soon made itself conspicuous by the vigour and spirit of its remarks on the literature of the day; the example was extensively followed, and the Russian literary historians date a new era in criticism from the articles of Polevoy. It was naturally supposed that the editor had little spare time at his disposal, but the public was surprised to hear in 1829 that he had completed a history of the Russian nation, in 12 vols., containing a continuous narrative from the earliest times to the reign of the Emperor Nicolas. The early volumes of this history were assailed without mercy by many who were astonished at the presumption of its author in measuring himself with Karamzin, and of the twelve volumes only six appeared in print, the last in 1833. Possibly its further progress may have been checked by the censorship, as the 'Moscow Telegraph' was thought too liberal in its tendencies, and suppressed by the Russian government. This was in or about 1835. Polevoy removed to St. Petersburg, and his activity, instead of slackening, became greater than ever. "In Moscow," says Nikitenko, in an article on his work in the 'Biblioteka dlya Chteniya' for 1846 (vol. lxxvi.), "Polevoy was a journalist, an historian, a romance-writer. In St. Petersburg he was both an editor and a contributor to several journals; he composed romances, tales, essays, translations from Shakspere, and such a multitude of dramas, tragedies, comedies, vaudevilles, national farces, and so on, that criticism gave up the attempt to follow him. We do not know what to be most astonished at—the number and bulk of his productions, the variety of their character, or the rapidity with which he threw them off." The natural result of this rapidity was, that the name of Polevoy, which at one time promised to be one of the brightest in the Russian literary horizon, lost much of its lustre. For the last ten years of his life his reputation sunk instead of rising. He died at St. Petersburg, on the 22nd of February 1846 (o. s.), after three weeks of nervous fever, and it was declared by his medical attendants that his constitution was completely worn out by his incessant literary labours. He died in poor circumstances, and left a large family.

The most interesting work of Polevoy is perhaps his 'Ocherki Russkoy Litteraturni,' or 'Sketches of Russian Literature,' 2 vols. 8vo, St. Petersburg, 1839. It consists of reprints of select critical articles which had appeared in the 'Telegraph' and elsewhere, on Devzhavin, Karamzin, Pushkin, and other of the most prominent names in Russian literature. The collection entitled 'Dramatic Works and Translations of N. A. Polevoy' ('Dramaticheskie Sochineniya i Perevodui'), 4 vols., St. Petersburg, 1842-43, comprises only the more popular of his productions, several of which enjoyed a great success, in particular the 'Grandfather of the Russian Fleet' ('Diedushka Russkago Flota'), founded on the history of the old boat which bears that name, which Peter the Great took as the model for his ship-building. The author's favourite, as he tells us himself, was 'Parasha Siberiachka' ('Parasha the Siberian Girl'), founded on the same historical anecdote which supplied Madame Cottin with the ground-work of 'Elizabeth, or the Exiles of Siberia.' In another play, 'Soldatskoe Serdtse' ('A Soldier's Heart'), the hero is his still-living friend Bulgarin, on a real incident in whose life it is founded. Polevoy's translation of 'Hamlet,' which was produced at Moscow in January 1837, is unusually close to Shakspere; not even the scene of the gravediggers is omitted, and the dialogue passes from blank verse to prose, in imitation of the original, but the versification seems to be far from successful. His 'Life of Suvorov,' or Suwarrow, is a very popular book in Russia. His 'Life of Peter the Great' (4 vols., 1843), is the best biography of that wonderful man the Russians yet possess, and superior beyond all comparison to the tedious compilation of the author's kinsman Golikov. His 'Life of Napoleon' (5 vols.) was only brought by himself to a point a little beyond the conflagration of Moscow, and was finished after his death by his brother Xenophont. His 'Stolietie Rossii' ('Century of Russia'), or an historical picture of Russia from 1745 to 1845 (2 vols., 1845), is perhaps the least satisfactory of his historical works, but it contains passages of interest to a European reader.

Though the 'Moscow Telegraph' was suppressed in Polevoy's hands, and its author is spoken of by Hertzen as having the reputation of a decided liberal, his patriotism as a Russian is one of the qualities which most forcibly strike the attention of a foreigner. "Russia," he exclaims at the conclusion of this work, "is not a shapeless mass like the Roman empire, not violently put together like the dominions of Napoleon, not scattered over the whole world like the British sovereignty, the three examples of vast empires composed of different and various parts, brought together in one mass. . . . . Russia like the ocean dashes on the shores that surround it, and what its waves have covered becomes its incontestable dominion—no human force shall tear from it its subject provinces." "Assuming the title of Emperor in place of that of Tzar, moving the capital from Moscow to St. Petersburg, shaving beards and shortening caftans, altering manners, customs, and laws, it was after all from the original elements of the Russian empire, from the Russian mind and the Russian soil, that Peter the Great reconstructed Russia. He still remained a Russian sovereign, and his subject, though fraternising with the German, remained a Russian man. With his decided tendencies towards western Europe, it was impossible that something superfluous should not find admission, that traces of it should not remain till even now, but they are perishing and will perish, as the Gallicisms die out of our Russian tongue." . . . . "And sixty millions of a nation like this, fastened together by one power and inspired with faith in that power, are directed by a single will, and acknowledge that will as sacred. What will not these sixty millions do? The future belongs to us. Whence otherwise comes the fear with which we inspire Europe and the West, the fear from which it strives to reassure itself by calumnies against us. This fear takes its rise from a consciousness which is not the consciousness of strength, from a feeling different from that of hope in the future, on which we Russians look with such boldness and such faith."

POLICE. The establishment of a police force all over England has at last been made compulsory by the Statute

19 and 20 Vict. c. 69; which subjects the whole force to the inspection, and, to some extent, control of the Secretary of State. One fourth of the charge for the pay and clothing of the police of any county or borough must be paid by the Treasury, when the force has been certified to have been maintained for the previous year in a state of efficiency in point of numbers and description. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. i. p. 352.)

POLISHING SLATE. [MINERALOGY, *S.* 1.]

POLPERRO. [CORNWALL.]

POLYERGUS, a genus of *Formicidæ*, separated from *Formica* by Latreille. The type of the genus is *F. rufescens*, the Amazon Ant. The species are destitute of stings, and have the antennæ near the mouth and the mandibles narrow, curved, or very much hooked. The habits of the Amazon Ant, *P. rufescens*, are very remarkable. The neuters of this species unite with those of *Formica sanguinea* in making war upon the neuters of other species of *Formicidæ*, especially *F. cunicularia* and *F. fusca*. The result of the conquest is the making slaves of the latter, who are always found doing the hard work of the colonies of their enslavers. [ANT.]

POLYPTERUS, a genus of Fishes belonging to the family *Clupeidæ*. The sides of the upper jaw are immoveable; the head is covered with sharpened bony plates; the body with strong scales; it has one gill ray; a number of separate fins on the back; the teeth like a rasp, with long ones in front; the stomach large; a double air-bladder, with large lobes, the left one opening freely into the gullet. There are two species; one found in the Nile, the other in the river of Senegal. These fish are interesting as forming the only living representatives of a large family now extinct. They belong to the large division of extinct fish called Sauroid, on account of their resemblance to the Lizard tribes.

POLYZOA, frequently termed *Bryozoa*, are animals belonging to the Molluscous Sub-Kingdom, closely allied in some respects with the *Tunicata*, and especially with the Compound Ascidians, whilst in others they approach the *Brachiopoda*.

The analogies presented in their structure with that in other Molluscous groups having been pointed out in the article MOLLUSCA, *S.* 2, it will be needless here further to refer to them. The present article, after giving a brief view of the more important structural peculiarities of the class, will be devoted more especially to their mode of classification; but since the term *Polyzoa*, here employed, has by no means obtained universal adoption, it appears requisite to say a few words explanatory of the reasons which have induced us to prefer that term to the name *Bryozoa*, more usually employed by many British and by most Continental naturalists.

Section I. Historical.

Formerly confounded with the Sertularian and other phytoid *Zoophytes*, or *Radiata* [POLYPIFERA], it is only within the last thirty years that the *Polyzoa* have been admitted to their proper place in the animal kingdom, having been advanced in fact from one sub-kingdom to another. Their advance from the *Radiata* to the *Mollusca* may be said to date from the researches of Dr. Grant, contained in his 'Observations on the Structure and Nature of Flustræ,' in 1827; and of Milne-Edwards, in conjunction with M. Audouin, given in their 'Résumé des Recherches sur les Animaux sans Vertèbres faites aux îles Chaussey,' in 1828. To the former of these observers we are indebted for the first intimation of several important facts in the anatomy of these creatures—among others, of the existence of cilia on the tentacles, and the curvature of the intestinal canal, with other particulars of less importance. He failed, however, to notice the existence of a second or anal orifice to the intestinal canal; a fact of the highest importance, as indicating in that respect their close approximation to the *Ascidiæ*, or tunicate molluscs. This opening was discovered by Milne-Edwards and Audouin, and its importance was by them duly appreciated. In other respects their observations agreed with those of Dr. Grant. The existence of this anal orifice was regarded by its discoverers as sufficient to justify a complete change in the ideas then generally entertained with respect to the natural affinities of these animals with the rest of the *Zoophytes*. They proposed to distribute the animals belonging to the class of *Polypi*, as then received, into four principal groups, which are in fact pretty nearly identical with those in which they are at present most generally placed. The fourth of these families contained the *Flustræ* and other Polypes whose digestive canal opened on the exterior by two distinct openings, and whose organisation approached that of the Compound Ascidians.

The latter class, though thus distinguished from its apparent allies, received no name from the eminent naturalists to whom its foundation was due; and of the names subsequently applied to it, it remains simply to determine which is entitled to the priority. The appellations proposed for this class that have received any acceptation at all are three—*Polyzoa*, *Bryozoa*, and *Ciliobrachiata*. The first of these terms (as a singular noun) was used by Mr. J. V. Thompson in a Memoir, constituting the fifth part or number of his 'Zoological Researches,' and applied by him "to a distinct class of Polypes hitherto in great measure confounded with the *Hydroida*." This paper was published in December, and probably on the first of December, 1830. The appellation of *Bryozoa* was given by Professor Ehrenberg to those Polypes in which two openings existed to the digestive canal, and which he thus distinguished from a second class, termed by him the *Anthozoa*, in which but one orifice was presented. His paper on the 'Corals of the Red Sea,' in which this subdivision of the Polypes was first proposed, was read, or rather was in part read, before the Berlin Academy, on the 3rd of March, 1831. It was not completed, however, till December, 1833, nor published until February, 1834; and this date, for reasons it is needless here to refer to, should most probably be regarded as the true date of its publication. The part of the same writer's 'Symbolæ Physicæ,' in which the term is used, was not published till June, 1831. Consequently, the earliest date which can, by any latitude of admission, be given to the first publication of the term *Bryozoa*, is March, 1831, or at least three months after that of Mr. J. V. Thompson's 'Researches,' in which that of *Polyzoa* is proposed. In a very valuable paper published in the 'Philosophical Transactions' for 1837, Dr. A. Farre proposes to employ the term *Ciliobrachiata* for this class of Polypes, from the circumstance that their tentacles are ciliated. But this term, though appropriate and good, has since been but rarely employed, and is obviously without any claim to priority.

Section II. Structure and Functions.

The main points in the anatomy and structural relations of the *Polyzoa* will be found under the article MOLLUSCA, *S.* 2; but in order to render the account of their classification (which is properly the subject of the present article) more intelligible, it will be necessary briefly to detail the structural, and with them some of the physiological conditions presented in the soft and hard parts of the animals.

The *Polyzoa* may be defined as Compound Molluscous Animals, in which the nervous system consists of a single ganglion, situated between the mouth and the anus, having a distinct mouth surrounded more or less completely by a row of ciliated tentacles; usually hermaphrodite, and propagated by buds or ova; in the mature state mostly fixed, though some possess the power of locomotion.

Though differing widely in external appearance, the animal itself is constructed upon a very uniform type throughout all the subdivisions of the class, and for this reason, the anatomy of one species or order will, with trifling exceptions, apply to all. The following account of their structure is, in great measure, taken from that given by Professor Allman in his 'Report on the Freshwater Polyzoa,' published in the 'Proceedings of the British Association' for 1850; and, with the exception of the word 'polyzoary,' or 'polyzoarium,' which is here used to express the compound growth formed by the associated animals, instead of 'cœnœcium,' proposed by that naturalist, the terms used by him have been adopted—

1. Polypide, to signify the soft or retractile portion of the *Polyzoon*. 2. Ectocyst and Endocyst, to express the two distinct tunics of which the cells of the polyzoary are formed; the former being applied to the external and the latter to the internal tunic. The part surrounding the mouth, upon which the tentacles are placed, is termed, 3, the Lophophore; and 4, the Perigastric Space, is the space included between the walls of the endocyst and the alimentary canal.

But besides these terms, which apply more particularly to the polypide itself, several others are required in the description of the polyzoary. These are—

Cell, the hard portion of the external tunic, into which in most cases the polypide is capable of being retracted by the action of certain muscles. The parts of the cell are—1, the

Mouth, or that opening, as it may be termed, through which the polypide makes its exit and its entrance. The borders of this opening are sometimes furnished with Oral Spines, and it is sometimes closed when the creature has retreated into the cell, by a Crescentic Lip, usually having a cartilaginous border, and closed by special muscles. (*Figs.* 5 and 5*a*.) In many cases the wall of the cell is of equal thickness and similar structure throughout, but in the Cheilostomatous sub-order the front of the cell, or that side upon which the mouth opens and the animal comes out, very often differs in structure from the rest. That is to say, a greater or less extent of the front may remain wholly or in great measure membranaceous, as in the genus *Membranipora* (*fig.* 14); or be filled in by a sculptured or perforated calcareous expansion, as in *Catenicella* (*figs.* 1, 2), *Lepralia* (*fig.* 15), and many others. The space thus defined when left membranaceous (as it appears in most if not all cases to be at an early period in the formation of the cell), is termed the Aperture. The borders of the aperture are sometimes furnished with Marginal Spines. In some instances, as in *Caberea* and *Scrupocellaria* (sp.), the aperture is protected in front by a curious outgrowth from near the margin, which is termed a Pedunculate Operculum. The back of the cell is that part, of course, which is opposite to the front; the mouth is situated at or near the upper part of the cell, and is either terminal or subterminal. Other parts, which may be regarded as appendages to the cells, but which are not universally present, are certain organs, either of offence, defence, or prehension, termed Avicularia and Vibracula; the former constituting a sort of pincers, and the other consisting of a long, slender, moveable seta. However diverse in appearance, these two kinds of organs are all constructed upon the same general type; that is to say, the organ consists of a hollow cup, or cell, containing two sets of muscles, for the movements of the mobile limb, the mandible, as it is termed, in the one case, and the seta in the other. The avicularia again are either pedunculate and moveable upon the peduncle, or sessile, which latter may be either simply sessile or deeply immersed. The Ovicell is an organ of an arched or globose or pyriform shape found on many of the *Cheilostomata* and on some of the *Cyclostomata*, apparently destined for the development of ova. In the former class it is invariably situated above the mouth; and in the latter the analogous organ seems to represent a metamorphosed cell, and in situation corresponds with the other cells of the polyzoary.

The importance of the avicularian and vibracular organs, in a systematic point of view, may be estimated from the circumstance that, out of 36 genera of Cheilostomatous *Polyzoa*, 20 include species armed with one or the other, or with both; and that of 191 species no less than 126 are so furnished. They appear to be confined solely to the *Cheilostomata*.

In many cases the polyzoary is affixed by numerous slender corneous tubes, which seem to be merely subservient to that purpose; these are termed Radical Tubes.

The Polyzoary, or colony itself, is formed of an aggregation of cells, which throughout the two former orders of the class as here arranged, arise one from another, either singly or in pairs, from each cell (*fig.* 15*a*, which represents the beginning of the polyzoary of *Lepralia ciliata*), and from various parts of the cell, as on the back or sides, near the top or not far from the bottom. And it is to the variety of modes in which the cells arise that the diversity of form of the polyzoary is due. In one division of the third sub-order, the *Ctenostomata*, the cells do not arise one from another, but from a tube common to several cells, and which is either divided or not into distinct internodes. This portion of the polyzoary is termed the Basal Tube.

Having thus defined most of the terms which it is necessary to employ for the purposes of classification, we will briefly describe the anatomy of the various parts of the animal in the order in which it is given by Professor Allman.

Organs for the Preservation of the Individual.

A. Dermal System.

The Polyzoary is formed of a number of little chambers, or cells, organically united, each of which contains a polypide, and consists of two portions—an internal tunic, soft, transparent, and contractile (the Endocyst), and an external investment (the Ectocyst). The endocyst lines the interior of the cells and when it arrives at their orifice would protrude beyond the ectocyst, were it not that here it becomes invaginated, or inverted into itself, and then terminates by becoming attached round the base of the tentacular crown; during the exsertion of the polypide it undergoes eversion, sometimes complete, sometimes incomplete. The endocyst consequently constitutes a cell, or sac, in which the polypide is suspended, surrounded by the perigastric space. These sacs are all closed above where they are attached to the polypide, and below, in some cases, their cavities are in communication with those of the neighbouring sacs (or with the basal tube); but more generally no such communication exists. The ectocyst and endocyst represent respectively the external and middle tunics of the *Tunicata*, or the mantle and shell of other Molluscs.

The endocyst is in all cases thin and membranaceous, and often contains transverse muscular fibres. A portion, perhaps the whole, of the inner surface is clothed with vibratile cilia. The ectocyst varies greatly in composition and aspect. Throughout the greater number of the *Polyzoa* it is hardened by the deposition of calcareous matter, whilst in many others it is horny and flexible, and in some even of an almost gelatinous consistence. In the *P. hippocrepia* it is in most species composed of a tough pergamentaceous brown membrane, strengthened by the deposition of irregularly formed siliceous particles, sometimes rendering it quite opaque. In other cases again, as in the genus *Anguinella* v. Ben., the soft and flexible, and as it were flocculent ectocyst, is pervaded by aluminous and siliceous particles, and the same is the case, to a less marked extent, in some other of the *Ctenostomata*. In *Cristatella* and *Pedicellina* the ectocyst would, at first sight, seem to be entirely absent, and the cell to be composed exclusively of the endocyst. Careful examination however shows that both are present, and that the ectocyst consists of a highly organised and transparent tunic, free from any earthy deposit. In some instances, and very distinctly in the *Selenariadæ*, or Lunulites, the surface of the calcareous ectocyst is further covered with a thin horny cuticle, apparently resembling that on the shells of many Molluscs.

B. Organs of Digestion.

These consist of an alimentary canal, commencing at the mouth and terminating at the anus; and subdivided into several portions, which have received the same names as those of the apparently corresponding parts of the alimentary tract in the higher animals. The mouth is edentulous and usually unarmed, though sometimes (as in the proper *P. hippocrepia*) furnished with a valve-like organ of very peculiar formation, and which is considered by Professor Allman to be analogous with the 'languet' of the Ascidians.

From the mouth an œsophagus, or pharynx, leads downwards to the stomach, or in some cases, as in *Bowerbankia*, into a sort of gizzard, which in that genus is armed on each side with a serrated tooth. The stomach is a thick walled sac, which in most cases dilates inferiorly into a rounded cul-de-sac, or pyloric cavity, from which the intestine springs.

The pyloric orifice is distinctly valvular, and is furnished with prominent lips, which project into the intestine. The intestine, wide at the origin, rapidly diminishes in diameter till it terminates at a distinct anus near the mouth. The liver is represented by spherical corpuscles of a brown colour, seated on the wall of the stomach. The mouth and upper part of the œsophagus and the commencement of the intestines, are, in most cases, at any rate, furnished with vibratile cilia.

C. Organs of Respiration and Circulation.

Upon the tentacular crown and the walls of the perigastric space, which corresponds with the 'sinus system' of the *Tunicata*, would seem chiefly to devolve the function of bringing under the influence of the aerating medium the nutritious fluid of the tissues.

The tentacular crown of a Polyzoon consists of two portions: 1, a sort of stage, or disc, which surrounds the mouth—the Lophophore; and 2, of a row of tentacles, which are borne in an uninterrupted series round the margin of the lophophore. The lophophore throughout almost the entire class is orbicular or annular; but in the *Hippocrepia* its posterior margin, or that which corresponds to the rectum, is prolonged into two triangular lobes, or arms, so that in that order it exhibits the form of a deep crescent. This condition of the lophophore is found in no marine species, and in *Fredericella*, a fresh-water form, the arms of the crescent are obsolete, and the lophophore might, on a superficial view, be regarded as orbicular; but a careful examination, Professor Allman goes on to say, will render manifest its departure from the orbicular form, the side corresponding to the arms of the crescent being slightly prolonged obliquely upwards. In all cases the lophophore forms the roof of the perigastric space; in the species with crescentic lophophores the interior of the arms is clothed with vibratile cilia.

The tentacles are tubular, closed at their free extremity and opening at the opposite end through the lophophore into the perigastric space. In all the *Polyzoa* they are armed upon their opposed sides (in *Pedicellina* on one only?) with vibratile cilia, arranged in a single series, and vibrating towards the extremity of the tentacle upon one side and towards the base on the other. A nervous filament and muscular fibres may be traced into the tentacles. In the proper *P. hippocrepia* the entire plume of tentacles is surrounded at its base by an exceedingly delicate transparent membrane in the form of a cup or calyx, considered by Professor Allman as analogous to the membrane of the respiratory sac in the *Tunicata;* but this calyx has not yet been detected in any marine polyzoon. In the genus *Pedicellina* the tentacles are also surrounded at their base by a kind of membranous calyx, but this is of an entirely different import from the membrane connecting the bases of the tentacles of the *P. hippocrepia.*

The perigastric space and the interior of the lophophore and tentacles all freely communicate with one another, and are filled with a clear fluid, in which float numerous particles of a very irregular form and size. This fluid obviously represents the blood or common nutrient and respiratory fluid of other Mollusca. It is kept in motion by the cilia with which the endocyst is lined, but there is no special circulatory organ as in the *Ascidiæ.*

D. Organs of Motion.

The muscular system in the *Polyzoa* is highly developed, and the muscles are especially interesting in a physiological point of view, for they seem to present an example of true muscular tissue reduced to its simplest and essential form. They are composed of bundles of elementary fibres, totally separate from each other, throughout their entire course, and which are distinctly marked with transverse striæ. They resemble in fact very closely the fibres of the thoracic muscles of insects. In the marine *Polyzoa* however another kind of fibres may be noticed, presenting nodular enlargements, which would seem to resemble very closely the isolated, organic muscular fibres of the higher animals. The muscles are disposed in distinct sets, and it is by the agency of these various groups that the different movements of protrusion and retraction of the polypide are effected, together with the actions of the tentacles and of the avicularia and vibracula. For the arrangement of the muscles in the former class of organs see *fig.* 2 (5), in the article MOLLUSCA, *S.* 2. The curious analogies in the disposition of these muscles in the *Polyzoa* with that of the muscles which act upon the shells of the *Brachiopoda* are also pointed out in that place.

E. Organs of Sensation.

A distinct nervous system was first shown to exist in the *Polyzoa* by M. Dumortier in *Lophopus crystallinus,* and has been demonstrated by Van Beneden in *Laguncula,* and by Allman in all the Hippocrepian genera except *Paludicella;* it may be deemed therefore to exist generally in the class, and will probably be found essentially alike in all. In all the species of the Hippocrepian order there may be seen, attached to the external surface of the œsophagus, on its rectal aspect, just below the mouth, a hollow oval body of a yellowish colour, which is undoubtedly a nervous ganglion, as Professor Allman has succeeded in distinctly observing nervous filaments in connection with it; some of which may be traced going to each tentacle. The ganglion also sends off filaments upwards towards the mouth, and one may be observed passing downwards along the œsophagus; but nothing like a complete collar surrounding the tube has been observed. The *Polyzoa* do not seem to possess any special organs of sense.

F. Organs of Locomotion.

In *Cristatella,* the ectocyst, according to Professor Allman, is highly contractile, and presents, below, a flattened disc, destitute of apertures. Upon this disc, which closely resembles the foot of a Gasteropod, the singular polyzoary creeps about upon the stems and leaves of aquatic plants. Except in the embryonic condition no other Polyzoon would seem to possess any power of locomotion; or at any rate none has been noticed, but several reasons would seem to render it probable that the species belonging to the *Selenariadæ* may be capable of locomotion by means of their curiously constructed vibracula.

G. Reproduction.

In the *Polyzoa,* observes Professor Allman, three distinct modes of reproduction may be witnessed, namely:—By buds or gemmæ; by true ova: and by free locomotive embryoes.

1. Reproduction by Gemmæ.—The gemmæ always originate in the endocyst, first appearing as small tubercles projecting into the perigastric space, but which may soon be seen to take a development in an outward direction. The bud now presents the appearance of a vesicle projecting from the exterior of the parent-cell, closed at its external or free extremity, but having its cavity in communication with the perigastric space. The polypide is gradually developed in the interior of the gemma by the differentiation of its fine granular contents, and the extremity of the bud ultimately opens so as to admit of the exsertion and retraction of the young animal. Thus is produced a fresh cell of the polyzoary, whose ultimate form, as has been before observed, depends upon the point of the cell at which the bud springs. This differs in almost every species, and upon this difference depends the diverse physiognomy of the various species. For instance, if each cell pullulates at a single point at the upper and back part, a polyzoary, consisting of a single series of cells, such as that of *Ætea,* or of *Hippothoa* (*fig.* 6), will be presented; if from each cell two are given off and remain in close apposition, a circularly expanded disc of greater or less regularity will be produced, as seen in *Lepralia* (*figs.* 15 and 15 *a*), some *Membraniporæ,* &c., and so on.

2. Reproduction by Ova.—All the fresh-water, and probably, also, all the marine *Polyzoa,* produce true ova, which are formed in a definite organ or ovary; and from the existence of a true ovary and of ova, we are at once led to expect the co-existence of a male organ. That a testis is present in all the species of fresh-water *Polyzoa,* at any rate, no doubt, according to Professor Allman, can be entertained, and in *Laguncula* (*Farrella*) *repens,* the existence of this organ is described and figured by Van Beneden. In *Paludicella* Professor Allman says, "that the ovary and testes are both found in the same cell. The former is an irregularly shaped body, adherent to the inner surface of the endocyst, towards the upper part of the cell. The testicle is an irregularly lobed mass attached, like the ovary, to the inner surface of the endocyst. It occupies a position near the bottom of the cell, and is thus separated by a wide interval from the ovary. Both organs are attached to the side of the stomach by a cylindrical cord." The form of the ovary in the proper *Hippocrepia* would appear more to resemble a moniliform cord. In *Laguncula* (*Farrella*), according to Van Beneden, the ovary and testis, in form and situation would seem very closely to resemble those in *Paludicella.* It would appear also that the impregnation of the ova is effected by their escaping from the ovary into the perigastric cavity, where they are brought into contact with the spermatozoa, which have in like manner escaped from the testis into the same cavity, and are swimming actively about in vast numbers in the fluid with which it is occupied. There does not appear to be any special opening for the escape of the ova after impregnation, which is probably effected by a rupture in some part of the endocyst. The forms of the ova vary a good deal in different genera, and in some cases they are ciliated.

3. Professor Allman also describes a mode of reproduction by free embryoes, but does not seem to have noticed their mode or plan of development.

The embryo upon its escape from the ovum appears sometimes to be ciliated, sometimes not. In the case of *Lepralia coccinea,* a cheilostomatous species, the appearance of an embryo of the ciliated kind and its subsequent development are well described by Mr. Gosse. ('Naturalist's Rambles on the Devonshire Coast,' p. 218.)

But although the above brief description of the reproduction of the *Polyzoa* by ova formed and impregnated within the perigastric sac be undoubtedly correct, as applied not only to the species in which it has actually been observed, but from analogy to others as well, it cannot be denied that very considerable obscurity rests upon the mode in which the ova are developed in the ovicells or receptacles, which have received that name, and as to the relation which those organs bear to the rest of the animal. There can be no doubt that these organs do contain an ovum or ova, and that these ova are developed ab origine, in them, and there undergo segmentation; but how these ova are fertilised, and why a difference so great as this in the position of the ovigerous organ should exist in apparently closely allied genera or even species, is at present inscrutable.

Section III. Classification.

The more general relations of the *Polyzoa* having, as before observed, been described under the head of MOLLUSCA, the remainder of this article will be devoted to the mode in which they may be conveniently arranged among themselves.

With our present defective knowledge of many particulars respecting the conformation of the *Polypides*, the classification of the *Polyzoa* can only be attempted with any prospect of useful results, from the study of the Polyzoary; that is to say, so far as regards the determination of the subordinate groups—the orders themselves being defined by characters derived from the Polypide, or soft portion of the animal. The following scheme, which in its main features has been long received, appears to offer as convenient, and so far as our present acquaintance with the subject allows, perhaps as natural a classification as can be expected.

Class POLYZOA.

Social molluscous animals, whose nervous system consists of a single post-œsophageal ganglion, with branches, but without a nervous ring around the œsophagus; and without any special organs of sense or of circulation. Mouth surrounded more or less completely with a single row of ciliated tentacles.

Polyzoa, J. V. Thompson, 'Zool. Research.,' Mem. 5, p. 92 (1830).
Bryozoa, Ehrenb., 'Corallen-Thiere des Roth. Meer,' 1831 (1834?).
Molluscan Zoophytes, seu Zoophyta Ascidioida, Johnston, 'Mag. Zool. and Bot.,' 1836.
Ciliobrachiata, Farre, 'Phil. Trans.,' 1837.

Order I. *Polyzoa infundibulata*, Gervais.

Tentacles disposed on an uninterrupted annular lophophore, surrounding the unarmed mouth.

Sub-Order I. *Cheilostomata*.

The crescentic subterminal mouth of the cell is furnished with a moveable lip, by which it is closed when the animal retreats.

Escharadæ, Flustradæ, Cellariadæ (ex. *Crisia*), Fleming.
Polypiaria operculifera et cellariæa (ex. *Crisia*), Blainville.
Escharina, Celleporina, Ehrenberg.
Urceolata (pars), Hagenow.

A. Cells disposed in a single series.

Family 1. *Catenicellidæ*, Busk.

Cells connected by short flexible tubes.

Gen. 1. *Catenicella*, Blainv. (*Figs.* 1, 2.)

Cells connected by short corneous tubes, all facing the same way; polyzoary phytoid, erect, dichotomously branched; cell at the bifurcation geminate.

a. Fenestratæ. Cells fenestrate in front; ovicells terminal.
β. Vittatæ. Cells with a narrow elongated band or vitta on each side in front; ovicells galeriform, not terminal.

Catenicella, Blainville; 'Brit. Mus. Cat.,' p. 3.
Catenaria, Savigny, 'Egypt,' pl. 13.
About seventeen species known; mostly Australian.

Gen. 2. *Alysidium*, Busk.

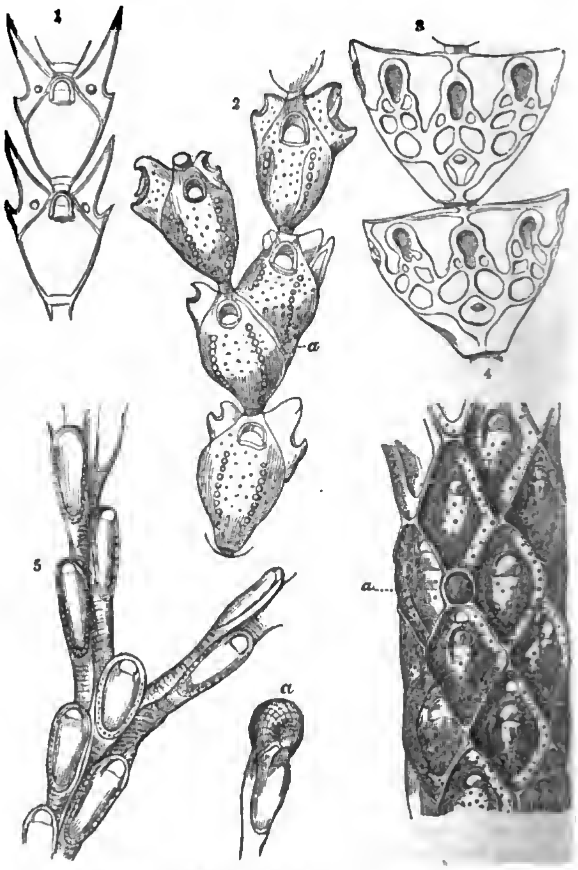
Cells connected by short corneous tubes. Two cells arising from each cell at a bifurcation.

Alysidium, 'Brit. Mus. Cat.,' p. 13.
Three species known.

Gen. 3. *Calpidium*, Busk. (*Fig.* 3.)

Cells with an avicularium on each side; each cell with three distinct apertures, arising one from the upper part of another in a linear series, connected by short corneous tubes.

Calpidium, Busk; 'Voyage of Rattlesnake,' i. 364 (*fig.* 3); 'Brit. Mus. Cat.,' p. 14.
One species.



1, *Catenicella taurina.* 2, *Catenicella elegans*; *a*, geminate cell. 3, *Calpidium ornatum.* 4, *Salicornaria farciminoides*; *a* avicularium. 5, *Cellularia Peachii*; *a*, ovicell.

Family 2. *Scrupariadæ.*

Junctions of the cells rigid.

Crisiadæ (part), Gray.
Scrupariadæ, Gray.
Eucratiadæ (part), Johnst.

Gen. 1. *Scruparia*, Oken.

Cells decumbent; aperture oblique, subterminal; branches given off from the front of a cell below the aperture.

Scruparia (*a*), Oken.
Scruparia, 'Brit. Mus. Cat.,' p. 28.

Gen. 2. *Hippothoa*, Lamouroux. (*Fig.* 6.)

Cells decumbent, adherent; branches given off from the sides of the cells.

Hippothoa, Lamx.; Gray; Johnst.; 'Brit. Mus. Cat.,' p. 29.
Catenicella (pars), Blainville (non M. Edwards).
Terebripora, D'Orbigny.
Tubulipora (sp.), Jameson.
Three species known.

Gen. 3. *Ætea*, Lamouroux.

Cells tubular, erect, scattered; adnate and decumbent at the base.

Ætea, Lamx.; Gray; 'Brit. Mus. Cat.,' p. 30.
Anguinaria, Lamarck; Johnston.
Falcaria (*β*), Oken.
Four species.

Gen. 4. *Beania*, Johnston. (*Fig.* 7.)

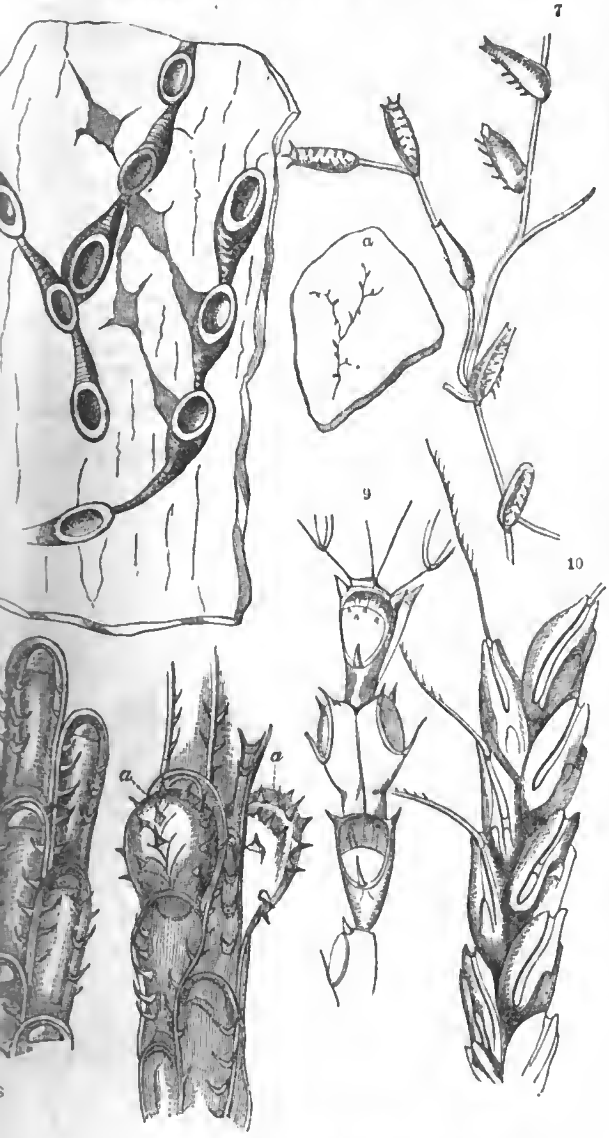
Cells arising one from another by a slender filiform prolongation or tube, and open in front; marginal spines hollow, inarching.

Beania, Johnst.; Gray; 'Brit. Mus. Cat.,' p. 32.
Two species.

B. Cells disposed in a double or in multiple series.

Family 3. *Salicornariadæ.*

Cells disposed around an imaginary axis, forming cylindrical branches of a dichotomously divided erect polyzoary.
Salicornarianæ, Gray.
Salicornariadæ, 'Brit. Mus. Cat.,' p. 15.



6, *Hippothoa catenularia.* 7, *Beania mirabilis; a*, natural size. 8, *Farciminaria aculeata; a*, ovicells. 9, *Dimetopia cornuta.* 10, *Caberea Boryi.*

Gen. 1. *Salicornaria*, Cuvier. (*Fig.* 4.)

Front of each cell much depressed, surrounded by an elevated ridge, by which the surface of the branch is divided into more or less regular, rhomboidal or hexagonal spaces; avicularia scattered; ovicells immersed, inconspicuous; branches articulated.
Salicornaria, Cuvier; Johnston; 'Brit. Mus. Cat.,' p. 15.
Farcimia, Fleming; Johnston, 'Ed.' i.
Cellaria (*a*), Lamarck; Lamx.; De Blainville.
Five species.

Gen. 2. *Nellia*, Busk.

Front of cell convex, with a distinct raised border; aperture very large; ovicells (?); no avicularia.
Salicornaria (sp.), Busk., 'Voyage of Rattlesnake,' i. 367.
Nellia, 'Brit. Mus. Cat.,' p. 18.
Two species.

Gen. 3. *Vincularia*, Defrance. (*Fig.* 19.)

Polyzoary rigid, calcareous, inarticulated; surface not areolated; aperture large; no avicularia; ovicells inconspicuous.
Vincularia, Defrance; Blainv.; Hagenow; 'Brit. Mus. Cat.,' p. 96.
Glauconoma, Goldfuss.
Siphonella, Hagenow.
Cellaria (pars), Reuss.
One recent species; numerous fossil.

Gen. 4. *Farciminaria*, Busk. (*Fig.* 8.)

Polyzoary corneous, flexible; margin of aperture much raised; aperture very large; ovicells cucullate, prominent; no avicularia.
Farciminaria, 'Brit. Mus. Cat.,' p. 32.
One species.

Family 4. *Cellulariadæ*, Busk.

Cells disposed in the same plane, forming linear branches of a dichotomously divided phytoid, erect, articulated polyzoary.
Bugulidæ (pars), Gray.
Cellularidæ (pars), Johnston.
Escharidæ (pars), Johnston; Gray.
Cellulariadæ, 'Brit. Mus. Cat.,' p. 19.

Gen. 1. *Cellularia*, Pallas. (*Fig.* 5.)

Cells bi-triserial; more than four in each internode; oblong or rhomboidal, contiguous; perforated behind, unarmed, or very rarely with an avicularium on the upper and outer angle of the cells.
Cellularia (pars), Pallas; Fleming; Johnston (pars); 'Brit. Mus. Cat.,' p. 19.
Bugula (pars), Gray; Oken.
Three species.

Gen. 2. *Menipea*, Lamouroux.

Cells oblong, or elongated and attenuated downwards; imperforate behind, with a sessile avicularium (frequently absent) on the upper and outer angle, and one or more sessile avicularia on the front of the cell below the aperture (not always present).
Menipea, Lamx.; 'Brit. Mus. Cat.,' p. 20.
Cellaria (pars), Linn.; Solander.
Crisia (pars), Lamx.
Tricellaria, Fleming; Blainville.
Six species.

Gen 3. *Scrupocellaria*, Van Beneden.

Cells rhomboidal, with a sinus on the outer and hinder aspect; each furnished with a sessile avicularium at the upper and outer angle, and with a vibraculum behind. Cells biserial and numerous in each internode.
Scrupocellaria, Van Beneden; Gray; 'Brit. Mus. Cat.,' p. 23.
Bicellaria (sp.), Blainville.
Cellularia (sp.), Pallas; Johnston.
Cellaria (sp.) Solander; Lamarck.
Scruparia (sp.), Oken.
Seven species.

Gen. 4. *Canda*, Lamouroux.

Cells rhomboidal, sinuated on the outer side for the lodgment of a vibraculum; no avicularium on the upper and outer angle; sometimes one in front of the cell.
Canda, Lamx.; Blainville; Gray; 'Brit. Mus. Cat.,' p. 26.
Cellaria (sp.), Lamarck.
Cellarina, Van Beneden.
Bicellaria (sp.), Blainville.
Scrupocellaria, Gray.
Cellularia (sp.), Johnston.
Two species.

Gen. 5. *Emma*, Gray.

Cells in pairs or triplets; a sessile avicularium (sometimes wanting) on the outer side below the level of the aperture.
Emma, Gray; 'Brit. Mus. Cat.,' p. 27.
Two species.

Family 5. *Cabereadæ*, Busk.

Polyzoary dichotomously divided into ligulate bi-multiserial branches; on the backs of which are vibracula, each of which is common to several cells.

Cabereadæ, Busk.; 'Voyage of Rattlesnake;' 'Brit. Mus. Cat.,' p. 37.

Gen. 1. *Caberea*, Lamx. (*Fig.* 10.)

Cells bi-multiserial, in the latter case quincuncial. Back of branches covered with large vibracula, which are placed obliquely in two rows, diverging in an upward direction from the middle line, at which the vibracula of either side decussate with those of the other.
Caberea, Lamx.; Blainville; Gray; 'Brit. Mus. Cat.' p. 37.
Selbia, Gray.
Crisia (sp.), Audouin.
Cellaria (sp.), Lamarck.
Cellularia (sp.), Fleming; Johnston.
Four species.

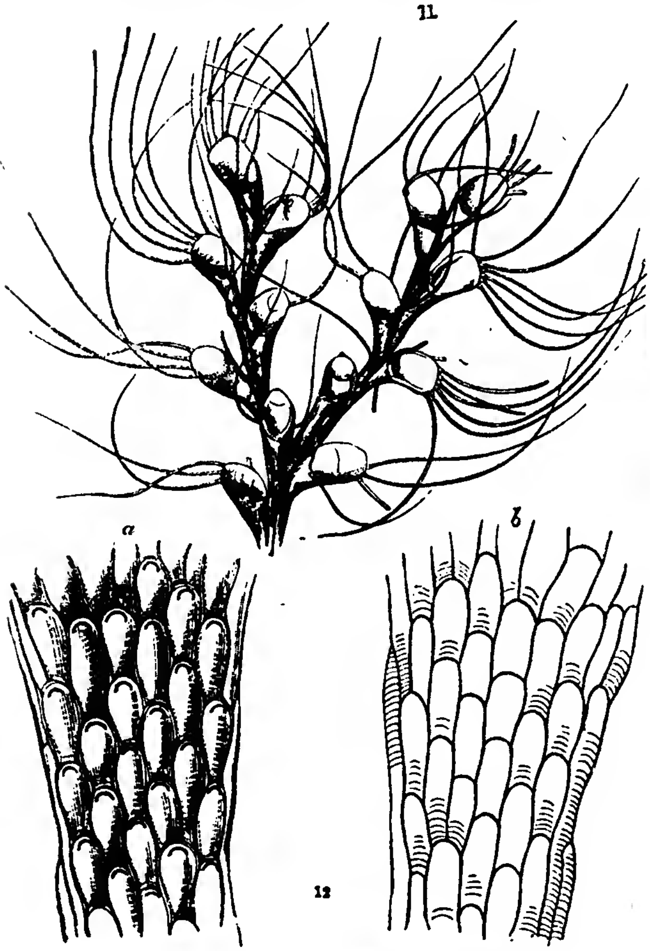
Gen. 2. *Amastigia*, Busk.

Cells bi-quadriserial; vibracula small, resembling avicularia.

One species.

Family 6. *Bicellariadæ*, Busk.

No vibracula; avicularia, when present, pedunculate.
Bicellariadæ, Busk.; 'Voyage of Rattlesnake.'
Bugulidæ, Gray.



11, *Bicellaria ciliata*. 12, *Carbasea elegans*: *a*, front; *b*, back.

Gen. 1. *Bicellaria*, Blainville. (*Fig.* 11.)

Cells turbinate, distant. Aperture directed more or less upwards. Several spines, marginal or dorsal.
Bicellaria, Blainville; Gray; 'Brit. Mus. Cat.,' p. 14.
Cellularia, Fleming; Pallas (sp.)
Cellaria (sp.), Oken; Lamarck.
Bugula (sp.), Oken.
Four species.

Gen. 2. *Halophila*, Gray.

Cells contiguous, attenuated downwards; much expanded above, with a large plain aperture unarmed.
Halophila Gray, 'Dieff. New Zealand;' 'Brit. Mus. Cat.,' p. 43.
Bicellaria, Busk., 'Voyage of Rattlesnake.'

Gen. 3. *Bugula*, Oken.

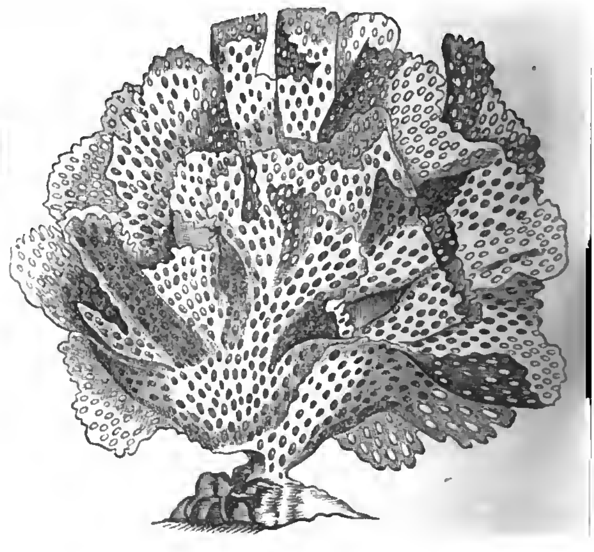
Cells elliptical (behind), closely contiguous, bi-multiserial; aperture very large; margin simple, not thickened.
Bugula, Oken; Gray; 'Brit. Mus. Cat.,' p. 43.
Acamarchis, Lamx.; Blainville.
Crisia (sp.), Lamx.
Cellularia (sp.), Pallas; Johnston (sp.).
Cellaria (sp.), Solander; Lamarck.
Bugulina (sp.), Gray.
Crisularia (sp.), Gray.
Six species.

Family 7. *Gemellariadæ*, Busk.

Cells opposite in pairs. Polyzoary continuous.
Gemellariadæ, Busk; 'Voyage of Rattlesnake;' 'Brit. Mus. Cat.,' p. 33.

Gen. 1. *Gemellaria*, Savigny. (*Fig.* 29.)

Cells joined back to back; all the pairs facing the same way.
Gemellaria, Savigny; Van Beneden; Johnston; Gray; 'Brit. Mus. Cat.,' p. 34.
Gemicellaria, Blainville.
Loricaria, Lamx.
Notamia (pars), Fleming.
Loricula, Cuvier.
Crisia (sp.), Lamx.; Lamarck.
Scruparia (β), Oken.
One species.



29, *Gemellaria loricata*.

Gen. 2. *Didymia*, Busk.

Cells joined side to side; no avicularia.
Didymia, Busk.; 'Voyage of Rattlesnake;' 'Brit. Mus. Cat.,' p. 35.
One species.

Gen. 3. *Dimetopia*, Busk. (*Fig.* 9.)

Cells joined back to back; aperture oblique; each alternate pair of cells looking the same way.
Dimetopia, Busk; 'Voyage of Rattlesnake.'
Two species.

Gen. 4. *Notamia*, Fleming.

A pair of tobacco-pipe shaped avicularia, visible above each pair of cells.
Epistomia (sp.), Fleming; Gray.
Dynamena (sp.), Lamx.; Blainville.
Notamia, Fleming; 'Brit. Mus. Cat.,' p. 36; Johnston.
Gemicellaria (sp.), Blainville.

Sertularia (sp.), Gmelin.
Cellularia (sp.), Pallas.
One species.

Family 8. *Flustradæ*, Gray.

Polyzoary flexible, expanded, foliaceous, erect; sometimes decumbent and loosely attached. Cells multiserial, quincuncial, or irregular.
Flustra, Linn; Johnston (pars).
Flustradæ, Gray (pars); 'Brit. Mus. Cat.,' p. 46.
Escharidæ (pars), Johnston; Gray.
Polypiers à Réseau (pars), Lamx.
Flustrées (pars), Lamx.

Gen. 1. *Flustra*, Linnæus.

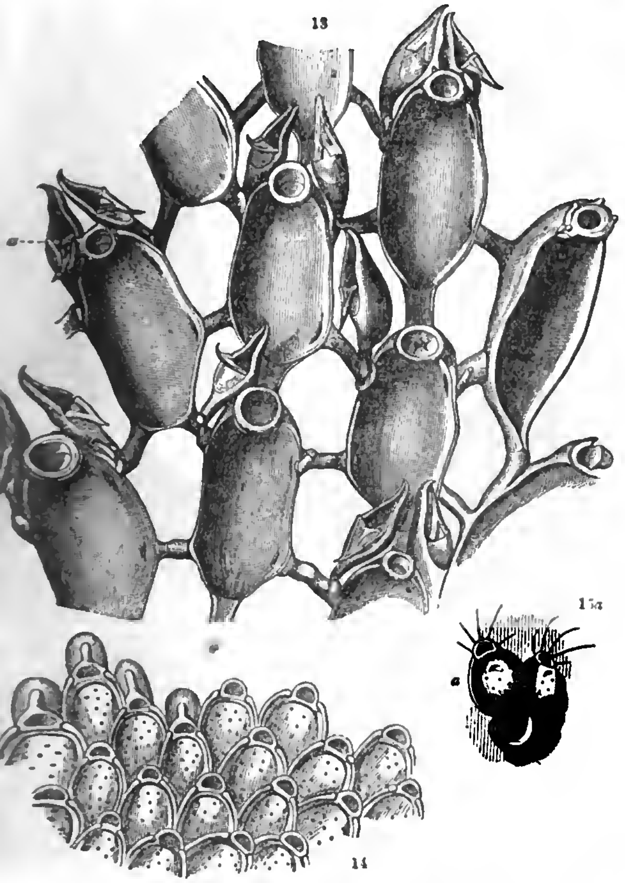
Cells contiguous; on both sides of the frond.
Flustra (sp.), Linn.; Lamarck; Gray; &c.
Five species.

Gen. 2. *Carbasea*, Gray. (*Fig.* 12.)

Cells contiguous; on one side only of the frond.
Flustra (sp.), Linn.; Johnston.
Carbasea, Gray; 'Brit. Mus. Cat.,' p. 50.
Ten species.

Gen. 3. *Diachoris*, Busk. (*Fig.* 13.)

Cells disjunct; each connected with six others by tubular processes.
Diachoris, Busk., 'Voyage of Rattlesnake.'
Three species.



13, *Diachoris magellanica*; *a*, avicularia. 14, *Membranipora coriacea*. 15*a*, Young state of *Lepralia ciliata*.

Family 9. *Membraniporidæ*, Busk.

Polyzoary membranaceo-calcareous, or calcareous, expanded, encrusting (sometimes foliaceous, contorted, and sub-erect). Cells horizontal, quincuncial, or serial.
Flustra, Dinn. (pars).
Flustradæ (pars), Gray.
Celleporidæ (pars), Johnston.
Membraniporidæ, Busk.; 'Brit. Mus. Cat.,' p. 55.

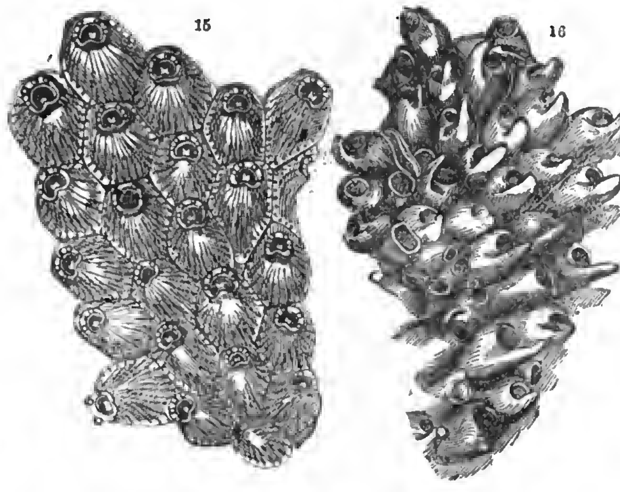
* Cells more or less open in front, with raised margins.

Gen. 1. *Membranipora*, Johnston. (*Fig.* 14.)

Polyzoary encrusting (or suberect, foliaceous, and contorted), spreading irregularly. Cells more or less irregularly disposed or quincuncial, with raised margins; a greater or less extent of the aperture occupied by a thin membrane
Eschara (pars), Pallas.
Flustra (sp.), Linn.; Esper; Berkeley; Lamarck; Grant; Fleming; Risso; Johnston; Lamouroux.
Membranipora, Johnston; 'Brit. Mus. Cat.,' p. 56; W. Thompson; Hassall.
Discopora (pars), Lamarck.
Annulipora, *Conopeum*, *Callopora*, *Amphiblestrum*, *Micropora*, Gray.
Eighteen species.

** Aperture of cells entirely filled in by a convex calcareous expansion. Cells disposed in more or less regularly radiating lines.

Gen. 2. *Lepralia*, Johnston. (*Figs.* 15 & 15*a*.)



15, *Lepralia Peachii*. 16, *Cellepora pumicosa*.

Polyzoarium adnate, crustaceous, spreading from a centre in a more or less circular form; composed of contiguous, or connected, calcareous, decumbent cells, the wall of which is complete in front.
Eschara (sp.), Moll.; Pallas.
Lepralia, Johnston; Gray; 'Brit. Mus. Cat.,' p. 63.
Berenicea, Fleming (non Lamouroux nor Peron).
Escharina (sp.), Milne-Edwards; Gray.
Escharoides (sp.), Milne-Edwards.
Cellepora (sp.), Oken; Audouin (pars); Lamouroux (pars); Hagenow (pars).
Flustra (varior).
Discopora, Lamarck (pars); Gray (pars); Lamouroux (pars).
Cribrillina, *Herentia*, *Escharella*, *Porella*, *Celleporella* (all sp.), Gray.

1. *Armatæ*. Species provided with either avicularia or vibracula.
A. Species having avicularia.
α. Median and single.
* Superior (above the mouth).
** Inferior (below the mouth).
β. Avicularia double, or azygous and lateral on each cell, or only on some cells in the polyzoary.
B. Species having vibracula.
2. *Inarmatæ*. Species without either avicularia or vibracula.
α. With oral spines.
β. Mouth unarmed.
About fifty or sixty species.

Family 10. *Celleporidæ*, Busk.

Polyzoarium composed of cells, standing more or less vertical to its axis or plane, heaped together, or irregularly overlying each other.

Celleporidæ, Johnston (pars); 'Brit. Mus. Cat.,' p. 58.

Gen. 1. *Cellepora*, O. Fabricius. (*Fig.* 16.)

Polyzoarium calcareous, rigid, adnate or erect, composed of urceolate, suberect, contiguous cells, heaped together irregularly, or arranged quincuncially. An ascending rostrum on one or both sides of the mouth usually furnished with an avicularium.

Cellepora (sp.), O. Fabricius; Johnston; Linnæus; Müller; Berkeley; Stewart; Lamarck; Lamouroux; Fleming; Olivi.
Spongites, Oken.
Tubipora (pars), Linn.
Millepora (pars), Pallas; Ellis and Solander (pars).
Eschara (pars), Pallas.

* Adnate, globose, or spreading.

** Erect.

Eight species.

Family 11. *Escharidæ*, Busk.

Polyzoary erect, rigid, foliaceous and expanded, lobate or reticulate. Cells disposed quincuncially in the same plane, on one or both surfaces.

Escharidæ (pars), Johnston.
Lepralianæ (pars), Gray.
Reteporanæ, Gray.

Gen. 1. *Eschara*, Ray. (*Fig.* 17.)

Polyzoarium foliaceous and expanded, or contorted, or branched and sublinear. Cells disposed on both surfaces, back to back, immersed, coalescent, horizontal to the plane of the axis.

Eschara, Ray; Fleming; Johnston; Lamarck; Gray; Pallas (pars); Moll (pars); 'Brit. Mus. Cat.,' p. 89.
Nullipora (sp.), Solander.
Cellepora (sp.), Esper.

* Polyzoary more or less expanded, foliaceous.

** Polyzoary subdivided into branching lobes.

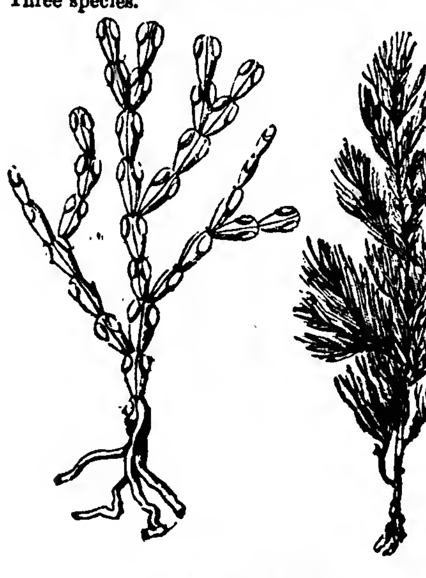
Eleven species.

Gen. 2. *Retepora*, Imperato. (*Fig.* 28.)

Polyzoarium foliaceous, calcareous, reticulated. Cells immersed, opening at one surface only.

Millepora, Linn. (pars); Ellis and Solander; Esper; Marsigli; Cuvier.
Retepora, Imperato; Lamarck; Risso; Fleming; Stark; De Blainville: Couch; Johnston; Goldfuss (pars); Hagenow (pars); 'Brit. Mus. Cat.,' p. 93.
Frondipora, Oken; De Blainville.

Three species.



28, *Retepora cellulosa*.

Family 12. *Selenariadæ*, Busk.

Polyzoary more or less regularly orbicular, convex on one side, plane or concave on the other (probably free). Furnished with large and powerful vibracula, with variously formed setæ (probably locomotive).

Selenariadæ, Busk; 'Brit. Mus. Cat.,' p. 97.

Gen. 1. *Cupularia*, Lamouroux.

(*Fig.* 18; vide also *figs.* in CELLARIÆA.)

Each cell throughout the polyzoary with a vibraculum at the summit.

Cupularia, Lamouroux (proposed); 'Brit. Mus. Cat.,' p. 97.
Lunulites, Lamouroux (pars); Defrance (pars); Deslongchamps (pars); Goldfuss (pars); De Blainville (pars); Gray; Cuvier and Brongniart; Lonsdale (pars); Michelin (pars).
Fenestella (pars), Lonsdale.

Five species (recent); numerous fossil.

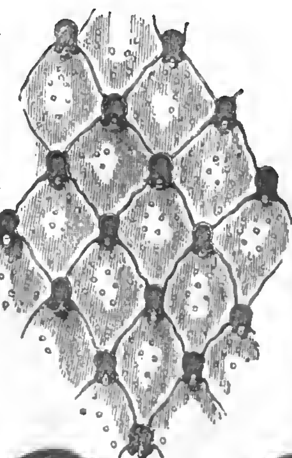
Gen. 2. *Lunulites*, Lamouroux.

Cells arranged in series radiating from the centre and bifurcating as they advance; vibracula in linear series alternate with those of the cells.

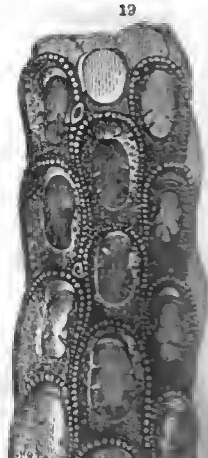
As in the preceding species.

Four species (recent); numerous fossil.

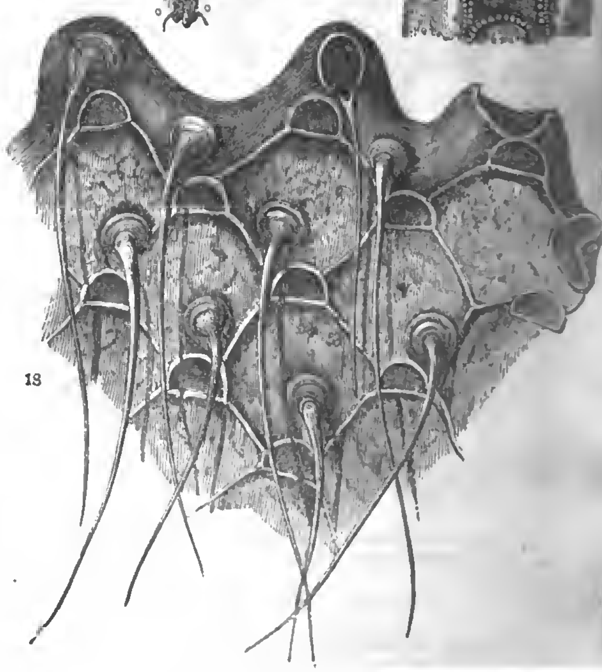
17



19



18



17, *Eschara foliacea*. 18, ria *Lowei*. 19, *Vincularia ornata*.

Gen. 3. *Selenaria*, Busk.

Only a certain number of cells, dispersed at uniform distances apart, furnished with vibracula. The front of each cell furnished, covered by a cribriform calcareous expansion; the others arched above and contracted below.

Lunulites (pars), Busk, 'Voyage of Rattlesnake.'
Selenaria, 'Brit. Mus. Cat.,' p. 101.

Sub-Order II. *Cyclostomata.*

Cells tubular, calcareous, immersed or exserted; mouth terminal, without any moveable appendage or lip.

Tubuliporina, Milne-Edwards.
Tubuliporidæ, Johnston.
Auloporina (pars), Ehrenberg; Johnston.

A. Erectæ.

Polyzoary erect, free, simple or branched, linear or expanded above; branches articulated or continuous.

Family I. *Crisiadæ*, Milne-Edwards.

Polyzoarium divided into distinct internodes, connected by a horny substance.

Gen. 1. *Crisidia*, Milne-Edwards.

A single cell in each internode.

Sertularia (pars), Linn.; Berkeley (pars); Esper (pars).
Cellularia (pars), Pallas; Hogg.
Cellaria, Ellis and Solander (pars); Lamarck (pars).
Eucratea, Lamouroux (pars); Risso (pars); Fleming (pars); Templeton.
Unicellaria (pars), Blainville.
Crisidia, Milne-Edwards.
Crisia (pars), Johnston; Hassall (pars), &c.

One or two species.

Gen. 2. *Crisia*, Lamouroux. (*Fig.* 20.)

Two or more cells in each internode.

Syn. as above.

Three species recent; several fossil.

20, *Crisia bicellata*; *a*, ovicell. **21**, *Alecto granulata*. **2**, *Idmonea radians*; *a*, natural size. **23**, *Tubulipora serpens.*

Family 2. *Idmoneadæ.*

Polyzoarium continuous throughout, usually polymorphous.

Gen. 1. *Idmonea*, Lamouroux. (*Fig.* 22.)

Openings of cells disposed in transverse or oblique alternate series on each side of the front of the branches of the polyzoary, on which is a raised line or ridge separating the rows of cells.

Retepora (sp.), Lamarck.
Hornera (sp.), Defrance.
Idmonea, Lamouroux; Blainville.

Three or four species recent; many fossil.

Gen. 2. *Pustulipora*, De Blainville. (*Fig.* 26.)

Openings of cells disposed irregularly, on all sides of the cylindrical or compressed branches or lobes of the polyzoary.

Ceriopora (pars), Goldfuss.
Idmonea (sp.), De Blainville.
Pustulipora, Blainville; Milne-Edwards; Johnston.
Tubulipora, (sp.), Couch.

Five or six species recent; many fossil.

Gen. 3. *Hornera*, Lamouroux.

Openings of cells disposed irregularly, or in more or less regular opposite transverse series, on one side only of the branches or lobes of the polyzoary.

Millepora (sp.), Esper.
Retepora (sp.), Lamarck.
Hornera, Lamouroux; De Blainville; Milne-Edwards.

Several species recent; many fossil.

B. Adnatæ, *s.* decumbentes.

Polyzoarium adnate or suberect above, decumbent and adnate below.

Family 3. *Tubuliporadæ.*

Polyzoarium divided into linear or sublinear branches or lobes, sometimes more expanded and lobate upwards, always decumbent, and closely adnate.

Gen. 1. *Alecto*, Lamouroux. (*Fig.* 21.)

Polyzoarium composed of a single or of multiple series of cells.

Alecto, Lamouroux; Milne-Edwards; Johnston (pars); De Blainville; Fleming.
Millepora (sp.), Linn.
Aulopora (sp.), Goldfuss, &c.

Three or four species recent; several fossil.

Gen. 2. *Tubulipora.* (*Fig.* 23.)

Polyzoarium arising from a contracted base, and expanding above; either simple or irregularly subdivided; decumbent and adherent below, usually free and suberect above.

Tubulipora, Milne-Edwards (pars); Johnston (pars); Fabricius; Turton; Gmelin; Couch (pars); Fleming (pars); Lamarck (sp.); Risso (sp.).
Tubipora (sp.), Linn.; Jameson; Stewart; Bosc.
Millepora (sp.), Ellis and Soland.
Cellepora (sp.), Esper.
Pherusa (?), Lamouroux, &c.

Five or six species recent; several fossil.

Family 4. *Discoporadæ.*

Polyzoarium in the form of a closely adnate, circular, or irregular disc or patch.

Tubuliporidæ (pars), Milne-Edwards, &c.

Gen. 1. *Discopora*, Lamarck.

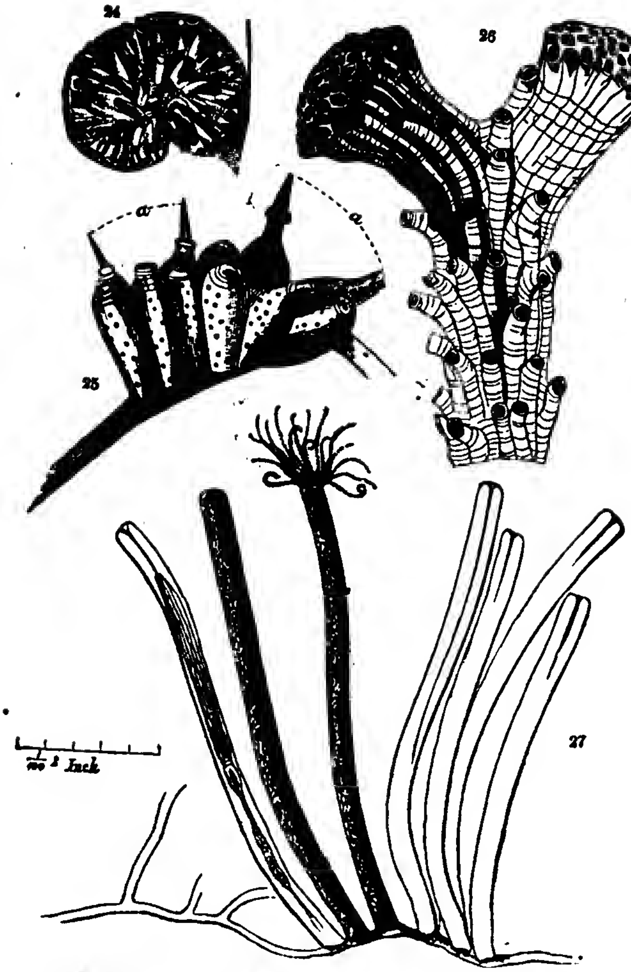
Polyzoarium a circular disc, either flat, concave, or convex in the centre, with the suberect tubes opening irregularly in all parts of the surface, and usually surrounded by a thin calcareous border.

Discopora, Lamarck; Lamouroux; Fleming.
Tubulipora (pars), Johnston.
Melobesia, Audouin.
Obelia, Quoy and Gaimard.
Madrepora, Ellis and Solander; O. Fabricius.

Gen. 2. *Diastopora*, Lamouroux. (*Fig.* 24.)

Polyzoarium more or less depressed, circular, discoid; the cells subalternating, horizontal, immersed; openings elliptical.

Millepora (sp.), Esper.
Mesenteripora, De Blainville.
Diastopora, Milne-Edwards (pars); Johnston (sp.); Hagenow (pars).
Aulopora (sp.), Goldfuss.
Berenicea (sp.), Lamouroux.
Rosacilla, Römer.



24, *Diastopora* (sp.?); 25, *Serialaria lendigera*; *a*, oral setæ. 26, *Pustulipora*, (sp.?). 27, *Farrella prælonga*.

Gen. 3. *Defrancia*, Bronn.

Polyzoary either discoid and adnate throughont, or fungiform and attached by a short stem; openings of tnbes disposed in lines or rows radiating from the centre.
Pelagia, Lamouroux.
Lichenopora, Michelin.
Tubulipora, Milne-Edwards (sp.); Johnston (sp.).
Ceriopora (anct., pars).
Defrancia, Bronn.; Hagenow; Reuss.

Sub-Order III. *Ctenostomata*.

Cells corneous, or fleshy, tubular or depressed, free or coalescent; mouth terminal or subterminal, contractile, and when the polypide is exserted, surrounded with a fringe or row of setæ, connected by a delicate membrane.
Vesicularina, Johnston.
Polyzoa cornea, Gray, and inclnding—
Halcyonellea, Johnston.
Polyzoa carnosa, Gray.
Alcyoniadæ and *Alcyonidulæ*, Johnston.

Family 1. *Vesiculariadæ*, Johnston.

Cells tubular or ovate, separate, arising from a basal tube common to all or to several; mouth terminal.
Vesiculariadæ, Johnston.

Gen. 1. *Serialaria*, Lamarck. (*Fig.* 25.)

Cells uniserial or biserial, and nnilateral, placed in close sets at stated intervals; basal tnbe divided into internodes.
Serialaria, Lamarck; Risso; Fleming; Templeton; Couch; De Blainville.
Amathia, Lamouroux, &c.
Three or four species.

Gen. 2. *Vesicularia*, J. V. Thompson.

Cells ovate or subtubnlar, disjnnct, nniserial, and unilateral; polypide with a gizzard.
Valkeria (sp.), Fleming.
Vesicularia, Thompson; Farre; Johnst.; Van Beneden; Couch.
One species.

Gen. 3. *Valkeria*, Fleming.

Cells ovate, clustered in whorls at the joints of the basal tnbe; polypides without a gizzard.
Valkeria, Johnston; Fleming; Farre; Van Beneden.
Vesicularia (sp.), Thompson.
Cuscutaria, De Blainville.

Gen. 4. *Bowerbankia*.

Cells unilateral, irregularly placed, sessile; polypides with a gizzard (armed with two teeth).
Bowerbankia, Farre; Johnston; Van Beneden.
One species.

Gen. 5. *Farrella*. (*Fig.* 27.)

Cells elliptical, scattered; polypide without a gizzard.
Farrella, Ehrenberg; Johnston.
Lagenella, Farre.
Laguncula, Van Beneden.
Two species.

Gen. 6. *Anguinella*, Van Beneden.

Cells tubular, supported on a common stalk, and branching ont in a palmate fashion.
Anguinella, Van Beneden.

Family 2. *Alcyoniadæ*, Johnston.

Cells fleshy, immersed, augular; month terminal, simple, contractile.
Halcyonelleæ, Johnston.
Polyzoa carnosa, Gray.
Alcyoniadæ, Johnston.
Alcyonidulæ, Johnston.

Gen. 1. *Alcyonidium*, Lamouroux.

Polyzosry varionsly lobed, massive, fleshy, erect, or adnate.
Alcyonium, Ellis; Baxter; Pallas; Linn.; Olivi; Esper; Müller; Lamouroux; De Blainville; &c.
Alcyonidium, Lamouroux; Gray; Hooker; Johnston; W. Thompson; &c.
Halodactylus, Farre; Van Beneden.
Cycloum (sp.), Hassall.
Sarchochitum (?), Hassall.
Three or four species.

Sub-Order IV. *P. Pedicellinea*, Gervais.

Lophophore prodnced npwards on the back of the tentacles, nniting them at their base in a sort of muscular calyx.

Family 1. *Pedicellinidæ*, Johnston.

Gen. 1. *Pedicellina*, Sars.

Polypide not retractile within the delicate closely adnate ectocyst, which is produced downwards into a long tubular pedicle, containing muscular fibres, and rising vertically from a creeping radicle tube.
Hydra (sp.), Fleming; Bosc; Lister; Sharpey.
Pedicellina, Sars; Johnston; Van Beneden.
Lusia, Milne-Edwards; De Blainville; Gervais; Hassall.
Crinomorpha, Van Beneden.
Two or three species.
Sertularia (sp.), Müller; Bosc.; Lamarck.
Three species.

Order II. *Polyzoa hippocrepia*, Gervais.

Tentacles disposed on a crescentic or horse-shoe shaped lophophore; eversion of endocyst only partial.
Polypiaria hippocrepia, Gervais.
Polyzoa hippocrepia, Gray.
Lemniades, Johnston; Allman.

Freshwater *Polyzoa*, Allman.
Freshwater *Bryozoa*, Hancock.
Bryozoaires Fluviatiles, Van Beneden.

Family 1. *Cristatellidæ*, Allman.

Polyzoary free, locomotive.

Gen. 1. *Cristatella*, Cuvier.

Polyzoary sacciform, hyaline, with a common flattened disc adapted for locomotion; orifices placed on the surface opposite to the disc, and arranged in several concentric marginal series; ova lenticular, with annular and marginal spines.
One species.

Family 2. *Plumatellidæ*, Allman.

Polyzoary rooted.

A. Lophophore with two long arms.

Gen. 1. *Lophopus*, Dumortier.

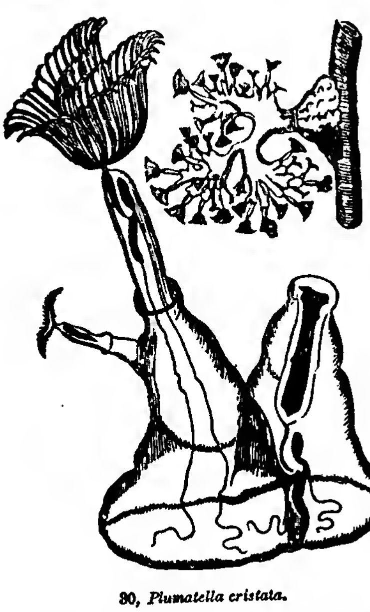
Polyzoary sacciform, hyaline, with a disc which serves for attachment, but not for locomotion; orifices scattered; ectocyst gelatinous.
Polype à Panache, Trembley.
Bell-Flower-Animal, Baker.
Naisa, Lamouroux; Deslongchamps.
Plumatella (sp.), Schweigger; De Blainville; Gervais; Lamarck.
Alcyonella, Raspail; Johnston; Allman.
Lophopus, Van Beneden; Allman.
One species.

Gen. 2. *Alcyonella*, Lamarck.

Polyzoary tubular; tubes united by their sides; orifices terminal; ectocyst pergamentaceous.
Tubularia, Pallas.
Leucophra, Müller.
Alcyonium, Bruguière.
Spongia, Schmiedel.
Alcyonella, Raspail; Pallas (sp.); Allman, &c.
Plumatella, Gervais.
Three species.

Gen. 3. *Plumatella*, Lamarck. (*Fig.* 30.)

Polyzoary tubular; tubes distinct; ectocyst pergamentaceous.
Tubipora, Linnæus.
Tubularia, Müller; Linnæus; Vaucher; Turton.
Naisa, Lamouroux; Deslongchamps.
Plumatella, De Blainville; Carus; Lamarck; Dumortier; Johnston; Gervais; Allman; Thompson; Van Beneden; Dalzell; Schweigger; Risso, &c.
Ten species.



30, *Plumatella cristata.*

B. Lophophore with the arms obsolete.

Gen. 4. *Fredericella*, Gervais.

Polyzoary confervoid, composed of a membrano-corneous branched tube, with the branches distinct and terminated by the orifices; lophophore nearly circular, tentacular crown campanulate; ova bean-shaped, destitute of annulus or spines.
Tubularia, Blumenbach; Gmelin.
Naisa, Lamouroux.
Difflugia, Meyen.
Plumatella, Fleming; Dumortier; Johnston.
Fredericella, Gervais; Van Beneden; Thompson; Allman; Johnston; Hancock.

Family 3. *Paludicellidæ*.

Lophophore orbicular, mouth destitute of valve. (Does not perhaps properly belong to *P. hippocrepia*.)

Gen. 1. *Paludicella*, Gervais.

Polyzoary membrano-corneous, branched; branches composed of a series of claviform cells, placed end to end, and separated from one another by complete septa; orifices tubular, lateral, placed near the wider extremity of each cell; ova lenticular, with a narrow annulus.
Alcyonella (sp.), Ehrenberg; Nordmann.
Paludicella, Gervais; Van Beneden; Allman; Thompson; Johnston; Hancock.

POLYSTICHUM, a genus of Plants belonging to the natural order of *Filices*, the sub-order *Polypodiaceæ*, and the tribe *Aspideæ*. The indusium is circular, attached by the centre; the veins are distinct after leaving the midrib. There are three British species:—

P. Lonchitis, with rigid simply pinnate fronds. Found in Alpine rocks.

P. aculeatum, with linear rigid bipinnate fronds; the pinnules obliquely decurrent. Common in hedge banks.

P. angulare, with the fronds lax, drooping, bipinnate, pinnules truncate below, distinctly stalked. Found in the west of England, on sheltered banks.

(Babington, *Manual of British Botany;* Lindley and Moore, *The Ferns of Great Britain and Ireland*, nature-printed.)

POMPILIDÆ, a family of Fossorial Hymenopterous Insects. They are sometimes included with the *Sphegidæ*. They have the collar either transversely or longitudinally square, with the abdomen more or less oval, and attached to the thorax by a very short peduncle. The legs are very long. The fore wings have two or three perfect submarginal cells, and another commenced at the tip of the wings. The species are called Sand Wasps, and are amongst the most ferocious of the insect tribes. The species of the exotic genus *Pepsis* are amongst the largest of the *Hymenoptera*. The genus *Pompilus* is British. The species are very active, running amongst grass and other plants in hot sandy situations. They are quick in their motions, and their wings are constantly agitated. Their long legs give them the appearance of spiders. (Westwood, *Families of Insects.*)

PONERA (Latreille), a genus of Insects belonging to the family *Formicidæ*. In this genus the neuters and females are armed with a sting. The peduncle of the abdomen is formed of a single knot; antennæ in these individuals thickened at the tip; mandibles triangular; head subtriangular. *P. contracta* is a small species, a native of England.

POOL, or WELSHPOOL. [MONTGOMERYSHIRE.]

POONAHLITE. [MINERALOGY, *S.* 1.]

POOR LAWS. There have been several statutes making slight alterations and amendments in the details of the administration of these Laws, but none calling for particular mention, any analysis or enumeration of their provisions being impossible within the compass of this article.

Under the head of PAUPERISM ['Penny Cyclopædia,' vol. xvii. pp. 327-30], an account was given of the establishment of the new Poor Law in England in 1834, and of its early operation up to the year 1840. Since that time the number of Unions has been increased from 587 to 624, including 14,168 parishes in England and Wales, and leaving only 436 parishes which do not make returns to the General Poor Law Board. The new Poor Law had, on its introduction, effected a large reduction of the expenditure on the poor, but from 1839 a gradual increase took place for several years. In the former article it was shown that there was no connection between the amount of relief required by the poor and the price of corn. As the subsequent returns only confirm the same fact, we shall omit the price of wheat, and give the total amount levied for poor-rates in each year. The years end uniformly at Lady Day. The second column gives the total amount levied for poor-rates, the third the amount expended for the maintenance and relief of the poor.

Years.	£	£	Years.	£	£
1840	6,014,605	4,576,965	1849	7,674,146	5,792,963
1841	6,351,828	4,760,929	1850	7,270,493	5,395,022
1842	6,552,890	4,911,498	1851	6,778,914	4,962,704
1843	7,085,595	5,208,027	1852	6,552,298	4,897,685
1844	6,847,205	4,976,093	1853	6,522,412	4,939,064
1845	6,791,006	5,039,703	1854	6,973,220	5,282,853
1846	6,800,623	4,954,204	1855	7,864,149	5,890,041
1847	6,964,825	5,298,787	1856	8,201,348	6,004,244
1848	7,817,450	6,180,765	1857	8,139,003	5,898,756

In the years above mentioned we may observe that in 1852 the average price of wheat was 39*s.* 4*d.*; in 1840 it was 68*s.* 6*d.*; yet the amount of relief shows but a small difference. The number of persons relieved is an imperfect guide to the amount of distress, as it does not distinguish, except as regards in-door relief, between a single meal or assistance for a lengthened period, but we add a few statements of numbers at different periods. In the quarter ending Lady Day 1840, there were 169,232 persons relieved in workhouses, and 1,030,297 had out-door relief. The number continued to increase till 1843, when the number in the house was 238,560, and receiving out-door relief 1,300,930. The numbers then slowly decreased till 1847, when the in-door numbers mounted to 265,037, and the out-door to 1,456,313, increasing respectively in 1848 to 305,956 and 1,570,585. Until 1848 the quarter ending Lady Day was taken as representing the number of persons relieved in each year. Since then the numbers in receipt of relief on Jan. 1 and July 1, have been taken, being the periods of greatest and least distress. Thus, on Jan. 1, 1849, there were 131,591 persons in the house, and 855,573 receiving out-door relief; on July 1, there were only 102,841 in the house, and 783,096 receiving out-relief. The estimated total for the year, however, including 214,870 for places not included in the returns, was 1,043,886. In 1853 the number similarly calculated had sunk to 857,035. On Jan. 1, 1857, the total number of paupers in receipt of relief, in-door and out-door, in 624 unions and parishes of England and Wales, was 843,340, being a decrease from 1856, in the same number of unions, of 33,225, or 3·8 per cent. Of adult able-bodied paupers relieved, exclusive of vagrants, there were 139,130, a decrease of 13,044, or 8·6 per cent. Of the number relieved, 50,362 were widows, a decrease in the same class of 2291. Of the gross number of able-bodied paupers, 22,368 were in the receipt of in-door relief, a decrease of 1128 only, so that the chief decrease is in out-door relief. The greatest decrease took place in Bedford, Lancaster, Nottingham, Rutland, and Caernarvon, where it exceeded 20 per cent. In Kent, Hereford, Durham, Oxford, Sussex, and Worcester, there was an increase, as also in several of the Welsh counties. Of the in-door adult able-bodied there were 842 married men, 1007 married women, 5952 other males, and 14,567 other females. Of the out-door adult able-bodied, 83 males had been relieved in cases of sudden or urgent necessity; 17,210 males in cases of their own sickness or accident, 6885 males in cases of sickness or accident in their family, or for a funeral; 3784 males for want of work or other causes; 22,839 females were wives of adult males, 50,362 were widows, 5114 were single women without children, 2660 the mothers of illegitimate children; 2018 were wives relieved on account of the husband being in jail, &c.; 1268 were wives of soldiers, sailors, and marines; and 4389 were wives of other non-resident males.

The amount expended in the half year ending Lady Day 1857 for the relief of the poor was 1,979,885*l.*, of which 493,076*l.* was for in-door maintenance, and the remainder for out-door relief.

IRELAND. In consequence of the distress occasioned by the potato rot and bad harvests in previous years, it was considered necessary to provide a poor-law for Ireland. Accordingly, in 1838, an Act (1 & 2 Vict., cap. 56), mainly founded on the reports and recommendations of Mr. (now Sir George) Nicholls, was passed. In its main features it resembled the English poor-law, but the workhouse as a test of need was more stringently enforced. Mr. Nicholls was appointed chief commissioner, and under his direction it came into operation in 1839. The unions were formed gradually, and the expense of erecting workhouses was so great, that loans to a large amount were granted for that purpose by government, a considerable portion of which was subsequently remitted. In 1840 there were but four unions in operation, North and South Dublin, Cork and Londonderry, and on Dec. 31, there were in them 5468 inmates, 10,910 had been relieved in the year, and the expenditure had been 37,057*l.* On Dec. 31, 1841, there were 37 unions in operation, and there had been relieved 31,108 destitute persons, and 15,246 were then in the workhouses; the expense having been 110,277*l.* On Dec. 31, 1842, there were 31,572 inmates in 92 union workhouses, 87,604 persons had been relieved, and the expense had been 281,233*l.* On Dec. 31, 1843, there were 33,510 inmates in 106 workhouses, 87,898 persons had been relieved, and the expense had been 244,374*l.* On Dec. 31, 1844, there were 39,175 inmates in 113 workhouses, 105,358 persons had been relieved, and the expense had been 269,530*l.* In 1845 another period of distress occurred through the failure of the potato, and the number of the destitute continued to increase. On Dec. 31, 1845, there were 42,068 inmates in 123 workhouses (in March 1845 there had been 50,717), 114,205 persons had been relieved, and the expense amounted to 316,026*l.* In 1846 the potato-rot continued, and the distress increased to such an extent that the government was forced to intervene for its relief by providing public works to employ the able-bodied, by reducing the duty on the import of corn, and by furnishing food at a low price to the destitute poor, in which last act it was aided by a general subscription, which amounted to 98,000*l.*, the whole sum contributed amounting to 831,372*l.* The greatest number of persons employed at one time on public works was 97,000. On Dec. 31, 1846, in 130 workhouses there were 94,437 inmates, 243,933 persons had been relieved, and the expense had been 435,001*l.* But the evils arising from the continued failure of the potato continued to operate. Food was scarce, and the public works, instead of alleviating the distress, seemed likely to increase it. Agriculture was abandoned for the 'government work,' the fisheries were deserted, and even artisans left their trades. In October 1846 there were 114,000 men employed; in January 1847 the number had increased to 570,000; and in March to 734,000. It was evident a change of system must be adopted. Exertions were made to apply again the workhouse test, and the number rapidly fell, in April to 520,000, in May to 419,000, in June to 101,000, on the 26th of which month it was reduced to 28,000, and in August the system was discontinued. Cooked food had also been supplied, and in July 1847, 3,020,712 persons received separate rations. The entire amount advanced by government in 1846 and 1847 had been 7,132,268*l.*, and the amount subscribed had been upwards of half a million. It was in these years that the large amount of emigration took place. On Sept. 21, 1847 (the date of making up the accounts had been altered), the number of workhouse inmates was 86,376, and the total number relieved in the house had been 417,139; but the houses were crowded, and the mortality had been great; the expenditure during the year had been 803,684*l.* The harvest of 1847 proved a good one, and the pressure upon the public funds decreased, but not upon the workhouse relief. On Sept. 29, 1848, there were 124,003 inmates in 131 workhouses, 610,463 had been relieved in the house during the year, and 207,683 persons were then receiving out-door relief, while 1,433,042 had received out-door relief in the course of the year; the total expense had been 1,732,597*l.* On Sept. 29, 1849, there were 141,030 inmates, 932,284 had been in the house, and 1,210,482 had been relieved out of the house during the year, the total expense being 2,177,651*l.* On Sept. 29, 1850, the number of unions had been increased to 163, the total number relieved in the house during the year was 805,702, out of the house 368,565, and the expenditure was 1,430,108*l.* On Sept. 29, 1851, the number relieved in the house during the year was 707,443, out of the house 47,914, and the expenditure was 1,141,647*l.* On Sept. 29, 1852, the number relieved in the house during the year was 504,864, out of the house 14,911, and the expenditure was 883,267*l.* On Sept. 29, 1853, the number in the house during the year was 396,436, out of the house 13,232, and the expenditure was 785,718. By the 10 & 11 Vict., cap. 31, 1847, permission had been given to guardians of unions to hire or purchase limited quantities of land, to be occupied as agricultural schools for pauper children. These had gradually been instituted, and in Sept. 1853 the total number of boys in the workhouses of Ireland, between the ages of 9 and 15, was 12,320; of girls, between the same ages, 14,273; of these, 3,873 boys were employed in agricultural labours on land attached to the unions, amounting to 1,506 acres, of which 1,070 were under crop, wholly or partially cultivated by boys; and 3,196 were receiving instruction in trades. Of the girls, 9,166 were receiving industrial education of various kinds. 2,940 boys and 2,425 girls, under fifteen, had obtained employment, during the year 1852, out of the workhouse. On Sept. 29, 1854, the total number of persons receiving in-door relief during the year had been 318,320, ont-door 7954, the total expenditure being 746,407*l.* On Sept. 29, 1855, the number relieved in the house during the year had been 269,800, out of the honse 35,342, total expenditure 683,596*l.* On the first Saturday of January, 1857, in the 163 unions of Ireland, there were 55,183 persons receiving in-door relief, and 911 out-door relief, showing a total decrease of 16,989 persons—23·3 per cent.—from the Return of the same date in 1856. Less than a third of the workhouse accommodation was in use, provision having been made for 199,667, which is itself a reduction of the provision for previous years. The poor-rate collected in the year ending September 29, 1856, amounted to 723,797*l.*, of which 76,160*l.* were expended for Poor Law purposes, being a decrease on the preceding year of 109,099*l.* For medical charities 89,899*l.* were paid, and 4436*l.* on account of annuities. In the week ending Saturday, January 2, 1857, the amount of out-relief paid throughout Ireland was 44*l.*; in the year ending Sept. 29, 1856, it was 2198*l.*, while emigration expenses amounted to 4170*l.*

In Scotland there had been no effective legal provision for the poor. As early as 1579 power was given to magistrates in burghs and justices in the country, a power afterwards transferred to the heritors and kirk sessions of parishes, to assess the parish for the support of the poor; but no assessment was made under this act for a century after its passing, and when it became necessary in some few parishes it was confined to them alone. Other acts were passed for preventing begging, for providing houses of correction for vagrants, for compelling each parish to maintain its own poor, and for providing work for the able-bodied. But, as a general practice, the wants of the infirm, sick, and impotent poor were relieved by the voluntary contributions received at the kirk, and distributed by the kirk sessions, usually in the form of assistance to the relatives or connections of the destitute persons who undertook their support. This system did not work badly in country districts, except in periods of extreme and general distress. But when, by the extension of manufactures and commerce, the towns increased largely in size, and an influx of strangers took place to them, the necessity of a more perfect system was very shortly felt. This had been experienced in Glasgow, Paisley, and Dundee on various occasions, but temporary expedients and increased voluntary contributions had been the only resort. In 1840, 1841, and 1842, however, the distress in Paisley could not be thus relieved, although it had been in less severe trials in 1819, 1827, and 1837. At the census of 1841 the population of Paisley amounted to 48,416; in January, 1842, the number of persons depending on the relief fund was 12,703, and in the following June it was still 10,417. The inhabitants at a public meeting, agreed to a voluntary assessment of 15 per cent. on their parochial rating, and this produced 574*l.*, only 473 of the rate-payers contributing. Extraneous aid was sought, and subscriptions to the amount of 25,000*l.* were obtained, a trifling alleviation of a suffering that the relief committee described as frightful. The law and the practice had always been in Scotland to refuse relief to able-bodied adults, consequently the unfortunate artisan, deprived of his employment by the commercial difficulties occurring between 1838 and 1843, was not considered as belonging to the class receiving relief from the kirk sessions. The number of this class during the year ending June 1842 had been 700, and the expenditure on them had been 3682*l.*, neither the number nor the amount varying much from the usual average.

In 1843 a government commission was appointed to inquire into the state of pauperism and the mode of managing the poor in Scotland. They reported that the parishes in most large towns had been forced to resort to assessment, but that it was generally disliked, and that the modes of assessment were so various in different places that it was difficult to make one that should be strictly legal. Here and there they found a poor-house of very inadequate accommodation, and the system was almost uniformly one of out-door relief. The report recommended a legislative enactment for a regular system of poor-laws, and accordingly in 1845 the 8 & 9 Vict. c. 83 was passed. It constituted parochial boards of management elected by the rate-payers, a board of supervision; gave the power of levying assessments; the option of combining parishes for the erection of poor-houses; made a more certain provision for relief of the lunatic, casual, and unsettled poor, for medical relief, and for purposes of education; but it still leaves the able-bodied adult without a legal claim on parochial assistance. Each parish is allowed to decide whether the requisite sum for the relief of the poor shall be raised by voluntary contribution or assessment, and if by assessment, how certain properties shall be classed; but having once decided in favour of assessment, they cannot retract such decision without the consent of the board of supervision. The voluntary system had been the custom, and out of 880 parishes in Scotland, only 230 were legally assessed in 1842-43; these have been gradually increased, so that now (1858) there are but few in which a legal assessment has not taken place. Although the Act was brought into immediate operation, it was some time before the registers and accounts could be reduced into proper forms. Officers and inspectors were alike inexperienced. But according to the best returns the commissioners could obtain from the several parishes, the expenditure for the year ending February 1, 1845, was 258,815*l.* From the returns made in 1843 it appeared that from all sources there was raised for the relief of the poor in 1836 the snm of 171,042*l.*, and 218,481*l.* in 1841; the amonnt having gradually increased in every intervening year. The number of poor in those years is not stated, but on February 1, 1845, there were 63,070 on the poor roll. In the year ending February 1, 1846, there had been raised 306,044*l.*, of which 295,232*l.* were expended in poor relief. In the autumn of 1846 the potato rot visited Scotland, and again in 1847, creating a vast amount of distress, particularly in the Western Highlands and Islands of Scotland. Government aid was offered, and poor-houses and medical relief were strongly recommended, and in most instances adopted, particularly that of medical relief. For the few following years we present the progress in the annexed table. The years end on the 14th of May.

	Registered poor.	Casual poor.	Medical relief.	Poorhouse buildings	Other expenses.	Total.
	£	£	£	£	£	£
1847	336,515	36,340	12,879		48,181	433,915
1848	401,886	53,384	30,340	10,971	47,753	544,334
1849	417,463	51,470	33,011	14,776	60,324	577,044
1850	414,680	31,557	26,574	42,815	65,927	581,553
1851	404,219	25,918	20,311	21,576	63,920	535,944
1852	401,954	25,987	21,436	21,186	65,305	535,868
1853	411,135	24,114	21,737	21,645	65,921	544,552

During these years the highest number of the poor on the register was 82,357 in 1849, the lowest 69,432 in 1846; the greatest nnmber of casual poor relieved was 126,684 in 1848, the lowest 46,031 in 1852. The nnmber of insane or fatuous poor average about 3500; and the number of orphans or deserted children have increased from 4794 in 1847 to 8328 in 1853. The figures for the succeeding years vary little in their details, showing chiefly an increase as the system extends, and we therefore give only the latest published. In the year ending May 14, 1857, the total amount expended in poor-law relief was 629,348*l.*, including 27,277*l.* on buildings, on medical relief 61,553*l.*, on law charges 27,277*l.*, and on management, 7399*l.* The number of registered poor who received relief in the year ending May 14, 1857, was 88,622, a decrease of 10,740 from the previous year; and the casual poor receiving relief amounted to 36,545. The number of poor-houses in 1856 numbered 30, belonging to 120 parishes, either singly or in combination, affording accommodation for 10,443 inmates, and 16 others were in course of erection. The number of registered poor on the 14th of May, 1857, was 69,217. (*History of the Poor Laws. By Sir George Nicholls.*)

PORTER, ANNA MARIA, born at Durham about 1781, was the youngest child of a family all of whom attained considerable celebrity. Her eldest brother was an eminent physician at Bristol; another brother was Sir R. K. Porter; and her eldest sister was Jane, the subject of the following notice. When only a few months old her father died, and the mother, for the sake of educating her children economically, removed to Edinburgh. Anna Maria was the most precocious; and as a lively and intelligent child attracted the notice of Sir Walter Scott, then a youth, who delighted in relating tales to her, and this probably led to her own early attempts in the same line. While still almost a child she had written 'Artless Tales' in two volumes, which were issued in 1793 and 1795, of which she afterwards regretted the publication. Her mother had before this time removed with her family to London, and subsequently, with her sister Jane, they settled first at Thames Ditton, and finally at Esher. After the death of her mother in 1831, while travelling in hopes of restoring her delicate health, she was attacked by typhus fever, and died on June 21, 1832, at the seat of Mrs. Colonel Booth, Montpelier, near Bristol. Besides many contributions to periodical works, she had published numerous novels, among which 'The Hungarian Brothers,' 'Don Sebastian,' 'The Recluse of Norway,' 'The Village of Mariendorpt,' 'The Fast of St. Magdalen,' and 'The Knight of St. John,' enjoyed and retain considerable popularity. They belong, more or less, to the class of historical novels, and show skill in the management of the story, and some discrimination of character; but her heroes and heroines too often possess a superhuman excellence that becomes palling. 'Tales of Pity,' were published anonymously, and are intended to inculcate kindness to animals. In 'The Barony' she has developed her religious feelings. She also published a volume of poetry, 'Ballad Romances and other Poems,' in 1811, of no great value.

PORTER, JANE, the elder sister of the preceding, was born in 1776. Her life followed that of her sister, with whom and her mother she constantly resided till their deaths. She then, as she described herself, "became a wanderer," living with one or other of her friends till, in 1842, she went with her brother to St. Petersburg. On his death she returned to England, and resided with her eldest brother, the physician at Bristol, where she died May, 24, 1850. Miss Jane Porter did not adventure into the field of literature so early as her sister, and in some respects came better prepared, but she has the same fault in the unmitigated excellence or depravity of her characters. Still, in many of her characters there is a firmer delineation, and perhaps somewhat greater knowledge, though not very rigidly adhered to, of the manners of the times of which she treats. Her first work was 'Thaddeus of Warsaw,' published in 1803, which was extremely popular, and procured for her the admission as a canoness into the Teutonic order of St. Joachim, and a complimentary letter from Kosciusko. In 1809 she published the 'Scottish Chiefs,' a romance of Wallace and Bruce, in which there is considerable vigour of description, some character, but a total misconception of the condition of the time. Wallace and Bruce are depicted as little less than demigods. To these followed the 'Pastor's Fireside' and 'Duke Christian of Luneburgh,' the latter said to have been suggested by George the Fourth. She next joined with her sister in 'Tales round a Winter's Hearth,' and these were succeeded by 'The Field of Forty Footsteps,' founded on a London tradition connected with the spot where now stands University College and Hospital, and which was almost immediately dramatised. After a considerable interval, during which she contributed largely to periodical works, among other things a biography of Colonel Denham, the African traveller, in the 'Naval and Military Journal,' she published anonymously in 1831 'Sir Edward Seaward's Diary,' in which she so successfully imitated the style and adhered so closely to the manners and history of the period, that it was for a considerable time doubted whether or not it was a fiction. This was her last work.

PORTER, GEORGE RICHARDSON, was born in London in 1792. He was educated at Merchant Taylors' school, where he became intimate with the Ricardo family, and subsequently married the sister of David Ricardo. His father, a merchant in London, designed him for his own profession, and he became a sugar-broker. He was unsuccessful in trade; but his commercial knowledge was made available for literary objects. In 1830 he published a work, 'On the Cultivation of the Sugar-Cane.' A paper on 'Life Assurance' was published in the 'Companion to the Almanac for 1831.' In the same year 'A Treatise on the Origin, Progressive Improvement, and Present State of the Silk Manufacture,' was issued in a volume of Lardner's 'Cabinet Cyclopædia,' for which series, in 1842, he wrote a similar treatise 'On the Manufacture of Porcelain and Glass.' His paper in the 'Companion to the Almanac,' of which Mr. Charles Knight was the projector and editor, led to Mr. Porter's official appointment in the Board of Trade. In an article in the 'Gentleman's Magazine,' for October 1852, the circumstance is thus correctly stated:—"Mr. Knight was written to by the late Lord Auckland, then president of the Board of Trade, requesting that he would wait on that minister at his office at his earliest convenience, and was asked at the interview whether he would undertake the task of arranging and digesting for the board the mass of information contained in blue books and parliamentary returns; in short, if he would do for the Board of Trade what Mr. Porter has since done so well, and what Mr. Fonblanque continues to do for the same office, with the same accuracy and success. Mr. Knight hesitated. The engagement, should he accept it, must necessarily interfere in a great measure with his business as a publisher. In this dilemma, he consulted a distinguished friend, and by that friend was advised to wait on Lord Auckland, and decline the office. This he did; and at Lord Auckland's request, he named Mr. Porter, to whom the office was given."

The first appointment of Mr. Porter at the Board of Trade took place in 1832. It was an experimental appointment at a small salary. When the statistical department of the Board of Trade was fully organised, Mr. Porter was placed at its head. In 1840 he was appointed in addition, senior member of the railway department of the board, then newly constituted to meet the growing increase of projects in that direction. His able reports, which were laid before parliament, were of the utmost value, and were properly appreciated by official men and by the public. For his labours in this department he had an additional salary of 200*l.* a-year. On the retirement of Mr. McGregor, as one of the secretaries of the Board of Trade, in 1841, Mr. Porter was appointed to succeed him, at the salary of 1500*l.* a-year. His labours in all these positions were increasing and successful. He had a genius for tabulating the most incongruous materials, and he formed the model, which he was always improving, of the returns which are now periodically issued from the Board of Trade with so much advantage to the commerce of the country. But his active mind was not confined to his official duties. In 1833 he published 'The Tropical Agriculturist.' In 1834 he exerted himself in the founding of the Statistical Society, of which he was for a considerable time one of the vice-presidents, and on the resignation of Mr. Hallam in 1841, he was chosen treasurer. To the 'Journal' of the Society he was a frequent contributor. In 1836 he published 'The Progress of the Nation, in its social and commercial relations, from the beginning of the Nineteenth Century to the Present Time. Sections I. and II., Population and Production.' Sections III. and IV., 'Interchange, and Revenue and Expenditure,' followed in 1838; and the work was completed in 3 vols. 12mo, by Sections V. to VIII., including 'Consumption, Accumulation, Moral Progress, Colonial and Foreign Dependencies.' This valuable work necessarily admits of constant correction and new matter, and other editions were issued each in a large 8vo volume, in 1847 and 1851. The mass of information clearly set forth in this work presents the best and most complete picture of the progress and state of the country for the period of which it treats. On the establishment of the British Association for the Advancement of Science, he became one of its most active members, always attended its annual meetings, and usually read a paper to the statistical section. Mr. Porter had been ever a firm and unwavering advocate of the doctrines of free-trade, and in 1849 he published a translation, with notes, of F. Bassiat's 'Popular Fallacies regarding General Interests,' in 16mo. In the same year he wrote the Fifteenth Section of the 'Admiralty Manual of Scientific Inquiry,' edited by Sir J. F. Herschel, which was subsequently published alone in 1851. In 1850, in conjunction with Mr. George Long, he wrote the 'Geography of Great Britain. Part I., England and Wales,' published by the Society for the Diffusion of Useful Knowledge. This was his last unofficial labour. Sedentary pursuits had induced a bad habit of body, and the sting of a gnat produced inflammation of the leg, from the consequences of which he died on September 3, 1855, at Tonbridge Wells, whither he had gone in hopes of relief.

PORTSEA. [PORTSMOUTH.]

PORTUGAL. The political divisions of the Kingdom of Portugal, with the area and population of each, are as follows:—

Provinces.		Districts.	Area in Square Miles.	Population in 1851.
Alemtejo		Portalegre	2,382	86,175
		Evora	2,609	88,617
		Beja	4,991	123,107
			9,982	297,899
Algarve		Faro	2,140	143,851
Beira	Beira Alta	Viseu	1,291	302,070
	Beira Baixa	Guarda	2,128	206,736
		Castello Branco	2,474	139,042
	Douro	Porto	1,087	369,583
		Aveiro	1,458	247,103
		Coimbra	1,327	261,856
			9,765	1,526,390
Entre Douro e Minho		Viana	954	184,359
		Braga	1,086	297,969
			2,040	482,328
Estremadura		Leiria	1,312	140,114
		Santarem	2,315	161,342
		Lisbon	3,615	423,705
			7,242	725,161
Tras os Montes		Bragança	2,374	126,617
		Villa Real	1,646	184,779
			4,020	311,396
Total			35,189	3,487,025

In addition to the above political divisions, each of the sub-provinces or districts is subdivided into comarcas (or judiciary divisions), cancelhos (or communal divisions), and parishes. The total number of comarcas is 111; of cancelhos, 379; of parishes, 3774.

PORTUMNA, Galway, Ireland, a market-town and the seat of a Poor-Law Union, is situated at the head of Lough Derg, in 53° 6′ N. lat., 8° 12′ W. long., 41 miles E.S.E. from Galway, and 94 miles W.S.W. from Dublin. The population in 1851 was 1542, besides 147 in the Union workhouse. Portumna Poor-Law Union comprises 15 electoral divisions, with an area of 77,046 acres, and a population in 1841 of 30,714; in 1851 of 19,731. The town has been much improved by the increased trade of the Shannon. It contains the parish church, a handsome structure in the perpendicular style; a large Roman Catholic chapel; a dispensary; Union workhouse; and bridewell. The Shannon is here crossed by a causeway and wooden bridge 820 feet in length. Quarter and petty sessions are held in the town. Saturday is the market-day; fairs are held six times a year. Portumna Castle, a fine baronial mansion, the seat of the Marquis of Clanricarde, was destroyed by fire in 1826.

POST OFFICE. In the 'Penny Cyclopædia,' vol. xviii. p. 453, there was given under this head an account of the Post-office up to and inclusive of the improvements introduced by Mr. Rowland Hill. All that remains is to notice what has been done in the way of extension of the advantages derived from rapid and cheap intercommunication, and a few figures to show the enormous increase which has taken place. In 1838, as stated in the previous article, the total number of documents transmitted by post, including franks, public statutes, and newspapers (of which there were 44,500,000), was 126,423,836. In 1839 the new system was introduced, but 1840 was the first entire year of the penny postage, but then letters might be paid, or stamped, or were charged double. In that year 191,931,365 of letters only passed through the post-offices of the United Kingdom. The revenue derived from the post-office had been 1,649,088*l.* in 1839; in 1840 it only amounted to 495,514*l.* In 1845 the number of letters had reached 329,161,811, and the revenue 760,588*l.* The number of letters and the amount of net revenue continued to increase rapidly. In 1848 the additional advantage was given of a book-post, by which single books could be sent, open at the ends, at an uniform rate of 6*d.* per pound. This privilege was gradually extended to the British Colonies. In 1855 the rate of postage for printed sheets was reduced to one penny for a quarter of a pound, twopence for half a pound, and twopence extra for each fraction above half a pound; but if fourpence or upwards were paid, the packet might contain any number of sheets written or printed, except that the writing must not be of the nature of a letter. The last regulation in 1857 is that the packet may contain, in every case, any number of sheets, written or printed, but the written matter must not be of the nature of a letter, and may consist of bound books, or maps or prints on rollers, or whatever is necessary to the safe transmission of literary or artistic matter, such packets, however, not to exceed two feet in length, depth, or width, and all must be open at the ends or sides. Such packets may also be sent to all the British Colonies at the rate of 3*d.* for 4 oz., 6*d.* for 8 oz., and then proceeding at the rate of 6*d.* for every 8 oz., or portion thereof, except to Ascension Island, the East Indies, Hong Kong, Australia, New Zealand, and the Gold Coast, to all of which the rates are one-third more, and the weight is restricted to three pounds. By various conventions the foreign postage of letters has been materially reduced, in some cases 50 per cent., and in others varying from 17 to 20 per cent. The rates to all the British Colonies were in 1857 reduced to an uniform rate of 6*d.* per half ounce, payable in advance.

The fourth annual return of the Post-Office for 1857 states that the total number of letters delivered in the year was 504,421,000, of which 410,003,000 were in England and Wales, 42,806,000 in Ireland, and 51,612,000 in Scotland. These numbers give an average, in England, of 21 letters for each person of the population (in London it amounts to 43 for each), in Ireland to 7 for each, and in Scotland to 16 for each person. The number of newspapers passing through the Post-Office was 71,000,000, about three-fourths of which bore the newspaper stamp. The number of book-packets was about 6,000,000. There were 580,000 newspapers, and 1,700,000 letters that from various causes could not be delivered, chiefly from illegible or erroneous directions. The gross revenue was 2,928,858*l.*; the cost of management 1,720,815*l.*; the net revenue 1,322,237*l.* The cost of management includes the following items:—Salaries, pensions, &c., 948,573*l.*; buildings, 29,367*l.*; conveyance of mails by railways, 420,000*l.*; by coaches, carts, &c., and wages of mail-guards, 165,000*l.*; by mail-packets (when paid for by the Post-Office) and private ships, 12,298*l.*; for manufacture of postage-stamps, 28,566*l.*; miscellaneous, including conveyance of mails in the Colonies, under the postal direction of the postmaster-general, the conveyance of the mails through Egypt, clothing for letter-carriers and guards, rents, taxes, law expenses, &c., 109,672*l.*

The business of the Money-order Office has also greatly increased; and, while it affords great advantages to the public in the transmission of small sums, has become a source of profit to the establishment. In 1857 the total number of money-orders issued in the United Kingdom was 6,389,702, to the amount of 12,180,272*l.*, an increase of 3¼ per cent. over 1856. Of the total number 5,417,203 orders, to the amount of 10,410,863*l.*, were issued in England; 459,625, to the amount of 818,537*l.*, in Ireland; and 512,874, to the amount of 950,872*l.*, in Scotland. The commission gave a profit, after deducting expenses, in England, of 23,613*l.*, and in Scotland of 1180*l.*; in Ireland there was a loss of 618*l.* The number of orders gives an average of 1 for every 4 persons in England, for every 6 in Scotland, and for every 14 in Ireland. Money-order offices have also been established at Malta and Gibraltar.

In 1855 some important improvements in matters of detail were introduced with great success. Country letters to London, or passing through London, were either sorted at the provincial offices or during their transmission, and this expedited the morning delivery in London by nearly an hour. Pillar letter-boxes were also erected in London, Edinburgh, Dublin; they have been since extended to most considerable places in the United Kingdom, and of these there are now 703. London was also divided into 10 districts, each having a district head-office, by which letters posted in a district for a neighbouring place, are spared the loss of time incurred by transmission to the chief office, and thus a more speedy delivery is attained; and this division also greatly facilitates the sorting of inland letters; but to effect this the initial letters of East Central, West Central, North, East, South, West, North East, North West, South East, and South West, must be distinctly placed at the end of the direction after 'London.' A book, price one penny, has been published, distinguishing all the streets and places within the different districts.

Nearly every town of any size throughout the three kingdoms has at least two deliveries a day from and to its metropolis and the larger provincial towns. In 1856 there were 52 such towns added to the list; for instance, in 1858 Manchester has four mail communications daily with London, Birmingham, Oldham, Bradford, Ashton-under-Lyne, Halifax, Sheffield, Wakefield, and Cheetham; seven with Liverpool; and five with Leeds, Stockport, Rochdale, and Bolton; twenty-nine mails are despatched from, and the same number received at, the Manchester post office every day. In 1856 the mails within the United Kingdom were conveyed daily over 129,480 miles of way; of this 30,172 miles are by railway at an average rate of 9½*d.* a mile; 32,997 by coaches, mail-carts, &c., at an average of 2½*d.* a mile; 63,432 by carriers on foot, at an average rate of 1½*d.* a mile; and 2879 miles by packets and boats between different places in the United Kingdom, at rates varying from 5*s.* 6½*d.* a mile to ½*d.*

The total number of persons engaged in the service of the Post-Office for the United Kingdom was 23,731 on December 31, 1857, including 1 postmaster-general; 5 secretaries, assistant secretaries, and secretaries for Ireland and Scotland; 15 surveyors; 19 other superior officers, such as heads of departments, chief clerks in the Metropolitan offices, &c.; 11,101 postmasters; 1610 clerks (exclusive of some employed temporarily); 204 guards; 10,427 letter-carriers, messengers, &c.; 8 marine officers; 125 postmasters, clerks, &c., in the Colonies; and 51 agents in foreign countries. Of this number about 2000 are attached to the London staff, and (including this number) about 3200 are employed in the London district.

The third annual report of the postmaster-general for 1856, in an Appendix, states that "in no part of the United Kingdom has more been done for the welfare of the people by the use of railways for carrying mails and by the penny postage system than in Ireland." In 1784 there were posts six days a week on only four lines of road; letters to all other places being conveyed only twice or thrice a week. Now there are daily posts to almost every village, and but one important town that has not two daily mails both with London and Dublin. In 1784 the whole expense of the office in Ireland was 15,000*l.*, including salaries of provincial postmasters and the conveyance of mails. Out of this, 5500*l.* only was allotted to the provinces; the sum now (1856) allotted for the like service is 134,000*l.*, divided thus:—conveyance of mails by railways, 65,505*l.*; by coaches and cars, 27,168*l.*; by foot-messengers, 10,334*l.*; and salaries and wages paid in provincial offices, 31,122*l.* In 1829 the cost of conveying the mail by mail-coaches was nearly four times the average rate of England; this excess has now disappeared, and in 1856 the average rate per mile was for England 2½*d.*, for Scotland 3*d.*, and for Ireland 2*d.*

The same paper pays the following just tribute to the exertions of Mr. Bianconi for the improvement of intercommunication in Ireland, particularly in reference to the transmission of letters:—

"In 1815, Mr. Bianconi first carried his Majesty's mails in Ireland; but he did so for many years without any contract. He commenced in the county Tipperary, between Clonmel and Cahir; and he then made his own bargain with the postmaster, as he did for many subsequent years. The postmaster usually retained one moiety of the sum allowed, as his own perquisite, and Mr. Bianconi performed the work for the remainder. What Mr. Bianconi received was thus very small; and he could not and would not therefore run at any hours inconvenient to his passenger traffic, or faster than was convenient to him. From 1830, when the English and Irish offices were amalgamated under the Duke of Richmond, the public, as Mr. Bianconi says, got something like fair play; and he and others were allowed to carry the mails by direct contract with the Post-Office. From that time till 1848 Mr. Bianconi continued to increase his establishment; and in the latter year he had 1,400 horses, and daily covered 3,800 miles. The opening of railways has, however, so greatly interfered with this traffic, as to expel his cars from all the main lines. But Mr. Bianconi has met the changes of the times in a resolute spirit. He has always been ready at a moment's notice to move his horses, cars, and men to any district, however remote, where any chance of business might show itself; and now, in the winter of 1856-57, when nearly the whole of that district in which he was working ten years since has been occupied by railways, he still daily covers 2250 miles, and is the owner of about 1000 horses; working in the four provinces, from the town of Wexford in the south-east, to the mountains of Donegal in the north-west. Mr. Bianconi has done the State good service. By birth he is, as is well known, an Italian, but he is now naturalised, and England, as well as Ireland, should be ready to acknowledge his merits. It may perhaps be said that no living man has worked more than he has for the benefit of the sister kingdom."

The amount of postage collected at different towns in the United Kingdom (including the postage-stamps sold by the Post-Office and by the Board of Inland Revenue) shows some curious results. London, of course, through which passes nearly one-half of the total correspondence of the kingdom, attains a great predominance, the amount in 1857 being 833,952*l.*; Liverpool, with 255,000 inhabitants, contributes 104,865*l.*; while Manchester, with 316,000 inhabitants, only contributes 89,765*l.*; and Birmingham, with 232,000 inhabitants, but 42,107*l.* Bristol, with about 100,000 inhabitants (including Bedminster), furnishes 31,264*l.*; and Leeds with 172,000 inhabitants, only 23,844*l.*; and Sheffield, with 135,000 inhabitants, no more than 16,565*l.* In Ireland the contributions are more in accordance with the size of the towns:—Dublin contributes 60,391*l.*; Belfast, 15,547*l.*; Cork, 11,915*l.*; and Limerick, 7115*l.* In Scotland:—Edinburgh, with 160,000 inhabitants, contributes 59,177*l.*; and Glasgow, with 358,000 inhabitants, only 68,877*l.* It must be recollected, however, that in many cases some towns are used as a sort of depôt, from whence postage-stamps are distributed over a wider district than others.

POTATO, SWEET. [BATATAS.]

POTTINGER, RIGHT HON. SIR HENRY, BART., G.C.B., was born in 1789, of an English family which had been long settled in Ireland. He was the fifth son of the late Edward Curwen Pottinger, Esq., of Mount Pottinger, county Down, by Anne, daughter of Robert Gordon, Esq., of Florida Manor, in the same county. He went to India as a cadet in 1804. At an early age he attracted the attention of the civil and military authorities of that country by his energy and administrative capacity, as well as his ready store of information bearing on his profession. Rising by gradual steps, he became successively judge and collector at Ahmednugger in the Deccan, political resident at Cutch, and president of the regency of Scinde. For his services in these capacities he was raised to a baronetcy, when General Keane was rewarded with a peerage after the Afghanistan campaign in 1839. He had scarcely returned to England when war broke out between England and China on account of differences relating to the opium trade. In this emergency he was sent out to China as ambassador extraordinary and minister plenipotentiary, and superintendent of the British trade in that country; and in this two-fold capacity he took very decisive measures. Having warned the British residents against the perfidy of Chinese officials, he proceeded to concert his measures with Admiral Sir W. Parker, the result of which was the capture of Amoy. The effect of this step was to throw open to English vessels a commerce with upwards of 300,000,000 natives, and the terms of the treaty were thought to be such as to afford a guarantee against the necessity of the repetition of offensive measures. For these services Sir Henry Pottinger was made a Knight Grand Cross of the Order of the Bath, and governor and commander-in-chief of the island of Hong Kong. Having returned to England in 1844, he was sworn a member of the Privy Council, and a pension of 1500*l.* a year was settled on him by a vote of the House of Commons. In 1846 he was again sent upon active service as successor to Sir Benjamin Maitland in the governorship of the Cape of Good Hope; this office he held until the September of the following year, when he returned to India as governor and commander-in-chief of the presidency of Madras. He returned to England in 1854, having previously been raised to the local rank of lieutenant-general in India. He died at Malta, on the 18th of March 1856, leaving behind him the reputation of an able and upright administrator of public affairs, and an officer who had rendered great services to his country.

POTTON. [BEDFORDSHIRE.]

PRADIER, JAMES, was born at Geneva in May 1792. While quite young he was sent to Paris, and placed in the studio of the popular sculptor Lemot. His first public success was gained in 1812, when, through a technical informality, his model being pronounced unqualified to compete for the first prize of the Academy, an extra gold medal was awarded to him for its unusual excellence. The next year he obtained for his group of Philoctetes the first prize, and with it the privilege of proceeding as Academy student to Rome. In that city he remained five years, and produced during that time several original works. Although he is said to have there diligently studied the antique and formed his own style upon it, there can be little doubt that the influence of Canova was much more powerful, and that the softness, finish, and elegance, for which that eminent sculptor was so celebrated, were what Pradier most anxiously endeavoured to realise; but whilst in these qualities he at the least rivalled Canova, he went far beyond him in that tendency to the sensuous and the voluptuous which was no less decidedly characteristic of the great Italian. The countrymen of Pradier are enthusiastic in their admiration of his nude forms so "delicatement voluptueuses;" but to a colder English critic the delicacy often seems wanting, and while he cannot but admire the exquisite modelling of the form, he is constrained to turn with regret from what seems the perverse meretriciousness of the sentiment.

From his return to France in 1819 down to his death, M. Pradier enjoyed a career of unbroken Parisian popularity; and during his later years, while all admitted him to be one of the most accomplished, by many he was regarded as the greatest of living French sculptors. Of the works by which he achieved and maintained his high position the following are some of the more celebrated—the dates are those of the years in which they appeared at the Exposition:—'Bacchante and Centaur,' 1819, now in the Museum at Rouen; 'The Children of Niobe,' 1822; 'Psyche,' 1824; 'The Three Graces,' 1831, now at Versailles; 'Venus and Love,' 1836; 'An Odalisque,' 1841; 'Cassandra,' 1843; 'Phryne,' 1845, well known in this country from having been placed in the Great Exhibition of 1851; 'Sappho,' 1848, a favourite subject with him—there was a statue of Sappho in the Exposition the year of his death; 'Spring,' 1849: Hebes, Amazons, Pandoras (one of these is in the possession of Queen Victoria), Satyrs and Bacchantes, Venuses and the like, make up the list of that class of subjects in which he chiefly excelled, and which was most characteristic of his chisel. He also produced a large number of religious pieces, and many of them of considerable size, but out of France they have found few admirers. Among these are a colossal figure of 'Christ on the Cross,' executed for Prince Demidoff; a 'Pietà,' executed in 1847, and now at Toulon; a 'Marriage of the Virgin' for the Madelaine, four 'Apostles,' a 'Virgin' for the cathedral of Avignon, &c. Of portrait-statues he sculptured Gaston de Foix, Marshal Soult, General Damremont, Vendôme, Rousseau (for Geneva), Jouffroy (for Besançon), the Duc d'Orleans, &c. He also executed busts of Louis XVIII., Charles X., and other persons distinguished by their rank or social celebrity. Among his other works may be mentioned the Tomb of Napoleon I., some fountains, vases, &c. He likewise modelled numerous small statues of a very meretricious character.

Pradier was made a Chevalier of the Legion of Honour in 1822. In 1827 he was elected Member of the Institute on the death of Lemot. He died somewhat suddenly on the 5th of June 1852. There are two or three casts after Pradier among the modern sculptures in the Crystal Palace at Sydenham.

PRAED, WINTHROP MACKWORTH, son of Mr. Sergeant Praed, was born in 1802. In 1820 a monthly magazine appeared, entitled 'The Etonian.' George Canning, while at Eton, wrote some clever essays in 'The Microcosm.' Rennell and the nephew of Canning (the present Lord Stratford de Redcliffe) subsequently produced 'The Miniature.' These publications were regarded as exhibitions of youthful talent, were admired in a small circle, and forgotten. But 'The Etonian' aimed at something higher than school-boy essays; it paid slight regard to the 'microcosm' of Eton, and presented no 'miniature' of its scholastic life; it gave vivid pictures of general society; it was bright with wit and poetry, with fun and satire. There was little of the boyish about it but the freshness of boyhood. The principal writer in 'The Etonian' was Winthrop Mackworth Praed. From Eton he went to Trinity College, Cambridge. His career at the university corresponded with the expectations that had been formed of his brilliant talents. In 1822 he was a Browne's Medallist both for Greek ode and epigrams; in 1823, for Greek ode; in 1824, for epigrams. In 1823 he obtained the Chancellor's prize for an English poem, 'Australia;' and in 1824 the same prize for 'Athens.' He was one of the chief speakers in the Union—the famous Cambridge Debating Society—his most formidable rival being Thomas Babington Macaulay. 'The Etonian' was printed at the office of Mr. Knight, then editor of the 'Windsor Newspaper,' and the intimacy that consequently arose led to the publication of 'Knight's Quarterly Magazine' in 1823, to which Mr. Praed was one of the chief contributors, both in prose and verse. His poems are amongst the most original in our language; their wit and pathos are as remarkable as their finished elegance. A collection of some of these poems was published at New York in 1844, but it is far from complete; and those who desire that justice should be done to the memory of one of the most remarkable writers of his time, regret that these works, so often announced, should be so unaccountably delayed.

Mr. Praed took his degree of B.A. in 1825. In 1829 he was called to the Bar; and in 1830 and 1831 was returned to Parliament for St. Germans. In the earnest and protracted conflicts that preceded the passing of the Reform Bill, he took a decided part in opposition to the Reformers. His speeches, as reported, exhibit a readiness of debating power rather than the flashes of wit which were expected from him. He was a most ardent opposer of the Whig administration, though we can trace in him a generosity of feeling and a hatred of mere party calumny, which was to be expected from the nobility of his nature. In the election of 1832 he unsuccessfully contested St. Ives; but in 1835 he was returned to Parliament for Great Yarmouth. In that year he married. During a short time he was Secretary to the Board of Control. He was subsequently member for Aylesbury, was Recorder of Barnstaple, and Deputy High-Steward for the University of Cambridge. Had Mr. Praed's life been longer spared, there can be little doubt that some of the most important offices of the state would have been within his reach; and his contributions to literature, like those of his friend Macaulay, might have carried forward the promise of his youth into new fields of excellence. He died on the 15th of July 1839, in his thirty-seventh year.

PRASCOLITE. [MINERALOGY, S. 1.]

PRASILITE. [MINERALOGY, S. 1.]

PREROGATIVE COURT. One effect of the transfer of the jurisdiction of all the Ecclesiastical Courts to the Court of Probate [PROBATE, COURT OF, S. 2], is that the doctrine of *bona notabilia* has ceased to exist. This court, whose jurisdiction arose from the possession of *bona notabilia* by the deceased person in two dioceses, has consequently, although without formal abolition, altogether disappeared from our judicial system.

PRESCOT. [LANCASHIRE.]

PRESCOTT. [CANADA, S. 2.]

PRICE, REV. THOMAS, one of the most distinguished Welsh scholars of his age, was born on the 2nd of October 1787, at Pencaerelin, in the parish of Llanafan Fawr, near Builth, in Brecknockshire. His father, the Rev. Rice Price, had originally been a stonemason, but having at the age of seventeen formed an attachment to Mary Bower, the descendant of a long line of clergymen, had acquired by incessant diligence and frugality the means of attending the college-school at Brecknock, and finally obtained ordination from the Bishop of St. Davids, and in 1784 the hand he sought, after a courtship of twenty years. He was so fortunate as afterwards to be presented to three livings, but his income, like that of some other Welsh pluralists, was never believed to exceed fifty pounds a year. He had two sons, both of whom were brought up to the church; the elder taking his degree at Oxford, while the second, Thomas, was obliged to finish his studies at the college of Brecknock. Welsh was the language the two boys heard constantly in the family, English they acquired at their second school, the elements of Latin and Greek were learned subsequently, and from some French officers, who were prisoners of war at Brecknock, Thomas acquired an excellent knowledge of

French. In 1812 he received holy orders, and in 1825, after performing for thirteen years the duties of various curacies near Crickhowel, he was appointed to the vicarage of Cwmdu. This was his last preferment. The rest of his life was passed in his professional labours, and in a great variety of voluntary pursuits. Mr. Price carved in wood, modelled in wax and cork, etched with some skill, could play on the Welsh harp by ear, and had the honour of presenting a harp from his own design to the Queen at Buckingham Palace in 1843. He made a great number of drawings, some of which were engraved as early as 1809, in his friend Theophilus Jones's 'History of Brecknockshire.' He was a great promoter of the Eisteddfods, or meetings for the cultivation of Welsh poetry, literature, and music, and frequently bore off the prizes. He was looked up to by most of his countrymen with enthusiastic admiration as an accomplished champion of his country's language and literature. His health began to fail somewhat early, and he died at Cwmdu on the 7th of November 1848.

The best of his English works are collected in the 'Literary Remains of the Rev. Thomas Price, with a Memoir of his Life by Jane Williams, Ysgafell,' 2 vols, 8vo, Llandovery, 1854-55. The first volume contains an account of a 'Tour through Brittany,' made in the summer of 1829, written in a lively and agreeable style, and peculiarly interesting as containing the observations of one familiar with the language and literature of Wales on the kindred language and literature of Brittany. 'An Essay on the Comparative Merits of the Remains of Ancient Literature in the Welsh, Irish, and Gaelic Languages;' 'An Essay on the Influence which the Welsh Traditions have had on the Literature of Europe;' 'A Critical Essay on the Language and Literature of Wales from the time of Gruffydd ap Cynan and Meilyr (in the eleventh century) to that of Sir Gruffydd Llwyd and Gwilym Ddu' (in the fourteenth), make up the remainder of the first volume. The second is entirely occupied with Miss Williams's memoir, which is enlivened with some interesting correspondence, and presents the fullest picture that has yet been drawn of a Welsh literary life. By far the greater part of Mr. Price's literary labours were in his native language: he was a contributor to fifteen Welsh periodicals, for one or the other of which he made it a rule to write an article once a month, and under such a variety of signatures, that it would now be impracticable to form a collection of the whole. His favourite signature however was 'Carnhuanawc' ('Man of the Sunny Mound'), which was familiarly known to every magazine-reader in Wales. His great work in Welsh was the 'Hanes Cymru a chenedl y Cymry o'r Cynoesoedd hyd at Farwolaeth Llewelyn ap Gruffydd' ('History of Wales and the Welsh Nation from the Early Ages to the Death of Llewelyn ap Gruffydd'), when the country was united with England. It was published in numbers, sometimes with long intervals, the first of the fourteen of which it consisted appearing in 1836 and the last in 1842, the whole forming a volume of about 800 pages. It has been pronounced by competent judges the best history of Wales extant in any language, and it is somewhat singular that no translation has yet appeared in English. The omission may serve in some degree to justify the complaint which Mr. Price was accustomed to make "of the extraordinary neglect of Welsh literature and total ignorance of British History prevailing in England, and the consequent contempt evinced by the English for everything relating to Wales, in contradistinction to the high appreciation of Welsh literature shown on the Continent, especially in Germany, and the superior knowledge and desire for information on all subjects connected with the principality by German scholars."

On the subject of his native language Mr. Price was so enthusiastic that his feelings sometimes outran his judgment. At the Eisteddfod at Welshpool in 1824, he exclaims, in an oration in the Welsh language, "We are told our language cannot last; but let them inform us what language will last, and we will instantly adopt it. When we are chafed and goaded to it—when we are taunted with the extinction of our native tongue—shall we not reply! shall we not say that we likewise perceive the seeds of decay in the English? Who can tell but that when the present English sleeps with the Latin, the Saxon, and the Norman-French, the accents of our mountain tongue may yet rouse some remains of the Britons to patriotism and glory." Most Englishmen, we believe, who have urged the adoption of the English language in Wales, have supported the measure not on the ground of its supposed superior duration in the future, but of its evident superior usefulness in the present.

A notion of Mr. Price's, to which he appears to have attached considerable importance, was, after communicating it to the 'Athenæum' and the 'Allgemeine Zeitung,' made the subject of a separate publication, 'The Geographical Progress of Empire and Civilisation' (Llandovery, 1847-48). Every one is familiar with the idea of the 'westward progress of empire,' which the Americans are so fond of quoting from Bishop Berkeley's fine stanzas; but Mr. Price fancied he had made a discovery, "that the average rate of progress corresponds with that of the retrogradation of the equinoctial points, which is 50 seconds and a fraction in a year, or a degree in 72 years, something short of a British mile, subject to periodical retardations and accelerations." "The focus, or pole, was in 1847," according to his speculations, "located in the northern portion of this island, near the Frith of Forth in Scotland, moving in the direction of the Solway Frith at the rate of four miles a year." On the whole, Mr. Price's works are more remarkable for vigour, animation, and learning, than for sound judgment.

PRICHARD, JAMES COWLES, an eminent ethnologist, was born at Ross in Herefordshire in the year 1785. He was educated for the medical profession, and took his degree of M.D. at Edinburgh. He chose for the subject of his inaugural thesis the physical history of mankind. This seems to have determined the current of his thoughts throughout life, for he subsequently became distinguished as one of the most laborious ethnologists of his day. He commenced the practice of his profession at Bristol, and in 1810 was appointed physician to the Clifton Dispensary and St. Peter's Hospital. He also had a private dispensary, to which he devoted considerable attention. Although much engaged with his professional duties, he still kept the subject of his inaugural thesis before his mind, and in 1813 he published his 'Researches into the Physical History of Mankind.' This work, which was originally published in one volume, reached a second edition in two volumes in 1826, and a third edition was finished in 1849, extending to five volumes. From the period of the first publication of this work it took the first rank amongst ethnological works, and the last edition is undoubtedly the most important systematic work that has hitherto appeared upon the physical history of man. Dr. Prichard, whilst an anatomist and physiologist, was one of the first to avail himself of the study of philology as a means of arriving at the history of the various races of men. His contributions to ethnology took a variety of forms. In 1832 he read an elaborate paper to the British Association, then assembled in Bristol, 'On the Application of Philological and Physical Researches to the History of the Human Species.' In 1843 he published a more popular resumé of his labours on the physical history of man under the title of 'The Natural History of Man.' A second edition of this work appeared in 1845, and it has been translated into the French and German languages. He has likewise written many papers and minor works on the same subject. In the twelfth volume of the proceedings of the Zoological Society is a paper 'On the Crania of the Laplanders and Finlanders.' He also published a work 'On the Eastern Origin of the Celtic Language,' in which he pointed out the relations between the Celtic language and the great group of Indo-Germanic languages derived from the east. Another work also arose out of his ethnological researches, which was entitled an 'Analysis of Egyptian Mythology.'

Although thus occupied with a great and important department of science, Dr. Prichard was not inattentive to professional studies. His ethnological and philological reading naturally led him to contemplate man psychologically, and we find him addressing himself successfully to the study of the nervous system, and the results of its deranged condition on the mind of man. In 1822 he published a work on 'The Diseases of the Nervous System.' This was followed by a 'Treatise on Insanity.' In this work he displayed great power in analysing mental phenomena, and speedily became recognised as one of the first authorities on the subject of mental derangement. He was appointed visiting physician to the Gloucestershire Lunatic Asylum. He subsequently published a work 'On the Different Forms of Insanity in Relation to Jurisprudence.' His labours connected with insanity led to his appointment as one of the Commissioners of Lunacy in 1845. On this occasion he removed from Bristol to London, where he continued to reside till his death. Besides the works already mentioned, Dr. Prichard enlarged an essay which he read before the Philosophical Society of Bristol into a work entitled 'A Review of the Doctrine of a Vital Principle.' He was also an extensive contributor to the 'Cyclopædia of Practical Medicine.' He was made M.D. of Oxford on the occasion of the installation of the Duke of Wellington as chancellor of that university. He was president during one session of the Provincial Medical and Surgical Association, now the Bristol Medical Association. He was president of the Ethnological Society, and published an anniversary address delivered before that society. He was a Fellow of the Royal Society of London, and of many other scientific societies in this country and on the Continent. He died in London, December 22, 1848, of an attack of rheumatism complicated with pericarditis.

PRIESSNITZ, VINCENZ, the founder of Hydropathy, or Water-Cure (Wasserheilkunde), was born on the 4th of October 1799, at Gräfenberg, in Austrian Silesia, where his father was a farmer. He received only a small amount of ordinary education at the town-school of Freiwaldau; for his elder brother having died, and his father become blind, he was obliged at an early age to assist his mother in managing and working the farm. He continued in this employment several years; but one day, when he was taking some sacks of barley to the fields for sowing, the horse became restive, seized Priessnitz with his teeth, threw him down, and dragging the loaded cart over him, broke two of his ribs. A medical man, after examining him, expressed an opinion that the injuries sustained were so great that, even if he recovered, he would be a cripple for life. Priessnitz however, by placing his body in a certain position, which allowed him to expand his chest to the utmost extent, replaced his ribs, and by the free use of cold water kept down inflammation; so that in a short time he was enabled to return to his work. The process of cure by cold water, which had been so beneficial in his own case, was successfully used in other cases of inflammatory disorder. His reputation gradually extended; he studied medical books, formed a sort of system of medical treatment, established cold-water baths at Gräfenberg, and about the year 1826 patients began to resort to him from distant parts of Germany. In 1829 his system may be said to have been in full operation, and from the first of January of that year till the 1st of January 1844 the number of his patients had amounted to 8573. The total number of his patients in 1843 was 1050, and the number of both sexes and all ages generally present at Gräfenberg was about 360. No particle of medicine, vegetable or mineral, no tonic, no stimulant, no emetic, no purgative, was ever administered in any form whatever. No bleeding, blistering or leeching was employed. Water variously applied, externally as well as internally, the process of sweating, fresh air, out-door exercise, plain diet, regulated clothing, early hours, and cheerful society, constituted the only remedies. This system continued in successful operation till the death of Priessnitz, which occurred on the 28th of November 1851, at Gräfenberg. The disease of which he died is stated to have been dropsy on the chest. Hydropathic establishments are now in operation in various places on the continent of Europe, in the United Kingdom of Great Britain and Ireland, and on the continent of America.

Priessnitz did not write any medical work himself, but accounts of his system have been published in German and English. Captain R. T. Claridge in 1849 published 'The Water-Cure, or Hydropathy, as practised by Vincent Priessnitz, at Græfenberg, Silesia, Austria,' 8vo, London; and 'Every Man his own Doctor: the Cold Water, Tepid Water, and Friction Cures, as applicable to every Disease to which the Human Frame is subject, and also to the Cure of Diseases in Horses and Cattle,' 8vo, London.

(*Vincenz Priessnitz, eine Lebensbeschreibung*, von Dr. J. E. M. Selinger, 12mo, Vienna, 1852.)

PRINCE'S RISBOROUGH. [BUCKINGHAMSHIRE.]

PRINTING, INVENTIONS IN. Since our account of Cowper and Applegath's machine for printing 'The Times' newspaper [PRINTING MACHINE, vol. xix. p. 18], a number of improvements have been introduced. Steam power has also been applied to flat machines, which are a modification of the Stanhope press, in which the table, with a form of type at each end, moves backward and forward, under the platen, which gives the impression to one form while the other is being inked by the rollers. This description of press was for a time supposed to be best adapted for the finer sorts of book-work; but the process was very much slower, and the belief in their superiority of work was not universally admitted. Cylindrical machines were frequently used, not only for newspapers, where rapidity of production was required, but for books containing engravings on wood, where excellence of workmanship was demanded. Several of these machines were exhibited at the Paris Universal Exhibition in 1855, the French printers having devoted much attention to the improvement of cylindrical machines. In his report as juryman on 'Class XXVI.—Drawing and Modelling, Letter-press and Copper-plate Printing, and Photography' Mr. Charles Knight says—"In the Paris Exhibition several machines, offering the advantage of more perfect inking, and of preventing what is called 'setting-off' [that is, the sheet becoming blurred by the moist ink being pressed upon], showed that the attention of the French printers had been more directed, than with us, to the practicability of producing the finest work by the machine instead of by the hand-press. Some of our artists, who have watched the dependence of the wood-engraver on the printer, have long been of opinion that the equal operation of the cylinder is superior to the irregular force of the hand-press. But the heads of our printing establishments have generally considered that the cylindrical machine was only calculated to save labour, and not to produce fine work. Our machine-makers have, therefore, made various labour-saving machines upon the principle of flat-pressure; which, as it is the principle of the hand-press, at which the most expensive work was produced, was thought to be the only principle for a more perfect machine. The French, on the contrary, have turned their attention to the perfection of the cylindrical machine, knowing that it had natural advantages which could not be obtained by flat-pressure. When a sheet of paper is brought into contact with an inked surface of types, by being laid flat upon that surface, a large body of air has to be expelled by the heavy platen, operating at once upon the whole surface. The cylinder, on the contrary, touches the type, and produces the impression on the paper, line by line, and there is no atmospheric resistance to be overcome. The French printers have, therefore, sought for the improvement of the cylindrical machine. The single cylinder-machine of M. Dutartre produces work which cannot be excelled by the most careful operations of the press. It prints only on one side [the process having to be repeated to 'perfect' the sheet]; and the form passes under a double set of inking-rollers, at each end of the table, before it receives the impression. In the double-cylinder machine of the same inventor, a waste sheet of paper is interposed so as to prevent setting-off; and thus both sides of the paper may be printed at once, without leaving that blurred impression of one side which so commonly disfigures machine-printing. The French printers now do their finest work by the cylindrical machine, and much of their common work by the hand-press." The report goes on to say that, on the whole, the average work of the French printers is superior to that of the English. It attributes this, partly to the better quality of their paper, which is farther improved by being passed through powerful rollers, thus creating a more even surface, partly by using dry paper instead of wet, partly by the use of silk instead of parchment for tympans in their hand-presses and flat-pressure machines; and other little niceties, the results of long practice based upon scientific investigation. M. Dutartre's double-cylinder machine has been introduced into England; and a patent has been taken out for an improvement in the manufacture of paper, by which the necessity of wetting it to enable it to receive the ink will be removed; we believe, as far as this experiment has been carried out, that it has been successful.

M. Dutartre also exhibited a machine for printing in two colours—for which he received the silver medal; others were exhibited for printing newspapers, but their rapidity was not equal to ours as it appears from the report, 6000 sheets perfect being the highest number stated, but several ingenious adaptations and movements are noticed in Mr. Fairbairn's report.

In England, however, the demands of the newspaper press had not been met by even such improved machines as above described. The 'Times' could not be produced sufficiently early at the rate of 5000 or 6000 an hour. Mr. Applegath again employed his inventive faculty and produced a printing-machine on the vertical cylindrical system, which could produce, on one side, from 10,000 to 13,000 copies an hour. With two such machines the 'Times' has been worked since 1848; and it has been used for the production of the

'London Illnstrated News,' and other newspapers having a large circulation.

In this machine a central drum 200 inches in circumference, or 64 inches in diameter, turns on a vertical axis. We copy the following description from C. Tomlinson's 'Cyclopædia of Useful Arts and Mannfactures.' "The inking-table and the columns of type are secured to the surface of this drnm; the colnmns of type are placed vertically, not conforming to the curve of the drum. This is contrived in the following manner. A slab of iron is curved on its under side, so as to fit the large cylinder, while its upper surface is fitted into facets, or flat parts, corresponding in width and number to the width and number of the columns of the newspaper; between each column there is a strip of steel, with a thin edge, to print the 'rule,' the body of this strip being wedge-shaped, so as to fill up the angular space left between the columns of the type, and to press the type together sideways, or in the direction of the lines; the type is pressed together in the other direction by means of screws, and is firmly held together. The surface of the type thns forms a portion of a polygon, as already noticed; and the regularity of the impression is obtained by pasting slips of paper on the paper cylinder. The large central drum is surrounded by eight cylinders, each about 13 inches in diameter, also with vertical axes. They are covered with cloth, and upon them the paper to be printed is carried by means of tapes. Each of these cylinders is so connected with the central drum, by means of toothed wheels, that the surface of each must move with the same velocity as the surface of the drum. It will thus be evident that if the type on the drum be inked, and each of the cylinders be properly supplied with a sheet of paper, a single revolution of the drnm will cause the eight cylinders to revolve also, and produce an impression on one side of each of the sheets of paper. But for this purpose, it is necessary that the type be inked eight times during one revolution of the drum. This is accomplished by means of eight sets of inking rollers—one for each paper cylinder. The ink is held in a vertical reservoir (supplied from above), formed of a ductor-roller, against which rests the two straight edges connected at the back, so as to prevent the ink running out. It is conveyed from the ductor-roller by one of the inking rollers in the following manner:—As the inking-table on the revolving drum passes the ductor-roller, it receives from it a coating of ink, and then coming immediately in contact with the inking rollers, it inks them, the types next follow and receive from the inking rollers their coating of ink, and the drum still revolving brings the inked type into contact with the paper cylinders, and the sheet is printed. It must not be forgotten, as one of the distinguishing featnres of this machine, that the various processes which have just been enumerated for one set of inking rollers, and one paper cylinder, are repeated eight times for every single revolution of the central drum, so that in this period eight sheets are printed, and turned ont of the machine. For this purpose it is necessary to supply the eight cylinders each with a sheet of paper. Over each cylinder is a sloping desk, upon which a number of sheets of white paper are placed. The layer-on stands by the side of this desk, and pushes forward the paper a sheet at a time towards the tape-fingers of the machine. These tapes seize it and draw it down in a vertical direction, between tapes, in the eight vertical frames, until its vertical edges correspond with the position of the form of type on the drum. When in this position its vertical motion is arrested for a moment, it then moves horizontally, and is carried towards the printing cylinder by the tapes. Passing round this cylinder it is instantly printed. It is then conveyed horizontally, by means of tapes, to the other side of the frame, and is moved along to another desk, where the taker-off pnlls it down. As soon as one sheet is thus disposed of, accommodation is made for another; and as each layer-on delivers to the machine two sheets every five seconds, sixteen sheets are thns printed in that brief space, and this is continued for any length of time, supposing no accident occurs, such as a sheet going wrong, in which case it is the duty of the taker-off to pnll a bell-handle, and the machine is instantly stopped by the engine-man. As the type-form on the central drum moves at the rate of 70 inches per second, and the paper to be printed moves at the same rate, if by any error in the delivery and motion of a sheet of paper it arrive at the printing-cylinder 1-70th of a second too soon or too late, the relative position of the colnmns on one side as compared with those on the other side of the paper will be ont of register by 1-70th of 70 inches, viz., one inch; in which case the edge of the printed matter on one side will be an inch nearer to the edge of the paper than on the other side. . . . . All the layer-on has to do is, to draw forward the sheets so as always to have the edge of one ready for the machine to take in. If the steam-engine which works the machine be pnt on a greater speed, the central drum, and all the attendant apparatus, would work with greater rapidity; and such a speed might easily be obtained as to render it impossible for the layers-on to present the paper fast enough to satisfy the improved appetite of the machine; but in any case the machine wonld not take in the sheets *as* the layers-on chose to present them; but only at those periods, rapidly recurring though they be, which are provided by the peculiar functions of the machine."

This machine, with certain modifications to adapt it for printing wood-cuts of a large size, has been nsed for the 'Illustrated News,' and was shown at work during the Exhibition of 1851; it has also been adopted in other instances where rapidity of production was necessary. Another machine, likewise on the vertical principle, has been invented by the Messrs. Hoe, of America, and several of these have been brought into use in London.

The inventive faculty has also been applied to methods for facilitating the arrangement of the type, thongh with far less success. In the Report on Printing, &c., of the Paris Exhibition of 1855, Mr. Knight says:—"During the last twenty years there have been various attempts to prodnce a machine that will, to some extent, snpersede that portion of manual labour in printing which is called 'composition.' Without attempting to describe the various contrivances by which a more rapid method of arranging moveable types was to be effected than by the ordinary method, it may be sufficient to say that by keys, like those of a pianoforte, some force might be applied to remove a single letter from its proper receptacle, and arrange it in a combination of words and sentences. In the ordinary method, the varions types which are necessary for the nsual language lie in separate cells before the compositor, those most in use being nearest his hand. In his left hand he holds a little iron frame, in which, picking up letter by letter, he forms words, pntting spaces between each word. As he approaches the end of his line, he finds that the next word is too long to come within the line, and he therefore divides it by a hyphen, or carries it over to the next line. He then spaces ont the words, so as to make the line fit closely, but not tightly. Now it is evident that if the most perfect instrument conld be made to pick np the letters and spaces, the intelligence of the workman is absolutely necessary to make this 'justification' as it is called of each line. Hence every composing-machine must be an imperfect instrument.

"But, nevertheless, it may in some cases be of the utmost importance to have the type picked up, and placed in order more rapidly than by the fingers. In a trial of comparative expedition between the logographic system of Major Beniowski, and the common mode (in which trial Mr. Rennie was referee), it was fonnd that a compositor at Mr. Clay's printing-office picked np and 'justified' 6000 letters in two hours and twenty minutes. He distributed or returned the same when used, to the case in fifty-one minutes. There were several composing and distributing machines in the French Exhibition, but the most remarkable one, and that which appears to me, as it appeared to M. Didot and other competent judges, to approach nearer than any other invention to the accomplishing of this long sought for object, is thus entitled—'Machine à composer et mettre bas pour l'usage de l'imprimerie, composée et execntée par Christian Sörensen.' It was stated that a Copenhagen newspaper, of which a copy was shown, had been printed for some time by this method. It would be impossible to convey an adequate notion of the details of this machine withont drawings. I will endeavour briefly to state the principle:—The types are of the usual thickness and height. In the centre of each type, in the front, is a deep nick of a dovetail shape, which fits upon a metal edge, so that the type cannot be displaced. But of 111 letters which are required in the fount, each letter has two, three, or four nicks cut at right angles, the nicks of no one letter being the same as another. A cylinder, which may be described as a large basin, has a nnmber of metal edges placed vertically in its sides, upon which the types without any regard to order, being the matter for distribution, are rapidly slid by the dovetail nick.

When the basin is filled, it is inverted upon a cylinder of corresponding size below. Upon the rim of this cylinder is a separate opening for the reception of each of the 111 letters, but no one opening is like another. The distributing and the composing go on at the same time. The compositor is seated; with a treddle he moves the upper cylinder, which, as it slowly revolves, finds in the lower cylinder, which is stationary, a fit place for every separate letter as it descends by its own gravity to the bottom of each metal edge. The *n* having two broad nicks, one about ½ of an inch from its top, the other at the same distance from its bottom, falls into the *n* opening, which having points corresponding, alone can admit it from its similarity of form, while the *u* having four nicks, two broad and two narrow, passes into its own division, and cannot be confused with the *n*.

"But whilst this process of distribution is steadily proceeding, without any care but to keep the upper cylinder occasionally supplied with new material for its operation, the process of composition is rapidly going on. The compositor sits before a compact little frame of keys, each key having a connecting wire for each division of the lower cylinder. He strikes a key and the lower letter is instantly detached and falls into a funnel-shaped receptacle below, where, without being inverted in any way, it runs into a groove, and arranges itself in its proper order, in the line of its fellows. This is a long line of several feet. By an ingenious contrivance each such line is passed on one side, as it is completed, to another workman, who takes up as many letters as will fill the due width of his page or column, and spaces out the words in the ordinary way. I saw 1000 letters thus placed in line in the short space of four minutes, and the spelling and punctuation appeared as correct as in most matter of common composition before it is read. When the necessary loss of time in refilling the cylinders, and through other hindrances, is taken into account, it was stated by the exhibitor that 50,000 types are set up and distributed each day. This gives a rate of about 6000 an hour, which is treble that of the ordinary compositor's rate."

The interest connected with the question of 'Types for the Blind,' to which considerable impetus was given by the Society of Arts for Scotland at Edinburgh, who offered their gold medal for the best alphabet for the blind, has tended greatly to bring about a change in the intellectual education of the blind. The publication of the article BLIND in the 'Penny Cyclopædia,' at a time when the minds of many were thus directed, and the strictures therein contained on the absence of intellectual training in most of the asylums, also rendered essential benefits on this point. Dr. S. G. Howe, of Boston in the United States, in 1833 contrived an alphabet, founded upon that of Haüy, of a very compact form, in which the New Testament was printed in 1834, and is now in general use in America. The late Mr. John Alston, the treasurer of the Glasgow Asylum, than whom no man connected with the blind deserves more honourable mention, contributed greatly to this educational movement. He saw that, by adopting any character more or less arbitrary, the evil would necessarily follow of isolating the blind by putting them in a position to require special teachers. He therefore adopted the plain Roman characters deprived of their small extremities—the *sans-serif* of type-founders; and, finding that it could be easily read, that it would also enable any seeing person who could read to be a teacher of the blind, be at once procured founts of type, and published several works in raised letters; the success of these for their special object established the pre-eminence of his alphabet. Having thus laboured for several years, he visited more than once the principal asylums for the blind in the kingdom. In his work 'Statements,' &c., published in 1846, he says, that after the introduction of his system, "I found a considerable improvement. Subsequently I visited the English institutions a third time, and found a very great number who could read with ease and intelligence; and I have reason to know that there are some hundreds reading these books, and that many families are in possession of the whole of the Bible in raised types: thus in a short time showing the sufficiency of the system placed before the public." It may be added, that Mr. Alston also brought out some beautiful embossed music and maps, and that be published the Old and New Testament in 19 vols., super-royal 4to. The paper used for these works is strongly sized, to retain the impression. In order to account for the great extent of the Bible, it must be borne in mind that the paper can only be printed on one side, and that the letters require to be of considerable size in order to be distinct to the touch. The printing is effected by a copper-plate press. The types being strongly relieved, and liable frequently to give way under the heavy pressure required, it was necessary to have them re-cast four times during the progress of the work. The whole of the works were completed within the walls of the Glasgow Asylum, a man and a boy acting as compositors, there being one pressman, and the ordinary teacher acting as corrector of the press. These books are now used in most of the British asylums for the blind, and also in America. The success which has attended Mr. Alston's exertions was a new assurance to the Society of Arts for Scotland that they had acted wisely in regarding the stenographic and all other arbitrary characters, as well as the angular modifications of the Roman alphabets, unfavourably.

An invention by Aloys Auer, of Vienna, called 'Naturselbstdrück,' deserves mention. By it impressions are taken from the natural objects themselves, and by an ingenious process brought into a form fitted for printing from. Some of the specimens produced, such as the veins and markings of agate-stones, are of remarkable clearness and beauty. The invention, with some improvements in the process, has been patented by Mr. Henry Bradbury, and the 'Fern Flora of the United Kingdom,' produced by him in a folio volume, with 51 plates, is a proof of its capabilities of affording all the advantages of a herbarium, without the defects; as well as to its being available for many other branches of natural history.

In type-founding also an ingenious machine has been invented. In this, by turning a crank-wheel, the metal is injected with considerable force into the type-mould, brought by the machinery in front of a reservoir of metal kept fluid by a gas-fire beneath it, and by a continued movement is delivered out of it, at a rate varying from six to ten times the rapidity with which the operation can be performed by hand. Both in casting by hand, and in the machine, the mould is liable to become obstructed by particles of the metal remaining, when it has to be brushed clean. When this happens to the machine, it ceases to act, and thus at once informs the operator of the defect.

PRIVY COUNCIL. [JUDICIAL COMMITTEE, *S.* 2.]

PROBATE, COURT OF. The right of granting letters of administration of the effects of persons dying intestate, and probate of the wills of testators, which was formerly the prerogative of the Ecclesiastical Courts [ECCLESIASTICAL COURTS, *S.* 1. p. 509.] has by a recent statute (20 & 21 Vict. c. 77) been vested in a newly established court, called the Court of Probate. The functions of this court are confined entirely to deciding upon the authenticity of wills, and upon the proper persons to whom administration is to be committed, when no will exists. With the distribution of the property of deceased persons, and the rights of the various parties who claim it beneficially, the court has nothing to do. These matters must be decided by the courts of law and equity, as before the passing of the Act. The duties of executors and administrators remain the same as formerly. A central registry of wills and administration is established in London, and district registrars are established in forty of the principal towns of England. The office or registry in which probate or letters of administration are to be sought, is no longer determined by the locality of the *assets* of the deceased person, but by the place where the deceased had a fixed abode at the time of death. Should the testator or intestate have a permanent place of residence in one of the registry districts at the time of his decease, probate or letter of administration may be obtained at the registry of the district. The executors or parties claiming administration may, if they think fit, apply to the principal or metropolitan registry for probate or administration, and this may in some cases be found more convenient than to apply to the district registry. Original wills proved in the country will be preserved in the district registries; but copies of them will be transmitted to the principal registry in London, so that in future the metropolitan registry will be the most convenient office of search for any will whatsoever.

The practice of the Court of Probate in all contentious matters is thrown open to the whole legal profession, so that the monopoly of testamentary business enjoyed by advocates and proctors is now at an end.

The court is presided over by a single judge, who sits at Westminster. An appeal from his decision lies direct to the House of Lords.

In cases where a person dies in one of the forty districts, leaving personal property nnder 200*l.*, and real property nnder 300*l.*, the Connty Court of the district has jurisdiction shonld any contention arise. From the decision of the County Court judge, an appeal, which is final, lies to the Conrt of Probate.

One principal advantage of the new system lies in the removal of all difficulty as to the question where a will ought to be proved, and the old question of *bona notabilia*, on which the necessity of obtaining prerogative prohate or administration was founded. The rules of evidence in the Court of Probate are to be the same as those in courts of law and equity, while its proceedings are likewise assimilated to those of the conrts of common law.

PRODUCTIDÆ, a family of Brachiopodons *Mollusca*, including the genera *Producta, Strophalosia*, and *Chonetes*. The shell is concavo-convex, with a straight-hinge line; valves rarely articnlated hy teeth; closely adpressed, furnished with tubular spines; ventral valves convex; dorsal concave; internal surface dotted with conspicuons funnel-shaped punctures; dorsal valve with a prominent cardinal process; hrachial processes (?) subcentral; vascular markings lateral, hroad, and simple; addnctor impressions dendritic, separated by a narrow central ridge; ventral valve with a slightly-notched hinge-line; adductor sac central, near the umbo; cardinal impressions lateral, striated.

Producta has the shell free, auricnlate, heak large and rounded; spines scattered; hinge area in each valve linear, indistinct; no hinge-teeth; cardinal process lobed, striated; vascular impressions simple, curved; ventral valve deep, with two rounded or subspiral cavities in front.

The species are all fossil. There are about sixty species. They are fonnd ranging from the Devonian to the Peruvian rocks of North and Sonth America, Enrope, Spitzbergen, Tibet, and Australia.

Strophalosia has its shell attached by the nmbo of the ventral valve. There are 8 species.

Chonetes contains 24 species, which are fonnd fossil from the Silnrian to the Carboniferons rocks.

PROPYLE. [CHEMISTRY, *S.* 2.]

PROTECTION ACTS. The object of these statutes is to enable a debtor in insolvent circumstances to avert or forestall the impending danger of imprisonment; for any person not a trader within the Bankrupt Acts, or who, being a trader, owes less than 300*l.*, whether in prison or not, may apply in London to the Insolvent Court, in the country to the County Conrts, for protection from process. A *schedule* of debts, and of the names of his creditors, must accompany the petition; which mnst set forth an account of his whole estate and liabilities, and be verified by affidavit.

On the petition being filed, the court makes an *interim order*, which protects the petitioner from all civil process until his *examination*, but he may still be arrested under a jndge's order, to hold him to bail. If in prison, the order effects the petitioner's discharge. The presentation of the petition vests all the petitioner's effects in the registrar, who, as *official assignee*, proceeds to possess himself of all that can be obtained without suit. Notice of the petition is given to the creditors, and inserted in the 'Gazette' and local newspapers, a pnblic sitting of the court being at the same time appointed for the first examination of the petitioner. If it appear that the allegations in the petition and the matters in the schedule are true, and that the debts have not been contracted fraudulently or improperly, and do not arise from any of the acts of misconduct ennmerated in the statutes, a day is fixed on which a *final order* shall be made, unless cause he shown to the contrary. If made, its effect is to permanently protect the petitioner from all process, in respect of the dehts due, at the time of filing the petition, to the creditors named in the schedule. On the other hand, if cause is shown, the conrt may adjonrn the consideration of the final order *sine die*, or dismiss the petition.

At any time *after* the final order, the assignees of the estate may claim property since acquired hy the insolvent, which claim may he summarily enforced hy the order of the conrt. So that under the Protection Acts, as in the case of an Insolvency, the *future* as well as *present* property of the debtor may be applied in payment of his debts. In this consists the great distinction between the relief afforded by the bankrupt laws to a *trader*, and that obtainable by an *insolvent debtor*, or a petitioner under the Protection Acts.

(Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. ii. p. 516.)

PROTEIN. [CHEMISTRY, *S.* 1; TISSUES, ORGANIC, *S.* 1.]

PROTOZOA, a term applied hy Oken to the lowest forms of animal life. *Protophyta* has been applied to the same forms of vegetable life. As employed at the present day it embraces the group of *Infusoria* termed by Ehrenberg *Polygastrica* [INFUSORIA], the *Rhizopoda* of Dujardin embracing the *Foraminifera* [FORAMINIFERA, *S.* 2] and the Sponges. [SPONGIADÆ.] The *Acrita* of M'Leay, and the *Oozoa* of Caius, correspond to this section of the animal kingdom.

PROUT, SAMUEL, was horn on the 17th of September, 1783, in Plymouth—the birthplace of so many English painters. From earliest childhood he was noted for an irrepressihle fondness for drawing the various objects around him, and the passion increased with his years. His associate in his early artistic stndies was Benjamin Haydon, hnt instead of yielding to the eager impulses after an unattainable grandeur of his enthusiastic friend, young Pront contented himself with nnceasingly sketching from nature "the ivy-mantled hridges, mossy water-mills, and rock-built cottages, which characterise the valley scenery of Devon." Whilst uncertain as to his fntnre course, he had the good fortune to be introdnced to Mr. John Britton, the antiquary, then at Plymonth on his way to collect materials for an account of Cornwall, which he was preparing for the 'Beanties of England.' [BRITTON, JOHN, *S.* 2.] Mr. Britton, pleased with his sketches, proposed that he should accompany him into Cornwall to make some drawings, and Pront gladly accepted the offer. The portfolio of Cornish drawings which he afterwards transmitted to Mr. Britton, excited by their boldness of style considerahle notice, and the young artist was easily persnaded to remove to London.

He arrived in the metropolis in 1805, and found an adviser and patron in Palser the printseller, then residing in the Westminster-road and afterwards in Fleet-street, who used readily to pnrchase his water-colour drawings, and dispose of them among his customers. Palser gave but low prices for these works, but Pront had the good sense, on comparing his pictnres with those of the established artists, to recognise his own deficiencies; and he was well pleased to be thus enabled, by means of nnamhitious drawings, to snpport himself whilst making a resolute effort to extend his artistic knowledge and execntive skill. During these years he painted marine views, especially coast-scenes with fishing-craft, more than architecture, for which a very decided inclination had not yet developed itself. He also devoted a good deal of time to teaching, and he etched some lessons and studies for the nse of teachers and pupils; but perceiving the capabilities of the newly-introduced art of lithography for yielding fac-similes of the painter's pencil-sketches, he began early to draw on stone, which, from his singular skill in the use of the lead-pencil, he did with great facility. He published in 1816 a series of 'Studies' which met with great snccess, and was followed by 'Views in the North and West of England,' 'Progressive Lessons,' 'Rudiments of Landscape,' and other drawing-books, which by their vigour of drawing and hrilliancy of effect raised that class of publication far above the estimation in which it had been previonsly held, and did much to extend the repntation of the artist.

Mr. Pront had already secured a high position when he was led in 1818—partly in the hope of restoring his health, which had become much enfeebled, but also with a view to turning to professional account the taste for foreign scenery engendered by the facilities for continental travel opened by the return of peace—to make a tour in France. The qnaint street-architecture of Rouen, and the civic and ecclesiastical structures of other Norman towns, seemed to reveal in him an entirely new sense. From this time he gave himself, with nndivided zeal and nnapproached success, to the delineation of the weather-worn and mouldering remains of mediæval architecture. Year after year he continued to journey through the fairest parts of France and Switzerland, of Germany and Italy; but still it was the old southern or northern gothic bnildings that attracted his pencil, or those tumbledown heavy-gabled domestic houses which, though hardly ranking among any of the architectnral divisions, had in his eyes an equal attraction in their antiqne pictnresqneness. The remarkable popnlarity of his pictures indnced him to pnblish a handsome folio of lithographic 'Fac-Similes of Sketches made in Flanders and Germany.' This was the first of the numerous series of lithographic copies of painters' finished sketches which have added so greatly to the enjoyment of all lovers of art, and done so much towards the extension of a sounder taste; and notwithstanding the many beautiful volumes which have since appeared, it remains in many respects the best—the most marked by a vigorous sketch-like simplicity of means and fidelity, and a happy boldness and playfulness of execution, combined with striking originality and brilliancy of effect. Mr. Prout subsequently published a series of 'Sketches in France, Switzerland, and Italy,' fol., 1839, more finished in style, but scarcely so brilliant or interesting as the former series Besides these he published various works intended to facilitate the progress of the student in art. Of these the first was entitled 'Hints on Light and Shade, Composition, &c., as applicable to Landscape Painting,' fol., 1838, in which he explains very clearly, by precept and example, the principles which regulated his own practice: another and extended edition was published several years later. He also published 'Microcosm: the Artist's Sketch-Book of Groups of Figures, Shipping, and other Picturesque Objects,' fol., 1841; 'Hints for Beginners,' &c.; besides making the drawings for several volumes of the 'Landscape Annual,' and for some other works.

During all this time, and to his death, Mr. Prout continued to be one of the most prolific contributors to the annual exhibitions of the Society of Painters in Water-Colours, where his pictures never failed to form a prime attraction. Yet, many and beautiful as were his works, they were produced amid much suffering. When a child of four or five years old, having wandered into the fields alone, he was found lying under a hedge insensible from the effects of a sun-stroke, and from that day forward he was subject to the frequent recurrence of sudden attacks of pain in the head; to this was added injuries received from protracted exposure to damp and cold in his earlier sketching excursions; so that, till towards the close of his life, as is mentioned in a memoir of him by Mr. Ruskin, from materials furnished by Prout himself ('Art-Journal' for 1849, p. 76), "not a week passed without one or two days of absolute confinement to his room or to his bed." He died on the 10th of February, 1852.

Samuel Prout was undoubtedly one of the greatest and most original of our old school of painters in water-colours. His style was entirely self-formed, and singularly effective. To a great extent it was conventional; but it was the result of prolonged working from the actual objects, and it therefore forcibly conveyed the artist's own idea. His drawing was very uncertain and confined: to the last he remained utterly incapable of drawing a tree, or representing foliage with the least approach to natural truth. His colouring was unequal, but often very beautiful and harmonious. He painted, with rare exceptions, wholly by washes of transparent colours, the outlines and details being made out by the skilful use of the reed-pen, with a few dexterous touches of which he produced effects never equalled by any other manipulator. His chiaroscuro was broad, simple, and so nicely adapted as always to have a true and natural appearance, which was greatly aided by the singularly clever introduction and arrangement of his figures, ill-drawn as these often were. In a word, Prout may fairly be regarded as the founder of a new school of architectural painting. He first showed what a world of picturesque capability lay in the quaint streets and market-places of Normandy, Flanders, and Germany, and the grander palaces of Venice; and no less did he show how to render the broad features and deep sentiment of the old ecclesiastical gothic, without being lost in a multitude of petty details.

PROUT, WILLIAM, distinguished as a chemist and physician. He was brought up to the medical profession, and took his degree of Doctor of Medicine at the University of Edinburgh. On establishing himself in London he connected himself with the Royal College of Physicians, of which body he ultimately became a Fellow. He early directed his attention to chemistry, and was amongst the first in this country to attempt to apply this science to the explanation of the phenomena of life, and he published many papers in reference thereto in the 'Philosophical Transactions.' All his researches and discoveries on this subject were combined in a great work entitled 'On the nature and treatment of Stomach and Renal Diseases, being an inquiry into the connection of Diabetes, Calculus, and other affections of the Kidneys and Bladder with Indigestion.' However brilliant the discoveries which have been made subsequently to the publication of this work, there can be no doubt that Dr. Prout had correctly appreciated the importance of chemistry, in explaining the functions of living beings, and that he was the first physician who sought to apply the doctrines of modern chemistry to the explanation of the phenomena of disease. He was an exceedingly careful and accurate experimenter, and with regard to some of his conclusions, which were at one time brought into doubt, a more careful investigation has confirmed the truth of his views.

Dr. Prout was one of the gentlemen chosen to write the 'Bridgewater Treatises.' The subject of his essay was 'Chemistry, Meteorology, and the Function of Digestion considered with reference to Natural Theology.' This work abounds with evidence of his profound knowledge of the laws of chemistry. Although principally occupied with chemistry in relation to his profession, he took an interest in all sciences which the discoveries in his favourite science affected. He was one of the first to analyse the so-called Coprolites, and to discover the large quantity of phosphate of lime they contained. This he did in a paper published in the third volume of the 'Transactions' of the Geological Society. The paper was entitled 'On the Analysis of the Fossil fæces of Icthyosaurus and other Animals.' Dr. Prout was a Fellow of the Royal Society, and many other learned societies. He died at his house in Sackville-street, London, on the 9th of April 1850, in the sixty-fourth year of his age. He was a man of exceedingly retiring habits, and greatly respected by those who knew him intimately.

PRUSSIA. The area and population of Prussia and its Provinces are as follows:—

Provinces.	Square Miles.	Population in 1852.
East Prussia	14,946	1,531,272
West Prussia . . .	9,981	1,073,476
Posen	11,353	1,381,745
Pomerania	12,153	1,253,904
Silesia	15,695	3,173,171
Brandenburg . . .	15,534	2,205,040
Prussian Saxony . .	9,747	1,828,732
Westphalia	7,786	1,504,251
Rhenish Prussia (Rhein-Provinz), and Hohenzollern	10,759	2,972,130
Total . .	107,954	16,923,721

PSAMMA, a genus of Grasses belonging to the tribe *Arundineæ*. It is known by its flower being enveloped in long silky hairs, the lower glume shorter than the upper, and its panicle being spike-like.

P. arenaria, Sea-Reed, Marram, is the only British species. It is found on sandy sea-shores, where its roots assist in binding the shifting sands.

PSOLIDÆ, a tribe of *Echinodermata*, in the order *Holothuriadæ*. The only British genus included by the late Professor E. Forbes in this tribe, is *Psolus*, which is thus characterised:—Body irregular, ascidiform; suckers in five rows, three only of which are developed and placed on a soft foot or disc; tentacula ten.

P. phantapus (*Holothuria phantapus*, Linnæus), the Snail Sea-Cucumber, is an inhabitant of the British Seas. It is of a brown colour, has the head reddish-white with orange spots and orange tentacula, the body covered with pectinated scales, or rugæ. It adheres to substances with great firmness by means of its ventral disc. "So powerfully does it adhere," says Professor E. Forbes, "that I have known the head of the animal carried away by the dredge when it brought up entire every other fixed animal which it came in contact with." It is found in European seas, and the genus ranges to the Indian seas. Professor Forbes says, "the *Psolus ternaria* of Jäger and Lesson, should form the type of another genus, distinguished by its twenty tentacula. The genus *Cuvieria* of Peron should be united with *Psolus*."

(Forbes, *History of British Star-Fishes*.)

PUBLIC HEALTH. The general interest taken by all classes in whatever concerns the public health, and the still-growing desire for the adoption of measures of sanitary improvement, which form so marked a characteristic of the present age, may be said to have received their earliest impetus from the 'Inquiry into the Condition of the Working Classes,' which resulted in the passing of the Poor Law Amendment Act of 1834, and the proceedings of the Poor Law Board called into existence by that Act. The Commissioners appointed to conduct the preliminary inquiry were made conscious of a state of things connected with the dwellings of the working classes, their social circumstances, and their physical condition generally, far more unfavourable than they had previously formed any conception of; and the statements which appeared in their Report produced a strong impression on the public mind, already startled by the dread march of Cholera. When the Poor Law Amendment Act was brought into operation, the information obtained from the various Unions, and published in the Annual Reports of the Commissioners, deepened and strengthened this impression, and led to a desire for a fuller and more specific investigation. Such an investigation the Poor Law Board determined to undertake; the inquiry, in the first instance confined to the metropolis, being entrusted to Dr. Arnott, Dr. Kay, and Dr. Southwood Smith. The Reports of these gentlemen, which were printed in the Fourth and Fifth Annual Reports of the Poor Law Commissioners, disclosed an appalling extent of vice, misery, and disease, as the direct and almost inevitable result of the neglect of the plainest and most rudimentary sanitary laws. The statements of the Commissioners, as might be expected, excited a very painful sensation, and the then Bishop of London (Dr. Blomfield) moved in the House of Lords (Aug. 19, 1839) an address to her Majesty, praying that a further inquiry might be made as to the disease and destitution prevalent among the labouring classes in certain districts of the metropolis; how far the same prevailed in other populous parts of England and Wales; and what measures would be necessary for the removal of those evils. By a subsequent vote the inquiry was extended to Scotland.

The Inquiry was placed in the hands of the Poor Law Commissioners. The general scheme having been organised by the Board, the local investigations were carried on mainly through the medium of the Assistant Poor Law Commissioners, and the medical officers of Unions, but much assistance was derived from the medical profession generally, the clergy, and others; and a large body of information was brought together of a kind similar to that previously obtained by the Metropolitan Commission. This information was arranged and digested by Mr. Edwin Chadwick, then Secretary to the Poor Law Board. His 'Report on the General Sanitary Condition of the Labouring Classes in Great Britain,' printed in 1842, presented not merely the fullest and most complete view that had been brought before the public eye of the physical and social condition of the labouring classes throughout the country, the causes of the prevalence of endemic and epidemic diseases, and the clearest and most comprehensive suggestions for remedying the evils shown to be so widely prevalent, but from it may be dated the origin of those important measures of sanitary reform which we shall presently have to notice, and the broad outlines of which were in fact here firmly sketched. We must not, however, omit to mention, in noticing these pioneers of sanitary improvement, the very important statistical researches of Dr. Farr and the Registrar-General, commenced and carried on simultaneously with the inquiries just described, which have been continued to the present day, and which have served, and still serve, to give precision and specific direction to the observations of other inquirers.

In the Report of Mr. Chadwick, it was shown that whilst in each there were local and peculiar causes of mischief, in all the great towns there were common sources of danger and disease, in the existence of close and confined localities where the over-crowded houses were badly constructed, undrained, or insufficiently drained, damp, dirty, and ill-ventilated, and surrounded with numerous sources of malaria; the seats of almost constant fever and sickness, and that, as a consequence of their enfeebled physical condition, the inhabitants were the earliest and most certain victims of cholera and other epidemics. So evident indeed was the influence of locality on disease, that Mr. Chadwick was able to show that, whilst the mean rate of mortality in a town would be represented as 1 in 42 annually of the whole population, in one district the mortality may be (as in St. George's, Hanover Square, London) only 1 in 57; in another district of the same town (Whitechapel) as much as 1 in 28 annually; or to take another illustration, that whilst in one street, and among a particular class, the average chance of life is sixty years, in another street of the same town, amongst a different class, the average duration of life is only fifteen years. But it was further shown, that although almost necessarily owing to their rapid increase and greater density of population—sanitary considerations having been equally disregarded in all—the evils particularised were, so to speak, intensified in towns like London, with its miserable purlieus inhabited by thousands of wretched wanderers and outcasts; Liverpool, with its 8000 damp cellars, and its 2000 close courts, each with an opening only at one end; Manchester, with whole quarters of narrow lanes and alleys, without any main sewer, unvisited by the scavenger, unpaved, almost impassable from mire, and reeking with filth and stench; the smaller towns, whether agricultural or manufacturing, were all more or less obnoxious to similar charges—all were insufficiently drained and ill supplied with water; all had their St. Giles's, their pestiferous lodging-houses, their fever-nests, their labourers' dwellings, where comfort and cleanliness were impracticable, and where sickness and mortality were greatly in excess. Looking at these statements in the mass and in detail, it was impossible not to agree with the report that this was a state of things discreditable to the intelligence and civilisation of the country, and that immediate and comprehensive remedial measures were imperatively required. For, as Mr. Chadwick forcibly observed, it was incontestible, from the facts deduced, that "noxious physical agencies depress the health and bodily condition of the population, and act as obstacles to education and to moral culture; that in abridging the duration of the adult life of the working classes, they check the growth of productive skill, and abridge the amount of social experience and steady moral habits in the community; that they substitute for a population that accumulates and preserves instruction, and is steadily progressive, a population that is young, inexperienced, ignorant, credulous, irritable, passionate, and dangerous, having a perpetual tendency to moral as well as physical deterioration." And happily he was also able to show that, by the adoption of proper remedial measures, not only might the more palpable and offensive evils be removed, but that "it is probable that the full insurable period of life indicated by the Swedish tables, that is, an increase of thirteen years at least, may be extended to the whole of the working classes."

The remedial measures pointed out as of primary importance were the providing of a sufficient supply of good water to every house, an ample supply being at the same time furnished for the cleansing of the streets, for sewerage, and for protection against fire; the enforcement of improved drainage by the adaptation of drains and public sewers, and the construction of water-closets in houses of every class; the preservation of the natural streams flowing near towns from the pollutions caused by the influx of the contents of the public sewers, and the employment of the sewage for agricultural purposes; the adoption of measures for securing a better class of labourers' dwellings; the licensing of common lodging-houses, and placing them under strict sanitary and police regulations; the establishment of baths, &c., and the appointment of district medical officers, "independent of private practice, and with the securities of special qualifications and responsibilities, to initiate sanitary measures, and reclaim the execution of the law." By careful estimates he was able to show that, whilst the expenses of executing these various improvements would in fact be a pecuniary saving, "by diminishing the existing charges attendant on sickness and premature mortality," those expenses might be met with facility by means of loans, on the security of the rates, the charge being spread over 30 years, during which the original outlay as well as the interest should be repaid, and thus be avoided "the oppressiveness and injustice of levies for the whole immediate outlay on such works, upon persons who have only short interest in the benefits." These suggestions have since for the most part been embodied in the Health of Towns Act, and other sanitary measures passed by the Legislature. The subject of intra-mural interment was considered by Mr. Chadwick in a special report in the following year.

But, searching as had been the investigation, and undeniable as appeared to be the facts, and urgent as seemed the necessity for combating the wide-spread evil, so large an aggregate expenditure was requisite for executing the works, and so extensively would the suggested administrative organisation interfere with existing interests, and, as some might conceive, with local management and individual freedom of action, that the government deemed it prudent not to initiate any legislative enactment without instituting still further and more formal inquiries. A Royal Commission, consisting of eminent members of both houses of parliament, civil engineers, and scientific men, was accordingly appointed, in 1844, to investigate, in a systematic manner, the entire range of questions connected with the public health. The evidence collected entirely corroborated that of the former commissions, and the conclusions arrived at were in effect the same as those of Mr. Chadwick. In their Reports, dated June 1844 and February 1845, the Commissioners entered fully into all the great questions bearing on the sanitary regulation of populous places — sewerage, drainage, paving, cleansing, removal of nuisances, consumption of smoke, supply of water, public baths and washhouses, ventilation, arrangement of buildings and streets, and interment in towns—and found, almost universally, all of them in an extremely unsatisfactory condition; and having examined the existing law with regard to those subjects, expressed their opinion that it would "be necessary to have recourse to the aid of the legislature for further enactments, before the improvements so much desired can be fully accomplished."

Thus fortified, the ministers framed a bill embodying many of the recommendations of the Health of Towns' Commissioners, which was laid before the House of Commons in 1845 by Lord Lincoln, then Chief Commissioner of Woods and Forests; but it was explained that it was introduced mainly with a view that its provisions might be carefully considered during the recess, and no attempt was made to carry it further. A change of ministry interfered with its progress in the next session. In 1847, however, Lord Morpeth, who had succeeded Lord Lincoln as Commissioner of Woods and Forests, introduced an amended bill, but though, in consequence of the strong opposition of powerful local interests, he consented to withdraw the clause which included the metropolis within its provisions, he failed to carry the measure that session. In the next session it was again brought forward, and, its urgency having been pressed on the attention of parliament in the speech from the throne, it was passed by both houses; and, on the 31st of August, 1848, it received the Royal Assent.

The object of the Public Health Act of 1848, as stated in its preamble, is to make "further and more effectual provision for improving the sanitary condition of towns and populous places in England and Wales" [the metropolis being excepted from its operations]; for which purpose it is declared to be "expedient that the supply of water to such towns and places, and the sewerage, drainage, cleansing and paving thereof, should, as far as practicable, be placed under one and the same local management and control, subject to the general supervision" of a 'General Board of Health,' consisting of the First Commissioner of Woods and Forests for the time being, and two commissioners appointed by royal warrant, to whom the superintendence and execution of the act are to be entrusted. The Act is of great length, containing no fewer than 152 clauses; but as it is an Act of the greatest public importance, as forming the basis of all subsequent sanitary improvement, it seems advisable to indicate briefly its leading provisions—as, for a similar reason, we have entered at some length into its history.

And first, as to the application of the Act. It was in no case to be applied without a public preliminary inquiry, which the General Board had the power to order on the petition of one-tenth of the ratepayers of any such place as came within the cognisance of the Act, or where the average deaths for seven years should appear, from the Registrar-General's Returns, to be above 23 in a thousand. In either of these cases a superintending inspector may be sent—14 days' notice by advertisement, &c., having been given in such locality—to examine personally and by witnesses into the sewerage, drainage, water supply, burial grounds, &c., and report thereon to the Board. If the General Board now deem it expedient to apply the Act, the Queen may, if there be no local act, by an Order in Council order the Act, or any part of it, to be put in force in such place: where there is a local act, the Privy Council may make a provisional order for its application, such provisional order to be afterwards sanctioned by parliament. In every such case the carrying out the provisions of the Act is entrusted to the Local Board of Health created by it, who are to appoint a surveyor, an inspector of nuisances, and a medical officer, with other necessary officers. In a corporate town the members of the Corporation are to constitute the Local Board of Health, in other places the members are to be elected by the ratepayers; in all cases the entire sanitary government is vested solely in the Local Board of Health.

As to the powers of the Local Board,—it is imperative on them to provide for the effectual drainage of their locality, by the construction of new, or the repair of existing sewers; and for house drainage by causing sufficient drains to be constructed in all new houses, or in any house which may be without a proper drain communicating with a main sewer; they may also cause due provision to be made as to privies, water-closets, &c., public and private; and they must at all proper times cause a thorough surface cleansing and watering of all streets; provide for the storing and taking away of dust, &c.; and cause nuisances to be removed, and filthy and unwholesome dwellings, &c., to be purified and whitewashed. The board may also provide a constant supply, at pressure, of pure water, for the purposes of the Act; but not construct new water-works if a Company is able and willing to provide a sufficient supply on reasonable terms; and in any case the local board must obtain the sanction of the General Board before contracting to purchase old, or to construct new water-works or gas-works. The office of surveyor of highways is vested in the local board, who must see that the highways are properly paved and lighted; that new streets are formed, and that all new buildings are constructed in accordance with the terms of the acts of parliament. The local board may also, subject to the control of the General Board, close any surcharged burial ground, and provide general cemeteries for persons of all religious denominations. Also, subject to like control, form, or contribute to the forming, of public walks, pleasure grounds, &c. Slaughter-houses are in future to be registered and regulated by the local boards; as are likewise common lodging-houses. To provide the means for the purposes of the Act, the local board may levy taxes, and for the construction of any permanent work may—but only with the sanction of the General Board—borrow money, to be repaid with interest, by means of a special rate, within a period not exceeding 30 years. Provision is made for appeal, in various cases, to the General Board, on the part of persons who regard as excessive the assessments or charges made upon them for private improvements, and also against various orders of the board which may lie open to the appearance of being partial or oppressive to individuals.

The intention of the Act in respect of local management and central control has been, in short, to cast upon the inhabitants of a town the duty of making provision for the public health, and of carrying out local improvements, by means of a local agency elected by, and responsible to, the rate-payers; while, in order to ensure the efficiency of the more costly and permanent works and their economic construction, the due qualification of the sanitary officers, the security of individuals from local bias and oppression, and the assuring of future rate-payers from the burdens arising out of an unthrifty mortgaging of rates, a General Board is provided with a certain well-defined power of supervision and control. Mr. Chadwick, who, beside the Reports noticed above, had taken a leading part in inquiries embodied in two other reports on the water-supply and the drainage of towns—in the former of which he strenuously advocated the adoption of the constant service system, and in the latter gave an elaborate and lucid exposition of the advantages of drainage by glazed earthenware pipes—was one of the members of the General Board appointed under the new Act; and to his intimate acquaintance with the whole subject, and well-directed energy, its early success must mainly be attributed. Subsequent acts, continuing, and in certain minor points amending, the original Act, have been passed; and in 1854 one by which the General Board was re-constituted, under the provisions of which the Board now consists of a President, the principal Secretaries of State, and the President and Vice-President of the Board of Trade.

There appears, however, a probability that the great principle of the Health of Towns Act, local agency combined with well-defined central supervision and control, is about to be abandoned; a bill having been introduced (April 22, 1858) by the present government, with the declared intention to "decentralise the whole system." It proposes to allow the General Board of Health to expire in September 1858; and to enable the ratepayers of towns to constitute local boards, which, as well as the existing local boards, "shall have the amplest powers of self-administration, and shall no longer be subjected to the necessity of referring to a Central Board in London." Individuals feeling themselves to be aggrieved are to have a power of appeal to the Secretary of State for the Home Department. In its present crude shape the bill is unlikely to become law, but as it is a concession to a popular delusion against centralisation, it is not improbable that it may, in its main features, be adopted; and thus the accumulated experience and scientific information of the officers of the General Board will be lost, and the door opened wide for a return to the old apathy, mismanagement and negligence, to local inefficiency, waste, peculation, and favouritism. The "general medical functions of the Board of Health" are to be dealt with in a separate measure, "they being distinctly central and governmental functions."

Since the passing of the Health of Towns Act, applications have been made by several hundred places for a 'preliminary inquiry' into their sanitary condition by the inspectors of the General Board. How much such an act was needed—how little had been accomplished by mere local effort, notwithstanding the appalling disclosures of the Poor Law Board Reports, the Reports of the Royal Commission, the Returns of the Registrar-General, and the teaching of cholera and fever—has been shown in the most convincing manner by these 'preliminary inquiries,' ranging in time from the passing of the Act to the present day, and extending over almost every district of England and Wales. We had selected from recent reports of the superintending inspectors a few special instances as illustrating the present state of too many 'towns and populous places,' not yet brought under the cognisance of the Health of Towns Act, including sea-side and inland watering-places and resorts of invalids; mining and manufacturing towns and villages in the north of England and of Wales; rural towns of the eastern, southern, and midland counties, &c.; but our space is limited, and they, after all, but tell, with variations, the same sickening story of wretched quarters—often in close, though scarce-suspected proximity with the open and airy dwellings of the affluent—dark, close, crowded, loathsome, undrained, and without the commonest appliances for decency, with an insufficient supply of water, and, what is to be obtained, hard and impure; many of the streets where fever is never absent; lodging-houses where men, women, and children are huddled together by the score in low filthy dens; slaughter-houses, with all their abominations, in the very midst of the most densely populated localities; burial grounds surcharged, and the like—all seemingly continued in defiance of sanitary principles the most obvious to the commonest understanding, but, in truth, usually continued through sheer ignorance on the part of the influential classes that such things exist, and the absence of any responsible officer whose duty it is to make himself acquainted with their existence and to apply the remedy. And, unhappily, it now needs no reference to our towns and populous places, where every one has been left to do as he likes with himself and his own, to illustrate the evil consequences of neglect of sanitary regulations. For the miserable loss of health and life among our soldiers at Scutari and in the Crimea, where—as military authorities themselves admit—the arms of the enemy slew but few in comparison with the ravages of disease, and the recent astounding disclosures respecting our barracks at home, more than sufficiently prove all that the most earnest advocate of sanitary reform has asserted of the necessity for constant and judicious watchfulness, and authoritative control. Happily, too, in the same quarter we have a striking illustration of the benefit of sanitary regulations. For, both in the hospitals of the Bosphorus and in the camp in the Crimea, no sooner had the remedial and precautionary measures of the Sanitary Commissioners, sent out from England in January 1855, been brought into operation, than the number of deaths, and the amount and violence of the sickness, were abated; and ultimately the very remarkable fact was established, that notwithstanding all the hardships, exposure, and fatigue attendant on a state of warfare, the actual mortality was lower than in the barracks in England—a fact which renders the more strange and indefensible the state in which those barracks should afterwards have been suffered to continue.

Up to the end of 1857 about 250 places had been brought under the operation of the Health of Towns Act. In a fair proportion of these places sanitary works of an efficient order have been executed. The sanitary works have of course been chiefly those of drainage and water supply, and in both these matters some of the works have been on a scale of considerable magnitude. By the earthenware pipe drainage system, which adapts itself readily to any size of place or peculiarity of site, the local boards have in most instances been enabled to effect thorough drainage with comparative readiness and economy. The utilisation of the sewage has not however yet been brought into general successful operation; and in some places complaints have been made that the successful drainage of the town has resulted in the pollution of the natural streams—a necessary consequence of such works where the outfall is into the water courses, and no sufficient measures are taken for the utilisation of the sewage, and the purification of the waste water. The means adopted for obtaining and distributing an ample supply of pure water have proved very generally satisfactory, and now in numerous places where only a scanty supply of hard and impure water was obtainable, every house is abundantly provided with water of excellent quality. And wherever these sanitary works have been judiciously planned and properly carried out, there has followed a marked improvement in the general health and comfort, while the expenditure and attendant taxation have been for the most part far less burdensome than where very inferior works have been executed under the old local improvement acts.

To the improved health and decreased mortality in several of these towns the Registrar-General has in his Reports borne testimony; and still more striking testimony has been borne by the Local Boards of Health themselves. Thus the Macclesfield Board say, in a Report addressed to the Town Council, that the death tables of the borough show that the mortality, which before the application of the Act averaged 33 in a thousand, has during the three years of the operation of the Board been reduced to 26 in a thousand; that infantile mortality—always a trustworthy test of sanitary condition—has been reduced 13 per cent.; that in the "old haunts of fever" not a single fatal case has occurred; and that the mean duration of life in the town has been lengthened. The application of sanitary measures has not however been confined to the towns under the Health of Towns Act. Several of the largest towns are carrying on similar works under their local acts. At Liverpool and Manchester, for instance, vast and very costly works have been constructed for bringing to those places a supply of pure water from a considerable distance; and at Glasgow a similar supply has been obtained, at a great expense, from Loch Katrine.

We stated that the metropolis was exempted from the operations of the Health of Towns Act. Several Acts were indeed passed to meet particular evils, but notwithstanding that the necessity for stricter sanitary supervision was admitted on all hands, so strong was the feeling of the civic corporation and the parish vestries against centralisation of authority, that it was not till 1855 that a measure intended to secure to London the same sanitary improvements as the Health of Towns Act offered to the rest of the country, became law. The Metropolis Local Management Act is however a far longer and more cumbersome measure than the former (it contains 251 clauses and several schedules), and its machinery is larger and more complex; it must suffice therefore to say that its objects and scope are very similar, however different in some respects are its modes of operation. The executive body created by it is entitled the 'Metropolitan Board of Works,' and consists of a president, with a salary of 1500*l.* a-year, and 45 members elected by the vestries of the metropolitan parishes, and the common council of the city. To this board was transferred the powers of the former Commissioners of Sewers, the supervision of all metropolitan buildings, the laying out of new streets, and the entire sanitary regulations of the metropolis. But within certain limits a controlling power was entrusted to the Chief Commissioner of Works and Buildings. The great work which was cast upon the new board was the purification of the Thames, by the interception of the sewage of London, which the board was ordered by parliament to accomplish. In this it has however made little progress, not having been able to satisfy the government (or the public) of the sufficiency of its plans. In other great matters, as the laying out of new main thoroughfares, the formation of parks, &c., it has also been content to discuss and to plan. In small matters its officers have found sufficient occupation. But on the whole, as from its constitution might have been anticipated, it has hitherto proved rather a board of discussion than, as it claims to be, a board of works.

The Health of Towns Act, and special Acts similar to the Metropolis Local Management Act, would pretty well suffice, if properly carried out, for the sanitary regulations of the towns in which they are brought into operation. But as there are many towns in which such acts have no force, general measures have been, and still continue to be, required to meet particular sanitary evils. We cannot enumerate all of these, but it may be convenient to mention the chief sanitary laws enacted during the last ten years. The Act to encourage the establishment of Baths and Washhouses, passed in 1846, is noticed under another head, [Baths and Washhouses, *S.* 2]; and as the Towns Improvement Act of 1847, which consolidates previous acts respecting paving, draining, cleansing, and improving towns, and contains many valuable new clauses, created no new machinery for carrying its provisions into effect, and accomplished much less than its framers anticipated, we may pass at once to the measures passed subsequently to the Health of Towns Act.

The Nuisances Removal Act (1848) was intended to effect with respect to the removal of nuisances, and the enforcement of regulations for the prevention or mitigation of epidemic, endemic, or contagious diseases, the same end in places not subject to the Health of Towns Act, as in such towns would be accomplished under its powers. Like that Act this has been more than once amended. In 1849 the only sanitary enactment was an extension of the Metropolitan Sewers Act.

In 1850 was passed an important "Act to make better provision for the Interment of the Dead in and near the Metropolis." Recognising the great truth that all interment within the boundaries of a city is in opposition to sanitary principles, it provided that when the General Board of Health, who were appointed to carry into effect the provisions of the Act, should see fit, they might report to her Majesty that interment in any church, chapel, or burial ground, ought to be discontinued; whereupon the Privy Council was empowered to issue an order directing burials to be wholly discontinued therein after a certain fixed period. The Act also empowered the General Board to purchase existing, or to form new cemeteries at convenient distances from the metropolis. This Act was repealed in 1852, and a new one substituted for it; but to this Act may be ascribed the abolition of intra-mural burial, and the construction of spacious and neat cemeteries on all sides, but at some distance from the metropolis, though the actual accomplishment of these good objects was left to its successor. By the Act of 1852 parishes or districts willing to construct new burial grounds were empowered to elect Burial Boards, to which were entrusted the construction and management of the burial grounds, subject to the approval of the Secretary of State for Home Affairs. An Act was passed the following year amending the Burial Act of 1852, and extending its provisions to any city or town in England. Another emendatory Act was passed in 1857.

In 1850 was also passed an Act bearing on the health of young persons and females working in factories,—by which, as amended in 1853, the period of labour of such persons was restricted to between the hours of six in the morning and six in the evening, or during winter from seven to seven, and on Saturdays only to two in the afternoon.

A much needed Act was passed in 1851 for the Well-ordering of Common Lodging Houses; and in the same session one for encouraging the establishment of such houses of a superior kind. These Acts did not apply to the Metropolis or to Scotland. The former of these Acts was much improved, and extended to all common lodging-houses, by an additional Act in 1853. How much such a measure was required, what has been already said will have sufficed to show; but as the power of entry and of regulation is still by some regarded as oppressive, an instance or two, exhibiting in detail the true character of such places immediately before the passing of the first Act, from the reports of the superintending inspectors of the Board of Health, may not be superfluous. But we shall only give one or two instances; for such details, though it is unwise to shut one's eyes to their reality, are too painful and humiliating to dwell on; and we select them not from the great centres of population, where their condition is pretty well understood, but from smaller places, where their existence might hardly be anticipated. In Bacup, Lancashire, Mr. Lee found the common lodging-houses "hot-beds of disease and vice. . . . Men, women and children, and frequently dogs, form a promiscuous herd, all sleeping in the same room, from which every breath of pure air is excluded. . . . Most of the lodgers sleep in a state of absolute nudity, and decency, with the greater portion of them, has long ceased to be thought of." In one house he found, in a single room, six beds, in which were "4 females, 9 males, and a dog." In another he found in one room 7 beds, containing 7 females and 9 males. But bad as this seems it is purity itself in comparison with what has been found in other parts of the country. Thus at Cardiff Mr. Rammell, another Superintending Inspector, describes and gives plans of a street (Stanley-street), several of the houses in which are common lodging-houses. One, No. 17, is larger than most others in the same street. Like the rest it has but a single living room, which is 15 feet 10 in. long, 17 feet 2 in. deep, and 8½ feet high. This room the Superintendent of Police visited by Mr. Rammell's desire. On the first visit he found in it "54 persons, men, women, and children; they live, eat, and sleep all in this one room." He visited it again the following week in the day time, and "found 45 inmates, but many more came in to sleep at nights. . . . There are no bedsteads, but all the lodgers lie on the ground or floor. . . . Each party had with them all their stock, consisting of heaps of rags, bones, salt-fish, rotten potatoes, and such things. The stench was hardly endurable." This living room opened into a small outer court, in one corner of which was an open privy. On a third visit, seven days later, he found on the floor of the crowded room a woman who had been confined there two days before. Who shall say that places such as these did not need "well-ordering," even at the risk of some little infringement on the owner's right over his castle? The "well-ordering" Act has everywhere operated good; and as far as it has been realised the other has been extremely beneficial.

The Smithfield Market Removal Act of 1851; and the Metropolis Water Supply Act of 1852 (by which the water companies taking their supply from the Thames are, with the exception of the Chelsea Company, prohibited from taking any water for such purposes from any part of the Thames, or its tributary streams below Teddington lock), are sufficiently referred to in the following article. [PUBLIC IMPROVEMENTS, *S.* 2.]

In 1853 was passed an Act which, as amended by the Act of 1857, renders it compulsory to have all furnaces employed for manufacturing purposes within the limits of the metropolis, and the furnaces of all steam-boats plying on the Thames, so constructed or altered as to consume their own smoke, a measure which has already produced an appreciable influence on the London atmosphere. In the same year the legislature rendered the practice of vaccination compulsory.

In 1854 was enacted the Board of Health Reconstitution Act, and amendments of the Metropolitan Burials Act, and the Metropolitan Sewers Act, which have been already referred to. In 1855 were passed—an extremely useful Act for the Inspection of Coal Mines, which may be expected eventually to effect important sanitary improvements in such places; an Act for the better Prevention of Diseases, which gives the General Board of Health additional and stringent powers in case of the recurrence of any formidable epidemic, endemic, or contagious disease; an Act for the amendment and consolidation of previous Nuisances Removal and Diseases Prevention Acts—of considerable importance, as in fact repealing all previous acts and more strictly defining the powers of the various bodies appointed to enforce its provisions; an Act to amend the Laws relating to the construction of Buildings in the Metropolis and its Neighbourhood; and an Act for Facilitating the erection of Dwelling-houses for the Labouring Classes. Subsequent acts of a sanitary character have been chiefly emendatory.

Our review has been confined to England and Wales, and it is there that the greatest progress has undoubtedly been made. But in Scotland, by the very important 'Act to make more effectual provision for regulating the police of towns and populous places in Scotland, and for paving, draining, cleansing, lighting, and improving the same' (1850); the Burial Grounds Act (assimilating the system to that of England), and the Act to Facilitate the Erection of Dwelling-houses for the Working Classes (1855); and the Smoke Nuisance Abatement Act of 1857; and in Ireland by the Towns Improvement Act of 1854; the Act to encourage the providing of Improved Dwelling-houses for the Labouring Classes (known as the Cottier Tenant's Act), and the Burial Grounds Act (similar to the English Act) of 1856, very much has been done towards placing those portions of the empire on a level with England in reference to its sanitary provisions. Much doubtless remains to be accomplished in and for our populous places—indeed sanitary improvement can but be regarded as in its early stage of progress—but it is impossible to look thus cursorily over what has been accomplished within the last few years without thankfulness, or forward without hope.

All that we have said has had reference to 'towns and populous places,' and it is in them that sanitary laws are most needed, and sanitary legislation most applicable. The average excess of mortality in town districts is at least 8 in the thousand over that of the country districts of England. Yet even in country districts, as was well observed by the

Registrar-General in one of his valuable reports (1856), "there is room for immense improvements in the sanitary condition of the population." And we cannot perhaps better conclude a paper on the Public Health, in which the sanitary state of the town population has been almost exclusively dwelt on, than by quoting what he—speaking with the authority derived from a knowledge unrivalled in extent and accuracy of the sanitary state of the whole of England and Wales—whilst asserting his belief that the mortality of England as a whole is lower than that of any other country in Europe,—says of the sanitary condition of the rural districts:—

"The germs of insalubrity are scattered about in every village; for the rational laws of health are violated alike in the cottage and in the farmhouse. The dwelling-houses sometimes rest on damp undrained ground; they lie often at the bottom of pit-like depressions of the earth, instead of standing on the sides of the higher grounds, from which the water flows away naturally, and the decaying organic emanations are dispersed and decomposed by the winds. The farmhouse is often close to the farmyard, on a low part of the farm, and is surrounded by buildings, ricks, and trees. In the yard, or near it, the refuse of the house, and of all the animals, is kept month after month undergoing fermentations, and giving off noxious vapours. Into the pond, out of which the cattle drink, the ammoniacal liquor falls that should find its way over the land. And it happens that if the air is stagnant for some days, if the temperature is high, if some sick person or diseased animal enters the place which is surrounded by salubrious fields, the farm becomes a scene of suffering, the cattle perish by pleuropneumonias, the children are attacked by scarlatinas, the wife has low fever, or the farmer himself dies, and his name, at a premature age, is enrolled in the register of deaths. About 6,426 English farmers die in a year, and of them many are young; 2,605 are under 65 years of age.—In the dairy, a little dirt spoils the milk, butter, or cheese; unless the vessels of the brewery are clean the ale is injured; and farmers have hence learnt by experience the importance of cleanliness in the interior of their houses. From them the taste for household cleanliness has been diffused through the surrounding population. They have only to render the air which they breathe about their houses pure, to become, with those around them, the halest people in the world.—To place any of the new farmhouses and cottages to be built on certain elevations is the first point; to carry out and to cover with earth all the refuse of the house and yards daily would prevent the escape of the ammonia, the most precious part of the manure, and at the same time rid the atmosphere of the fatal malaria that surrounds the farmhouses and cottages of the country.—These matters well deserve the attention of English landed proprietors, as they are generally much better informed in sanitary matters than their agents, and can at once give effect to improvements beyond the reach of the small proprietors of other countries."

PUBLIC IMPROVEMENTS. The present article is intended to indicate broadly the progress of architectural and other public works of an important character in the metropolis since the publication of the 'Penny Cyclopædia,' and, though with less particularity, similar progress in provincial towns.

Since that date London has been greatly altered. If there have been no such rapid or extraordinary architectural transformations as in Paris, there has been continuous and steady improvement. New streets have been opened, and obstructions removed in many old streets. New towns almost of so-called 'villas,' have been added to the suburbs on nearly every side. New parks and public places have been formed. The drainage of the vast area which is now included within the metropolitan boundaries, has come to be regarded as a question of general concernment, and while the existing system has been greatly improved, a scheme of metropolitan drainage, of a magnitude unrivalled in the capitals of ancient or modern Europe, by which the entire sewage of London and its environs will be carried some miles below the metropolitan limits before it is discharged into the Thames, only seems to wait for its adoption by the government a decision as to certain subsidiary points on which the representative of the government and the representatives of the London parishes hold different opinions. Intra-mural interment has been declared illegal, and numerous convenient cemeteries, some of them of great extent, have been formed at a due distance from the City. The water-supply has been increased and purified; and many other sanitary reforms have been accomplished. New museums and other educational institutions of a national character have been established. A vast legislative palace has been reared; a new Royal Exchange, numerous churches and chapels, and many other public buildings of considerable size and costliness, as well as many great commercial works, have been constructed; and street architecture has assumed an entirely new character and consequence. And in all these matters the larger provincial towns have in their proportions kept pace with the metropolis. It would indeed be scarcely an exaggeration to assert that more and greater public works have been constructed, and more public improvements have been effected during the last twenty years, than during any previous hundred years.

New Streets.—The new streets in the metropolis have added much to the public convenience, and greatly improved the appearance of certain quarters; but much more might have been easily accomplished had the improvements been carried out as part of a well-considered general plan, instead of being disconnected and local expedients. In the City, however, something like a general plan has been observed. The erection of the new London Bridge led to the formation of new lines of approach, and the opening of these showed the necessity of still greater changes; and the civic authorities have since kept that necessity steadily in view. The erection of the new Royal Exchange afforded an opportunity for opening the area surrounding that building. By the removal of the south side of Cannon Street, and the houses westward to St. Paul's, an excellent street—New Cannon Street—has been formed from King William Street to the east side of St. Paul's Churchyard. This street has been for the most part lined with large and lofty warehouses, many of them of considerable architectural pretension: it is greatly to be hoped that the corporation will not allow the fine view of St. Paul's Cathedral opened by New Cannon Street to be obstructed by the erection of a building on the triangular space at present left unoccupied at the north-western corner of the new street. To render New Cannon Street as serviceable for traffic as from its width and position it ought to be, it will be necessary to make very extensive alterations in the area surrounding St. Paul's Cathedral—and such alterations are equally desirable for the architectural effect of that edifice. Another, though less important new line of thoroughfare, is Gresham Street, extending from Lothbury to the Post Office. More recently a wide street has been formed as a continuation northward of Farringdon Street. It is called Victoria Street, and extends from the foot of Holborn Hill to Clerkenwell Workhouse. It passes through a very poor neighbourhood, and as yet no buildings have been erected along it.

Beyond the limits of the 'City,' the first place among the new lines of street must be assigned to New Oxford Street, which connects Holborn with Oxford Street by a straight and wide road, which passes to the north of the old mean and circuitous way by St. Giles's Church. On the north side of New Oxford Street a few good houses have been built, but much less has been done for the architectural aspect of the street than could have been wished. In the same vicinity Endell Street has opened a way from Long Acre to Bloomsbury, and thus formed a tolerably broad though somewhat awkward and indirect thoroughfare from the Strand by Waterloo Bridge to New Oxford Street and Tottenham Court Road. Cranbourne Street at the west end of Long Acre and New Coventry Street, between Leicester Square and Coventry Street, have in like manner afforded a somewhat better outlet eastward from Piccadilly, but further improvement is still greatly needed in that quarter. At Westminster a fine line of road has been formed from the Abbey to Pimlico, but the greater part of it remains uncovered with buildings; at present only a few blocks of lofty houses, intended to be let out in flats, have been built, and of these the larger part are unlet or unfinished—the system of separate floors, or flats, appearing to be by no means congenial to English tastes or habits. At Pimlico considerable improvements have been effected by the removal of the large mass of houses about Buckingham Gate which formed so great an obstruction to the road-way, and so unsightly an appendage to the royal abode, the grounds of which have thus been somewhat extended; and at Chelsea by the continuation of Sloane Street, and by the formation of some streets as approaches to the new suspension bridge. At the east-end of London the most important new line of street is one called Commercial Street, extending from Whitechapel

High Street (opposite Leman Street) to Spitalfields Church, whence it is continued by New Commercial Street to Shoreditch, near the terminus of the Eastern Counties Railway; thus, with certain improvements at the other extremity, opening a direct thoroughfare from the London Docks to Shoreditch. A new line of street on the Surrey side of the water, from High Street Southwark to the Waterloo Road, and others on the Middlesex side have been approved by the Metropolitan Board of Works, but the execution of neither of them has been commenced.

Parks.—The oldest of the new parks is *Victoria Park*, on the eastern side of London, which was commenced in 1842. Its area is about 290 acres; it stretches east and west from Bethnal Green to Hackney Wick, and is bounded on the south by Duckett's Canal. Victoria Park was laid out with more regard perhaps to convenience than to picturesque effect, but it is yearly increasing in attractiveness as the trees with which it is planted increase in size and vigour. A portion of this park has been appropriated as a free cricket and play-ground, and a free gymnasium has also been formed—both of which have proved, as well as the park itself, invaluable sources of enjoyment to the poorer classes of the extreme east of London. *Battersea Park*, occupying the marshy tract on the right bank of the Thames, of which the notorious Red House may be taken as the centre, was commenced, after much delay, in 1854, and was thrown open in 1857. The works here have been of a more ornamental character than in Victoria Park, and altogether it already wears much more the aspect of a pleasure-ground. Its area is about equal to that of Kensington Gardens. It contains a large sheet of ornamental water; and a portion of the park is set apart as a sort of garden, and well stocked with shrubs and flowers; a noble river esplanade, 120 feet wide, extends the whole length of the park; and the park itself is well provided with broad walks and convenient approaches. A handsome suspension-bridge gives the inhabitants of Chelsea ready access to the park. As in Victoria Park, it is proposed to build villa residences along its borders. Like Victoria Park, it has provided an agreeable and much-needed place of open-air recreation to a very poor and densely populated locality. Its total cost has been about 313,000*l.* Kennington Common, which had been permitted to fall into a very disreputable state, has by government assistance been enclosed and planted. It has been somewhat absurdly dignified with the title of *Kennington Park*, but, though it has no claim to such a designation, it forms an agreeable pleasure-ground. The model cottages erected by Prince Albert near the site of the Exhibition of 1851, have been re-erected as an entrance lodge to Kennington Park. *Primrose Hill* has also been secured for public use, and a level piece of ground at its foot has been appropriated as a play-ground. As in Victoria Park a gymnasium has been formed here, and is much resorted to during the season. An Act has been obtained for the formation of a park between Highbury and Stoke Newington to be called Finsbury Park, but its construction has not yet been commenced (May, 1858). Another park has been projected for the use of the inhabitants of the south-eastern extremity of the metropolis, to be formed in the meadows between Rotherhithe and Deptford; but it is at present only a project. In the old parks many improvements have been made by better draining, the formation of new walks, the erection of new lodges and gates, the addition of numerous seats, &c. The most extensive improvements have been perhaps effected in St. James's Park, where a new broad entrance has been made between Marlborough House and St. James's Palace, and in a line with it a suspension-bridge for foot passengers (by no means a favourable specimen of that kind of bridge, however) has been thrown across the ornamental water, new approaches being at the same time formed on the other side. The lake has also been cleared, and a new bottom constructed of thick concrete, thereby at once increasing the facilities for cleansing the water, and affording greater safety for skaters.

Architecture.—The most important building erected in London during the period of which we are treating—the most important indeed which has been erected in London since St. Paul's Cathedral—is the new Palace at Westminster. The old Houses of Parliament were destroyed by fire on the 16th of October 1834. In July 1835 the government advertised an open competition for a new building in the 'Gothic or Elizabethan style.' Ninety-seven designs, comprising above eleven hundred drawings, were sent in, and the Commissioners who had been appointed to adjudicate, decided in favour of a design by Mr. Charles Barry, R.A., then best known as the architect of the Travellers' and Reform Club-Houses. After the usual preliminary inquiries Mr. Barry was instructed to carry out his design. The first portion of the works undertaken was the river wall, which was constructed by means of a coffer dam, under the joint superintendence of the architect and Mr. Walker, the celebrated civil engineer. On the completion of the river wall, the foundations of the building having been simultaneously proceeded with, the first stone of the building was laid, without any ceremony, by the architect's wife, April 27, 1840. From this time the works have been prosecuted with only such interruptions as were necessitated by the appointment and proceedings of committees of the two Houses of Parliament, royal and parliamentary commissions, commissioners of works, ventilation directors, and other principal and subordinate authorities, and the alterations they at different times made in the plans of the architect and of each other. The House of Peers, with its libraries and offices, was opened on the 15th of April 1847. The House of Commons, with its offices, was opened on the 3rd of February 1852; and on the same day all the public entrances, the great Central Hall, and St. Stephen's Hall, were thrown open—all, like the laying of the first stone, being done without any public ceremony: but about the same time the architect was knighted. "Since that time," says the architect's son, Mr. E. M. Barry, (in a paper descriptive of the new palace, read before the Royal Institute of British Architects, Feb. 1, 1858, and of which, as it may be regarded as semi-official, we have made free use) "most of the remaining portions of the edifice have been completed, and at this moment very little remains to be done. The Speaker's House is all but finished, and will be occupied after Easter. The residences in the south wing will be completed in a few months, and before long the main towers, the royal gallery, and the royal staircase will be ready for occupation, so that by the close of the year the present works at the new palace will be brought to a close. Much has been said," continues Mr. Barry, "about the time the edifice has taken to construct, . . . but when the difficulties of all kinds which have beset the work are duly considered, and it is borne in mind that the public business of the country has never been interrupted for an hour, but has always possessed temporary accommodation on the site, which has only been handed over piecemeal to the builders—architects, at any rate, will not think the time that has elapsed between the laying of the first stone in 1840, and the completion of the building in 1858, has not something to show in the work that has been done." In this we quite agree with the writer. Whatever else there may be to complain of, the time that has been spent on the building, the extent, character, and complexity of the works, even had there been no extraneous hindrances, would have amply explained and justified; indeed it is probable that no other building at all approaching it in size, solidity of construction, and richness and extent of ornamentation, has ever been erected in anything like so short a time.

The style of architecture adopted for the new palace is that commonly known as the perpendicular Gothic of the reign of Henry VII., but that style is chiefly known from the ecclesiastical and collegiate buildings erected in or about the reign of that monarch, whereas the architect himself says of the new palace, "it has been my aim to avoid the ecclesiastical, collegiate, castellated, and domestic styles, and to select that which I consider better suited to the peculiar appropriation of the buildings." The east, or river front, which stretches along the Thames a length of upwards of 900 feet, and contains the libraries and committee-rooms, was the first portion of the exterior completed. Of this façade the central portion is a story higher than the rest, and two towers with high roofs flank each extremity. Except that the end towers project somewhat, the river front is not only uniform in character but unbroken by projecting or receding parts, "reliance being placed," says Mr. Barry, "on breaking up the sky-line to avoid monotony." Throughout this front, as indeed with scarcely an exception throughout the building, the wall-surface is covered with panelling and profusely enriched with carving. "The carving between the stories of the river front was intended as a record in stone of English history. There are thirty-five bays exclusive of the two oriel bays; each of these thirty-five bays contains the arms of an English sovereign, beginning with William I. and ending with William IV. The oriel bays bear the present Royal

Arms of England, with the motto, 'Victoria Regina feliciter regnans.'" Examined closely the effect is extremely rich, though somewhat monotonous; but the enrichment is almost entirely lost when the façade is looked at from a sufficient distance to be viewed as a whole, and this is almost necessarily the case as, being turned to the east, it is never varied or invigorated by the play of light and shadow. It is impossible not to regret that, by the adoption of bold breaks in the outline, a more picturesque combination has not been presented to the river.

The western front is much more varied, and promises to be much more satisfactory. But for its full effect it must wait for the removal of the present most unsightly law-courts, and the completion of the architect's design by the erection of the great public entrance gateway with flanking turrets at the corner of Palace Yard. The great feature of this front is the Victoria Tower, which occupies the south-western extremity of the building. This magnificent structure is 70 feet square, and rises to an altitude of 345 feet to the top of the turrets, being the loftiest tower in existence. It forms the royal entrance to the palace, the basement being a noble arch 60 feet high and 22 feet wide, under which the royal carriage passes. Triple windows of very rich and beautiful design occupy the chief wall-space of the two principal stories. The entire unpierced wall-surface of this vast tower is covered with panelling, with canopied niches containing statues of the monarchs of England, and with the arms and supporters of the different sovereigns. A pierced parapet 16 feet high terminates the walls. Four turrets rise from the angles to a height of 85 feet above the cornice. From the summit of the roof will float on state occasions the royal standard; and the scale on which the whole is contrived may be conceived from the statement that the flag-staff will be "of rolled sheet iron firmly bolted together, 110 feet long, 3 feet in diameter at the base, and weighing between 16 and 18 tons," while the flag, which will be 60 feet long and 40 feet wide, will have to be hoisted to its place by machinery. The Victoria Tower may fairly rank with the very finest tower of mediæval date for beauty and grandeur as well as for mere size. Two other towers form equally important features in the design—the Central Tower, less lofty in itself than the Victoria Tower, but surmounted with a light and elegant spire, which rises to a height of upwards of 300 feet, in many points of view grouping admirably with the main features of the palace; and the Clock Tower at the north-western angle, by Bridge-street, which though little lower than the Victoria Tower, is much less ornate, it being the architect's object "in designing this tower to make the clock the predominant feature: all else was to be pedestal or roof."

In the interior, the chief interest of course centres on the 'Houses of Parliament.' These are placed pretty nearly in the midst of the building. In the very centre is the Central Hall, a noble octagonal chamber covered by a stone groined roof 70 feet in span, which forms the principal floor of the Central Tower. From this hall a corridor and lobby on the south lead to the House of Peers, and a similar corridor and lobby on the north to the House of Commons. The House of Peers, as the chamber in which the sovereign delivers the royal speech in the presence of the members of both houses of parliament, as well as the members of the diplomatic corps and of the royal household, is the larger and more splendidly fitted apartment. But knowing its purpose, the first emotion of the stranger is usually surprise at its apparent smallness. Its proportions are—length 90 feet, breadth and height 45 feet. It has six windows, filled with stained glass, on the east, and the same number on the west side, and three compartments corresponding to them in shape, but filled with paintings in fresco, at the south, or throne end, and three similarly shaped and gilded compartments at the north, or bar end. The ceiling is flat, and divided by longitudinal and transverse beams into 18 compartments, which are subdivided into panels, and these, as well as the wall panels, are richly gilt and emblazoned; indeed every portion of the wall-surface which is not occupied by carved work or statuary, is decorated with gilding or colour; and in respect of its decoration the room is probably the most elaborate and gorgeous which has been constructed since the decline of mediæval architecture. The House of Commons is 69 feet long, 45 feet broad, and 44 feet to the centre of the present ceiling, the original ceiling being concealed by one of a different form, with a view to remedy certain acoustic defects. In character this apartment bears a general resemblance to the House of Lords, but it is much less ornate. Still more than that room, it wears a close and confined appearance. Indeed, though capacious enough for ordinary occasions, it is incapable of containing the entire body of members in their proper places, while the accommodation for strangers is almost ludicrously insufficient, persons who have obtained the necessary tickets of admission being under the necessity, on a debate of any importance, of being in attendance hours before the time for opening the doors in order to have a chance of gaining admission to the gallery. Modern architects have too often designed their buildings with a view rather to certain architectural effects, or to the exigencies of some particular order or style, than to their perfect adaptation to the purpose for which they were erected; but rarely has there been so remarkable an instance as this, where the House of Commons—the very heart and centre of legislation—is, in a legislative palace covering an area of some eight acres and costing upwards of two millions sterling, provided with a chamber too small to hold all the members, yet so ill-adapted for its object that the members can with difficulty hear each other speak, and the public reporters have constantly to note that "the hon. member was quite inaudible in the gallery." The room is however a very handsome one, though less handsome than before the alterations: and for its faulty form and insufficient size the architect is said to be not to blame, the shape and proportions having been imposed upon him by the instructions of his employers.

Connected with the houses are libraries for Lords and Commons, conference rooms, nineteen committee rooms (admirably adapted for their purpose), refreshment rooms, &c.; and it may be mentioned as showing the singular completeness of arrangement which modern appliances permit, that in all the rooms resorted to by the members of the Commons bells are fixed, which are connected with a galvanic battery, "so that the principal doorkeeper is enabled to make contact and ring all the bells at once, by pressing his hand on a button attached to the arm of a chair," and thus announce to the inmates of some thirty rooms that a division is about to take place. These rooms where the business of the country is carried on are approached and connected by numerous corridors—some of extreme richness and splendour, and all very effective architecturally. The old Westminster Hall has been preserved and worked into the edifice, to which it serves as the grand public entrance, and now opens at its northern end into a remarkably fine vestibule and a splendid apartment designated respectively St. Stephen's Porch and Hall. The old crypt of St. Stephens is to be the chapel of the House of Commons. A royal robing room of singular magnificence has been provided by the state entrance, and from it her Majesty passes through the Royal Gallery—another stately chamber—to the House of Lords. The Speaker's House, with its noble reception rooms, occupies the north end of the structure, and there are seventeen other official residences in the building.

Of the fine arts decorations which have been employed with a liberality unknown in any other English edifice we must be content to borrow Mr. Barry's brief summary: "Frescoes have been painted in the House of Lords by Messrs. Dyce, Cope, Maclise, and Horsley. In the upper waiting hall, river front, by Messrs. Cope, Watts, Herbert, Horsley, Tenniel, and Armitage. The Queen's robing room is now in the hands of Mr. Dyce, and the Peers' robing room is committed to Mr. Herbert. Mr. Ward is also engaged on a series of pictures for the corridors leading from the central hall, some of which have already been exhibited. Bronze statues have been placed in the niches of the House of Lords by Messrs. J. Thomas, J. C. Thomas, MacDowell, Wodington, Timbrell, Westmacott, Thornycroft, Thrupp, and Ritchie. Large white marble statues have also been erected in St. Stephen's Hall by Messrs. Foley, Bell, Marshall, MacDowell, Baily and Carew;" a colossal marble group of her Majesty, by Gibson, in the prince's chamber; and Mr. Maclise is engaged in painting the walls of the royal gallery. The whole of the statues and carving of the exterior, were executed by and under the superintendence of Mr. Thomas; the wood carving of the interior, the brass fittings and the furniture, under the superintendence of the late Mr. Welby Pugin, which may account for their excessively ecclesiastical and mediæval character. "The total cost of the structure up to February 1858, as far as the architect is concerned, has been 1,768,978*l.* 8*s.* 1*d.*" (Barry). The entire expenditure has, however, probably already reached two millions. And this expenditure has not been ill-bestowed. In mere extent the building is one of the most spacious of modern structures, covering as it does an area of upwards of eight acres, and comprising eleven hundred apartments, above a hundred staircases (some of them of grand proportions), and more than two miles of corridors and passages; while as a specimen of constructive skill it is in the highest degree honourable to the architect and to the country. We have spoken freely of what we regard as its defects as a work of art, but we gladly record our conviction that, with all its defects, it is by far the most satisfactory, as well as the most magnificent great public building which has during the present or the last century been erected in England, and we believe it to be the finest which during the same period has been erected in any part of Europe.

A year or two back it appeared likely that another building, or series of buildings, would be erected in contiguity with the new palace, and worthy of that edifice, the government having in 1856 offered premiums to the amount of 5000*l.* to the architects of all nations, without restricting them as to style or cost, for a block plan which should exhibit "the best scheme for the concentration of the principal Government Offices, on a site lying between Whitehall and the New Palace at Westminster; and also designs for two buildings which her Majesty's Government have determined to erect forthwith, as parts of such general scheme,—one for the department of the Secretary of State for Foreign Affairs, the other for the Secretary of State for War." By the specified time 218 designs, embracing nearly 2000 drawings, were sent in, and 17 of them, by French and German as well as British architects, received the promised premiums. The premiated block-plans proposed the most extensive, and in fact impracticable, re-arrangements of the site: the designs extremely magnificent but quite practicable buildings. On all hands it was allowed that the successful (and some of the unsuccessful) architects had displayed a very unusual amount of professional knowledge, taste, and power; and that the competition was by far the most successful of any of recent years. In the House of Commons, however, there appeared a very natural disinclination to provide at once funds for so large and costly a scheme, and without any public intimation, the Lords of the Treasury have cast aside the designs which they had induced the profession to prepare on the implied understanding that the work should be given to the successful competitors, and in spite of the earnest protest of Sir Benjamin Hall as commissioner of public buildings, directed a non-competing architect to design a new War Office on a more limited scale. Happily the transaction has been made public before the works have been actually commenced, and it is hardly conceivable that so flagrant a breach of faith can be persisted in, now that its real character is understood. We therefore still have hope that whatever be the size and character of the buildings decided on, it will be referred to the premiated competitors to prepare new designs, and to superintend their execution unless they be found unsuitable.

Next to the new palace at Westminster, the most important recent architectural work is the British Museum, of which the architect was Sir Robert Smirke R.A. This building was in progress when the article LONDON was written: and the portico was completed in April 1847; it was not however opened throughout till 1851. The building itself is the largest and most imposing example in the metropolis of the Grecian Ionic order, and the exterior has a certain monumental grandeur of character not inappropriate to its purpose. The interior few have been found to admire, either æsthetically or for its adaptation to the object for which it was designed. Even before it was completed it was found to be too confined in size, and not sufficiently elastic in plan for its purpose. As early as March, 1837, in an article on 'The New Buildings at the British Museum,' which appeared in the 'Mechanics Magazine,' vol. xxvi. p. 45, the question how best to obtain more room than the new buildings would afford, was discussed, and it was pointed out that "the space thus unfortunately wasted [by the great inner quadrangle] would have provided accommodation for the whole library, much superior to what is now proposed to afford it. A reading-room of ample dimensions might have stood in the centre, and been surrounded on all four sides by galleries for the books, communicating with each other, and lighted from the top:" and the writer, Mr. Thomas Watts (now one of the superior officers of the Museum Library), goes on to show in detail the many advantages which this arrangement possesses over Sir Robert Smirke's arrangements for the library and reading-room in the new building. But as so much care and money had been expended on the architectural features of the great quadrangle "that it might seem barbarous to propose filling up the space," Mr. Watts suggests as another, and perhaps more practicable plan, for obtaining the requisite additional room, to remove one side of Montague Street and Montague Place and make an extension of the building on the eastern and northern sides, on a grand scale, the works to be executed "as occasion shall arise." This latter plan is the same in principle as that officially proposed to the Treasury on the part of the Museum Trustees in March 1848, but first made public in the Reports of the House of Commons for 1852 (except that Mr. Watts proposed to afford accommodation to the chief learned societies, on condition of their collections being opened to the Museum visitors); as the former is in principle the plan which was proposed on the rejection of the other in 1852, and has been carried out in the new Reading Room. Some years later Mr. Hawkins of the antiquarian department in the British Museum proposed to erect a Board-room for the trustees, with studies for the chiefs of departments, offices for clerks, &c., in the centre of the quadrangle, connecting them by corridors with the galleries of the building itself. Mr. Hosking, the first professional architect who appears to have taken up the subject—laid before the Commission of Inquiry into the constitution of the British Museum in 1848, and before the Museum Trustees in November 1849, a plan for erecting within the quadrangle a modified or somewhat reduced copy of the Pantheon at Rome, or in other words a cupola-covered rotunda, 120 feet in diameter, and 120 feet high, "to form a grand central hall for the exhibition of the finer and more important works of sculpture, and of such other objects proper to the purposes of the museum as most require that steady and equable light which is so well obtained from the eye of a cupola, with connected corridors and galleries;" but the project did not meet the approval of the Trustees. In 1849 Mr. Fergusson published a plan of a building within the quadrangle to be used as a reading room and for library purposes; and in 1853 Sir Charles Barry, by direction of the government, designed very extensive alterations in the museum buildings, the chief feature of his design being a grand central hall within the inner quadrangle: but neither the voluntary, nor the commanded design was destined to be carried into execution. Mr. Panizzi, now principal librarian, then keeper of printed books at the museum, had in 1851 pressed on the trustees the necessity for providing additional room for the library, and laid before them a plan for obtaining a reading room and space for a large number of additional bookshelves within the quadrangle. In 1852 he produced a more elaborate scheme, and this on the recommendation of the trustees, the government sanctioned. His plan, as put in working form by Mr. Sydney Smirke, was to erect within the inner quadrangle of the museum a Reading Room, circular in plan, crowned by a hemispherical dome, and to provide space for a large portion, if not the whole, of the printed books in galleries surrounding this great central apartment. This building, of which Mr. Sydney Smirke was the architect, was commenced in March 1854, and opened for the use of readers in May 1857. It is constructed principally of iron,—the supports being cast-iron piers, which carry girders of wrought iron strongly tied together, and these bear the dome. Between the main ribs are brick arches, but the frame-work is of iron, and hence an immense saving of space is effected. The Reading Room is 140 feet in diameter, and 106 feet high: exceeding therefore in diameter every other dome in Europe, except that of the Pantheon at Rome, which is 142 feet in diameter. But it differs from the Pantheon greatly in its proportions and general character; and also in its manner of lighting, the Pantheon being entirely lighted by a circular opening at the top 28 feet in diameter, while the Reading Room has a similar light at the top 40 feet across, and 20 large windows in the base of the dome. Little is seen of the exterior, but the interior proportions and general effect are very pleasing, and it answers the purpose for which it was erected admirably. It affords ample accommodation for 300 readers, for whose comfort and convenience abundant provision is made. In the Reading Room itself the book-shelves hold 80,000 volumes: in the connected galleries and passages there is shelf-room for above a million volumes: and the whole arrangements afford an example of ingenious contrivance, as the building itself is a fine example of constructive science.

Buckingham Palace has been greatly altered both externally and in the inside within the last few years. The front of Nash's Palace is now concealed from the public eye by a new façade designed by Mr. Blore. In magnificence it is however greatly inferior to Nash's façade, bad as that was in most respects. The new front merely suggests the idea of a 'terrace' of a rather superior class of private residences: and the original poverty of character has been increased owing to the circumstance that the stone selected was of so friable a kind that it has been deemed necessary to cover it with paint. The Marble Arch too, which, however incongruous with the palace, assisted in imparting to it a certain dignity of appearance, has been removed; and now forms the Oxford-street entrance to Hyde Park.

The Treasury Buildings, Whitehall, have likewise undergone transformation. By some strange misconception the original building, erected in 1833, was so set out by the architect (Sir John Soane) that it could not be completed according to his design, and it accordingly was left unfinished. About 1845 Mr. Barry received directions to complete it according to a design he had prepared. Soane's façade was consequently made to give place to one of a much more florid character, which was completed in 1847, and which is a rich and elegant example of Italianised Corinthian. Chambers's Somerset House has been as far as possible completed by the erection of a west wing—the construction of a correspondent east wing being rendered impracticable by the erection of King's College. The west wing of Somerset House has been built in a manner in every respect satisfactory: the architect was Mr. Pennethorne. The same architect has also erected several other buildings for the government. One of the most pleasing of these is the Museum of Practical Geology, Jermyn Street and Piccadilly—the back of the building being, for some occult reason, turned towards the leading thoroughfare, the front towards the narrow bye-street. The building is a neat example of the Venetian palatial style; and it has a well constructed lecture-theatre: but the exhibition part of the edifice is not remarkably effective or convenient. Mr. Pennethorne is also the architect of the fragment of the General Record Repository, Fetter Lane; of the additions made to the Ordnance Office in Pall Mall; and of the extensive range of offices for the Duchy of Cornwall erected (1857) in Pimlico. The only other government building which requires notice, and that rather from its extent and massiveness than from its architectural merits—for it is in the most vulgar style of builder's castellated—is the new building at the Tower.

Of civic buildings the chief is the new Royal Exchange by Mr. William Tite. The old exchange was destroyed by fire on the 10th of January, 1838, but the first stone of the new building was not laid till the 17th of January, 1842: it was opened by the Queen in person on the 28th of October, 1844. As in the old exchange there is an open central area appropriated to merchants (110 feet by 53) which is surrounded by a spacious corridor or merchants' walk. The eastern end is chiefly appropriated to 'Lloyd's,' and contains some fine apartments—one being 100 feet long and another 80 feet by 40. The principal feature of the exterior is a Corinthian portico, at the west end, of eight columns with two intercolumniations. This portico is of noble proportions, the diameter of the columns being above 4 feet, their height 41 feet; and the pediment is filled with sculpture by Mr. Westmacott. The other parts of the building display considerable picturesqueness of character, but the southern side has been a good deal marred by the vandalism of the authorities, who have caused the granite piers to be cut away in order to give a little more room to the windows of the shops with which, from motives of economy, the architect had been compelled to disfigure his design. Another corporation building may be noticed here, the Coal Exchange by Mr. Bunning, which was opened with some ceremony by Prince Albert in 1849. Architecturally however it is rather peculiar than beautiful, but it is said to be well arranged: both the Royal Exchange and the Coal Exchange were somewhat freely decorated with arabesques and other designs in fresco by Mr. Sang, but in both the painting has failed to withstand the test of the civic atmosphere.

London has fully participated in the general revival of Gothic church architecture. Churches have sprung up with surprising celerity everywhere beyond the limits of the city proper, but with greatest profuseness in the outskirts. Most of the new churches we had occasion to refer to in the article London were Greek or pseudo-Greek; now not only is every new church belonging to the Establishment as a matter of course Gothic, but almost invariably every dissenting place of worship and every Roman Catholic chapel is also in strict conformity with one of the three 'periods' of pointed architecture. That this has been a great gain cannot well be doubted. Instead of grim caricatures of temples of Jupiter or Venus, or at best Minerva, we have fanes which can only suggest associations of Christian worship—though it may not be at its purest period; and which as architectural features serve to diversify the general monotony of our streets, and by their towers and spires to break the formality of what architects call the 'sky line.' But hitherto there has been, as was the case with the so-called Greek churches, by far too constrained an adherence to mere precedent. The nineteenth century Gothic architects—forced thereto probably in many instances by their clerical employers—have sought chiefly to produce a building which should faithfully accord in general form, as well as in the window-tracery, carvings, and other details, with some supposed type of the 'Early English,' 'Decorated,' or 'Perpendicular' period; and it is not too much to say, with very little regard to the actual forms of worship and requirements of a church whose peculiar system of prayer and preaching was modelled after the latest of those styles of architecture had not merely ceased to exist as a vigorous living reality, but had perished with the season and the order of things to which it belonged. The merit of the majority of recent churches lies therefore in their picturesqueness of external form, and, in the best of them, in the sober 'religious' splendour and impressiveness of their interior. There is abroad however a longing for a more perfect adaptation of ecclesiastical buildings to their actual use, a more thorough application of the discoveries of modern science in their construction, and on the part of architects a growing desire to cast off the merely servile adherence to mediæval precedent: the return, in a word, to the mediæval spirit—to earnestness and truth of purpose, and freedom of thought. And this has already effected much improvement, and we believe will lead to a still greater advance; and if it fail to create for this nineteenth century an architectural character of its own, it will at any rate save it from the condemnation of being purely mimetic. So numerous are the recent London churches and chapels, that it would be impossible, were it even desirable, to particularise them, and it will be sufficient, in order to avoid invidious distinctions, to refer as characteristic examples to the church of St. Stephen, Rochester Row, Westminster (by Mr. Ferrey) erected at the expense of Miss Burdett Coutts; to that at Highbury, by Mr. Allom, which is noteworthy for its effective, though not costly interior; and to the very remarkable one of red and black brick by Mr. Butterfield, in Margaret Street, Langham Place, which will when finished exhibit probably the most perfect illustration in London or its vicinity of the views and anticipations of the 'ecclesiologists;' to Pugin's Roman Catholic cathedral of St. George, Southwark; to the cathedral of the Catholic and Apostolic church, Gordon-square; to the Independent Chapels at Clapham, and at Avenue-road, St. John's Wood; and to the Baptist Chapel, Bloomsbury.

Of recently erected places of public entertainment, the principal is the new Opera House, Covent Garden. Covent Garden Theatre, built by Sir Robert Smirke in 1808-9, after various reverses of fortune was finally abandoned by the English drama, and in 1846 the interior was entirely remodelled by Mr. Albano, to adapt it to the service of the Italian opera. But it met with the usual fate of theatres, being destroyed by fire March 5, 1856. For a time it seemed probable that it would not be rebuilt, but the obstacles were ultimately removed, and a new theatre is rapidly advancing towards completion, which has been designed by Mr. E. M. Barry with special reference to the requirements of the opera, but with various novel arrangements, which are intended to render it easily available for the regular drama, or for concerts, public meetings, &c. In size the new theatre is about one-fifth larger than its predecessor, being 240 feet long, 122 feet wide, and nearly 100 feet high, which is nearly equal to the dimensions of La Scala at Milan, the largest theatre in Europe. The proscenium is to be 50 feet by 40; the stage will be 90 feet deep and 50 feet high. In form the audience part will be nearly a semicircle instead of a horse shoe, as in the late theatre; in size it will be 75 feet deep, 65 feet broad, and 80 feet high; and there will be only three tiers of boxes. (The proportions of the old building will be found under Theatres, vol. xxiv., p. 299.) In the construction iron has been much more freely used than in any former building of a similar kind. The roof formed of nine immense wrought iron lattice girders, each 90 feet long, 1 foot 6 inches thick, and 9 feet 6 inches deep, and weighing 18 tons. The chief feature of the exterior—about which we regret to see a great deal too much flimsy 'compo' ornament—is a Hexastyle Corinthian portico, 82 feet wide, and 80 feet high: the columns being 3 feet 8 inches in diameter, and 37 feet high. Flaxman's bassi-relievi, which were saved at the fire of the old theatre, have a place in the new portico, and his statues of tragedy and comedy in niches on either side of it. The basement or lower story of the portico is intended to serve as a carriage porch, while the principal story will serve as a promenade, the entrance to it being from the crush room. It is announced that the theatre will be opened in May 1858. A kind of conservatory or 'floral arcade,' of glass and iron, 240 feet long, 80 feet wide, and 60 feet high, is proposed to be built alongside of it, to be employed as a market for choice flowers by day, and as a promenade for the audience on opera nights.

The increasing passion for music has also led to the erection of three or four large music halls—to say nothing of as many 'music and supper halls' for a less refined auditory, but which in size and style of decoration would a few years back have excited no little admiration if constructed for more aristocratic circles. The first of the former kind, St. Martin's Hall, Long Acre, built primarily for the use of Mr. Hullah's music classes, was first opened in 1850, but only fully completed in 1853. The great hall is 121 feet long, 55 wide, and 40 feet high; and there are smaller halls beneath. The architect was Mr. Westmacott. In form and general appearance it has been modelled on the old baronial hall, but though a handsome and well proportioned room, it wears too sombre an aspect for a music hall. Its acoustic properties are respectable, though far from perfect, and the floor being level, and the stage low, only those of the audience who have front seats can see the singers; moreover, it has the usual lack of sufficient, safe, and ready outlets. The exterior makes no architectural pretensions. The Surrey Music Hall, in what used to be the Surrey Zoological Gardens, is a more pretentious structure both externally and internally; and though rather fantastic than pure in style, the exterior wears a certain festive air which goes some way towards atoning for its solecisms. The interior is light, gay, and lofty; and though it will, it is said, contain 10,000 persons, it is so well planned for its specific use, that when most crowded every person is able to hear perfectly: there being neither absorption of sound nor reverberation in any part. Its dimensions are—length, 155 feet; width, 66 feet; height, 72 feet. The architect was Mr. Horace Jones. St. James's Hall, between Regent Quadrant and Piccadilly, the most recent of these erections, as far as it has yet been tested, also appears to have been constructed on sound acoustic principles, but it has some orchestral defects. In size the great room is inferior to Exeter Hall and the Surrey Hall, being 140 feet long, 60 feet wide, and 60 feet high: there are two lesser halls, 60 feet square and 25 feet high. Little of the exterior is seen, but the interior is more splendid in its emblazoning than any previous edifice of the kind in this country; the architect, Mr. Owen Jones, having here carried out to the fullest extent his well-known views of decorative colour. The ceiling especially glows with the most brilliant hues, the unbroken primary colours being combined with gold in elaborate Alhambresque patterns, but the whole is admirably subdued and harmonised in effect under the novel and very effective system of lighting adopted. Great pains have also been taken with the ventilation; and the outlets are, if not all that could be desired, at least superior to those of either of the other metropolitan halls. Another building, originally called the Panopticon, in Leicester Square, should perhaps be mentioned in this connection, since, though erected for a purpose similar to that of the Polytechnic Institution, it has been lately employed for concerts. Constructed in what is called the Saracenic style, with minarets, &c., it presents a sufficiently incongruous exterior, but the interior has many excellences, and with little change would perhaps form a good lecture hall, if it should not be found adapted for music. The architect was Mr. T. H. Lewis. The Crystal Palace—the most magnificent place of entertainment for London, though not in it, has been referred to elsewhere. [EXHIBITION of 1851, *S.* 2.]

To our former list of club-houses we have now to add some of a still more costly character. First of these in point of time was the Conservative, in St. James's Street, a stately Italian edifice, erected in 1844, from the designs of Messrs. G. Basevi and Sydney Smirke. The front of the old Carlton, by Sir Robert Smirke, has been made to give place to a much more ornate façade by his brother Sydney. This, however, has no claim to originality, it being an almost exact reproduction of the Library of St. Mark at Venice by Sansovino. Its chief novelty consists in the use of polished red granite shafts; but the richness which they, in combination with the elaborate entablature, might in a happier situation have produced, is almost lost from the house being placed on the shady-side of Pall-Mall. Nearly opposite to it is another club-house copied from Sansovino: the Army and Navy, by Messrs. Parnell and Smith, who have taken for their type the Palazza Cornaro of the great Venetian, or rather Florentine, architect. More originality has been displayed by Messrs. Nelson and Innes in the Junior United Service Club, Regent Street, a spacious and very stately pile, which replaces a smaller and less assuming one by Sir Robert Smirke.

A few private residences have been built at the west-end during the last few years which may help to maintain the prestige due to the abodes of our nobles and wealthy commoners, somewhat endangered by the palatial splendour of the club-houses. Of these the first and grandest is Bridgewater House, Cleveland Row, built by Sir Charles Barry, 1848-50, for the late Earl of Ellesmere. In its general character, and in the gracefulness and finish of its details, it reminds the observer of the designer of the Travellers' and Reform Club-Houses, but it is more ornate than either, while retaining their chaste dignity. Its dimensions are 142 feet by 120. It has a noble state dining-room, 48 feet by 25, and a state drawing-room 68 feet by 28; but the great feature of the interior is a spacious picture gallery, with loggias, 110 feet long, and which, were the lighting somewhat more satisfactory, would be in every way worthy of its magnificent contents. Scarcely less palatial in scale or style is Dorchester House, Park Lane, erected in 1852-53 for Mr. R. S. Holford, by Mr. L. Vulliamy. In style it belongs rather to the English renaissance, as represented by Inigo Jones, than to the Italian adopted by Barry; and in many respects it is hardly so satisfactory, but it is a stately and imposing structure: its dimensions are 135 feet by 105. The mansion of Mr. H. T. Hope, erected in 1848-49 by Professor Donaldson from the designs of M. Dusillon, at a cost of 30,000*l.*, also deserves a word of notice, though in an artistic point of view it cannot be considered a happy effort. Like the mansions just noticed it is fitted up with great splendour, and like them it contains a singularly choice collection of paintings—indeed the finest collection of works by the Dutch and Flemish masters in this country.

Turning to 'The City,' we are at once struck by the great improvement in the ordinary street architecture, which is there still more distinctly manifested than at the west-end, though at the west-end the improvement has not been inconsiderable. In the new streets have sprung up a long succession of warehouses of a size and costliness quite unprecedented in London. Many of them are faced with stone, decorated with carving, and make considerable architectural pretensions; and all are built in a style of construction at once bold and substantial. The most striking feature of these new city warehouses is their great loftiness; five, six, and even seven stories being far from unusual. Of these warehouses the most noticeable are those in New Cannon Street and its vicinity, Wood Street, &c.; but piles of 'offices' of almost or quite equal magnitude have been built, or are building, in every part of the city which lies within the business boundaries, in the narrowest alleys, courts, and lanes, as well as in the main lines of traffic. The most remarkable of these blocks of offices for extent is one which it is impossible for an architect to look at without a certain feeling of regret; for to make room for it one of the most artistic edifices in the city was pulled down. This was the Excise Office in Broad Street, built by James Gandon in 1769, of which it was remarked in the article LONDON ('Penny Cyclopædia,' vol. xiv. p. 114) that "for imposing grandeur of mass, and greatness of manner, combined with simplicity, it surpasses everything else in the metropolis." Unfortunately on the removal of the Excise department no other use was found for it, and it was destroyed to make way for a building, the chief merit of which is that it contains a greater number of separate offices than any other in the kingdom.

Another class of city buildings which has done much to raise the character of London street architecture is that which includes the banking-houses and insurance-offices. To the former several have been added by the joint-stock companies, as the Bank of London and the City Bank, which stand nearly opposite to each other in Threadneedle Street, the Australian Bank by the Royal Exchange, and several others of more or less architectural pretence; and among them must now be placed the well-known South-Sea House, which was converted to the use of another company of as had eminence as the corporation for which it was originally built—the Royal British Bank. Among private establishments may be named that of Jones, Loyd, and Co., in Lothbury, whose new office, by Mr. Hardwick, is a very meritorious work. We may also in this connection refer to the as yet unfinished office of the National Discount Company in Cornhill, which is a work of unusually florid character, as well as of considerable size—but the ornament is mere stucco, and the whole affair looks rather 'showy' than substantial. The earliest, and among the best of the recent city insurance offices are the Sun (by Mr. Cockerell), in Bartholomew Lane, and the Imperial in Threadneedle Street: the latest are the Royal, in Lombard Street; the Union (a substantial but rather plain building) in Cornhill; the Crown, with some piquant Byzantine features, in Bridge Street; and the Law, in Chancery Lane.

Some of the City Companies have also built new halls, or put new fronts to their old ones. The largest of the older City halls, the Merchant Taylors', in Threadneedle-street (erected by Jarman after the fire of London), has been concealed from view by a screen of offices of no great elegance built by the company. The Weavers' Company have built themselves a new hall in Basinghall Street—a substantial structure, but deficient in character, the lower part being appropriated to offices. A somewhat better building is Dyers' Hall, Dowgate Hill, (by Mr. Corbett); but, like the companies just noticed, the Dyers have combined profit with display, having also appropriated the lower portion of the building to mercantile offices. The Clothworkers in their new hall, in Mincing Lane,—now in progress, from the designs of Mr. S. Angell,—have been less thrifty. Their building is wholly appropriated to the purposes of the company, and it is a very costly as well as substantial edifice. The façade, which is of Portland stone, is Italian, of a somewhat florid character, and, like the interior, it is much enriched with carving. The chief feature of the interior is of course the great hall, which when finished will be a very splendid apartment. It is 80 feet long, 40 feet wide, and 40 feet high; the vaulted roof being supported on Corinthian columns of polished red granite with columns of Caen stone. The windows are to be of stained glass. The court drawing-room, of somewhat smaller dimensions, is of corresponding richness; and there are two or three other stately apartments, and a grand staircase lighted by a dome.

In shop architecture the City has also of late taken the lead. A very recent example—a silversmith's shop in Cornhill, opposite the Royal Exchange, of which Mr. J. Barnett was the architect—is perhaps the most costly as well as the most pretentious specimen of shop architecture in London. As an illustration of the tendencies of London shop architecture we may spend a few lines upon it. The building, though not more than 40 feet wide, rises to a height of about 100 feet. The shop is 26 feet high, and the whole of the front above it (of Bath stone) is carried on a wrought-iron tubular girder, which is borne (or seemingly so) by red granite pilasters having Corinthian capitals of Bath stone. The upper part, of four stories, has attached Corinthian pillars of polished granite; a balcony at the fourth story; and crowning the summit a very bold cornice. The style is Venetian, and a great deal of ornamentation is everywhere introduced. In the spandrils of the windows of the second story are emblematic figures. The space between the arch of the shop-windows and the cornice above is of statuary marble, carved in a bold and florid style by Trentanova. On the whole, the façade has a rich and striking character, with an allowable excess of ornament, the chief defect being the appearance of weakness, arising from the want of sufficient apparent support in the ground story for the enormous mass above. The disagreeable aspect which a building so narrow, as compared with its height, would almost necessarily have, is removed by the house on each side being built of a uniform height, though somewhat lower than the central building, and in a similar though much plainer style, thus evidently forming with it part of one design—the sides supporting but being plainly subsidiary to the central compartment. The interior of the building is even more ornate than the exterior. The ground floor is open to the room above, around which runs a broad gallery supported by coupled Doric columns, over which are coupled composite columns with shafts of coloured marble. The ceiling, like the gallery, has deep and richly ornamented coffers, the beams being supported by coupled caryatidic figures. From the centre hangs a very large chandelier. Everywhere is a profusion of coloured marbles, carvings, looking-glasses, and decorations, with the glittering stock rather dazzling than satisfying the eye. Such a building as this, with all its faults, shows of how much consequence shop architecture is becoming. We believe that in London it is opening a fertile field for the abilities of architects of artistic tastes, constructional knowledge, and original fancy. By Mr. Ruskin and his followers shop architecture is denounced in unmeasured terms. But shops form of necessity the great feature in the streets of a city such as London, and shopkeepers in such a city must endeavour to render their places of business as attractive as possible. If houses are to be built expressly for shops, there can be no good reason why architects should not construct them of as ornamental and beautiful a character as is consistent with the purpose for which they are designed. In the great majority of recent shops everything else has been made to yield to the desire for as large a surface of plate-glass as possible; and hence what was indicated as the most palpable fault in the shop front just noticed—the want of sufficient apparent support in the ground story for the floors above—is the almost universal defect in the showier class of such buildings: and it is a fault fatal to all architectural effect. In its excess it may be seen in a shop on the south side of Fleet Street, where the whole upper part of the house rests on a heavy carved cornice, and this, with all that it carries, on two immense sheets of—plate-glass. Yet, if possible, the absurdity has been rendered even more palpable in St. Paul's Churchyard, where an extremely long shop front, formed by throwing two or three houses together, is made in appearance to bear the whole superincumbent mass of brick-work upon a few slender glass pillars, and even the wider attached pilasters at the end are covered with looking-glass. Of course in all these cases the upper parts of the building are really supported on wrought-iron girders, and for bearing these sufficient provision is made by strengthening the side walls, and by adding piers, &c., where necessary. Now, instead of trying, as some architects advise, to deceive the eye by giving to the shop front an arched form, and thus inducing the appearance of sufficient support for the upper stories—a method which the shopkeeper will not in many instances allow, and when he does, will probably shortly destroy the effect of by some gaudy decorative additions—why not accept the necessities of the case, and endeavour honestly to surmount them? Railway and other recent engineering works have too much accustomed the eye to the girder for its vast strength to be for a moment questioned where it is seen to be adequately upheld. If the strength of the supports be satisfactory, there will be no doubt—none of the latent doubt even which unconsciously produces the feeling of distrust in the uninstructed observer—of the sufficiency of the girder, and consequently none as to the stability of the building. What seems to be wanted, then, is to frankly admit and not to endeavour to conceal the girder form, and to give to the supports the greatest possible emphasis. Then trabiated, equally with circular or pointed arched, architecture will be found to satisfy the eye in the primary essential of security, while it alone can be found adequate for the varied requirements of the London tradesmen of this present century, as it alone can, within due limits as to altitude, securely bridge over wide spaces. It has therefore the great recommendations of structural truth, and of affording ample scope to the architect's inventive skill. Where a very wide window surface is not required, a different method of treatment is applicable; and the stationer's shop at the corner of Chancery Lane is a favourable example of what may be done under such circumstances, and a sufficient illustration of the opportunity which shop architecture affords for architectural taste and ingenuity; and also, we may remark in passing, a satisfactory illustration of the service which may be rendered by composition as an adjunct to well-executed brickwork in London street architecture, when it is used as composition and not as a deceptive imitation of stone.

Before quitting the City we may just mention that two of the best known of its buildings have been considerably altered: the Bank of England both externally and in the interior, under the direction of Mr. Cockerell, who, as regards the outside, has, without changing any of the better parts of Soane's design, by giving elevation in certain portions of the façades certainly improved its general character; and Newgate prison, of which the whole interior has been rebuilt on a very superior plan, while the exterior—a classic example of prison architecture in general estimation—has with excellent taste been preserved untouched. A building usually associated with Newgate in the architectural mind, as being by the same architect, Dance, very similar in design as well as purpose, and its near neighbour, Giltspur-street Comptoir, has however been less fortunate, having been pulled down when the new city prison at Holloway was completed. The site is still unoccupied, as is also that of the Fleet prison, pulled down in 1844. The new City Prison at Holloway is an extraordinary looking castellated pile, of great size and enormous cost, but said to be a very convenient and healthy place inside. Two or three other prison-palaces have been constructed within the last few years for the care of metropolitan rascaldom: the chief being the Model prison, Pentonville, and an enormous structure on Wandsworth Common.

Of semi-public and corporate buildings outside the city walls a few must be noticed. Lincoln's Inn Buildings, of which the first stone was laid by Vice-Chancellor (now Lord Justice) Knight Bruce, April 20, 1843, and which were inaugurated by her Majesty, October 30, 1846, form one of the most striking and picturesque of the recent buildings of the metropolis. They consist of a dining hall, a library, and a benchers' dining and council rooms, united by a handsome vestibule; the architect was Mr. P. Hardwick, R.A. The buildings are in the later Tudor domestic style; and are constructed of red and black bricks, with stone quoins and dressings—the whole being executed in the best manner. The dining hall is 120 feet long, 45 feet wide, and 64 feet high; has an open roof of oak, with a louvre lantern, a series of five large and handsome windows on each side, two large windows at the dais end, and a noble window of five lights at the opposite or south end. All the windows are enriched with heraldic emblazonings, the pendants of the roof are gilt, and the front of the gallery is adorned with sculpture: on the whole it is undoubtedly the finest room of its kind in London—we are of course not comparing it with Westminster Hall, which is wholly different in character. The library, which stands transversely to the hall, is also a very handsome room,—80 feet (or including the oriels 90 feet) by 40, and 35 feet high—its chief features being an elegant semi-octagonal oriel at each end (like the windows in the hall enriched with stained glass), and an oak roof of good design: as a reading-room it is comfortable and even luxurious in its arrangements. In the Temple, New Buildings, somewhat similar in style but less imposing in intention and effect, have been erected by Mr. Sydney Smirke, R.A. With these we may place, as conformable in style though not in object, University Hall, at the back of University College, by Professor Donaldson. The Abbey Buildings, Dean's Yard, Westminster, require special mention as a very admirable though not servile adaptation of Gothic forms to modern purposes: they are by Mr. Gilbert Scott, whose recent advocacy of a free adaptation of Gothic "as the basis of future development" in English architecture has attracted such very general attention.

The buildings called into existence by philanthropy in the metropolis and its immediate vicinity are so numerous, that —although some of them are, from their size and merits, architecturally of importance—we must be content to enumerate only a few which recur to the memory. St. Mary's Hospital, at Paddington, King's College Hospital, in Carey-street, and the Consumption Hospital, at Victoria Park, are chiefly noticeable for their admirable sanitary arrangements. The Brompton Hospital for Consumption (by Francis) is of large size and effective design, and has an elegant chapel by Lamb. The Small Pox Hospital, near Highgate, is admirably situated, and has some good features; and something similar may be affirmed of the Convalescent Hospital at Walton. The numerous metropolitan orphan schools and asylums have been judiciously placed in healthy sites at a little distance from London: such are the Working Orphan school, a large Italian edifice on Haverstock Hill, the Orphan Asylum at Wanstead, the Royal Patriotic Asylum at Wandsworth Common, the Soldiers' Daughters' School and Home at Hampstead, the Idiot Asylum near Reigate, and numerous others, some of them displaying an amount of architectural character hardly to be looked for in such establishments, but, what is better, almost all showing a regard for the health and comfort of the inmates in the highest degree meritorious. The same may be said of some of the old guild schools of London, and some of the parochial schools, which have been removed to healthy, and often picturesque sites, a few miles in the country, where more extensive buildings have been erected, with all the modern sanitary as well as educational appliances: as, for example, the Freemasons' School, Wandsworth Common, the Welsh School, Ashford, Middlesex, the City of London Orphans' at Brixton, the City Industrial Schools, at Penge, the South Metropolitan Industrial Schools, at Sutton, Surrey, the Whitechapel Industrial Schools at Forest Gate, Essex, and many more.

London is indebted for some recent additions to its architecture to railway progress. The new terminus of the London and North Western Railway, by Hardwick, is really a very imposing, as well as very costly structure: its expense was above 150,000*l.* Scarcely so much can perhaps be said of the Great Western terminus, as it is rather remarkable as an engineering than an architectural work, but it has the superior merit of showing adaptation to its purpose in a very unusual degree, and, to our thinking, is consequently the most satisfactory of all the London termini; it was the joint production of Messrs. Brunel and Digby Wyatt. Adjoining it is an hotel built for the railway Company by Mr. Hardwick, which in size, architectural pretension, and costliness, surpasses any yet constructed in London. The style—late French renaissance, with its bold mansard roofs to the centre and turrets, the colossal terminal figures supporting the balcony, &c.,—was a novelty in London, and altogether it excited much notice. The terminus of the Great Northern Railway, at King's Cross, by Mr. L. Cubitt, merely presents, externally, brick terminations to the carriage sheds, with a lofty central tower; but inside the vista formed by the sheds is characteristic and effective. Alongside the station the Company have built an hotel rivalling in size that of the Great Western: like that the style is continental, but rather strange than beautiful. None of the other metropolitan railway termini of recent erection have any architectural character.

Though we have left ourselves no room to describe, we must just refer to the great works completed and in progress in connection with the docks of London. Of those of the old companies, the most extensive are the new works of the London Docks at Shadwell, to make way for which many hundreds of houses have been removed. The object has been to afford greater facilities for the admission and unloading of the immense vessels which the requirements of modern commerce have called into existence, as well as to obtain increased room for general purposes. With this view new basins of great depth have been formed, a new entrance constructed, with gates of enormous size, and various hydraulic and other appliances added of great power, as well as new warehouses and other works. At the Commercial Docks, on the Surrey side of the Thames, extensive alterations and improvements have been carried out. On the Plaistow Marshes, just below Blackwall, have been constructed the Victoria Docks, which afford at present about 90 acres of water area, with entrances admitting larger vessels than any of the older docks, though not, we believe, larger than the new works at the London Docks mentioned above. At Woolwich, a steam dock has been constructed, and vast works of various kinds erected, in connection with the arsenal, foundries, steam factories, &c., of the Government. And, finally, at Brentford a large new dock has been constructed, chiefly with a view to afford increased facilities for water carriage in connection with the Great Western Railway.

A few words on some of the larger works resulting from the progress of sanitary reform will conclude what we have to say respecting the public improvements of London. After a protracted struggle, the city corporation were compelled, in 1852, to remove their fondly cherished Smithfield market; but it is due to them to say, that when compelled to provide a new cattle market in the suburbs instead of in the centre of the city, they performed their task honestly and well. The site chosen was an elevated and very convenient one, the notorious Copenhagen Fields, adjoining both the Great Northern and North London Railways. The market covers an area of about 25 acres, but a large space is reserved for lairage for sheep and cattle, and for extension at a future time if it be found necessary. The provisions for the comfortable accommodation of the cattle have been made in a thoroughly humane spirit, and, in fact, whatever forethought could suggest for avoiding the evils usually attendant on large cattle markets has been done with a bold disregard of expense, which only a corporation wealthy as that of London, content to look to a somewhat remote future for repayment, could have ventured upon. Though it is rather on account of its skilful arrangement and adaptation to its special purpose that the Metropolitan Cattle Market is to be regarded, yet it is not without claims to notice architecturally. Its hotels and banking-houses, and some of the offices are in very good taste, and its lofty central tower forms not only a prominent feature in the landscape for many miles northward, but gives an air of completeness and unity to the whole design. The plan of the Metropolitan Cattle Market, with all the details of its arrangement, is due to the city architect, Mr. Bunning, who also, two or three years before, had rebuilt Billingsgate Market in a very skilful manner, and with a special regard to convenience, cleanliness, and salubrity.

In 1852 an Act was passed rendering it unlawful for any water-company drawing its supply from the Thames, to take such supply after a certain day from any part of the river below Teddington lock. The several companies accordingly at once set about the construction of very extensive works—the Grand Junction, the West Middlesex, the Vauxhall, and the Southwark, at Hampton; the Chelsea and the Lambeth just above Kingston. The works at these places are some of them on a magnificent scale, the entire new works, for example, of the Chelsea Company, rendered necessary by the Act, have cost 450,000*l.* The water is conveyed from Hampton and Kingston, in mains of from 30 inches to three feet in diameter, to the reservoirs of the several companies in the immediate vicinity of London. The mains of three of the companies are passed under the Thames at Richmond by means of the coffer dams; those of another company are carried above the bed of the river, near Putney bridge, on piers formed by Mitchell's screw piles. But even more extensive and costly have been the works of the New River Company, who, in works near the head of their river (including the drainage and diversion of the sewerage of the town of Hertford), in forming capacious new reservoirs, and covering their old ones, &c., have expended considerably over half a million. Very extensive new works, and alterations in existing works, have also been carried out by the East London, the Kent, and the Hampstead companies.

The result of these vast operations has unquestionably been a very great improvement in the quality of the water supplied to the inhabitants of London. The Registrar-General, in his Report on the Health of London for the week ending April 17, 1858, says that the London water "contains less than half the previous amount of impurity. A gallon of water of the Chelsea Company formerly contained from 37 to 66 grains of extraneous matter; the Southwark water contained from 23 to 73 grains; while the analysis now shows that only 21 grains of extraneous matter are to be found in a gallon of the water of either company." In several of the other companies a still smaller quantity of extraneous matter is found (in the West Middlesex only 17·64, in the Grand Junction 17·76 grains): but then the water of these companies was always purer than that of the former. Still it is very questionable whether,—when so great and costly an alteration was rendered compulsory,—the legislature might not well have gone further, and prohibited the use of the Thames at all for the purpose. For before it has reached the place where the supply is now drawn, it has been polluted by the drainage of Windsor, Chertsey, Staines, and other towns, and, as Mr. Ranger, the Superintending Inspector of the General Board of Health, has pointed out in his recent Report on the Sewerage, &c., of Aldershott village, the new sewerage works of the camp at Aldershott have been so constructed as to have "their outfall into the Blackwater river . . . one of the tributaries of the Thames, entering the latter above the point from which a very large portion of the London supply is now taken, and thus a new source of pollution" has been introduced. In fact, it is stated in a Report just laid before the House of Commons by the Royal Commission appointed expressly to inquire into the best mode of distributing the sewage of towns that "the Thames, before it reaches the point where the water supply of London is at present derived, receives the refuse of districts containing upwards of 700,000 persons." Under the circumstances, it would therefore be consolatory to believe, with another set of Commissioners,—the engineers and chemists employed by the Metropolitan Board of Works to report on the Main Drainage of the Metropolis,—that this is of comparatively little consequence, Thames water being, in fact, a disinfectant: "sewage matter," they say, "being poured into a much larger volume of fresh or freshened water, becomes immediately oxygenised, and ceases to exist as a noisome and offensive agent."

Of the rival plans for intercepting the main drainage of the metropolis, as they are yet only plans, we shall not speak; and it is the more advisable not to do so, as although the government referees and the engineers of the Metropolitan Board of Works were directed to proceed upon the basis, that a vast intercepting sewer extending on each side of the Thames was agreed upon, and the point to be settled was the distance below the metropolitan boundaries to which it should be carried, the whole question has been re-opened by the Royal Commission mentioned above, who have just laid before the House of Commons (April, 1858), the outline of an entirely new plan, which is in effect to execute at once the embankment scheme of the Metropolis Improvement Commissioners of 1844. The embankments they propose to be made to contribute to the beauty as well as utility of the river, the relief of the over-crowded streets by means of advanced terraces which are to afford carriage ways between London and Westminster, and the connection of railways on the southern side of the river; while the sewage is to be received into reservoirs in the embankments at the months of the existing main sewers, and having been there deodorised and purified, the liquid part is to be permitted to flow into the river, and the precipitated matter to be carried away for agricultural purposes or discharged into the sea. Of the desirability of such an embankment as they describe there will hardly be a second opinion. The sewage part of the scheme is more questionable; but the Commissioners are sanguine as to its practicability, and they assert that the reservoirs and apparatus would be hidden beneath the surface, and that no nuisance whatever is to be apprehended. The entire cost they estimate at 3,250,000*l.*, which is some 500,000*l.* less than the intercepting sewer scheme of the Metropolitan Board, and 2,200,000*l.* less than that of the Government referees is estimated to cost. But this reminds us that among the metropolitan improvements we have not mentioned the embankment of the Thames between Pimlico and Chelsea, a very excellent work, and thoroughly well executed, but which, estimated at 62,000*l.*, has cost 112,000*l.*

Among the greater sanitary improvements in London we must not pass unnoticed the substitution of spacious suburban or more distant cemeteries for the crowded churchyards of the city. Of new cemeteries the most remarkable is the London Necropolis, or Woking Cemetery, formed by a private company, which under powers of an Act of Parliament purchased 2100 acres of forest heath land, extending upwards of four miles along the line of the South-Western Railway, towards Farnborough and Pirbright. Of this land the company has, in the first instance laid out 400 acres, consisting of a slightly undulating heathy tract, singularly quiet and picturesque in character, as a cemetery, and built chapels for the use of members of the establishment and nonconformists, with convenient waiting-rooms for mourners. A neat station is provided for the exclusive use of the cemetery, in London, and special trains carry the funeral direct from it into the cemetery—a short line of railway having been constructed for the purpose. Funerals are thus conducted with economy, privacy, a careful regard to the feelings of mourners, and in all respects with singular propriety. As near an approach to the best mode of interment as in the present state of society is perhaps practicable, appears indeed to have been attained. In connection with no other cemetery, we believe, has there been made such judicious arrangements for the conveyance of funerals from London—a matter of great consequence where the cemetery is at some distance from the city, and one which, like some other sanitary improvements, presses with peculiar severity on the poor. A very extensive and well-planned cemetery has been formed by the City of London at Ilford, Essex; Marylebone and St. Pancras parishes have constructed theirs at Finchley; Lambeth parish has one at Tooting, and others newly formed are to be seen on journeying a few miles on any side of London.

Turning to the Provinces, we can do little more than repeat our former statement, that great as has been the progress in architecture and public improvements generally in the metropolis, the provincial towns have in their proportion made equal, or nearly equal progress. We can only venture in vindication of this statement to refer briefly to a few particular instances. At Liverpool this has been eminently the case. St. George's Hall, designed by Mr. H. L. Elmes, but, in consequence of his death, completed by Mr.

Cockerell, may not only be fairly placed in comparison with any similar building in London, but without hesitation be pronounced in many respects the finest, as it is undoubtedly the richest, recent example of a Romano-Corinthian edifice in the kingdom. The hall itself, 168 feet long, 100 feet wide, and 85 feet high, is spanned by a vaulted roof, and forms one of the noblest public halls we possess. The rooms devoted to the assize courts are not so satisfactory. The exterior has, at the south end, a Corinthian portico of grand proportions, with a pediment filled with sculpture; a semi-circular portico at the north end; and a portico of sixteen columns without a pediment at the side. It is not impervious to criticism, perhaps, but undoubtedly St. George's Hall is one of the great architectural works of the day. Among other new buildings of the town are the Collegiate Institution, a large and handsome Tudor collegiate structure, also by Mr. Elmes; the Sailors' Home, a spacious Gothic building by Mr. Cunningham; the Branch Bank of England, by Mr. Cockerell, &c.; but perhaps the most characteristic of the new buildings of Liverpool are the extensive and costly piles of 'offices,' which are as much superior to similar buildings in London as the Manchester warehouses are to the warehouses in the City. The Docks of Liverpool, with vast ranges of connected warehouses, have been increased in number and extent, at an outlay of several millions sterling, and are now probably unrivalled. The floating stages on the Mersey, for landing from steamers, likewise claim a word of notice: one, at Prince's Pier, finished in 1857, is 1000 feet long by 82 feet wide, and cost about 140,000*l*. Liverpool is one of the towns which has provided itself at a great cost with a supply of pure water from a distant source. Whether as a rival or an adjunct, its neighbour on the Cheshire side of the Mersey, Birkenhead, cannot be left unnamed in speaking of the material progress of Liverpool. The docks and warehouses of Birkenhead, its vast market, &c., are among the most remarkable illustrations of recent commercial progress.

"Manchester," it was said, in the article MANCHESTER ('Penny Cyclopædia,' v. XIV. p. 369), "is not distinguished for architectural beauty." That could scarcely be said with truth now. It is not certainly a beautiful city architecturally even yet, but buildings of a very superior order of excellence are now numerous, and their number is rapidly increasing. Foremost, as forming a sort of central point of the city, is the Exchange; which as lately enlarged affords the most spacious room, we believe, in Europe, for the meeting of commercial men; and both externally and in the inside is a very admirable work of its class. Free Trade Hall (by Mr. Walters), is in its title as well as its purpose, a structure characteristic of Manchester, and moreover a very fine building. Other buildings of a semi-public character are the Theatre, the Branch Bank of England, by Cockerell; the bank of Messrs. Haywood; the Manchester and Salford Free Library; churches, chapels, synagogues, &c. But indisputably the warehouses form the distinctive feature of Manchester in an architectural point of view. They are very numerous, and new ones are springing up on all sides. They are for the most part of great size—one, but we believe it is the largest in Manchester, built for Sir James Watt, the late mayor, by Messrs. Travis, is of the enormous dimensions of 300 feet long, 90 feet deep, and 100 feet high, three of the fronts being wholly of stone. And these warehouses are constructed in the most substantial manner, of stone or of excellent brick-work, with stone quoins and dressings: 'compo' is not in repute in Manchester. The style usually affected by the merchant princes, or their architects, is the Italian palatial, which is in most instances carried out (as for example in those designed by Mr. Walters) with great refinement and finish, the carving and details being often worthy of a London club-house. The best of the London warehouses would certainly compare badly with many of their Manchester prototypes. A good beginning has likewise been made towards the embellishment of the city and suburbs with public monuments and parks. The front of the infirmary has been laid out as a sort of public place, and here statues of her Majesty, of Wellington, Peel, John Dalton, and James Watt, have been erected. New streets have been opened in the city, and old streets have been widened. The drainage has been greatly improved; and an ample supply of water has been brought into the city at a great cost from a considerable distance. And outside the city three new parks have been formed: two of which, Queen's Park, Harpurhey, and Peel Park, Salford, are very attractive resorts.

Birmingham has hardly kept pace with the two great towns of Lancashire: yet it has added some new buildings worthy to rank with its noble town hall; as for example the grammar school, the news hall, the music hall, the midland institute now in progress, and some others. It has also its park; but we cannot add that it has its improved drainage. At Bristol something has been done. The Victoria rooms is a spacious and very noble building for musical festivals and public meetings. The guildhall has a façade which is rather a favourable example of the Tudor period, but the interior is ill-arranged and undignified. An academy of fine arts, and a general hospital are the most recent additions to the architecture of the old city, and both are more than ordinarily ambitious in design.

Turning from our manufacturing and commercial to our university towns, we find no falling off, though the architectural zeal has taken a different direction. At Oxford the handsome range of buildings by Mr. Cockerell, called the Taylor Institute and University Galleries may be taken as marking the close of the passion for classic art in that university. Oxford is now, and has been for some years, the head quarters of mediævalism, and there the 'ecclesiologists' hold unquestioned sway. Perhaps nowhere else can the good and the evil of the Gothic revival be more distinctly seen. For years past the grand old city seems to have been given up to the gothic builder and the gothic restorer. It would be idle to attempt an enumeration of the works which have been accomplished. Almost every college has added a new chapel, or chamber, or sculptured gateway, or made some little addition to its existing architectural treasures, or restored and re-edified its old ones. Many of the new works are of great beauty and richness, as could not indeed fail to be the case, for they arose out of the promptings of a zealous love of Gothic architecture, and their execution—provided for with no niggard hand—was entrusted to architects already famous for their peculiar devotion to this branch of the art. It is, perhaps, not too much to say, that some of the new works are worthy to stand beside the glorious structures which surround them. But we can afford no such liberal praise for the so-called 'restorations.' They may have been well done professionally: they may have been correctly performed according to ecclesiological conceptions: but the buildings which have been restored are not now the same buildings we knew a few years back, venerable in their hoary and unmistakeable antiquity. They have been, too many of them, made to wear the gay drapery of youth upon the seared and bending frame of age. They now consequently exhibit neither the solemn majesty of the one, nor the lightsome beauty of the other. Our ancient Gothic structures,—marvellous in the grandeur of their forms, in the evidences of mental power and artistic fancy, in their quaint carvings and playful tracery, over which sun and shadow love to linger,—structures on which the cultivated and the uninstructed alike gaze with awe and wonder and endless admiration,—ought only to be touched with a reverential hand. Our fathers, bowing before the sovereignty of the Greek and Roman, regarded our glorious mediæval buildings with something like contempt as the productions of a dark age and a Gothic understanding; and they altered, improved, or destroyed them with almost equal indifference. But their contempt was, we cannot but think, less dangerous than our too ardent love. They thought it folly to spend time over the rude structures of the dark ages, when they could study the temples of the brightest days of Greece and Rome, or of those enlightened times when the lore of antiquity was restored to the scholars of modern Europe. We have come to worship mediævalism, and in our foolish fondness have sought to replace the decaying vesture in which the object of our affection was clothed, by one as exactly resembling it as we could contrive to fabricate, forgetting, till too late, that our new and gay drapery is after all but a modern fiction, and that the old weather-worn garment which we have replaced was the only true one—that we have indeed copied, but in copying have destroyed it. 'Restoration' in truth is for the most part a mistake. Ancient buildings regarded as works of art are to be preserved—like ancient statues—with jealous care from the chisel of the modern artist. If anything can be done to arrest their decay, well: but it must be so done as not to remove, if possible, a hair or a finger-nail of the original—assuredly not to substitute for it a new one, though that be the exactest copy of what the chipped and battered fragment we have removed was in its pristine condition. As well might the Theseus or Ilyssus in the British Museum be submitted to the 'restoring' chisel of Westmacott or Baily, or any other living Phidias, as our cathedrals and colleges be subjected to the tender mercies of modern representatives of the ancient builders. We are not, of course, objecting to necessary repairs, or even, where imperative, to rebuilding, but simply to the destructive process of 'restoration' by the removal of portions of the ancient work (usually the carved details and secondary features which are the characteristic signatures as it were of the old artists), and replacing them by new work intended to represent (and therefore to form a deceptious imitation of) the genuine old work.

Cambridge has proceeded somewhat more slowly of late than the sister university with its mediæval reproductions and restorations, but it too has made a real architectural advance. Such works as those which in the first quarter of the present century Wilkin raised amidst the plaudits of enthusiastic gownsmen, would now excite a shout of universal execration. But Cambridge retained longer than Oxford her love of the classic orders; and some of her latest works of that kind are of a very superior character—as the library by Cockerell, and still more the Fitzwilliam Museum, a work of much beauty and stateliness.

But not to dwell longer on particular towns, we may point to the number of the different kinds of public buildings which have been lately erected in every part of the country, as the best evidence of the reality and extent of architectural progress. In ecclesiastical edifices the progress has been something wonderful. During the last twenty years churches and chapels have been built by the thousand, and a very large proportion of our ancient cathedrals and parish churches have been repaired, or as it is termed 'restored.' As in London, so through the country, all the recent churches have been mediæval in character; indeed, as Mr. Scott, in no exaggerated tone of triumph, exclaims in one of his recent contributions to the literature of Gothic architecture—" No revolution was ever, so far as it goes, more complete; for while, forty years ago, no one, in building a new church, would ever have dreamed of making it Gothic, no one now dreams of making it anything else." But although the reproduction of a mediæval church is infinitely preferable to the reproduction of a Greek or Roman temple as a Protestant place of worship, it must be obvious that mere crude reproduction or imitation of ancient examples, without regard to altered forms of worship and modes of thought, has the double disadvantage of curbing the genius of the architect, and of preventing the erection of an edifice designed with a single eye to its use and character. Many of the most recent churches are however—with the qualification we have suggested—of the highest order of merit, and many have been constructed and decorated with an almost profuse liberality of expenditure, but with unimpeachable taste. Among the more costly some have been built at individual outlay, many more by the combined exertions of a few zealous friends, and most by voluntary efforts. Even where the cost seems fairly to belong to a parish or town, as in the case of the new church at Doncaster (rendered necessary by the conflagration of the splendid old church), an appeal to a wider public is sure to meet with a cheerful response, if an announcement can be made that the building is to be a magnificent work of art, or the exigencies of the neighbourhood justify the appeal. We feel safe therefore in saying that the public feeling for church architecture, and the public wish for church extension, are deeply rooted as well as widely spread, and that great as has been the progress of church building and church architecture during the twenty years to which our survey is limited, the coming years will see a yet greater extension of the one, and we earnestly hope a great advance in the other.

As may be supposed from the character of the revival and the faith of one of its earliest, ablest, and most active champions—Welby Pugin—the Roman Catholic body have fully participated in the Gothic movement. Indeed some of the finest and richest of the recent specimens of Gothic have been the Roman Catholic cathedrals and churches at Birmingham, Derby, Nottingham, Cheadle, Preston, and elsewhere—though many of them have been left to be completed at a future day. Yet the recent Roman Catholic churches have not all been Gothic, here and there one being still occasionally built in the Italian or even classical style. Not of course so numerous as the churches of the establishment, but still very numerous have been the dissenting chapels built within the last twenty years, and not a few of them have been of spacious dimensions and of considerable architectural pretension. The old puritan dislike to a 'steeple-house' seems quite to have passed away; indeed, some of the loftiest spires recently built in England have been appended to nonconformist meeting-houses, as in that belonging to the Independents at Halifax, completed in 1857, which rises to an altitude of nearly 250 feet. Among the Independents—who have taken the lead in the chapel building movements—the Gothic style has been adopted in the great majority of instances; so it has, though not to the same extent, among the Wesleyans; the Baptists have come more slowly into the fashion; the Unitarians seem to adhere to the classic; the Quakers as of old repudiate style altogether: but all build where they can find opportunity and means, and all build in a far superior manner to that in which they built thirty or forty years ago.

Among the architectural features of the period of which we are treating, a place alongside the extraordinary church-extension movement, and accompanying revival of Gothic ecclesiastical architecture, must be given to the parallel extension of educational establishments of a superior class, and the revival of the old collegiate style of building. Not to speak of what has been done in college extension and new building at Oxford and Cambridge, at Eton, Harrow, Rugby, &c., we can but mention, as among many, such magnificent structures as the Church Missionary College, St. Augustine's, Canterbury, built by the munificence of Mr. Hope, and which is so admirable a specimen of the abilities of Mr. Butterfield; and the numerous proprietary and other Church of England colleges, like that at Brighton, by Mr. Scott; at Cheltenham, by Mr. Wilson; St. John's, Hurstperpoint, Sussex, by Mr. Carpenter; at Cuddesden, near Oxford, by Mr. Street; the Lansdowne College, at Bath, by Mr. Wilson; the Wellington, at Sandhurst, &c.: theological institutions belonging to the Independent body at Manchester, by Mr. Irwin; New College, St. John's Wood, by Mr. Emmett; and at Spring Hill, near Birmingham, by Mr. James—all spacious and handsome edifices in the Tudor collegiate style: and the institutions—similar in purpose and similar in architectural style—of the Wesleyan Methodists, at Richmond, Surrey, by Mr. Trimen; at Taunton, by Mr. Wilson; and the school at Kingswood, near Bath, by the same architect.

Of new corporate and town buildings the number has been surprisingly large. We might mention new Town Halls, at Leeds (a work of a high order of merit by Mr. Brodrick); at Colchester (Doric, by Blore and Raphael); at Burslem (Italian, by Mr. Robinson); at Cardiff (by Mr. Jones); at Whittlesey (by Mr. Rowe); at Alfreston (by Mr. Wilson); at Eye, Suffolk (by Mr. Lamb); at Chatham, at Halifax, at Leamington, Stockton, Bilston, Chertsey, Louth, and very many other towns: Market-places at Bolton, Wolverhampton, Stockport, Swindon, Worcester, at Leeds (a very fine one, costing 14,000*l.*), at Ashby-de-la-Zouch, at West Hartlepool, and elsewhere: Corn Exchanges,—on some of which a large amount of money has been expended—at Colchester (by Raphael and Brandon); at Wolverhampton (by Mr. G. Robinson); at Southampton, at Peterborough, at Grantham, at Hitchin, at Louth (a handsome Venetian pile, by Mr. Bellamy); at Banbury, at Hemel Hempstead, at St. Albans, at Grimsby (Elizabethan, by Bellamy and Hardy); at Gloucester (a large and ambitious Corinthian edifice, by Medland and Maberly); at Alcester (Italian, by Mr. Holmes), &c.: Assize Courts at Reading (by Mr. Clary); at Taunton, at Swansea, &c.; County Courts, Post-Offices, Music Halls (some of the very recent ones, like that at Bradford, by Messrs. Lockwood) large and somewhat pretentious works; Lyceums, Mechanics Institutes, Free Libraries, Baths, &c.

Beyond the limits of the towns among the largest and most costly, and from their size and character often the most remarkable modern buildings, are the County Lunatic Asylums, but it must suffice to refer to them thus generally. The County and Borough jails are often curiously enough works of an inordinately ambitious architectural character; and Reformatories, of which there are now in England 41 Protestant and 5 Roman Catholic, must likewise be named in this connection.

Of industrial establishments of a more pleasing order—such as Marshall's Flax Mills, at Leeds; the extraordinary manufacturing village of Mr. Titus Salt, Saltaire, near Bradford, and other great manufactories of recent erection—we should be glad to speak, for they, in their architectural character, and in their admirable arrangements, are among the most striking evidences of material improvement in the country. But we must pass them by, as we must also pass by the termini, the bridges and viaducts, and other great works connected with the railways, remarkable and noteworthy as they in every way are among the recent public works of England. So again we must pass by the magnificent new docks, &c., governmental as well as those constructed by private companies, at Plymouth, Portsmouth, Chatham, Sunderland, Great Grimsby, Cardiff, and elsewhere, vast as they are in extent, and costly but most important in character; and the equally magnificent works which have been in progress at Dover, Holyhead, Portland, &c., for affording to our mariners harbours of refuge from the perils which beset them. The defensive works which are erecting on the more vulnerable parts of our coast, and for affording additional protection to our naval ports and arsenals, hardly perhaps belong to an article on Public Improvements. But such an article ought scarcely to conclude without at least a reference to the great naval and military hospitals which have been recently erected or are in progress at Plymouth, Portsmouth, Netley, Chatham, &c.; and although we have heard much of deficient barrack accommodation, even that must be largely increasing, and ought to be rapidly improving when we see by parliamentary returns that in a single year, 1856-7, upwards of a million sterling has been spent in building and repairing barracks (*i.e.* new works and enlargements 808,996*l.*, repairs 222,745*l.*). Of the many mansions which have been erected in the country we must also refrain from speaking, though the list is headed by her Majesty's Marine and Highland palaces at Cowes and Balmoral.

Though at some length, we have yet but very inadequately set forth the progress of public improvement in England during the last twenty years. In Scotland and Ireland architectural progress, taken as a whole, has not been proportionate to that of the sister country; yet when we look at the noble buildings which have been erected in Edinburgh and Glasgow, the unrivalled railway termini and some other recent buildings in Dublin, the warehouses and public works in Belfast, the Irish Queen's Colleges, &c., we cannot but feel that Scotland and Ireland, as well as England, have made a great stride in the path of architectural progress during the past twenty years.

PUBLIC LIBRARIES. [LIBRARIES, PUBLIC, *S.* 2.]

PUFFINUS. [PETRELS.]

PUGIN, AUGUSTUS, an eminent architectural draftsman, was a native of France, but settled in London at an early age. He was engaged as a draftsman and assistant by Nash, with whom he remained many years. He then found employment among publishers in the preparation of architectural drawings for engraving; one of the most important of his earlier works being the buildings in Ackerman's 'Microcosm of London,' 1808-11. He also made the drawings for a 'Series of Views in Islington and Pentonville, with descriptions by E. W. Brayley.' Subsequently he directed his attention more particularly to the architecture of the middle ages; and in 1821 he began the publication of his 'Specimens of Gothic Architecture, selected from various Ancient Edifices in England, consisting of Plans, Elevations, Sections, and parts at large; calculated to exemplify the various styles, and the practical construction of this class of admired Architecture:' it was completed in 1823, and forms 2 vols. folio and 4to, containing 114 plates, with descriptions, chiefly by Mr. E. J. Wilson. In 1824 he commenced, in conjunction with Mr. John Britton, 'Architectural Illustrations of the Buildings of London,' also completed in 2 vols. 4to; and with the same gentleman he published, in folio and quarto 1825-28, 'Specimens of the Architectural Antiquities of Normandy, measured and drawn by A. Pugin, and engraved by John and Henry Le Keux.' This is his best and most important work, and did much to enlarge our knowledge of mediæval architecture; he was assisted in this work by his son, the subject of the succeeding notice. In 1829 Mr. Pugin made the drawings for a work entitled 'Paris and its Environs displayed;' and in 1831 he prepared, with the assistance of his son, 'Gothic Ornaments, selected from various buildings in England and France.' He died December 19th, 1832.

PUGIN, AUGUSTIN WELBY NORTHMORE, son of the preceding, was born in 1811. Instructed by his father in the principles of architecture, he early acquired under him remarkable facility in drawing, and travelled with him as his assistant, collecting materials in Normandy and England for his works on Gothic architecture. [PUGIN, A.] His first distinct employment was as assistant to Messrs. Grieves, in painting the architectural scenery in her Majesty's and Covent Garden theatres. He afterwards made drawings for the furniture in Windsor Castle, and designs for plate in the mediæval style for Messrs. Rundell and Bridge. In 1833 he removed to Ramsgate, and commenced preparing for publication a series of works illustrative of the furniture and ornamental work of the middle ages. In 1835 appeared his 'Designs for Gothic Furniture, in the style of the Fifteenth Century,' and 'Designs for Iron and Brass-Work, in the style of the XVth and XVIth centuries.' These were followed in 1836 by 'Designs for Gold and Silver-smiths' Work,' and 'Ancient Timber Houses,' all of which met with a ready sale, and tended not a little to stimulate the growing taste for Gothic forms. His next work was one that, by its caustic and irritating way of setting forth some home-truths, aroused not a little professional feeling—'Contrasts; or a parallel between the Noble Edifices of the 14th and 15th centuries, and similar buildings of the present decay of Taste;' a second and improved edition of it was published in 1841.

Mr. Pugin had by this time joined the Roman Catholic Church, to the service of which he henceforth devoted his best energies. Having received a handsome bequest from an aunt, Mrs. Welby, he built himself a fanciful residence in the neighbourhood of Salisbury, and removed there, resolved to study and evolve the principles of the ecclesiastical architecture of the middle ages. Having found in the Earl of Shrewsbury a warm patron, Mr. Pugin soon obtained opportunities of exerting his ability; and during the few years that he lived to practise his profession he was called upon to erect a larger number of Roman Catholic churches, chapels, convents, and schools, than has probably fallen to the lot of any Englishman since the Reformation. The following list, we believe, includes his chief works—(we are indebted for it, and many of the other facts contained in this notice, to a memoir of Pugin by his friend Mr. Talbot Bury, which appeared in the 'Builder' shortly after Pugin's death):—The cathedral church at St. Marie at Derby, one of his earlier and more pleasing works; St. Chad's, Birmingham; three churches at Liverpool; St. Wilfred's, Manchester; church and convent at Edge Hill; churches at Oxford, Cambridge, Reading, Kenilworth, Stockton-on-Tees, Newcastle-upon-Tyne, Preston, Keightley, Rugby, Northampton, Stoke-upon-Trent, Brewood, Woolwich, Hammersmith, Fulham, Pontefract, St. Edward's near Ware, Buckingham, and St. Wilfred near Alton; a church, and a convent and chapel, at Nottingham; convents of the Sisters of Mercy at London, Birmingham, and Liverpool; a priory at Downside near Bath; colleges at Radcliffe and Rugby; improvements at Maynooth; and cathedrals, with schools and priests' houses attached, at St. George's (Southwark), Killarney, and Enniscorthy. To these must be added the extensive and costly works executed for his great patron the Earl of Shrewsbury, consisting, besides the alterations made in the mansion, of a church, school-house, and monastery at Alton Towers; and a church at Cheadle, which has the most splendid interior of any of his churches. The very pretty gateway to Magdalen College, Oxford, is one of the few works executed by him for any Protestant body; indeed he is said to have refused to accept any commissions for Protestant places of worship. The list of works given above would in truth seem to have been more than sufficient to exhaust the time and energies of a man who ceased working at the age of forty; yet he was chiefly employed during his last years in designing and superintending the ornamentation of the New Palace of Westminster, which probably owes its somewhat extravagantly mediæval and ecclesiastical character to Pugin's idiosyncracies. But, besides the practice of his profession, he found time to add to its literature a second and revised edition of his 'Contrasts;' a treatise on the 'True Principles of Pointed or Christian Architecture,' 1841; 'An Apology for the Revival of Christian Architecture,' 1843; a 'Glossary of Ecclesiastical Ornament,' 1844; a treatise on 'Floriated Ornaments,' 1849; and 'A Treatise on Chancel Screens,' 1851. We ought also to add that he was connected commercially with the house of Messrs. Hardman of Birmingham, who manufactured ecclesiastical brass-work from his designs; and he is said to have filled up his leisure hours with landscape-painting.

Mr. Pugin had always been fond of the sea—(indeed it is stated in one of the biographical notices of him that he once owned "and for a time commanded a merchant smack trading to Holland," though it is difficult to see when that time could have been)—and having realised by his profession a handsome sum, he purchased an estate at Ramsgate, in order at once to enjoy his favourite element, and carry out unfettered his notions of architectural propriety. Here he expended all his property in erecting for himself a house, a church, schools, &c., the whole being dedicated to St. Augustine. As he advanced in life his religious feelings took more and more entire possession of him. He now (1850) wrote and published 'An Address to the Inhabitants of Ramsgate,' 'An Earnest Appeal for the Revival of the Ancient Plain Song,' 'The Present State of Public Worship among the Roman Catholics,' and other pamphlets of a religious character. At length, overtasked with all this excessive labour and excitement, his intellect began to give way, and in his fortieth year it was deemed necessary to remove him to a lunatic asylum. For a brief space his mental powers were so far restored that it became practicable for him to return to his home at Ramsgate; but his life was ebbing, and he expired there on the 14th of September 1852, three days after his return. He was buried in a vault of his own church of St. Augustine. He had been three times married, and shortly after his death a pension of 100*l.* a year was granted to his widow from the Civil List.

As will have been seen, Mr. Pugin was a man of extraordinary industry and energy, and he possessed a very unusual amount of knowledge and great ability. He attempted too many things, and he worked too much and too fast to produce many great works, even had he been a man of original power; but in truth his was not a creative mind, and he lacked comprehensive thought. His great principle was, that, except as to size, the architect should aim at a faithful reproduction of an ecclesiastical edifice of the mediæval period; or, as he stated it in his 'True Principles of Pointed or Gothic Architecture,' "We may indeed improve in mechanical contrivances to expedite its construction—we may even increase its scale or grandeur; but we can never successfully deviate one tittle from the spirit and principles of Gothic architecture. We must rest content to *follow*, not to *lead*. We may indeed widen the road which our Catholic fathers formed, but we can never depart from their track without a certainty of failure being the result of our presumption." Following such a dogma, it is evident that the highest success must be a respectable imitation. But even on his own principles, few of his works are entirely satisfactory as a whole; in particular parts and in details he is generally very happy, and some of his interiors have a rich and pleasing effect. His writings have had a powerful influence on the taste and practice of professed architects, and still more on the taste of ecclesiastical amateurs, and the influence has not been entirely a happy one. More than any single man perhaps has he been the cause of that perverse fashion which has predominated during the last fifteen or twenty years, of building modern churches in all their parts on the precise model of the churches of the middle ages, although—at least in Protestant churches—the forms of worship and the requirements of the congregations are so changed. In Pugin it was consistent: in his Protestant disciples it is absurd.

PURPLE COPPER ORE. [MINERALOGY, *S.* 1.]

PUSEY, PHILIP, elder brother of the Rev. Edward Bouverie Pusey, D.D., was born in 1799. Having succeeded in 1828 to the Pusey estates in Berkshire (held originally by the tenure of a horn, which has been in possession of the family upwards of 800 years), he became member for the borough of Chippenham in 1830, and in the following year for that of Cashel. In December, 1834, he was elected for Berkshire, for which he had been an unsuccessful candidate two years previously; and he continued to represent that county until the dissolution in 1852. A Conservative in politics, and a decided supporter of the Corn Laws, on finding that agricultural protection, however desirable he might deem it, was practically unattainable after the passing of the Corn Law measures by Sir Robert Peel in 1846, he, instead of continuing with the bulk of the Protectionist party to agitate for a repeal of the free trade measures, urged the agriculturists to make the best of their position, and to adopt without delay every improvement which scientific investigation and practical experiment had shown to be beneficial, in order to enable them to compete advantageously with the foreign producer. Already well known as a practical agriculturist, and as one who had given his attention to, and carefully watched and tested, every scientific improvement which had been introduced from time to time into the system of draining, ploughing, and reaping, his advice was listened to with respect, and his various practical papers in the 'Agricultural Journal' were received as authoritative, and probably to the influence of his high character and sober judgment may be attributed in no small measure the great advance which has been made within the last few years in every department of English agriculture. Mr. Pusey was president of the Royal Agricultural Society of England in 1854, and one of the chief contributors to the Journal of that society, which he also edited for several years. He died July 6, 1855.

QUATA. [ATELES.]

QUATREMÈRE DE QUINCY, ANTOINE CHRYSOSTOME, a celebrated French archæologist, was born at Paris, October 28, 1758. Before the outbreak of the first revolution he had made himself known by his researches on ancient art; a memoir on Egyptian architecture was crowned by the Academy in 1785, and in 1786 he commenced his 'Dictionnaire d'Architecture,' which he did not complete till more than forty years later (1828). In 1790 he published 'Considerations sur l'Art du Dessin en France.' But his political opinions having led to his election as a member of the Legislative Assembly in 1790, he at once took his place among the party known as constitutional monarchists. He in consequence became obnoxious to the revolutionists, and during the Reign of Terror was thrown into prison, where he remained thirteen months. On his release he appears to have continued to act with those who were opposed to the new order of things. In the affair of the 13th Vendémiaire (October 5, 1795), he took part against the Convention, and was in consequence tried "par contumace" and condemned to death; but he managed to secrete himself. When power had fallen into new hands he again emerged, and was in 1797 elected to the council of the Five Hundred for the department of the Seine. But true to his royalist principles, he set himself in opposition to the Directory, and in consequence was one of the first on the list of the 19th Fructidor (5th September 1797) of those condemned without trial to deportation to Cayenne; but he was again fortunate enough to make his escape. After Bonaparte had secured his position, M. Quatremère de Quincy was permitted to return to Paris, and even we believe obtained some official appointment; but he appears to have thought it most prudent to quietly prosecute his literary and artistic studies. On the Bourbon restoration his sufferings for monarchy were amply recompensed. He was named in 1815 by Louis XVIII., Intendant-Général des Arts et des Monumens Publics, Censeur Royal, and Membre du Conseil d'Instruction. In the following year he became a Member of the Institute, and was appointed perpetual secretary of the Académie des Beaux Arts. At one time he seemed disposed to renew his political life, procuring himself in 1820 to be elected member for the department of the Seine, but he retired to his literary pursuits at the close of the session of 1822. He survived till near the end of 1849, but he had for some years outlived his faculties.

From the restoration, partly on account of his position as director-general of public monuments and secretary of the Academy, and partly from his great literary activity, M.

Quatremère de Quincy occupied a prominent and influential place among the French writers on the history and theory of art. He outlived however his reputation as an archæologist, for his learning was bnt shallow as compared with later scholars, especially those of Germany; and as a writer on the principles of art, he was specious rather than profound. Yet his works contain much valuable matter, and his speculations are mostly interesting, bowever unsatisfactory. The following, in addition to those already named, are his principal works:—'Lettres Addressées à M. Canova sur les Marbres d'Elgin,' 8vo, Rome, 1818; 'De la Nature, du But, et des Moyens de l'Imitation dans les Beaux Arts,' 8vo, 1823—the most original and the most satisfactory of his speculative works; Lives of Raffaelle (1824), of the Most Celebrated Architects (1830), of Canova (1834), and of Michel Angelo (1835); 'Monumens et Ouvrages d'Art Antiques restitués d'après les Descriptions des Ecrivains Grecs et Latins,' 2 tom. 4to, Paris, 1826-29; 'Snr la Statne antiqne de Venus découverte dans l'Isle de Milo en 1820;' and 'Essai snr l'Ideal,' 1837. He also wrote several pamphlets, discourses, and papers, as well as a great many dissertations in the 'Magasin Encyclopédique' of Millin, and various lives in the 'Biographie Universelle,' besides nnmerous 'éloges' read by him at the Academy: of these last he published a selection, of little value or interest, in two bulky volumes, entitled 'Recueil de Notices Historiques lués dans les Séances Publiques de l'Académie Royale des Beaux-Arts á l'Institnt,' 8vo, Paris, 1824-37. Two of his works have been translated into English—'The Destruction of the Works of Art, and the Use to which they are applied, considered with regard to their Influence on the Genius and Taste of Artists, and the Sentiments of Amatenrs,' by Henry Tbomson, 12mo, 1821; and the 'Essay on Imitation in the Fine Arts,' by J. C. Kent, 8vo, 1837.

QUEENSTOWN, or COVE OF CORK, County Cork, Ireland, a sea-port town, is situated on tbe south side of Great Island, in Cork Harbour, in 51° 51′ N. lat., 8° 18′ W. long., distant by road 14 miles E.S.E. from Cork, and 167 miles S.W. by S. from Dublin. The population in 1851 was 11,428. Previous to the French war Cove was a small village consisting of fishermen's cabins; it then rose into importauce by becoming an admiral's station. It was the port of embarkation for troops going on foreign service, and a place of rendezvous for merchant vessels about to sail uuder convoy. It now depends on the number of invalids who resort to it, especially in summer, when it is much frequented as a favourite bathing-place. The name was changed from Cove to Queenstown on the occasion of her Majesty's visit to Cork in 1850. The town, which occupies a steep acclivity overlooking the harbour, consists of several streets rising one above another in lines parallel to the beach. It contains a handsome parish church, erected in 1812; a Roman Catholic chapel, which serves as the cathedral of the diocese of Cloyne and Ross; a Wesleyan Methodist chapel; national schools; a club-room; a literary society; a public library; and reading-rooms. It has also a market-house, a fever hospital, dispensary, and bridewell. The pier, erected in 1805, forms a fine promenade, commanding a view of the magnificent barbour. The harbour of Cove is 3 miles long by 2 milcs broad, with an entrance 2 miles loug and 1 mile wide. It contains Spike Island, on which are artillery barracks and a depôt for convicts; the small island of Hawlbowlin, with the ordnance depôt, and near it Rocky Island, with two powder-magazines cut out of the rock. Steamers ply daily in summer between Queenstown and Cork. The Royal Yacht Club of Cork holds its annual regatta in the harbour. Petty sessions are held weekly. A market is held on Satnrday.

QUINOLEIN. [Chemistry, *S.* 1.]

QUINQUINA, or QUINA, names given to the species of Plants which are now generally referred to the genus *Cinchona.* In the article Cinchona will be fonnd an account of the species of *Cinchona,* as recognised by botanists previous to the investigations of M. Weddell. This traveller dwelt in tbe Cincbona districts of the Andes duriug the years 1845-6-7, and has since pnblished a work on this subject, entitled 'Histoire Naturelle des Quinquines.' In addition to a highly interestiug accouut of the districts, M. Weddell gives a full description of the methods of preparing the Cinchona Barks by the natives, who live in the forests. By dwelling on the spot he was euabled to correct mucb that was erroneous with regard to the nature and character of the species used in medicine. He also discovered the real plant which yields the yellow-bark, that furnishes the largest quantity of quinine. The followiug table from M. Weddell's work exhibits the names of Commercial Cinchona Barks, and the species from which they are believed to be obtained:—

I.—Gray Cinchona Barks.

§ 1. Loxa Cinchona Barks. (Crown Bark, Angl.—China-Loxa, Kron China, Germ.)

Loxa Cinchona Bark, gray compact	*Cinchona Condaminea,* H. et B.
Loxa Cinchona Bark, brown compact (Dunkele Ten China, Germ.—China pseudo-Loxa, Bergen). Loxa Cinchona Bark, red chestnut.—Light Calisaya	*C. scrobiculata,* H. et B.
Loxa Cinchona Bark, red fibrous of the King of Spain. (Quina Estoposa, Pav. in collect., Lamb. Mus. Brit.)	
Loxa Ciuchona Bark, yellow fibrous	*C. macrocalyx,* Pav.

§ 2. Lima or Huanuco Cinchona Barks. (Silver Bark, Gray Bark, Angl.—China-Huanuco, Graue China, Germ.)

Lima Cinchona Bark, gray-brown. (Cascarilla Provinciana, Perux.) Lima Cinchona Bark, gray ordinary	*C. micrantha,* Ruiz et Pav. or *C. lanceolata,* Ruiz et Pav.
Lima Cinchona Bark, white	(?) *C. purpurea,* Ruiz et Pav.
Lima Cinchona Bark, very rugous, resembling the Calisaya Bark.—Cascarilla Negrilla, Peruv. (?Cascarilla Lagartijada, Laubert)	*C. glandulifera,* Ruiz et Pav.
Cinchona Bark, red of Jaen or of Loxa	(?)

II.—Red Cinchona Barks.

(Red Bark, Angl.—Rothe China, Germ.)

Red Cinchoua Bark, becomiug white in the air	(?)
Red Cincbona Bark of Lima. Red Cinchona Bark true, non-verrucous (Cascarilla Roja Verdadera Laubert). Red Cinchona Bark, officinsl. Red Cincbona Bark true, verrucous	*C. nitida,* Ruiz et Pav.
Orange-Red Ciuchona Bark, verrucous. Pale-red Cinchona Bark, with a white snrface. Brown Carthagena Bark. Red Carthageua Bark	(?)

III.—Yellow Cinchona Barks.

Yellow Cinchona Bark of tbe King of Spain (Cascarilla Armarilla del Rey, Laubert). Calisaya Cinchona Bark, or Royal Yellow Bark (Königs China, Germ.—Yellow Bark, Angl.—China Regia, Bergen)	*C. Calisaya,* Wedd.
Orange-Yellow Cincbona Bark; Cinnamon Cinchona Bark (Quinquina—Cannelle), Light Calisaya (Cascarilla Claro-Amarilla, Laub.)	*C. micrantha,* Ruiz et Pav.
Pitaya Ciuchona Bark (Quinquina de la Colombie ou d'Antioqnia, Guib., 'Hist. Nat. des Drog.'—Cascarilla Parecida à la Calisaya, Lanbert). Woody Carthagena Bark (Quinquina de Colombie Ligneux)	*C. Condaminea,* Humb. et Boup.
Orange Cinchona Bark of Mutis (Spongy Carthagena Bark; New Spurious Yellow Bark, Pereira)	*C. lancifolia,* Mutis.

§ 3. Huamalies Cinchona Bark. (Rusty Bark, Angl.—China Huamaliss, Braune China, Germ.)

Huamalies Cinchona Bark, dull gray	*C. hirsuta,* Ruiz et Pav.

Huamalies Cinchona Bark, thin reddish	(?) *C. purpurea*, Ruiz et Pav.
Huamalies Cinchona Bark, white	(?)
Huamalies Cinchona Bark, ferruginous	*C. micrantha*, Ruiz et Pav.
Yellow Cinchona Bark of Cuenca	*C. ovalifolia*, H. et B.

IV.—White Cinchona Barks.

Ash-coloured Loxa Cinchona Bark (Ash-Bark, Angl.—Blasse Ten-China, Germ. — China Jaen, Berg.)	*C. ovata*, Ruiz et Pav.
Gray Cinchona Bark, pale ditto .	*C. ovata*, Ruiz et Pav.
White Loxa Cinchona Bark . .	*C. ovata*, Ruiz et Pav.
White Fibrous Jaen Cinchona Bark	*C. ovata*, Ruiz et Pav.
Cuzco Cinchona Bark	*C. pubescens*, Vahl., or *C. cordifolia*, Mutis.
Arica Cinchona Bark . . .	*C. pubescens*, Vahl., or *C. cordifolia*, Mutis.
Pale-Yellow Carthagena Cinchona Bark (Hard Carthagena Bark, Angl.—Quina Amarilla, Mutis. —China Flava Dura, Bergen) .	*C. pubescens*, Vahl., or *C. cordifolia*, Mutis.
Orange-Yellow Carthagena Cinchona Bark (Quinquina de Maracaïbo. —China Flava Fibrosa Bergen) .	*C. pubescens*, Vahl., or *C. cordifolia*, Mutis.
Pitayon Cinchona Bark, or False Pitaya Cinchona Bark . .	(?)

The following, according to M. Guibourt, are the most active barks:—

1. Calisaya Cinchona Bark.
2. Yellow Orange Bark.
3. Pitaya Bark.
4. Verrucous True Red Bark.
5. Von-Verrucous True Red Cinchona Bark.
6. Red Lima Bark.
7. Gray Lima Bark.
8. Verrucous White Huamalies Bark.

On the subject of distinguishing the various barks of commerce, M. Weddell points out the fallacy of the present method of distinguishing the sorts of bark by the colours red, yellow, and gray, as frequently the same barks at different ages have different colours. Having shown also the impossibility of a chemical classification, he proceeds to make the following remarks:—

"If a classification be absolutely needed, one which should be based on the anatomical structure of the bark would be found to be of far greater utility than either of the preceding, inasmuch as we shall find existing, even in the Cinchonas, a certain relation between the structural and chemical characters.

"The following are the data which my researches on the subject have furnished me with:—

"1. If a large piece of the *Cinchona Calisaya* met with in commerce be attentively examined, it will be found that the exterior surface is entirely deprived of its peridermis, and presents broad superficial furrows, short, more or less confluent, and divided by projecting ridges, the bases of which are of a fibrous texture, similar to the inner surface of the bark or of the layer which is immediately in contact with the wood. The examination of a transverse section shows that the texture of the bark is homogeneous, and composed of ligneous fibres of almost equal thickness, uniformly distributed in the midst of cellular tissue gorged with resinous matter, tissue which may be said to isolate each fibre, being interposed in thin layers between them. Finally, when these fibres are examined longitudinally, we find that they are short and fusiform, and that their cut extremities are but loosely attached to each other, and are sometimes completely separate, and appear to float in the midst of the cellular tissue which surrounds them.

"2. If we take a similar piece of the bark of *C. scrobiculata*, we shall find that instead of these furrows of fibrous texture, which so well characterise the *C. calisaya*, the exterior almost presents a smooth surface of a cellular texture, traversed here and there by slight linear indentations, the inner surface being, as in the preceding bark, of a fibrous texture. In the transverse section the fibres are more numerous than in the *C. calisaya*, especially towards the inner surface; but they lessen in numbers rapidly near the exterior, and the outermost layer is entirely without them. These fibres, if examined in a longitudinal section, will be found to be of nearly double the length of those of the *C. calisaya*, and their extremities are invariably attached one to the other, their ends being by this means more elongated.

"3. If we study with equal attention the bark of *C. pubescens*, we shall there find a peculiar structure. The external surface somewhat resembles the preceding bark, with the exception of a slight whitish marbling, formed by the continuity of the peridermis, and scissures which may result from desiccation. The internal surface is fibrous, as in the preceding barks; but a transverse section shows us that it is principally composed of cellular tissue, in which the fibres form but a small number of irregular and concentric series in the interior half of the bark; and that which draws attention at the first glance is the size of these fibres, each one being three or four times as large as those of either of the former varieties; the result being that several of them are attached and united together in bundles, which may be fully proved by the examination of a longitudinal section of this bark.

"As may be perceived, we have only spoken of Cinchonas which have been deprived of their peridermis, because it is in this state that they are now usually met with in commerce. If perchance they were again to be used with their natural coating, it would afford additional means whereby to distinguish them, but would not in any way affect those of which we have just treated; for nothing would be easier than to remove the peridermis and to expose the surface beneath. Be this as it may, the structure of all the Cinchona barks more or less resemble one or other of the three types we have spoken of, and on this plan there might be formed, without much difficulty, a series of groups comprehending all the known Cinchonas. The purpose however in noticing these peculiarities, has been to facilitate the comprehension of a very important fact in the diagnostics of the different kinds of Cinchonas; that of the vast difference they present in their mode of fracture. However singular it may in the first instance appear to be, it is easy to prove that, to a certain extent, the chemical composition of the bark operated upon may be determined by its mode of fracture; or, more properly speaking, there exists a relation between the chemical and the anatomical characters of the Cinchonas, this being constantly proved by a particular form of fracture: smooth or corky where it divides the tunic or cellular covering of the bark; fibrous, stringy, or woody in those cases where it has affected one or other of the three forms of liber before described. Another fact which is now fully proved is, that the bark containing the largest proportion of quinine is that of the *C. calisaya;* and experience has shown us, that after the *C. calisaya*, the barks possessing it in the greatest quantities are precisely those the structure of which most resembles this bark; for instance, those in which the dermis is reduced to a single liber by the successive exfoliation of the outer tunics, or at least by their adjunction to the peridermis. On the other hand, experience seems to have shown, to a certain extent, that the Gray Cinchonas (which we have generally found to be the young barks of other species) contain a larger proportion of cinchonine than of quinine; we also know that many old barks, which have retained the cellular coating they had when young, yield a proportionably larger quantity of cinchonine; from which circumstance we may conclude that quinine is contained in the liber, or, more correctly speaking, in the cellular tissue interposed between the fibres of the liber, and that the cinchonine is principally found in the tunic or cellular coating. As to the tannin, it is found in larger quantities in this latter part than in the fibrous tunic—a fact which is easily determined with reference to the fresh bark where the exterior layers of the derm are more styptic than the internal layers." ('Pharmaceutical Journal,' vol. ix.)

The following are the specific characters of the *Cinchona calisaya:*—Leaves oblong or lanceolate, obovate, obtuse, attenuated at the base, rarely acute on both sides; smooth, polished, or pubescent beneath; scrobiculate in the axils of the veins; filaments usually shorter than one half the length of the anthers; capsule ovate, scarcely equal in length to the flowers. Seeds frequently fimbriate, denticulated at the margin. Of this there are two varieties:—

C. C. vera. A tree with obtuse oblong-ovate or oblong-lanceolate leaves.

C. C. Josephiana. A shrub with somewhat acute-oblong-lanceolate or ovate-lanceolate leaves.

Both varieties are natives of Bolivia and Southern Peru. (*Pharmaceutical Journal*, vol. ix.)

QUINTANA, MANUEL JOSÉ, a very eminent Spanish poet and patriot, remarkable for the depth of his feeling in both characters, and remarkable also for the strange vicissitudes of his long career, was descended from an Estremaduran family; but was a native of Madrid, where he was born on the 11th of April, 1772. He studied and took his degrees in canon and civil law at the University of Salamanca, where he became intimate with the poets Cienfuegos and Melendez, who introdnced him to the friendship of Jovellanos [JOVELLANOS], at that time the leading representative of liberal ideas in Spain. Quintana was from the first distinguished for his spirit of manliness and independence, and when he commenced his career as an advocate at Madrid, his house, at which a party of literary friends assembled every evening, became the ordinary resort of those who were opposed to the degrading policy of Godoy, the all-powerful favourite of the day; while the house of Moratin, the dramatic poet [MORATIN], the other literary focus, was the resort of those who paid homage to the minister.

From about 1795 Quintana became known as a poet only second to his friend Melendez, and in almost every case the themes he selected were of a large and lofty character, and treated in a corresponding strain. One of the finest odes in the Spanish language is his 'Ode to the Sea.' He had lived to his twenty-sixth year without ever beholding the ocean, and in 1798 he was seized with so irrepressible a longing to fill up the deficiency, that he made a journey from Madrid to Cadiz for that express purpose, wrote this ode, which is worthy of the occasion, and returned. Such an incident would have been noticeable in any country, but it was particularly so in that country and age, for, as Alcalà Galiano remarks, in his excellent history of Spanish literature, travelling, except on unavoidable business, then had no part in the habits of Spanish life. Many of Quintana's other odes are scarcely less admirable than this, and they constitute by far his best title to poetical fame. It may be remarked that the patriotism, which is the animating principle of almost every one of them, is a very intense, but at the same time a narrow feeling. Two of these odes, which will be found translated into English in Kennedy's 'Modern Poets and Poetry of Spain' (London, 1852), are on the introduction of vaccination into America by the Spaniards, and on the battle of Trafalgar. In the first, after celebrating the great discovery of Jenner, Quintana exclaims—

> "The gift of the discovery is the gift
> Of chance; that let an Englishman enjoy,
> But let Spain show her noble, generous heart," &c.

by conveying it to her colonies, apparently forgetting that England imparted the discovery not only to her own colonies, but also to the nations with which she was at war, in spite of their at first receiving it with insulting suspicion. In the ode on Trafalgar, the battle is represented throughout as between the English and Spaniards, the French not being even honoured with a mention; and the poet appears to think he is paying a very generous compliment to the memory of Nelson by saying, "As an Englishman, I abhorred thee; but as a hero, I admire." These points are worthy of notice as characteristic not only of Quintana but of the majority of his countrymen.

In dramatic poetry Quintana was far less successful than in lyric poetry. As early as in 1791 he had contended for a prize offered by the Spanish Academy for a poem on the 'Rules of the Drama' ('Las Reglasdel Drama'), and in this production, which was not printed till long afterwards, he expresses unbounded admiration for Corneille and Molière, makes but lukewarm mention of Lope, Calderon, and Moreto, and none whatever of Shakspere, though, probably in consequence of his friendship with Melendez, he had studied English. In his own tragedies, of which he gave two to the public, the same line of thought is apparent. One of them, 'El Duque de Viseo' ('The Duke of Viseo'), acted in 1801, is acknowledged by the author to be founded on an English drama, which he does not name; and the finest passage in it, the description of the villain's dream, is evidently taken from the well-known dream of Osmond in Monk Lewis's 'Castle Spectre,' but in other respects the resemblance is very slight. The other tragedy, 'Pelayo,' which is somewhat better, is however less a drama than a collection of patriotic declamations, some of them fine when separately taken, but quite undramatic, and reading like passages from the author's odes.

Up to the time of the French invasion in 1808, Quintana's position continued one of great prosperity. As an advocate, in spite of his liberal opinions, he held several important offices, among others, those of fiscal agent of the junta of commerce, secretary of the department for the interpretation of foreign languages, and censor of the theatres. As a literary man his reputation was constantly increasing. He edited a periodical entitled 'Variedades,' which was considered the best of its time in Spain. In 1807 he issued the first volume of a prose work, the 'Vidas de Españoles célebres' ('Lives of celebrated Spaniards'), commencing with the Cid, and going on to Gonzalvo de Cordova, the Great Captain. In the following year he published in three volumes a selection of specimens of the best Castilian poetry from the time of Juan de Mena, 'Poesias Selectas Castellanas,' to which he prefixed a short history of Castilian poetry, superior to anything of the kind that had before appeared, and which was afterwards rendered into English by Wiffen as an introduction to his translation of 'Garcilaso de la Vega.' This was in the year of the French invasion. That great event had a very different effect on the three friends, Cienfuegos, Melendez, and Quintana. Cienfuegos, seized by Murat, and sent a prisoner to the south of France, died of indignation at the treatment of his country and himself; Melendez passed over to the ranks of the enemy; Quintana became of all the literary antagonists of the French by far the most active and the most dangerous. He was the author of most of the manifestos of the insurrectionary Juntas, the fervid eloquence of which startled Europe. He drew up most of the official documents of the first Cortes. His weekly periodical, 'El Semanario Patriotico,' was the leading organ of the patriotic party, and exercised great influence on the march of events, for Quintana was no less uncompromising an advocate of liberal institutions than of the expulsion of the foreign invader. The six years of the war were the most glorious of his long life. They were followed by six years of imprisonment. The return of Ferdinand VII. was to Quintana, as to others who had saved his throne, the signal of ruin. His having been the advocate of the Cortes and of a constitution was regarded as a crime that called for punishment. He was suddenly seized and thrown into the fortress of Pamplona, where he was left imprisoned with no hope or promise of release, debarred from all intercourse with his friends, and not allowed access to pen and ink. In this state of rigorous incarceration he remained till he was released by the outbreak of Riego's insurrection, on the 1st of January, 1820. He was then at once set at liberty, saw himself surrounded with popularity, restored to his old offices and honours, and was named president of the department of public instruction, but he was no longer the man he had been before his imprisonment. His detestation of tyranny was still strong, and his powers of eloquence unimpaired, but he had no faith in the continuance of the new order of things, and with guarded prudence he abstained from making himself conspicuous in the ranks of the liberal party. When the second French invasion overthrew the constitution, he received the reward of his reserve by being allowed to remain on the soil of Spain, while his friends and companions took refuge in England and France. Commanded to leave the capital he retired to Cabeza del Buey, the town in Estremadura to which his ancestors belonged, and there lived in obscurity and absolute poverty for some years. In this retreat he composed a series of 'Letters to Lord Holland,' with whom he had become acquainted at Madrid, which contain an eloquent and touching vindication of the proceedings of the constitutional party in Spain, not unmingled with reproach at the injustice with which they had been treated by England. These letters, the last of which bears date in 1824, were of course carefully concealed at the time they were written, and did not see the light till they appeared in a collected edition of Quintana's works in 1852. At the time of King Ferdinand's marriage to his third wife, Queen Maria Christina, in 1828, he sent an intimation to Quintana that he would be permitted to return to Madrid, if he would write an ode in honour of the nuptials. The poet's proudest boast had hitherto been that he had never written a line in praise of the powers that were, and his friends were at once grieved and astonished to find that he complied. The poem was pronounced to be the best of all that were produced on the event, although Galiano, an excellent judge, considered it the worst Quintana had ever written. The poet returned to Madrid, was no longer regarded as inflexible, and found himself on the road to fortune. Soon after he was named a member of the committee of the Museum of Natural

Sciences, in 1833 he was for a third time appointed secretary of the interpretation of languages, in 1835 he resumed the office of director-general of studies and of public instruction, which he had held under the Cortes, and was elevated to the dignity of a senator and peer of the kingdom. During the regency of Espartero he was entrusted with the superintendence of the education of the present Queen of Spain. The Madrid newspapers of 1855 had to record an instance of public honours conferred on a poet, for a parallel to which the whole history of many nations might be searched without success. Quintana was conducted in public procession through the streets of the capital, he was introduced to the sitting of the Cortes, and a crown of laurel was publicly placed on his head by the Queen of Spain. The coronation of Oehlenschläger [OEHLENSCHLÄGER, S. 2] is the only event of our times which bears much resemblance to it, but the coronation of Petrarch and Tasso afforded some precedent for it in the past. Quintana, then very advanced in years, did not long survive this act of public homage to his genius. He died at Madrid on the 11th of March, 1857, at the age of eighty-four, and his funeral, which took place on the 13th, was attended by Olozaga, by the Duc de Rivas, and almost all the literary men of note in the Spanish capital.

In the great collection of the Spanish classics now in course of publication, Rivadeneyra's 'Biblioteca de Autores Españoles,' Quintana was the only author whose works were admitted during his lifetime. One of the volumes, edited by Ferrer del Rio, and published in 1852, comprises what are called the 'Complete Works' of Quintana, but no specimen even is given of the proclamations and manifestos issued in the name of the insurrectionary Juntas which excited the admiration of Southey. Among the poems also we have been unable to find that on the nuptials of Ferdinand and Christina, an event so fortunate in one sense for the poet; but in addition to those fine odes we have already mentioned, there are some 'On the Invention of Printing,' 'The Pantheon of the Escurial,' 'To Spain, after the Insurrection of March' (written in April 1808), 'On the Armament of the Spanish Provinces against the French' (written in July 1808), which will continue to testify how well Quintana deserved the name of the Spanish Tyrtæus. The prose part of the volume is principally composed of the 'Lives of celebrated Spaniards,' of which Ferrel del Rio complains in the preface that a single edition has hardly been sold in Spain, while seven have been exhausted in the United States of America. English translations of these biographies have been issned by Preston and Mrs. Hodson. It is to Quintana's honour that one cause of their scanty popularity in his native country was the freedom with which the atrocities of the Spaniards in the conquest of America are spoken of, and which he refused to modify. "Let us give at least some place to justice in books," he exclaims in the preface to his life of Las Casas, "since unfortunately so little is now usually left to it in the affairs of the world."

R

RACZYNSKI, EDUARD, a Polish nobleman of literary tastes and talents, was born at Posen in 1786, the son of Count Philip Raczynski, a Polish general. Count Eduard entered the Polish army, and took some share in Napoleon's campaign of 1807; but on the fall of Napoleon I., when he became a simple Prussian subject, he withdrew from a military career. He travelled in Turkey in 1814, and published an account of his journey in one of the most splendid volumes in the Polish language, 'Dziennik Podróży do Turcyi' (folio, Breslau, 1821, illustrated with numerous plates). The rest of his life was chiefly devoted to literary pursuits. His 'Obraz Polakow i Polski' ('Picture of the Poles and Poland in the 18th Century,' 21 vols., Breslau, 1840, &c.), is a valuable collection of memoirs, most of them before unpublished. Another of his most prominent works is his 'Gabinet medalow Polskich,' or 'Cabinet of Polish Medals,' in 4 vols. 4to (Berlin and Posen, 1841-45), with a text in Polish and French. His 'Wspomnienia Wielkopolski' ('Memorials of Great Poland,' 2 vols, with an atlas of plates), is also deserving of mention. The 'Codex Diplomaticus Majoris Poloniæ,' or collection of documents illustrating the history of Poland, which he edited, had been originally compiled by his grandfather, Count Kazimierz Raczynski; but a companion work, the 'Codex Diplomaticus Lithuaniæ,' was his own. Among other benefactions to Posen, he founded a public library in that town, erecting a building for the purpose, presenting to it a collection of 21,000 volumes, and endowing it with a fund for the maintenance of the librarian, who is at present Lukaszewicz, one of the first historians and antiquaries in Poland, to whom the Count gave the appointment. On the 20th of January 1845 Raczynski destroyed himself, by means of an ornamental cannon which was kept in his park. It was currently reported that the motive of the act was, that in looking over some old family papers, he had found that one of his ancestors had received part of the family estates as a bribe from Catharine II. of Russia to betray the cause of his country. The lady of Count Raczynski, who survived him, was the widow of Count Jan Potocki, also a Polish author of eminence, who destroyed himself thirty years before in 1815. His son, Count Roger Raczynski, who succeeded him, generously abolished the feudal dues that were payable to him by 4000 peasants of the twenty-seven villages on the estates of the family.

RADETZKY DE RADETZ, FIELD-MARSHAL, COUNT JOSEPH, was born at the castle of Trebnice, in the Klattauer district, in Bohemia, on the 2nd of November, 1766. He was the son of Count Peter Eusebius Radetzky, and of the Baroness Maria Bechyne. The family name was formerly spelt Hradecky. Having entered the army as cornet, in the 2nd Austrian Cuirassiers, in 1784, he became sub-lieutenant, February 3, 1787. In 1788 he served in the Turkish campaign under Marshal Lacy, and was raised to the rank of first lieutenant for his services at the siege of Belgrade. When the Austrian army entered France in 1793, Radetzky, then a captain, was sent to the new scene of war; and he was present in all the Italian campaigns from 1795 to 1800, serving alternately under Beaulieu, Wurmser, Alvinzi, and Melas, and distinguishing himself greatly at the battles of Arcola, Rivoli, and Marengo. Meanwhile, in 1797, he was promoted to the rank of major, and in 1799 he became adjutant-general to Melas, who soon learned to appreciate his zeal and gallantry, and repeatedly mentioned his name in his despatches. For his gallant behaviour at the battles of Novi (May 15, 1799) and Marengo (June 14, 1800), he was created colonel, and appointed to command the Archduke Albert's cuirassiers, and received the order of Maria Theresa.

From the peace of Luneville, in 1801, to 1805, Colonel Radetzky was not employed in the field; but at the latter period he was made major-general. During the contest at Aspern, May 21-22, 1809, when the place was six times retaken by the Austrians from the French, few officers contributed so much to the victory as Radetzky. On the 1st of June he received the command of the 4th corps, with the rank of lieutenant-field-marshal. At the battle of Wagram, July 6, 1809, he commanded the Austrian cavalry. In April 1810 he was nominated commander of the military order of Maria Theresa. From that period until the end of 1812 his services were employed at home in the war-office.

During the whole campaign of 1813, when the tide of war had turned against Napoleon I., Lieutenant-Field-Marshal Radetzky acted as chief of the staff to Prince Schwartzenberg; and the Austrian commander attributed the victory of Kulm mainly to Radetzky's skill and gallantry. But his crowning feat of arms was at the battle of Leipzig, October 18, 1813, the plan of which he drew up. As is well known this decisive action was a succession of battles which lasted three days. The Emperor of Russia and the King of Prussia were present, and 1600 pieces of artillery thundered over the field. Although he had then been nearly thirty years in the service, Radetzky received his first wound at Leipzig. Throughout the campaign of 1814 within the French territory he was continually in action, and on the 31st of March he entered Paris, riding by the side of the Emperor Alexander. Radetzky was appointed in 1822 Commander-General of the Lombardo-Venetian Kingdom; and in 1830, in his sixty-fourth year, after forty-six years of service, he was created field-marshal.

But it was the Italian insurrection, in 1848, which first gave prominence to the name of Radetzky. As early as the year 1846 manifest signs of a turbulent spirit were visible in Italy. The stringent rule of the Austrian government had long excited a rancorous feeling in the Italians against their foreign masters, and they panted for an opportunity to reject the yoke. The reforms of Pope Pius IX. served only to promote the smouldering irritation. Societies were formed to diffuse the secret spirit of revolt throughout the entire peninsula. In 1847, the movement was all but brought to a crisis, when Austria claimed and enforced the right to place a garrison in Ferrara. Immediately a Civic or National Guard was constituted in every Italian state. Then came the revolution in Paris, in February 1848, followed by similar movements in Vienna and Berlin, which raised the spirit of insurrection to its height.

On the 18th of March 1848, barricades were erected in every street in Milan; the fighting lasted for three days; after which Marshal Radetzky drew his troops out of that city, and retreated to Verona. The Austrian army at that time in Italy amounted to nearly 75,000 men; but it was scattered over an extensive line of operations. Consequently the insurgents were at first triumphant; the tricolor flag appeared upon all the towers of Italy, except those of Verona, Mantua, Legnano, and Peschiera; and Charles Albert, King of Sardinia, having united himself to the league, a most gallant contest was maintained for five months. More than once the veteran marshal had to quit the field; but every time he retired in good order. At other times victory was on his side. At length, on August 4, 1848, Radetzky, after a series of successful attacks on the Italian posts, advanced against Milan, at the head of the Austrian army; the Milanese lost heart, and deaf to the remonstrances of Charles Albert, urging them to defend the city, they held a council of war, and determined to abandon Milan. A deputation was sent to Marshal Radetzky, and the terms obtained were: "that the Piedmontese army was to be withdrawn in two days from the Lombard territory; that the Austrians were to enter Milan on the 6th of August; and that the lives and property of the people were to be respected." The struggle was now virtually at an end. Radetzky's superior strategy, and the disunion of his opponents, rendered it an easy task for him to break up the Sardinian forces, and he was again master of all Lombardy. The Emperor of Austria in return for his services sent him an autograph letter of thanks, accompanied by the first class order of St. George. In March 1849, the rebellion in Hungary incited the Italians to make a new attempt to establish their independence; but it was rendered abortive by the prompt and energetic measures of the marshal. Full of years, and loaded with honours by his sovereign, he several times afterwards applied in vain for leave to resign his command. Nor was it until the opening of 1857 that he obtained this permission, in a courteous letter from the Emperor, after a prolonged service of seventy-three years in the Austrian armies. He died Jan. 5, 1858, at Milan.

Marshal Radetzky married in 1798 the Countess Frances Strassoldo-Gräfenberg, by whom he has left a son and daughter.

RAFFLESIACEÆ, a natural order of stemless leafless Parasitical Plants, consisting of flowers growing immediately from the surface of branches, and immersed among scales. The perianth is superior, with a 5-parted limb, thickened processes or calli either distinct or united into a ring being attached to the throat of the tube. The essential organs are combined in a column which adheres to the tube of the perianth. Anthers 2-celled, either distinct and opening by vertical apertures, or combined together so as to become a multicellular mass opening by a common pore. Ovary 1-celled; placentas parietal. Fruit indehiscent. The species are East Indian and South American plants, parasitic on the species of *Cissus* and on some *Leguminosæ*. There are 16 species. Some of them are said to be styptic. Their perianth has a fungoid appearance.

Rafflesia Arnoldi, a Sumatra parasite, is capable of containing 12 pints of fluid in its cup. The flower is said sometimes to have a weight of 14 lbs.

R. Patma is employed as an astringent and styptic in Java. *R. Horsfieldi*, *R. Cumingi*, and *R. Rochusseni* have similar properties.

The genera are *Rafflesia*, *Sapria*, *Brugmansia*, *Apodanthes*, and *Pilostyles*.

(Balfour, *Classbook of Botany*; Lindley, *Vegetable Kingdom*.)

RAGGED ROBIN. [LYCHNIS, *S.* 1.]

RAGLAN, JAMES HENRY FITZROY, BARON (previously Lord FITZROY SOMERSET), was the younger son of Henry, fifth duke of Beaufort, by Elizabeth, daughter of Admiral the Hon. E. Boscawen, and was born in 1788. He received his early education at Westminster School, but before completing his sixteenth year obtained a commission in the 4th Light Dragoons. In 1807 he attended the late Sir Arthur Paget in his embassy to Constantinople; and was in the same year placed on the staff of the Duke of Wellington. Two years later he became aide-de-camp to the duke, in which capacity Lord Fitzroy Somerset was present in every engagement throughout the Peninsular campaign. He was wounded at Busaco, and he was among the first who mounted the breach at the storming of Badajoz. Having been promoted to the rank of lieutenant-colonel, he attended the Duke of Wellington as aide-de-camp at Waterloo, where he lost his right arm; and in consequence of his military services he was made a K.C.B. and a colonel in the army. In 1814 he had acted for a short time as secretary to the embassy at Paris, and so great was the confidence reposed in him that he remained in that city as minister plenipotentiary *ad interim* from the following January to March. He continued to act as secretary to the embassy at Paris until 1819, when he was appointed by the Duke of Wellington, then master of the ordnance, to be his military secretary. This post he retained until 1827, when he accompanied the duke to the Horse Guards as military secretary. Here he remained until after the duke's death in September 1852. He had accompanied the duke to the congresses of Vienna and Verona in 1822, and to St. Petersburg in 1826, and on another occasion was sent on a special mission to Madrid. He also represented the borough of Truro in the parliaments of 1818 and 1826.

Upon the death of the Duke of Wellington, and the promotion of Viscount Hardinge to the command of the army, Lord Fitzroy Somerset was appointed Master-General of the Ordnance, and raised to the peerage as Baron Raglan, a title derived from Raglan Castle, a ruin in possession of the ducal family of Beaufort. He had been little more than a year at the head of the Ordnance when war broke out between England and Russia, and Lord Raglan was appointed to command the forces sent out to the east, with the rank of full general. He left England in March 1854, and after spending some months at Varna and Constantinople, during which time the army suffered very severely from sickness, he landed on the shores of the Crimea in the September following. In conjunction with Marshal St. Arnaud, who commanded the forces of our French allies, he fought the battle of the Alma on the 20th of that month. It has been stated that he wished to attempt carrying Sebastopol by a *coup-de-main*, but this not being agreed to by his colleagues, it was determined that it should be invested. Unfortunately, the siege proved one of longer duration than either of the generals had calculated. Difficulties in furnishing provisions and clothing for the troops, which appear to have been for a long time but feebly attempted to be overcome, resulted in a large portion of both the English and French troops perishing in the trenches before Sebastopol during the subsequent winter, 1854-55. The failure of more than one assault upon that city, and the consequent loss of his men, for whose sufferings he felt most tenderly, together with the censures of the English press upon his line of conduct, unhappily increased the symptoms of diarrhœa, by which he was attacked in the following June, and he died in camp before Sebastopol on the 28th of that month, leaving behind him the memory of an able and brave soldier and a general of high ability, who commanded at once the confidence and respect of his men. The general orders issued by the commander-in-chief at home, and by Marshal Pelissier, his colleague in the divided command over the allied troops in the Crimea, bore testimony to his great and important services. His body was carried back to England, and interred in the church of Badminton, Gloucestershire. A life pension of 1000*l.* a year was settled on his widow, and 2000*l.* a year on his son, who succeeded him in his title. He married, in 1814, Harriet, daughter of the third earl of Mornington, and niece of the Duke of Wellington, by whom he left two daughters and an only son, Richard Henry Fitzroy, now second Lord Raglan, who was formerly in the civil service at Ceylon, and afterwards held the post of secretary to the King of Hanover. His eldest son, a major in the army, was killed in the first Punjab campaign, while serving on the staff of Lord Gough, in December 1845.

RAIANIA, a genus of Plants so called in honour of the great naturalist John Ray, is known by the staminiferous flowers having a bell-shaped perianth in six deep oblong pointed segments, most spreading in their upper part. Corolla none; stamens with six filaments, bristle-shaped, shorter than the calyx; anthers simple. Pistilliferous flowers, the perianth superior, of one leaf, bell-shaped, in six deep segments, permanent, withering; corolla none; pistil with the germen inferior, compressed, with a prominent border at one side, 3-celled; styles 3, the length of the calyx; stigmas obtuse; capsule membranous, of three cells without valves, crowned by the calyx; two of the cells barren, almost obliterated, without wings; the third fertile, compressed, extended into a very large half-ovate membranous wing; seed solitary, nearly elliptical, compressed.

R. hastata, Halberd-Leaved Raiania, is found in the island of St. Domingo. The root is perennial, sometimes large and ovate, sometimes 4 or 5 inches long and 2 inches thick, round at each end. Its substance resembles that of a radish without any internal fibres; the back thin, ash-coloured, a little rugged and warty, the flesh very white, tasting like a bean. The flowers small, whitish, in simple axillary drooping clusters.

R. cordata, Heart-Leaved Raiania, has ovate leaves somewhat heart-shaped at the base, 7-ribbed. It is a native of the West Indies, from whence it was sent to Kew Gardens in 1786, by Mr. Alexander Anderson. Plumier represents the habit of the root, stem, &c., much like the foregoing; but the leaves are regularly ovate, pointed, more or less heart-shaped at their base, and furnished with seven ribs continued from that part to the point. These ribs are connected by numerous transverse veins.

R. ovata, Ovate-Leaved Raiania; has ovate-pointed 3-ribbed leaves. It is a native of the hills of St. Domingo, and has a shrubby stem, turning thread-shaped, sub-divided with slender smooth leafy branches. The leaves rather distant, stalked, smooth on both sides, pointed, entire, 3-ribbed, being ovate at the base. The flowers diœcious, the males in compound clusters, females in simple ones; all stalked and turned toward one side. Corolla very minute, yellowish-green in the male, reddish in the female blossoms.

R. angustifolia, Narrow-Leaved Raiania, is a native of the west part of St. Domingo, where it climbs upon high trees, flowering in May.

R. quinata, Five-Leaved Umbellate Raiania, has five leaves on a common stalk. It was observed by Thunberg about Nagasaki, and in Japan, flowering in April and May. The stem is twining, round, smooth, ash-coloured, and branched. Leaves several together, axillary, stalked, smooth. Flowers in umbels from the same buds as the leaves, on slender stalks, as long as the footstalks.

R. hexaphylla, Six-Leaved Clustered Raiania. Leaves six, on a common stalk, oblong-acute. Flowers racemose. It is a native of the country of Fakonia, in Japan, among bushes, flowering in April. The stem is round, striated, smooth, climbing. The flowers in axillary racemes, clusters snow-white. It differs from *R. quinata* in having mostly six leaflets on a stalk, which are acute, reticulated, with veins at the back, and larger than in that species. The flowers moreover grow in clusters, not in umbels.

RAIIDÆ, or RAIINÆ, a sub-order, or family of Plagiostomous Cartilaginous Fishes, of which the Common Ray is the type. The body of these fishes is horizontally flattened, and more or less discous; the dorsal fins are mostly placed on the tail; a peculiar cartilage, called naso-pectoral, arises from the nasal part of the skull, and extends towards or meets the anterior part of the crest or pectoral fin; the branchial openings are inferior.

This sub-order is divided into the following families or tribes:—

1. *Cephalopteridæ*, Horned Rays.—They have a muzzle distinguished by two horn-like processes; the mouth before or beneath very broad; teeth very small, in some wanting in upper jaw; tail as long or longer than body, with a back-fin and spine. The genus *Cephaloptera* has large lateral eyes and a transverse mouth, with small teeth like a file.

C. Giorna is the only species known in the European seas. A specimen of this fish was once taken on the southern coast of Ireland. It has been described by M. Risso as frequent on the coast of Nice. It approaches the shore, and is most frequently taken in the month of July. In Italy the small ones are called Vachetta, and the larger ones Vacha. It dies immediately on being taken out of the water. It is eaten by the poorer classes at Nice, but is not tender. They grow to a prodigious size. Risso records a male weighing 800 lbs. and a female weighing 1200 lbs.

2. *Myliobatidæ*, Eagle Rays.—The head is partially disengaged from pectorals; mouth transverse; teeth large, mosaic-like; eyelids wanting; tail long, with a back-fin on root and a serrated sting behind. The genus *Myliobatis* has flat teeth; the central plate much longer than those which are lateral; pectoral fins wing-like; the tail armed with one fin upon the root, behind that a serrated spine.

M. aquila, the Whip Ray, the Eagle Ray, and the Mullen. This fish, though rare, has been found on the British coasts. Dr. Johnston has described a specimen found at Berwick-upon-Tweed. It inhabits the Mediterranean, and has been taken as far south as the Cape.

3. *Trygonidæ*, the Sting Rays.—The head is laterally inclosed by the pectorals; the teeth transversely elliptical; the tail without any fin, or merely a low vertical cuticular hair, and with one or more sharp serrated spines.

The genus *Trygon* has the characters of the family.

T. pastinaca, the Common Trygon, the Sting-Ray, the Fire Flaire, La Pastinaque of the French, is an example of this family. It was well-known to the ancients, who entertained many fictions with regard to the venom of the spines of these fish. It is not unfrequent on the British coasts. The powerful serrated spine on its tail is used as an organ of defence.

4. *Anacanthidæ*, Stingless Rays.

5. *Raiidæ*, the Skates.—The body is rhomboidal; tail depressed, slender, generally with a low terminal fin, and frequently with rows of small spines; skin smooth or with small curved prickles; teeth flat, pavement-like, and pointed in males in spawning time. The genus *Raia* has two small fins near the end of the tail; the eyes and temporal orifices are on the upper surface of the head; the nostrils, mouth, and branchial apertures beneath.

The Skates are very numerous on the British coasts, and some of the species are used as food. The young are deposited in a similar manner to the sharks, in their horny cases of a square form, with four projecting horns, giving them the form of a butcher's tray. These cases are very frequently picked up on the sea-shore, and are sometimes called sea-purses. In Cumberland they are called Skate-Barrows, on account of their form. As the young fish increases in size it at last separates the edges of the horny layers in which it is inclosed, and escapes into the ocean. The following are the British species of this genus:—

R. mucronata, the Long-Nosed Skate, remarkable for its long pointed nose.

R. oxyrhynchus, the Sharp-Nosed Ray, the White Skate, the Burton Skate.

R. intermedia, the Flapper-Skate.—This species was first taken in the Frith of Forth by Dr. Parnell, and first described by him.

R. batis, the Skate, the Blue Skate, the Gray Skate, the Tinker, La Raie Cendrée of the French. This is one of the commonest species on our coast. The preceding species as well as this, the Thornback, and the Homelyn, are all commonly called Skate.

R. marginata, the Bordered Ray. It has been only occasionally taken in Great Britain.

R. microcellata, the Small-Eyed, or Painted Ray. This is a rare species.

R. miraletus, the Homelyn, the Home, the Sand Ray, and Spotted Ray. It is one of the commonest species along the line of our southern coast. With the Thornback it is the most common species found in the London market.

R. spinosa, the Sandy Ray, Raie Râpe of the French. It has been only occasionally taken in the British Islands.

R. fullonica, the Shagreen Ray. This species is known by its rough back. It is only occasionally taken in the British Islands.

R. clavata, the Thornback, the Rough Ray. This Ray is easily distinguished by the spiny plates with which it is covered. Its flesh is regarded as the finest of all the Rays. It is in the best condition for the table about November.

R. radiata, Starry Ray. A rare species.

6. *Torpedinidæ*, the Torpedoes.—The head is very large and surrounded by pectorals, so as to form a circular disc; the tail is short, fleshy, depressed at the base, cylindrical at the extremity; mouth beneath; teeth pointed or flat. These fish are many of them remarkable for their power of giving electric shocks. There are two species of *Torpedo* found on the British coasts.

Torpedo vulgaris, the Old British Torpedo, the Common Cramp-Fish, the Numb-Fish, the Electric Ray, and the Cramp-Ray. This fish is only occasionally found on our coasts.

T. nobiliana, the New British Torpedo. This is identical with the *Torpedo* of the Mediterranean.

7. *Rhinobatidæ*, the Beaked Rays, have the muzzle generally beaked and pointed; the mouth undulated; the teeth rounded or elliptical, in some broader than long, and longer on summit of undulations; body smooth; caudal fin bilobular, or cut obliquely, forming one lobe. These fishes connect the Sharks and Rays. The species inhabit the Mediterranean, the Atlantic, and the coasts of Brazil. They are not found on the coasts of Britain.

8. *Pristidæ*, Saw Fishes.—The snout is produced into a long flat osseous saw-shaped blade, with teeth on the lateral edges; body flattened before, somewhat elongated posteriorly; skin with very small, flat, roundish, or 6-cornered scales; mouth beneath.

(Adams, Baikie, and Barron, *Manual of Natural History*; Yarrell, *History of British Fishes*.)

RAILWAYS. Since 1846, down to which an account was brought in the 'Penny Cyclopædia,' article RAILWAY, vol. xix., and TRANSIT, *S.* 1, no material alteration has been made in the system, and some account of the peculiar construction of some of their works will be found in *S.* 2, under BRIDGES. There have been no new trunk lines undertaken, unless the North Kent be considered such, but the construction of branches and connecting lines has been pursued unintermittedly; and there is now no important town in the United Kingdom but what is connected with the railway system, if not directly, at least by a short transit by means of omnibuses or other public conveyances. The legislation, therefore, has been principally as to deviations, connecting branches, the raising of capital, the granting or amending of powers for amalgamation, for the purchase or leasing of constructed branches, and a few of the acts passed were for railways in the East Indies and the colonies. In 1846 there were passed 272 railway acts, 184 in 1847, 83 in 1848, 35 in 1849, 36 in 1850. In 1850, in June, there were 6307 miles open in the United Kingdom, of which 891 miles were in Scotland, and 515 miles in Ireland, and the capital which had been authorised by parliament to be raised was 359,065,115*l.*, of which 178,412,625*l.* had been received on shares, and 51,335,154*l.* by way of loan; and 21,904,047*l.* had been paid in the year on shares, and 7,670,064*l.* had been raised by loan. During the year 72,848,422 passengers were conveyed by railway. In 1851 there were 61 railway acts passed, 52 in 1852, 102 in 1853, 82 in 1854, 76 in 1855, 60 in 1856, and 84 in 1857.

On Dec. 31, 1856, there were in the United Kingdom 8710 miles of railway open for public traffic; there were 1080 miles in course of construction; and there were 3321 additional miles authorised, which had not been commenced at that date. On Dec. 31, 1857, there were 9091 miles open. The total amount of capital and loans authorised to be raised up to Dec. 31, 1856, was 377,767,907*l.*, of which 307,594,086*l.* had been paid up, 70,173,821*l.* had yet to be raised, and the total of the debts of the various companies was 77,359,419*l.* In the year 1856 (during which 963 miles had been constructed) there had been conveyed 129,347,592 passengers, of whom 108,368,901 were in England and Wales, 13,097,238 in Scotland, and 7,881,453 in Ireland. During the year, 27 passengers had been killed, and 298 injured. The total number of accidents had been 281 killed, and 394 injured. In the year 1857 the number of accidents had materially increased; they had amounted to 236 killed, and 738 injured. Of these 25 passengers were killed, and 631 injured, from causes beyond their own control; and 23 were killed, and 15 injured, from misconduct or want of caution. The remaining accidents occurred to servants of the companies, trespassers, &c. The receipts from passenger traffic amounted to 10,153,745*l.*, and the receipts for the conveyance of goods, cattle, minerals, parcels, &c., amounted to 13,011,748*l.* Of the goods traffic, 7,685,379*l.* were for the carriage of 23,823,931 tons of merchandise, 3,585,991*l.* were for the carriage of 40,938,675 tons of minerals, 517,786*l.* were for the conveyance of 10,450,175 head of live stock, and 1,222,628*l.* for the carriage of parcels, &c. In England and Wales the total receipts averaged 3120*l.* per mile, in Scotland 2022*l.*, in Ireland 1092*l.* per mile; the average working expenses were in England and Wales 1531*l.*, in Scotland 970*l.*, and in Ireland 427*l.* per mile. The number of persons permanently employed on the various railways on June 30, 1856, in the capacities of secretaries, engineers, store-keepers, station-masters, clerks, engine-drivers, guards, artificers, porters, plate-layers, labourers, &c., was 102,117.

Railways in England are now as extensive, or nearly so, as turnpike roads; but foreign railways have assumed a position of so much importance as to claim the attention of our own country. Great as may be the advantage to the United Kingdom of having eight or nine thousand miles of railway open, it is of yet more importance to society at large that the other countries of the civilised world should be similarly provided; that prejudices of race and of creed should be softened down by intercommunication; and that each country should benefit from the produce of the others by interchange. It is no inconsiderable a fact in the world's history that the Magyar of Hungary, the Slavonian of Western Russia, and the gay Neapolitan of Southern Italy, should now be travelling in the same way, with locomotives displaying the same kind of highly-finished mechanism, as the inhabitants of the more developed and commercial countries of Europe. We have yet to see whether European nations, if at war, would tear up each other's railways; but so long as this is not the case, a railway line must inevitably be a line of civilisation. It is a "great fact" that a man may now 'book through' from London to so many continental cities, in spite of rivers, mountains, passports, custom-houses, and national jealousies. And if, directing our glance across the Atlantic, we watch the progress of American railways, we shall there be struck with the conquests over the barren wilderness made in a few short years.

In Europe Belgium took the lead. King Leopold proposed to the Legislature, in 1833, the adoption of a government system of railways; and a law was passed in 1834 in conformity with the proposal. The plan comprised a trunk line from Ostend to Liège, with lateral branches to Antwerp and Brussels, and a line from Brussels to the French frontier at Quievrain, making a total of about 247 English miles; in 1837 further lines were sanctioned from Ghent to Courtray, Courtray to Tournay, Braine-le-Comte to Namur, and Landen to St. Trond—a further distance of 94 miles; these various lines were opened to Brussels in 1835, to Antwerp in '36, to Ghent in '37, to Ostend in '38, to Courtray in '39, to Trebize in '40, to Mons in '41, to the French frontier in '42, and to the Prussian frontier in '43, by which time 326 out of the 341 miles were opened; and these had cost 4,114,354*l.*, or about 12,600*l.* per mile, exclusive of stations and carrying stock, which raised the cost to 16,500*l.* per mile. The Belgian lines open in 1858 were, from Ostend to Brussels, 89 miles; from Brussels to Tournay, 47 miles; from Brussels to the French frontier at Quievrain, 50 miles; and from Mons to Quevy, 9 miles; from Brussels, by Malines and Liège to Herbesthal, where it joins the Prussian line to Aix-la-Chapelle, 96 miles; from Landen to Maastricht, also joining the line to Aix-la-Chapelle, 36 miles; from Bruge to Poperinghe, joining a line to Calais, 59 miles; from Brussels to Mouscron, connected with the line from Lille to Paris, 72 miles; from Brussels to Antwerp, 26 miles; from Ghent, through Brussels, to Ath, 46 miles; from Ghent to Antwerp, 31 miles; from Brussels, by Namur, to Verviers, joining the Aix-la-Chapelle line, 85 miles; from Brussels to Erquelinnes, the direct Paris line, 56 miles; from Brussels to Namur, by Braine-le-Comte and Charleroi, 68 miles; from Louvain to Charleroi, by Wavre, 41 miles; from Charleroi to Vireux, 39 miles; from Manage to Wavre, 25 miles; from Wavre to Mons, 15 miles; a total of 890 miles. The Great Luxembourg line, of which only parts are completed, is to join the French railways at Metz, and thus connect Belgium with Nancy, Strasbourg, Cologne, and Mannheim. It is at present only open as far as Namur, though the works are nearly completed as far as Arlon. The Great Luxembourg line, when finished, will form an important link in the chain of communication from England to the centre and south-east of Europe.

The portion of this railway system near Liège required very heavy works; but the average character has been easier than that of English railways. One great cause for this has been, that Belgian railways cross common roads on a level much more frequently than those of England and France, by which many bridges and viaducts have been rendered unnecessary. Very few accidents seem to have resulted from this plan, partly because the speed of Belgian railways is lower than that of England.

With the addition of a few miles of branches, the total length of the Government railways is about 350 miles; these, down to 1848, had cost 6,359,611*l.*, including all expenses and an efficient working stock, or about 18,000*l.* per mile. About 850,000*l.* of this sum was for rolling stock. All the other Belgian lines of railway have been planned and carried out (so far as they are yet completed) by joint-stock companies, under certain concessions from the State. Among these are the 'Namur and Liège,' about 66 miles of main line and branches; the lines from Brussels to Luxembourg, and from Charleroi to Louvain, about 140 miles; the 'Sambre and Meuse,' to join those two rivers, 70 miles of main line and branches; the 'Tournay and Joubise,' and the 'Landen and Hasselt,' 46 miles together; the 'West Flanders,' 93 miles, to accommodate the province of that name; and probably one or two others.

A glance at a map of Europe will show that the Belgian main line from Ostend to Liège forms part of the trunk route to central and eastern Europe; and when the great railway-bridge shall have been built by the Prussian Government across the Rhine at Cologne, this route will become still more important. From the circumstance here mentioned, the Belgian railways have had a very important and international character.

The northern neighbours of Belgium, the Dutch, have hitherto been very modest in their railway enterprises. The principal towns of Holland happen to be packed together in a tolerably small space, between the Rhine-mouths and the Zuyder Zee; and a railway connection between them has thus been easily established. From Rotterdam to the Hague; from thence along the coast to Leyden and Haarlem; from Haarlem to Amsterdam; thence to Utrecht and Arnhem; and from Rotterdam to Utrecht, seven busy towns are placed in intimate communication. There are however but two railways that cross the frontier; one from Amsterdam by Rotterdam and Dordrecht, crossing the Maas by steamer from Dordrecht to Moerdyck, and by Breda to Antwerp; and from Amsterdam by Arnhem to Emmerich in the Prussian states, and thence to Cologne.

France allowed herself to be anticipated by Belgium in the adoption of the railway system. While the lines were being rapidly extended from Malines as a centre, France was doing nothing but watching hesitatingly the result of English enterprise. While this hesitation on the part of the Government yet continued, a joint-stock company was quietly formed for constructing a little line of passenger railway from Paris to St. Germain; the necessary powers were obtained in 1835, and the line was finished and opened in 1837. In this last-named year a commission was appointed to suggest a plan for a system of railways; the commission made a report in 1838; but as the Government and the Chamber of Deputies could not agree whether the railways should be national property or joint-stock private property, the plan fell to the ground altogether. Two companies, however, came forward, and offered to construct railways with their own capital—from Paris to Orleans and from Paris to Rouen—on certain favourable concessions being made to them by the Government. These lines were formed, under many financial difficulties, and were at length opened.

It was not until 1842 that the Government system of French railways was matured. The system comprised seven trunk lines—"the first directed upon the Belgian frontier; the second, upon one or more ports of the channel; the third, upon the ocean, by one or more of the western ports; the fourth, upon the Spanish frontier, by Bayonne; the fifth, upon the Spanish frontier, by Perpignan, passing through the centre of France; the sixth, upon the Mediterranean, by Marseille; and the seventh, upon the Rhine, by Nancy and Strasburg." Besides these, there were to be two additional railways from Marseille—one to Toulouse and Bordeaux, and one to Lyon and the Rhine at Mulhausen. These were to be constructed at the expense of the State, of the departments and communes, and of joint-stock companies—all contributing on certain prescribed terms. The law of 1842 has had to undergo many modifications, but the general outline of the Government plan has been adhered to.

In some cases, private enterprise has come to the aid of the Government in another way. Thus, two short lines of railway have been formed from Paris to Versailles; and one or both of these are to form parts of the route to Brest. Another company formed the Boulogne and Amiens line, which works in harmony with the State line from Amiens to Paris. The Rouen railway has been extended by a private company to Havre, and a branch made to Dieppe. The Paris and Orleans railway, made by a private company, has been adopted as the commencing portion of both the state lines to the Spanish frontier.

The peculiarly central position of France relatively to neighbouring countries, renders its system of State railways one of considerable importance. England, of course, has no other connexion with it than through the medium of the ports, of which Dunkirk, Calais, Boulogne, Dieppe, and Havre, have railway communication with Paris. Nantes, near the mouth of the Loire, has a continuous railway route of about 270 miles to Paris. The Bordeaux line has been opened from Paris; but everything beyond Bordeaux, towards the Spanish frontier, is only yet in process of formation. The railway down southward, through the centre of France, has two branches, one of which is completed to Limoges, and is to be carried on to Bordeaux; the other goes by Bourges to Clermont Ferrand, and is to be connected with Lyon and Toulouse. The great Marseille line is open throughout its whole length. The Strasburg line has been opened throughout from Paris to the Rhine—a very important route in respect to the intercommunication between France and South Germany. In the north of France the railways are now rather thickly congregated; for not only is the traffic with England and Belgium important, but there is considerable mineral wealth in the district near the Belgian frontier. France, as a whole, has very few cross lines of railway; nearly all of them radiate from Paris as a centre.

Before noticing the railways of Germany, it may be well to say a few words concerning the thinly inhabited countries further north, such as Denmark, Norway, and Sweden. The trade in those countries being comparatively small, and capital scarce, there has hitherto been neither a strong inducement nor a practical power to construct railways. But English capital has lately begun to flow thither for these purposes. The Danes have made for themselves a short railway of about 17 miles from Copenhagen to Roeskilde, in the busiest part of the kingdom; but all the other railway projects, both in Denmark and in Norway, are connected with English enterprise. The attempt to establish a steamboat route from Lowestoft to Denmark, will be nugatory unless aided by the formation of railways; and many surveys have since been made in Holstein, Schleswig, and Jutland, to determine on the feasibility of such constructions, as also across the islands which separate Copenhagen from the German Ocean. In Holstein itself, which is Danish in ownership but German in feeling, there is a railway open from Antona to Kiel, with branches to Rendsburg and Glückstadt; but no railways have yet been made in the more northern provinces of continental Denmark. A railway of 43 miles in length, from Tönningen to Flensburg, one on the west and the other on the east coast of Schleswig, establishes a route from the German Ocean to the Baltic, and one 56 miles in length has been opened from Copenhagen to Corsör. Other routes will very probably be determined on before any long time has elapsed, for surveys have been made, or are being made, from Flensburg to Rendsburg, and from Copenhagen to Elsinör; and many of the Danish merchants are looking forward hopefully to the time when Copenhagen may possibly be brought within two days' journey of London.

With respect to Sweden, nothing (that we are aware of) has been effected towards the construction of railways in that lake-covered country, except two short lines from Orebro to Arboga, and from Orebro to Nora, the two not much exceeding 40 miles; but a prospectus has been issued relating to a Swedish company, whose operations will be sanctioned and aided by the government. There is to be a railway from Stockholm to Göteborg, 350 miles in length, which will connect the Baltic with the German Ocean or North Sea. Norway, too, has made a beginning. An English company began the works on a line of railway from Christiania to Miösen; the former town is the capital, and near the sea coast; while Miösen is in a lake connected with the extensive inland navigation of the eastern part of Norway. At present this is only completed as far as Eidsvold, a distance of 42 miles.

In the wide-spreading region to which the general name of Germany is applied—extending as it does from the confines of Denmark in the north to those of Turkey in the south; from the Carpathians in the east to the Rhine in the west—the construction of railways must necessarily be very unequally distributed, arising from the great diversities in population and commercial industry. There is, however, collectively a large and important system of railway here developed. Some of the railways have been constructed by the respective governments, and others by private companies. Nearly the whole of those in the Austrian empire, in Bavaria, in Würtemburg, in Hanover, in Brunswick, and in Hesse, have been constructed by the governments; and even those made by companies have in most cases been redeemed or purchased by the state—so unwilling are most of the states to allow the control of locomotion to slip out of their hands. In Prussia, and in a few of the other states, the government has abstained from any direct interference with the construction or working of the railways; it has rather lent a fostering hand to private companies, in cases where the traffic did not appear to be large enough to pay an adequate dividend on the outlay. In order to keep down the expenditure to a reasonable limit, all costly works are avoided unless absolutely necessary; hilly districts are traversed by steep inclines and numerous curves, instead of by costly tunnels, cuttings, viaducts, and embankments; inasmuch as a slower rate of speed than that adopted in England renders such gradients and curves easily manageable.

Taking Germany in its widest sense, as including the Austrian empire as well as the various states north and west of it, there were completed and in operation in 1845 about 1590 miles of railway, in 1847 about 2800 miles, and by the end of 1849 about 4550 miles. At the last-named date there were also 800 miles more in progress of construction, and about 3100 miles either decided on or contemplated, but without having been commenced; making a total, real and projected, of about 8450 miles. Prussia, with the Rhine states, possesses the larger portion, forming a net-work connecting them with France, Belgium, Bavaria, Austria, and Russia, and they show a great superiority of commercial activity over that of the more widely extended empire of Austria with its dependencies. Berlin is now connected by railways with Dresden, Prague, Vienna, Cracow, and Warsaw, but of course much of the line is beyond her own dominions. The lines in Prussia, though numerous, are generally, from the form of her territory, not long in themselves, though forming links on far longer lines; the single exception is the line from Berlin to Danzig and Konigsberg in East Prussia, 400 miles. Austria, on the contrary, has a few which run on her own soil for great distances, such as the railway from Vienna to Trieste, 363 miles; from Vienna to Temesvar, 358 miles; and from Vienna to Dembica, 68 miles beyond Cracow, of 326 miles. Vienna at present is only connected with the general German system by the lines from that city through Dresden, or through Breslau, to Berlin. By the beginning of 1858, there appear to have been about 6200 miles of railway open in the whole of the German states, besides what is in progress.

There are many noticeable features in German railways, as compared with those of England. Passenger carriages of three classes, 1st, 2nd, and 3rd, are generally used as in our own country, but more comfortable for second and third-class passengers. There are also more of the long carriages, on the American system, holding from 70 to 120 persons. The cost of carriages per passenger, according to the number carried and the luxury of accommodation, varies from 4*l.* to 15*l.* In America, attempts have been, in some few cases, made to establish a cheaper class of carriage with less accommodation; but these have been so little patronised, that the companies have reverted to the uniform or non-classified system. In Germany, more than in any other part of Europe or America, passengers travel by the cheapest mode that can be obtained. All the trains comprise all three classes of carriages (except a few special instances connected with the express "through route" from London viâ Dover and Ostend); and of all the passengers, only four in every 100 travel by the 1st class, the 3rd class ratio being so high as 74 in the 100. As the 3rd class fare is only about ⅘ per mile, and the 1st class a fraction over 1½*d.*, the average fares paid by the whole of the passengers is within 1*d.* per mile.

In the vast Russian empire, the first attempt to obtain railways was made by offering great advantages to any capitalists who would establish companies for this purpose; they were to have a gratuitous grant of all the land necessary, and all the timber and raw material which they might find on the spot; they were permitted to import iron and working stock free of duty; they were guaranteed by the Emperor a minimum dividend of four per cent. on their capital; and the great land-owners offered the use of their serfs in constructing the works. It is only to a partial extent that these offers have been accepted, owing to the backward state of joint-stock enterprise in Russia. Some of the railways now constructed or under construction are undertaken by companies; while the rest belong to the State.

The most important line of railway in Russia is that from St. Petersburg to Moscow, of 400 miles in length. The next in importance, in so far as it will connect Russia with central Europe, is the St. Petersburg and Warsaw, about 680 miles. A goods railway, worked by horses, about 100 miles in length, has been formed to connect the Don with the Volga. There is a railway from St. Petersburg through a place near it called Tsarskoé-soélo to Louga, about 84 miles. This is a part of the Warsaw line. Tsarskoé-soélo has a royal residence, and between it and St. Petersburg there is a busy traffic, somewhat akin to that of our Greenwich railway, or to the Varseilles railway near Paris. Southern Russia is to have a railway from Odessa to Kief, to be continued possibly, at some future time, to Moscow, and thus completing a railway line of 1600 miles from the Baltic to the Black Sea. There are also lines planned from St. Petersburg to Cronstadt, and St. Petersburg to Baltischport in Esthonia. The railway from Warsaw to Cracow is open, as is that from St. Petersburg to Moscow; but in the other districts mentioned above, the works, so far as commenced at all, are proceeding slowly.

Of the countries lying south of the Alps, and west of the Pyrenees, little can yet be expected in respect to railway enterprise, Italy being cut off by the Alps from France, Switzerland, and Austria, and Switzerland itself being surrounded by the Alps. Nevertheless Switzerland has not been inattentive to the subject. There are now open lines from Basel to Lucerne, from Basel to Waldshutt, from Berne to Aarau, from Herzezenbuchsee to Bienne, from Yverdun by Lausanne to Morges, from Villeneuve to Bex, from Zurich to Baden and Brugg, and from Zurich to Winterthur and Schaffhausen. Its connection with France is formed by a line from Basel to Mulhausen, and with Germany from Zurich to Zug, crossing the lake of Costanz, and thence to Ulm and Augsburg. In Piedmont a railway has been constructed from Turin to Susa, 34 miles; this is to be continued by a tunnel under Mount Cenis, an enormous undertaking, to join the line now open from St. Jean Lanslebourg to Chambery, and thence to Geneva: lines are also open from Turin to Piñerolo, 23 miles; from Turin to Cuneo, 55 miles; from Turin to Genoa, 103 miles; from Turin to Novara, 60 miles, with a branch of 17 miles to Biella; and from Alessandria to Arona on the Lake of Como through Novara, 63 miles, with a branch of 8 miles to Vigevano. By reaching Milan, from whence this line is not far distant, a communication would be opened with Verona, Mantua, and Venice; and the completion of the line to Geneva, which involves expensive engineering difficulties, would open a communication with France by Lyon.

In Italy, distracted as it is by political disputes, and broken up into so many states, the progress of railway enterprise has been much retarded. Down to the beginning of 1850, nothing had been done towards establishing international railways from state to state; but each state, or at least three of them, have now short lines confined to their own territories. In Tuscany, there are lines from Leghorn to Pisa, Florence to Sienna, Pisa to Lucca, and Florence to Prato; and in Naples the lines extend from Naples to Cava, and from Naples to Capua; from Rome a line of 12 miles is open to Frascati, and some other works are in progress. In Austrian Italy a railway communication has been opened from Milan eastward by Treviglio and Brescia to Verona and Venice, 176 miles, with a branch to Mantua. This line also communicates northward by Monza with Camerlata on the Lake of Como. Venice, as is well known, is situated on a series of islands; and these islands are connected with the mainland by a viaduct of great magnitude: it is 12,000 feet long, and has 222 arches, the piers of which rest upon 80,000 larch piles, driven into the bed of the lagune or channel.

Spain and Portugal have always been much isolated from the rest of Europe by the formidable Pyrenean barrier; and, from various causes, they have been slow to adopt the canal and railway systems which have been so valuable to the rest of Europe. The principal line in Spain now open is from Madrid by Aranjuez to Albacete in Murcia, 174 miles, which it is proposed to continue to Zaragoza and Alicante. The other lines are from Barcelona to Arenys del Mar, from Barcelona to Granollers, from Barcelona to Martorell, from Barcelona to Tarrasa, from Tarragona to Reus, from Alar del Rey to Reynosa, approaching Santander on the French frontier; from Cadiz to Xeres (or Jeres) de la Frontera; and from Valencia to Alcudia; all of them short lines, the length of the longest, that from Valencia to Alcudia, being only 39 miles. Portugal has but one railway, under 30 miles in length, from Lisbon to Virtudes.

The Mohammedan, imitating the European in so many things, is now imitating him in railway enterprise. The Pacha of Egypt, eager to do all that can be done for facilitating the overland route to India, is now having a railway constructed from Alexandria towards Cairo, to touch the Nile at a point which will get rid of the slow transit along the canal from Alexandria, and thence to extend to Cairo. The crossing of the desert itself to Suez, whether from Cairo or from some port in the Mediterranean, has been very amply discussed for several years past; schemes for ship-canals and for railways have been brought forward in considerable number; but the difficulties in a region of loose sand are great; and there is not at the present time, so far as we are aware, any strong probability that either a canal or a railway over the Isthmus will be constructed.

In India itself much has been done, and much more is in progress. From Calcutta 120 miles of railway have been opened for traffic, and 1100 are in progress, to connect it with Delhi. But the terminus at Delhi, in consequence of the recent rebellion in India, it is now said, is to be changed, and that the railway is to run by Allahabad to Meerut, which is to be made the capital of north-western India. From Bombay lines are to run to Mirzapoor, where it will join the Calcutta line to Delhi, to Madras, and to Ahmedabad; on the first 49 miles, and on the second 71 miles, have been opened, but 32 miles are common to both; and 1050 are in progress on the two lines; on the third nothing is opened, but the earth-works are completed from Surat to Ahmedabad, 150 miles. From Madras a line is laid out to the western coast of the peninsula, of which 90 miles are open, and 300 are in progress; and from Madras to Bellary, 296 miles are in progress of construction. [INDIAN EMPIRE, p. 320, *S.* 2.]

In the United States of America, as early as 1843, we find that there had been more than 5000 miles of railway constructed, belonging to 143 companies, an average of only 36 miles as the length of each railway. The railways were constructed, as in England, by joint-stock companies, and not by the State; and although each railway was constructed mainly for local traffic, there had nevertheless arisen eight great trunk lines of communication, by junctions of various lines. American railways have been constructed very much more cheaply than those in England, partly because the legal and legislative expenses are extremely small, partly because the land is bought at a low price, partly because timber is very cheap, partly because no useless expenditure is bestowed upon splendid stations, and partly because the relatively low speed of travelling enables steep inclines and sharp curves to be worked safely. The eight great arteries of communication were,—1st, parallel to the sea-coast, throughout the whole vast distance from New England to Florida; 2nd, east and west from Boston to Lake Erie; 3rd, New York to Lake Erie; 4th, Philadelphia to Lake Erie; 5th, Philadelphia to Pittsburg, over the Alleghany Mountains, and comprising a system of railways and canals; 6th, Baltimore to the Ohio; 7th, Charleston to Cincinnati, uniting the Atlantic with the Ohio; 8th, Georgia to Savannah. It is not that all these routes were actually completed in 1843, but that sufficient had been done to show that such routes would result from the united labours of many companies influenced primarily by local wants alone. By 1849 the length in work had increased to 6500 miles. The Atlantic states, thickly inhabited and commercially active, were naturally those in which railways were formed earliest and in greatest number; but the system gradually extended to the vast agricultural districts of the west; insomuch that by 1849 there were five short railways in the state of Mississippi, ten in Louisiana, and a few in Alabama, Illinois, Michigan, Indiana, and Ohio. Dr. Lardner describes the utter strangeness of the sights and sounds presented by this encroachment of civilisation on the wilds of the west, this conquest of the locomotive over the forest and the prairie. "Travelling in the back woods of Mississippi, through native forests where, till within a few years, human foot never trod, through solitudes the stillness of which was never broken even by the red man, I have been filled with wonder to find myself drawn on a railway by an engine driven by an artisan from Liverpool, and whirled at the rate of twenty miles an hour by the highest refinements of the art of locomotion. It is not easy to describe the impressions produced as we see the frightened deer start from its lair at the snorting of the ponderous machine, and the appearance of the snake-like train which follows it."—'Railway Economy.'

Of the 6500 miles of railway at work in the United States in 1849, more than half were in New York, Pennsylvania, and the New England States. Of these, the most remarkable, perhaps, is that which traverses Pennsylvania from east to west, as part of the route from Philadelphia to Pittsburg. First there are 81 miles of rail from Philadelphia to Columbia on the Susquehanna. Then there are 172 miles of canal from Columbia to Holidaysburg, which bring the traveller to the eastern base of the Alleghany Mountains. Next is the Portage railway of 37 miles, from Holidaysburg on the eastern to Johnstown on the western base of the Alleghanies; this railway has to climb a height of 1398 feet, and then descend 1172 feet; the trains are drawn up to the summit level by stationary engines and ropes; different levels being reached, one by one, by the aid of separate engines and ropes. Lastly, there is another canal from Johnstown to Pittsburg. This fourfold division of the route is not so troublesome as it would be in England; for by an ingenious contrivance, the canal-boats are made available for land transit. The boats, which are of considerable magnitude and length, are divided into segments or sub-boats, by partitions made transversely and at right angles to their length; so that each boat can be separated into three or more smaller boats. When the canal route is traversed, these several pieces are placed each on two railway trucks which support it at its ends; a proper body being provided for the trucks, adapted to the form of the bottom and keel of the boat; each short stumpy boat thus forms a passenger carriage or a goods waggon on the railway; while three or four of them form a spacious boat on the canal.

By about the middle of the year 1851, it was estimated that the railways in the United States were more than 10,000 miles in length, having cost about 67,000,000*l*., or 6700*l*. per mile. In the spring of 1852 the railways open were stated to be 11,500 miles, besides 11,200 in course of construction, making a total of little less than 23,000 miles. An estimate for 1852 gives 13,000 miles as the probable length in the early autumn of that year, and ten miles a day as the average rate of increase in the length open for traffic. In 1854 there were 17,317 miles completed, and 12,526 miles in course of construction. Since that period there has been a lull, and the chief new lines undertaken have been in connection with those of Canada. In January 1857 there were open and in work 24,220 miles of railway in the United States, and a line of 49 miles in length from Aspinwall to Panamá. Including Canada there were in January, 1858, 440 lines, but many of them form portions of a longer line.

The American railways have several advantages which, to our discredit, have not been introduced upon English lines. Whether the abandonment of all 'classes' in railway carriages, the non-distinction into 1st, 2nd, and 3rd class—whether this be an advantage or not, each reader must determine for himself. We shall simply state, therefore, that such is the case in the United States, and that the passengers —though they have not all the cushioned luxuries of first-class passengers in England—have far more comfort than our second and third-class passengers. The following is the type of an American railway carriage. It is two or three times as long as a London omnibus, but much wider and higher; there are doors at each end, and a row of windows along each side. There is a central passage from end to end, wide enough for one person to walk; and on both sides of this passage are rows of seats, transverse to the length of the carriage, and each accommodating two persons. There are from fifteen to twenty of these seats on each side of the avenue, thus affording accommodation for sixty or eighty persons in the carriage. The seats are cushioned; and their backs, consisting of a single padded board about six inches broad, are so supported that the passenger may at his pleasure turn them either way, so as to have either his face or his back to the engine. At night there is a good lamp at each end of the carriage; and in winter there is a small stove in the middle, with a smoke-pipe projecting through the roof. Some of the carriages have a ladies' compartment at one end. If these very large and roomy vehicles were set upon wheels in the same manner as English carriages, it would be impossible to work them over curves of any but very wide radius; the arrangement adopted is, however, one which renders them even more manageable than our shorter carriages. Each end is supported on a small four-wheeled railway truck, on which it rests on a pivot; similar to the expedient by which the fore-wheels of an ordinary road-carriage sustain the perch. On a sharp curve, the front truck may be moving in one direction, and the hind truck in a direction a little inclined to it, while the body of the vehicle forms the chord of the arc or curve. These long-bodied carriages have much less dead weight per passenger than English railway carriages. In American towns, the locomotive depôts are always in the suburbs, but the passenger stations are in the heart of the town, the carriages being drawn from the suburbs to the centre by horses, along the level of the streets. It should be remembered, however, that in many cases they are laid down as single lines.

We may here state that a new tunnelling machine has recently been introduced in the United States, to excavate tunnels through hard rock. So far as descriptions of it have yet reached this country, it appears as if it would be a very valuable engineering aid. The machine works horizontally, and is set in action by a steam-engine. A rapidly revolving tool bores a hole horizontally in the rock, a few inches in diameter. An enormous vertical wheel, equal in diameter to the intended section of the tunnel, has cutters or tools projecting horizontally from its periphery, and these cut a large circular groove in the rock, concentric with the hole first bored. The central hole is then charged with gunpowder, and a blast loosens and shatters the huge mass of rock between the hole and the groove. If, as is alleged, this machine will tunnel ten feet per day, it will greatly expedite railway works, and cheapen them also.

It is a grand achievement to have the means of locomotion brought to places which were so little time ago quite unknown and even non-existent. It is a great thing to have railways touching four out of five of the Canadian lakes, and this, too, at many different points; these are yet almost wholly on the south or United States side of the lakes, for reasons before adverted to. It is a fact fraught with important social results, that the Mississippi is beginning to hear the steam whistle of the locomotive, and that the cotton regions of the south are becoming connected by rail with the manufacturing states of the north. It would be useless to speculate on the probable amount of time which must elapse before the locomotive will reach the base of the Rocky Mountains; sufficient cause for marvel is it that the valley of the great river is brought within the scope of a commercial system which our own Stephensons introduced less than a quarter of a century ago. One of the Mississippi railways alone, from Lake Michigan to the mouth of the Ohio, will, when completed, be 700 miles in length.

In Canada a variety of circumstances prevented so early an adoption or so wide an extension of railways as in the United States; but since 1852 rapid advances have been made. The Grand Trunk Railway, 935 miles long, is now open from Portland in Maine, in the United States, to Windsor on the Detroit river. From Portland it crosses a part of New Hampshire and Vermont to Richmond, where a branch proceeds northward to Quebec, 96 miles; the other line goes on to Montreal, a distance from Portland of 292 miles. It is to cross the St. Lawrence by the Victoria tubular bridge which is in course of construction, for a notice of which see Bridges, *S.* 2, p. 83. It is expected to be opened in the summer of 1860. Thence the line proceeds west-south-west by Hamilton and Kingston to Toronto, at the head of Lake Ontario, 333 miles; and from Toronto to Stratford and Windsor on the Detroit river, where it connects itself with many of the United States railways, 221 miles; but a portion of this was not open though nearly completed. The Great Western Railway runs from the Niagara Falls by Hamilton and London to Windsor on the Detroit, 229 miles; and from Hamilton to Toronto, 38 miles. The St. Lawrence is crossed by a suspension bridge of 822 feet span, and 255 feet above the water, available both as a railway and a common roadway, and connects the Great Western with the Rochester and Lockport line. There are also lines open from Toronto to Collingwood on Georgian Bay, 95 miles; from London to Port Stanley, 24 miles; and from Prescot to Ottawa, 54 miles. These, though independent lines, form junctions with the two main lines. A third line, parallel with the Great Western, but keeping closer to the river St. Lawrence, has been projected, to be called the Great Southern Railway, to run from Niagara Falls to the Detroit river at Amherstburg.

In the colony of Victoria a railway has been for some time open from Melbourne to Geelong, and others have been projected. In Jamaica a railroad was opened from Kingston to Spanish Town in 1845; and upwards of 500 miles of railway have been opened in Cuba. A railway has also been opened from Algiers to Blidah; and a line is in course of construction in Brazil, to run from Pernambuco to San Francisco, both on the eastern coast.

RALEIGH, or RAYLEIGH. [Essex.]

RAMSBURY. [Wiltshire.]

RAMSEY. [Huntingdonshire.]

RANA. [Frogs.]

RANGIFER. [Deer.]

RANICEPS, a genus of Subbrachial Malacopterygious Fishes, belonging to the family *Gadidæ*. It has the following characters:—Head depressed; body compressed; two dorsal fins, the first very small, the second dorsal and the anal fins elongated; ventral fins small, the first two rays lengthened and separated.

R. trifurcatus, the Lesser-Forked Beard, the Tadpole-Fish. Pennant describes two species of *Raniceps*, as belonging to the British Fauna, *R. Jago* and *R. trifurcatus*. Dr. Johnston, of Berwick, was the first to suspect they might be the same fish; and Mr. Yarrell, after comparing Dr. Johnston's specimens with descriptions by Mr. Couch, of Cornwall, comes to the conclusion that the two species mentioned by Pennant are one and the same. It is a rare fish; but Mr. Thompson records a specimen as taken in Ireland, and Dr. Parnell describes it in his 'History of the Fishes of the Frith of Forth.'

RAOUL-ROCHETTE, DÉSIRÉ, an eminent French archæologist, was born at St. Arnaud in the department of Cher, on the 9th of March, 1789. Educated at Bourges, he was called to Paris when little more than twenty-two, to fill the chair of history in the Lyceum; and in 1815 he supplied the place of Guizot as lecturer on Modern History in the University of Paris. In 1815 appeared the work which first gained him a more than local celebrity, 'Histoire Critique de l'établissement des Colonies Grecques,' 4 vols. 8vo. The following year he was made member of the Académie des Inscriptions, and one of the editors of the 'Journal des Savans;' and in 1818 he was appointed keeper of the medals, &c., in the Royal Library. His attention having been directed to modern Swiss history he, during the following years, made several exploratory journeys in Switzerland, of which he published ample particulars under the title of 'Lettres sur la Suisse écrites in 1819-21,' 3 vols. 8vo, Paris, 1823-26, and 'Voyage Pittoresque dans la Vallée de Chamouni et autour du Mont Blanc,' 4to, 1826. His 'Histoire de la Révolution Helvétique de 1797 à 1803,' appeared in 1823. But whilst thus engaged on topography and modern history, he was still diligently prosecuting the study of classical antiquity, to which he thenceforward devoted himself, making various journeys to Greece and Sicily, Italy, Germany, Holland, &c., in order to familiarise himself with particular localities and to examine the treasures collected in museums. In 1822 appeared his 'Antiquités Grecques du Bosphore Cimmérien.' He had already come to be looked upon as the legitimate successor of Quatremère de Quincy, before the delivery of his lectures in 1826 on his appointment as professor of archæology, which considerably added to his celebrity. These lectures were published in 1828, under the title of 'Cours d'Archéologie,' and again in 1836.

From this time M. Raoul-Rochette was one of the most active and most widely known of the French writers on ancient art, communicating numerous papers to the Memoirs of the Académie, as well as to the journals of other learned societies, and frequently appearing before the public in distinct works. In 1828 he published 'Monumens inédits d'Antiquité figurées Grecques, Etrusques, et Romaines,' 2 vols. fol. His 'Peintures Antiques inédites' appeared in 1836. In 1839 he was appointed perpetual secretary to the Académie des Beaux Arts, the post previously held by Quatremère de Quincy; and, like his predecessor, he composed a large number of official éloges and résumés. In 1840 appeared his 'Mémoires de Numismatique et d'Antiquité,' 4to; in the same year 'Lettres Archéologiques sur la Peinture des Grecs;' and in 1846, 'Choix de Peintures de Pompei.' His last work of importance—one which he describes in the introduction as having for its object "to direct the investigations of the mythographists and antiquaries of the present day to the only course which, I believe, will prove fruitful in new discoveries —the relationship between Greece and Asia"—was entitled 'Mémoires d'Archéologie comparée, Asiatique, Grecque, et Etrusque,' but only one part was published (in 1848), and that, though a bulky 4to volume of 404 pages, is wholly occupied with the 'Premier Mémoire sur l'Hercule Assyrien et Phenecien considéré dans ses Rapports avec l'Hercule Grec.' Except some controversial letters directed to M. Carnot, referring to some charges brought against him in respect of his official conduct, he does not appear to have issued subsequently any separate publications. He died on the 6th of July 1854. An English translation of his 'Lectures on Ancient Art,' by H. M. Westropp, was published in 1854.

RASSOVA, a small town in Bulgaria, situated on the right bank of the Lower Danube, at the point where the river makes its great bend to the northward, about 30 miles E.N.E. from Silistria. It is of importance from its position at the western end of the line of earth-works called Trajan's Wall, which extends across the isthmus of the Dobrudscha from near Rassova to Kusteuje, on the Black Sea. Rassova is slightly fortified; it was occupied for a short time by the Russians in their invasion of Bulgaria in 1854.

RATHDRUM. [WICKLOW.]

RAUCH, CHRISTIAN, an eminent German sculptor, was born at Arolsen in the principality of Waldeck, on the 2nd of January 1777. He early showed an aptness for art, and received instructions in it from the sculptor Professor Ruhl of Cassel. In his twentieth year he went to Berlin, having been presented to an office in the court of the Queen of Prussia; but his spare hours were all devoted to art. He here secured the friendship of Count Sandrecky with whom he set out in 1804 on a tour through a part of France to Genoa, and thence to Rome. There with the advice and aid of William von Humboldt, then Prussian minister in that city, he devoted himself to the study of the antique, while he availed himself of the friendly instruction of the chief living sculptors, Canova and Thorwaldsen. After a due probation he produced several original works, among others, bassi-rilievi of 'Hippolitus and Phædra;' a 'Mars and Venus wounded by Diomedes;' a 'Child praying,' &c. But he began still more to distinguish himself in the line to which he has continued to owe his chief celebrity, that of portraiture; besides abundant private patronage, he received from the King of Prussia commissions to execute a colossal bust of the King of Prussia, and a life size bust of the queen; and from the King of Bavaria, a bust of Rafael Mengs. In 1811 he was recalled to Berlin, to execute a monumental statue of the Queen Louise. His design was approved, and his health having failed, he was permitted to proceed to Carrara to complete the work, which he did in 1813, in a style that secured his reputation. He then went on to Rome, where he remained till 1822, when he returned to Berlin, where he afterwards resided. During his second residence in Rome, Rauch was chiefly engaged on busts and statues; he executed for the King of Prussia, besides a marble statue of the king himself, monumental statues of Generals Bulow and Scharnhorst. By 1824 he had executed with his own hand seventy marble busts, twenty of them being of colossal size. Among the more important of his later works may be mentioned two colossal bronze statues of Field-Marshal Blücher; the first, representing the hero in vehement action, was erected with great solemnity at Breslau, July 9, 1827; the second, designed after Blücher's death, for the King of Prussia, represents the veteran in repose.

Another of his principal works is a seated bronze statue of Maximilian of Bavaria, erected in 1835 in Munich. The 'Victories' for the Walhalla, near Ratisbon, are also from his chisel. A well-known statue of Göthe, modelled from the life, is the most perfect representation of the great poet of modern Germany. Statues in marble or bronze of Schiller, Schleiermacher, and others of his chief contemporaries, and of Luther, Albert Dürer, and other famous Germans of an older time, serve to show the high estimation in which his works are held by his countrymen; while bronze statues of two or three of the old Polish kings, which he executed for Count Raczynski, to be placed in Posen Cathedral, and a bas-relief erected at Dublin in memory of Miss Cooper, show that his ability was appreciated beyond Germany. His chief work, however, is the grand monument of Frederick the Great of Prussia, erected in the finest part of Berlin. This work, in the design of which Rauch was assisted by Professor Schinkel, the architect, and which called into exercise all the resources of the two artists, was commenced in 1830. The general model was completed in 1839; the colossal model of the king was not however ready till 1842, and the statue was cast in 1846. Four more years were required for the execution of the bas-reliefs, and the statues of military commanders, ministers, judges, literary men, &c., and figures of the Virtues and the like, which were to be placed around the base. Meanwhile the granite basement was being constructed, and by the beginning of 1851 the whole was finished. It was inaugurated with the greatest pomp in May 1851. Of this—perhaps the most elaborate monumental work of recent years—a small model may be seen in the Crystal Palace, Sydenham, as well as casts of the colossal equestrian statue of the king which crowns the monument, of the bassi-rilievi which represent the chief transactions of his life, and of some of the detached statues. The work is a sort of compromise between the severity of classic and the freedom of romantic art, and will not in its details stand the test of rigorous criticism; but, casting aside minute criticism, it must be held to be one of the very finest as well as most imposing of recent commemorative works. And we may add that, even without this his master-work, Rauch would unquestionably stand in the highest class of modern portrait and monumental sculptors, though far from ranking among the first in ideal sculpture. Rauch died Dec. 3, 1857.

RAUPACH, ERNST BENJAMIN SALOMON, one of the most prolific of modern German dramatists, was born at the village of Straupitz, near Liegnitz, in Silesia, on May 21, 1784. He received his early education at the gymnasium at Liegnitz, and in 1801 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University there, to which in 1818 was added the professorship of German literature. In 1822 he quitted Russia, and having received somewhat later the solicited discharge from his professional duties, he travelled for a time about Germany, visited Italy, and at length returned and settled at Berlin. The result of his journey to Italy appeared in 1823 in 'Hirsewenzel's Briefe aus Italien.' His dramatic productions had already been numerous, ranging from 1810 downwards, though many did not appear in print till long after they had been written. In 1837-38 he published his series of historical plays in illustration of events connected with the Hohenstaufen dynasty of emperors of Germany, which formed eight volumes. His dramatic works were published in a collected form in two divisions, 'Dramatische Werke komischer Gattung' ('Dramatic Works of the Comic Species'), in 3 vols., 1826-34; and 'Dramatische Werke ernster Gattung' ('Dramatic Works of the Serious Species'), in 18 vols., 1830-44. These works display considerable inventive powers, a great command over his materials, a thorough knowledge of stage resources, a sense of fitness, with a happy introduction of interesting situations. In his serious dramas he often reaches to the expression of deep passion, and in his comedies and farces, a rich vein of verbal wit. His poetic style is harmonious and natural, and he has consequently been a favourite with the public. His defects are a want of poetic consistency, a weakness of characterisation, and occasionally a lapse from pure morality, as in his 'Robert der Teufel,' and one or two others. His series of historical plays on the Hohenstaufen, by provoking a comparison with those of Shakspere, appear the most defective in dramatic merit, but they contain some fine passages. He also published two collections of tales, one in 1820, another in 1833; but they possess little merit, and attracted but little attention. In 1842 he was created a privy-councillor, having previously been made a councillor. He died in March, 1852.

RAY. [RAIIDÆ, S. 2.]

RAZOR-BILL. [AUK.]

RECEPTACLE, in Botany, is that part of the flower on which any of the other organs rest. It represents the axternodes of the stem and branches in their changed condition. It assumes a variety of forms, and enters very variously into the forms of flowers and fruits. [CALATHIDIUM; FLOWERS, *S.* 2; FRUIT, *S.* 2.]

RED-BREAST. [ERYTHACA, *S.* 2.]

RED-EYE. [LEUCISCUS.]

RED-SANDSTONE. The term Red-Sandstone is more especially applied to two formations, the Old Red-Sandstone [OLD RED-SANDSTONE, *S.* 2], and the New Red-Sandstone Rocks. The latter are also sometimes called Saliferous, on account of the salt they contain, and they are also called Triassic.

"It is in Cheshire and the southern part of Lancashire, and the northern part of Shropshire, which together form an extensive and rich plain, watered by the Dee, the Mersey, and the Weaver, that the uppermost beds of the New Red-Sandstone are chiefly developed; and by a minute examination of these beds, and those of Warwickshire, the saliferous marls have been identified with the uppermost strata of the foreign Triassic System. Throughout this range the beds are nearly horizontal, the dip rarely exceeding ten or twelve degrees, and being constantly towards the east, or a few degrees north or south of that point. They are, however, affected by some important faults. The whole district abounds with salt-springs, which are more especially plentiful in Cheshire; and in that county also there occur extensive masses of rock-salt in a solid state, their total thickness amounting to not less than sixty feet. These alternate with beds of gypsum; with numerous bands of indurated clay of a blue, red, or brown colour; and with sandstones, frequently marly, and of a red colour.

"The red-marl district, with brine springs, is continued southward into Worcestershire, and northward into the valley of the Iden, and the same part of the formation extends also eastwards, occupying for the most part the plains through which the Humber and its tributaries make their way to the German Ocean. In Somersetshire and Devonshire similar sandstones recur, and lie unconformably, overlapping the inclined edges of the older rocks, or abutting against them, but uniformly composed of the same materials, remarkable throughout for the ochraceous colour pervading them. Between Sidmouth and Seaton, in Devonshire, the red marls contain gypsum in abundance; and near Teignmouth the cliffs, which are of considerable height, consist of alternations of argillaceous beds of sandstone and of conglomerate.

"The beds which are lowest in position of the upper new red-sandstone are chiefly found in the middle of England, and consist of thick masses of whitish soft sandstone. In some places (as in Staffordshire) these are surmounted by conglomerates, composed of rounded pebbles of quartz rock, and other fragments, chiefly of Silurian rocks and old red-sandstone. The total thickness of this part of the formation is considerable, but has not been accurately calculated. It is only to be distinguished from the overlying saliferous marls by small differences of mineral character." (Ansted.)

Viewed on the great scale, the New Red-Sandstone system of rocks is one of the most varied and interesting we are acquainted with. There are peculiarities in its limestones, sandstones, and clays, as well as in its gypseous and salt deposits; the occurrence and nature of its organic contents, and the relation which it bears altogether to earlier and later classes of rocks, are worthy of careful study.

Sulphate of lime is found perhaps as frequently, and under almost as many curious circumstances in the stratified rocks, as carbonate of lime, in mealy aggregations, acicular prisms, broadly foliated crystals (selenite), fibrous masses and beds, and marmoroid or alabastrine rocks. It lies in strata of almost every age, and is not absent from diluvial, alluvial, and recent deposits. The mode of its occurrence is in a considerable degree characteristic of each particular mineral type. While long prismatic crystals appear in cavities of shells and in recent excavations (as in the gallery of Felling Colliery, Newcastle), the solitary broad flaky crystals of selenite abound in blue-clays of the tertiary and secondary series (which receive their colour from protoxide of iron), and the fibrous gypsum marks, spots, and irregular lines in the red-clays (coloured by peroxide) of the Saliferous System, the fibres being (in agreement with a general law of structures) arranged so as to lie at right angles to the broader surfaces which bound the mass. The marmoroid texture is most commonly found in real however irregular beds, as at Montmartre, and in some points near Fairburn in Yorkshire, on the line of the York and North-Midland railway. At these places fibrous, marmoroid, and flaky sulphate of lime may be obtained in association.

From what is known to take place at the present day, and from appearances in the distribution of the gypsum and selenite in masses of clay and cavities of shells, &c., it appears that in a great proportion of cases these crystallised masses owe their origin to the processes of segregation since the deposition of the earthy masses in which they appear. In no other way is it at all conceivable, or even possible, that the irregular masses of gypsum which appear in red-marl at Axmouth, Aust Passage, and the Trent's mouth could be formed. The marls in which they here lie were deposited as fine mud, and if we suppose merely a slow extrication of the liquid, so that its contained salts might remain, the arrangement of these salts in such irregular masses during crystallisation presents no particular difficulty.

Salt shows itself in the Cheshire mines as either granular, broadly laminated, or fibrous; in great beds or minutely mixed with marls, nearly as gypsum is, and probably in regard to its origin, similar suppositions will apply, the solid beds (of limited extent, however, and irregular area) being due to a great evaporation of liquid over the previously deposited marls. That such water, in the case of rock-salt generally, was derived from the sea, is almost certain, from the occurrence of iodine and bromine in the brine springs connected with them. (Daubeny's Memoir in 'Phil. Trans.') But it does not follow that the area in which the salt was found was, at the time of its formation, or for some time previously or subsequently, connected with the sea. Lagoons may have been the theatre of the evaporation supposed, and earthy sediments, such as occur in Cheshire and Poland, may have been drifted in by fresh-waters or the sea, according to circumstances, and it is not difficult to imagine a repetition of the processes, such as might produce the two great beds of rock-salt in Cheshire. It is not known that organic remains of any kind accompany the salt of Cheshire, but this is almost true of the whole range of the red-marls, in which these deposits lie.

We find, then, associated together, abundance of red-oxide of iron, salt, and gypsum, but few or no organic remains. The prevalence of red-oxide of iron in any of the strata is accompanied by a paucity or total absence of organic remains. In the new red-sandstone these red strata extend through several hundred feet of thickness, and it is found in general terms, that the types of organic life above and below are widely different. Similarly the thick series of old red-sandstone contains few organic fossils, and separates two distinct groups of these productions. Some great physical changes then must be supposed to have occurred previous to and during the saliferous period, and to have influenced both chemical and vital phenomena.

M. Adolphe Brongniart ('Prodrome d'une Histoire des Végétaux Fossiles,' 1829), viewing the series of fossil plants, gives four great periods of ancient vegetation:—The first extending from the earliest strata to the new red-sandstone strata; the second including these strata; the third including the oolites and chalk; the fourth the tertiary strata. Of these the flora of the second period (chiefly terrestrial) is very limited, and may be looked upon as a transition group of plants connecting the earlier and later periods. Similarly the series of marine *Invertebrata* which lie in the new red-sandstone have characters intermediate between the early (palæozoic) and later races of pre-adamitic life.

Although the fossils of this rock are but few, they are highly interesting. It is amongst these rocks that we find the first traces of an air-breathing animal. This creature, which was at first called *Chirotheum*, is now known under the name of *Labyrinthodon*. It belongs to the amphibious tribe of Reptiles. Footmarks of an extinct reptile have also been found in the red-sandstone of America, and described by Dr. Lea.

The equivalents of the British beds of new red-sandstone on the continent of Europe are—the Kanper Marls, or Marres irisées, the Muschelkalk, and the Bunter Sandstein, or Grès Bigarre, of Germany and France.

REDPOLE. [LINNET.]

REDSCHID PASHA, or, MUSTAPHA RESCHID PASHA, was the son of parents in rather affluent circumstances, and was born at Constantinople in 1802. When only fourteen years of age, his brother-in-law, Ali Pasha, attached him to his person, and employed him in the Morea and Broussa during his government of those two provinces. In 1826, when the insurrection broke out in the Morea, Redschid served in the campaign under his patron. After the death of Ali Pasha he transferred his services to Selim Pasha, who made him his private secretary in 1829. He now began his preparation for the higher offices of state by a series of foreign missions. In 1831 he was sent as envoy to Mehemet Ali, viceroy of Egypt; and having taken an active part in negociating the treaty of Kutahia in 1833, he was in the following year raised to the dignity of Pasha. In the course of 1834 he was sent on a mission to the courts of London and Paris. Nearly two years were thus occupied, and the relations he formed with the leading statesmen, diplomatists, and party leaders in England and France, became the basis of the credit and influence he obtained on his return to his native country. The great measure of Parliamentary Reform had recently been carried in England, and the subject was still fresh in men's minds. Redschid Pasha was particularly impressed with this great change, effected as it had been without recourse to violence. When he was recalled to his own court, the following year, to fill an important office in the administration of Pestier Pasha, his mind was occupied with the subject. Almost immediately after his arrival he found himself exposed to imminent danger by the death of the prime minister, who had been overthrown by an intrigue within the palace, and afterwards put to death by the Sultan's orders. But the behaviour of Redschid Pasha was so circumspect as to baffle the designs of his enemies; whilst the credit he had obtained from his diplomatic missions was so high that he was created Grand Vizir in 1837. He did not however hold this position long, being sent into a sort of honourable exile to Paris.

When the report of the death of Mahmud II. reached Paris, he hastened to return to Constantinople, but not before he had raised up a bulwark to defend the throne of the new sultan against the ambition of Mehemet Ali, by concluding the Quadruple Alliance. By Abdu-l-Medjid he was made Foreign Minister, and to the practical knowledge and statesmanship which he had acquired in his European missions, are attributed the systematic reforms which, under the name of the 'tanzimat' have distinguished the reign of the present sultan. Indeed, it is generally believed that from the accession of the young monarch in 1839 until the end of 1857, a period of nearly nineteen years, Redschid Pasha steadily pursued his object of introducing political reforms into Turkey, and that to him is mainly due the many great—however imperfect—social and religious as well as political improvements which have been effected in that country. But it was amidst much hostility and discontent that Redschid Pasha prosecuted his system of reform. During the late war with Russia he was called to direct the government, which through that difficult period he accomplished with signal ability. Though afterwards for a time displaced, he again became the actual head of the Turkish government, and the high respect in which he was held by European statesmen gave him a strong hold on power. In private life he likewise, by example as well as otherwise, sought to modify the objectionable habits of his countrymen: he had but one wife; and he was said to be free from the corrupt practices commonly attributed to the higher officials of Turkey. He died on the 7th of January, 1858.

REED. [PHRAGMITES.]

REFORMATORIES. The establishment of new and the extension of existing Reformatory Schools have been provided for by the statute 20 & 21 Vict. c. 55; the previous statute 17 & 18 Vict. c. 86 having only provided for young criminals being sent to the schools which had theretofore been established by voluntary contributions. [JUVENILE OFFENDERS, *S.* 2. PARENT AND CHILD, *S.* 2.]

REGULUS. [COCKATRICE.]

REGULUS, a genus of Birds belonging to the family *Sylviadæ*. The genus is thus defined by Mr. Yarrell:—Beak slender, straight, the edges dilated at the base, compressed towards the point; nostrils basal, lateral, oval, partly covered by small feathers directed forwards. Wings of moderate length; the first quill-feather very short; the second shorter than the third; the fourth or fifth the longest in the wing. Legs rather slender; feet with three toes before, one behind; the outer toe joined at its base to the middle toe; claws curved and sharp. There are three British species of this genus.

R. cristatus, the Golden-Crested Regulus, Golden-Crested Warbler, or Kinglet.

R. ignicapillus, the Fire-Crested Regulus, Fire-Crested Wren.

R. modestus, the Dalmatian Regulus. This is a very rare species.

There are three other species natives of North America.

REIN-DEER-MOSS. [CLADONIA, *S.* 1.]

RELAPSING FEVER. [PHYSIC, PRACTICE OF (*Blood, Diseases of*), *S.* 2.]

REMBUS. [LICINUS.]

REMORA. [ECHENEIS, *S.* 2.]

RENDEL, JAMES MEADOWS, a civil engineer of great eminence, was born in 1799, at a village on the borders of Dartmoor, in Devonshire. His grandfather, Mr. Meadows, was a well-known architect, and his father, who was a county surveyor and farmer, was a man of ability, excellent common sense, and determination of character, qualities which descended to the son, whilst to his mother, who was a woman of considerable acquirements, he owed the rudiments of his early education. After being practically instructed in the executive part of his profession, he went to London and obtained an engagement under Mr. Telford [TELFORD, THOMAS] by whom he was employed on the survey and experiments for the proposed Suspension bridge over the Mersey at Runcorn, and subsequently on the survey and construction of roads in the north of Devon, where the difficulties he had to contend with contributed much to create that self-reliance so useful to him in his subsequent career. In 1822, he had occasion to apply, on a professional subject, to the late (John, first) Earl of Morley, who, discovering the latent talents of the young engineer, then scarcely twenty-three years of age, shortly afterwards confided to him, with the approval of Mr. Telford, the construction of a cast-iron bridge across the Lary, an arm of the sea within the harbour of Plymouth, over which his lordship was proprietor of an ancient ferry, for which it was desirable to substitute a bridge, the south bank of the Lary at Saltram being his property. This bridge, consisting of five elliptical arches, was, with the exception of that of Southwark, the largest cast-iron structure of the kind in the kingdom. Mr. Rendel was engaged in its construction from 1824 to 1827. For his account of this work the Telford medal of the Institution of Civil Engineers was awarded to him. About this period he designed and executed the Boncombe bridge, where hydraulic power was for the first time applied to the machinery for working swing bridges. Soon after the completion of the Lary bridge, Mr. Rendel settled in Plymouth, and there exercised his profession with great activity, being engaged in surveying and reporting upon nearly all the harbours in the south-west of England, and executing the works at a great number of places, acquiring that mastery over hydraulic engineering on which his fame will chiefly rest. In 1831 he introduced a new system of crossing rivers by means of floating bridges worked by steam-power; they were applied at Saltash and at Torpoint on the river Tamar, and subsequently at Southampton and Portsmouth; but the rapid progress of the railway system prevented the further development of this useful invention, for which the Telford medal was awarded. Descriptions of the structure of these bridges, as well as of that over the Lary, were published in the 'Transactions of the Institution of Civil Engineers.' Particulars of the construction of the latter were also communicated by Mr. Rendel, in 1829, to the Plymouth Institution, of which he was a member, and published in the following year in the only volume that has hitherto appeared of its 'Transactions.'

The repairs of the Montrose suspension bridge, after its fall, were confided to him, and he there introduced the system of imparting that rigidity to the platform of the roadway which is now admitted to be so essential to the safety of the structure.

In 1838 Mr. Rendel removed to London, where he was soon consulted upon many important works, and was engaged in the chief parliamentary contests of that remarkable period in the history of engineering. About this time he designed the pier at Millbay, where he introduced the system of construction since employed with so much success at the harbours of Holyhead and Portland. Engagements poured in fast upon him, and his career was for the next few years one of unceasing activity, chiefly in the construction of harbours and docks, and the improvement of rivers and estuaries. In the year 1843, the projected construction of docks at Birkenhead, in Cheshire, of such an extent as to create a formidable rival to Liverpool, brought him very prominently before the world; and the protracted contests on this subject will be long remembered in the history of parliamentary committees, for the ability with which he defended his positions; and the evidence given by him and other engineers, as now collected, forms a valuable record of the state of engineering practice. The almost incessant labour, and the mental anxiety inseparable from this undertaking, were more than even his powerful constitution could support, and it is feared that they tended to shorten his life.

The daring project of constructing a dock at Great Grimsby, by projecting the works far out upon the mud-banks of the Humber, was next successfully accomplished; and he commenced the two great works which alone suffice to hand down his name to posterity beside those of Smeaton, Rennie, and Telford,—the harbours of refuge of Holyhead and Portland. Both these works were conceived with the largest views, and have been carried on with great rapidity. In both cases the system was adopted of establishing timber stages over the line of the jetties and depositing the large and small stones together, as they came from the quarries, by dropping them vertically from railway waggons into their positions, thus bringing up the mass simultaneously to above the level of the sea. These two great works are advancing very satisfactorily; and it is worthy of remark, in evidence of the engineer's sagacity in the adoption of this system, although the severe storms which have repeatedly occurred on the exposed coasts where they are situated, have done some injury to portions of the stages, and of the temporary works, at Holyhead—where the piles were not shod with Mitchell's screws, which proved so successful at Portland—not a stone would appear to have been carried away from the jetties; and the success of the system may be said to be complete, in spite of the sinister predictions which prevailed before it was tried. Among the other works upon which Mr. Rendel was engaged, should also be mentioned the constructions on the River Lea, and the improvements of the Neue River. He was also employed by the Exchequer Loan Commissioners to report upon the drainage and other public works in Ireland.

He was less engaged in railways than hydraulic works; but in England he executed the Birkenhead, Lancashire, and Cheshire Junction Line, and he had the direction of the 'East Indian' and the 'Madras' railways in India, the former projected by Mr. (now Sir Rowland) Macdonald Stevenson, as the first of the vast system now in progress, which will doubtless exert a mighty influence on the future destiny of our Indian Empire. The Ceylon line and that of Pernambuco in Brazil were also under his charge.

There was scarcely a harbour or a river of importance in the kingdom with which Mr. Rendel was not connected in some capacity. His advice was also sought by foreign countries; and he was engaged to report upon works for the Brazilian, the Prussian, and the Sardinian governments, and was nominated by the Viceroy of Egypt a member of the International Commission for considering the construction of the proposed canal across the Isthmus of Suez.

In consequence of the danger which threatens the port, and therefore the city and republic, of Hamburg with ruin, from the rapid accumulation of sand in the bed of the Elbe, the Senate, in 1855, invited Mr. Rendel to examine the state of the navigation of that river, and make proposals for averting the danger. A commission of such importance could not have been intrusted to more able hands. He spent some months in studying on the spot the nature of the difficulties to be overcome. Towards the end of the year he sent in a most able report, with a detailed account of his plan for remedying the navigation, and preventing any future recurrence of the deposit of sand and formation of a bar in the river. This report was printed and laid before the Bürgerschaft, or representative body of the citizens, but down to a very recent period the requisite works had not been commenced, or even determined upon, notwithstanding the rapid increase of the evil. Mr. Rendel proposed to construct a longitudinal dam or dyke in the middle of the Elbe, beginning at the island of Finkenwerder, a few miles below Hamburg, and extending down the stream for a distance of nearly forty miles. This would contract the main body of the river into about half its natural limits, and the constant rush of the ebb and flood tides would not only sweep away the present sand-banks and other existing obstacles, but prevent them from ever forming again, deepen the channel, and constantly keep clean the bed of the river. The time he allotted for the execution of this great work was seven years, and his estimate of the expense amounted to 680,000*l.*

In the words of the 'Proceedings of the Royal Society,' from which, with some omissions and corrections, the present article is principally, though not wholly, derived, the subject of it "was a man of great energy, clear perception, and correct judgment; his practical knowledge was well directed, and he knew how to make good use of the scientific acquirements and skill of all whose services he engaged. His evidence before parliamentary committees was lucid and convincing, seldom failing in carrying his point; and his reports on engineering works are distinguished by the clearness and correctness of his views, and the fearless expression of his opinion."

Mr. Rendel was a very early member of the Institution of Civil Engineers, having joined it in 1824. His professional character, administrative ability, and scientific knowledge, conspired to give him a seat in the council as Member and Vice-President for the sixteen years preceding his death; and he was elected president in 1852 and 1853. He had become a Fellow of the Royal Society on the 23rd of February 1843; and, agreeably to the system which has of late prevailed of adding to the representatives of science in the council of that body, those of other scientific establishments, during the years for which he was president of the Institution of Civil Engineers, he was also chosen upon the council of the Royal Society. Mr. Rendel was as amiable and kind in private life as he was energetic and firm in public, and his decease, which occurred on the 21st of November 1856, cast a gloom over the whole of the profession of which he was a brilliant ornament.

REPLEVIN. The proceedings in a replevin have been entirely altered, so far as the granting of replevins is concerned, by the statute 19 & 20 Vict. c. 108. Replevins were previously granted by the sheriff's deputies; they are now effected by the registrars of the county courts. A bond is taken, as formerly, that the replevisor shall bring an action for the trespass, either in the superior courts or in the county courts, the defendant being permitted to remove the cause from the latter, but to lose his cause unless he proves that the title in dispute, or the rent or damage in respect of which the distress was taken exceeded 20*l.* in value. The statute is confined to replevins of distresses taken for rent in arrear or damage fesant; but the restriction is practically needless, for the other species of distresses known to the law have long been almost entirely obsolete.

REPRODUCTION IN PLANTS AND ANIMALS. The term Reproduction has been employed to denote those processes in organic beings by which the individual being is produced, developed, and maintained. It has thus been employed to express processes which are functionally distinct, and have very different ends in the economy of creation. The constant reproduction of the same tissues in the same part, is the means by which the form of the individual being is maintained during its life, and is the result of the ordinary processes of nutrition. This function is carried on throughout the whole animal and vegetable kingdom, until the death of a part or the whole of the being occurs. The power, however, of reproducing the same tissues, varies in different beings, and we find that although it is possessed even to the restoration of a lost limb amongst the lower animals, no such power is possessed by the highest.

The term Reproduction has also been applied to the origination of the germ from which individual plants and animals grow. The process employed in the initiation of life seems to be essentially distinct from those engaged in carrying it on: hence the propriety of distinguishing in terms between that production of cells by which the life of the individual is maintained, and the arrangements by which its existence as an individual is ensured. It has been proposed to restrict the term Generation to the latter process.

Although formerly great difficulties existed in distinguishing between these two processes from the want of sufficient observations, recent researches seem to have supplied all that is necessary. In the ordinary reproduction of the tissues of plants and animals each cell has the power of producing other cells, or a large number of the same kind of cells are developed simultaneously, but in generation it is necessary that two cells should take part. At one time it was supposed that this process did not take place in the generation of the lower animals and plants, but recent investigations have shown that the union of two cells is necessary to so large a number of the forms of lower plants and animals, that it is a fair inference that this is a universal necessity in the generation of organic beings. The two cells thus engaged have been called the germ-cell and the sperm-cell. The germ-cell is that in which the process of growth of the new being commences, whilst the sperm-cell is that which communicates the growing tendency to the other. These cells are of different sizes and forms in the animal and vegetable kingdoms, and are placed in very various positions in relation to other organs, and the means by which they are brought together are very various, but in all cases they perform the same fundamental function.

The discovery of the necessity of the union of these two cells, for the production of a new being, has gone far to settle the question of 'equivocal' or 'spontaneous generation.' Ever since the extended use of the microscope in the investigation of the structure of the organic beings, it has become more and more apparent that there was no basis for the supposition that organic beings came into existence independent of a preceding organism. The only cases in which it is now pretended that such an origin of organic life could take place, are those in which the minuter forms of animal and vegetable life occur in infusions exposed to the atmosphere. But this occurrence admits of easy explanation, when it is remembered how exceedingly minute many of these organisms are, and that they are frequently produced from ova much smaller than themselves. Such organisms are easily taken up into the atmosphere, and can be thus conveyed from one spot to another. That such is the fact is proved by the experiment of passing atmospheric air through red hot tubes or strong sulphuric acid, when it is found that water exposed to such air never affords any indications of the existence of organic beings, whilst the same water exposed to ordinary atmospheric air will, in a few hours, teem with living beings.

Although the subject of the generation of animals and plants has been regarded as a subject of much mystery, the facts it presents are now as well understood as any other branch of physiological inquiry. The greatest mystery is the mystery of all nature, and that is the reason of the assumption of a particular form by what appears to be the same combination of elements. No difference can be discerned in the cells of the flowers of the oak and the apple, but the one always produce oak-trees, whilst the others always produce apple-trees. It is the same with the cells of animals, without the slightest appreciable external difference; the one set of cells will develop the form of one species of animal, and another set, another species. This fact has led some inquirers to the assumption of the existence of a 'vital principle,' of a distinct and independent essence, giving to each species its definite form and character. There is no objection to such an hypothesis, provided it is not made use of to explain phenomena which are clearly under the influence of chemical and physical forces. As so much misunderstanding prevails with regard to the word 'vital principle,' it is better perhaps to discard it, and to speak of the limitation of form to which each species is subject, as under the control of a 'formative force.' This formative force being the ultimate fact in the history of each individual plant and animal, and regulating the chemical and physical processes, the result of which is usually called life, it has been proposed to call this a germ-force, or a germinal capacity; but as it is very clear that it is the same force that is in action to produce the whole life or growth of the plant or animal, there is no necessity for distinguishing its first effects, as observed in the act of generation.

In studying, then, the phenomena of generation, there are three conditions which have to be regarded.

Firstly, the Formative Force, which is peculiar in every species, and identical in all the generative cells produced in that species.

Secondly, the Physical Conditions in which the generative cells are placed. These are more especially heat and light, and the condition of the cell-membrane through which absorption takes place.

Thirdly, the Elements which are supplied for the nourishment of the new being, and which by their Chemical Properties are capable of exercising an influence on the form and development of the plant or animal.

Each of these circumstances is found exercising varying degrees of influence in plants and animals. Thus, amongst the lower forms of both the animal and vegetable kingdom, the formative force appears to exercise less influence than among the higher. This is seen in the very varied forms which the same species of plant and animal assume under different circumstances. In fact, till very recently, many of the forms of *Fungi*, *Algæ*, and Infusorial Animalcules, which had received different generic names, are now found to belong to the same species. These variations are found to be chiefly produced by the influence of the third set of circumstances. The highest animals and plants are however liable to great modifications of the activity of the formative force by the operation of both physical and chemical circumstances. Many insects are not hatched till a certain amount of external temperature takes place. Plants will not produce their leaves without the influence of light. Tadpoles are not developed into frogs and toads when deprived of light and heat. The ordinary bee is converted into a queen-bee by the speciality of its food. The *Brassica oleracea* of the sea-shore is converted into red and white cabbages, cauliflowers, and broccoli, by garden culture. All cultivated plants exhibit more or less modification of their growth under the influence of physical and chemical circumstances. The dog, the pig, the horse, the sheep, and man himself, present varieties which, are manifestly dependent on external circumstances, and not on any change in the character of the formative or species-making force.

That there is no change in the character of this force is seen in the tendency which all the forms of a particular species have to recur to a definite type, or to cease to exist. This is seen especially in the case of cultivated plants and domesticated animals, which are subject to the greatest varieties of form, but which nevertheless retain through all, the evidence of a specific formative force. Thus, closely allied as are the species of apple and pear (the *Pyrus malus* and *Pyrus vulgaris* of botanists), and subject as they are to so great variations that above a thousand forms of apple have been produced in Great Britain alone, there is not the slightest tendency in any of these cases towards confusing the specific character of the apple-tree and the pear-tree. So with our domesticated animals. The horse and ass will even breed together, but the hybrid is not prolific, and there is no tendency on the part of the one species to degrade or develop into the other. All the facts that are known with regard to the nature of the formative force lead to the conclusion that it is specific and not general, and that it is regulated by the same laws throughout all time.

In what is called the alternation of generations [GENERATIONS, ALTERNATION OF, *S.* 2], it might be supposed that an exception occurred to the ordinary process of generation. It will be seen however that in all the cases in which this phenomenon occurs, it results from modifications of the ordinary processes of reproduction, and the unusual disposition of the sperm-cells and germ-cells.

Having made these general remarks, we shall now proceed to speak more particularly of the process of generation as it occurs in plants and animals, restricting this term to the phenomena which take place as the result of the union of two cells. That reproduction in plants which occurs as the result of the growth of the same tissues from single cells, when it results in the production of a bud, is termed Gemmation or Sprouting. This kind of reproduction also takes place in the animal kingdom, and amongst many of the lower animals the power of reproducing new individuals* by a process of budding is seen. To this process of forming new beings as it were, from single cells, Professor Braun of Berlin has applied the term 'Verjungung,' which has been translated by Mr. Henfrey 'rejuvenescence.'

Amongst plants the lowest position must be assigned to the families *Diatomaceæ* and *Desmidieæ*, and it is amongst these that the most clear evidence has been obtained of the union of cells in order to the production of the zoospores from which the new beings are developed. [DESMIDIEÆ, *S.* 2; DIATOMACEÆ, *S.* 2.] The union of two cells is also seen in a large number of *Confervaceæ*, especially in the groups to which the *Zygnæmata* belong. [ZYGNÆMA.]

Although amongst the *Algæ* the production of spores can be traced in so large a number of cases to the union of two cells, their multiplication more ordinarily takes place by means of zoospores or zoosporoid bodies, which are perfectly homologous with the buds or sprouts of the higher forms of plants.

In the *Fungi* we meet with a variety of reproductive organs. As these have been investigated very recently, we give the following extract from Dr. Sanderson's account of the vegetable ovum in the 'Cyclopædia of Anatomy and Physiology':—

The simplest form of reproductive organs in the *Fungi* are those in which the spores occur on a basis or basidium.

* The right use of the term 'individual' in Natural History is a difficulty. If the term is restricted only to the direct produce of the germ-cell and sperm-cell, then all trees propagated by slips belong to the same individual. In order to confine the term individual to such cases, it has been proposed among animals to give the term zooid or zoonites to the independent structures which result from sprouting, gemmation, or fission.

This form of organ is best seen in Geaster. The next form of reproductive organs in the *Fungi* is in the form of a vesicle or bag, which is called a theca, or ascus. "Of these, the first which we shall mention belong to a group of subterranean plants, of which the Truffle is the best known example. The receptacle of the Truffle consists of a fleshy mass, throughout which numerous sinuous cavities are interspersed. Each cavity is partly lined, partly filled with the thecæ and the cells upon which they are supported. This receptacle, like that of all other *Fungi* with which we are acquainted, originates from a pre-existing mycelium. In its unripe condition it displays on section a number of sinuous empty cavities, which either communicate with each other, or open at one or more points of the external surface. As the Truffle advances towards maturity the cavities are obliterated by the formation of a whitish tissue, so that on section, we observe the whole to consist of two substances—the one translucent, of firm consistence, and of a dark-brown colour; the other white and opaque. The former, which corresponds to the partitions which, in the young state of the Truffle, separated the cavities, is continuous with the external tissue which composes the envelope or peridium, and constitutes the vena interna of Vittadini. The laminæ which it forms consist of filaments running, for the most part, parallel to each other. The white substance which occupies the original cavities of the tuber is formed of closed tubes, which are given off in great numbers from the surfaces of the laminæ. These tubes, which are the terminations of the filaments of which the laminæ are composed, are of two kinds. Some are of equal diameter throughout, and divided at intervals by septa; others much shorter are dilated at their extremities, and contain spores (thecæ). Each theca is an obovate vesicle, and contains two, three, or more spores, never more than eight. Each spore is invested with a beautifully reticulate or sometimes warty epispore, within which may be distinguished a smooth inner membrane, immediately inclosing the oleaginous contents.

"The ascophorous *Fungi* are represented in their simplest form by the *Uredineæ*, a family which has been studied by numerous observers on account of the destructive properties of the plants belonging to it. The mass which is formed by the growth of the reproductive organs of *Uredo* under the epidermis of the leaves of the plants upon which it grows parasitically, may be aptly compared to a pustule, a grumous-looking substance, occupying, as it were, the place of the pus. On more minute examination of the cavity, we find that it is bounded by a kind of irregular wall, or lining of pyriform cells, the smaller ends of which rest upon a reticular cushion of mycelium. These are probably the enlarged extremities of the mycelium filaments, with which many of them can be distinctly traced to be connected. Towards the base of the cavity other cells are developed, resembling those first mentioned in their general form, as well as in their relation to the mycelium. In these however the membrane is produced inferiorly, so as to form a tubular pedicle; while in the club-shaped upper extremity it is lined by a considerable deposit of granular protoplasma, so that here the central cavity is very much smaller than that of the external membrane. It is in this cavity that the spore is formed, at first not exceeding it in size, but afterwards increasing at the expense of the protoplasma, so as almost to fill the theca. In other genera, as in *Phragmidium*, there are pedicled cells of a similar form, and originating in a similar manner, which, however, instead of one spore, develop another in their interior; these spores are arranged in linear series, and are formed in the same manner. The protoplasma however never disappears completely, but remains as a more or less consistent membrane, gluing the ripe spore to the spore-case which encloses it. Some of the *Uredineæ* possess a cyst which reminds us of the perithecium of the *Sphæriaceæ*, to which they are evidently closely related. The cyst is formed (*Œcidium*) of a single layer of roundish cells.

"From the *Uredineæ* we pass by a natural transition to the Discomycetes and Pyrenomycetes. These plants have been investigated with much success by Messrs. Tulasne, who have shown that they possess the closest relationship not only to the Lichens but to the most simple thread *Fungi*. The very remarkable facts which these observers have discovered, render the study of these plants more satisfactory and instructive than that of any other family of the class. The Pyrenomycetes are represented by *Sphæria*, the receptacle of which consists, as is well known, of a spherical cyst, which is open above. Its wall is frequently prolonged upwards into a tubular beak, which projects beyond the surface of the bark or wood in which the whole plant is imbedded. The membrane of the cyst (perithecium) is usually composed of polygonal tabular cells; it is lined by an inner layer, formed of the commencements of the paraphyses and thecæ, and of the filaments with which they are connected. The thecæ are obovate cells, the membrane of which is of extreme delicacy. When fully formed, they contain from three to eight oval spores, the epispores of which are in the early condition delicate and pellucid, but by degrees become brown and opaque. The contents of the spores, as is observed throughout the higher *Fungi*, consist of a fluid loaded with oily granules. The thecæ are arranged with their long axes perpendicular to the inner surface of the perithecium from which they spring, and are intermixed with a greater or less number of slender cylindrical paraphyses. The whole perithecium is usually enveloped in the filamentous stroma or mycelium, from which it takes its origin. The Discomycetes are represented by the *Pezizæ*; between these and the *Sphæriæ* there are differences of external form, which, though they strike the superficial observer as important, are in reality trivial. While the receptacle of the *Sphæria* is a cyst with an apical aperture, that of the *Peziza* is a cup-shaped disc, the concave surface of which looks upwards. This surface is lined with an ascophorous membrane, which resembles in every respect that of a *Sphæria*.

"Along with the *Pezizæ* and *Sphæriæ*, and those allied genera which resemble them in producing their spores inclosed in thecæ, there are other forms also included in the Pyrenomycetes and Discomycetes, which, while they resemble those last named in the general outline and structure of their receptacles, differ from them completely in the mode of origin of the spores. The simultaneous occurrence of some of these forms, along with their ascophorous analogues, or, in other instances, the successive development of both kinds of receptacles in the same position, had been frequently observed, and had given rise in the minds of some mycologists to the suspicion of the existence of a relation more close than was generally admitted. This suspicion did not, however, take a sufficiently distinct form to lead to observation, until the Messrs. Tulasne, in a series of researches scarcely completed, showed that the genera in question, hitherto considered as distinct, were in fact identical, and that receptacles containing thecæ and paraphyses, are produced on the same stroma, or, in other words, on the same individual plant, as those which contain acrogenous spores.

"The earliest researches of Messrs. Tulasne were directed to the Pyrenomycetes. In some species of *Sphæria*, they found not only that the same stroma produces receptacles with acrogenous spores, which are followed by others bearing thecæ, but that, under certain circumstances, it may give rise to spore-bearing organs of a much simpler character; namely, branching filamentous pedicles, bearing at their terminations single spores, and rising directly from the mycelium filaments, with which they are continuous. In this condition the plant cannot be distinguished from a thread fungus, and has been hitherto described as such.

"The later observations of Messrs. Tulasne, which are much more in detail, refer almost entirely to Discomycetes. In a species of *Rhytisma*, a genus of Discomycetes, which inhabits the epidermis of the leaves of plants, the stroma at first presents the appearance of a black spot of various extent on the surface of the leaf. In the substance of this stroma the first receptacles are formed; they are cushion-shaped capsules, furnished with apical apertures, like those of *Sphæria*, and are entirely occupied by a pulpy nucleus, which consists of slender branched filaments, often so long as to project considerably beyond the aperture. These filaments bear at their extremities innumerable minute linear sporules, which are enveloped in an abundant mucilage, and are expelled from the ripe capsules in the form of a long cirrhus. After the capsules, which are developed during the early summer months, have discharged their contents, they are succeeded by the lirelliform discs of the perfect *Rhytisma*. These do not arrive at maturity until the following spring, and bear upon their upper surface thecæ and paraphyses, like those of a *Peziza*. In other genera M. Tulasne found that the ascophorous receptacles are preceded by capsules, which produce, instead of the linear sporules above mentioned, cylindrical spores of a much larger size, each of which is supported at the extremity of a pedicle of its own.

"Thus in the plants under consideration we find that, without counting the sporules which are produced by filaments rising directly from the stroma, there are no less than three varieties of spore-like structures, which can be easily distinguished from each other. All of these may be produced upon the same individual, and one is recorded in which a capsule of a *Peziza* was found, which bore, among the normal thecæ, paraphyses with innumerable slender linear sporules at their extremities. As has been already hinted, the capsules which contain acrogenous spores, have been hitherto considered as belonging to genera distinct from those represented by the ascophorous receptacles with which they were found associated. The genus *Cytispora* is characterised by a structure which corresponds completely with that of the capsules described above in *Rhytisma;* and other genera, as, for example, *Sporocadus*, have a similar relation to the capsules, containing the larger variety of pedunculated cylindrical spores."

We know less of the reproductive organs of the Lichens; they however closely resemble those of the *Fungi*. The following is a summary of the reproductive organs found in these two orders:—1, Sporules which are formed by the constriction and separation of the extremity of a simple cylindrical filament. 2, Spermatia, with their supporting pedicles. 3, Stylopores, with their styles. 4, Thecæ, or asci. 5, Basidia, with their basidia-spores. Although the evidence is as yet imperfect, there is still good reason for supposing that the asci and spermata are truly sperm-cells and germ-cells, whilst the other organs represent the germs or buds.

An account of the reproductive organs of the higher *Cryptogamia* is given under the articles Filices, *S.* 2, and Musci. That the organs there described may be regarded as containing the two elementary cells, which we have called germ-cells and sperm-cells, is now matter of little speculation. Mr. Henfrey in a report made to the British Association in 1851, says, in regard to the question of sexes,—"We have several kinds of evidence:—

"1. The inferences to be deduced from the universality of the existence of two kinds of organs in connection with the reproductive process. We have seen that these exist in all the families at some period or other of the life of the representative of the species. In the Mosses and the *Hepaticæ* they occur in the fully developed plant. In the Ferns and *Equisetaceæ* they occur upon cellular structures of frondose character developed from all the spores, which frondose bodies or pro-embryos have an existence of some permanence, especially in the *Equisetaceæ*. In the *Lycopodiaceæ*, the *Isoëtaceæ*, and *Rhizocarpeæ*, the pistillidia occur upon very transitory cellular structures produced from one kind of spore, the larger, while the smaller spores at once develop in their interior cellules containing moving spiral filaments such as occur in the antheridia of the other families.

"2. The inferences to be deduced from the observations on the development of those plants in which the two kinds of organs, occurring in distinct places, can be separated. Strong evidence has been brought forward that the diœcious Mosses, as they are called, do not produce sporangia when the pistillidia are kept apart from the antheridia by natural accident. The majority of observers state that the large spores of the *Rhizocarpeæ* do not germinate if the small spores are all removed from contact with them; a few counter-statements however do exist. Again, the majority of authors, and all the recent ones, state that only the large spores of the *Lycopodiaceæ* and *Isoëtaceæ* produce new plants; while some older writers believed that they had seen the small spores do so.

"3. The direct observation of a process of fertilisation, of which we have only testimony from two authors, Suminski and Mercklin, in reference to the Ferns alone; since the assertions of Schleiden in regard to the *Rhizocarpeæ* have been demonstrated by Nägeli, Hofmeister, and Mettenius to have been based on very imperfect observations."

To the question as to the homologues of the organs in the higher *Cryptogamia*, Professor Henfrey gives the following answer:—

"In the Mosses and *Hepaticæ* the pistillidia occur upon the plant when the vegetative structure is perfect, and the immediate product of the great cell is a sporangium. If a process of fertilisation take place here, we may regard the antheridia and pistillidia as analogues of the anthers and pistils of flowering plants, the sporangia of their fruits; or with Hofmeister we may regard the phenomenon as an instance of an 'alternation of generations,' where the pistillidium would be looked upon as an ovule, producing (in the sporangium) a new individual of totally different character from that developed from the spore (the leafy Moss plant in the usual acceptation of the term).

"In the Ferns and *Equisetaceæ*, we find the spores producing a frondose structure of definite form, upon which are developed antheridia and pistillidia, or 'ovules.' Here then we seem to have one generation complete, and the new development from the pistillidium or 'ovule' appears in a totally new form, producing stem and leaves which have a distinct individual form and existence, and produce the spores after a long period upon temporary parts of the structure, on the leaves; and by no means cease to exist when those are matured. Here we seem to have a real 'alternation of generation;' and Hofmeister compares the whole permanent plant of the Fern, or *Equisetum*, to the sporangium of the Mosses and *Hepaticæ*. In all the other families, the *Lycopodiaceæ*, *Isoëtaceæ*, the *Rhizocarpeæ*, the pro-embryo is a very transitory production, and is developed from a different spore from the spiral filaments. This pro-embryo is clearly analogous to that of the Ferns and *Equisetaceæ;* and if the existence of sexes be a fact, we have here a diœcious condition as contrasted with a monœcious condition in the two last-named families. Hofmeister here again assumes that the pro-embryo developed from the large spore is an intermediate generation between the two perfect forms of the plant.

"It is rather difficult to decide upon the real analogies of these structures with those of the flowering plants. The resemblance of structure is so close between the pistillidia of the Mosses and *Hepaticæ*, and the 'ovules' of the other Vascular Cryptogams, that they must be regarded as analogues, and then the former could not well be conceived to be analogous to the pistils of flowering plants, but rather to ovules; if this be the case, the sporangium must be considered the analogue of the perfect plant in the Fern, &c., and the leafy stem as the analogue of the pro-embryo of the Ferns, &c. The pistillidium of the Mosses can indeed hardly be regarded as analogous to the fruit of a flowering plant, as in that case the spores would be ovules produced long after fertilisation; and on the other hand, if we consider the pistillidia of the Moss as an ovule, which it might be, analogous to that of the *Coniferæ*—in which a large number of embryonal vesicles or rudiments of embryos are produced after fertilisation on the branched extremities of the suspensors—then we seem to lose the analogy between the product of the pistillidium of the Moss and that of the ovule of the Fern, unless we would regard the entire plant of a perfect Fern as analogous to the ovule of a Conifer."

We close this part of our subject with a tabular view (given in the next page), of the analogies in the development of different classes of plants, drawn up by Dr. Sanderson.

The process of generation is much more clearly apprehended in the flowering plants. Here we have two sets of organs whose functions are clearly and definitely the preparation of germ-cells and sperm-cells. The organ in which the germ-cells are prepared is called the Pistil, whilst the Stamen, in that part of its structure called the Anther, elaborates the sperm-cells. In the pistil the germ-cells are called Ovules, or Seed-Buds; whilst in the anther the sperm-cells are called Pollen, or Pollen-Grains. In the growth and development of both these sets of organs great differences are observed, but their function is always the same.

The history of the development of the ovule of *Orchis Morio* may be taken as an example of the germ-cells of the flowering plants. In this plant the ovule springs from a placental surface as a single projecting cell, which by subdivision forms at last a central cell called the nucleus, and this becomes surrounded by a layer of cells. This nucleus, or central cell, becomes the embryo-sac, or germ-cell. The pollen-cells from the anthers having fallen on the stigma, now pass down the passage of the style, and at last, through a little opening in the ovule called the micropyle, come in contact with the outside of the apex of the embryo-sac. Within the embryo-sac are to be observed at this time three small cells called embryonal vesicles. "Soon after the pollen-cell has reached the embryo-sac, one of the embryonal vesicles begins to enlarge, and becomes divided by a cross septum into two cells; and while the upper one grows out in a filamentous form through the micropyle by a continued process of cell-division, the lower cell enlarges and divides repeatedly, so as to form a cellular globule." (Henfrey.)

This is the embryo. The prolonged part subsequently dies away.

The development of the pollen-cell is more uniform in the different families of plants. The part of the stamen called the anther at first appears in the young flower-bud as a little cellular papilla. In process of time this papilla divides into two portions. These are the rudiments of the future loculi, or valves. In each half, a single axile vertical column of cells soon becomes distinguished by their greater size and granular contents. In each of these cells the nucleus disappears, and is replaced by two others; this being followed by a division of the cell-contents, which form the primordial utricle, into a new cell round each nucleus. This process is repeated, and a mass of cells is thus formed which become the parents of the true sperm-cell or pollen-grains The walls of these parent cells now become thickened, their nuclei disappear, but are replaced by four permanent nuclei, which become each invested with a primordial sac. In this manner each of the parent cells is divided into four compartments. A cellulose integument is afterwards formed over each compartment, which now become the pollen-grains. Like the nucleus or embryo-sac of the ovule, these pollen-grains have no further power of independent development or growth, but by contact with each other the embryo of the seed is produced. When the anther is fully developed, the external case which contains the pollen bursts, and pollen-grains are distributed upon the surface of the stigma. No sooner does the pollen-grain arrive upon the stigma than it

loses its spherical shape, and becomes elongated, forming the so-called pollen-tube. It is this tube which, passing down the style, becomes applied to the embryo-sac, and is the cause of the development and growth of the embryo. A question has, however, arisen as to whether the pollen-tube acts dynamically upon the embryo-sac, or becomes part and parcel of the new embryo.

Schleiden maintains that if the pollen-tubes be followed into the ovule, it will be found that usually one, and rarely more penetrates the intercellular passages of the nucleus and reaches the embryo-sac, which being forced forward, is pressed and indented, and by its folding-in, forms the embryo in the first stage of its development. A bag is thus formed consisting of a double membrane, the indented embryo-sac, and the membrane of the pollen-tube itself. Schleiden infers the identity of the embryo and the pollen-tube from the three following circumstances:—1, The constantly equal diameter of the pollen-tube when it is just within it. 2, The invariable chemical similarity of their contents shown by the reaction produced by the application of water, oil of sweet almonds, iodine, sulphuric acid, and alkalies. The general contents of the grain of pollen are starch, and this either proceeds unchanged downwards through the pollen-tube, or else passes along after being changed by a chemical vital process into a transparent and colourless fluid, which becomes gradually more and more opaque; and is coagulable by the application of alcohol; out of this, by an organising process, the cells are produced which fill the end of the pollen-tube, extending in *Orchis Morio* far beyond the ovule, and thus forming the parenchyma of the embryo. 3, The identity of the embryo and the pollen-tube is further supported by the fact, that in such plants as bear several embryoes, there is always precisely the same number of pollen-tubes present as we find embryoes developed.

These views of Schleiden, with his conclusion that the pollen-tnbe should be regarded rather as the representative of the female than of the male in the animal kingdom, have been adopted by Wydler of Berne and others.

On the other hand, observations were made by Messrs. Mirbel and Spach, on another class of plants, in which they did not meet with the structure described by Schleiden, and consequently they object to the general application of his conclusions. They examined the development of the ovule of the *Zea Mays* (Common Maize). In this plant there is no true embryo-sac, bnt they found the commencement of the embryo, which they call the primary ntricle, and which Schleiden described as the result of an involution of the sac, existing in the cavity of the nucleus. In this plant also, only one, and not two membranes, as described by Schleiden, existed in the embryo. They also fonnd in other plants the primary ntricle existing in the interior of the embryo-sac, and at a period anterior to the act of impregnation. They therefore conclude that the pollen-tnbe does not become the embryo, and that no involution of the embryo-sac takes place. Their conclusions are probably as mnch too general as those of Scbleiden.

Mr. Griffiths, in a paper published in the 'Linnæan Transactions,' gives the result of a long series of investigations on the development of the ovulum in the genera *Santalum*, *Osyris*, *Loranthus*, and *Viscum*. From his observations on these plants, which differ from those investigated by Schleiden, and Mirbel and Spach, he has arrived at conclusions somewhat different from those of any of these observers, and he carefully refrains from drawing an inference from the facts which he bas observed that would apply to the whole vegetable kingdom. "The first process," he says, "in the development of the seed subsequently to the penetration or application of the boyan (the polleu-tuhe) to the embryo-sac would, in *Santalum*, *Osyris*, *Loranthus*, and *Viscum*, appear to consist of the formation of cellular tissue. This may be applied, I believe, to most if not to all instances. This cellular tissue appears to have two different origins; one, and this is the earliest in development, being perhaps referable to the embryo-sac, while the other appears directly referable to the anterior ends of the pollen-tnbes." Thus far he agrees with Schleiden, that the pollen-tube penetrates into the embryonal sac, and that the embryo is derived from its intruded extremity, his observations on *Santalum* and *Loranthus* confirming this fact, whilst *Osyris* is an exception confirmative of the rule. "Bnt none of my observations," says Mr. Griffiths, "have tended to confirm Schleiden's idea of the inflection of the embryo-sac before the pollen-tube; and it appears to me sufficiently obvious, that if snch were the case the cylindrical bag (the primary ntricle of Mirbel), constituting the embryo in its first stage of development, would consist of three membranes or layers, namely, the first, or outer, of the ordinary and uninflected membrane of the sac; tbe secoud, of its inflected portion; the third, that of the pollen-tube itself." He also expresses his couviction that the primordial or primary ntricle of Messrs. Mirbel and Spach is the sac of the emhryo, which no doubt often and perhaps generally exists before fecundation.

Dr. Giraud has published a paper in the same volume of the 'Liunæan Transactions.' He made a series of observations upon the ovulnm of tbe *Tropæolum majus*. He concludes from his observations on the *Tropæolum majus*, "that in this plant the primary utricle and the future embryo never have any structural connection with the extremity of the pollen-tuhe at their first origin, or at any suhsequent period of their development, as is snfficiently obvious from the fact that the pollen-tube is never brought into contact with the embryo-sac. As the primary utricle makes its appearance before impregnation has occurred, it cannot be possible that the organ has ever formed the extremity of the pollen-tube, as is believed by Schleiden and Wydler. Moreover, as the primary ntricle takes its origin wholly within the embryo-sac, and at the earliest period of its formation is not in contact with that membrane, it cannot have been formed by the pollen-tube pressing before it a fold of the embryo-sac in its passage into the cavity of that structure, as Schleiden has maintained."

In the 'Annals of Natural History,' 1852, Professor Henfrey has published a paper on tbe Reproduction of the higher *Cryptogamia* and *Phanerogamia*, in which he states that he has not been able to observe the penetration of the pollen-tube into the embryo-sac.

We now pass to the consideration of the function of Reproduction amongst Animals. General Reproduction occurs in many of the lower animals in the same manner as plants. There is a common reproduction of destroyed tissues which frequently extends to the production of an entire limb. This is seen amongst the *Radiata*, especially the *Echinodermata*, also amongst the *Articulata*. The highest families of animals in which this kind of reproduction occurs regularly are the Reptiles, in which instances are recorded of legs and tails being reuewed. Occasional instances occur in which the limbs of higher animals are reproduced. The case of a Thrush, in which such renewal had taken place in a leg, was brought before the British Association meeting at Hull. A case is also related in which an abnormal finger in a hnman being having been removed, it was again reproduced almost entire.

Reproduction by division into two, or by gemmation, the Fissiparous and Gemmiparous methods of Reproduction, occur to a very considerahle extent among the lower animals. These modes of reproduction do not essentially differ, and both occur in the same families of animals. [Hydra, *S.* 2; Polyzoa, *S.* 2.] The individuals which are thus produced by fission or by gemmation are called Zooids. This process occurs in unicellular as well as multicellular plants and animals, and the single cells produced hy the division of the *Desmidieæ*, the *Diatomaceæ*, and the *Vorticelloæ*, are as much entitled to the term Zooids as the more complicated forms of the *Acalephæ*.

The true generative act is performed in animals in the same manner as plants. In order to the prodnction of the new individual it is necessary that there shonld be a union of germ cells on the one hand with sperm-cells on tbe other. We shall not here attempt to describe the various forms of organs in the auimal kingdom in which these sperm-cells and germ-cells occur. They are described in considerable detail in this work under tbe head of the families, and sometimes of the genera and species of the various animals described. We shall however describe generally the nature of these cells. The germ-cells and sperm-cells in animals are nsually produced from tissues and organs that are structurally different, bnt as in plants these organs may be placed on different individuals, or on the same. When the two sets of cells are found on the same individual, or zooid, they are said to be Hermaphrodite; but if these cells are fonnd on different individuals tbey are said to be Monosexual. The term hermaphrodite is also applied to plants; but wheu their sperm-cells and germ-cells are placed on different flowers, as happens sometimes in the *Phanerogamia*, they are called Monœcious and Diœcious.

The sperm-cells in the animal kingdom assume a more definite form than those of the vegetable kingdoin. In the higher *Cryptogamia*, where they assume the form of self-moving filaments, they most closely resemble those of the animal kingdom. These filaments are formed in the interior of cells, from which they escape by bursting. They usually present an elongated filamentous appearance, with a slight dilatation at one extremity. At one time they were regarded as a kind of animalcule, and called 'spermatic animalcules,' and were supposed to have an interior organisation. This is not the case, and they have no more claim to be regarded as animalcules than moveable blood-discs, or ciliated epithelium-scales. The movements performed by tbese bodies are in many iustances due to the presence of cilia, which are found npon their surface. The movements of such filaments would vary according to the disposition of the cilia. In other cases the movement seems due to molecular activity. The object is very ohviously to bring the spermatozoon, as these spermatic filaments have been called, into contact with the germ-cell. These movements soon cease after the filaments have been removed from the matrix in which they have been formed. Some agents rapidly destroy these movements, whilst others renew them after they have apparently ceased. This subject has been recently investigated by Kölliker, and the results which he has arrived at in regard to the movements observed in the spermatic filaments of *Mammalia*, are embraced in the following propositions:—

1. In the spermatic fluid, taken from the epidermis and vas deferens, motile spermatic filaments exist in very great abundance.

2. In water and aqueous solutions of all innocuous indifferent substances and salts, the motion of the filaments ceases, and they form loops.

3. These filaments, thns furnished with loops, are not dead, as has hitherto been generally believed; for. on the

contrary, they revive completely upon the subsequent addition of concentrated solutions of innocuous indifferent substances (sugar, albumen, urea), and of salts.

4. In all animal fluids, when considerably concentrated, or highly saline, which are not too acrid nor too alkaline, nor too viscid, the motions of the spermatic filaments are unimpaired; this is the case, for instance, in blood, lymph, alkaline or neutral urine, alkaline milk, thin mucus, thick bile, the vitreous humour—but not in saliva, acid or strongly ammoniacal urine, acid milk or mucus, the gastric juice, thin bile, and thick mucus. When the proper degree of concentration of the latter fluids is successfully attained, and their reaction is rendered neutral, they are innocuous.

5. In all solutions of indifferent organic substances moderately concentrated, the filaments move with perfect facility—thus in all kinds of syrup, in albumen, urea, glycerin, salicin, amygdalin. More concentrated solutions of these substances cause the motion to cease, but it is restored upon their subsequent dilution with water. Too dilute solutions act in the same way as water (vide 2 and 3).

6. Certain solutions, as they are termed, of indifferent organic substances act like water, however much they may be concentrated, such as solutions of gum arabic, vegetable mucus (gum tragacanth, mucilage of quince-seeds), and of dextrin. Concentrated solutions of other substances, in this case also, restore the motions.

7. Many organic substances cause the motions of the filaments to cease, owing to their chemical action upon them, such as alcohol, creasote, tannin, and ether; others owing to their mechanical effects, as most oils. Narcotics, in certain degrees of concentration, are not injurious.

8. Metallic salts are injurious, even in extremely dilute solutions; such, for instance, as a solution containing 1-10,000th of corrosive sublimate.

9. Most of the alkaline and earthy salts are innocuous in certain degrees of concentration, which in some is greater and in some less; so little hurtful, in fact, are they, that the filaments may be kept alive in them for from one to four hours. Among these may be enumerated solutions of common salt; chloride of potassium; sal ammoniac; nitrate of soda; nitrate of potass, containing 1 part to 100; moreover, solutions containing from 5 to 10 parts in 100 of phosphate of soda; sulphate of soda; sulphate of magnesia; chloride of barium. As regards some of these salts, the fact had been previously noticed by older writers, and more recently by Quatrefages, Newport, and Aukermann. Solutions unduly diluted have the same effect as water, and cause the formation of loops, but the filaments are revived upon the addition of a concentrated solution of the same salts and of indifferent substances (sugar, urea, &c.). Stronger saline solutions than are required, also interfere with the motions; but, in this case likewise, the filaments are capable of revival upon the addition of water. These salts can scarcely be regarded properly as revivifiers, as was asserted not long since by Moleschott and Ricchetti, for filaments which have become quiescent in indifferent substances, as sugar, for instance, are not revivified again by them; and their action is widely different from that of the real excitants—the caustic alkalies. It cannot be denied that their influence is very favourable, and that (but perhaps owing only to their rapid diffusion in the water) they produce motion in a seminal mass more rapidly than other less diffusible substances, such as sugar and albumen; on which account the above-named authors ascribe revivifying properties to them—a fact which, before them, had been made known, as regards common salt, by Quatrefages, and by Newport, for carbonate of soda and potass; which latter salts, moreover, in certain experiments, caused the motion to cease in 10′ or 15′, almost like the caustic alkalies.

10. Acids, even in very small quantity, are injurious; such as hydrochloric acid, in the proportion of 1-7500th.

11. Caustic alkalies (soda, potass and ammonia, not lime and barytes), in all degrees of concentration, from 1-31th to 6-10th are special excitants of the spermatic filaments. Whether the latter have become quiescent spontaneously, as in old sperm-fluid, or have ceased to move in indifferent solutions, the above substances recal the most active movements which are not distinguishable from the vital. But these motions cease after two or three minutes, and from this quiescence the filaments cannot be roused by any means. When mixed with indifferent substances in small proportions (from 1-1000th to 1-500th), as, for instance, in syrup, the caustic alkalies afford a means by which the motions of the spermatic filaments may be maintained for a long time.

12. The sperm-fluid dried in indifferent substances, and in saline solutions, may, in certain cases, have its motion restored by dilution with the same fluid, or with water.

The cells which give origin to the spermatic filaments are found upon the surface of the organs which secrete them. At first they are not to be distinguished from ordinary epithelial cells, but they increase in size, and at last present a corpuscle (seminal corpuscle) in their interior. These corpuscles are filled with granular matter, which is gradually converted into the spermatic filament, which is at first coiled up, and lies in contact with the inner surface of the wall of the corpuscle. The spermatic filaments usually present themselves in clusters, which arises from their tendency when set free from their cells to arrange themselves in this manner.

The size of the spermatic filaments varies. In human beings they are from 1-500th to 1-600th of an inch in length. The head is about 1-5000th to 1-8000th of an inch long, and is about half as wide.

In the females of most animals it is not difficult to find a large cell, which is called an ovum or egg. If this ovum be examined in the *Mammalia*, it will be found to present a vesicle, which is called the germinal vesicle, and this vesicle presents a spot, called the germinal spot. There seems to be little doubt that this vesicle is truly the germ-cell. In the *Mammalia* the ova are found in an organ called the ovary.

"If the structure and formation of the human ovary be examined at any period between early infancy and advanced age, but especially during that period of life in which the power of conception exists, it will be found to contain, on an average, from fifteen to twenty small vesicles or membranous sacs of various sizes; these have been already alluded to as the follicles or vesicles of De Graaf, the anatomist who first accurately described them. At their first formation, the Graafian vesicles are small, and deeply-seated in the substance of the ovary; but as they increase in size, they make their way towards the surface; and when mature they form little prominences on the exterior of the ovary, covered only by the peritoneum. Each follicle is formed with an external membranous envelope composed of fine fibro-cellular tissue, and connected with the surrounding stroma of the ovary by networks of blood-vessels. This envelope or tunic is lined with a layer of nucleated cells, forming a kind of epithelium or internal tunic, and named membrana granulosa. The cavity of the follicle is filled with an albuminous fluid, in which microscopic granules float; and it contains also the ovum or ovule. The ovum is a minute spherical body situated, in immature follicles, near their centre; but in those nearer maturity, in contact with the membrana granulosa, at that part of the follicle which forms a prominence on the surface of the ovary. The cells of the membrana granulosa are at that point more numerous than elsewhere, and are heaped around the ovum, forming a kind of granular zone, the discus proligerus.

"In order to examine an ovum, one of the Graafian vesicles, it matters not whether it be of small size or arrived at maturity, should be pricked, and the contained fluid received upon a piece of glass. The ovum then, being found in the midst of the fluid by means of a simple lens, may be further examined with higher microscopic powers. Owing to its globular form, however, its structure cannot be seen until it is subjected to gentle pressure.

"The human ovum is extremely small, measuring, according to Bischoff, from 1-240th to 1-120th of an inch. Its external investment is a transparent membrane, about 1-2500th of an inch in thickness, which, under the microscope, appears as a bright ring, bounded externally and internally by a dark outline: it is called the zona pellucida, or vitelline membrane, and corresponds with the chorion of the impregnated ovum. It adheres externally to the heap of cells constituting the discus proligerus.

"Within this transparent investment, or zona pellucida, and usually in close contact with it, lies the yelk, or vitellus, which is composed of granules and globules of various sizes, imbedded in a more or less fluid substance. The smaller granules, which are the more numerous, resemble in their appearance, as well as their constant motion, pigment granules. The larger granules, or globules, which have the aspect of fat globules, are in greatest number at the periphery of the yelk. The number of the granules is, according to Bischoff, greatest in the ova of carnivorous animals. In the human ovum their quantity is comparatively small.

"The substance that combines the globules and granules of the yelk is in many animals quite fluid. The yelk then completely fills the cavity of the zona pellucida, and escapes in a liquid form when that membrane is ruptured: but in ova of the human subject, and some animals, the yelk is much more consistent, and sometimes escapes as a solid globular mass when the zona pellucida is torn. It is, according to Bischoff, solely owing to this firm consistence of the yelk that it in many cases preserves its form when a watery fluid passes by imbibition through the zona pellucida, and that an interval is then apparent between the yelk and that membrane. From the appearances resulting from the action of water on the ovum, and from other circumstances, it has been thought that the mass composing the yelk is surrounded by another membrane within the zona pellucida, but the evidence for such a view is not satisfactory.

"In the substance of the yelk is imbedded the germinal vesicle, or vesicula germinativa. This vesicle is of greatest relative size in the smallest ova, and is in them surrounded closely by the yelk, nearly in the centre of which it lies. During the development of the ovum the germinal vesicle increases in size much less rapidly than the yelk, and comes to be placed nearer to its surface. In a mature ovum of the rabbit it is about one-sixtieth of a line in diameter (Bischoff): its size in the human ovum has not yet been ascertained, owing to the difficulty of isolating it. It consists of a fine transparent structureless membrane, containing a clear watery fluid, in which are sometimes a few granules.

"At that part of the periphery of the germinal vesicle which is nearest to the periphery of the yelk is situated the germinal spot, a finely-granulated substance, of a yellowish colour, strongly refracting the rays of light, and measuring, in the *Mammalia* generally, from 1-3600th to 1-2400th of an inch (Wagner)." (Kirkes and Paget, 'Handbook of Physiology.')

The act of fecundation is effected in the same manner in animals as in plants, that is, by the contact of the sperm-cells with the germ-cells. Much discussion has taken place as to how this occurs, but the following account may be regarded as embracing the facts most generally accepted:—As the germinal vesicle becomes fitted for fecundation, it loses its pellucid character, arising from the development of a large number of cells in its interior. It is at this period that the spermatic filaments, coming in contact with it, produce that tendency to growth which results in the formation of the new being. The nature of this contact has been a question. Mr. Newport, however, in a series of very carefully-conducted experiments upon the *Amphibia*, comes to the conclusion that the spermatic filament penetrates the vitelline membrane, and comes directly in contact with the germinal vesicle. There is no special foramen for the admission of the spermatic filaments, but they pierce through this membrane, and may be seen floating about in the yelk. Mr. Newport found that a single spermatozoon did not produce fecundation, but that the penetration of several were required for this purpose.

In the human female the ova are brought from the ovaries along the Fallopian tube into an organ called the uterus. It grows rapidly after reaching the uterus; it at first consists of two sacs, one inclosing the other, and the inner containing a liquid. When it is about half a line in diameter a new element becomes visible in it; a round, opaque, granular disc is seen, with a dark spot in its centre, upon the surface of the internal globule or sac. This spot, which is seen either on or through the inner membrane of the ovum, corresponds with the cicatricula of the egg, and is the first rudiment of the fœtus.

In birds the cicatricula, or germ-spot, lies upon the surface of the yolk: soon after the commencement of incubation it expands and separates into two layers; the outer is called by Pander the serous layer, and subsequently forms the osseous, nervous, muscular, and tegumentary systems of the body; the inner, which is in contact with the yolk, is called the mucous, which (together with a third developed between the two others, and named the vascular layer) appears to give rise, by the changes which it undergoes, to the intestinal, respiratory, vascular, and glandular systems. The mucous layer of the germinal membrane gradually expands over the yolk, till it nearly incloses it in a sac, which towards the body of the chick contracts into an oblong canal, which extends the whole length of the embryo, and becomes the future alimentary tube. The sac containing the yolk, and communicating with the intestines, is called the intestinal vesicle, or yolk-bag, and towards the close of incubation is drawn into the belly of the chick, and its contents are used as nourishment. The lower end of the alimentary canal (the cloaca of birds) shoots out into a sac which is termed the allantoïs, or allantoïd membrane. After a time arteries and veins are seen ramifying upon this sac, which protrudes more and more out of the body of the chick, till at length it forms a double bag, laid immediately under the membrane of the shell. On this sac the blood-vessels are so distributed that their contents are influenced by the atmosphere through the porous egg-shell and its membrane, and thus a true respiratory organ is established.

The original structure of the ovum, and the early development of the embryo, in *Mammalia*, appear to be much the same as in the egg of a bird; though there are some characteristic differences. When a human ovum of any magnitude is examined, the embryo is seen suspended in a loose bag filled with fluid, called the amnios, which is a shut sac: this sac is the outermost product of the serous layer of the germinal membrane; for its formation a membrane is reflected from the sides and extremities of the embryo (the reflection, according to Valpean, not commencing before the twelfth day), so as to inclose a space behind it. As the walls of the trunk close in front, the circle at which the amnios is attached to the body of the embryo gradually contracts, till at length it is limited to the edge of the umbilical opening; it then invests the umbilical cord, and spreads out from its placental extremity into an ample sac filled with fluid, in which the fœtus floats. The mucous layer of the germinal membrane in *Mammalia* is supposed from analogy to form a sac, as in birds, containing a yolk, or substance subservient to the nourishment of the fœtus in its early stage. Whether this view of its formation and use be correct or not only rests on analogy; but in the early part of gestation a small sac or bladder, which from its being filled with a whitish fluid has been called the vesicula alba, may be found on the placenta, at or near the extremity of the umbilical cord, and exterior to the amnios; from this sac a fine tube may be traced along the cord to the navel, and in some animals it has been seen communicating with the intestinal canal. This tube becomes obliterated so early (Valpean says in the sixth week of gestation) that its communication with the intestines was long undetected, though the sac was known to the older anatomists. The intestinal vesicle finally differs in *Mammalia* and birds in this circumstance, that in the former it is not drawn into the body of the fœtus, but remains without between the membranes, and gradually wasting becomes obliterated by the third month. The duct of the umbilical vesicle is accompanied along the cord by an artery and vein, which are called the omphalo-mesenteric vessels; the artery communicates with the superior mesenteric, and the vein with the vena portæ. The allantoïs exists in all mammals as well as in birds, though its use in the former, which are furnished with a placenta, is not obvious. In some animals, as in man, it becomes obliterated at a very early period, as soon as the sixth week, but in others, as the *Carnivora*, &c., it attains a large size, and continues during the whole period of fœtal existence. In *Mammalia* it communicates with the fundus of the bladder, and the remains of the duct by which it is connected is denominated the urachus. The channel of communication between the allantoïs and the bladder, or cloaca (in birds), at first is short, so that the sac lies directly against the body of the embryo, but it afterwards becomes elongated, like the corresponding duct of the umbilical vesicle.

In man, after impregnation has taken place, a spongy membrane is formed on the inner surface of the uterus by an exudation of lymph. This membrane, called decidua, lines the whole of the uterus before the descent of the ovum; but when this passes down through the Fallopian tube it gradually pushes the deciduous membrane before it, inverting one portion of it which surrounds the ovum, and is called the decidua reflexa; this grows with the ovum till it fills the cavity of the uterus, and comes in contact with the other portion called the decidua vera, lining the walls of the uterus.

The point at which the decidua is reflected upon the ovum is where the placenta is fixed to the uterus. The ovum has two proper membranes, the amnios, which we have described, internally, and an outer membrane, which is called the chorion; this latter membrane in man, during the first two months of pregnancy, has a shaggy external surface, being covered with vascular villi, which become united with the membrana decidua, which is also thick and vascular. This thickening and vascularity of both these membranes gradually diminishes, and becomes concentrated on one part, usually towards the fundus of the uterus; this thickened part is called the placenta. In ruminating animals the thickening and vascularity of the chorion is confined to a number of circular and spongy elevations varying in number from thirty to one hundred, which are called cotyledons. These vascular processes dip in between corresponding processes attached to the uterus of the mother, which are called maternal cotyledons, the surface of which is supplied with numerous vessels derived from the uterine arteries and veins. The result of this arrangement is that a large vascular surface of the maternal system is applied to an equally extensive one of the fœtus, and though there is no direct communication between the arteries and veins, we must suppose that nourishment is imbibed from the vessels of the mother by those of the fœtus through the fine intervening membranes by which they are separated. In man the relation between the maternal and fœtal systems is not so clearly understood as in the preceding instance. In the human subject the placenta is a spongy vascular mass like a cake, from six to eight inches in diameter, about an inch thick in the middle, and two or three lines at the circumference. It adheres by one surface to the uterus, and by the other is connected with the fœtus by means of the umbilical cord. The uterine surface is lobulated, and is connected with the uterus by blood-vessels. The fœtal surface is covered by the chorion and amnios, and presents the ramifications of the umbilical vessels, which consist of two arteries and a vein. The radicles of these vessels communicate with each other, but no communication has ever been shown to exist between them and the utero-placentine vessels; for if we inject from the umbilical arteries we find that the placenta is rendered turgid, and that vessels are found filled in every part of it, but between their ramifications there will remain an uninjected substance, and the uterine surface will not be injected, for the fœtal vessels do not pass all the way to that surface. In like manner, if we inject from the uterine vessels, the placenta will be rendered turgid, but nothing passes into the fœtal vessels. From this circumstance it is concluded that the placenta consists uniformly of two portions: the one is furnished by the deciduous coat of the uterus, the other by the vessels of the chorion, and these two portions may, during the first three months, be separated from each other by maceration. The structure of the fœtal portion, so far as can be made out, appears to be similar to that of the pulmonary vessels, the artery terminating in the vein. But the maternal portion is somewhat different; there is not a direct communication, but the arteries, as Mr. Hunter thought, seem to terminate in irregular cells, and the veins appear to commence with open mouths from these cells, for by throwing wax in the uterine arteries we fill the cells, and frequently inject the uterine veins also.

It has always been considered doubtful whether the placental cells of Hunter were real or artificial, being, in the latter case, produced by extravasation of the injection; and recent researches have confirmed this doubt, but without throwing any satisfactory light on this very obscure subject. With regard to the use of the placenta we may infer that it is very similar in man to what it is in ruminating and other animals; it most probably serves to produce a change in the blood of the fœtus analogous to that which the blood of the adult undergoes in the lungs; and, from considering that the fœtus itself cannot create materials for its own growth and support, we may further infer that the placenta is the source of nutrition also.

The navel-string, or umbilical cord, which connects the child to the mother, is composed of the umbilical vein and two umbilical arteries twisted together, and surrounded by a gelatinous substance and the reflections of the chorion and amnios; it also contains the urachus, and the remains of the duct of the vesicula alba and omphalo-mesenteric vessels. It is visible in the human embryo in the sixth week as a short and straight cord; at birth the length of it is, on an average, about two feet. The outer tunic of the cord, the amnios, is continuous with the epidermis, or cuticle of the fœtus at the umbilicus; and in the same way the chorion, which is also reflected on the navel-string, is continued into the dermis, or true skin of the fœtus.

The following is Valentin's account of the development of the principal organs of the human embryo.

"The primitive streak or groove is the first indication of the future embryo. It consists of a very small longitudinal groove in the middle of the upper surface of the serous lamina. It soon after enlarges, while its two margins are raised to form the laminæ dorsales. They grow over towards each other, meet in a longitudinal suture, and thus inclose a cavity, the primitive tube. Anteriorly this tube dilates into several vesicles, which lie behind each other, and in which is deposited the cerebral substance. The spinal cord is laid down in its remaining cylindrical portion. The several parts of the brain of the human embryo gradually pass through numerous transitional forms, which correspond with their permanent conditions in various of the lower animals.

"A dense cord, the chorda dorsalis, is early deposited beneath almost the whole length of this primitive tube. At the same time, square spots are observed on either side, symmetrically arranged in pairs. Each two corresponding squares subsequently grow towards each other, to construct the body of a vertebra. In doing this, they include between them a corresponding segment of the chorda dorsalis, and gradually altogether displace it. In *Mammalia* and birds, the remaining portions of this structure subsequently disappear.

"The vertebral arches commence as dense curved pairs of streaks; each of which unites on the one hand with the body of the vertebræ, and on the other with its opposite fellow. The various processes of the vertebræ are only added subsequently.

"The first rudiment of the skull is formed by a membranous capsule, which gradually merges into a special cartilaginous covering, called the primordial skull. Some portions of the latter are ossified immediately afterwards, while others disappear after new pieces of bone have been opposed to them.

"The blastema adjoining the interior surface of the skull produces a series of pairs of processes, which finally give rise to the chief structures of the face and neck. Those which lie between the future mouth and the chest are called the branchial or visceral processes; and the fissures which remain between them, the branchial fissures. Their form and relations to the vascular trunks which supply them somewhat resemble the type met with in the gills or branchial respiratory organs of the fish.

"The margins of the central portion of the serous lamina are gradually involuted, so as to form the walls of the thoracic and abdominal cavities. But as they only subsequently meet in the inferior median line of the embryo (which we are supposing to be horizontal), there remains at first a long fissure, through which are protruded the heart, a large portion of the intestinal canal, and the allantoïs. This aperture afterwards closes in the region of the thorax, and the posterior part of the abdomen; and finally disappears, leaving no relic save the navel. The ribs commence as dense striæ, which first become cartilaginous, and are then ossified. The several pieces of the sternum are developed by a similar process.

"The extremities are at first altogether absent. They subsequently sprout in the form of small stumps. Each of these is first divided into an internal segment which pertains to the trunk, and corresponds to the thigh or upper arm, and a free terminal plate which is developed into the hand or foot. The fore arm and leg are only formed subsequently. The fingers and toes are at first united by a kind of web, so as to resemble fins. This membrane begins to disappear from without inwards.

"The eye at first forms a hollow vesicle, which is connected with the brain by a tubular handle, the future optic nerve. The retina is produced from a deposit which resembles that of the cerebral substance in the vesicles of the brain. The crystalline lens, the vitreous humour, and the iris, are only developed subsequently. A special vascular tunic, the capsulo-papillary sac, surrounds the lens of the early embryo. Its anterior segment then forms the papillary membrane, a vascular coat which is stretched immediately in front of the papillary aperture. By the gradual loss of its blood-vessels, this is converted into a simple transparent membrane, which disappears a few days after birth.

"The labyrinth of the ear also begins as a hollow vesicle, having a handle which is continuous with the brain. The vestibule, the cochlea, and the semicircular canals are then developed, at what is comparatively a very early date. The formation of the auditory ossicles is ultimately connected with the development of the most anterior visceral arches. At this period the long process of the malleus extends on the first maxillary process, or the future lower jaw, as far as to the median line; in the *Mammalia*, however, it afterwards gradually disappears, so as to leave scarcely a trace. The tympanic cavity is chiefly developed from the gap situated at the first visceral arch. The external ear is produced last of all.

"The organs of smell are also first indicated by vesicles, which are connected with the brain. The nose is developed afterwards, during the evolution of the face. The palate, which is subsequently laid down, ends by separating the cavities of the nose and mouth. The tongue grows out of the first maxillary arch. The external integument is only separated into corium and epidermis towards the end of the second month, or the beginning of the third. It afterwards acquires its nails, together with its various glands and hairs. In the advanced embryo, almost all the surface of the body is covered by a very fine down. The copious desquamation and fatty secretion of the skin result in a caseous substance which covers many portions of the fœtal body, and is capable of protecting it like an ointment from the injurious action of the liquor amnii.

"Those primary changes by which many of the embryonal organs commence, are effected without the aid of the vascular system. The heart subsequently begins as a tube, which, anteriorly, is continuous with centrifugal vessels or arteries; posteriorly, with centripetal tubes or veins. It afterwards undergoes a peculiar involution, divides into segments, produces the auricular appendages, and finally, presents two auricles and a single ventricle. The latter gradually acquires a septum, which is at first an incomplete, and finally a perfect one. These embryonal vessels gradually undergo numerous changes, which are due, not only to the formation or metamorphosis of those organs of the body that are rich in vessels, but also to a variety of causes which belong to the vascular system itself.

"The contrast of a systemic and a separative circulation obtains at a very early date. A great part of the surface of the yolk is at first covered by a vascular distribution, the aurea vasculosa, in which the blood of the embryo is changed by a process, the details of which are at present unknown. This vitelline circulation begins soon after the heart of the embryo has commenced to beat. In the *Mammalia* it subsequently disappears, to make way for the placental circulation. The blood then runs through the umbilical arteries into the fœtal placenta, where it undergoes a diffusion with the blood of the maternal placenta, returning to the fœtus through the umbilical vein. The renovation thus produced corresponds, not only to the respiration of the more developed being, but also to the most pressing requirements of its nutrition.

"The connection between the state of development of the heart and that of the great vessels, produces a peculiar movement of the blood which has been designated the fœtal circulation, or the circulation of Sabatier. It is most distinct shortly after the middle of pregnancy. The blood of the right ventricle then passes chiefly into the lower half of the body and the placenta; while that which returns from this organ goes chiefly to the left heart, in order to flow thence to the head and neck, from which it finally returns to gain the right auricle and ventricle. So that there is a partial contrast between the circulations of the upper and lower halves of the body. After birth it is replaced by the systemic and pulmonic circulations.

"The placental circulation ceases soon after birth, being replaced by the pulmonic on the respiration of air. But in the normal course of development the preparations necessary for this change are made some months before the end of pregnancy. Hence, under favourable circumstances, a child which comes into the world seven or eight months after conception may nevertheless continue to live.

"The foramen ovale is due to the fact, that the inferior vena cava originally opens into the left auricle, and not into the right, being only gradually pushed over into the latter. This explains why the greater part of the blood that returns from the umbilical vein and the lower parts of the body passes into the left auricle during the fœtal circulation. The groove which conducts it in this course is the relic of a special adaptation, which dwindles and disappears in proportion as the left auricle is claimed by the advancing development of the pulmonary veins. Immediately after birth, the foramen ovale is at first closed mechanically by the action of the auricle; but it finally becomes organically occluded. The superior and inferior vena cava then belong exclusively to the right auricle.

"The pulmonary artery and aorta of the new-born infant are connected with each other by means of the ductis arteriosus, or duct of Botalli. This structure—which is a necessary result of the development of the embryonal vessels—prevents the two divisions of the fœtal circulation being completely separated from each other, and also hinders the perfect separation of the scarlet and dark-red blood in the new-born infant whose lungs have begun to work. But in the first few weeks after birth, the ductus arteriosus is closed by a process which somewhat resembles that seen in a deligated artery. It is thus converted into a ligamentous band, in which form it remains during the remainder of life.

"After a certain period of embryonal life, the umbilical vein which returns the renovated blood from the fœtal placenta, sends branches to the liver. Besides this, it unites with the portal vein, which also ramifies in this gland. And it has also a certain communication with the inferior vena cava, by means of a vessel—the nervous duct of Arantius—which passes between the two. Hence, part of the purified blood which is returning from the fœtal placenta can avoid the liver, and flow immediately into the auricle.

"The umbilical cord of the infant is usually tied and cut through in some part of its course. The brute mammals gnaw it asunder as soon as their young have breathed. After some time that portion which remains attached to the belly dries up, and falls spontaneously from the navel. Those portions of the umbilical arteries which first run along the bladder, and then ascend on the abdominal walls to the umbilicus, become converted into ligamentous tissue. The duct of Arantius and a large part of the umbilical vein also experience the same fate.

"The development of the intestinal canal commences by the centre of the mucous lamina being raised and folded inwards. In this way it produces an intestinal groove, which is open towards the yolk. This groove is soon afterwards shut off anteriorly and posteriorly, so that there only remains a median gap, the intestinal navel. The circumference of the mucous lamina furnishes a covering for the umbilical vesicle. The portion which intervenes between this and the intestinal navel is drawn out into a cylindrical duct, the pedicle or stalk of the umbilical vesicle." (Valentin, 'Text-Book of Physiology.')

The fœtus has many peculiarities which distinguish it from the child after birth, most of which are peculiar to its mode of life, and are lost immediately after being separated from the mother, or are gradually removed during gestation. The most characteristic difference is that it lives in a medium of water, and not of air, and consequently does not breathe by lungs, but has the blood which is deteriorated by circulating through the system purified in some manner in passing through the placenta. The umbilical vein carries the blood from the placenta to the fœtus: it enters the liver by the longitudinal fissure, and in the transverse fissure communicates with the vena portæ, sending the greater part of the blood to be circulated in the liver. This organ is of great size, and seems to perform some important office in the fœtal economy. It is conjectured by Dr. R. Lee to secrete albuminous matter, which nourishes the fœtus. The rest of the blood is transmitted directly to the vena cava inferior by the ductus venosus, which seems to be a continuation of the umbilical vein in man, though in most animals it is merely a branch arising from the sinus of the vena portæ. The blood conveyed by the vena cava inferior to the right auricle of the heart, does not all pass, as in the adult, into the right ventricle, but a great portion goes immediately into the left auricle through an opening in the septum of the auricles called the foramen ovale, which closes up immediately after birth. The blood that still goes into the right ventricle through the auriculo-ventricular orifice is propelled into the pulmonary artery, but as there is no use for it at present in the lungs, it nearly all passes through a vessel named the ductus arteriosus into the aorta. This duct also becomes obliterated after birth, its functions having ceased when once the child has breathed.

By the aorta the blood is sent from the left side of the heart and ductus arteriosus to the different parts of the body, from which it is returned by the veins, but a great part of it passes out of the body of the fœtus by the umbilical arteries, which are continued from the internal iliacs, and pass out at the navel to go to the placenta. The blood of the fœtus differs in its physical and chemical qualities from that of the adult. There is before birth no distinction between arterial and venous blood: it is of a dark colour in both systems of vessels. The purified blood is brought from the placenta by the umbilical vein, and is mixed before arriving at the heart with that which has been circulating through the fœtus: the mixed blood is then transmitted by the aorta to various parts of the body; some of it only going again to the placenta by the umbilical arteries to be again purified.

The position of the child in the uterus is that which takes up the least room; it lies with the head downwards, the chin being bent on the breast; the knees are doubled up close to the belly, and the arms are folded in the space between the head and legs. This is the most general position, and the child thus forms an oval figure, of which the head forms one end and the breech the other. The long axis of this ellipse measures in the ninth month fully ten inches, and the short one five or six inches. The quantity of fluid which surrounds the child at the full time is, on an average, about two pints.

The ordinary period of utero-gestation in man is forty weeks, though labour often takes place before this period, or is delayed a little beyond it. The embryo having now arrived at a sufficient degree of maturity to exist separately, the fibres of the uterus contract, accompanied by contraction of the abdominal muscles and diaphragm. In consequence of this pressure the membranes gradually dilate the mouth of the womb; they then burst and evacuate the liquor amnii, when the pressure acts upon the child itself, which is gradually forced into the world, and commences a new existence. In man, and other *Mammalia*, the young being for a considerable time depends upon its mother for the whole of its nourishment, and very generally requires a supply of warmth and a degree of protection till it is able to provide for itself.

RESPIRATION is that function in the animal kingdom by means of which the various tissues of the body are exposed to the chemical influence of the gases of the atmosphere, and the products thus formed expelled from the body. The advance of chemical knowledge has demonstrated that this function is one essentially of oxidation, and hence it has been proposed to consider all cases of oxidation in organic bodies as instances of respiration. Such an extension of the use of the term has led to its application to plants as well as animals. It should however be remembered that the older physiologists applied the term Respiration to that function of plants by which they take up carbonic acid and give out oxygen, and which was regarded as an equivalent process to the taking up of oxygen and disengaging carbonic acid in animals. It was subsequently found that plants, during certain processes, gave off carbonic acid and absorbed oxygen gas; and it was hence inferred that plants performed a function essentially the same as that effected in animals by the oxidation of carbon in respiration.

The cases in which plants have been observed to consume oxygen and throw off carbonic acid are as follows:—1. During the growth of the order *Fungi*. 2. During the growth of the leafless parasites. 3. During night by most plants. 4. During the active growth of the *Coniferæ*. 5. During the flowering of most plants. 6. During the germination of plants.

This process has been observed to be attended with the same results in certain of these cases, as in respiration of the higher animals, that is, with the disengagement of heat. When the process of oxidation takes place rapidly, disengagement of heat is the necessary result. That these phenomena take place cannot be doubted, but the propriety of classing them with those of the respiration of animals must be questioned, and on these grounds:—

1. The oxidation that takes place in the vegetable kingdom is not a constant phenomenon, but only occurs occasionally in the life of the plant. It is during the latter stages of the growth of *Fungi* that it is observed, when it may be supposed that these plants are entering upon a stage of decay. The oxidation in the *Coniferæ* arises from their secreting resinous matters, which unite readily with oxygen. Again, in the flowering of plants it is only an occasional and exceptional phenomenon in the life of plants. The carbonic acid given out by plants at night can be quite as readily accounted for on the supposition that a certain quantity of the carbonic acid taken up in the day has been undecomposed, and is given out at night, as on the theory of its being the result of oxidation. So likewise in germination, the carbonic acid given off is not the result of a process of life in the young embryo, but of a process of decomposition going on in the starch of the albumen by which it is surrounded.

2. If the term Respiration is to be applied to the evolution of carbonic acid, and absorption of oxygen gas from the fluids of organic beings wherever found, then it must be used to comprehend the processes of fermentation, putrefaction, and eremecausis, which take place either out of the structure of organic beings, or in their interior. The carbonic acid given off from food in the stomach or intestines ought not most assuredly to be regarded as the result of respiration, yet this would be the case if we accepted a mere chemical definition of respiration.

Respiration then appears to be a purely animal process, by which the fluids of the animal are brought into contact with the oxygen of the air, the final result of which is the discharge of carbonic acid gas. This process is continuous in the animal kingdom; and in the great majority of cases in the higher animals, if it be suspended for a few minutes the animal dies. When an animal dies from being deprived of oxygen gas, it is said to be suffocated.

In the higher animals special organs are provided for the performance of that portion of this function which consists in the taking up of oxygen gas directly from the atmosphere, and allowing the carbonic acid to escape. Hence these arrangements have been called Organs of Respiration. It should however be understood that the chemical changes involved in the disappearance of the oxygen, and the appearance of the carbonic acid, are carried on in the tissues themselves. The lungs, gills, or sacs, are organs where the blood receives the oxygen gas, and gets rid of its carbonic acid; whilst the capillaries of the systematic circulation are the organs by which the blood gets rid of its oxygen, and the tissues their carbonic acid. The process of respiration then is the same in the highest as in the lowest animals, with this exception, that in the lowest animals there are no organs of circulation, and no organs of ventilation, as the lungs and gills may be called, for conveying the oxygen and carbonic acid to and from the tissues.

The absorption of oxygen by the animal cell seems to effect three great objects:—1. The preparation of the materials taken up as food for the purposes of nutrition. 2. The removal of certain constituents which have been employed in nutrition, and destroyed during the performance of the function of the part. 3. The production of heat, arrangements for the accumulation of which are made in the higher animals, which are from this circumstance called warm-blooded.

That the performance of one or other of these functions is essential to the life of animals is seen from the fact that, should the supply of oxygen to the tissues of animals be limited or suspended, they exhibit deficient vitality or die. It is not only one function of the animal body that is affected by this deprivation, but all; so that we find the amount of oxidation performed by this process becomes the exponent of the amount of vital activity displayed by any particular animal, or class of animals. When the functional activity of an animal is great it consumes more oxygen, and gives off more carbonic acid, than when it is small. Thus, in animals which hybernate, the amount of oxygen consumed, and carbonic acid given out, is much less during their period of repose than during their period of activity. Sluggish and slow-moving animals consume less oxygen than those which are active. Thus the *Mollusca* consume less oxygen than the various tribes of active insects. It is also found that animals whose movements are slow will support the absence of oxygen gas for a very much longer time than those whose movements are quick.

Under the head of the various articles devoted to the classes and families of animals some account is given of the general character and structure of what are called the Respiratory Organs. In the lowest forms of animals, the *Infusoria*, the whole surface of the animal is exposed to the fluid in which they live, and which contains the oxygen necessary to produce the respiratory changes. When a number of cells are congregated together, as in the sponges, and cavities or tubes are formed, special provision is made by means of cilia, or molecular movements, for carrying the fluid into these cavities, or tubes, as seen in many of the polygastric animalcules and the sponges. Passing higher in the forms of radiate animals, as in the *Polypifera*, we find the arrangements for introducing water into the interior of the animal becoming more complicated, till in the *Holothuriadæ* we find a special system of vessels for supplying this fluid, which have been called an 'aquiferous,' or 'water vascular system,' and which becomes more fully developed in the *Entozoa*, the lowest tribe of the *Articulata*.

These arrangements amongst the lower animals are preparatory to the two predominant forms of respiratory apparatus which are found in the higher animals. The provision for supplying the system with oxygen is in them made by means of a fluid called blood, and which is carried by a circulating apparatus to all parts of the body. This circulating apparatus brings the blood in contact with the air by one of two arrangements. Either the aërating organ is a projection from the surface of the body, when it is called a Gill; or it is a depression in the surface, when it is called a Sac or Lung. The first of these arrangements is found in all animals which breathe through the agency of water, whilst the second is fonnd in those which breathe air. In the Aquatic *Mollusca*, the *Cirripedia*, the *Annelida*, the *Crustacea*, the aquatic larvæ of insects, the fishes, the tadpole condition of the *Amphibia*, and the perennibranchiate forms of that family, we meet with a vast variety of forms of gills adapting these animals to lead an aquatic existence. On the other hand, we find in the Terrestrial *Mollusca* and the Insects the simplest forms of air-breathing apparatns; whilst in the Reptiles, the Birds, and *Mammalia*, we have varied forms of lungs.

Man breathes by means of lungs. The structure and arrangement of those organs, and the nature of the movements performed by the muscles which contribute to the performance of their peculiar function, are described under the article Lungs. The lungs of man are so constructed that they are alternately expanded and contracted. During each expansion, a certain quantity of air is taken into the lungs, and this act is called Inspiration. This expansion is followed by a corresponding collapse, during which the lungs occupy a smaller space, and a certain quantity of air is expelled—this is called Expiration. The quantity of air changed in the human lungs at each respiratory effort varies. It is however easily measured by blowing into a vessel filled with water or other fluid, when the amount of fluid displaced will be the measure of the quantity of air thrown out from the lungs. Instruments of this kind, with an index attached, under the name of Spirometers, are now frequently employed as a means of diagnosis in diseases of the chest. The difficnlty however of securing freedom from disturbing causes renders their resnlts less to be depended on than could be wished. The quantity of air thrown out from the lungs has been variously estimated, but probably from 20 to 25 cubic inches is near the truth. Scharling conducted a series of experiments on the quantity of carbonic acid thrown out of the lungs by persons of different sexes and various ages. The following table gives an idea of the average relations of the excretion of carbonic acid gas during one hour:—

Subject.	Age.	Weight.	Carbonic Acid expired in one hour.	Amount of Carbonic Acid expired in one hour for each 1000 grammes' weight.
	Years.	Kilogrammes.	Grammes.	Grammes.
Man	35	65·50	33·530	0·5119
Youth	16	57·75	34·280	0·5887
Soldier	28	82·00	36·623	0·4466
Girl	17	55·75	25·342	0·4546
Boy	9¾	22·00	20·338	0·9245
Girl	10	23·00*	19·162	0·8831

The air that is habitually and almost uniformly changed in breathing is by Mr. Hutchinson called Breathing Air. "The quantity over and above this which a man can draw into the lungs in the deepest inspiration he names Complemental Air; its amount is various, as will be presently shown. After ordinary expiration, such as that which expels the breathing air, a certain quantity of air remains in the lungs, which may be expelled by a forcible and deeper expiration: this he terms Reserve Air. But even after the most violent expiratory efforts the lungs are not completely emptied; a certain quantity always remains in them, over which there is no voluntary control, and which may be called Residual Air. Its amount depends in great measure on the absolute size of the chest, and has been variously estimated at from 40 to 260 cubic inches.

"The greatest respiratory capacity of the chest is indicated by the quantity of air which a person can expel from his lungs by a forcible expiration after the deepest inspiration that he can make. Mr. Hutchinson names this the Vital Capacity: it expresses the power which a person has of breathing in the emergencies of active exercise, violence, and disease; and in healthy men it varies according to stature, weight, and age.

"It is found by Mr Hutchinson, from whom nearly all our information on this subject is derived, that at a temperature of 60° Fahr., 225 cubic inches is the average vital capacity of a healthy person 5 feet 7 inches in height. For every inch of height above this standard the capacity is increased on an average by 8 cubic inches; and for every inch below it is diminished to the same amount. This relation of capacity to height is quite independent of the absolnte capacity of the cavity of the chest; for the cubic contents of the chest do not always or even generally increase with the stature of the body, and a person of small absolute capacity of chest may have a large capacity of respiration, and vice versâ. The capacity of respiration is determined only by the mobility of the walls of the chest; but why this mobility should increase in a definite ratio with the height of the body is yet unexplained, and must be difficult of solution, seeing that the height of the body is chiefly determined by that of the legs, and not by that of the trunk or the depth of the chest. But the vast number of observations made by Mr. Hutchinson leave no doubt of the fact as stated above.

"The influence of weight on the capacity of respiration is less manifest and considerable than that of height; and it is difficult to arrive at any definite conclusions on this point, because the natural average weight of a healthy man in relation to stature has not yet been determined. As a general statement, however, it may be said that the capacity of respiration is not affected by weights under 161 lbs., or 11½ stones; bnt that above this point it is diminished at the rate of one cubic inch for every additional pound up to 196 lbs., or 14 stones; so that, for example, when a man of 5 feet 6 inches, and weighing less than 11½ stones, should be able to expire 217 cnbic inches, one of the same height, weighing 12½ stones might expire only 203 cubic inches.

"By age the capacity appears to be increased from about the 15th to the 35th year, at the rate of five cubic inches per year; from 35 to 65 it diminishes at the rate of about a cubic inch and a half per year, so that the capacity of respiration of a man 60 years old would be about 30 cubic inches less than that of a man 40 years old of the same height and weight.

"Mr. Hutchinson's observations were made almost exclusively on men, and his conclusions are perhaps true of them alone; for women, according to Bourgery, have only half the capacity of breathing that men of the same age have.

"The number of respirations in a healthy adult person usually ranges from 14 to 18 per minute. According to Mr. Hutchinson, the force with which the inspiratory muscles are capable of acting is greatest in individuals of the height of from 5 feet 7 inches to 5 feet 8 inches, and will elevate a column of three inches of mercury. Above this height the force decreases as the stature increases, so that the average of men of 6 feet can elevate only about 2½ inches of mercury. The force manifested in the strongest expiratory act is, on the average, one-third greater than that exercised in inspiration; but this difference is in great measure dne to the power exerted by the elastic reaction of the walls of the chest, and it is also much influenced by the disproportionate strength which the expiratory muscles attain through being called into use for other purposes than that of simple expiration. The force of the inspiratory act is therefore better adapted than that of the expiratory for testing the muscular strength of the body.

"Much of the force exerted in inspiration is employed in overcoming the resistance offered by the elasticity of the walls of the chest and of the lungs. Mr. Hntchinson estimated the amount of this elastic resistance by observing the elevation of a column of mercury raised by the return of air forced, after death, into the lungs, in quantity equal to the known capacity of respiration during life; and he calculated that in a man capable of breathing 200 cubic inches of air, the muscular power expended upon the elasticity of the walls of the chest, in making the deepest inspiration, would be equal to the raising of at least 301 lbs. avoirdupois. In tranquil respiration, supposing the amount of breathing air to be 20 cubic inches, the resistance of the walls of the chest would be equal to lifting more than 200 lbs. The elastic force exerted in ordinary expiration must therefore be much

* The kilogramme = 2·205 lbs. very nearly. The gramme = 15·434 grains.

greater than enough to lift this weight; because in it the elastic force of the lungs is also in action—a force which is not included in these estimates, because the lungs were in both cases burst by the air forced into them." (Kirkes and Paget, 'Handbook of Physiology.')

The changes of the air in the lungs effected by the respiratory movements are assisted by the air itself. It is a well-known fact that carbonic acid, although heavier than atmospheric air, is speedily diffused through it, according to the known laws of the diffusion of gases. There is no doubt that this law is in active operation during the respiratory changes, and that it assists the oxygen in passing into the lungs, and the carbonic acid in passing out. If it were not for this interchange the reserve and residual air would probably be injnriously charged with carbonic acid. It is also probable that the difference of temperature within and withont the lnngs assists in the interchange of the air.

The air which is taken into the lungs during respiration is the air of the atmosphere, which in round numbers consists of 21 of oxygen, and 79 of nitrogen in every 100 parts. A small proportion of carbonic acid exists in it, abont 4 parts in 10,000. It also contains a varying qnantity of watery vapour. The changes which occnr in this air during respiration are: 1. It contains a larger quantity of carbonic acid gas. 2. Its oxygen is diminished. 3. Its watery vapour is increased.

An easy proof of the existence of carbonic acid in the air expired from the lungs, is afforded by blowing through a tube into lime water, when the carbonic acid will unite with the lime, and carbonate of lime will be precipitated. The quantity of this gas which is calculated by Valentin and Brunner, as thrown out from the lungs in 24 honrs, is 1345·3 cubic inches, or abont 636 grains an hour. This would make about 173 grains of carbou in an honr, or 8 ounces in the 24 hours. Andral and Gavarret calculated the qnantity at 9 ounces, and Mr. Coathupe at 5 ounces. Liebig gives 13 ounces as the quantity of carbon thrown off from both the skin and lungs.

The quantity of carbon however which is thrown out from the lnngs varies under different circumstances. As is seen in the preceding table, sex and age make a considerable difference in the quantity of carbon expired.

Diet exercises a considerable influence on the quantity of carbon thrown out from the lungs. The following table exhibits the quantity of oxygen required by certain articles of diet to convert them into carbonic acid and water. It should always be recollected in relation to this subject, that although carbon is spoken of so frequently, not only is carbon oxidated, but also hydrogen. Wherever hydrogen is present in the tissues, it sustains apparently the same relation to oxygen as carbon. Hence, in the calculation of the influence of diet on respiration it should never be left out:—

Substance.	Carbon.	Hydrogen.	Oxygen.	The qnantity of Oxygen required for the formation of Carbonic Acid and Water in addition to the amount already present.
100 parts of Fat	78·13	11·74	10·13	292·14
" Starch	44·45	6·17	49·38	118·52
" Sugar (C^{12}, H^{12}, O^{12})	40·00	6·66	53·34	106·67
" Malic Acid (C^4, H^2, O^4)	41·38	3·45	55·17	82·78
" Albuminates	47·48	4·98	13·14	153·31
" Collagen	42·52	4·47	13·59	135·56
" Mnscular snbstance " Muscnlar Fibrin and Collagen (Schmidt)	46·10	4·72	13·66	147·04

From this table it may be gathered that vegetable diet consumes more oxygen in the production of carbonic acid and water than animal diet. This is also found to hold good in the case of carnivorous and herbivorous animals—the latter taking up a larger quantity of oxygen than the former.

It has been found that the carbon and hydrogen of nitrogenous foods become oxidised, and are given out during respiration, but they do not supply sufficient for the wants of the system, and when animals are fed on nitrogenised foods, the fat is oxidised and converted into carbonic acid and water.

It appears to be now an established fact, that the imbibition of spirituous drinks of all kinds is attended by a diminished excretion of carbonic acid. This was indicated by Prout, and has since been confirmed by Vierordt and others. This shows the importance of such drinks in cases where the oxidating processes are proceeding too rapidly, and of their injurious tendency where these processes need to be stimnlated. Dr. Prout observed that strong tea exercises the same influence on the system.

Sleep produces a very considerable diminution of the excretion of carbonic acid. Scharling found that the ratio of carbonic acid exhaled during sleep in one hour in the night, to that eliminated in one hour in the day after dinner, was as 31·39 to 40·74. A much greater difference is found between animals during their waking and hybernating states.

Bodily exercise increases the exhalation of carbonic acid, whilst rest diminishes it. Seguin, Prout, Vierordt, and Hoffman, have all proved this by experiment.

With regard to the quantity of oxygen consumed during respiration, it was at one time supposed to be exactly equal to the quantity found in the carbonic acid expired. This however is not this case, for accurate experiments show that, after all allowance made for oxygen present in the tissues, there is constantly a small quantity more taken into the lungs than is thrown out. The destination of this oxygen is undoubtedly to be found in the carbonic acid gas thrown out from the lungs, in the formation of the substances found in the bile and urine, and in the formation of phosphoric and sulphuric acids. The quantity of oxygen consumed is nevertheless measured by the carbonic acid thrown off from the lungs, so that, where there is an increase of excretion of carbonic acid, there is an increase of absorption of oxygen. It is an interesting fact that small animals consume a relatively much greater proportion of oxygen gas than larger ones. It also a fact of practical importance, that the quantity of carbonic acid gas exhaled is not increased by increasing the quantity of oxygen in the atmosphere. As a proof of the necessity of the changes involved in the absorption of oxygen gas, it has been fonnd that the eggs of birds, and nndoubtedly this applies to the eggs of all animals, absorb oxygen and give ont carbonic acid. The following table gives the result of some experiments of Valenciennes on this subject:—

In 1000 grammes' weight of Eggs.	From the 9th to the 12th day of Incubation.	From the 16th to the 19th day of Incubation.
	Grammes.	Grammes
The loss of weight amounted to	26·26	41·72
The absorbed oxygen	5·74	10·70
The exhaled carbonic acid	4·33	11·92
The exhaled water	2·88	3·66
The ratio of absorbed O to the O in C O^2	100 : 54·9	100 : 31·0

The nitrogen of the atmosphere appears to act as a diluent, and to temper the activity of the oxygen gas. Although when animals are placed in atmospheres of pure oxygen, or hydrogen, a certain quantity of nitrogen is thrown out from their lungs, it still requires proof that this has been taken up from the atmosphere. It is not improbable that a certain quantity of nitrogen may be thrown off by the decomposition of the nitrogenous tissues in the blood, or excretions.

With regard to the watery vapour which passes off from the lungs, it may be stated as a general rule that it is sufficient to saturate the expired air. Its absolute amount is therefore influenced by the following circumstances: 1, By the volnme of air expired; 2, By the quantity of watery vapour contained in the air previous to its inspiration; 3, By the temperature of the expired air; 4, By the length of time which each volume of inspired air is allowed to remain in the lungs.

We have thus considered the principal physical and chemical phenomena presented during the respiration of animals. It should however be recollected that these phenomena are dependent for their existence on the influence of the nervous system. All the respiratory movements effected by the muscnlar tissnes, as far as they are independent of the consciousness of the individual, are nnder the absolnte governance of that part of the brain which is called the medulla oblongata. It is this portion of the nervons system which acts as the centre of all the impressions which convey the necessity of breathing, and which initiates all the motions which resnlt in respiratory action.

(Kirkes and Paget, *Handbook of Physiology;* Lehmann, *Physiological Chemistry*, translated for the Cavendish Society by Dr. Day; Valentin, *Text-Book of Physiology*, translated by Dr. Brinton.)

REST-HARROW. [ONONIS, *S.* 1.]

RETINALITE, a Mineral, having a resinous appearance, found with and allied to Serpentine. It is found at Granville in Upper Canada. (Dana.)

RETINITE, a Mineral Resin. It occurs in ronndish masses. Its colour is light yellowish brown, green, or red; lnstre earthy or slightly resinons in the fracture. It is snb-transparent to opaque. Often flexible and elastic when first dug up, but loses these qualities on exposure. Its hardness is 1-2·5, and its specific gravity 1·135. It takes fire, and bnrns with a bright flame and fragrant odonr. It is soluble in alcohol. It is fonnd in the Bovey coal of Devonshire, and also in the brown coal of Wolchow in Moravia, and near Halle. (Dana, *Mineralogy.*)

REUSSITE. [MINERALOGY, *S.* 1.]

REVENUE AND TAXATION.—On the accession of Qneen Victoria, in 1837, the total public revenue of the United Kingdom for that year was £50,592,646, arising from the following sources:—

	£
Customs	22,063,118
Excise	14,518,142
Stamps, including hackney-coach and hawkers' and pedlars' licences	7,039,538
Taxes nnder the management of the Commissioners of Stamps and Taxes	3,890,146
Post office	2,339,738
Tax on pensions and salaries	6,791
Crown lands	419,780
Small branches of hereditary revenne	5,067
Surplus fees of regulated public offices	32,846
Poundage fees, pells fees, &c., in Ireland	1,477
Money received from East India Company, on account of retired pay, pensions, &c., of her Majesty's forces serving in India	60,000
From the trustees of the king of the Belgians, out of the annnity granted to Prince Leopold	33,500
Imprest moneys repaid by public accountants, and other moneys paid to the public	128,105
Money received from the Bank on account of nnclaimed dividends	54,398
	50,592,646

The expenditnre for the same year was £51,319,112, under the following heads:—

	£
Charges of collection and other payments before reaching the Exchequer	4,188,159
Interest and management of National Debt	24,357,137
Terminable annuities	4,195,745
Interest on Exchequer Bills	936,688
Civil List	444,068
Annuities on pensions charged on Consolidated Fund	578,966
Salaries and allowances	194,042
Diplomatic salaries and pensions	188,140
Courts of jnstice	674,452
Miscellaneons charges on Consolidated Fund	331,788
Army	6,521,716
Navy	4,750,658
Ordnance	1,444,524
Miscellaneons charges on annual grants of Parliament	2,513,029
	51,319,112

Showing an excess of expenditnre over income of £726,466. The amonnt of the public funded debt, on Jan. 5, 1838, was £764,704,057.

The following table gives the gross results from 1838 to 1856:—

Years.	Revenue.	Expenditure.	Surplus.	Deficiency.
£	£	£	£	£
1838	52,124,471	52,566,289	...	441,818
1839	52,058,349	53,440,287	...	1,381,938
1840	47,567,565	49,161,536	...	1,593,971
1841	48,084,359	50,185,729	...	2,101,370
1842	46,965,630	50,945,169	...	3,979,539
1843	52,582,817	51,139,513	1,443,304	
1844	54,003,753	50,647,648	3,356,105	
1845	53,060,354	49,242,713	3,817,641	
1846	53,790,138	50,943,830	2,846,308	
1847	51,546,264	54,502,948	...	2,956,684
1848	53,388,717	54,185,136	...	796,419
1849	52,951,749	50,853,623	2,098,126	
1850	52,810,680	50,231,874	2,578,806	
1851	52,233,006	49,506,610	2,726,396	
1852	53,210,071	50,792,512	2,417,559	
1853	54,430,344	51,174,839	3,255,505	
1854	56,737,133	59,946,192	...	3,209,059
1855	63,364,605	84,505,788	...	21,141,183
1856	72,218,988	82,223,400	...	10,104,412

In 1857 the revenne amounted to £70,390,343, from the following sources:—

	£
Customs	22,464,354
Excise	17,472,000
Stamps	7,269,224
Taxes (land and assessed)	3,104,020
Property tax	15,137,996
Post Office	2,992,000
Crown lands	273,654
Produce of sale of old stores, &c.	1,122,004
Money received from East India Company	60,000
Imprest and other moneys	407,957
Unclaimed dividends received	87,134
	70,390,343

The expenditure was—

	£
Interest and management of permanent debt	23,626,907
Unclaimed dividends paid	88,531
Terminable annuities	3,979,136
Interest on Exchequer Bonds and Bills	988,810
Civil List	401,479
Annuities and pensions	337,828
Salaries and allowances	157,557
Diplomatic salaries and pensions	155,560
Courts of justice	578,421
Miscellaneons charges on Consolidated Fund	177,817
Compensation for abolition of Sound Dues	1,125,206
Army	13,616,557
Navy	10,390,000
Persian expedition	900,000
Expenses of war in China	590,693
Miscellaneous civil services	6,905,456
Salaries, &c., of revenue departments	4,334,288
Redemption of Exchequer Bonds	2,000,000
	70,354,246

The salaries of the Revenne Department form now a separate charge, and are no longer deducted as charges of collection before transmission to the Exchequer, and are consequently subject to parliamentary supervision.

The National Debt, fnnded and unfunded, at the end of 1857, was £805,282,699, of which 21,555,416*l.* had been created in 1856. In addition to the snms shown as excess of income over expenditure in the preceding years, the greater part of which had been applied to the reduction of the Debt, an Act was passed in 1853 by which the South Sea Stock, certain Bank Annuities, and Three per Cent. Annuities, were incorporated with the National Debt upon terms which added something to the nominal amonnt of capital, but prodnced a large reduction in that of the interest paid.

In 1842 the Property Tax, as proposed by Sir Robert Peel, was imposed to remedy the annnal defalcation in the revenue. It was assessed at 7*d.* in the pound on all incomes of 150*l.* a year and upwards. Its effects were visible in 1843, and enabled him to make extensive reductions in the customs and excise duties, to the great benefit of the commerce of the conntry, as well as the comfort of the inhabitants.

The excise duties necessarily interfere with the processes of manufacture—are nnavoidably inqnisitorial—and are a check upon improvement. In 1797, not fewer than 2[illegible] articles were subject to dnties of excise. The list includes salt, wine, beer, cider, and perry, hides and skins, printed goods, candles, bricks and tiles, starch, soap, stone bottles, sweets and mead, auctions and glass. There were separate

Boards of Excise for England, Scotland, and Ireland, the functions of which were discharged by 21 commissioners. In 1858 there is only one Board for the whole of the United Kingdom, the number of commissioners has been reduced to seven, and the number of articles in which officers of the board interfere during the process of growth or manufacture has been reduced to four; namely, hops, malt, paper, and spirits. The amount of vexatious meddling which has thus been got rid of can only be estimated by those who have had experience of the working of the excise system in its worst days, when the most conscientious respect for the law rendered it difficult at all times to avoid infringement of the regulations of the Board, and when a manufacturer was often at the mercy of the exciseman, and might easily be ruined by a venial offence committed under a misapprehension of very complicated rules which he was compelled to observe in carrying on his business.

In the department of the customs the practical reforms effected are equally gratifying. At one time the laws relating to customs were contained in not fewer than 1500 Acts of Parliament. In 1853 they were consolidated in a plain, simple, and intelligible form under one statute. At the same time the whole of the customs duties of the United Kingdom were consolidated into a single Act in which every article is arranged alphabetically. The Consolidated Act of Customs Regulations and the Consolidated Tariff Act are all that the merchant will now require for his guidance in place of hundreds of labyrinthine Acts which these two simple codes have superseded.

In 1810 five years were required to effect a digest of the customs laws into 1375 pages; and in 1826 the work of consolidation was compressed into eleven separate Acts, the first of which repealed 443 statutes, many of which were obsolete; and one of the eleven Acts enumerated 1150 different rates of duty chargeable on imported articles; and yet, in 1839, nearly 99 per cent. of the customs duty was contributed by 46 articles. In 1840 there were 1052 articles subject to these duties. In 1845 they were reduced to 590; in 1852 the number was 466, and in 1853 the duty was entirely repealed on no fewer than 105 articles, so that, since 1845 the number of articles on which customs duties are levied has been reduced from 1052 to about 360. In 1856, however, there were 139 articles charged with customs duties, no one of which amounted to 10,000*l.* in the year, and some producing the most insignificant sums; such as almond paste, 2*l.*; barley, pearled, 4*l.*; essence of spruce, 1*l.*; nux vomica and oil of almonds, 3*l.* each. The whole yearly produce of the 139 enumerated articles was 151,596*l.* Yet, however, in the seventeen years, from 1840 to 1857, the amount of customs duties reduced or repealed has amounted to upwards of 10,000,000*l*, while the amount collected has increased from 23,341,813*l.* in 1840, to 23,618,375*l.* in 1856. The exports and imports have enormously increased, and the amount of shipping tonnage has doubled [TRADE AND SHIPPING, *S.* 2.]; and yet, owing to the much smaller number of articles on which duty is levied, and to greater simplicity of arrangements, all this immense addition to the trade of the country has occasioned but small increase to the Custom-house staff, as compared with the number in 1840. Let the reader pause and consider for himself the vast benefits conferred on commerce, and on the people of this country, by the changes which have thus been briefly noticed. Trade has been extended and invigorated, and the prosperity of the country has been based on foundations which only war and scarcity can shake: and the influence of the latter calamity has been reduced to its minimum by wise and enlightened legislation.

It will thus be seen how each successive application of sound principles has added to the stability of our financial system; and the public confidence in these principles enabled the Chancellor of the Exchequer, in the session of 1853, to carry still further towards completion the work of commercial and fiscal reform. The remissions of taxation, which Sir Robert Peel commenced in 1842, and which were renewed on a very large scale in 1845 and 1846, completely, or almost completely, recovered themselves within a period, as to some of them, of eleven years, some of them of five or six years, and all in a mean term of seven or eight years. The safe test of experience has carried conviction to practical men, who are otherwise slow in adopting bold experiments. When, in April 1853, Mr. Gladstone, then Chancellor of the Exchequer, proceeded to unfold a great scheme for settling the finances of the country on a permanent basis for a future term of seven years, he was enabled triumphantly to refer to this popular test. He could show that the effect of remissions of duty, in the way of recovery, was twofold: upon the consumer of the particular article, by enabling him to increase his consumption; and next upon the general consumer, by extending and widening the means of consumption on the part of the great body of the people. Mr. Gladstone, therefore, proceeded, in reliance upon former facts, to carry on the work of tariff reform on the following principles, as far as his financial means permitted:—

1. To abolish altogether the duties which are unproductive, except in cases where there may be some special reason to retain them on account of their relation to other articles.

2. To abolish, as far as revenue considerations will permit, duties on articles of manufacture, except such as are in the last stage as finished articles, and are commonly connected with hand-labour, in regard to which it was considered more prudent to proceed in the mode, not of abolition, but of reduction.

3. Whenever it can be done, to substitute rated duties for duties *ad valorem*.

4. To get rid, except in a few instances where it is important on account of revenue, of the 5 per cent. addition to the customs duties made in 1840, which greatly complicates the transaction of business. The articles on which the 5 per cent. additional duty is still retained are seven in number, and the duty in question produced 327,167*l.*, in 1852:—Tobacco, wine, timber of British possessions, pepper, gloves, currants, and figs. The 5 per cent. additional on figs only realized 1253*l.*, and on gloves 1864*l.*

5. To merge the differential duties in favour of British possessions by lowering the foreign article to the level of the colonial; and where this is not expedient, not to raise the duty on the colonial article.

6. To lower the duties that press on foreign articles of food which enter largely into what may be called the luxuries and comforts of the mass of the people.

The result was, that the duty on 231 articles was dealt with on these principles—on 105 the duty was repealed, and on 126 important reductions were made. The immediate loss to the revenue consequent on these alterations was estimated at 1,338,000*l.* The changes are analogous to those effected in 1842 and 1845-46, and the same result was produced—the gradual recovery of revenue by increased consumption.

The soap duty was entirely abolished, on the ground that it was injurious to health and comfort, that the interference of the excise with the process of soap-making prevented improvement, and disabled the manufacturer from competing in markets abroad with the foreign soap-maker, who was free to carry on his business according to the most approved methods, and not under peremptory restrictions; and because the necessity of allowing drawbacks on soap used in certain textile manufactures entailed fraud and occasioned great loss to the revenue. It is evident that "considerations of revenue" alone prevented the duty on paper being similarly dealt with.

There were three different rates of duty in the United Kingdom on home-made spirits, and this antiquated mode of dealing with the article led to smuggling. An approximation was therefore made in 1853 towards their equalisation by adding 1*s.* per gallon to the duty on Scotch spirits, 8*d.* on Irish spirits, reserving to an early period the further advancement of the principle of equalisation. This was accomplished, as far as regards Scotland, in 1855, by advancing the duty on that kingdom to the same as that in England. This measure at once relieved the borders from a blockade of excise officers. At the same time the duty in Ireland was raised so as to bring it to so near an approximation, that smuggling almost ceased to be remunerative; and in April, 1858, Mr. Disraeli, Chancellor of the Exchequer, in his budget proposed an entire equalisation.

Another great object of the Budget of 1853 was to establish a general uniformity of taxation in the three kingdoms under another important head, by rendering Ireland liable to the income-tax; and to accomplish this end, the Chancellor of the Exchequer was willing to make a great sacrifice. He remitted a sum of 4,500,000*l.* due from Ireland to England, constituting an annual charge of 245,000*l.*, three-fourths of which burden would have continued for forty years. He swept away this debt, and commuted the charge in consideration of an addition of 8*d.* per gallon on Irish spirits, and the income-tax for seven years. Ireland had been exempted from this tax in 1842, in consideration of a duty of 1s. additional on spirits, and an augmentation of stamp-duties; but the first was abandoned almost as soon as enacted, and the second disappeared in 1850, when a reduction of stamp-duties took place both in this country and Ireland. Exemption necessarily implies a heavier burden on others. Great Britain had borne the income-tax, and Ireland had largely participated in the remission of duties which that tax was designed to supply. When, therefore, further benefits were to be placed within reach by assenting to the income-tax for a period of seven years, it was felt to be just in principle to impose the tax on Ireland, which would otherwise derive advantages at the cost of the people of England and Scotland.

The complex system of the assessed taxes, levied under seventy-two Acts of Parliament, was re-modelled with a view of securing simplicity and uniformity. With this object the progressive plan of assessment has been abolished, also compositions, and, as far as possible, exemptions.

Some important alterations have been made under the head of Stamps. Penny receipt-stamps have been substituted for stamps of varying value, in order to obtain the advantages of uniformity, and to remove the temptation to evasion; and the facilities of trade have been promoted by allowing the penny receipt-stamp to be used in connection with bankers' cheques, so as to add to their security. [STAMP DUTIES, *S.* 2.]

The most important portion of the Budget of 1853 was undoubtedly the new tax on successions, which subjects every description of property to the legacy duty. The income-tax, it was alleged, pressed unequally on intelligence and skill, as compared with property, and the succession-tax was designed to adjust the balance. Real property, whether settled or unsettled, had hitherto been exempt from legacy duty. This feudal claim of exemption permitted an estate in land of 50,000*l.* a year to pass to the heir without his contributing one farthing to the state, while a poor man who received a legacy of 100*l.* paid a tax of 10*l.* The anomaly has now ceased, and a person who succeeds to a landed estate of 10,000*l.* is taxed on the annual value of his property, which, on the principle of calculation adopted, gives a rental of 300*l.* a year.

The income-tax was retained, but was associated with remissions of indirect taxation to an amount exceeding 5,000,000*l.*; and its extinction was finally provided for in 1860, on the ground that it is not well adapted to form a permanent portion of ordinary public income. It is like the reserve of an army, which should only be brought forward to avert great dangers or accomplish important objects. It may reconcile those who dislike the inquisitorial nature of this impost to consider what it has effected under the opposite conditions of war and peace.

During the great war, which lasted, with two brief intervals, from 1793 to 1815, there were three periods, in the first of which there was no income-tax; in the second it was only incompletely adopted; and in the third it was fully brought into operation.

From 1793 to 1798 there was no income-tax. The charge of government, and the charge of debt incurred before 1793, together with the cost of war, amounted on the average of these six years to 36,030,000*l.* a-year. The revenue, with all the additional taxes laid on, amounted to 20,626,000*l.*, leaving an annual deficiency of 15,404,000*l.*

In 1798, the income-tax was imposed by Mr. Pitt, and from 1799 to 1802, the cost of the war and public charges rose to 47,413,000*l.*; but the revenue, aided by the income-tax, rose from 20,626,000*l.* to 33,724,000*l.*, and under an increase of expenditure, amounting to 11,400,000*l.* a year, the excess of expenditure over revenue was less by 2,000,000*l.* a year during these four years than from 1793 to 1798.

From 1806 to 1815, the income-tax was in full force. The expenses of the war and of government, and the charge of debt (9,500,000*l.*) incurred before 1793, amounted to 65,794,000*l.*, but the revenue rose to 63,790,000*l.* The annual deficiency, instead of being 15,404,000*l.* as in the first period, or 13,689,000*l.* as in the second, was only 2,004,000*l.* Omitting the charge of debt incurred before 1793, there was actually raised, during the heaviest period of war expenditure, 7,000,000*l.* a year more than the charge of government and the cost of the war.

If the resolution to submit to an income-tax had been adopted at an earlier period, the national debt need not at this moment have existed. Rightly, therefore, is it regarded as an auxiliary, to be reserved for great occasions.

In reimposing the income-tax for seven years, the intentions of the government were to mark it as a temporary measure, to equalise, as far as possible, its pressure on skill and intelligence as compared with property, to mitigate its operation by every rational means compatible with its integrity, and to associate it with extensive reductions of taxation; and on these terms it was accepted for the sake of the benefit which it brought in its train.

The Government, after giving the most mature consideration to the subject, declined to undertake the reconstruction of the tax, and staked their official existence on the success of their general financial plan. The Chancellor of the Exchequer showed that the incidence of the tax on real property was already heavier than was generally supposed, and he estimated that on land and houses it was 9*d.* and not 7*d.* in the pound, and that evasion or unfair assessment was impossible; while on trades and professions the principle of self-assessment entailed extensive frauds, of which he gave a striking instance. It was necessary to compensate twenty-eight persons for their profits for a single year, and they claimed 148,590*l.*; a jury awarded 26,973*l.*, but their return of profits for assessment to the income-tax was only 9,000*l.*! The case of the professions, which has often been brought forward as one of peculiar hardship, appears when analysed to be of less magnitude than the public have been led to believe. They do not contribute more than one-twenty-second part of the tax; but to mitigate their case as far as possible, persons who insure their lives up to one-sixth of their incomes, may deduct from their income the cost of insurance, but not so as to escape the tax altogether; and this will chiefly benefit the professions to the amount probably of 120,000*l.* a year.

The extension of the income-tax to Ireland has already been noticed. The tax has also been extended at a lower rate of assessment to all persons with incomes between 100*l.* and 150*l.* a year. They were benefited by all the remissions of taxation, which had been purchased at the cost of others by the payment of the income-tax; and when further remissions were to be made, it was only just that this exemption should cease. The Chancellor of the Exchequer adduced cases showing, that persons with incomes between 100*l.* and 150*l.* a year, had been benefited by the reduction of duties on necessaries and luxuries to a greater extent than those whose incomes varied from 150*l.* to 170*l.* a year; the first to the extent of 6 and 7 per cent., and the second only to 5 per cent., or deducting the payment by them of income-tax of 2 per cent. On the occurrence of the war with Russia, the tax was raised to 16*d.* in the pound on incomes of 150*l.* and upwards, and to 11½*d.* on farms rented to that amount; it was reduced to the original 7*d.* in 1857; and to 5*d.* in 1858.

"Considerations of revenue" alone prevent the further application of sound financial principles to other parts of our fiscal system. The duties on paper and wine, and particularly those on fire-insurance, are amongst the first which have claims to be abolished or reduced, and which promise when relieved from taxation to be productive of the greatest advantage to the community. The insurance tax operates against one of the very best principles of society—that of distributing losses which would ruin an individual, over the whole community, in a manner to render it scarcely appreciable by any. An exemption from the tax only shows its impolicy. Farming-stock and implements do not pay insurance duty, but a workman's tools do. The tax, however, yields upwards of a million to the Exchequer, and the Chancellor cannot afford to give it up.

Much has been already accomplished, more than could possibly have been anticipated a few years ago; and we will conclude by quoting the closing sentences of Mr. Gladstone's most able speech on introducing the Budget in April, 1853, as a fair statement of the principles which now regulate our fiscal system: "While we have sought to do justice, by the changes we propose in taxation, to intelligence and skill, as compared with property; while we have sought to do justice to the great labouring community of England, by further extending their relief from indirect taxation, we have not been guided by any desire to put one class against another; we have felt we should best maintain our own honour—that we should best meet the views of Parliament, and best promote the interests of the country—by declining to draw any invidious distinction between class and class, by adopting it to ourselves as a sacred aim, to diffuse and distribute—burden if we must—benefit if we may—with an equal and impartial hand; and we have the consolation of believing that by proposals such as these we contribnte as far as in ns lies, not only to develop the material resources of the country, but to knit the hearts of the various classes of this great nation yet more closely than heretofore to that throne and to those institntions under which it is their happiness to live."

As intimately connected with the ameliorations of our financial system, we append a list of the taxes repealed or reduced, and of taxes imposed or increased during the following years:—

Taxes Repealed or Reduced.

		£
1840.	Postage	1,240,000
	Other taxes	18,959
	Total	1,258,959
1841.	Rice in the husk	21,832
	Other taxes	5,338
	Total	27,170
1842.	Coffee	201,113
	Timber & wood	608,414
	Export duties	109,778
	Other customs duties	579,639
	Stage coaches	77,779
	Other taxes	19,643
	Total	1,596,366
1843.	Timber & wood	126,453
	Spirits, Ireland	240,000
	Other taxes	45,368
	Total	411,821
1844.	Coffee	86,174
	Currants	95,816
	Wool	97,140
	Marine insurances	101,959
	Glass	45,000
	Other taxes	32,721
	Total	458,810
1845.	Sugar	2,309,857
	Molasses	129,183
	Cotton, raw	682,042
	Coals, export duty	115,438
	Other customs dnties	380,786
	Auctions	305,000
	Glass	624,000
	Total	4,546,306
1846.	*Butter & cheese	205,437
	Silk manufactures	162,985
	Spirits	482,286
	Tallow	101,966
	Woollen manufactures	27,970
	Seed, Clover	36,077
	Other customs duties	135,069
	Total	1,151,790
1847.	Woods from foreign countries	243,085
	Sugar and molasses	53,152
	Rum	46,974
	Other taxes	1,675
	Total	344,886
1848.	Copper ore	35,745
	Rum, British Possessions	69,3 3
	Sugar and molasses	258,854
	Wood, Foreign	215,028
	Other taxes	6,988
	Total	585,968
1849.	Sugar and molasses	355,257
	Oil and sperm	29,327
	Other taxes	4,214
	Total	388,798
1850.	Sugar and molasses	331,073
	Stamps	520,000
	Bricks	456,000
	Other taxes	3,078
	Total	1,310,151
1851.	Window duty	1,878,800
	Coffee	149,161
	Sugar and molasses	359,804
	Wood & timber, Foreign	292,099
	Total	2,679,864
1852.	Sugar and molasses	95,928
1853.	Tea	968,877
	Butter & cheese	106,535
	Sugar and molasses	78,793
	Raisins	65,659
	Other articles	279,610
	Total customs	1,499,474
	Excise, Soap, &c.	1,171,000
	Stamps	277,000
	Taxes, Assessed	300,000
	Total	3,247,474
1854.	Customs:—	
	Tea	980,568
	Platting of chip, and other articles	2,539
	Stamps—bills of exchange	11,000
	Taxes, Assessed	290,000
	Total	1,284,107
1855.	Customs:—	
	Window glass and other articles	2,960
	Stamps:—	
	Newspapers†	250,000
	Stage Carriages	60,000
	Total	312,960
1856.	Customs:—	
	Spruce Beer	1,428
	Plums	1,886
	Other articles	161
	Excise:—	
	Malt—War-Tax	2,200,000
		2,203,475
1857.	Customs:—	
	Window glass	2,053
	Caoutchouc manufacture	6,004
	Carry forward	8,057
1847.	Brought forward	8,057
	Coffee	145,816
	Sugar and molasses	418,988
	Tea	1,054,637
	Other articles	1,084
	Property and income tax	9,125,000
	Total	10,753,582
1858.	Income tax reduced to 5*d*.	2,000,000

* In 1846 the prohibitory doty on foreign sugar was also reduced, but as the expected result was an increase of revenue, it is not specified.

† Portion of Stamp Duty lost by the repeal of the Act which made the stamp compulsory, allowing the sum of 50,000*l*. a year for the addition to the Post-Office revenue for unstamped newspapers sent with postage stamps.

Taxes Imposed or Increased.

		£
1840.	Customs 5 per cent.	1,060,226
	Excise 5 per cent.	438,000
	Ditto, spirits	344,000
	Assessed taxes 10 per cent.	311,477
	Postage, abolition of franking	118,567
	Other taxes	1,970
	Total	2,274,240
1841.	None.	
1842.	Income and property tax	5,100,000
	Export duty on coals	141,930
	Spirits, Ireland	240,000
	Stamps, Ireland	121,745

REVIVOR. [SCIRE FACIAS, *S.* 2.]

RHAYADER. [RADNORSHIRE.]

RHENITE. [MINERALOGY, *S.* 1.]

RHINOPOMA. [CHEIROPTERA.]

RHIZANTHEÆ, *Rhizanths*, *Rhizogens*, a small class of Plants, comprising the orders *Balanophoraceæ*, *Cytinaceæ*, and *Rafflesiaceæ*. They are parasitical plants, destitnte of true leaves, in place of which they are furnished with cellular scales. Their stem is either an amorphous, fungous mass, or a ramified mycelium, and is very imperfectly snpplied with spiral vessels, which are sometimes wholly deficient. They are of a brown, yellow, or purple colonr, never green. They produce flowers which have genuine stamens and carpels, and are surronnded by a whorl of petaloid bodies. They possess ovules, bnt their seed is not known.

These plants have been regarded by Lindley, Endlicher, and other botanists, as snfficiently distinct to warrant their being placed in a class by themselves. Their flowers, stamens, and ovules, indicate their relation to the phanerogamic plants, whilst their mycelial stem, parasitic habits, and cellnlar structure ally them with the *Fungi* and other low forms of vegetation. Mr. Brown however is of opinion that the Rhizanths are but less developed forms of Exogenons Plants. He regards them as having affinities with *Aristolochiaceæ*, and other orders of Exogens. More recently Mr. Griffiths has adopted the views of Brown, and advanced a number of arguments in favour of their being degraded forms of higher plants, and not a permanently low form of vegetation. He thinks the relations of Rhizanths various. Thus he places *Mystropetalon* near *Proteaceæ* and *Santalaceæ; Sarcophyte* and *Balanophora* he places near *Urticaceæ*. Finally, he places *Thismia* between *Taccaceæ* and *Burmanniaceæ*.

The following are the orders of *Rhizantheæ* as recognised by Lindley:—

Ovules solitary, pendulous; fruit one-seeded	*Balanophoraceæ.*
Ovules 00, parietal; fruit many-seeded; calyx 3-4-6-parted; anthers opening by slits	*Cytinaceæ.*
Ovules 00, parietal; fruit many-seeded; calyx 5-parted; anthers opening by pores	*Rafflesiaceæ.*

RHIZOBOLACEÆ, *Rhizobols*, a natural order of Plants, consisting of trees of very large size. The leaves are opposite, digitate, coriaceous, with a pointed stalk and no stipules; flowers large, regular, arranged in racemes, with their stalks pointed at the base and below the apex; the sepals are 5 or 6, more or less combined, imbricated in æstivation; petals 5 to 8, equal-sided, but unequal thickish, arising along with the stamens from a hypogynous disc; fruit of several combined indehiscent one-seeded nuts; seed reniform, exalbuminous, with a cord dilated into a spongy excrescence; radicle very large. The species are found in South America. They are large timber-trees, some of which yield edible fruit. It is from trees of this order that are produced the Souari (or Suwarrow) Nuts of the shops, the kernel of which is one of the most delicious fruits of the nut kind that is known. An oil is extracted from them not inferior to that of the olive. The timber of the tree is used for ship-building. (Lindley, *Vegetable Kingdom.*)

RHIZOCARPEÆ. [MARSILEACEÆ, *S.* 2.]

RHIZOPHOREÆ. [RHIZOPHORA.]

RHODALITE, a Mineral which appears to consist of small rectangular prisms with square bases. Hardness about 2. Colour between rose-red and flesh-red. Specific gravity 2. Before the blow-pipe per se not altered. With carbonate of soda fuses into a greenish-blue transparent bead in the exterior flame, becoming yellow in the interior flame: with borax gives a transparent colourless bead; with phosphate of soda does not fuse. It is found in Ireland, occurring probably in an amygdaloidal rock. An analysis by Mr. Richardson gives—

Silica	55·9	
Alumina	8·3	
Peroxide of Iron, and trace of Oxide of Manganese	11·4	
Lime	1·1	
Magnesia	0·6	
Water	22·0	
		99·3

RHODEORETINE. [CHEMISTRY, *S.* 2.]

RHODIOLA. [SEDUM.]

RHODIZITE, a Mineral resembling *Boracite* [BORON] in its crystals, but it tinges the blow-pipe flame deep red. It occurs with the Red Tourmaline of Siberia. (Dana.)

RHODYMENIACEÆ, an order of *Algæ*, consisting of purplish or blood-red Sea-Weeds, with an expanded or filiform inarticulate frond, composed of polygonal cells, occasionally traversed by a fibrous axis; superficial cells minute, irregularly parted, or rarely disposed in filamentous series; fructification double; conceptacles external or half-immersed, globose or hemispherical, imperforate, containing beneath a thick pericarp a mass of spores affixed to a central placenta. The root is disc-like or branched, sometimes much matted; frond variable in habit and colour, either leafy or filiform, and much branched, never articulate: in some an intense scarlet, in some crimson, in others brown-red or purple, usually growing somewhat darker in dyeing. The species are widely dispersed; all our genera having representatives in very distant countries, with very various climates.

Rhodymenia is an ill-defined genus, and will probably be divided into several distinct genera. Many of the species, especially of the section *Calophyllis*, are among the most splendidly coloured of crimson and carmine *Algæ*. Others, as *R. Hombroniana*, are clothed in royal purple; while others, like the sober dulse of our coasts, *R. palmata*, have often as much of brown as of purple in their attire.

Many of the *Rhodymeniaceæ* are valuable in an economic sense.

R. palmata, the Dulse of our coasts, is collected largely in Scotland and Ireland, and forms an important article of diet. Many of the *Gracilariæ* are largely used in the East as ingredients in soups and jellies, and also as substitutes for glue. One of them *G. spinosa*, is the Agar Agar of the Chinese, and is largely collected both for culinary purposes and as a component part of some of the strongest Chinese glues. It has recently been imported into England, and is occasionally used instead of carrageen moss in making jellies and blancmanges.

(Harvey, *British Algæ*.)

RHYDDLAN, or RHUDDLAN. [FLINTSHIRE.]

RHYNCHITES. [WEEVIL.]

RICCIACEÆ, a natural order of moss-like Plants or Herbs, inhabiting mud or water, swimming or floating, usually annual; their leaves and stems blended into a frond of a cellular structure, creeping, green or purple underneath, with a distinct epidermis, and a cavity of air-passages beneath it in some species.

These plants form a plain transition from *Thallogens* to *Acrogens*. Their spores are collected in large numbers within organs resembling the pistils of Phænogamous Plants. They have a distinct axis of growth, and an epidermis is distinctly formed with stomates for breathing with. The genus *Duriæa* is regarded as forming the nearest transition to Liverworts. It fructifies under water, which is very seldom the case with the other Crystal-Worts.

Of the species hitherto known two-thirds have been observed in Europe, and the remainder in various parts of the world. Several species in North America, the Cape of Good Hope, and Brazil, appear to be very similar to those of Europe. There are 8 genera and 29 species.

RINGWOOD, Hampshire, a market-town, and the seat of a Poor-Law Union, in the parish of Ringwood, is situated on the left bank of the river Avon, in 50° 50′ N. lat., 1° 47′ W. long., distant 27 miles S.W. from Winchester, 92 miles S.W. by W. from London by road, and 104 miles by the London and South-Western railway. The population of Ringwood parish in 1851 was 3928. The living is a vicarage in the archdeaconry and diocese of Winchester. Ringwood Poor-Law Union contains five parishes and townships, with an area of 16,425 acres, and a population in 1851 of 5465. The town is lighted with gas. The manufacture of thread and woollen gloves employs some of the inhabitants. The chancel and transepts of the parish church appear to have been erected about 1230; the nave and the tower are more recent. There are chapels for Wesleyan Methodists, Independents, and Unitarians, and National schools. There is an excellent corn-market, held every Wednesday. Fairs for horses and cattle are held on July 10th and December 11th.

RINTOUL, ROBERT STEPHEN, one of the most eminent of the writers of the newspaper press in London, was a native of Scotland, and was born in 1787. Of the history of his boyhood little is known. He was probably born in Leith or in Dundee, and he availed himself of the advantages afforded by the grammar-schools of Scotland to acquire a well-grounded education. His first known entry into public life was as editor of the 'Dundee Advertiser,' a weekly newspaper, somewhere about or a little before 1813. In this paper he at once evinced those remarkable powers of condensation and arrangement by which his after labours were distinguished. The paper advocated liberal, or rather the Whig, principles of the day, at that time by no means generally received in Scotland, though somewhat more favoured in Dundee, a large commercial and manufacturing town; and the talent he displayed not only ensured the popularity and success of the newspaper, but procured him the support and friendship of many of the leaders of the Whig party in Scotland. As editor he was the assailant of the corruptions of the close corporation of the town; the advocate for the improvement of the burgh schools; for the extension of harbour accommodation; and the exposer of fiscal mismanagement. About 1825 his connection with the 'Dundee Advertiser' ceased, and he endeavoured to establish a paper at Leith; it did not succeed; and on the recommendation of Mr. Douglas Kinnaird and Mr. Joseph Hume he was appointed editor of the 'Atlas' weekly newspaper in London. In this position he did not remain long; assisted by his friends he commenced 'The Spectator,' of which he was to have absolute control, and of which the first number was issued on July 5, 1828. He had now an opportunity of realising his notion of what a newspaper should be; and no man ever worked harder, more conscientiously, or more independently to effect his object. We have already noticed his faculty of arrangement, which he thoroughly carried out in 'The Spectator.' Besides writing on a multiplicity of subjects himself, he secured the assistance of a number of well qualified and distinguished men as contributors; but in most cases he suggested the subject, and in all he critically examined every one of their productions before they appeared in print. He was a supporter, through the paper, of all the great measures of social and political progress, from the time of its establishment, and probably few newspapers have had so much influence in forming opinions, particularly among the more highly educated class, as 'The Spectator.' The caution with which opinions were expressed; the avoidance of all exaggeration or depreciation of facts; the recognition of objections or defects in matters where an approval was given of the whole; though sometimes seeming to give an air of coldness to his judgments, and occasionally even of indecision, aided the influence by exciting thought. For thirty years he continued this laborious and useful life up to within a month of his death, which occurred on April 22, 1858.

RIOJA, LA, one of the provinces of the Argentine Confederation, comprehends the country between the Gran Salina and the Andes, and extends from north to south from 28° to 31° S. lat. It is bounded S. by the provinces of San Juan and San Louis, E. by Cordova, N.E. and N. by Catamarca, and W. by the republic of Chili. The area is about 5850 square miles. The population is variously estimated at from 18,000 to 25,000.

The country is described generally under PLATA, LA, STATES OF. It consists of a narrow strip of cultivable land along the eastern base of the Sierra de Velasco, the two valleys of Famatina and Guandacol, and a pastoral tract extending round the southern extremity of the Sierra de Velasco. Only the northern districts of the country east of the Sierra Famatina are fit for agriculture. The province is by its position almost cut off from intercourse with the more civilised parts of the Confederation. The roads leading to La Rioja are mere circuitous paths, hardly passable by mules, and the country is altogether in the most backward condition. The province is divided into four departments—Arauco, Famatina, Guandacol, and the Llaños. *Arauco* lies east of the Sierra de Velasco, and produces wheat, maize, and cotton; but its principal wealth is its vineyards. From 7000 to 10,000 barrels, of 16 gallons each, of a strong sweet wine, and 100 barrels of brandy, are annually made, nearly the whole of which is exported to Cordova and the neighbouring provinces. The capital, La Rioja, is also that of the whole province. *Famatina* lies to the west of Arauco, between the Sierra de Velasco and the Sierra Famatina. It contains rich orchards in its northern districts, and makes and exports about 6000 barrels of wine annually. This department takes its name from the Sierra Famatina, celebrated for its mineral wealth. The silver-mines of Famatina are very rich, but the remoteness and inclemency of their situation—they being above the line of vegetation, and only accessible by difficult mountain-paths—have hitherto prevented them from being worked except on a small scale. The capital, Chilecito, is a place of no importance. Goître prevails to a fearful extent in the valley of Famatina. *Guandacol* lies between the Sierra Famatina and the Andes, and produces very rich crops of wheat. It is thinly inhabited, and chiefly by aborigines, who hunt the vicuña in the adjacent mountains. The wool of the vicuña is the only article of export. Guandacol, the capital, and Vinchina are the only towns. The Llaños consist chiefly of a desert plain, containing a great number of grassy oases, on which there are numerous cattle-farms. About 20,000 head of cattle are annually reared. Like the other provinces of the Argentine Confederation, La Rioja is a federal state, owning a qualified dependence upon the central government. The state government is nominally vested in a governor and municipal junta of five members.

La Rioja, the capital of the state, is situated at the foot of the Sierra de Velasco, in 29° 12′ N. lat., 59° 50′ W. long. It contains some substantial houses, a few public buildings, the only school in the province, and about 3000 inhabitants.

RIPLEY. [YORKSHIRE.]

ROCAMBOLE. [ALLIUM.]

ROCCELLIC ACID. [CHEMISTRY, *S.* 1.]

ROCHEA (named after La Roche, a French Botanist), a genus of Plants belonging to the natural order *Crassulaceæ*. It has a 5-lobed calyx; petals 5, united into a gamopetalous hypocrateriform corolla, with a short tube, equal in length to the spreading limb or shorter than it; stamens 5, alternating with the petals, a little exserted; glands and carpels 5. The species are fleshy simple succulent shrubs. The leaves opposite, connate at the base, thick, and white. The flowers are disposed in terminal corymbs, without any bracts. A large number of the species are cultivated in our gardens and greenhouses.

ROGERS, SAMUEL, was born on the 30th of July 1763, at Newington Green, a suburb of London. His father, who was a Dissenter, and much respected by the Dissenters of London, was a banker by profession; and the poet, after a careful private education, was placed, when yet a lad, in the banking-house to learn the business prior to his becoming a partner. Among the reminiscences of this time was that of Wilkes calling at the banking-house to solicit his father's vote, and, as his father was out, shaking hands with him as his father's representative. From a very early period, the future poet exhibited a taste for letters, and he used to date his first determination towards poetry from the effect produced upon him by reading Beattie's 'Minstrel' when a mere boy. His admiration of literature and literary men led him, while still a clerk in his father's bank, to meditate a call on Dr. Johnson for the purpose of introducing himself; and once, with a young friend, he went to Johnson's house in Bolt Court bent on accomplishing the object, but his courage failed him when he had his hand on the knocker. It was in 1786—two years after Johnson's death—that Rogers, then in his twenty-third year, published his first volume of poetry, under the title of 'An Ode to Superstition, and some other Poems.' The date is important. "The commencement of a new era in British Poetry," says a critic, "dates almost exactly from this year. For a year or two before 1786, there had been manifestations of a new poetic spirit, differing from that of the poetry of the 18th century as a whole, and more particularly from that of Darwin, Hayley, and the Della Cruscans, who represented the poetry of the 18th century in its latest and dying stage. Crabbe, for example, had published his 'Library' in 1781; and Cowper had made his first distinct appearance as a poet in 1782, when he was already in his fifty-second year. Crabbe's 'Village' was published in 1783, and Cowper first made an effective impression by the publication of his second volume, including his 'Task,' in 1785. Thus Rogers was heard of as a poet almost at the same time as Crabbe and Cowper. But more exactly contemporary with Rogers than either Crabbe or Cowper, was Robert Burns, the first edition of whose poems appeared in that very year, 1786, which saw Rogers's *début* as an author." In short, Rogers's first appearance as a poet coincides with the opening of that era in our literature in which we still are, and of which Rogers himself is one of the minor stars.

Shortly after his first publication, Rogers travelled in France, where he saw Condorcet and many other men afterwards celebrated in the French Revolution. He also visited Scotland, where he saw Adam Smith, Dr. Robertson, and other celebrities. In 1792 he published his 'Pleasures of Memory,' by which, and by a subsequent volume containing 'An Epistle to a Friend and other Poems,' published in 1798, he "established his place among the men of letters who adorned Great Britain in the closing decade of the last century." During the next fourteen years he gave nothing new to the world, either to increase or to mar his reputation. It was during this long interval of silence that he retired from his hereditary business as a banker (though with an income still derived from the bank, and with the nominal character of partner continued to him) to enjoy, by means of his ample wealth, a leisure absolutely at the command of his private tastes. "The house of Rogers in St. James's-place," it is said, "became a little paradise of the beautiful, where, amid pictures and other objects of art, collected with care and arranged with skill, the happy owner nestled in fastidious ease, and kept up among his contemporaries a character in which something of the Horace was blended with something of the Mæcenas." As he had known Fox, and Horne Tooke, and Dr. Price, and Dr. Priestley, and Lord Nelson, and others of the eminent men of the former generation, so now he gathered round his table the political and social, and literary and dramatic celebrities who had succeeded them—Wordsworth, Scott, Byron, Coleridge, Mackintosh, Southey, Wellington, Chantrey, &c., &c. His own political sentiments were those of moderate Whiggism, but this did not prevent men of all parties from being his guests.

In 1812, Rogers, when his muse seemed dead, added to a republication of his earlier poems, the fragment entitled 'Columbus.' He was then in his fiftieth year. In 1814 his 'Jacqueline' was published in conjunction with Byron's 'Lara,' this being the period of the height of the intimacy between the two so dissimilar poets. "Composed with the same laborious slowness, and polished line by line to the same degree of smoothness," says the writer of a sketch of his life, "his 'Human Life' appeared in 1819. Finally, as the last and much the longest of his productions, came his 'Italy,' the first part of which was published in 1822, in the poet's sixtieth year, and the complete edition of which, illustrated, under the author's care, at an expense of 10,000*l.* by Stothard, Prout, and Tnrner, did not appear till 1836. With the preparation of this exquisite book his literary career may be said to have closed. He still wrote an occasional copy of verses at the rate of a couplet a week; and some of these trifles, including one written as late as his ninety-first year, are preserved in his collected works. But on the whole it was in his character as a superannuated poet, living on the repntation of his past performances, drawing the artists and wits, and men of rank of a more modern age arouud him, and entertaining them with his caustic talk, and his reminiscences of the notahle persons aud events of former days, that he figured in a select portion of London society duriug the last twenty years of his existence." The longevity of the poet was, indeed, one of the sources of the pnblic interest felt for him in his later life. Always fond of open air exercise and of going to public exhibitions, he might be seen strolling about in the parks, or in a stall or hox at the opera, to within a few years of his death. An accident in the streets at last disabled him from walking out; but the extraordinary tenacity of his constitntion enabled him to recover from it, when a younger man might have died. It was not till the 18th of Decemher 1855, when he was in his ninety-third year, and had already for many years heen the literary patriarch of his country, that he departed this life. Wordsworth and many others who had been born after him, and had attained old age under his view, had predeceased him, and left him alone among a generation of juniors.

Rogers will be remembered partly for his poetry, and partly from the peculiar connection in which he stood, in virtue both of his longevity and his social position and hahits, with the miscellaneons phenomena, and especially with the art and literatnre of his time. His poetry is of the highly finished and tasteful rather than the powerful kind. "We have in his works," says a critic, "a classic and graceful beauty; no slovenly or ohscnre lines; fine cahinet pictnres of soft and mellow lustre, and occasionally trains of thonght and association that awaken or recall tender and heroic feelings." His relations to his time were less those of active influence than those of shrewd ohservation and interesting reminiscence. They are best exhibited in the volume of his 'Tahle Talk,' pnblished since his death, by his friend Mr. Dyce.

ROMEINE. [MINERALOGY, *S.* 1.]

ROSE-WOOD. [TRIPTOLOMEA, *S.* 2.]

ROSITE. [MINERALOGY, *S.* 1.]

ROSS, REAR-ADMIRAL SIR JOHN, Knight, was born June 24, 1777, at Balsarroch, Wigtownshire, Scotland. He was the fourth son of the Rev. Andrew Ross, of Balsarroch, minister of the parish of Inch. He entered the navy as a first-class volunteer November 11, 1786, on board the Pearl, 32 guns, and served in the Mediterranean till 1789. From November 7, 1790 till 1791, he served on board the Impregnable, 98 guns, in the English Channel. After being some years in the merchant-service he became, in September 1799, a midshipman on board the Weazel, sloop-of-war, which in that year formed part of the expedition to the coast of Holland. After having served on board several other king's ships, he received his commission as lieutenant, March 13, 1805. While attached to the Surinam, 18 guns, in 1806, he was severely wonnded in four places in cntting out a Spanish vessel nnder the hatteries of Bilbao, for which, in 1808, he was granted a pension of 98*l.* a year, increased in 1815 to 150*l.* He attained the rank of commander February 1, 1812, and was appointed to the Briseis, sloop-of-war, and afterwards to other vessels, till the termination of the war in 1815, dnring which period he performed several valuable services. He married his first wife in 1816.

In December 1817, while in command of the Driver, sloop-of-war, iu Loch Ryan, on the coast of Scotland, he received a letter from Sir George Hope, one of the Lords of the Admiralty, informing him that two ships were to be sent out, to "ascertain the existence or non-existence of a north-west passage;" and inquiring whether he was disposed to nndertake the command of the expedition. Having expressed his willingness to do so, he was directed to repair to London, where he arrived on the 30th of December. On the 15th of January 1818, he received his commission as commander of the Isabella, 385 tons, Lientenant W. E. Parry heing appointed to the command of the Alexander, 252 tons. The two ships departed from the Thames, April 25, 1818. They sailed np the eastern side of Davis's Strait and Baffin's Bay, and returned by the western side. They entered Lancaster Sound, and after proceeding some distance up it, Ross and the officer of the watch thought that they saw "land round the hottom of the Bay, forming a chain of mountains connected with those which extended along the north and south sides." The Alexander being a slow-sailing vessel, was a considerahle distance behind the Isabella. Parry however and his officers could see no monntains, aud were greatly surprised and disappointed when the Isabella turned her head eastwards, and gave the signal for the Alexander to follow the example. Ross named the supposed high land the Croker Mountains, and has laid them down in his chart as a continuous chain closing up the bottom of the supposed bay. This was a mistake, as Parry believed at the time, and as he proved the following year when he sailed throngh Lancaster Sonnd into Barrow's Strait. [PARRY, SIR WILLIAM EDWARD, *S.* 2.] The ships arrived in the Thames on the 14th of Novemher, 1818. On the 7th of December, the same year, Ross was advanced to the rank of post-captain. In 1819 he published 'A Voyage of Discovery, made under the Orders of the Admiralty, in his Majesty's ship Isabella and Alexander, for the purpose of exploring Baffin's Bay, and enqniring into the Probability of a North-West Passage,' 2 vols. 8vo.

After the nnsnccessfnl attempt of Captain Parry to reach the north pole, in 1827, Captain Ross submitted to the Lords of the Admiralty and to the Lord High Admiral the plan of another voyage of discovery to the Arctic seas. The government however did not undertake it; but after some delay a steam-ship was equipped at the expense of Mr. Felix Booth (afterwards Sir Felix Booth), then sheriff of London. The ship was named the Victory, and was fitted with an engine, invented and patented by Messrs. Braithwaite and Ericsson, which proved to be so bad as to be almost useless. Commander James Clark Ross, nephew of Captain Ross, was chosen as second in command. They had an attendant vessel of 16 tons hurden, granted to them by the Admiralty, named the Krusenstern. The Victory, with its attendant, left the Thames May 24, 1829, and using partly her sails, and partly her "execrahle machinery," as Ross calls it, entered Davis's Straits, July 5. Captain Ross expected to find a north-west passage through Prince Regent Inlet, which Parry had discovered, and in which one of his ships, the Fury, had been wrecked. The Victory and the Krusenstern entered the Inlet on the 12th of Angust, and on the following day discovered the wreck of the Fnry. They afterwards took such of her stores as they required, passed farther down the Inlet, and on the 8th of Octoher were frozen up in Felix Harbonr, on the west side of the Gulf of Boothia. They were not released from the ice till the 17th of September 1830, and were able to advance bnt a very short distance before they were again frozen np on the 31st of October. On the 29th of August 1831, the Victory was again released from the ice, bnt on the 25th of September was forced by the pressnre into another harbour. In April 1832 the sailors commenced carrying northwards two boats, with sledges and provisions, and on the 29th of May the vessels were finally abandoned. Captain Ross, in his jonrnal, observes, "In the evening I took my own adieu of the Victory. It was the first vessel that I had ever been obliged to abandon, after having served in thirty-six, during a period of forty-two years." Some of the crew had died, and the rest were mnch weakened, but they struggled on till the 15th of August 1833, when the ice hroke, and they were enabled to set sail in the hoats. On the 26th of Angust, when near the entrance of Lancaster Sound, they came in sight of the Isabella, which was ont on a whaling voyage. The mate in command of a boat that was sent to them, on Captain Ross asking him the name of the vessel, said it was the Isabella of Hull, once commanded by Captain Ross, "on which I stated that I was the identical man in qnestion, and my people were the crew of the Victory." Unshaven as they all were, dirty, dressed in tattered skins, and wasted almost to the bones, the man doubted the statement, and said that Captain Ross had been dead two years. He was easily convinced of his error, and they were received on board the Isabella, with the yards and rigging manned, and with three hearty cheers. The Isabella arrived at Hull on the 18th of September, 1833, and on the 19th Captain Ross reached London by steamer.

While the ships were frozen up in the Gulf of Boothia, many journeys and surveys were made by Commander Ross, and some by Captain Ross himself, chiefly of the coasts and country which they named Boothia Felix. During one of these journeys Commander Ross discovered, June 1, 1831, a spot which he considered to be the north magnetic pole, 70° 5′ 17″ N. lat., 96° 46′ 45″ W. long., where the dipping needle indicated a dip of 89° 59′, or within one minute of the vertical.

On the 24th of December 1834, Captain Ross received the honour of knighthood, together with the companionship of the Bath. Many other honours and several rewards were conferred upon him. In 1835 he published a 'Narrative of a Second Voyage in Search of a North-West Passage, and of a Residence in the Arctic Regions during the years 1829, 1830, 1831, 1832, 1833, by Sir John Ross, C.B., &c., Captain in the Royal Navy, including the Reports of Commander (now Captain) James Clarke Ross, R.N., F.R.S., F.L.S., &c., and the Discovery of the Northern Magnetic Pole,' 4to, with Maps and Plates. In the same year was published an 'Appendix to the Narrative,' &c., also in 4to, chiefly consisting of accounts of the Esquimaux, and of the zoology, the meteorology, and similar matters. On the 8th of March, 1839, Sir John Ross was appointed consul at Stockholm, where he remained till February 1845. In 1850 he went out in search of Sir John Franklin, in a small vessel of 90 tons, named the Felix, and remained one winter in the ice. The government lent him no assistance, and early in 1855 he wrote a pamphlet, in which he complained of his own treatment, and blamed Sir John Richardson and others. The pamphlet is entitled 'A Narrative of the Circumstances and Causes which led to the Failure of the Searching Expeditions sent by government and others for the Rescue of Sir John Franklin,' 8vo.

Sir John Ross's first wife having died in 1822, he married a second, October 21, 1834. By his first wife he had issue one son, who is a magistrate at Cawnpoor in Hindustan. Sir John Ross is the author of 'Letters to Sea-Officers,' 'Memoirs and Correspondence of Admiral Lord de Saumarez,' a 'Treatise on Navigation by Steam,' and other smaller works. He attained the rank of Rear-Admiral July 8, 1851, and died in London, August 30, 1856.

ROSSIA, a genus of Cephalopodous *Mollusca*, named by Professor Owen in honour of Sir John Ross, who found one of the first specimens in the Arctic Seas. It belongs to the family *Teuthidæ*, and has a rounded or oval body, furnished on each side with a suborbicular fin; a large head, with eyes covered by an epidermic expansion, and pierced by a very small hole; arms ten, two tentacular and retractile, eight corneous, flexible, small, and sub-spatulate. There are five species, of which two are British, *R. macrosoma* and *R. Oweni*. These have been both taken in Ireland, and the latter also near Bonchurch, in the Isle of Wight.

ROTIFERA, Wheel-Animalcules, a class of animals placed by Ehrenberg among the *Infusoria*, under the name of *Rotatoria*. They have acquired these names on account of the apparent rotation of the disc-like organs which surround their mouths and which are covered by cilia. These creatures are very minute, and although some of the larger forms may be detected by the naked eye, their organisation can only be seen by the aid of the microscope. We are indebted to Leeuwenhoek for the discovery of their existence, and the first account of their structure and habits. In the 'Philosophical Transactions' for 1702, he gave an account of the discovery of what is now called *Rotifer vulgaris*, one of the most common forms of these animals. He afterwards described another form, *Melicerta ringens*.

Subsequent observers added to the discoveries of Leeuwenhoek, so that in 1824 Bory St. Vincent described 80 species. In 1838 Ehrenberg published his great work on the *Infusoria*, and there describes 189 species of *Rotifera* in 55 genera. Although classed by Ehrenberg with the *Polygastrica*, their organisation is much higher and more complicated, and the only claim they appear to have to be classed together is the fact of their minute size. [INFUSORIA.]

The *Rotifera* are very widely diffused on the surface of the earth. They inhabit both fresh-waters and the ocean, and are found in the cold, temperate, and tropical parts of the earth. Although capable of swimming freely, they are generally found near or attached to the leaves of plants. They are found constantly present in ponds and streams in which *Ceratophyllum*, *Callitriche*, *Valisneria*, and other fresh-water plants abound.

A curious point in their history, which first attracted the attention of Leeuwenhoek, is their power of retaining their vitality after having been more or less perfectly desiccated. This property is undoubtedly possessed by the ova of the lower animals, especially those which are called 'winter eggs;' but it does not appear to be very generally possessed by animals of an organisation as high as the *Rotifera*. Professor Owen states that he has observed the revivification of one of these wheel-animalcules after having been kept four years in dry sand.

The *Rotifera* have usually an elongated form, although some of them are nearly as broad as they are long. In most instances they are covered with a lorica or double envelope, the outer layer of which is often of a horny consistence. Some of them build for themselves a little case, or tube, in which they live, but this must not be confounded with their proper envelope. When the lorica is soft the animal has considerable power of elongating and contracting its body, as seen in *Rotifera vulgaris*. Many of the species are furnished with an elongated tail, which is often supplied with pincer-like organs, to enable them to remain stationary whilst feeding. Those which form tubes are usually fixed.

The rotatory organs, or wheels, are fleshy retractile lobes, covered with vibratile cilia, and are capable of being contracted or expanded. These organs are moved by means of a muscular system. Muscular bands are observed attached to the tegumentary system, and also to that part of the digestive system connected with the rotatory organs. The fibres of these muscles have been observed to present the striæ which are characteristic of voluntary muscles.

The digestive system consists of a mouth, jaws, frequently a dilatation which may be regarded as a stomach, and an intestinal tube which has an anal orifice. The jaws generally consist of two semicircular pieces, to which are attached one or more teeth, which act upon a central plate. The number of teeth varies, and also the form and character of the jaws in different species.

The *Rotifera* have no true circulating or respiratory organs, although Ehrenberg has described certain parts of their structure as such. In most of the species minute vessels can be seen, which terminate in blind sacs or cæca. In these cæcal branches a vibratile body exists, which keeps up a peculiar flickering movement, and it is to these bodies that Ehrenberg has given the name of 'gills.' This system of vessels is regarded by Mr. Huxley and other observers as a true aquiferous or water-vascular system. Connected with the respiratory apparatus, according to Ehrenberg, is an organ projecting from the under surface of the mouth, which he has called the 'calcar,' 'siphon,' or 'respiratory tube.' Ehrenberg describes it as a tube, and supposes currents to pass from it. It is connected with the nervous ganglion. Dujardin and Huxley have not observed either currents or an orifice in this organ.

All observers agree that the *Rotifera* possess a nervous system, which presents itself in the form of a pair of cephalic ganglia, from which proceed nervous filaments. The extent of the development of the nervous system is a subject for further inquiry. The red spots which Ehrenberg calls eyes are subject to considerable variations in appearance. Mr. Huxley says he observed them in young *Lacinulariæ*, but not in adult individuals.

The existence of sexes in a species of *Notommata* has been clearly made out by Mr. Brightwell of Norwich. The male however is much smaller and less developed than the female. All observers agree that the parts to which Ehrenberg has assigned the functions of male organs are not so. Certain caudate bodies have been described by Kölliker as *Spermatozoa*, but their nature is doubted by other observers. Mr. Huxley describes in *Lacinularia* certain "vacuolar thickenings," which he suggests have been previously mistaken for male organs, ganglia, &c. Ovarial organs are easily made out in most of the species. The ova are of two kinds. Mr. Huxley says in *Lacinularia* they consist, first, of bodies which resemble true ova in their origin and subsequent development, and which possess only a single vitellary membrane; second, of bodies half as large again as the foregoing, which resemble the ephippium of *Daphnia:* like it they have altogether three investments, and which do not resemble true ova either in their origin or subsequent development; which therefore probably do not require fecundation, and are thence to be considered as a mode of asexual reproduction. Professor Williamson has described very fully the development of the true ova in *Melicerta ringens,* from which it appears the young after they are hatched do not pass through any of those larval changes which are characteristic of animals both higher and lower in organisation. All the changes which take place occur in the ovum.

The position of the *Rotifera* in relation to the other forms of animal life has been the subject of much discussion. Dr. Grant was one of the earliest writers to take them out of the *Radiata,* and place them amongst *Articulata.* The relation of such forms as *Stephanoceros* to the Ciliobrachiate Polyps is very evident. In his 'Memoir on Lacinularia,' Mr. Huxley gives his reasons for regarding these creatures as permanent larva-forms of *Echinodermata.* After referring to the various forms of *Rotifera,* and their homologous organs, he thus concludes:—

"We may say, therefore, that the *Rotifera* are organised upon the plan of an Annelid larva, which loses its original symmetry by the unequal development of various regions, and especially by that of the principal ciliated circlet or trochal band; and it is curious to remark that, so far as the class of the *Rotifera* can be considered to be made out (approximately), the diœcious forms belong to the latter of the two modifications of the type which have been described, while the monœcious forms belong to the former.

"It is this circumstance which seems to me to throw so clear a light upon the position of the *Rotifera* in the animal series. In a Report in which I have endeavoured to harmonise the researches of Professor Müller upon the Echinoderms, 'Annals of Natural History,' 1851, I have shown that the same proposition holds good of the latter in their larval state, and hence I do not hesitate to draw the conclusion (which at first sounds somewhat startling) that the *Rotifera* are the permanent forms of Echinoderm larvæ, and hold the same relation to the Echinoderms that the Hydriform *Polypi* hold to the *Medusæ,* or that *Appendicularia* holds to the Ascidians.

"The larva of a *Sipunculus* might be taken for one of the *Rotifera;* that of *Ophiura* is essentially similar to *Stephanoceros;* that of Asterias resembles *Lacinularia* or *Melicerta.* The pre-trochal processes of the Asterid larvæ *Brachiolaria* are equivalent to those of *Brachionus.*

"Again, the larvæ of some Asterid forms and of *Comatula* are as much articulated as any *Rotifera.*

"It must, I think, have struck all who have studied the Echinoderms, that while their higher forms, such as *Echiurus* and *Sipunculus,* tend clearly towards the diœcious *Annelida,* the lower extremity of the series seemed to lead nowhither.

"Now, if the view I have propounded be correct, the *Rotifera* furnish this wanting link, and connect the Echinoderms with the *Nemertidæ* and Nematoid worms.

"At the same time it helps to justify that breaking up of the class *Radiata* of Cuvier, which I have ventured to propose elsewhere, by showing that the *Rotifera* are not 'radiate' animals, but present a modification of the Annulose type—belong, in fact, to what I have called the *Annuloida,* and form the lowest step of the Echinoderm division of that sub-kingdom."

Dr. Leydig, in a paper in the 'Zeitschrift für Wissenschaftliche Zoologie,' vol. vi., on the other hand, regards the relations of *Rotifera* as much more with the *Crustacea* than with the Worms. The points of resemblance to which he draws attention are:—

1. Their external figure and hard tegument, which more nearly resembles the carapace of the *Crustacea* than the rings of the *Articulata.*
2. Their muscular structure, which resembles that of many *Crustacea.*
3. Their nervous system resembles that of many *Entomostraca,* as *Daphnia.*
4. The alimentary canal resembles that of *Daphnia.*
5. The resemblance in the character of their ova, the *Entomostraca* having two kinds of ova, as the *Rotifera.*
6. The development of *Rotifera* and Entomostracous *Crustacea* correspond.

Leydig concludes a very able paper by proposing to call the *Rotifera* Ciliated Crustaceans.

With regard to the arrangement of the *Rotifera,* that of Ehrenberg, which is exceedingly defective, has been given under ROTATORIA. From the previous observations on structure it will be seen that this arrangement is open to many objections.

Dujardin, who was one of the earliest observers that pointed out the defects of Ehrenberg's arrangement, has proposed the following:—

Order I. *Systolides.*—Fixed by a pedicel.
 Family 1. Flosculariens.
 Family 2. Melicertians.

Order II. Swimming *Systolides.*
 Family 3. Brachionians.
 Family 4. Furcularians.
 Family 5. Albertians.

Order III. *Systolides.*—Alternately swimming and fixed.
 Family 6. Rotifers.

Order IV. Crawling *Systolides.*
 Family 7. Tardigrades.

Leydig has proposed an arrangement of his own, which is preferable to either of the above.

Ciliocrustacea.

Animals with a jointed body and a ciliary apparatus at the cephalic extremity. The nervous system consisting of a cerebral ganglion, and filaments radiating from it. Digestive and respiratory systems much developed. No heart or blood-vessels. Sexes separate. The female produces 'summer-ova' and 'winter-ova;' many undergoing metamorphosis.

A. Figure between clavate and cylindrical.

I. With elongated transversely-ringed attached Foot.
 1. *Floscularia proboscidea,* Ehrenberg: *F. ornata,* Ehr.; *F. appendiculata,* n. s.
 2. *Stephanoceros Eichhornii,* Ehr.; *S. glacialis,* Perty.
 3. *Œcistes crystallinas,* Ehr.
 4. *Conochilus volvox,* Ehr.
 5. *Lacinularia socialis,* Ehr.
 6. *Limnias ceratophylli,* Schrank.
 7. *Tubicolaria najas,* Ehr.
 8. *Melicerta ringens,* Schrank.

II. With elongated jointed Foot, retractile, like a telescope.
 1. *Callidina elegans,* Ehr.; var. *C. rosea,* Perty; *C. cornuta,* Perty.
 2. *Hydrias cornigera,* Ehr.
 3. *Typhlina viridis,* Ehr.
 4. *Rotifer vulgaris, R. citrinus, R. erythræus, R. macrurus, R. tardus,* Ehr.
 5. *Actinurus neptunius,* Ehr.
 6. *Monolabis conica,* Ehr.
 7. *Philodina erythrophthalma, P. roseola, P. macrostyla, P. citrina, P. aculeata, P. megalotrocha,* Ehr.

III. With elongated jointed non-retractile Foot.
 1. *Scaridium longicaudum,* Ehr.
 2. *Dinocharis Pocillum, D. tetractis, D. paupera,* Ehr.

IV. With a short Foot and long Pedal Forceps.
 1. *Notommata* (?), *N. tigris, N. longisetas,* Ehr.
 2. *Monocerca rattus, M. bicornis, M. valga,* Ehr.
 3. *Furcularia gibba, F. Forficula, F. gracilis,* Ehr.
 4. *Microdon clavus,* Ehr.

V. With short Foot and Pedal Forceps, which are of equal length with or somewhat shorter or longer than the Foot.
 1. *Hydatina senta, H. brachydactyla,* Ehr.
 2. *Pleurotrocha gibba, P. constricta, P. leptura,* Ehr.
 3. *Furcularia Rheinhartii,* Ehr. (probably not a *Furcularia,* but a *Notommata*).
 4. *Notommata tuba, N. petromyzon, N. saccigera, N. copeus, N. centrura, N. brachyota, N. collaris, N. najas, N. aurita, N. gibba, N. ansata, N. decipiens, N. felis, N. parasita, N. tripus,* Ehr.; *N. tardigrada,* n. sp.; *N. vermicularis,* Duj.; *N. roseola, N. onisciformis,* Perty.
 5. *Lindia torulosa,* Duj.
 6. *Synchæta pectinata, S. baltica, S. oblonga, S. tremula,* Ehr.
 7. *Diglena grandis, D. forcipata, D. aurita, D.*

catelina, *D. conara*, *D. capitata*, *D. caudata*, Ehr.
8. *Rattulus lunaris*, Ehr.
9. *Distemma forficula*, *D. setigerum*, *D. marinum*, *D. forcipatum*, Ehr.
10. *Triophthalmus dorsalis*, Ehr.
11. *Eospora najas*, *E. digitata*, *E. elongata*, Ehr.
12. *Cyclogena lupus*, *C. elegans*, Ehr.
13. *Theorus vernalis*, *T. uncinatus*, Ehr

Note.—Ehrenberg's genus, *Enteroplea hydatina*, is the male of *Hydatina senta;* and his *Notommata granularis* stands in the same relation to *Notommata brachionus*, which latter genus however is placed far more correctly under the genus *Brachionus* than under *Notommata*. *Diglena granularis*, Weisse, lastly, is the male of *D. catellina*, Ehr.

VI. Without Foot.
1. *Albertia*.

Includes the *A. vermiculus*, found by Dujardin in the abdominal cavity of the Earthworm, and in the intestine of the *Limacina;* and *A. crystallina*, discovered by Schultze in the intestine of *Nais littoralis*.

B. Figure sacciform.

I. Foot short.
1. *Notommata clavulata*, *N. myrmeleo*, *N. syrinx*, Ehr.
2. *Diglena lacustris*, Ehr.

II. Foot absent.
1. *Notommata Anglica*, Dalrymple; *N. Sieboldii*, n. sp.
2. *Polyarthra platyptera*, Ehr.
3. *Triarthra longiseta*, *T. mystacina*, Ehr.
4. *Ascomorpha helvetica*, Perty; *A. Germanica*, n. sp.

C. Figure compressed.

a. Depressed from above downwards.

I. With a foot.
1. *Euchlanis triquetra*, *E. Hornemanni*, *E. luna*, *E. macrura*, *E. dilatata*, *E. Lynceus*, Ehr.; *E. emisetata*, n. sp.; *E. bicarinata*, n. sp. (*E. bicarinata*, Perty, I consider a *Salpina*.)
2. *Lepadella ovalis*, *L. emarginata*, *L. salpina*, Ehr.
3. *Monostyla cornuta*, *M. quadridentata*, *M. lunaris*, *M. carinata*, Ehr.
4. *Metopidia lepadella*, *M. acuminata*, *M. triptera*, Ehr.
5. *Stephanops lamellaris*, *S. muticus*, *S. cirratus*, Ehr. (Dujardin declares that *S. muticus* is *Lepadella ovalis*.)
6. *Squamella bractea*, *S. oblonga*, Ehr.
7. *Notogonia Ehrenbergii*, Perty.
8. *Noteus quadricornis*, Ehr.
9. *Brachionus pala*, *B. amphiceros*, *B. urceolaris*, *B. rubens*, *B. Mülleri*, *B. brevispinus*, *B. Bakeri*, *B. polyacanthus*, *B. militaris*, Ehr.
10. *Pterodina patina*, *P. elliptica*, *P. clypeata*, Ehr.

II. Foot absent.
1. *Anurea quadridentata*, *A. squamula*, *A. falculata*, *A. curvicornis*, *A. biremis*, *A. striata*, *A. inermis*, *A. acuminata*, *A. foliacea*, *A. stipitata*, *A. testudo*, *A. serrulata*, *A. aculeata*, *A. valga*, Ehr.

β. Laterally compressed.

1. *Salpina mucronata*, *S. spinigera*, *S. ventralis*, *S. redunca*, *S. brevispina*, *S. bicarinata*, Ehr.
2. *Mastigocerca carinata*, Ehr.
3. *Monura colurus*, *M. dulcis*, Ehr.
4. *Colurus uncinatus*, *C. bicuspidatus*, *C. caudatus*, *C. deflexus*, Ehr.

ROUTH, REV. MARTIN JOSEPH, D.D., was born September 15, 1755, at South Elmham, near Beccles, in Suffolk. His father was the Rev. Peter Routh, who was rector of South Elmham from 1753 to 1764, when he resigned it for Beccles. In 1774 he became master of Beccles grammar-school. Martin Joseph Routh, after having been educated under his father, matriculated as a battler at Queen's College, Oxford, May 31, 1770, but in July, 1771, was elected a demy of the college of St. Mary Magdalen. Having taken his degree of B.A., he became a Fellow in July, 1776, and on the 23rd of October, in the same year, took his degree of M.A. In 1781 he was appointed college librarian; in 1783 he was elected senior proctor of the university, and in 1784 junior dean of arts. He proceeded B.D. July 15, 1786, and in 1789 was appointed one of the college bursars. He was elected president of Magdalen College April 11, 1791, on the resignation of Dr. Horne, bishop of Norwich.

Dr. Routh's first literary publication was an edition of the Euthydemus and Gorgias of Plato, 'Platonis Euthydemus et Gorgias, recensuit, vertit, Notasque suas adjecit Martinus Josephus Routh, A.M., Collegii D. Mariæ Magd. Oxon. Socius,' 8vo, 1784.

Having taken his degree of D.D., Dr. Routh in 1810 became rector of Tylehurst, near Reading, in Berkshire, whither he used to retire occasionally for the benefit of his health, and to enjoy the vacation allowed him by the statutes of his college. In 1814 he published the first two volumes of his 'Reliquiæ Sacræ; sive Auctorum jam Perditorum Secundi Tertiique Seculi post Christum natum quæ supersunt,' 8vo. The third volume was published in 1815. In 1820 he married Eliza-Agnes, daughter of J. Blagrave, Esq., of Chalcot Park, near Tylehurst. In 1823 he edited Bishop Burnet's 'History of his Own Times.' In 1832 he published 'Scriptorum Ecclesiasticorum Opuscula,' 8vo, and a second edition in 1840. In 1833 he published an improved edition of Burnet's 'History of his Own Times.' In 1846 appeared four volumes of a new edition of the 'Reliquiæ Sacræ,' to which he added a fifth volume in 1848. He died December 22, 1854, at the age of ninety-nine, and was buried in the vault of the chapel of Magdalen College.

ROYLE, JOHN FORBES, M.D., a distinguished botanist, was educated for the medical profession, and was a pupil of the late Dr. Anthony Todd Thomson, from whom he acquired that love of botany and taste for materia medica for which he was afterwards so distinguished. After passing the usual medical examinations in England, he entered the service of the East India Company. In Hindustan he worked with great diligence in the collection of plants, and especially in acquiring a knowledge of their medical properties and history. He wrote a work 'On the Antiquity of Hindoo Medicine,' in which he included a great amount of valuable information on the subject of the practice of medicine amongst the Hindoos. Having spent a large portion of his time in the Himalayas, where he was superintendent of the East India Company's botanic garden at Saharunpoor, he was enabled to form a large collection of plants, and to make observations on other departments of natural history. On his return to England he published his great work, entitled 'Illustrations of the Botany and other Branches of the Natural History of the Himalaya Mountains.' This work, which appeared in parts, was commenced in 1839, and finished in two volumes 4to. It contained a large amount of valuable information on the natural products of India, especially those which are useful in medicine and the arts. Although Dr. Royle did not practise medicine, his knowledge of drugs and their uses pointed him out as a fit and proper person for the chair of Lecturer on Materia Medica at King's College, London, a position he occupied till the year 1856. The results of his experience in this department of knowledge were given in a volume entitled a 'Manual of Materia Medica,' which has been since the time of its publication a text-book in medical schools. Dr. Royle's botanical knowledge was often employed on the productive resources of

India. He several times read papers on the cultivation of tea and cotton in India at the meetings of the British Association for the Advancement of Science. His activity at those meetings led to his appointment for a short time as co-secretary with General Sabine of that association. In 1840 he published an 'Essay on the Productive Resources of India.' In 1855 he also published a volume on 'The Fibrous Plants of India,' pointing out those which could be made more especially available for the manufactures of Great Britain. He took an active part in the Great Exhibition of 1851, especially in arranging the East Indian department. He was a Fellow of the Royal and Linnæan societies, and held an appointment in London in connection with the East India Company. He died January 2, 1858, at his residence, Heathfield Lodge, Middlesex.

RUSSIA. The following table, giving the popular divisions, area, and population of the Russian Empire, is taken from the Baron de Haxthausen's recent work on Russia:—

Divisions.	Area in Square Miles.	Population.	
		1846.	1852.
Great Russia	328,781	19,220,900	20,403,371
Little Russia	150,141	11,093,400	11,775,865
New Russia	96,636	3,070,700	3,259,612
White Russia	70,399	2,767,200	2,937,436
Western Provinces	47,076	2,704,300	2,870,667
Baltic Provinces	36,616	1,659,800	1,761,907
Northern Provinces	536,226	1,338,300	1,420,629
Ural Provinces	447,788	10.146,000	10,770,181
Cossak Districts	123,776	1,089,700	1,156,736
Poland	49,230	4,857,700	5,156,543
Finland	135,808	1,412,315	1,499,199
Total in Europe	2,022,477	59,360,315	63,012,146
Caucasian Provinces	86,578	2,850,000	
Western Siberia	2,681,147	3,500,000	
Eastern Siberia	2,122,000	237,000	
American Russia	371,350	61,000	
Total out of Europe	5,261,075	6,648,000	6,648,000
Totals	7,283,552	66,008,315	69,660,146

In respect to race, the Baron gives the following approximations in round numbers:—

1. Slavonic races—Russians, 49,000,000; Poles, 6,500,000; Lithuanians and Lettes, 2,000,000; Bulgarians and Illyrians, 500,000: total, 58,000,000.

2. Other races—Germans, 650,000; Dacian Romans (Wallachs), 750,000; Tschudes, 3,400,000; Tartars, 2,150,000; Mongols, 250,000; Munshns, 100,000; Hyperboreans, 200,000; Caucasian tribes, 2,750,000; Greeks, 70,000; Jews, 1,600,000; Gipsies, 30,800; Miscellaneous, 50,000: total, 12,000,000.

The revenues of Russia, of which we have no recent return, amount to about 350,000,000 silver rubles, of which 45,300,097 silver rubles were derived from the domains of the crown. The debt in January, 1856, amounted to 1,042,455,179 silver rubles. (The value of the silver ruble is about 3*s.* 4*d.*)

The state of the army and navy of Russia, in the year 1857, is given in the article MILITARY AND NAVAL FORCES, *S.* 2.

RUSTSCHUK, a fortified town in Bulgaria, capital of an eyalet in European Turkey, is situated near the right bank of the Danube, about 40 feet above the level of the river, 40 miles S. from Bukharest, and has a population variously estimated at from 20,000 to 40,000. The Danube opposite Rustschuk is nearly two miles wide, but its surface is broken by a number of islets and shallows, and the banks are low. From a distance Rustschuk has an agreeable appearance, with its white chimneys and graceful minarets, rising up from among the foliage of extensive orchards. This impression however is removed by a view of the interior, which presents dirty ill-paved streets, flanked by low wooden houses, most of which stand in little courts or gardens. The Pasha's konak, or palace, and the mosques, are the only buildings worth notice. The town has baths, a bazaar, and about 3000 houses; it has also some trade with Vienna in cloth, indigo, corn, wine, &c. A harbour for river craft is formed below the town by a small recess of the river, which is sheltered towards the north-east by a cape crowned by a bastioned citadel. Rustschuk is commanded by heights to the south-west, on which five detached bastioned earth-works have been recently thrown up. The town itself is surrounded by an earthen rampart, which presents eight bastioned fronts, revetted half-way up with masonry, and surrounded by a moat and counterscarp. The front towards the river is irregularly fortified. The Russians took Rustschuk after enormous losses of men in 1811; it opened its gates to them in the invasion of 1828. The fortified enceinte of Rustschuk measures four miles. On the left or Wallachian bank of the Danube, opposite to Rustschuk, is *Giurgevo*, which was originally the fortified tête-de-pont to Rustschuk. Its defences were razed in carrying out the treaty of Adrianople, but have been since repaired. A ferry connects the two places. A tall clock-tower stands in the principal square. One of the islands in the Danube is fortified. A pentagonal fort built with stone defends the harbour. Beyond this fort the town of Giurgevo is built; its enceinte presents a semicircle towards Wallachia. Giurgevo trades with Austria in the produce of the country, and has about 7000 inhabitants. In the wars between Russia and Turkey, Giurgevo has been frequently the scene of hard fighting between the two nations. The Russians took it in 1711, and completely defeated the Turks in the vicinity the same year; they took it again in 1810. The Russians occupied Giurgevo in 1854, and were defeated by the Turks under its walls on July 7 of that year.

RUTHEN. [DENBIGHSHIRE.]

RYDE. [WIGHT, ISLE OF.]

S

SABADILLENA. [CHEMISTRY, *S.* 1.]

SACCHARIC ACID. [CHEMISTRY, *S.* 1.]

SACCHARITE, a Mineral resembling granular felspar, of a greenish-white colour, and with the constitution of *Leucite*. It is found in Silesia.

SACCHULMIC ACID, SACCHULMIN. [CHEMISTRY, *S.* 1.]

SACLACTIC ACID. [CHEMISTRY, *S.* 1, under *Mucic Acid.*]

SACRAMENTO CITY, the capital of Sacramento County, State of California, United States of North America, is situated on the left bank of Sacramento River, at the confluence of American Fork, in 38° 34′ N. lat., 121° 40′ W. long., about 150 miles N.E. from San Francisco. The city was founded in the spring of 1849; in 1850 it contained 6820 inhabitants, of whom only 474 were females; and at the State Census in 1852 the population was above 10,000.

Sacramento City owes its origin to the discovery of gold, which gave so remarkable an impetus to California generally. It was on the south branch of American Fork, about 50 miles from Sacramento City, that gold was first discovered. The growth of the city was, from its foundation, remarkably rapid. In April 1849 there were only four houses on the site; in the following year it was a large and regularly laid-out town of nearly 7000 inhabitants. The city stands in the midst of a fine farming country, and about 30 miles from the commencement of the gold diggings. Occupying a low site, it has been found necessary, in order to protect it from inundations, to which it is liable in the rainy season, to construct a levee along the bank of the river. The streets of the city cross each other at right angles; those running east and west are designated by the letters of the alphabet, and those running north and south by the numerals. Many of the streets are lined with oak and sycamore trees, some of large size, imparting a considerable degree of picturesqueness to their general appearance. The city contains Episcopalian, Presbyterian, Methodist, Baptist, Roman Catholic, and other churches, schools, numerous stores, above 150 eating saloons and hotels (some of which are of a very costly and splendid character), several steam-mills, and a few manufactories. Like San Francisco, Sacramento City has suffered severely from several very destructive fires; but the parts of the city which were destroyed have always been quickly rebuilt, and generally in an improved style. Several daily and weekly newspapers are published here. Regular daily communication is maintained with San Francisco by steam-boats.

SADDLEWORTH. [YORKSHIRE.]

SAGUINUS. [SAGOUIN.]

SAGUS, or SAGUERUS, a genus of Plants belonging to the family of Palms. The leaves are pinnated; the flowers monœcious; the spadix branched, without any common spathe, but with numerous partial ones; the fruit hard, shining, its surface divided into numerous rhomboidal spaces. The species are natives of the islands of the Indian Archipelago, and yield sago.

S. lævis, the true Sago-Palm, has the petioles and spathes unarmed. This palm furnishes most of the sago sent to Europe.

S. Rumphii has the petioles and spathes guarded by strong prickles. According to Martin, the sago yielded by this plant is used principally in India, and seldom exported.

SAINT-ARNAUD, MARÉCHAL LEROY DE, was born in Paris, of poor parents, on the 20th of August 1798. Having entered the Royal Body-Guards at the age of sixteen, he rose to the rank of sub-lieutenant in the infantry of the line in 1818. Owing to some youthful vagaries, he left the army shortly after, and embraced the theatrical profession, when he first performed at the suburban Théatre des Batignolles. In this new vocation he continued upwards of ten years, but the revolution of July revived his taste for martial life; he returned to the army in 1831, and having entered the 64th regiment as sub-lieutenant, was made full lieutenant within six weeks. The insurrection of the partisans of the Duchesse de Berri, in La Vendée, soon afforded him an opportunity of earning the favourable notice of Marshal Bugeaud. He was subsequently appointed to the charge of the citadel of St. Blaye, where the Duchesse de Berri was confined—a post in itself, from the circumstances, somewhat painful to an honourable man, and his conduct in it incurred for him considerable odium.

In 1836 Saint-Arnaud was sent to join the army in Algiers, with the rank of captain; he behaved with much gallantry at the siege of Constantina, and received the decoration of the Legion of Honour. The brilliant courage he displayed in these campaigns obtained for him the rank of commandant of the 18th regiment of infantry in 1840, but his erratic disposition induced him to quit it to enter the Zouaves the same year. In 1842 he was created lieutenant-colonel; and in 1844, on the recommendation of Bugeaud, he became colonel of the 32nd regiment. During the next three years he was constantly in the field; his reputation increased, and he was made major-general in 1847. In 1850 he was appointed to command the province of Constantina, which was then in a very unsettled state; but he subdued the whole country within the year. In the early part of 1851 General Saint-Arnand was despatched on an expedition against the Kabyles, which was entirely successful, and was considered one of the most brilliant campaigns of the French in Algeria. His little army did not amount to 7000 men, and with this he overran that rugged country, and in spite of a desperate resistance he conquered the whole province. This was the service which fixed upon him the attention of the President of the French Republic.

Saint-Arnaud returned to Paris in the autumn of 1851, as general of division. Louis Napoleon at once took him into his confidence, giving him the command of the second division of the army of Paris immediately after his arrival, and then appointing him minister of war. He acted cordially with the Prince-President: "Nothing," he wrote to his mother, November 19, 1851—"nothing in this world is wanting, but to go straight forward and be bold." In the famous coup d'état of the 2nd of December following he was the President's chief adviser and instrument. Honours now accumulated upon him: he was made marshal of France, then a senator, and received the grand cross of the Legion of Honour in 1852. His health had gradually declined under so harassing a life; yet he so strongly solicited the command of the French army intended for the east, at the outbreak of the war with Russia, that his request was granted. The events of that war are so well known that we need not dwell upon them. It will be enough to say that Marshal Saint-Arnaud entered upon it with the utmost eagerness. He evidently felt that a splendid chance was afforded of professional distinction. For a time his impetuosity enabled him to bear up under his constantly-increasing malady. The landing in the Crimea, which he calls his "favonrite idea," he tried to the utmost to hasten forward; and fearing at last that his life was ebbing, he insisted on forward movements, regardless of the opinions of his colleagues. On the morning of September 20, 1854, Marshal Saint-Arnaud mounted his horse with great difficulty, and by the constant exercise of great spirit sustained all the fatigues of command during the battle of the Alma. He exhibited the same energy in his despatch after the victory, but the intensity of his feelings is only fully seen in his letters to his wife, published in the collection referred to below. But the effort proved too much for his remaining strength: his malady increased daily, and on the 27th he was obliged to embark on board the Berthollet to return to Constantinople. He died on the 29th of September, 1854, whilst yet on his passage.

The career of Marshal Saint-Arnaud, almost up to the outbreak of the Russian war, shows him too much in the light of a daring and not very scrupulous adventurer; and he did not live long enough, when a nobler field was opened to his ambition, to show whether he possessed the abilities of a great general. But while in his last days, as in his earlier, he exhibited the most brilliant and dashing courage, combined with judgment and energy, devotion to his duty was never so strongly evinced as at the close of his career. Two volumes of his private letters have been published by his brother, 'Lettres du Maréchal de St.-Arnaud,' Paris, 1855, which, though exhibiting many suppressions, give much curious information respecting the last twenty-five years of his remarkable career.

SAINT HYACINTHE. [Canada, *S.* 2.]

SALICARIA, a genus of Birds belonging to the family *Sylviadæ*, and separated by Mr. Selby from the genera *Locustella* and *Sylvia*. "The rounded form of the tail," says Mr. Yarrell, "the outer feathers being much shorter than those in the middle, and the partiality of these birds to moist situations, particularly conspicuous in the Sedge and the Reed Warblers, appear to separate them from the Sylvan Warblers." There are four British species of this genus.

S. locustella, the Grasshopper Warbler, is so called from its very peculiar and almost incessant cricket-like note. It comes to this country from the south, and appears about the middle of April, and departs in September. It is a shy bird, keeping at the bottom of a hedge, and creeping along more like a mouse than a bird. It feeds on small snails, slugs, and insects.

S. phragmites, the Sedge-Warbler, Sedge-Bird, is found during the summer in thick patches of reeds or willows, in marshes, or on the low sides of rivers, or on islands. Like the last, it is a summer visitor, arriving in April and leaving in September. White of Selbourne first observed its power of imitating the notes of other birds, as well as of its occasionally singing at night. It measures 4¾ inches, and is somewhat a less bird than the last.

S. luscinoides, Savi's Warbler, Willow Locustella. It is a rare bird in this country, but like the group to which it belongs, it frequents moist and shaded situations, among reeds and bushes, near water.

S. arundinacea, the Reed-Warbler, the Night-Warbler, the Reed-Wren. It is always found in company with the Sedge-Warbler, but is not so numerous in this country as that bird. It arrives here in April and departs in September. It sings usually in the day, but sometimes at night. "The character of the beak, the entire absence of the buffy white stripe over the ear-coverts, and the uniform colour of the whole of the upper surface of the body of this bird, distinguish it from either the Grasshopper-Warbler or the Sedge-Warbler, with both of which however it has many habits in common." [Sylviadæ.]

(Yarrell, *History of British Birds.*)

SALICIN. [Chemistry, *S.* 1.]

SALOP. [Shropshire.]

SALSIFY. [Tragopogon.]

SALTA, the most northern of the provinces of the Argentine Confederation, South America, extends between 22° and 26° 30′ S. lat., 61° and 68′ W. long. It is bounded S. by the province of Tucuman, E. by the Gran Chaco, N. and W. by the republic of Bolivia. The area is about 56,000 square miles; the population is about 60,000. It has been described generally under Plata, La, and we therefore only add the following more recent information.

The country possesses a remarkable variety of soil, and a climate ranging from extreme heat to the most intense cold, permitting the cultivation of almost every kind of natural production. But the country is too thinly peopled, the difficulties of transit are too great, and the inhabitants have too little energy and industry to allow the resources of the country to be other than most imperfectly developed, if even the country itself were in a less disturbed state. The inhabitants are now chiefly settled in the larger towns, and in the valleys of the lesser affluents of the Vermejo and Salado. The cereals grown are wheat and maize, which are raised in considerable quantities in the valleys of the south, for the supply of the other parts of the province. The vine is extensively cultivated in the same district, and a good deal of common wine made and exported to the neighbouring provinces. The cocoa plant is cultivated in the department of Oran. In the valleys of the Jujuy and its tributaries tobacco and the sugar-cane are grown in sufficient quantities to supply the whole of Salta, and to furnish exports to the rest of the upper provinces, and also to Chili. Cotton and indigo are also cultivated to some extent; and the cochineal insect furnishes a source of profit. Along the valley of the Vermejo there are very extensive forests of valuable timber-trees, as well as the palm, the carob, and other trees which furnish the natives with fruit and a substitute for bread, the maté plant, &c. The cochineal cactus and the aloe are found in every direction. One of the chief sources of wealth to the province has always been the rearing of mules, which are bought in the southern provinces in a very lean state, acquire strength in the rich pastures of Salta, and are sent to Peru and Bolivia in large numbers. Before the revolution from 50,000 to 60,000 mules were annually exported from Salta to Peru alone, but the trade with Peru has greatly declined. In the colder parts of the province alpacas, vicuñas, chinchillas, and guanacos are indigenous. The mountains contain gold, silver, copper, and other metals. The mines have not proved very successful; but the inhabitants of the valleys obtain considerable quantities of gold, after the rains, from the rivers, and in the alluvial soil which has been left by the receding waters. In the desolate country known as the Desplobado are extensive saline plains, from which the inhabitants of the adjacent districts obtain large quantities of salt, which they carry for sale to the towns of Salta and Jujuy.

Like the other provinces of the Argentine Confederation, Salta is a federal state, owning however little more than nominal dependence upon the central government. The executive power is vested in a governor elected by the junta or provincial assembly.

Salta, the capital of the province, is situated on the left bank of the Sileta, in the valley of Chicnana, in 24° 51′ S. lat., 64° 48′ W. long. Population about 8000. The streets are regular, but narrow. In the central square are the government-house, the cathedral, and other public buildings. *Jujuy* is built in an extensive basin, surrounded by high mountains, on the banks of the Rio de Jujuy. Population about 3000. It has some traffic, as the carriage-road leading to Bolivia terminates here, and the goods must be transported farther north on mules. At Jujuy begins one of the most extraordinary mountain-passes in the world. A narrow valley extends from the town to the summit of the range called Abra de Cortaderas, a distance of 90 miles by the road. The highest summit of this road appears to have an elevation of between 11,000 and 12,000 feet. *Oran* is a small town, founded in 1793, on the Rio de Tarija, about 30 miles above its junction with the Rio de Jujuy. As the centre of a very fertile district, Oran is a place of considerable trade.

SALTATORES. [Araneidæ, *S.* 2.]

SALVANDY, NARCISSE-ACHILLE, COUNT DE, was born at Condom, in the department of Gers, June 11, 1795, but was sent to Paris in early youth, and educated at the Lycée Napoleon. He enlisted as a volunteer in 1812, and served with so much distinction during the campaigns of 1813-14, that on the 6th of April, 1814, the emperor bestowed upon him, with his own hands, the decoration of the Legion of Honour.

After the restoration of the Bourbons, in 1814, M. de Salvandy was made an officer of the royal household, and in March 1815, attended Louis XVIII. to the frontiers. About this time, in his twentieth year, he began that long series of argumentative pamphlets, for which he afterwards became so celebrated, by the publication of two brochures, one called 'Mémoire sur les Griefs et les Vœux de la France,' the other 'Observations sur le Champ de Mai.' In 1816 he brought out 'La Coalitiòn et la France,' in which he displayed considerable talent. It produced a great sensation in more than one court.

In 1819 he became a member of the conseil d'état, holding the office of Maître des Requêtes. But he was incapable of submission to any control. The measure presented by M. Barthélémi, on the 'Loi des Electeurs,' appeared to him an organic change unfavourable to the constituency; he therefore published his 'Vues Politiques,' in which, regardless of place and emoluments, he fully described the nature of political parties, their power, influence, and objects. This act of independence was followed by several others, as the restored family seemed to advance in their system of aggression upon public liberty, until the startling pamphlet 'Sur les Dangers de la Situation présente,' produced a rupture between him and the ministry.

In 1824 M. de Salvandy went to Spain, and shortly afterwards married Mademoiselle Oberkampf. The result of this journey was a work of more than usual length, 'Don Alonzo, ou L'Espagne,' comprising a full account of the Peninsula, and its various political changes. It was in the course of the same year, 1824, that he began to write his well-known articles in the 'Journal des Débats,' the most conspicuous of which at that period were entitled 'Les Funérailles de Louis XVIII.,' and 'Le Nouveau Règne et l'Ancien Ministère,' recommending a course of constitutional policy to Charles X. Like Châteaubriand, Armand Carrel, and other independent political writers, he steered a middle course between the opposite parties, and flattered neither of them. Ever constant to his principles, and equally averse to arbitrary rule and anarchical divisions, he maintained for forty-two years the same moderate opinions of equity and justice. In all his writings he took for his basis the maxim—there is no security for France but in constitutional monarchy. His style is energetic, and his arguments are expressed in warm language; yet he never abandons the fundamental principle; notwithstanding the strong measures adopted by the French government to embarrass him, especially by the revival of the 'censure.'

In 1827, during the short liberal ministry of M. de Martignac, M. de Salvandy was created Conseiller d'Etat, on which occasion Charles X. said to him: "You must admit that you have sometimes gone a little too far." But when the Polignac cabinet was formed, in 1829, he resigned immediately.

From 1830 to 1848, during the whole reign of Louis Philippe, M. de Salvandy continued to publish his separate pamphlets, and his articles in the 'Journal des Débats.' Amongst these few have been more admired than his 'Seize Mois; ou la Révolution de 1830 et les Révolutionnaires.' M. de Salvandy became a deputé in 1832, when he observed the same course of moderate and liberal policy as in his writings. He was more than once called to fill some of the highest ministerial offices of state, during the reign of the Citizen King. He likewise became a member of the French academy, and was created a count. After the coup d'état, in December 1851, he withdrew, like most of his eminent fellow-countrymen, into comparative retirement. He died December 15, 1856, at the age of sixty-one.

SAN DIEGO. [California, *S.* 2.]

SAN FRANCISCO, a city, port of entry, and the capital of San Francisco county, State of California, United States of North America, is situated on a narrow neck of land forming the southern side of the entrance to San Francisco Bay, and between that bay and the Pacific Ocean, in 37° 47′ N. lat., 122° 26′ W. long. The population, which was only 150 in 1845, was omitted from the Census of the United States in 1850; but in 1852 it was, according to the State Census, 34,776, of whom only 5245 were females. The government of the city is vested in a mayor, recorder, aldermen, county assessors, street commissioners, &c.

The sudden rise of the present city of San Francisco, is perhaps the most remarkable on record. But the place is not devoid of interest in other respects, being one of the earliest settlements of the old Spaniards for the charitable purpose of converting the Indians to Christianity. Their fort, or stronghold, called the Presidio, was fixed near the entrance of the bay, on the southern shore, about half a mile inland. It was a square inclosure, the sides of which were about 300 yards in length, surrounded by a mud wall about 15 feet high, pierced for musketry. Against the inner sides of the walls were the dwellings of the settlers, the centre being left clear for exercise and military evolutions. The walls are now in ruins. From this primary settlement, which was termed the Mission Dolores, emanated the five following missions, which were established in various parts of the adjacent country under the protection of the Presidio:—San Francisco, founded in 1776; Santa Clara, 1777; San José, 1797; San Francisco Solano, 1823; San Rafael, 1827.

The town, which arose in connection with the mission of San Francisco, was called Yerba Buena, or Good Herb, from a plant used as a beverage, and also as a medicine, which grew abundantly in the vicinity. From its foundation the mission continued in a very flourishing condition till about 1831, when in the political disturbances which distracted Mexico, the Indians were driven away from Yerba Buena, and the settlement soon fell to ruin. In 1839 the site was regularly laid out as a town, which, however, six years later, as already mentioned, only contained 150 inhabitants. But about this time it began to attract the attention of adventurers from the United States, and soon became in effect an American settlement, though still nominally belonging to Mexico; it was not formally ceded to the United States till 1848. A local government was established, similar to that which prevails in the towns of the United States; an American school was founded, and in January, 1847, an 'ordinance' was issued by the town council directing that the name of the town should henceforth be San Francisco, instead of Yerba Buena. Towards the end of 1847 the first discovery of gold was made, and soon after San Francisco, the port of California, experienced the most extraordinary influx of adventurers ever heard of, accompanied by an unparalleled rise in the cost of provisions and the value of property. The remarkable scenes which were subsequently witnessed in the town, or city as it had now come to be designated, its rapid extension in every direction, the reckless habits and almost extravagant energy of the strangely diversified population, are too familiar to need more than a word of reference. Nor less well known are the terrible conflagrations which have so often laid large portions of the city in ruins, to be however restored with surprising rapidity to far more than its previous condition, the opportunity afforded by every fire being seized upon to rebuild the destroyed places on a larger, more costly, and substantial scale.

The magnificent bay of San Francisco, on which the city stands is described under California, *S.* 2. The city is built on the western side of the bay, at the extremity of the peninsula, which forms the southern side of the entrance to the bay. It occupies an inclined plane of about half a mile in extent from the hills in the rear of the city. The houses have been carried far up these hills, and a shallow portion of the bay lying between two projecting points of land in front of the city, has been filled up and built upon. The city is regularly laid out, with broad streets intersecting at right angles, and squares at convenient distances. The streets are now tolerably well paved, and many of them are laid with planks; well lighted, and watched; and arrangements have been made for their sanitary supervision. Several of the public buildings and churches are comparable with those in most of the cities of the United States, but the city is still so entirely in a transition state, that the most accurate account of to-day would be inapplicable a few months hence. Besides the churches there are several schools, general and marine hospitals, and numerous benevolent institutions. The warehouses, stores, and shops, are on a capacious scale, and abound with every variety of articles of necessity and luxury. The hotels are among the most noticeable features of the place as it now is, and some of them are carried on in a very costly manner. There are also numerous eating and drinking saloons, theatres, concert-rooms, lyceums, and other places of amusement or dissipation, including not a few gaming-houses of various grades. The manufactures of the city are comparatively inconsiderable.

The commercial facilities of San Francisco are very great. The bay, which is 8 miles wide, affords excellent anchorage, and is the natural outlet, not only for the almost unparalleled mineral riches of California, but of a district the extreme fertility of which has as yet hardly begun to be developed. The city fronting the bay is now lined with wharfs and quays, and vessels of great burden can lie alongside to land and take in their cargoes. Steamers are in regular and constant communication with New York and the Atlantic ports, and with the ports of Central America. The character and extent of the commerce of San Francisco have been given pretty fully under California, *S.* 2, and it is needless to repeat the details here. In the years subsequent to that there given, there has been a considerable, though fluctuating, increase in the number and tonnage of vessels arriving and departing at San Francisco, but the returns are informal and incomplete. The annual clearances of shipping from the port at present, average about 500,000 tons; the entrances somewhat less. The amount of gold dust annually shipped from San Francisco exceeds in value 50,000,000 dollars. Up to the close of 1853 there had been deposited at the United States mint and branches, gold from California amounting to 207,316,177 dollars, nearly all of which had passed through San Francisco; besides which a very large quantity has been received in this country and elsewhere direct from San Francisco. Coal is found near the city; and there are quarries of good limestone. Eight or ten daily and several weekly newspapers are published in the city.

SAN JOSÉ. [California, *S.* 2.]

SAN JUAN DE LA FRONTERA, one of the provinces of the Argentine Confederation, South America, extends between 30° 30′ and 32° S. lat.; 67° 30′ and 70° 20′ W. long. It is bounded S. by the province of Mendoza; E. by that of San Luis; N. by La Rioja; and W. by the republic of Chili. The area is about 40,000 square miles. The population is estimated at from 22,000 to 25,000.

The province lies to the north of Mendoza, which it resembles in its general character and productions. [Plata, La, *States of*.] The surface of the country is described generally under Plata, La. Extending along the eastern declivity of the Andes, San Juan comprehends the northern part of the Vale of Uspallata and a large portion of the plain which separates the Paramilla range from the mountains of Cordova, and contains the Lakes of Guanacache. The Vale of Uspallata is barren and nearly uncultivated. The soil of the plain consists of sand, and is without grass, but covered with stunted prickly trees of the mimosa kind. It is quite barren, and produces no kind of grain or vegetables, except where it is irrigated by the sweet water of the Rio de San Juan and some of its minor affluents. This irrigation renders the land exceedingly fertile; without any other manure, they produce most plentiful crops of wheat and maize. The ordinary crops of wheat are fifty for one, in better lands eighty or a hundred for one, and at Augaco, about 5 leagues north of the city of San Juan, they have been two hundred and even two hundred and forty. The distance from a market and the difficulties attendant on the transport of heavy goods through desert plains, greatly diminish the value of this fertility. But as fruit trees, especially vines, succeed very well in this soil, wines and brandies are exported to a considerable amount. In the northern district, called Jacbal, there are some gold-mines, whose produce is however not very great. Like the other provinces of the Argentine Confederation San Juan is a federal state, owning little dependence on the central government. The executive power is vested in a governor, elected by the junta, or provincial assembly.

San Juan, the capital of the province, is situated on the Rio de San Juan, in 31° 4′ S. lat., 68° 57′ W. long.: population about 7000. It contains the government house and other public buildings, and has considerable commerce, being the mart whence the wines and brandies of the province are exported, and from which foreign goods are distributed to the interior. In 1833 the city was nearly destroyed by an innudation of the Rio de San Juan, by which three churches and several other public buildings, with numerous private houses, were thrown down, and many of the inhabitants lost their lives.

SAN LUIS DE LA PUNTA, one of the provinces of the Argentine Confederation, South America, extends between 31° and 35° S. lat., 64° and 67° 30′ W. long. It is bounded S. by the province of Buenos Ayres, E. by Cordova, N. by La Rioja, N.W. by San Juan, and S.W. by Mendoza. The area is about 36,000 square miles. The population is about 20,000.

The country included within this province is described under PLATA, LA, *States of*. It comprehends that immense tract of country which extends between the provinces of Mendoza on the west and Cordova on the east. Its north-western part runs northward to the border of the Great Salina, and it reaches southward to the country of the Ranqueles Indians, but now claimed by the province of Buenos Ayres. No part of it possesses any considerable degree of fertility. The greatest number of the widely-separated and isolated settlements, consisting mostly of estancias, or cattle-farms, occur along the road leading from Buenos Ayres to Mendoza, in the hilly country, where tracts of grassy land alternate with ridges of hills and sandy deserts overgrown with mimosas. As the grass is coarse and long, the pastures are indifferent; still cattle, horses, mules, and sheep are abundant, and are exported to a small amount, together with some wool. The corn and maize which are raised are not sufficient for the consumption of the scanty and widely-scattered population. The country between the Sierra de Cordova on one side, and Mendoza and San Juan on the other, is still worse. As no fresh-water stream runs through it, it cannot be irrigated; and with the exception of a few spots, is a complete desert. The climate is dry and hot; rain seldom falls. The gold-mines of La Carolina, about 60 miles N. from the city of San Luis, have ceased to be worked; but the people of the village sift the alluvial soil at certain places in the neighbourhood, and collect annually a small quantity of gold in dust and small lumps (pepitas). Like the other provinces of the Argentine Confederation, San Luis is a federal state; the executive power being vested in a governor elected by the junta, or provincial assembly, but for many years there has been no really effective government.

San Luis de la Punta, the capital of the province, is pleasantly situated on the western slope of a hill, 2417 feet above the level of the sea, in 33° 17′ S. lat., 65° 46′ W. long.; but it is merely a straggling village-like collection of mud-huts, and does not contain more than 1500 inhabitants. There is no other place in the province above the rank of a hamlet.

SAN PAULO, the capital of the province of San Paulo, Brazil, South America, is situated on two of the head streams of the river Tiete, in the plain of Piratininga, at an elevation of 2464 feet above the level of the sea, in 23° 33′ S. lat., 46° 45′ W. long. The population is about 22,000, exclusive of the suburbs. San Paulo is one of the oldest towns in Brazil, having been founded by a colony of Portuguese in 1560. The streets are wide, and lined with houses of two stories, built of 'taipa,' which is a frame-work of wood filled in with earth. The public buildings are—the palaces of the governor of the province, formerly a Jesuit college, and of the bishop; a spacious cathedral, 12 churches, and a convent of the Carmelites; a college, schools, &c. The only manufactory is a government establishment for making fire-arms. Some coarse woollen cloths and hats are made. San Paulo is the general emporium of the commerce of the plain in which it stands. The exports are—maize, tobacco, cotton, coffee, sugar, rum, jerked beef, hides, horns, and tallow; the manufactured goods of Europe and North America are imported. Santos, the port of San Paulo, is 42 miles S.W. from the city; and the descent to it is so steep that nearly all goods are carried on the backs of mules.

SAN QUENTIN. [CALIFORNIA, *S.* 2.]

SAN SALVADOR, Republic of, Central America, extends along the Pacific Ocean from the Bay or Gulf of Conchagua to the Rio de Paz. It lies between 13° 10′ and 14° 15′ N. lat., 86° 45′ and 89° 45′ W. long.; and is bounded E. by Nicaragua, N. by Honduras, W. by Guatemala, and S. by the Pacific Ocean. The area is about 6880 square miles. The population is about 300,000.

San Salvador is the smallest, but, in proportion to its size, much the most populous, of the republics of Central America. The surface is very unequal. The main portion of the coast extends along the Pacific in a generally west-north-west and east-south-east direction for about 140 miles; while on the east a smaller portion of it forms the western half of the Bay of Conchagua. There are four harbours—Acajutla or Sonsonate, Libertad, and La Union, which are ports of entry, and Jiquilisco or Triumfo de los Libres. Except La Union, which is on the west shore of the Bay of Conchagua, and is extensive and safe, these harbours are, properly speaking, only open roadsteads, hardly accessible during the rainy season and the prevalence of the south-west winds. As far northward as Libertad the shore is bordered by a narrow tract of low and generally level land from 10 to 12 miles wide; but farther north, up to Sonsonate, the coast is more elevated and broken. The interior is very rugged, being broken by several short ranges of mountains of moderate height, but separated into distinct groups. About 12 to 15 miles from the coast, and nearly parallel to it, are the five volcanoes of Apaneca, Yzalco, San Salvador, San Vicente, and San Miguel. San Salvador and San Vicente are the loftiest, being upwards of 8000 feet above the level of the sea. The eruptions of San Salvador have at times been very destructive; but Yzalco is by far the most remarkable, from its unceasingly active condition, surpassing it is said, in this respect, and in the impetuosity of its eruptions, any other volcano in America. Neither of the other volcanoes has exhibited other than very slight eruptions of late years.

The rivers of San Salvador have only a short course, and are in their natural state of little importance; though it is asserted that they might easily be rendered of great service for irrigation, and some of them be made navigable for barges and other small craft. The chief river is the Lempa, which rising in Esquipulas, in Guatemala, forms for a short distance the boundary between Honduras and San Salvador, receives the outflow from Lake Guixar, thence crosses San Salvador in a southern direction, and falls into the Pacific a little to the westward of the Bay of Jiquilisco. It is a deep but rapid stream, and the bar at its mouth prevents vessels of even moderate burden from entering it. The other larger streams are the Rio de Paz, at the western extremity of the republic; the Jihoa, which falls into the sea between the Lempa and Port Libertad; and the Sirama, or San Miguel, all of which have their mouths obstructed by sand-bars. There are two lakes of some size in the state. The Lake of Guixar, near the north-western boundary of the state, has a circuit of about 80 miles, and is one of the principal feeders of the Rio Lempa. It is said to communicate by a subterranean channel with the much smaller Lake of Metapa. Lake Ylopango, about 6 miles E. from the city of San Salvador, is about 9 miles long and 3 miles wide: its only outlet is a small tributary of the Jiboa. Mineral- and thermal-springs occur very numerously in various parts of the country.

Owing to the great inequality of surface, there is considerable variety of climate. As a whole, it is warmer than in Guatemala; but it is generally regarded as healthy. The hottest and least healthy part is the low tract along the coast.

San Salvador has great agricultural capabilities. The soil is generally good, and in some parts remarkably rich, and the climate permits a considerable variety of crops to be profitably cultivated. The inhabitants are an industrious race, and more skilful agriculturists than the natives of other parts of Central America. Nearly all the available land in the country is appropriated to individuals, and much attention has been paid to its cultivation, though now, from the long continuance of civil dissension, agriculture is in a very neglected condition. Maize is cultivated to a considerable extent; wheat succeeds well only in a few places; several varieties of frixoles, and most of the usual vegetables, are raised for the ordinary food of the people. Oranges, lemons, pine-apples, plantains, and various fruits are extensively grown; sugar, cacao, coffee, tobacco, and cotton succeed very well, and might, were the country in a more settled state, be raised largely for exportation. Since the gold discoveries in California, a very large quantity of sugar has been grown in the neighbourhood of Sonsonate, chiefly for the purpose of distilling rum for the Californian market. Indigo has however always been the chief source of wealth to San Salvador. During the Spanish supremacy, upwards of 1,600,000 lbs. are said to have been annually exported, and though the quantity raised has greatly fallen off, it is still considerable. The coast west of Point Libertad is commonly known as the Balsam Coast, it being the only place where the article known as the Balsam of Peru is collected. This part of the coast is in the possession of the Indians, who live in five villages, have their own chiefs, with a kind of municipal government, and subsist chiefly on the produce of the balsam, which they collect to the amount of about 15,000 to 20,000 lbs. annually, and dispose of in Sonsonate. They also cut and carry to Sonsonate a considerable quantity of cedar-trees. There are large forests on the slopes of the mountains of the interior.

Cattle are numerous, and of a good breed; sheep do not succeed very well; hogs are everywhere abundant. Turkeys and fowls are plentiful; but there are few ducks and geese. An inferior kind of cheese is made in large quantities; butter is seldom made.

The mineral wealth of the state appears to be considerable, but it has been very imperfectly developed. Gold has been obtained in several places. Some rich silver-mines were formerly worked, but, owing to the general insecurity of life and property, they have been for many years almost entirely neglected. Excellent iron-ore is obtained near Metapa. Lead and copper have also been found.

The only manufactures are of the common articles of domestic consumption. They consist chiefly of coarse cotton goods, cutlery, and iron ware, and some of them used to be in considerable request throughout Central America. The foreign trade is of comparatively little importance. The exports in 1852 amounted in value to 700,000 dollars; the imports to 1,360,000 dollars.

San Salvador is divided into four departments, which are named after their respective capitals—San Salvador, San Vicente, San Miguel, and Santa Anna. In all, the republic contains 6 principal towns, 142 smaller towns, and 62 villages. The following are the more important places; the populations are merely a loose approximation:—

San Salvador, the capital of the republic, is situated on the Rio de Aselhuate, a small affluent of the Lempa, in 13° 44′ N. lat., 89° 8′ W. long. The site of the city is more than 2000 feet above the level of the sea, on undulating ground, in a kind of valley, surrounded by high hills covered with wood, among which, in a north-eastern direction, and at a distance of about nine or ten miles, is the volcano of San Salvador, which at different periods has caused great devastation by its eruptions. The city itself was laid out with considerable regularity, and had in the centre a plaza, or square, three sides of which were lined with shops, with porticoes before them, supported by a colonnade; while on the fourth side was the cathedral, an edifice which had no great claims to architectural beauty. The population was about 20,000. But on the night of the 16th of April, 1854, the city was entirely destroyed by an earthquake, and a very large number of the unfortunate inhabitants killed. For several days previous to the sad catastrophe there had been slight tremblings of the earth, but as they caused no mischief, little heed was given to their premonition. On the evening of the night named however the shocks became more frequent and severe, and, being unattended with noise, the inhabitants became seriously alarmed, and many of them assembled in the great square. At length, at about ten minutes to eleven o'clock, a violent heaving motion of the earth occurred, which in a few seconds levelled the cathedral, churches, university, and every other public building in the place. Of the private houses a few were left standing, but these were rendered uninhabitable; and the wells and fountains were either filled or dried up. Many of the inhabitants, as we have said, perished, and of the survivors many fled to other towns. The movements of the earth continued for some time after the fatal night; and the president of the republic, in his address to the departments calling on them to assist the destitute citizens, intimated that measures were to be immediately taken for the selection of a better site on which to rebuild the city. Some manufactures of iron, especially of cutlery and coarse cotton stuffs, were carried on in San Salvador; and some sugar and indigo used to be exported. Sugar-plantations are numerous in the neighbourhood, as are also extensive orchards. Mestizoes, or ladinoes, as they are called here, constituted the bulk of the population. Near the city there are some warm and some cold rivulets, which afterwards unite, affording the inhabitants the advantage of having natural baths of every degree of temperature.

San Miguel, some distance east of the Rio Lempa, population about 7000, is noted for its fairs, of which the most important is held in November after the indigo crop.

San Vincente, on the right bank of the Lempa, contains about 8000 inhabitants in the town and its suburbs. In its neighbourhood are extensive plantations of indigo, and near the village of Istepeque excellent tobacco is grown, which is known under that name all over Central America.

Santa Anna, situated in the western part of the state, at a considerable elevation above the sea, population about 9000, has in its neighbourhood extensive plantations of indigo and sugar; in the mountains near the town are iron-mines, which were formerly profitably worked.

Sonsonate, near the western extremity of the state, population about 8000, carries on at present considerable commerce by means of the port of Acajutla, exporting sugar to Peru and Chili, and rum, &c., to California. The Indians inhabiting the country about the town make very beautiful mats, which are also exported. In the neighbourhood of Sonsonate is the Yzalco, a very active volcano.

Other towns of less importance than those above mentioned are—Aguachapa, Apastepeque, Cojutepec, Metapa, Sacatecoluca, &c.

San Salvador is a republic with a legislative chamber of 25 deputies, but the government is really vested in the president. The history of San Salvador is similar to that of the other republics of Central America. [Costa Rica, *S.* 2; Guatemala, *S.* 2; Honduras, *S.* 2; Nicaragua, *S.* 2.] On the formation of the republic of the United States of Central America, San Salvador became one of the federal states, and its capital was made the seat of the federal government; but the union was speedily dissolved, and San Salvador, like the other states, became an independent republic, and like them its progress has hitherto been arrested by constant internal discord.

(Juarros, *History of Guatemala;* Haefkens, *Reize naar Guatemala;* and *Centraal Amerika;* Baily, *Central America*, &c.)

SANA is the capital town of the province of Yemen in Arabia, situated in 15° 5′ N. lat., 44° 5′ E. long. Sana, though the chief town of Yemen, is the seat of an independent chief, the Imam of Sana, who exercises authority over a wide district around, and is often opposed to the Egyptian government, which has advanced its frontiers to Beit-el-Fakih, a town in the Jehameh, about midway between Sana and the port of Mokha, on the Red Sea. Sana is pleasantly situated on an elevated table-land, surrounded on three sides by higher mountains. The valley thus formed is about nine miles broad, but extending uninterruptedly to the north. The country round about supplies a considerable quantity of coffee, which at present is transmitted to Mokha on camels; but the exactions of the Egyptian government are so great, that it has been considered likely that the traffic may be turned to Aden, to which port Sana is as near as to Mokha. Coffee forms almost the only export; the imports are piece-goods, thread, and twist, Persian tobacco, glass, silks, spices, and sugar. The town is walled, and indifferently fortified. It is about 5½ miles in circumference, with narrow streets, but with many good houses; those of the more opulent having windows of stained-glass. The imam has two handsome palaces, both built of hewn-stone and fortified, in the town, and there are about twenty mosques, some very handsome, and many baths and public fountains. Across the principal street a handsome bridge has been thrown, as in rainy seasons a torrent runs down the street, but occasionally the town is seven years without rain, and is much too dry in general to be healthy. The population is estimated at 40,000; and of three neighbouring towns in the same valley, Rodah, Wady-Dhar, and Jeraf, the population is at least 30,000 more. In Sana, and probably in the other towns, the principal part of the artisans are Jews, who pay a capitation-tax for permission to reside in the town: they live in a quarter by themselves, and their number is about 3000. (*Geog. Journal*, vol. viii.; *Journey of Mr. J. C. Cruttenden to Sana*, 1836.)

SAND-TUBES. [FULGURITES.]

SANDWICH. [CANADA, *S.* 2.]

SANGUINARINE. [CHEMISTRY, *S.* 2.]

SANICULA, a genus of Plants belonging to the natural order *Umbelliferæ* and the tribe *Saniculeæ*. The calyx has 5 leaf-like teeth; the petals erect, obovate, with a long inflexed connivent point. Fruit sub-globose, covered with hooked spines; no ridges; vittæ numerous.

S. Europæa, the Wood-Sanicle, is a native of Great Britain, in woods and thickets. The lower leaves are palmate, 3-5-lobed; lobes bifid, unequally serrate. The fertile flowers are sessile; barren flowers slightly stalked.

(Babington, *Manual of British Botany*.)

SANTA FÉ one of the riverine provinces of the Argentine Confederation, South America, has been described under PLATA, LA, (vol. xviii. p. 26). It was formerly the centre of communication between Buenos Ayres and the western provinces, with Paraguay, whose enormous supply of maté to those provinces, Chili, and Peru, mostly pass through Santa Fé. But the closure of Paraguay to external commerce, the disturbed state of Santa Fé, owing to domestic dissensions, and the frequent encroachments of the Indians from the Gran Chaco, almost entirely destroyed its trade, and reduced the inhabitants to poverty. Santa Fé is however so admirably situated for commerce that it cannot be doubted that, if the tranquillity of the country could be secured, the partial revival of trade, which has taken place since the opening of the navigation of the Rio Paraná, will be more than maintained; indeed it might be almost indefinitely extended with a larger, more wealthy, industrious, peaceable, and energetic people. The major part of the inhabitants are of Guarini origin, who settled here after the expulsion of the Jesuits in 1790. There are also many Indians, who reside in villages (of which Sance, 7 miles west of the city of Santa Fé, is the chief), and spin the cloth and make the ponchos usually worn in the country; they are however generally wretchedly poor and degraded. Santa Fé, like the other provinces of the Argentine Confederation, owns a nominal dependence on the central government; the executive power is vested in a governor elected by the provincial assembly.

Rosario, situated on the high and precipitous bank of the Paraná, a considerable distance below Santa Fé, appears likely to become the commercial emporium of the province, being situated in a fertile district, conveniently placed for the steamers navigating the Paraná; and much the most convenient port for the foreign commerce of the western and north-western provinces. It wears already a far more commercial appearance than the capital; has a larger population; and the inhabitants are said to be industrious and diligent. Mr. M'Cabe, whose visits were made for commercial purposes, says, in his 'Two Thousand Miles Ride through the Argentine Provinces,' that "next to Monte Video, Rosario is the most rising port in this part of South America."

SANTA FÉ. [NEW MEXICO, *S.* 2.]

SANTIAGO DEL ESTERO. [PLATA, LA.]

SAPHIRINE. [MINERALOGY, *S.* 1.]

SAPONINE. [CHEMISTRY, *S.* 2.]

SAPONITE, a Mineral consisting of silica, magnesia, alumina, iron, and potash. It is found at Lizard's Point, Cornwall. When first extracted it may be kneaded like dough. It becomes brittle on drying, and is of a white, yellow, blue, or red colour.

SARAWAK, a province on the north-western coast of the island of Borneo, of which Sir James Brooke is the Rajah, or governor, under the appointment of the Sultan of Borneo. The province of Sarāwak extends between 1° and 2° N. lat., 109° 40′ and 111° 40′ E. long. It is watered by the river Sarāwak and its tributaries. [BORNEO.] The capital, Sarāwak, formerly Kuchiu, contains a population of about 12,000.

SARCOCOL. [PENÆACEÆ, *S.* 2.]

SARCOCOLLIN. [CHEMISTRY, *S.* 2.]

SARDINIAN STATES. The dominions of the House of Savoy constitute a monarchy, the head of which derives his title of king from the island of Sardinia. A general account of them will be found under SARDINIAN STATES; and we add the more recent information. These states consist of—1, the duchy of SAVOY; 2, the principality of PIEDMONT; 3, the duchy of GENOA; 4, the county of NIZZA; 5, the island of SARDEGNA. The continental territories have an area of 19,775 square miles. The population in 1848 amounted to 4,368,972. The total area of the kingdom, including the island of Sardinia, is 29,075 square miles (about one-seventh of the area of France), and the total population in 1848 (the latest census) amounted to 4,916,084 (less than one-seventh of the population of France at the census of 1851). The continental territories are divided into 11 administrative divisions and 30 provinces; the area and population of which are given in the following table:—

Divisions.	Provinces.	Area in Square Miles.	Population in 1848.
Torino	Torino	1,117	411,959
	Pignerol	593	133,233
	Susa	539	81,834
Genoa	Genoa	358	285,280
	Chiavari	354	116,077
	Novi	289	65,013
	Levante	261	78,859
Savona	Savona	311	78,906
	Acqui	445	101,102
	Albenga	263	59,993
Nizza	Nizza	1,180	118,377
	Oneglio	175	60,072
	San Remo	265	64,541
Coni	Coni	1,003	179,636
	Mondovi	679	148,450
	Alba	408	118,844
	Saluzzo	622	153,942
Alessandria	Alessandria	332	117,870
	Asti	351	136,065
	Voghera	308	101,695
	Tortona	257	58,853
	Bobbio	269	37,833
Novara	Novara	533	178,069
	Lomellina	480	139,649
	Pallanza	312	64,030
	Ossola	521	36,331
	Valsesia	292	35,879
Ivrea	Ivrea	562	168,561
	Aosta	1,233	81,232
Vercelli	Vercelli	473	121,806
	Biella	377	130,691
	Casale	335	120,428
Chambéry	Chambéry	634	152,468
	Alta Savoia	377	50,872
	Moriana	798	64,239
	Tarantasia	[illegible]	45,723
Annecy	Annecy	620	107,474
	Faissigny	786	105,474
	Chablais	356	57,563
Total	. . . .	19,774	4,368,972

An account of these divisions and their chief towns is given under their respective heads.

Each province is administered by a governor called Intendente, appointed by the king. The province is an aggregate of communes; each commune has a sindaco, or mayor, who is subordinate to the intendente. For judicial purposes each province has a court, called Tribunale di Prefettura, which sits in the chief town. The provinces are divided into districts called Mandamenti, in each of which there is a justice of the peace, who has a secretary. There are in all 412 of these mandamenti. There are four supreme courts, which are also courts of appeal. The supreme court of Turin has jurisdiction over all the provinces on the Italian side of the Alps and north of the Ligurian Apennines. The jurisdiction of the High Court of Genoa extends to all the provinces of the duchy of Genoa, with the exception of San Remo. The High Court of Nizza has jurisdiction over the provinces of Nizza, Oneglia, and San Remo. The High Conrt of Savoy, which sits at Chambéry, decides all suits within the limits of the duchy of Savoy. Each conrt has two chambers, one for civil and the other for criminal matters. The jndges are irremovable. There is an Admiralty Conrt which sits at Genoa; and tribunals of commerce are established in all the leading towns. The tribunals of commerce of Nice, Genoa, Chiavari, Savona, Novi, and San Remo, Turin, Chambéry, and Nice are called Consolati. The towns and other communes have a communal council composed of notables of the place, at the head of which is the syndic. The council superintends the local and economical administration of the commune, but its acts are subject to the sanction of the intendente of the province.

The government until lately was an absolute monarchy. The late king, Carlo Alberto, published a constitution for his subjects, dated February 8, 1848, which has been since faithfully acted upon. It declares the Catholic religion to be the dominant religion, but gives perfect freedom of conscience to dissenters. The executive is vested in the king, who acts by responsible ministers; the command of the army, the right to make peace or war, to make appointments to office, to sanction laws, also rest in the king. The legislative power is exercised by the king and two chambers—a Senate and Chamber of Depnties—which must be convoked every year by the king; or if dissolved, the king must convoke a new chamber within four months. All financial laws must first be introduced into the second chamber. The freedom of the press and of the person is guaranteed. The jndges are irremovable.

The army is recruited yearly by means of a conscription. Every conscript, unless he provides a substitute, is bound to serve eight years in the regular army, after which he is enrolled for eight years more in the provincial battalion of his respective district. In time of war the provincial battalions are called into active service, and the army becomes thereby increased to about 150,000 men. The regular army in 1854 numbered 47,524 men and 7602 horses. The corps of carabineers, in number about 4000 (of whom 885 are in the island of Sardinia, which is free from the conscription), are charged with the police of the country, being scattered in detachments over the various provinces. In 1855 the army was increased in consequence of the king sending 15,000 men to aid the French and English against Russia in the Crimea. In 1857 it numbered 48,273.

The naval force consists of 4 sailing and 4 steam frigates, 4 corvettes, 3 brigantines, 1 brig, 6 war steamers, and several smaller vessels, carrying in all 900 guns, and manned by 2860 men, besides officers. The stations of the royal navy are at Genoa, Villafranca, and in the island of Sardinia. The mercantile navy numbered in 1857 2934 ships, carrying an aggregate of 197,924 tons, and 31,987 men, including captains, sailors, and workmen.

The public revenues of the state, as estimated in the budget of 1857, amounted to 135,967,321 francs; and the expenses to 147,326,866 francs. The national debt on the 1st of January 1851 amounted to 680,605,040 francs (27,224,200*l.*), including the loan guaranteed by the British government in 1855. The revenue is derived chiefly from land-tax, customs and excise duties, post-office, public works, &c.

The ecclesiastical administration of the continental states is under the 4 archbishops of Turin, Chambéry, Genoa, and Vercelli; and 26 bishops of Maurienne, Tarantaise, Annecy, Aosta, Susa, Pinerolo, Acqui, Alba, Asti, Cuneo, Fossano, Ivrea, Mondovi, Saluzzo, Alessandria, Biella, Casale, Novara, Vigevano, Albenga, Nizza, Bobbio, Sarzana, Savona, Tortona, and Ventamiglia. The number of parishes is 3756; that of collegiate churches, besides cathedrals, is 74; and that of clerical seminaries, 54. There is an ecclesiastical academy for the higher theological studies at Superga, near Turin. There are in all the continental states about 240 convents of monks and 82 convents of nuns; by a law passed by the Sardinian Chambers in May 1855, all religious orders are suppressed, with the exception of those employed in "preaching, teaching, or tending the sick." The Valdenses are the most numerous Protestant sect as yet in the Sardinian states. They dwell chiefly in the valleys of Pignerol. Their clergy study at Geneva or Lausanne in Switzerland. They have churches in Genoa and Turin.

Public instruction is afforded by the royal and communal colleges. In every province there are one or more royal colleges, in which grammar, rhetoric, and philosophy are taught; and in some of them there are chairs of law, medicine, and divinity. In most towns there is a communal college, besides grammar schools. Female education is afforded almost exclusively in convents of nuns, of which there are forty-two thus engaged. Scientific instruction is given in the two universities of Turin and Genoa, in which cities there are academies of sciences and of the fine arts. [Genoa; Torino.] There are a veterinary school at La Veneria near Turin, a school of mineralogy at the mines of Moutiers in Tarantasia, and a naval school at Genoa. Most communes have schools for boys.

The continental states of the king of Sardinia have several fine carriage-roads across the Alps and Apennines, which intersect their territory. The most remarkable are:—1, the great road of Mont Cenis, leading from Chambéry to Turin, constructed by Napoleon; 2, that of the Simplon, leading into Switzerland, likewise constructed under Napoleon; 3, the road from Genoa to Sarzana and Lucca along the Eastern Riviera; 4, the road from Genoa to Novi by Serravalle; 5, the road Della Cornice, from Genoa to Nizza, along the Western Riviera, begun under Napoleon, and finished under king Charles Felix. There is a well-regulated and cheap post-office system throughout the Sardinian dominions, as well as diligences for travellers on all the high roads; and public conveyances, called 'velociferi,' on the provincial or cross roads. Under the late king, Carlo Alberto, railroads were begun to be constructed in the continental states. Lines now extend from Turin to Genoa through Alessandria; from Turin to Cuneo, to Pignerolo, and to Susa; from Alessandria a line runs up to Novara. Along these roads electro-telegraphic wires are laid down; and the city of Turin has electric communication through Chambéry with Paris, and by the Gulf of Spezzia with the island of Sardinia, from the south-western point of which it has been proposed to carry electro-telegraphic cables to Bona in French Africa. A railway is projected from Annecy to Chambéry, thence to Montmelian on the Isère, up the left bank of that river to the confluence of the Arc, and up the valley of the Arc to Modane. This line in all probability will be extended from Annecy to Geneva, from Montmelian to Grenoble, so as to form a junction with the French railway system; and the project of cutting a tunnel through the Alps under Mont Cenis, so as to unite the Savoy railroad at Modane with an extension of the Turin-Susa line to Grande-Croix, has been long entertained with great favour by the people and government of the Sardinian States.

The plains of Piedmont are well supplied with canals, chiefly for the purpose of irrigation, the principal of which are in the provinces of Alessandria, Vercelli, Biella, Casale, Ivrea, Alba, and Turin. The river system of Piedmont is described under Po.

The staple products of the continental Sardinian territories for exportation are—silk, rice, hemp, wine, and oil. Most of the wine is consumed in the country. The principal manufactures consist of paper, silks, woollens, linen, glass, and cotton-yarn. The importation of colonial articles and foreign manufactures takes place chiefly through the port of Genoa. A considerable trade is carried on with Switzerland and Germany by the Lago Maggiore, and the Bernardin road leading to the Grisons.

The Sardinian States have Switzerland on the north, France on the west, the Mediterranean on the south, Austrian Italy, Parma, and Tuscany on the east. They comprise the countries between the Var and the Magra, the Rhône and the Ticino. The Sardinian portion of the Lunigiana lies east of the Magra. The surface is covered on the west and north by the Alps, on the south by the Apennines, and between these two great mountain systems lies the most extensive and valuable portion of the country, comprising the slopes, valleys, and plains that form the basin of the Po to the junction of the Ticino. The face of the country is described in the articles Alps, Apennines, Genoa, Piedmont, Savoy, and under the names of the several administrative divisions or provinces.

SARGASSUM. [Fucaceæ, *S.* 2.]

SASIN. [Antelope.]

SATURNIA, a genus of Insects belonging to the order *Lepidoptera* and the family *Bombycidæ*. The antennæ are fringed in the male; the head is small; the wings are very broad and entire; the palpi and trunk are wanting.

S. Pavonia minor, the Emperor Moth, is one of the handsomest of the British species of Moths. It is about 3 inches wide. The colour is grayish-brown, faintly tinged with purple; the hinder margin of all the wings has a band of pale brown and purple, the hinder band being much waved. The centre of each wing has a large spot or ocellus, which is placed on a light ground; it consists of a black pupil, with a yellow or gray iris, and partly surrounded by a light blue crescent. The larva is of a green colour, having a black band on each segment adorned with pink tubercles, bearing a whorl of six hairs diverging like a star. It constructs a curious cocoon, the extremity not being close, but terminated by a converging circle of very stiff hairs, which enables the insect to make its escape from within, but completely prevents all ingress.

To the genus *Saturnia* some of the largest of the *Lepidoptera* belong. *S. Atlas*, the Giant Atlas Moth, has wings measuring 7 or 8 inches across. This species also, with *S. Cecropia* and *S. Luna*, have their wings produced into a tail. The cocoons of *S. Cynthia* and *S. Mylitta* are used in India for the production of silk. Latreille states that these are the wild species of silk-worm of China. *S. Cynthia* is the Arrindi Silk-worm of India. (Roxburgh, 'Linn. Trans.,' vol. vii.) *S. Promethea*, a North American species, forms its cocoon within the leaf of a sassafras-tree, having previously fastened the stalk of the leaf to the stem by a strong silken web, whereby it is prevented from falling with the other leaves. (Westwood.)

SAURIANS. The following is a synopsis of the families of the *Sauria*, adopted by Dr. J. E. Gray in his 'Catalogue of the Specimens of Lizards in the British Museum.' The genera and species of the *Lacertinidæ* are given, the other large families are described under their proper names :—

Order I. Lizards. *Saura.*

Mouth not dilatable, jaws toothed, the lower jaw-bones being united by a bony suture in front. Eye generally with distinct eyelids; drum of the ear generally distinct. Limbs four, distinct, rarely in such a rudimentary state as to be hidden under the skin. Toes clawed. Body elongate, rounded, covered with imbricated or granular scales; ribs distinct, mobile, and with a distinct sternum. Tail elongate, tapering, rarely prehensile, generally covered with whorls of scales. Egg with hard skin. The young not undergoing any metamorphosis.

Sub-Order I. *Leptoglossæ.*

Tongue flat, elongate, and bifid.

Tribe I. *Cyclosaura.*

Scales of the belly square, in cross bands, of the back and tail rhombic and imbricate, or circular and subgranular. Tongue elongate, flattened, free, nicked, or with two elongate cylindrical horny tips. Eyes diurnal, with two valvular lids. Feet for walking; toes unequal, compressed.

a. Head with small many-sided shields. Tongue sheathed at the base.

1. *Monitoridæ.*—Head-shields flattish, scales small. Inhabit the Old World and Australia. [Monitors.]

2. *Helodermidæ.*—Head-shields and scales of body convex, tubercular. Teeth with a groove behind. Inhabit the New World.

b. Head with large regular shields. Tongue mostly free at the base.

* Sides flattish, covered with small often granular scales.

3. *Teidæ.*—Supra-orbital plate horny. Teeth solid, rooted. Scales small, granular, often with large plates. Inhabit the New World. [Teinæ, *S.* 2.]

4. *Lacertinidæ.*—Head pyramidical, covered with regular many-sided shields; supra-orbital plate rigid. Throat scaly, often with a cross fold in front, and a collar of larger scales behind. Tongue elongate, flat, free at the base, exsertile, long-forked. Teeth hollow, rooted. Scales granular or rhombic, keeled. Sides flat, covered with small granular scales. The species inhabit the Old or Eastern world and Australasia.

Synopsis of the Genera.

i. Nostril erect, in the lower hinder angle of the nasal shield, just above the labial shield, with one or two shields behind it. Eyelid distinct.

A. Toes simple, compressed, not keeled nor fringed. Collar distinct.

a. Scales granular or 6-sided, elongate. Posterior nasal shield single. Collar distinct.

Zootoca.—Lower eyelid scaly, opaque.

Z. vivipara, the Scaly Lizard, Common Lizard, and Nimble Lizard. It is the *Lacerta vivipara* of Jacquin; *Lacerta agilis*, Pennant; *Zootoca muralis*, Gray. It has the ventral shields 8-rowed, the temple covered with many-sided shields, with a large central shield; its colour olive; back with a white-edged blackish streak on each side, and a central black streak; belly orange (in summer), black-spotted.

This little lizard is a common inhabitant of heaths and banks in most of the districts of England, extending even to Scotland. It is also one of the few reptiles found in Ireland. Its range is very limited on the Continent, and is not found in Italy or France. Its movements are graceful and rapid, it comes out of its hiding place during the warm parts of the day, from the early spring till autumn. It lives upon insects, which it seizes with its mouth. In this species the eggs are retained in the oviduct until the young are ready to be hatched, and they are thus produced alive. The young when brought forth are fully-formed, and capable of running about and taking their own food. The usual length of this lizard when full grown is from 5½ to 6½ inches.

Z. muralis, the Tiliquesta, is a native of the south of Europe.

Z. oxycephala, the Long-Headed Lizard, is a species brought by Mr. Webb from either Spain or Madeira.

Z. Taurica, a native of the Crimea, Morea, Corfu, and Sicily.

Z. tæniotata, the Striped Lizard, a native of South Africa.

Z. Derbiana, a native of Australia.

Z. Galloti, Madeira.

b. Scales granular or 6-sided, elongate. Posterior nasal shields 2, small, one above the other. Collar distinct.

Lacerta.—Lower eyelid opaque. Chin-fold distinct. Abdominal shields narrowed behind.

L. agilis, the Sand-Lizard. It is the *L. stirpium* of Milne-Edwards and others. The upper hinder nasal small, rather in front of the larger lower one; scales of the temple small. unequal, irregularly many-sided, often with a larger central one; throat fold indistinct, brown, spotted or eyed with black; sides green, brown-eyed, beneath white. This species is a native of Great Britain, and is especially abundant in the neighbourhood of Poole in Dorsetshire. Its general abode is on sandy heaths, where, from the rapidity of its movements, it is often mistaken for some form of snake. On account of the rapid locomotion it is not often caught. It does not bear confinement, but pines away and dies. When caught it often bites, but no ill-consequences are the result. The female lays her eggs to the number of 12 or 14 in hollows in the sand, which she excavates for the purpose. They are subsequently hatched by the heat of the sun. The eggs appear to be laid a considerable time before they are hatched. In this respect this species differs very much from the common lizard, which always brings forth her young alive. This lizard is larger than the *Zootoca vivipara*, as those of average size measure about 7 inches in length.

L. viridis, the Green Lizard, has the scales of the temple inequilateral, many-sided, with a central larger one: back granular, oblong, with shelving sides; throat-fold distinct. This species is a native of Guernsey and Jersey, and also of the south of Europe. It is much more readily caught than the last species, and never attempts to bite. It may be readily tamed and taught to come to the hand for food. It will lie coiled in the two hands, and never attempt to escape.

L. ocellata and *L. lævis*, both natives of the south of Europe, are the only other species of the typical genus *Lacerta*.

Thetia.—Lower eyelid transparent. The only species is *T. perspicillata*, a native of Algiers.

Teira.—Lower eyelid opaque. Chin-fold distinct. Abdominal folds and shields square. *T. punctata*, a native of Madeira, is the only species.

Nucras.—Lower eyelid opaque. Chin-fold indistinct. Abdominal shield narrow behind. Preanal shields one before the other.

N. Lalandii, is a native of the Cape of Good Hope.

N. tesselata, is a native of South Africa.

N. exigua and *N. chalybdea*, the Small Lizard and Steel-Black Lizard, are natives of the Caucasus.

c. Scales rhombic, keeled. Posterior nasal shields 2, small, one above the other.

Notopholis.—Collar and throat-fold distinct.
N. Fitzingeri is a native of Sardinia.
N. Capensis is a native of South Africa.
N. Moresticus inhabits the Morea.
N. nigropunctata, a native of the island of Corfu.
Tropidosaurus.—Collar and throat-fold indistinct. *T. montana*, a native of Java, is the only species.

d. Scales rhombic, keeled. Posterior nasal shields single. Collar indistinct.

Algira.—Ventral shields roundish, thin.
A. barbarica, the Zermonmeah, is a native of Algiers.
A. Capensis and *A. Dumerilii* are natives of the South of Africa.

B. Toes keeled beneath, and sometimes fringed on the sides. Scales keeled. Posterior nasal single.

Acanthodactylus.—Toes fringed on the sides.
A. velox. A native of North Africa.
A. Bellii. Found in Algiers.
A. Capensis. South Africa.
A. Savignii. Algiers.
A. lineato-maculatus. Marocco.
A. Boskianus. North Africa.
A. inornatus. Tripoli.
Psammodromus.—Toes not fringed on the sides. Collar indistinct.
P. Hispanicus, the Garriques, is a native of Spain.
P. cinereus inhabits the South of France.

II. Nostril horizontal on the ridge, between three swollen scales, one between the nostril and labial. Toes keeled beneath or fringed on the side.

a. Eyelid distinct.

Scrapteira.—Toes depressed, fringed on the edge, not keeled beneath. Collar indistinct. *S. graminea*, a native of Nubia, is the only species.
Eremias.—Toes compressed, keeled beneath, not toothed on the edge. Collar distinct. Preanal shields small, in several series, in central series one behind the other.
E. arguta. The Arguta is a native of Tartary.
E. velox. The Crimea.
E. Knoxii. South Africa.
E. Capensis; E. Burchellii; E. dorsalis; E. Namaquensis; E. lugubris, are also described by Dr. Smith as natives of South Africa.
E. guttulata. North Africa.
E. lineo-ocellata. South Africa.
E. pulchella. South Africa.
Mesalina.—Toes compressed, keeled beneath, not toothed on the edge. Collar distinct. Preanal shield single, semicircular, with 1 or two arched series of smaller ones round it.
M. Pardalis. North Africa.
M. rubro-punctata, North Africa.
Cabrita.—Toes rather compressed, keeled beneath, not fringed on the sides. Collar none.
C. Leschenaultii, a native of India, is the only species.

b. Eyelid rudimentary. Eye circular, exposed.

Ophiops.
O. elegans is found on the shores of the Mediterranean.
O. macrodactylus is a native of Asia Minor.

** Sides with a distinct longitudinal fold, covered with small granular scales.

5. *Zonuridæ.*—Ears distinct. Limbs distinct, or rarely quite hidden.
6. *Chalcidæ.*—Ears hidden under the skin. Limbs very short; femoral pores none. Lateral fold indistinct. [CHALCIDES.]

*** Sides rounded, covered with scales like those on the back.

7. *Anadiadæ.*—Scales of the back and sides thin, imbedded, smooth, in alternating cross series; of the tail elongate, smooth, in longitudinal series. Ears distinct. Femoral pores distinct.
8. *Chirocolidæ.*—Scales of the back imbricate, 6-sided, lanceolate, keeled, narrow, in cross series; of the tail in rings, alternating with each other. Ears hidden. Femoral pores distinct.
9. *Cercosauridæ.*—Scales of the back, sides, and upper part of the tail keeled, in longitudinal series. Limbs 4: feet for walking.
10. *Chamæsauridæ.*—Scales imbricate, all elongate, rhombic, keeled in longitudinal series, the keels forming longitudinal ridges. Limbs simple, undivided. Temple scaly.

Tribe II. *Geissosaura.*

Scales of the belly and (almost always) of the back and sides quincuncial, rounded, imbricate. Sides rounded. Tongue narrow, short, flat, and slightly nicked. Head with regular shields.

a. Eyes distinct, exposed, eyelid rudimentary. Head conical.

11. *Gymnophthalmidæ.*—Head-shields normal. Nostrils lateral, in a nasal shield. Limbs 4 or 2. Body fusiform.
12. *Pygopidæ.*—Head-shields normal. Nostrils over the upper edge of the first labial. Pupil round or oblong. Abdominal shields 6-sided, in 2 or 3 series. Tail with a central series of larger shields. Limbs 2, posterior. Australasia.
13. *Aprasiadæ.*— Head-shields normal. Nostrils in a suture between the nasal and first labial (sometimes united ?). Limbs none. Ventral and dorsal scales nearly similar. Australasia.
14. *Lialisidæ.* — Head-shields subimbricate, scale-like. Cheeks scaly. Nostrils in a small single nasal on ridge of the face.

b. Eyes distinct, eyelids distinct, connivent. Head conical.

15. *Scincidæ.*—Rostral shield moderate, triangular. Nostrils in a plate between the frontal and labial shields. [SCINCOIDIANS.]
16. *Ophiomoridæ.*—Rostral moderate, triangular. Nostrils in a notch on edge of nasal and the supranasal shields.
17. *Sepsidæ.*—Rostral rather large, square. Nostrils in a notch in the hinder edge of the rostral.
18. *Acontiadæ.*—Rostral large, cup-like. Nostrils in the rostral, with a narrow slit to its hinder edge.

c. Eyes hidden under the skin.

19. *Typhlinidæ.*—Head conical. Rostral shield cup-like. Nostrils in the rostral shield, with a slit to its hinder edge.
20. *Typhlopsidæ.*—Head short, depressed. Rostral shield elongated, extended up the forehead. Nostrils in an elongated nasal shield. [TYPHLOPS.]

Sub-Order II. *Pachyglossæ.*

Tongue thick, convex, attached to the gullet at the base.

Tribe III. *Nyctisaura.*

Scales of the belly small, rhombic, imbricated; of the back and sides granular. Tongue thick, short, convex, end slightly nicked. Eyes nocturnal; eyelids circular, not connivent, pupil linear, erect. Feet for walking; toes subequal, scaly beneath, and generally dilated.
21. *Geckotidæ.*—The Old and New World. [GECKO.]

Tribe IV. *Strobilosaura.*

Scales of the belly small, rhombic, imbricate; of the back and sides imbricate. Tongue thick, short, convex, end slightly nicked. Eyes diurnal, with valvular eyelids; pupil round. Feet for walking; toes unequal, compressed.
22. *Iguanidæ.*—Teeth on the inner side of the jaw-bone. New World. [IGUANA.]
23. *Agamidæ.*—Teeth on the edge of the jaw-bones. Old World and Australasia. [DRACONINA, *S.* 2.]

Tribe V. *Dendrosaura.*

Scales of the belly, sides, and back, granular. Tongue elongate, subcylindrical, worm-like, very exsertile. Eyes globular, very mobile, with a small, central, round opening. Toes equal, united into two opposing groups.
24. *Chameleonidæ.*—Teeth on the edge of the jaw-bone. Old World. [CHAMELEONS.]

SAUSSUREA, a genus of Composite Plants belonging to the sub-order *Cynarocephaleæ.* The florets are all hermaphrodite and tubular; the anthers with ciliated setæ at the base; the involucre is imbricated and unarmed, the receptacle scaly; the pappus in 2 rows, the outer one consisting of short rough bristles, the inner one feathery.

S. alpina has a stem from 3 to 12 inches high, erect, downy, and simple, terminating in a small corymb of heads with pinkish florets and purple anthers; the leaves are nearly glabrous above, cottony beneath, the lower ones ovate-lanceolate, the upper ones sessile-lanceolate, all distantly toothed, the heads in a dense corymb, the involucre subcylindrical, with depressed hairy scales. This is the only British species. It is found in alpine situations.

(Babington, ***Manual of British Botany***.)

SAXIFRAGE. [Saxifraga.]

SAXIFRAGE, GOLDEN. [Chrysoplenium, *S.* 1.]

SCARLATINA RHEUMATICA. [Physic, Practice of, under *Dengue*, *S.* 2.]

SCHADOW, JOHANN GOTTFRIED, an eminent German sculptor, was born at Berlin in 1764. Passionately found of art when a boy, he was yet unable, owing to the poverty of his father, to obtain any instruction until a sculptor kindly offered to teach him to draw. He soon mastered the rudiments of art, and eventually determined to devote himself to his teacher's profession. But having formed an attachment to a young lady, he fled with her in his twenty-first year to Vienna, and there married her. The event proved the commencement of his good fortune; for his father-in-law not only forgave the young couple, but furnished funds wherewith Schadow might proceed to Italy to complete his studies. He remained at Rome from 1785 to 1788, chiefly occupied in the study of the antique. He then returned to Berlin and soon found ample patronage. The first important work executed by him after his return was the monument to Count Von der Mark, natural son of Frederick William II., erected in 1790 in the church of St. Dorothy at Berlin. Among other great works with which his chisel has adorned Germany are the colossal statue of General Ziethen in hussar's uniform; the equestrian statue of Frederick the Great at Stettin; a life-size marble group of Queen Luise of Prussia, and her sister the Duchess of Cumberland; a statue of Duke Leopold of Dessau for the Lustgarten at Berlin; an equestrian statue of Field-Marshal Blücher at Rostock; the monumental statue of Tauenstein at Breslau; that of Luther at Wittenberg; the quadriga on the Brandenburg Gate; and the sculpture en the Mint at Berlin: he also executed a considerable number of portrait busts of his more eminent countrymen.

For many years before his death Schadow was regarded as the patriarch of the modern school of sculpture in Germany: as an evidence of the honour in which he was held, it deserves to be mentioned, that whilst the old man still lived, the street in which he dwelt in Berlin was called by his name. Schadow was one of the very first of his countrymen to break through the classic conventionalisms of his predecessors, and, without departing from the sober dignity of sculpturesque style, to add a more forcible expression of character, and a stricter adherence to the actual model in attitude as well as in drapery. His great excellence lay in portrait, and he had ample opportunities of putting forth his powers. Appointed professor in the Academy of the Fine Arts at Berlin some time prior to the close of the 18th century, he from 1822 to his death held the office of director of that institution, and among those who were successively his pupils are a large proportion of the best sculptors of Germany, including Rauch, Dannecker, Tieck, Zanner, &c., in most of whose works evident signs of his influence may be traced. He died at Berlin January 26, 1850.

Schadow has enriched the literature of art with the following works: 'Wittenberg's Denkmäler der Bildnerei, Baukunst, und Malerei, mit historischen und artistischen Erläuterungen' ('Monuments of Statuary, Architecture, and Painting, with historical and artistic Illustrations'), Wittenberg, 4to, 1825; 'Polyklet, oder von den Massen des Menschen nach dem Geschlechte und Alter, mit Angabe der wirklichen Naturgrösse nach dem Rheinlandischen Zollfaden, und Abhandlung von dem Unterscheide der Gesichtszüge und Kopfbildung der Völker des Erdbodens' ('Polyklet, or the Groups of Mankind, according to their Races and Periods, with an Appendix on their natural Size according to the Rhenish Standard, and an Essay on the Distinction of Features and Forms of the Head among the Peoples of the Earth'), Berlin, 4to, 1834; and 'Nationalphysiognomien, oder Beobachtungen über den Unterschied der Gesichtszüge und die äussere Gestaltung des Menschlichen Kopfes in Umrissen bildlich dargestellt' ('National Physiognomy, or Observations upon the Distinction of the Features and of the external form of Human Heads, represented in Typical Outlines'), Berlin, 4to, 1835.

SCHELLING, FRIEDRICH WILHELM JOSEPH, one of that famous series of modern German philosophers, of which Kant, Jacobi, Herbart, Fichte, and Hegel are the other chiefs, was born at Leonberg in Würtemberg, in 1775. He studied first at Tübingen, where he had Hegel for his college-fellow, and where the two future rivals in philosophy formed an intimate friendship. Schelling, though somewhat the younger man, was somewhat the older philosopher, and Hegel was first indoctrinated by him in philosophy. From Tübingen, Schelling went to Leipzig and Jena—his attraction to Jena being Fichte's philosophical lectures. He started in his philosophical career as an ardent admirer and disciple of Fichte; and it was not till 1798—when, on Fichte's removal from Jena, Schelling succeeded him in the Philosophy chair of that university—that Schelling became aware of his own differences from Fichte's system. He had already been a contributor to Fichte's Jena Journal; but now, in preparing his own course of lectures, he necessarily enlarged his speculations. In 1799 he published 'Erster Entwurf eines Systems der Naturphilosophie, zum Behuf seiner Vorlesungen;' but it was orally by means of the lectures themselves that he first effectively disseminated his new philosophical ideas. Hegel, who had in the mean time been living at Frankfurt-on-the-Main and elsewhere, now joined his friend at Jena (1800), and Schelling's doctrine was advocated in common by himself and Hegel—the two acting as joint editors of a journal, and Hegel appearing independently, in Schelling's interest, as the author of an essay on the 'Difference of the Systems of Schelling and Fichte.' In 1803 Schelling left Jena for Würzburg, Hegel succeeding him at Jena, as he had succeeded Fichte; and in 1807 he removed from Würzburg to Munich, where he remained till 1841.

By the year 1814, when Fichte died at Berlin, the philosophy of Schelling, who had then been seven years settled at Munich, may be considered as having gained the ascendant throughout Germany, as a development beyond that of Fichte and superseding Fichte's system. This had been owing partly to the diffusion of Schelling's views by himself personally in the lecture-room at Jena, at Würzburg, and at Munich; but partly also to various scattered writings—some in the form of contributions to journals, some as reports of the substance of his lectures, some as public addresses, and some as distinct essays for the press—published by him up to the date in question. Among the more important of these publications were the following:—'On the System of Transcendental Idealism,' 1800; a discourse entitled 'Bruno: oder, über das göttliche und natürliche Princip der Dinge,' 1802; an essay entitled 'Ideen zu einer Philosophie der Natur, als Einleitung in das Studium dieser Wissenschaft,' 1803; 'Darlegung des wahren Verhältnisses der Naturphilosophie zu der verbesserten Fichtes'chen Lehre,' 1806; a discourse, 'Über das Verhältniss der bildenden Künste zu der Natur,' delivered before the Royal Academy of Sciences in 1807; a work entitled 'Von der Weltseele, eine Hypothese der hoheren Physik zur Erklärung allgemeinen Organismus; nebst einer Abhandlung über das Verhältniss des Realen und Idealen in der Natur,' 1809; the first volume of a collection of his 'Philosophische Schriften,' published in the same year; and a series of fourteen lectures, 'Über die Methode des Academischen Studium,' published in 1813.

Living at Munich on the reputation of these writings, Schelling continued from time to time to develop portions of his doctrines in public addresses or in detached essays; but on the whole there was in these no important alteration of his philosophy as already given forth in the first fifteen years or so of the present century. Meanwhile, as he had burst away from Fichte, so his old friend and associate Hegel had burst away from him. The germs of a difference between Hegel's philosophical teaching and that of Schelling had manifested themselves in Hegel's lectures at Jena as early as 1806, if not earlier; they had been developed in subsequent works of Hegel; and at length, in 1817—when Hegel was appointed to the Philosophy chair at Berlin, which had been vacant since Fichte's death—Hegelianism began to appear in the German atmosphere as a system calculated to dispossess Schellingism, as that had dispossessed the system of Fichte. The struggle between Hegelianism and Schellingism increased—the former system evidently victorious on the whole—till 1831, when Hegel died at Berlin, and Schelling remained alone, in a Germany already filled with the adherents of his opponent, and regarding *him* as superannuated and left behind in the philosophic march. Schelling was aware of his position; but he was of opinion that, without altering the essence of his own system as it had preceded Hegel's, but by only bringing out aspects of it not formerly made apparent, and developing some modifications, the necessity of which he had overlooked, he should be able to present Schellingism in a form which would enable it to stand its ground or recover its ground even in Hegel's Germany, and which would at the same time bring it into harmony with other modern movements of German thought with which he sympathised, and especially with the religious movement which aimed at a restoration of deep Christian faith as opposed to Rationalism. Accordingly, the later portion of Schelling's life—first at Munich, and afterwards at Berlin, to which he was transferred in 1841—was spent in the rumination, and partly in the public announcement of this second or matured edition of his philosophy. In Berlin—where he retained his chair but for a few years, but where he afterwards lived habitually—the old man was revered as a philosophic patriarch, and his society, like that of Humboldt, was sought after by savans and thinkers. Bunsen, and others of the modern German school of theology, appear to have held him in high esteem. To them the nature of his second or final philosophy may have been made clear by his own conversations; but he had not published any connected exposition of it, nor was it known throughout Germany otherwise than vaguely when he died, in August 1854, at the age of seventy-nine. His death took place at Ragaz in Switzerland, whither he had gone for the benefit of his health.

For the right appreciation of Schelling's philosophy, it is necessary to remember it in its historical relations as a portion of that continuous development of philosophic thought in Germany which Kant began. Kant may be said to have bequeathed two contrary tendencies to the philosophy of his countrymen—the tendency to Objective Realism, which supposes a firm external reality in the universe, underlying all phenomena, and constituting the Not-Me; and the tendency to Subjective Idealism, which regards the thinking mind as the sole reality, and sees all the so-called objects and phenomena of the universe only as modifications or projections of the Me, or as so much various *thought* of the thinking being. "All subsequent German philosophy has been the prosecution of one or other of these speculative directions, or the attempt to reconcile them." Earliest on the realistic side were Jacobi and Herbart; the latter of whom especially fought against the too great Subjectivism that there was, or that there might be found, in Kant's system as a whole. Fichte, on the other hand, appeared as the thorough-going champion and exponent of the Kantian Idealism. Not content with the notion of the thinking mind and the external universe, the Ego and the Non-Ego, as being two co-ordinate realities to be both accepted on the evidence of consciousness, Fichte allowed independent reality only to the Me, and regarded the universe only as variations of this Me in thought or consciousness. Out of this doctrine he developed his powerful philosophy. Towards the end of his career however he was becoming unsteady in his Idealism, from fear that Nihilism might be its logical consequence, and he was straining after a doctrine of so-called 'absolute identity,' which should refer all to one absolute eternal substance, involving both the Me and the Not-Me. What Fichte was striving after Schelling accomplished. His system is properly post-Fichtean in historical order, and its main characteristic consists in a kind of universal Objectivism arrived at by first passing through Fichte's universal Idealism. In fact, Schelling was not at first aware that he was doing more than pushing Fichte's doctrine out in a direction in which Fichte meant it to be pushed.

Fastening, as it were, on the universal Me or 'World-Me,' which Fitche had set forth as the one reality on which philosophy should gaze, Schelling conceived the idea that this absolute eternal subject might be regarded and proceeded from as also the absolute eternal object, out of which all things, both in the mode of the Me and in that of the Not-Me, might be considered as evolving themselves. This doctrine of absolute identity, of a universal and infinite subject-object out of which all things have proceeded by a law of self-movement, is the cardinal doctrine of Schelling. According to Schelling, a knowledge of the absolute is the only true philosophy, and such knowledge is possible. But it is possible only by a capacity above consciousness and understanding—by what he calls 'Intellectual Intuition;' which is a kind of falling back or swooning of human reason into the absolute as being identical with itself. If man can know the absolute, it can only be because man himself is identical with that absolute; because knowledge is the same thing as existence, because thinking and being are one. But this is but one aspect of the doctrine of the identity of thought and being, of the subjective and the objective. That absolute, which we come to cognise only through identification with it, and which we name Deity, is to be regarded in its original condition as neither object nor subject, neither nature nor mind, but as the union, the indifference, the slumbering possibility of both. It has *become* all that exists by a process of self-movement, continually potentiating itself higher and higher, from the lowest manifestations of what is called matter, up to organic existence and the activity of reason itself in the guise of humanity. In this movement of Deity or the Absolute One, which constitutes the Life of the Universe, there are two modes—first, the expansive movement, or objectivising tendency, by which the absolute rushes forth, so to speak, into actual existence, and out of the *natura naturans* there comes the whole variety and complexity of the *natura naturata;* and, secondly, the contractive movement, or subjectivising tendency, by which the *natura naturata* falls back on the *natura naturans*, and becomes conscious of itself. The study of the absolute as engaged in the first movement—that is, as coining itself off into the objective—is natural philosophy; and only when the philosophy of nature is so considered—that is, when nature is considered as so many successive potentiations of the absolute in the form of thought—can it be rightly studied. "A perfect intellectualising of the laws of nature into laws of intuition and of thinking would be the highest perfecting of the science of nature." Of this style of treating the laws of nature, as modes by which the absolute proceeded in the process of thinking itself gradually out into all that as yet exists, Schelling himself set the example. He interpreted what is called inorganic nature, with its laws of gravity, light, magnetism, and electricity, as being the absolute in what he called its "first potence," or working on in its first efforts for converting the possible into the actual. Even here the subjective and the objective were already differentiated, but objectivity predominated. Then came the second potence, or potence of chemism, representing a higher stage in the life, or intellectual activity of the absolute. To this succeeds the third potence, of organically living nature, where we first see the aspect of consciousness or predominating subjectivity. Though Deity is immanent in all nature, it is in man that Deity becomes most conscious; and the highest reason of man is identification with Deity—a relapsing into the infinite. The ideal in man also corresponds to the real in nature; and in the perception of this is the true philosophy of art.

Such was the doctrine of 'absolute identity,' as it was propounded in Schelling's first or earlier philosophy. For a fuller view of the immense extension which he gave to it as affecting every possible department of thought, we must refer to his own writings; or to a very accurate and profound summary of Schelling's system given by Chalybæus in his 'Historical Development of Speculative Philosophy from Kant to Hegel' (of which there are two English translations); or (for more popular purposes) to Mr. Morell's account of 'Speculative Philosophy in the Nineteenth Century.' Information on the same subject is to be obtained from Cousin; and there is a French work entitled 'Schelling; Ecrits Philosophiques, et Morceaux propres à donner une Idée générale de son Système: traduits de l'Allemand par Ch. Bénard,' 1847. This work includes Schelling's lectures on the methods of academic study. His discourse on the philosophy of art is accessible in English. (Chapman's 'Catholic Series,' 1844.)

Apart altogether from the scientific comprehensiveness and precision at which Schelling aimed, there was much in the spirit and phraseology of his system—in such phrases, for example, as the 'rhythm of the Universe,' the 'Infinite becoming finite,' the 'Immanence of Deity in Nature'—to captivate poetical and enthusiastic minds. In fact, the system was a species of sublime Pantheism, which accorded well with the tone of German thought as affected or determined by Göthe, Tieck, and other poets. But, as we have said, the system did not remain satisfactory even in Germany. On the one side Hegel had tried to tear it to pieces on the score of its substitution of enthusiasm and poetry for logic, and had promulgated a system which found more acceptance with harder minds; on the other, the re-awakened Christian zeal of German theology complained that it was but a vague pantheism, leaving no room for that 'personal God' which the human soul demanded as essential to true religion, and, moreover, in its identification of man with deity, contradicting those notions of sin, redemption, and the like, which form the basis of Christianity. To prop up his system against these attacks, or, at least, to re-issue his system in a form which would save it from attacks from the latter quarter, was Schelling's object during the last portion of his life. A summary of his 'later views,' so far as they are ascertainable, will be found in Chalybæus. Suffice it here to say that, by a peculiar modification of his theory of the absolute,—according to which modification he now maintained that, though nature and Deity were identical, yet nature might not be and was not co-extensive with all Deity, that is, that the absolute might be considered as being in all objects and yet as not being exhausted in all objects taken collectively, but as being moreover a certain force or fund of unobjectivised will and reason,—Schelling imagined that he set himself right with theology at all points, and emerged out of Pantheism into pure Theism, and out of Rationalism into warm Christian faith. Working his new notion into such phrases as that "the part of the absolute immanent in the finite cannot be the whole nor the most peculiar part of Deity," and that "what is immanent in nature is that in God which is least God himself," he arrived at the doctrine of a 'personal God,' and also at the notions of 'human imperfection,' and 'moral evil,' and so he reconciled his philosophy with the Christian scheme of the world's history as a fall from good and a divine recovery.

SCHIRRHUS. [Physic, Practice of, under *Microscopic Diagnosis*, S. 2.]

SCHIST. An Argillaceous Rock, of a coarse laminated structure. [Slate.]

SCHNORR VON KAROLSFELD, JULIUS, was born at Leipzig on the 26th of March, 1794. His father, Hans Schnorr von Karolsfeld (born 1764, died 1840), a painter of some celebrity in his day, was director of the Art-Academy at Leipzig, and Julius received his earliest instruction in art from him, though he was desirous that his son should adopt a different profession. But the boy displayed at an unusually early age such remarkable talent for art, and so earnest a desire to follow it, that the elder Schnorr was induced to yield, and at the age of sixteen Julius was entered a student in the Academy of Painting, at Vienna. There he distinguished himself, though the formal conventionalisms inculcated were anything but favourable to the development of original genius. Happily in good time he proceeded to Rome (1815) where he at once attached himself to the society forming under the auspices of Cornelius and Overbeck, and when that remarkable cluster of young German painters brought their productions fairly before the artistic world, Julius Schnorr was recognised as one of the most accomplished of the promising band. His work the 'Wedding in Cana,' attracted so much notice that he was chosen along with Cornelius and Overbeck to paint the walls of the villa Massimi at Rome, in the revived art of fresco, with designs from the trio of great Italian poets, Dante, Ariosto, and Tasso. To Schnorr was assigned Ariosto, and his designs were received with general approbation. He also produced while at Rome 'Jacob and Rachel,' 'Madonna and Child,' 'Ruth in the field of Boaz,' 'Flight into Egypt,' and other important works.

At Rome Schnorr had gained the friendship of Niebuhr, Humboldt, and Bunsen, by whom he was introduced to the munificent patron of artists, Ludwig, crown-prince and afterwards king of Bavaria. When Ludwig set about the construction of his magnificent works at Munich, Julius Schnorr was one of the artists he summoned to assist in decorating them. He removed to Munich in 1825, and in 1827 was appointed professor of historical painting in the Academy of the Fine Arts there. His first great commission was to paint the state apartments of the new palace, with a series of frescoes from the ancient national poem of the Nibelungenlied. After these had proceeded some way however, they were suspended in order to complete the decoration of that portion of the palace called the Fest-Saalbau, three grand saloons of which were given to Schnorr to adorn with paintings of large dimensions representing leading events in the history of Charlemagne, Frederic Barbarossa, and Rudolf of Hapsburg, the three rooms being severally named after those personages. These three series of paintings occupied Schnorr above ten years. He made all the designs, prepared the working cartoons, and executed several of the more important paintings, but the greater number were painted under his supervision by his pupils. They are painted in encaustic, and have a grand appearance. In some may be discovered much superfluous energy and occasional exaggeration, in others simplicity carried to excess, in many a great redundancy of drapery, and exceptions may, perhaps justly, be taken to much of the colouring; but after every drawback is allowed, it must be confessed that they display abundant and vigorous imaginative power, immense technical skill, and that they produce a very impressive effect.

On the completion of his historical, Schnorr returned to his mythic series. Having destroyed such of the frescoes already done as did not satisfy his more mature judgment, he set himself with characteristic diligence to his great task. As completed the Nibelungen series occupies five chambers, each named from the section of the Lied which is depicted in it. The first called the 'Entrance Hall,' contains the personages of the poem. The second or 'Marriage Hall' is devoted to the leading events in the life of Siegfrid. The third, the 'Hall of Treachery,' contains the story of Hagen's treachery, from the moment when Kriemhild informs Hagen of the secret of Siegfrid's vulnerability, to its consummation in Siegfrid's murder. The fourth, the 'Hall of Revenge,' carries the story on to the death of Hagen by the hand of Kriemhild, and her own death by the sword of Hildebrand. The fifth is the 'Hall of Lamentation.' These paintings, which are in fresco, were likewise all designed by Schnorr and painted by himself and his pupils. They have all the artistic excellences of the historic series just noticed, and are painted with a broader and more genial feeling. Of all the many great modern paintings in Munich, these are perhaps the most generally popular, both among the artist's countrymen, and with strangers.

Schnorr continued to reside in Munich till he had completed his great works in fresco and encaustic, busy also during the whole time on other paintings, and designs for engravings, of various degrees of importance, but sufficient alone to have secured him a foremost place among modern painters. In 1846 he accepted an invitation to become director of the Picture Gallery, and professor in the Academy of the Fine Arts at Dresden, where he remained pursuing a course of persevering diligence till his death, which occurred on the 13th of April 1853.

Several of the works of Julius Schnorr have been engraved. In England he is perhaps best known by his extensive series of Bible-Pictures 'Die Bibel in Bildern,' Leipzig, 4to, 1852, &c. These have been reprinted in London from the original wood-blocks, and though more suited to the taste of Germans than ordinary English Bible-readers have met with a large sale. They exhibit wonderful animation, variety, and power, though like most of Schnorr's works most successful in passages admitting of somewhat exaggerated expression and action. Schnorr also made the designs for an illustrated edition of the Nibelungen published in 1843, but he is seen to a disadvantage in designs of so small a size. An elder brother Ludwig Schnorr, born in 1789, also acquired considerable notice in early life by a large altar-piece of St. Cecilia, a Faust, and some other pictures, but he scarcely maintained the position his early success promised. He settled at Vienna where he painted many portraits, as well as various historical and genre pictures.

SCHOLEFIELD, REV. JAMES, M.A., was born November 15, 1789, at Henley-on-Thames, Oxfordshire. His father, Nathaniel Scholefield, was minister of the Independent Dissenters' chapel, in that town. He was educated in the school of Christ's Hospital, London, became a Grecian there, and obtained several prizes. He was entered of Trinity College, Cambridge, in 1809. Having been elected Scholar in 1812, he in that year obtained the Craven University Scholarship. He took holy orders in 1813, by special permission, before he had taken his degree of B.A. Soon afterwards, on proceeding to his degree, he attained the place of Senior Chancellor's Medallist, and was first in the list of Senior Optimes. About the same time he became curate to Mr. Simeon, of Trinity Church, Cambridge. In October 1815, he was elected a Fellow of Trinity College. Having taken his degree of M.A., he obtained in July 1823, by presentation of his college, the perpetual curacy of St. Michael's, Cambridge, where for thirty years he performed the duties of his sacred office with unwearied zeal and assiduity. On the death of Mr. Dobree, he was elected, October 22, 1825, Regius Professor of Greek in the University of Cambridge. In 1827 he married, and in the same year he commenced the courses of lectures on the principal Greek authors, which, with few interruptions, he continued for a quarter of a century. In the Lent Term of each year he delivered lectures on Æschylus, Plato, Aristophanes, Thucydides, Sophocles, Demosthenes, and Pindar, returning to each, on an average, once in seven years. In 1844 he made a tour in Scotland, and he visited that country three times afterwards. On the 11th of November 1849 the church of St. Michael was burnt down. On the following day Dr. French, canon of Ely, died, and Mr. Scholefield succeeded him in the canonry, the preferment being attached to the Regius Professorship of Greek. St. Michael's church was rebuilt, and was re-opened January 11, 1852. Professor Scholefield's health, however, had been failing for some time, and he was ordered by his medical adviser to refrain from preaching, and take rest in some healthful and pleasant place. For that purpose he retired to Hastings, on the coast of Sussex, and there died, April 4, 1853. He was buried at Fairlight, near Hastings.

Professor Scholefield's principal literary publications are as follows: In 1826 he published a new edition of Porson's Four Tragedies of Euripides; in 1828 an edition of Middleton's 'Treatise on the Greek Article;' an edition of Æschylus, with notes critical and explanatory; and a new edition of Bishop Leighton's 'Prælectiones.' His next work was 'Petri Pauli Dobree Adversaria,' containing Dobree's notes on the Greek historians, philosophers, and minor orators, of which Part I. was published January 1831; Part II. November 1831; and Part III. January 1833. In 1832 he published 'Hints for an Improved Translation of the New Testament,' and in 1834 an edition of the New Testament, in which the original Greek and authorised English version are printed in parallel columns. In 1843 he published an edition of the 'Eumenides' of Æschylus. Several of his sermons have been published in a separate form.

(*Memoirs of the Rev. James Scholefield, M.A., late of Trinity College, Regius Professor of Greek in the University of Cambridge, Perpetual Curate of St. Michael's, and Canon of Ely*, by his Widow, *with Notes on his Literary Character* by the Rev. William Selwyn, M.A., Canon of Ely, 8vo, 1855.)

SCHOLZ, JOHANN MATTHIAS AUGUST, was born at Kapsdorf near Breslau in Prussian Silesia on February 8, 1794. He received his early education in the Roman Catholic gymnasium of Breslau, in 1812 entered the university there, where he studied theology and philology; and in 1814 gained a prize in the Roman Catholic theological faculty for his essay on the Parable of the Vineyard. Shortly afterwards he commenced his critical labours on the text of the New Testament, and with this object after he had for two years availed himself of the materials in the library of Vienna, in 1817-19 he visited Paris and London, Switzerland and Italy. In 1820, immediately after being appointed professor extraordinary of theology at Bonn, he joined the expedition under Minutoli for the exploration of Egypt and the neighbouring countries. The travellers disagreed and parted, but Scholz journeyed through Egypt, Palestine, and Syria for four months, when he returned to Trieste. At Breslau in 1821 he took priest's orders, exercised his functions at Bonn, and in 1823 was made professor of theology in the university and a canon of the cathedral. He died in November 1852. Among his principal works we may mention 'Reise in die Gegend zwischen Alexandrien und Parätonium, die libysche Wüste, Siwa, Ägypten, Palästina, und Syrien, in den Jahren 1820 und 1821,' which was a selection from his diary, and was published in 1822. In 1825 he issued at Bonn his 'Commentatio de Golgathæ et Jesu Christi Sepulcri Situ,' in 1834 his 'Handbuch der biblischen Archäologie,' and in 1830 and 1835, the great object of his studies, the text of the New Testament, under the title of 'Novum Testamentum Græce,' in two volumes. Scholz's excellence as a philologist has been generally acknowledged, and his labours are held in high estimation.

SCHOOLS.—Under the head of SCHOOLS in vol. xxi. page 50, we remarked on the increased interest which was then taken in the subject of the education of children especially those of the poorer classes. From that period the interest has greatly increased; many plans have been proposed, some have been adopted, and even in the establishments for the education of the more wealthy classes, much improvement has taken place.

From the time of the Reformation, when the Scriptures were freely opened to all, no one believed that it was a necessary qualification for a Christian man or woman that he or she should be able to read the Scriptures. The oral instruction of the Church was thought all-sufficient in religion. To have an educated class, as distinguished from a class totally uneducated, was the object of those who most valued sound learning. The first colonists of New England founded a common school wherever they met to clear the forests and to raise their towns. All who sought a country where opinion should be free, felt the duty of keeping the light of religious intelligence burning amongst them. Not so in the mother country. Neither the motive of love nor the motive of fear led us to think of the education of the masses till the times in which we now live. The education that was amongst our forefathers was sufficient, in their estimate of what was good. There *was* a system of education amongst them which they cherished and upheld. We live in another era; but it is not wise to contemn those who walked by other lights.

There are four clear divisions in the progress of education in England, limiting the inquiry to that education which is wholly, or in part, gratuitous:—

1. Education by the Church, from the establishment of monastic institutions to the Reformation.

2. Education by endowment, immediately subsequent to the Reformation, for the most part limited to schools for the higher branches of learning, called grammar-schools.

3. Education by what are commonly termed free schools, mostly established by endowment, and further supported by subscription, for the instruction of a select portion of the poor in reading, writing, and arithmetic.

4. Education by voluntary associations, whether as Sunday schools or day schools, some of which have, within a few years past, received a limited measure of assistance from the State.

The exclusive education by the Church has passed away. Education by the State never existed in England—even in the most restricted sense of state-counsel and small money-aid—till within the last eighteen years. The education of the people since the Reformation has proceeded from the people. It has been uniformly in a state of progress, though occasionally exposed to corruption and consequent decay. The endowed grammar-schools are coincident with the progress of the middle class; the free schools which are not grammar-schools go along with the gradual rise and progress of the operative class; the Sunday schools, and the other schools of voluntary association—the schools of the present century—belong to a new era, when the universal education of the people is held to be a matter of duty and necessity. The advance of public opinion as to this duty and necessity forces on the last condition of progress—education by the State.

The endowed grammar-schools were the natural successors of the schools and chantries of the unreformed Church. They contemplated no education except the most liberal. Children were to be brought up as scholars, or to be taught nothing. The grammar-schools were the nurseries of the learned professions, and they opened the way for the highest honours of these professions to the humblest in the land. About the time of the Revolution the commercial classes, who had grown into wealth and consequent importance, began naturally to think that schools in which nothing was taught but Latin and Greek, were not altogether fitted for those who were destined to the life of traffic. Uneducated men who had pushed their way to fortune and honour, generously resolved to do something for their own class; and thus we came to see in every town, not a free grammar-school, but a free school, over whose gates was generally set up the effigy of a boy in blue or green, with an inscription betokening that by the last will of Alderman A. B. this school had been founded for twenty poor boys, to be clothed, and taught reading, writing, and arithmetic. With a comparatively small population these free schools, we venture to think in opposition to modern authorities, were admirable beginnings of the education of the poorer classes. While the grammar-schools were making divines and lawyers and physicians out of the sons of the professional classes and the wealthier tradesmen, the free schools were making clever handicraftsmen and thriving burgesses out of the sons of the mechanics and the labourers; and many a man who had been a charity-boy in his native town, when he had risen to competence, pointed with an honest pride to the institution which had made him what he was, and he drew his purse-strings to perpetuate for others the benefits which he had himself enjoyed.

According to the digests of the Reports made by the Commissioners for Inquiry into Charities presented in 1842, the annual income of the grammar-schools of England and Wales amounted to 152,047*l*., but some schools were excluded from the inquiry. The annual income of the free schools, described by the Commissioners as "schools not classical," was 141,385*l*.

The digest of the Commissioners' Reports does not give us the number of endowed schools, nor of children therein educated. But we may form a tolerable approximation to the number, from the returns furnished by the ministers of the respective parishes in England to a committee of the House of Commons, in 1818. According to these returns the annual revenue of the endowed schools of England was 300,525*l*., to which if we add 7000*l*. for Wales, we have a very near approach to the revenue of the digest of 1842; the same returns state the number of endowed schools in England as 4167, and of children educated therein, 165,433; and in Wales, schools 209, children 7625. In 1833 a series of questions was addressed to the overseers of the poor in England and Wales, the answers to which would show a falling-off both in the number of endowed schools and of children therein educated, giving the schools as 4106, and the children as 153,764. If there were such a falling off, it may be accounted for by the fact that some of the endowed schools had been illegally converted into national schools. Comparing all the returns, we may say in round numbers that the income of the endowed schools was 300,000*l*.; the number of schools 4000; and the number of scholars 150,000.

The 300,000*l*. thus derived from the rent of land, rent charges, funded securities, &c., during three centuries, has been the foundation upon which has been built up much of the sterling worth of the English character. One hundred and fifty thousand children have been receiving, for a long series of years,—some the most liberal education, some the commoner rudiments of worldly knowledge, all of them religious instruction,—at an average cost of 2*l*. per child. The average cost of each scholar in the national schools is 11*s*. 2*d*. per annum. There have been many attempts, and some have been successful, to turn the funds of the endowed schools, contrary to the wills of their founders, into schools for universal education; and had these attempts been supported by the Court of Chancery, or encouraged by the legislature, we might now have been educating out of the same funds, upon the monitorial system, about 540,000 children, instead of 150,000. We apprehend that, with the best intentions, some unsound opinions have been taken up on the subject of endowed schools. The registrar-general, in his very able Seventh Annual Report (1846), says: "The insufficiency of the national education is the more to be regretted, as the means of education exist, and the funds left for educational purposes, *if properly applied*, in the charities and public institutions, would, with some assistance from Parliament, supply the children of the poor with the sound knowledge which the scanty earnings of the parents do not enable them to purchase." We affirm that these funds are properly applied when they are applied to the precise objects contemplated by the endowment. There have been great abuses in the management of some of these institutions, which have been corrected. The Commissioners of Inquiry into Charities reported a vast amount of delinquency and neglect, especially with regard to grammar-schools. The Court of Chancery, upon the representations of the Commissioners through the attorney-general, has remedied many of the most glaring evils; and we have now many institutions distributing a large measure of good, where formerly were only decay and uselessness. "Incompetency of the master," —"school discontinued,"—"no scholars for many years,"— "master non-resident,"—"grammar-school abolished by trustees,"—"no free scholars taught,"—these are not uncommon statements amongst the original reports upon grammar-schools. There is a better spirit now abroad; and trustees and visitors at the present day would be ashamed of such gross misapplications of the means of preserving sound learning amongst the people. Legislative action has been brought to bear upon some; and the Harpur Charity at Bedford, and Dulwich College, for which an Act was passed in 1857, now make their ample means much more generally advantageous. Abuses, no doubt, still exist; but, as a whole, the grammar-schools have worked well in this country. They have kept alive amongst us the liberal studies which have nourished a race of divines, lawyers, physicians, statesmen, that may challenge comparison with those of any nation. They have opened the gates of the higher employments to industry and talent unsupported by rank and riches. They have mitigated the inequalities of society. They have ploughed up the subsoil of poverty to make the surface-earth stronger and richer. What the grammar-schools have done for the higher and middle classes, the free schools have done for the lower, in a different measure. They were the prizes for the poor boy who had no ambition, perhaps no talent, for the struggles of the scholar; they taught him what, amongst the wholly untaught, would give him a distinction and a preference in his worldly race,—and he was unenvied by the less fortunate, because they knew that there was no absolute bar to their children and their kindred running the same course. Do we assert that there is nothing to be desired beyond this state of things? Unquestionably not. But we do desire that no feelings falsely called utilitarian, should induce us to wish the appropriation of funds to one purpose, that were appropriated to another purpose. An American writer, speaking of the property given to endowed schools, says: "It is easy to see that, if this sum were consolidated, and then distributed on principles of equality, it would be productive of incomputable good." (Horace Mann's 'Educational Tour,' 1844.) The evil is computable, as well as the good. The good would be the education after some universal manner of 400,000 more children than are now educated out of these funds; the evil would be, that they would not be educated after the manner prescribed by the founders of these schools, and we think that the manner prescribed by the founders is more than ever necessary as education of some sort becomes universal. We desire most ardently to see the whole body of the people educated; but we also desire to see some portion of the people—not the rich only, but some portion of the poor—better educated than the great bulk of the community ever can be. It is a common saying that, if the founders of these schools could remodel their endowments, they would distribute their benefits as widely as possible, by teaching the larger number cheaply instead of the smaller number expensively. We doubt if any sound lover of knowledge, even at the present day, would not feel that he was doing more good as an individual by leaving a thousand pounds to support a highly meritorious poor scholar by an exhibition at the university, than by leaving a thousand pounds to instruct fifty boys and girls in reading and writing. And why? The elementary education of the whole people has become too large a matter for individuals to deal with. They can more properly employ their charity in raising the character of education, by encouraging the higher branches of knowledge. The spirit of voluntary association, aided in a considerable degree by the State, must do the work of instructing millions. That spirit is not slumbering when we know —as we shall have to show in detail—that nearly 900,000 scholars are now receiving instruction more than the number that were instructed in 1833. These 900,000 scholars cost more for their annual instruction—in addition to the cost of the schools which contain them—than the annual revenue of all the endowed schools that survived the Reformation, that have been founded since the Reformation, and which furnished, with the exception of private schools, the only systematic education which the people of England received, up to the beginning of the present century.

Up to the year 1833 the legislature had limited its duties with regard to education to inquiries into its state, and lamentations over its inefficiency. In the session of 1833 the principle was first established that it is just and wise to appropriate some portion of the public income to the purposes of education in England. Twenty thousand pounds were then voted, in aid of private subscriptions for the erection of schools for the education of children of the poorer classes. The Treasury regulations for the application of this sum prescribed, that no grants should be made except under a Report from the National School Society, or the British and Foreign School Society. Upon this foundation, narrow indeed with reference to the amount of the grant, but ample and solid as regards its capacity of extension, was raised up, in 1839, a new branch of administration,—the Council of Education. It is beside our purpose to recount the few opposition to this great measure, which had been adopted upon the responsibility of the executive government. The administration persevered in their plan, against a powerful minority in the House of Commons, and a vast majority in the House of Lords, who prayed her Majesty to revoke the order in council by which the Board of Education had been appointed. The first parliamentary grant placed under the direction of the Council on Education was 30,000*l.*, which was continued annually to 1842; it was then raised to 40,000*l.* for 1843 and 1844; in the session of 1844-45, it was 75,000*l.*; in those of 1846 and 1847, 100,000*l.* each year; in 1848 and 1849, 125,000*l.* each year; in 1850, 110,000*l.*; in 1851, 150,000*l.*; in 1852, 160,000*l.*; in 1853, 260,000*l.*; in 1854, 263,000*l.*; in 1855, 396,321*l.*; in 1856, 451,213*l.*; and in 1857, 541,233*l.*; a total since 1833 of 3,206,767*l.*

But the efforts of the legislature have not been confined to grants of money. Without noticing the number of schemes proposed, and the debates upon them, in which the adherents of the voluntary principle, and those advocating a national superintendence and support, have contrived to neutralise each other's efforts, we will shortly notice what has been actually done. In 1842 an Act was passed for facilitating the acquisition of sites for school-houses, which was repeated, amended, and extended in 1850, 1852, and 1853. In 1843, land and buildings occupied by societies for literary and scientific purposes were exempted from the payment of county, borough, parochial, and other local rates; and in 1854 further facilities for the institution of such societies was afforded by another Act. In 1844, in a Poor-Law Amendment Act, the Poor Law Commissioners were empowered to combine parishes and unions into school districts, to form boards for their governance, which boards, subject to the regulations of the Commissioners, were to appoint, pay, and control its teachers and other officers, for the purpose of instructing the children of the poor; but no child was to be compelled to attend any religious service contrary to the principles of, or be instructed in any religious creed contrary to that professed by, the parents; and in 1848 the provisions of the Act were amended, by extending them to parishes not in unions, and removing the limitation of expense, previously limited to one-fifth of the aggregate of the poor-law expenditure. In 1847 the law regulating the attendance at school of children employed in print-works was amended. In 1850, an Act was passed empowering town-councils to establish public libraries and museums, by imposing a small rate, such libraries and museums to be open to the public free of expense; extended in 1855 to places not having councils and to parishes; and similar Acts were passed for Scotland and Ireland in 1853, 1854, and 1855. While this attention was continually bestowed on the subject of general instruction of the children of the honest poor, it was felt that there was a lower class, in which, probably to a great extent, ignorance was the parent of crime. In Aberdeen a successful effort had been made to recall youthful vagrants or petty offenders to the paths of rectitude by judicious instruction; and after an experience of several years, both in England and Scotland, supported by voluntary contributions, it was endeavoured to diffuse the benefit by the legal establishment of reformatory schools, and in 1854 there was passed 'An Act to render Reformatory and Industrial Schools in Scotland more available for the benefit of Vagrant Children;' and in the same year an Act was passed 'for the Better Care and Reformation of Youthful Offenders in Great Britain;' in which, after paying a tribute to the existing establishments, it enacts that they shall be licensed by the Secretary of State, and then receive youth of both sexes, who, on being convicted before a magistrate, shall by him be considered proper objects for the institution, the expense to be defrayed in the first instance by the Treasury, but to be recoverable from the parents, if able to pay. Other Acts, with the same object, were passed in 1856 and 1857, by the last of which justices of the peace in session, or the council of a borough, may grant money in aid of such schools. In 1857 there was also passed an Act 'to make better Provision for the Care and Education of vagrant, destitute, and disorderly Children, and for the Extension of Industrial Schools.' By this Act, without waiting for any actual crime, a neglected child may be transferred to a place of education, and his careless or probably dissolute parents may be forced to contribute to his support.

Besides the above, which relate chiefly though not entirely to England, an Act was passed in 1845 for amending the provision for parish schoolmasters in Scotland; a provision, however, yet far from equivalent to the services they perform. To Ireland the grants of money for the diffusion of education have also been large, and, on the whole, increasing. An Act for establishing Public Libraries and Museums in Ireland (18 & 19 Vict. c. 40) was passed in 1855; and a number of schools have been established, chiefly under the direction of the Roman Catholic clergy, which to some extent supply the place of Reformatory schools. The repeal of the compulsory tax on newspapers in 1855, and the reduction of postage on printed papers, books, and MSS., may also be fairly considered as aids to education.

In addition to this legislative action, the general public have not been wanting in efforts to diffuse education. In most of the large towns Ragged Schools have been formed and supported for the instruction of the more destitute children; and, in conjunction with mere school learning, it has been endeavoured to inculcate habits of industry, by establishing Shoe-Black Brigades and Crossing Sweepers, by which boys during the day are enabled to earn money, a part being devoted to their support, and the remainder placed to their account, to form a fund for their future advancement; their evenings being spent in school. The results, on the whole, have been very satisfactory. Schools have also been established for teaching girls Common Things, chiefly in domestic economy. The preparation of teachers has been also more attended to, and few of the paid instructors, either male or female, are now appointed to any of the schools, without certificates of capability from recognised examiners. For this purpose the British and Foreign School Society and the National Society have established normal and model schools, where instruction is afforded, capability tested, and certificates granted. Inspectors are appointed to visit all the schools by the Board of Education, and also by the above-named societies to visit their own; and in the Report of the British and Foreign School Society in 1857, one of them, Mr. William Davis, B.A., says: "Remembering, as I do, the kind of education given in most of our British schools some ten years ago, it is with no ordinary gratification that I observe the vast improvement that has been effected, both in the quality of instruction and in the methods of imparting it." The Report, in 1854, of Mr. Horace Mann on Education, compiled upon the materials furnished by the census of 1851, confirms this. He states that there were then 40 colleges, supported at an annual cost of 90,000*l.*; and that from five belonging to the National School Society, 270 qualified teachers issue annually. By the whole about 400 masters and 250 mistresses are annually prepared for their duties.

Looking, then, to the prodigious exertions that have been made since 1833, we may conclude that from official returns we should find such an increase of school accommodation, and of children under instruction, as would leave little to be done beyond a steady perseverance in the same course of voluntary exertion with Government aid. We speak here with reference only to the numerical amount of education; the quality of the education given embraces a much wider range of inquiry. Important as it is to ascertain with exactness the number of children daily receiving instruction by the aid of voluntary benevolence, or by endowment, the means of such computation are not yet perfect; and the computations of those who take different views as to the necessity of State interference are so widely different, that it requires a very careful analysis, and, what is more, a complete abnegation of the spirit of partisanship, to enable us to arrive at safe conclusions.

The Rev. Mr. Hook, in a pamphlet published in 1846, calculated that for the proper instruction of the people, one in every six of the total population should be at school. Some enthusiasts say the proportion should be one in four. Mr. E. Baines in 1845 estimated that one in every nine was then at school. Mr. Mann, in his Report, thinks that one in eight would be sufficient for all useful purposes. In 1833, with a population of 14,386,415, the number of day scholars was 1,276,947, which gives one in every 11·27; and of Sunday scholars, of 1,548,890, or one in 9·28; the total is 2,825,837, or one in every 5·25. But to include the Sunday schools would be a fallacy; for the instruction, though extremely beneficial in itself, only extends, generally, to so much reading as to enable children to read their Bible and a few other religious books, and many of the children are also attendants at day schools. By the census of 1841 the number of children between five and fifteen years of age, the period during which children generally commence and conclude their school education, was, in round numbers, 3,620,000, leaving nearly 800,000 unprovided for. But among the industrious and working classes comparatively few can afford to keep their children at school till they are fifteen, and the far greater portion will only be at school for periods of four or five years, or even less. It is not easy to test the amount of education imparted, but in the year ending July 30th, 1839, out of 121,083 marriages, 40,587 men and 58,959 women signed the register with marks, so that only 59·5 per cent. of the males could write, and only 41·1 of the women.

In 1851 the total number of children between five and fifteen, was 4,005,716. But, probably from the extension of infant schools, it was found by the census that a large number of children were sent to school at the ages of three and four, and therefore the number between three and fifteen is raised to 4,908,696, of whom 2,466,481 were boys, and 2,442,215 were girls. Of this number, beginning at five years old, 381,774 boys and 218,055 girls were employed. Between five and ten, upwards of 2000 boys are messengers; nearly 6000 are farm labourers; upwards of 5000 boys and 7000 girls are engaged in the cotton and woollen manufactures and in straw-plaiting; and 1209 boys and 11 girls in coal-mining. Between ten and fifteen the numbers employed in nearly every profession become very large, showing clearly that, though fifteen may be taken as one extreme of the period of education, the ordinary term seldom extends beyond twelve or thirteen. The demand for juvenile labour, and the prospect in a labourer's family of gaining an additional shilling or perhaps two shillings per week, must frequently overcome the prospective advantage of sending the children to a school, where the instruction gives little promise of promoting the child's pecuniary interest. To the number thus withdrawn from school, must be added a considerable number educated at home, sometimes by teachers and often by the parents themselves: the returns give 17,302 boys and 27,323 females, which there is little doubt represent those having teachers. Deducting these classes, we have 4,264,242 children who ought to be provided with the means of education. Though illness will, of course, prevent attendance, yet as it is not likely to be continuous through the period, we make no deduction on that account. To supply the want, the census return shows an attendance of scholars in day schools of 2,144,378, a proportion of one in 8·36 of the population, but little more than half of the number of children. The Sunday schools make an addition of 2,407,642, which carries the number above what is required; many, however, of the younger day-scholars attend them, and some of the employed may attend, but, as we have said, the education afforded at these schools is ineffective for practical purposes.

The Report gives a table showing the number of scholars for each year of age between three and fifteen, by which it would appear that the average attendance of scholars between their third and fifteenth year is five years, and between five and fifteen, four and two-fifths. What a child can learn from three years old to eight cannot be much, supposing it is kept at school for the five years, and then leaves, and is almost certainly lost when subsequently employed in labour, without the aid of secondary schools to keep their scholastic acquisitions in use. This is shown by the marriage registers for 1856, in which, out of 304,226 persons married, 44,806 men and 62,672 women signed with marks, or 34 per cent. of the whole. This is certainly a great advance on 1839, but as in the last eighteen years such great efforts have been made, a more satisfactory result might have been expected, although the greater part of the marriageable people must have received their education before the most material improvements had been introduced.

Great part of what we have written applies equally to Scotland and Ireland. Scotland shares in the Parliamentary grants we have enumerated, and has also adopted most of the extensions of school education we have mentioned. On the whole, in that country education is more widely diffused than in England, and in the parochial schools it is of a higher order, the teachers in most of them having received collegiate instruction; and mathematics and Latin, with occasionally Greek, is taught where the scholars are capable and desirous of receiving such instruction.

By the census of 1851, the population of Scotland was 2,888,742, and by the returns, the number of scholars was 368,517, or one scholar to every 7·84 inhabitants, but under the heading of 'Occupations,' the number returned as 'scholars' was 426,566, or one in every 6·87. In the latter number the term 'scholar' may have been loosely understood, but the probability is that all were being taught something. Of the number in the census return 205,348 were boys and 163,169 were girls, attending at 5342 schools. At public day schools there were 280,045 scholars, and at private day schools there were 88,472 scholars. It must be noticed, however, that the census includes all persons at school, and that of the 286,611 of whose teaching accounts were obtained, 17,768 were from fifteen to twenty and upwards. This would reduce the comparative number with England to rather more than one in every eight. Sunday schools are not so much frequented as in England. At the time of the census there were but 292,545 scholars, or little more than one in ten of the population. At adult evening schools there were, however, 15,071 scholars.

Of the total number of boys in the public day schools, out of 153,712 of whom information was given, 134,327 were being taught reading, 83,005 writing, 68,174 arithmetic, 42,282 English grammar, 48,802 geography, 6770 modern languages, 9111 ancient languages, 5400 mathematics, 4197 drawing, 31,887 music, and 1092 industrial occupations. Of 112,058 girls in public day schools, 98,612 were being taught reading, 51,890 writing, 34,495 arithmetic, 24,435 English grammar, 28,279 geography, 3990 modern languages, 556 ancient languages, 190 mathematics, 1570 drawing, 21,816 music, and 17,096 industrial occupations. The proportions are nearly the same in the private day schools. We may remark, however, that in the parochial schools music only means psalmody. A similar enumeration has not been given for England; only the number of schools in which such subjects are professed to be taught. In Scotland the average yearly salary of the parochial schoolmaster is 50*l*., with, in general, a residence; of the mistresses the salary is 16*l*., with a residence. In 1846 an Act was passed for amending the condition of parochial schoolmasters, but the improvement was not great, as is shown by the census returns.

In Ireland the endeavour to promote education has been constant, but till lately very ill-applied. Under Henry VIII. an Act was passed that every clergyman should teach the English tongue to all in his cure. By the 12 Eliz., cap. 1 (1570), a free school was to be established in every diocese. The statute of Henry VIII. was re-enacted under William III. Of course, the object in the two last-named reigns was that Protestantism should be taught; of course the schools were ineffective; and almost of course they became a mere form, the clergyman giving forty shillings a year to some one called a schoolmaster, and taking no further trouble. In 1731 'The Incorporated Society for Promoting English Protestant Schools in Ireland' was established, and was liberally assisted from the public funds. In 1741 they had formed 18 schools, at which they had educated 372 children (who were rigidly separated from their parents), and had expended 10,000*l*. These were the Charter Schools. In 1784, after an expenditure of 490,000*l*., the celebrated John Howard proved that the children were ill-treated, their education neglected, and that they were made to work for their masters, and yet only the children of Roman Catholics were admitted for the purpose of conversion. The Irish House of Commons admitted the facts, but continued to vote money. In 1803 orphans and children of Protestants were admitted as well as Roman Catholics, but with the same separation from their families as before. The number of scholars increased, but were still under 2000, and the annual cost was 35,000*l*., of which sum three-fourths were paid by the State. After a report on their condition in 1825, the government support was gradually withdrawn from them. But though these efforts utterly failed, the Irish poor were far from being an uneducated people. There were 'Hedge' schools, where the children of the peasantry were taught by the priest so effectually, that Wakefield in his 'Tour in Ireland' calls the Irish an "universally educated" people. In 1817 the Kildare Place Society began their operations. They were to form two model-schools in Kildare Place; they were to assist with grants the founding of schools; to receive and qualify masters and mistresses; to publish and furnish gratuitously proper books; to cause the schools to be inspected annually; and to encourage deserving masters and mistresses by gratuities. These schools were at first a success. They were supported by government grants, and were attended by scholars of all religious persuasions. In 1825 there were 1490 schools, and upwards of 100,000 scholars, but they at length became distasteful to the Roman Catholics. In 1831, therefore, after a Parliamentary inquiry, a Board of

National Education in Ireland was established, composed of eminent men from all the religions beliefs in Ireland, who were commissioned to draw np a scheme of instruction, and provide such books as were necessary, to enable the children of all creeds to attend them. This was done very successfully. The government were liberal in their grants; and at the close of 1833 they had established 789 schools which were attended by 107,118 scholars. These schools continned to thrive, and the government grants to increase. From 1848 to 1850 those grants were 120,000*l.* annnally; in 1851, 134,560*l.*; in 1852, 164,577*l.*; in 1853, 182,073*l.*; in 1854, 193,400*l.*; in 1855, 215,200*l*; in 1856, 227,641*l.*; and in 1857, 213,000*l.*; a decrease arising probably from a decrease in the scholars attending the schools, in consequence of the large emigration of the few preceding years. The census retnrns of 1851, however, tell a very nnsatisfactory tale. The total population of Ireland was 6,551,970; and the number of males who could neither read nor write was 1,202,650; of the females, 1,563,633. Bnt in that year the number of the National Society schools had increased to 4704, there were 94 in progress of erection, and 13 had been suspended. The number of children on the rolls was 520,421; there had been 257 teachers trained in the school dnring the year, and 33 at their own expense. Of the 290, there were 21 of the Established Chnrch, 39 Presbyterians, 2 other Protestant Dissenters, and 228 Roman Catholics. There were also 28 model and 37 ordinary agricultnral schools, with 2003 pnpils, of whom most pay either fully or in part. On Dec. 31, 1855, the number of schools was 5193, and the nnmber of children on the rolls was 538,246, a decrease from 1854 (np to which year the nnmber had regularly increased), probably arising in part from an unfortunate feeling of dislike taken to the schools by the Roman Catholic priesthood, and partly from the large emigration that had taken place from the kingdom. In 1855 the annual Report of the Chnrch Edncation Society claimed 90,572 scholars, bnt these include "schools in connection;" and in 1851, nnder the same heading, they nnmbered 103,878 scholars. The Sunday schools in 1855 mustered 213,919 scholars.

In 1845 an Act was passed for endowing Maynooth College for the better edncation of the Roman Catholic priesthood. In the same year was also passed an Act "enabling her Majesty to endow new Colleges," in consequence of which the Queen's Colleges of Belfast, Cork, and Galway have been bnilt and endowed. A snm of 100,000*l.* was assigned ont of the Consolidated Fnnd for purchasing the sites, and erecting and furnishing the bnildings of the three Colleges. Her Majesty and her sncceseors were made visitors, with power to appoint, by sign manual, persons to execute the office. The appointment of the presidents, vice-presidents, and professors, was entrusted to the Crown, nntil parliament should otherwise determine. The Commissioners of the Treasnry were empowered to issne annnally a sum not exceeding 7000*l.* for the payment of salaries and other expenses in each college; it being moreover provided that reasonable fees should be exigible from the students. Lecture-rooms were directed to be assigned for religions instruction; and it was enacted that no student should be allowed to attend any of the colleges unless he should reside with his parent or gnardian, or some near relation, or with a tntor or master of a boarding-house licensed by the president, or in a hall founded and endowed for the reception of students.

A president and vice-president for each college were soon after nominated, and the erection of the buildings was begun. The other appointments were made in Angust 1849, and the three colleges were opened in the end of October following. An additional snm of 12,000*l.* had shortly before been granted by Parliament for providing them with libraries, philosophical instruments, and some other requisites.

Originally it was intended that the number of professors in each college, exclnsive of the president and vice-president, should not exceed twelve, and letters patent constituting them upon that basis were passed for each under the great seal of Ireland in December 1845. Afterwards it was determined that the nnmber should be augmented for the present to nineteen, bnt that it should not at any time exceed thirty. The vice-president however is also a professor. New letters patent embodying that extended scheme were granted in favour of each of the three colleges in November 1849.

Under the existing constitntion, then, the body politic and corporate of each college consists of a president, with a salary of 800*l.* and a house; a vice-president, with a salary of 500*l.* and a house; and professors of Greek, Latin, mathematics, history, and English literatnre, logic and metaphysics, chemistry, natnral philosophy (each with a salary of 250*l.*), modern langnages, natnral history, minerslogy and geology (each with a salary of 200*l.*), English law, jurisprudence, and political economy, civil engineering, and agricultnre (each with a salary of 150*l.*), the Celtic languages, the practice of snrgery, the practice of medicine, materia medica, and midwifery (each with a salary of 100*l.*). There are also attached to each college a registrar (with a salary of 200*l.*), and a bursar and librarian (each with a salary of 150*l.*). A snm of 300*l.* annually is allowed for the payment of porters and servants. The total annnal expenditnre for salaries is thns (dedncting 250*l.* for the professorship held by the vice-president) 5500*l.*

The remaining 1500*l.* of the annual charge on the consolidated fnnd is allocated to the payment of scholarships and prizes. The scholarships awarded at the commencement of the session at Belfast are: 48 of 24*l.* each to stndents of the facnlty of arts; 4 of 20*l.* each to students of the faculty of medicine; 2 of 20*l.* each to stndents of the facnlty of law; 2 of 20*l.* each to students of civil engineering; and 4 of 15*l.* each to stndents of agriculture; the number being eqnally divided in all cases between students of the first and students of the second year. The scholarships are all held for one year only.

The session in all the colleges extends from the third Tuesday in October to the second Satnrday in June, and is divided into three terms by recesses of a fortnight at Christmas and at Easter. The fees for each class vary from 1*l.* to 2*l.* 10*s.*; and there is besides a payment from each matricnlated stndent to the bnrsar on behalf of the college of 3*l.* at the commencement of the first year, and 2*l.* at the commencement of every snbseqnent year.

It had been all along contemplated that matriculation and attendance at these colleges, as at similar institntions established by pnblic anthority in onr own and other conntries, should condnct to graduation both in arts and in every other faculty, except only that of divinity; and all the regulations and arrangements of the academic curricnlum in each have been moulded npon that understanding. It was a question however we believe, for a considerable time whether, with a view to the conferring of degrees and other pnrposes, each college shonld be erected into a distinct university, or the three constitnted into one nniversity. The latter plan has been adopted, nndonbtedly to the placing of the new establishments in a greatly superior position to what they wonld have held if they had been left each to its provincial insulation; for it conld never have happened that a mere Belfast, Cork, or Galway degree would have carried the same weight with one from the Queen's University in Ireland. In the letters patent creating such a nniversity, her Majesty has declared that "gradnates of onr said University shall be fnlly possessed of all snch rights, privileges, and immunities as belong to persons holding similar degrees granted them by other universities, and shall be entitled to whatever rank and precedence is derived from similar degrees granted by other nniversities."

The peculiarity of and the need for such colleges arose from the state of religious feeling in Ireland. The greatest proportion of the people are Roman Catholics, and there is a large number of Presbyterians; but in Trinity College, Dublin, there are no arrangements which even recognise the existence of any form of religious belief but that of the Established Chnrch; not only is the student who may hold any other creed (in so far as snch dissenting students are admitted at all) left without any spiritual superintendence whatever, but the entire system of teaching and discipline is in the hands of members of the Church established by law, and is regulated and administered in all respects in conformity with the doctrines and ritual of that Chnrch. Freedom of admission to Oxford and Cambridge has always been one of the demands which Protestant Dissenters have urged most clamorously. Notwithstanding considerable opposition the experiment has succeeded. The colleges are attended by stndents of all religious creeds; but while thns free to all, the morals and the pecnliar faith of the student is sednlously attended to.

Neither in England have the efforts to promote edncation been confined to the poor. At Dnrham the bishop and dean and chapter obtained an Act of Parliament in 1832, authorising the institution and endowment of a university, which was opened for students in October 1833. In 1837 a royal charter of incorporation was obtained by which the style and title of 'the Warden, Masters, and Scholars of the University of Durham' was given to the institution. The charter gave the power of conferring degrees, and confirmed the rights and privileges assured to it by Act of Parliament, usually enjoyed by chartered universities. The bishop is appointed visitor; the dean of Durham is constituted warden. To the professorships of divinity and ecclesiastical history and of Greek and classical literature, which are both in the patronage of the bishop, canonries in the cathedral are annexed. The professor of mathematics and astronomy, the readers in law, Hebrew, history and polite literature, and natural philosophy, the lecturer of chemistry and mineralogy, and other officers of the university, are appointed by the dean and chapter. Of University College the warden of the university is master. Bishop Hatfield's Hall, instituted in 1846, is for divinity students. It has four tutors, one of whom is principal, a censor, and a chaplain. The academical year consists of three terms of not less than eight weeks each, which are called Michaelmas, Epiphany, and Easter Terms. The age of admission to the academical course is from 16 to 21; and for the divinity course, between 21 and 26; beyond this age students must be admitted by special leave. Care has been taken that the necessary expenses of students should be as moderate as is consistent with comfort, and any approach to extravagance is sedulously guarded against.

In 1854 an Act of Parliament extended the right enjoyed by the graduates of Oxford and Cambridge to practise physic without farther examination, to the graduates in medicine of the University of London. In the same year by another Act, a commission was appointed to draw up regulations for the improvement of Oxford University, and in 1857 a similar one was passed for Cambridge. Under these commissions many valuable improvements have been effected, and more may be confidently expected. Among those effected are the breaking up of the close scholarships (especially those of Winchester school) and throwing them open to general competition; the dispensation with the taking of a number of unnecessary oaths; the establishment of private halls; and the abolishing of the oath on matriculation and on taking the degree of B.A.; by which last regulation Dissenters are admitted to the whole advantages of a university education. In Scotland also an agitation is being made for some improvement in the universities.

SCHORL. [TOURMALIN.]

SCHUMACHER, HEINRICH CHRISTIAN, was born on September 3, 1780, at Bramstedt in Holstein. He distinguished himself by his mathematical proficiency and by his predilection for astronomy. At the age of thirty he was created professor-extraordinary of astronomy in the university of Copenhagen, whence he was called in 1813 to be director of the observatory at Mannheim, returning to Copenhagen in 1815 as professor of astronomy and director of the observatory there. In 1817 he was employed by the Danish government to measure the degrees of longitude from Copenhagen to the west coast of Jutland, and those of latitude from Skagen, the northern cape of Jutland, to Lauenburg, on the frontiers of Hanover; afterwards continued through Hanover by Gauss. In 1821 he received from the Royal Scientific Society of Copenhagen the direction of the survey and mapping of Holstein and Lauenburg; and in that year the king caused a small but excellently furnished observatory to be built for him at Altona, where he resided till his death. In 1824, in conjunction with the English Board of Longitude, he fixed the measure of differences between the observatories of Greenwich and Altona, for which purpose the English admiralty furnished a steam-vessel, provided with twenty-eight English and eight Danish chronometers. In 1830 he was employed in ascertaining the length of the seconds' pendulum, which had been made the base of the Danish scale of measures. In 1813 he commenced the publication of the 'Astronomische Nachrichten,' a work that is still continued, and is the only one that serves as a vehicle for the communication of opinions and facts from the astronomers of all the world, and contains a number of highly valuable essays. From 1820 to 1829 he published his 'Astronomische Hülfstafeln,' a good example of a carefully calculated ephemeris. In 1836 in conjunction with Bessel he undertook the editing of the 'Astronomischen Jahrbuchs.' He was a diligent and correct observer; in 1822 he announced the exact distances of Venus, Jupiter, Mars, and Saturn from the earth; and the phenomena connected with Encke's planet Astræa attracted much of his attention in the latter part of his life. He died at Altona on December 28, 1850. Schumacher united great talents with much modesty. He enjoyed the confidence of his sovereign, which he repaid by his diligent services, and he uniformly treated his fellow-labourers with the greatest courtesy, and imparted his assistance with unostentatious liberality.

SCHUMANN, ROBERT, a composer who has a great reputation in Germany, but whose works are little known in this country. He was born about the year 1815, and spent a retired and uneventful life, chiefly at Leipzig, immersed in the study and practice of his art. His excessive application disordered his mind; and when he died, July 29, 1856, he had been several years the inmate of a lunatic asylum. He married Clara Wieck, the most celebrated female pianist of the day, who, with several children, survives him. Schumann was undoubtedly a man of great genius; but he has injured his reputation with his contemporaries by his endeavours to found a musical school, or sect, professing to disregard the authority of the older masters, and to establish a new system of musical composition. As music has always been in a progressive state, posterity may perhaps do him justice by adopting his innovations of style. His only work of magnitude which has been publicly performed in England is a cantata, 'Paradise and the Peri,' the words of which are a translation of a part of Moore's poem. It was produced at one of Philharmonic Society's concerts in 1856, when the principal part was sung by Madame Goldschmidt (Jenny Lind); and, though our critics were at variance respecting its merits, yet it was generally regarded as a work of no ordinary power and beauty.

SCHWANTHALER, LUDWIG MICHAEL, one of the most eminent of modern German sculptors, was born at Munich on the 26th of August 1802. For some generations his ancestors had been sculptors in the Tyrol; his father, Franz Schwanthaler, was settled in Munich, where he acquired a very respectable standing as a monumental sculptor. Ludwig received a good classical and general education; and being intended to pursue the family calling, was early initiated into the arts of drawing and modelling, and the use of the chisel, in his father's studio. At the Munich Academy of the Fine Arts he was regarded with coldness if not dislike on account of his free notions in art, by Von Langer the director, who is said to have urged his friends to devote him to some other profession. The death of his father in 1821, by rendering it necessary that he should conduct the business for the maintenance of the family, fixed his destiny as a sculptor. The first commission which opened to him a prospect of making himself known was one from the King Maximilian Joseph in 1824, to design a centre ornament in silver for the table. It was to be of very large size, and the figures in relief, each about six inches in height, were to represent the procession of the gods of Olympus to the palace of Jupiter. So much as was executed is described as being very beautiful, but the death of Maximilian (October 1825) prevented its completion.

Schwanthaler now proceeded to Rome, where he remained a year, deriving great benefit from the advice and friendship of Thorwaldsen. He carried back with him to Munich two elegant bassi-rilievi of the 'Birth of Venus' and 'Cupid and Psyche,' and through the influence of Cornelius he was employed to execute two extensive Homeric bassi-rilievi friezes for the Glyptothek, then in course of construction. Among other works which about this time he produced were a statue of Shakspere for the theatre, and a grand basso-rilievo frieze, extending in all to a length of 150 feet, of the 'Apotheosis of Bacchus' for the dining-room of the palace of Duke Maximilian. In 1832 he again went by desire of King Ludwig to Rome, to complete Rauch's design for the south pediment of the Walhalla as well as to execute various other royal commissions for the new palace.

From the period of his return in 1833 his life was one of unceasing activity. The admitted head of the sculptors of Munich, the professor of sculpture (from 1835) in the Academy there, and the favourite of the art-loving King Ludwig, whose constant guide and assistant he was in planning and working-out the sculpturesque decorations of his vast architectural undertakings, Schwanthaler produced in rapid succession an astonishing number of works of unusual magnitude and grandeur, and was the centre of a crowd of able and devoted scholars and assistants. During the few remaining years of his life, all spent in ill-health be executed a succession of great works, such as would seem more than enough to have tasked the energy and indnstry of the most indefatigable and laborious workman whose days had been extended to the longest span, and who had been blessed with the most robnst health.

We can name bnt some of his more prominent works. The southern pediment of the Walhalla at Ratisbon, filled with a design intended to typify the liberation of Germany from the French, was only in part by him; bnt the design in the northern pediment, a later work, was wholly by himself, and was of a much higher order of merit. It is called the 'Hermann-Schlacht,' or 'Battle of Arminins,' and is one of the finest renderings of old Tentonic story which has ever been realised by the scnlptor's chisel. He also executed some of the statnes in the Walhalla, and the fourteen caryatides representing the Walkyren of the Tentonic mythology. For Ludwig's New Palace (Nene Königsban), Schwanthaler not only execnted several friezes and statues, bnt made the cartoons for nnmerons pictures which were painted in encaustic by Hiltensperger, Streidel, and others. Among these are a series of twenty-four compositions from Æschylns, twenty-one from Sophocles, twenty-seven from Aristophanes, a series from the tales of the Argonauts, another from the 'Works and Days' and the 'Shield of Hercnles' of Hesiod. His most famous piece of sculpture here is however the 'Myth of Aphrodite,' but the story of Venns was never more coldly told. For the Fest-Saalban he designed tho two lions, and the eight figures representing the eight circles of Bavaria, on the entablature; the frieze in relief of the 'Crnsade of Barharossa' ('Der Kreuzzug des Kaisers Friedrich Barbarossa'), placed above the paintings by Schnorr [SCHNORR, JULIUS VON KAROLSFELD, *S.* 2], one of his best works; the bassi-rilievi of Greek Dancers in the Ball-Room; and the twelve colossal gilt hronze statnes of the princes of the Honse of Wittelshach, in the Throne-Room, &c. For the façade of the Pinakothek he execnted statnes of twenty-five of the greatest painters. For the pediment of the New Art-Exhibition Gallery (Neue Kunstanstellnngs-Gebaüde) he execnted a representation of the Arts placing themselves nnder the protection of Bavaria. For the magnificent Ludwigs Kirche he modelled statnes of Christ and the fonr Evangelists, which are placed in a row of niches over the porch, and for the ends of the gable two colossal statues of St. Peter and St. Panl. There are also by him in Munich statnes, some of them of colossal size, and most of them in bronze, of Count Tilly, Field-Marshal Prince Wrede, Kreitmayer, the anthor of the Bavarian code, and one or two others. But the chief work with which he adorned his native city was his immense statue of Bavaria, which occupies the centre of the Bavarian Hall of Fame (Bairische Ruhmershalle). Bavaria is represented as a maiden crowned with the oak-garland; one hand is stretched out, and holds a laurel crown, the reward of merit; the other presses a sword against her bosom, to defend her independence; by her side reclines a lion. The gronp, which is of bronze, exceeds in magnitnde any other modern work. The figure of Bavaria is about 60 feet high, that of the lion is nearly 30 feet; the pedestal is 28 feet high: a staircase inside leads up to the head of Bavaria, which is large enough to contain several persons. This vast work was commenced in 1844, hut neither the sculptor nor the fonnder of thia nnparalleled work [STIGLMAYER, JOHANN BAPTIST, *S.* 1], lived to see it placed on its pedestal. It was inaugurated with great ceremony, October 9, 1850. Remarkable as this work is for its size, it is eqnally so for its grandeur. It was the crowning work of Schwanthaler's life, and as long as it endures it will be the most impressive monument to his genius. The Ruhmershalle however contains other proofs of his versatile imagination. In the tympana at the end of the wings of the building are fonr recumbent fignres by him, representing the four national divisions of the kingdom, Bavaria, the Palatinate, Swabia, and Franconia; and the frieze contains 92 metopes, all of them designed by him: 44 containing fignres of Victory, and the remaining 48 the arts and occupations of civilised life.

Among important pnblic works which he designed for other places may be mentioned, his grand fonntain in the Neumarkt, Vienna, around the basin of which he has placed figures typifying the Enns, Ips, Traun, and March, the four principal rivers of the archduchy of Austria, pouring their waters into the Dannbe, which is represented by a colossal figure in the centre; another and finer fountain in the Freinng, Vienna, in which are five beautifully designed bronze figures of Anstria with her fonr great rivers, the Danube, Vistnla, Elbe, and Po; the monnment of Carl Friedrich, grand-duke of Baden, with its fonr allegorical figures, at Carlsruhe; monnmental statues of the Emperor Rudolf von Habsbnrg at Spire, King Charles John of Sweden, the Grand-Duke Ludwig at Darmstadt, Mozart at Salzburg, Göthe at Frankfurt, Jean Paul Richter at Bairenth, and many more, one of the more remarkable being a series of twenty statues of eminent Bohemians for a national monnment at Liborch, near Prague, which however he left nnfinished. Among the works execnted for private patrons we can only name his statnes of Venns, Apollo, Cnpid, Diana, Vesta, Ceres, Bacchus, Pan, varions nymphs, and the like, from the Grecian mythology; statnes and statnettes of knights and old Tentonic heroes; and a vast number of sepulchral and portrait statues, bnsts, and medallions, which are to be fonnd not merely in the princely galleries and churches of Bavaria and Anstria, but scattered throughout Germany, and occasionally in England.

Lndwig Schwanthaler died—his feehle frame, it is said, literally worn ont by his nnceasing labour—on the 17th of November, 1848, having only a few months before completed his forty-sixth year. The above very incomplete ennmeration of his works will more than snffice to show the wonderful energy and indnstry of the man; bnt it ia necessary to examine the works themselves to form a just estimate of his varions and apparently inexhanstible genius. It will not of course be snpposed however that he accomplished the impossihle task of carving all these works with his own chisel. From the establishment of his stndio at Munich he had abont him a large body of pnpils, some of whom have since come to be among the more eminent of living German scnlptors, and to them was in most instances entrusted the duty of carrying ont the designs of the master. But Schwanthaler himself was a rapid, often an impatient designer, and hence, the imperfect design being left to be completed by insufficiently experienced assistants, it not seldom happens in his less important works that there is an absence of finish, an appearance of carelessness even, which is disappointing to the spectator and injurious to the repntation of the scolptor. Schwanthaler's strength is seen in his realisation of old Tentonic fable and history, like his Hermann-Schlacht, or those types of German ideas, snch as he has so grandly presented in his 'Bavaria.' Among the Grecian deities he falls into the old conventionalisms, or Germanises the Hellenic thonght.

By his will Schwanthaler bequeathed to the Mnnich Academy of the Fine Arts his stndio, with models of all the principal works execnted by him. The studio stands opposite to the honse in which he died, in the street named in honour of him, the Schwanthalerstrasse, and in it is carefnlly preserved the extensive collection of his works. It is open daily to the pnblic, and is one of the great art-sights of the German metropolis of art. The Crystal Palace at Sydenham contains casts of the head of the colossal 'Bavaria,' the 'Shield of Hercules,' and several other of Schwanthaler's prodnctions.

SCIENCE AND ART, DEPARTMENT OF. This department of the Committee of Privy Conncil on Edncation owes its origin to the suggestions contained in the Second Report of the Commissioners for the Exhihition of 1851. After nrging the necessity of the industrial classes of this conntry receiving more systematic instruction in science and art in order to enable them to maintain their pre-eminence in the neutral markets of the world, the Commissioners impressed on the government the advantages which would result from bringing the various institutions connected with science and art that were supported by the pnhlic fnnds, into close connection with each other, instead of their remaining nnder different departments of the government. The government took a favourable view of the suggestion; and as a part of the "comprehensive scheme for the advancement of the fine arts and of practical science," annonnced from the throne at the opening of the session of 1852-53, the Lords of the Treasury, in March 1853, gave their formal concurrence to the proposed arrangement of the Privy Council to "unite in one department, nnder the Board of Trade, with the Departments of Practical Art and Science, the kindred and analogous institutions of the Government School of Mines and Science, the Mnsenm of Practical Geology, the Geological Survey, the Musenm of Irish Industry, and the Royal Dublin Society, all of which are in part supported by Parliamentary grants;" and, the Treasury minute proceeds, "my Lords have given directions that the estimates for all these institutions shall be brought together under the general head of 'Board of Trade Department of Science and Art.'" The immediate purpose of this amalgamation, it was declared, was to bring the whole of these institutions under one common superintendence, to establish a central metropolitan school of practical science as well as of art, and to encourage and extend the formation of minor local institutions which should be in connection with, and assisted by, the central institutions, but as far as possible self-supporting and under the management of the local authorities.

As was said above, the institutions thus brought together under one department, were all in part supported by Parliamentary grants. The sums voted for each in the year previous to the amalgamation were: Government School of Mines and Science, 800*l.*; Museum of Practical Geology, 5272*l.*; Geological Survey, 5500*l.*; Museum of Irish Industry, 3348*l.*; Royal Dublin Society, 6340*l.*; Department of Practical Art, including the provincial Schools of Design, 17,920*l.*; in all 39,181*l.*; but the sum actually granted was 41,586*l.*, additions having been sanctioned of 150*l.* to the School of Mines, and 2255*l.* to the Department of Practical Art.

Of these institutions the character may be briefly indicated. The Government School of Mines and of Science applied to the Arts was founded in 1851, in consequence of memorials addressed to government by the mining districts of the United Kingdom, in which it was shown that the schools for the instruction of persons engaged in mining pursuits by various Continental governments had much increased the economy, efficiency, and safety of mining operations in the countries in which they had been established, and that the want of similar schools had long been felt in the mining districts of this kingdom. The Government School of Mines was accordingly opened in connection with the Museum of Practical Geology in 1851. It is now merged in the Metropolitan School of Science applied to Mining and the Arts, which forms one of the two great branches of the department which is the subject of this article.

The origin and purpose of the Museum of Practical Geology were stated under the head MUSEUM OF ECONOMIC GEOLOGY, *S.* 1 (vol. ii. p. 340), and it will be enough to add here, that it was in 1850 removed to the building erected for its reception in Jermyn Street, St. James's—now the head quarters of the Metropolitan School of Science. Ever since the establishment of the Museum, the Geological Survey of the United Kingdom has been carried on in connection with it, and thus extensive collections have been formed, and are continually augmenting, illustrative of the structure of the British Islands, and of the applications of geology to the useful purposes of life. The geological survey has been proceeding simultaneously throughout the United Kingdom, and in England and Ireland has advanced far towards completion. In Scotland it has, however, made but little progress owing to the maps of the Ordnance Survey of Scotland having been only recently issued.

To these metropolitan scientific institutions we may add the Royal College of Chemistry, founded in 1845, it having been, in 1853, transferred to the Department of Science and Art.

The Department of Practical Art was a development, or rather reconstitution of the central Schools of Designs of which a full account is given under DESIGN, SCHOOL OF, *S.* 1 (vol. i. 473). The Department of Practical Art was created but a short time before its amalgamation with the other institutions in the Department of Science and Art, and before it had come into full operation as a separate institution.

The Royal Dublin Society for the Improvement of Husbandry, Manufactures, and other useful Arts and Sciences, was founded in 1731, and incorporated by royal charter in 1749. It possesses a valuable museum of natural history; an agricultural museum; an excellent library; a museum of sculpture, casts, &c. From its establishment, we believe, it has had its schools of painting, sculpture, and the fine arts, from which many of the best native artists have proceeded. It has also a good chemical laboratory; and a convenient theatre for the delivery of lectures. The Botanic Gardens at Glasnevin belong to the Society, and the Zoological Gardens, Phœnix Park, are in connection with it. Though amalgamated with the Department of Science and Art, the Society is conducted wholly by its own council, the duties of the department being confined to supervision and suggestion.

The Museum of Irish Industry was established by the Government in 1845, and placed under the direction of Sir Robert Kane, so honourably distinguished for investigations in connection with the industrial pursuits of Ireland. In object, the Museum of Irish Industry resembles pretty closely the London Museum of Practical Geology, but takes a somewhat wider and more diversified range. It has a staff of professors who lecture in the theatre of the Royal Dublin Society, the professors since the union with the Department of Science and Art, being common to the two institutions. The system of lectures, which has some peculiarities, is an extension of that previously adopted by the Royal Dublin Society. Short courses are given during the day, chiefly to the upper classes; and other courses are given in the evenings chiefly to the sons and assistants of persons engaged in trade, and to artisans. Examinations take place at the end of every course, when prizes are awarded to the more successful students, and a general competitive examination is held at the end of every year. In addition to this, lecturers on science are sent to the provincial towns, and local examinations take place at stated periods in connection with their instruction.

The institutions which were united to form the Department of Science and Art, it will have been noticed, all belonged to England and Ireland. But in 1854 the necessary steps were taken for the formation of a National Museum of Industry for Scotland, similar to those of London and Dublin. A site was purchased by the government near the University of Edinburgh for the building; and the museum belonging to the town-council, and the valuable collection of models, minerals, &c., of the Highland Society, was transferred to the Crown, and thus an excellent basis was obtained for the proposed museum. These collections are at present exhibited in the University, and lectures are given in connection with them by competent professors.

The Department of Science and Art was originally constituted a section of the Board of Trade, but in February 1856 it was, by an Order in Council, transferred to the Committee of Privy Council on Education. Of that Committee it now forms a distinct division: its functions having reference to the secondary instruction of all classes of the community in those principles of art and science which conduce to the industrial interests of the country, while the functions of the other division of the Committee of Education refer to the primary instruction of the young; the two divisions being kept entirely unconnected. The Department itself consists of two sections—a School of Science, with its connected museums and affiliated institutions, having its head-quarters at Jermyn Street, and a School of Art, with its various collections and associated schools, having its head-quarters at South Kensington, where also are the offices of the Department. The sum voted for the Department of Science and Art in 1857 was 73,855*l.*, being an increase of 9180*l.* over the previous year, and 32,269*l.* more than the vote for the several institutions prior to their consolidation.

It remains to notice shortly the present position of the two sections of the Department. The Metropolitan School of Science, applied to Mining and the Arts, has, in the words of the official prospectus, "for its chief object and distinctive character (to which everything else is subsidiary), to give a practical direction to the course of scientific study." And the course of instruction which is imparted to the student, while it does not profess to qualify him to undertake the direction of mining or other technical operations, is intended, in combination with future training, to "render him in the highest degree competent, not only to engage in any special branch of industry, but to promote its further development." The institution is under the general supervision of a director, Sir R. I. Murchison, the eminent geologist, who succeeded the late Sir H. T. de la Beche, and the instruction is given by professors of Chemistry, Natural History applied to geology, Physical Science, Applied Mechanics and Mechanical Drawing, Metallurgy, Geology, and Mining and Mineralogy, each men of the highest standing in their respective departments. The mode of instruction is by lectures, by written and oral examinations, by practical teaching in the laboratories and drawing office, and by field surveying and geological and natural history excursions. The field of study is separated into—a general division, for those who desire a general knowledge of science; a mining and metallurgical division; a technical division for those who propose to engage in arts or manufactures depending chiefly either on chemical or on mechanical principles. For each of these divisions the course of study extends over two years, of three terms in each. Students must be at least 16 years of age on admission. Several exhibitions have been founded, to be competed for by matriculated students. The lectures are open to occasional or non-matriculated students, on payment of a somewhat higher fee; and special short courses of evening lectures, at an extremely low fee, are given every session to working men only, and are attended always by as large a number (600) of diligent students of that class as the theatre will accommodate.

The Metropolitan School of Science enjoys rare advantages from the ready access which the students have to the treasures accumulated in the Museum at Jermyn Street. These, as was said above, consist of the extensive and admirably arranged collections formed during the progress of the Geological Survey of the United Kingdom, "illustrative of the structure of the British islands, and of the applications of geology to the useful purposes of life," under the able directors and indefatigable staff of the Survey. To these have been added a numerous selection of models of mines, mining tools, and working models of mining machinery; and of tools, and models, and specimens of machinery for general purposes. The Museum is open gratuitously to the public during five days of the week.

The maps and sections of the Geological Survey, and a large collection of plans and sections of mines, &c., belonging to the Mining Record Office, are deposited in the building in Jermyn Street. The chemical laboratories are those of the Royal College of Chemistry in Oxford Street, which, as already mentioned, became in 1854 the property of the Government.

In connection with the Metropolitan School of Science, Special Schools of Science have been established since 1853 in several of the large manufacturing, mining, and pottery towns. These schools—of which there are, we believe, nine in operation—in accordance with the principle laid down by the government on the formation of the Department of Science and Art, are in a great measure self-supporting, the Department exercising a certain amount of control, and, in return, affording a limited pecuniary aid to certified masters of the schools. According to Dr. Playfair, the Chief Inspector of Science Schools, and Scientific Referee of the Department, "some, in fact all, of these schools are successful as to the disposition of the working classes to support them; but even those most numerously attended and increasing in numbers, running the risk of abandonment at any time, because, with one or two exceptions, the expenses are greater than the receipts." Dr. Playfair is, in short, of opinion, from his experience as inspector of these schools, that the "system of self-support is not adapted to secondary schools of science, having only a constituency of working classes to support them."

But another class of schools has been established in connection with the Department, which appears to have been on the whole more successful. These are called Trade and Navigation Schools, and are intended to afford instruction to officers of the mercantile marine on the subjects of their examination for certificates of the Board of Trade, and similar instruction to youth about to enter on a seafaring life. Besides three in London, Trade and Navigation Schools have been opened in nine of the principal outports, and could be readily established in other shipping towns if the Department could train masters fast enough to meet the demand. One of these schools had "its present locality," when Dr. Playfair wrote, "somewhere in the ocean between England and India;" Mr. Green, of Poplar, having fitted out "one of his finest ships as a School of Navigation, carrying a number of midshipmen under one of our [the Department] masters, who is bound also to instruct the common sailors in the principles of navigation." An example which might be well followed in our naval as well as mercantile marine.

The Art Schools are of older date than the Schools of Science, and, appealing to a wider circle, have almost necessarily made greater numerical progress. The Art branch of the Department has, as we have already said, its head-quarters at South Kensington, on the estate purchased by the Commissioners of the Exhibition of 1851 [EXHIBITION OF 1851, *S.* 2], and is a development or reorganisation of the old Schools of Design, whose history and constitution are given elsewhere. [SCHOOLS OF DESIGN, *S.* 1.] As at present organised, the special objects of the Art section of the Department are, in the words of the official programme—"1. To train male and female teachers to give instruction in Art, to certify them when qualified, and to make them annual fixed payments, varying according to their acquirements. 2. To aid and assist Committees in the provinces desirous of establishing Schools of Art. 3. To hold public inspections and examinations, and to award medals and prizes to the most deserving candidates. 4. To collect together works of art, pictures, &c., in the central Museum, and books and engravings in the central Library. 5. To circulate among the Schools of Art objects from the Museum, and books and engravings from the Library."

The buildings at South Kensington include the offices of the Department, the Training School for Masters and Mistresses, the Normal Central School of Art, the Art Library, and the various Art collections.

"The Training School has for its special object the education of Art-teachers, male and female, but it also aids in supplying certificated Art-masters or mistresses to teach drawing to schools in connection with the Committee of Council on Education. The course of studies embraces, besides all the ordinary branches of Art-Education, instruction in various direct applications of Art-power to mechanical and manufacturing industry. It comprehends the following subjects:—Free-hand, architectural, and mechanical, drawing; practical geometry and perspective; painting in oil, tempera, and water-colours; and modelling, moulding, and casting. These classes include architectural and other ornaments, flowers, landscape, objects of still-life, &c., the figure from the antique and the life, and the study of anatomy as applicable to Art; and some technical studies, such as enamel painting, and drawing and engraving on wood. The students have full access to the Museum and Library, either for consultation or copying, as well as to all the public lectures of the Department. Special classes are arranged in order to qualify schoolmasters and schoolmistresses of parochial and other schools to teach elementary drawing as a part of general education."

The collections brought together at South Kensington are already of great value and interest, and they are rapidly increasing. The Museum of Ornamental Art has been formed entirely by the Department. It was commenced in 1852, when a suite of rooms in Marlborough House was appropriated to its reception. It was removed to the new buildings, South Kensington, in February, 1857. It embraces the entire circle of ornamental art, and already includes the richest collection in existence of majolica and other examples of ancient, as well as many most admirable specimens of modern, ceramic ware; a fine collection of old furniture of an artistic character; watches, jewellery, and enamels; stained glass windows; casts, engravings, and photographs of fine specimens of ornamental art from the Imperial Collections of France and elsewhere; casts of classical, mediæval, and renaissance architectural ornaments, &c. There are also deposited in the Museum buildings rich trade collections; a collection of animal productions; educational collections; models of patented inventions (deposited here by the Commissioners of Patents); a collection of original statues and casts by British artists, lent for a stated period by the sculptors or owners of the works, &c. The very fine gallery of British Art, containing no less than 234 oil paintings, and a considerable number of sketches, by eminent living, or recently deceased. British painters—the munificent gift of Mr. Sheepshanks to the nation—is also, by his desire, deposited in a building erected for it, in immediate contiguity with the Museum; it having been "given for the purpose, as the primary object, of being used for reference and instruction in the Schools established in connection with the Department of Science and Art." All these collections are open free to the public on three days of the week; on the other three days (being 'students' days') the public are admitted on payment of 6*d.* each person. The collections are also opened to the public free on two evenings of the week—an innovation which has proved exceedingly popular. To the Art Library—a very excellent one—though formed primarily for the students, any person is admitted on payment of a trifling fee, which affords access for a week. Evening lectures to working men are also occasionally delivered in the Museum.

In connection with the Central School of Art there are seven Metropolitan District Schools, and one school for female students only. The provincial Schools of Art have increased greatly in number since the formation of the Department. These schools are, like the Schools of Science, in the main self-supporting, but the Department assists in paying the certified teachers, and in various ways aids in providing the school materials, and in rendering assistance to the institution. They are now in all sixty-nine in number; and at the last return they were the means of affording instruction in drawing and painting to upwards of 35,000 students—but this number "includes children in poor schools under instruction in drawing," who can hardly in fairness be ranked as Art-students. The Department, in fact, now, besides the training which it affords in its central and metropolitan schools, and the Special Provincial Schools of Art in connection with it, proffers the services of a certified teacher in drawing to any school or schools, furnishing an aggregate of 500 children for instruction in drawing; and it further offers the aid to such schools of examinations and prizes, at stated periods. It is intended also, as soon as arrangements can be made, further to extend the aid of the central institution to local schools and provincial towns, by sending any object or class of objects contained in the Musenm for exhibition and study upon application from the local authorities.

SCIRE FACIAS. A simpler, less expensive, and less dilatory method of proceeding than that by *scire facias*, has been provided by the Common Law Procedure Acts, 1852 and 1853. The former statute has at the same time extended the period during which execution may issue, from a year and a day to six years. In case of a change by death, marriage, bankruptcy, or otherwise, in one of the parties to an action, the representative of that party may enter a suggestion of the fact, and put himself in his place. The opposite party is also enabled to call upon the representative to do so, and if he fails to stop the proceedings. The proceeding by suggestion on the roll is adapted to the most simple cases of change in the parties to a suit. If it be not adopted, a writ of *Revivor*, as it is now called, may be issued, the object of which is the same as that of a *scire facias*. It is however directed to the party and not to the sheriff, and may be served anywhere. The writ of *sci. fa.* was directed to the sheriff of the county where the *venue* in the original action was laid, and was served by him. The subsequent proceedings in Revivor resemble those of an ordinary action. The writ of *scire facias* in Chancery to repeal patents is not affected by the above-mentioned statutes. Nor is the writ of *sci. fa.* itself abolished. In some cases it is still the only method of proceeding; for instance, to enforce a judgment against the *terre tenants* of a deceased judgment debtor.

SCILLITIN. [Chemistry, *S.* 1.]

SCITAMINACEÆ, a natural order of plants embracing the *Marantaceæ*, with 1 anther-valve, and the *Zingiberaceæ*, with 2 anther-valves. The separation of these orders is now generally recognised. [Marantaceæ; Zingiberaceæ.]

SCOMBERESOX, a genus of Fishes belonging to the family *Esocidæ*. The only British species of this genus is the Gar Pike or Skipper, called also Gowdnook in Scotland. It was first described as a British species by Ray. It is not an abundant fish, but has been taken off Berwick and Yarmouth, and Portland Island, and on some occasions has been even plentiful on the coasts of Scotland. [Esox.]

SCOPELIDÆ, a family of Malacopterygious Abdominal Fishes. This family is closely allied to the *Salmonidæ*. They have the snout short, the mouth deeply cleft, the teeth rather small and sharp; the branchial rays 8 to 15; the first dorsal behind the ventral; the body in some is semi-transparent.

The genus *Scopelus* is found in the Mediterranean.

(*Manual of Natural History.*)

SCORESBY, WILLIAM, was born in 1790, and commenced his nautical life only ten years afterwards, accompanying his father, William Scoresby, likewise a distinguished North Polar navigator, in the Dundee, on her voyage of the year 1800. The passion for naval enterprise which the child's examination of the ship had evoked, was confirmed by his first voyage, and in 1803 the father and son sailed together in the ship Resolution of Whitby. This they continued to do for the ensuing eight years, the sedulous junior keeping a regular journal of their voyages. He was promoted in succession, as he became qualified, without being unduly favoured, through all the gradations of the service, until he was appointed chief mate of the ship; which responsible office he held in his sixteenth year. The long intervals during which, from the nature of the whale-fishery, the ships were laid up in winter, were devoted by the young navigator, with the sanction and to the great satisfaction of his father, to regular study, and for a considerable portion of two sessions, at Edinburgh, where he secured the friendship of the late Professor Jameson and other professors of the university, and also of Dr. (now Sir David) Brewster. He thus acquired that definite knowledge of the principles of the various branches of science bearing upon his peculiar profession, which enabled him to extend them, by his own observations, in the voyages to the Arctic regions which alternated with and succeeded these periods of intellectual cultnre.

While filling the stations respectively of commander and chief-mate of the Resolution in 1806, the Scoresbys sailed to a higher latitnde than had been reached before. In May of that year they were successively in 80° 50′ 28″, N. lat., 81° 1′ 53″, and 81° 12′ 42″, and once, by estimation, as far as 81° 30′, the nearest approach to the pole—within about 510 miles—at that period authenticated. It has been exceeded only by the late Admiral Parry [Parry, William Edward, *S.* 2], who, in his celebrated boat expedition, during his fourth voyage, in 1827 reached 82° 45′, the highest point yet attained; but this was accomplished by travelling across the ice, which had to be commenced on gaining the latitude of 79° 55′ 20″, inferior to that attained by the Scoresbys by ordinary sailing, and the honour still remains theirs of having in ordinary sailing navigated the highest northern latitudes. It may be remarked here that the boat expedition had itself been adopted from a suggestion made by the younger Scoresby (in a proposition which had been rejected by the Admiralty), bnt had not, in his opinion been properly executed. It was always his conviction that by such an expedition, if carried out according to his views, the pole itself might have been arrived at; and at a later period he had the satisfaction of learning that Parry himself had expressed the same conviction. It is proper to note in this place, in order to preclude error, that the surgeon of the Resolution in this voyage, states, in an 'Account of a Voyage to Spitzbergen,' and in a manner taking the achievement to himself, that the highest latitude attained was 81° 50′, but this, as Dr. Scoresby has explained in his 'Memorials of the Sea,' p. 153, is erroneous; the highest latitude observed being 81° 12′ 42″, as already stated. The Resolution was the property of a co-partnery, of which the senior Scoresby was one, and—influenced in a considerable degree by a kindly and parental regard for his son—he formally resigned his command in 1811, on the very day on which the subject of this notice completed his twenty-first year; and on the same day, the earliest at which he could legally hold a command, William Scoresby junior was unanimously elected his father's successor.

In consequence of information communicated by Captain Scoresby to Sir Joseph Banks, the President of the Royal Society, the attention of the council of that learned body and of the government was directed in 1817 to the dormant enterprise of endeavouring to reach the North Pole and discovering the long-sought North-West passage; the latter of which objects has at length been accomplished by Sir Robert MacClure in one of the recent searching expeditions for the ill-fated Franklin. Sir Joseph Banks was very desirous that his yonng but experienced friend shonld be employed in the proposed adventure, his father having deferred tbe fitting ont of the ship Fame, which the son was to command, under the idea that she might be taken up for service. Their expectations however were altogether disappointed, and as is well known, Captain (the late Sir John) Ross with the Isabella and Alexander, and Captain Buchan with the Dorothea and Trent, were appointed to make the attempt. It appears to be the policy, not perhaps to be discommended on grounds of national justice, however the consequences of it may be regretted in particular instances, of the Board of Admiralty, to reserve these arduous expeditions and others destined for marine scientific research, as the encouragements and rewards of an inevitably laborious and ill-paid service. The history of this subject will be found in a paper by Dr. Scoresby, 'On some circumstances connected with the Original Suggestion of the Modern Arctic Expeditions' pnblished in the Edinburgh New Philosophical Journal, vol. xx. 1835-36.

Having made seventeen voyages to the Spitzbergen or Greenland Whale-fishery, Captain Scoresby published, in 1820, his celebrated work entitled, 'An Account of the Arctic-Regions, with a history and description of the Northern Whale-Fishery,' in 2 volumes consisting of 1217 pages, illustrated by twenty-four engravings. It had been undertaken at the suggestion of Professor Jameson, who did great service to scientific literature by stimulating his pupils or former pnpils to make public the results of the observations made by them in their professional or official employments in distant countries. This was the first original work on the physical and natural history of the conntries within the Arctic circle and on the nature and practice of the Whale-Fishery, published in this country, with the exception of a tract by Henry Elking on the latter snbject. It obtained for the anthor a more general reputation than he had hitherto enjoyed, and justified the owners of the whaling ships he commanded, in countenancing a degree of enterprise in geographical discovery—not nnconnected however with the object of the trade—which had not hefore been nnited with the pursuit of whales, except throngh accidental circnmstances. Bnt on Captain Scoresby's retnrn to Liverpool, from a voyage in 1822, in the ship Baffin of that port, nndertaken with these views, he received on entering the Mersey the afflicting intelligence of the decease of his (second) wife while he was absent. He now quitted the whale-fishery, bnt published the geographical results of the voyage, in a 'Journal of a Voyage to the Northern Whale-Fishery; including researchee and discoveries on the eastern coast of West-Greenland, made in the summer of 1822, in the ship Baffin of Liverpool,' Edinhurgh, 1823, 515 pages, with 8 plates, including a chart, &c. A German translation by Professor F. Kries was publisbed at Hamburg in 1825. Not long after the appearance of this work, on the 17th of June, 1824, he was elected a Fellow of the Royal Society, heing already a contributor to the 'Philosophical Transactions,' and having been for some years a Fellow of the Royal Society of Edinhurgh. He subsequently received one of the highest honorary rewards of scientific eminence, in being made a corresponding member of the Institute of France, or Academy of Sciences of Paris. As the captain of a whaler he had been a remarkable man. His crews were always distingnished by their discipline and respectability, and the lasting effect of his command upon the characters of some of those who sailed with him was a proof of the soundness of his jndgment, temper, and heart. "His success in whaling was remarkable; but he never, under any circumstances, allowed a whale to be pursued upon Sunday, and he sncceeded in convincing his men that upon the whole they did not lose by keeping the appointed day of rest. Upon his later voyages he adopted the temperance principle on board his vessel, finding that hot coffee was a very much stronger preservative than spirits against the intense cold of Arctic regions."

Some years after his retirement from the whale-fishing the religious impressions which he had first received from his father and had always entertained, impelled him to desire a more formal and authorised position as a teacher of religion. He entered the University of Cambridge as a etndent of Queen's College, took his degrees of B.D. in 1834, and Holy Orders in due course, taking the euperior degree of D.D. in process of time. The Mariner's Church at Liverpool having been then jnst established, he accepted the chaplaincy. Private circumstances occasioned his removal to Exeter, bnt he afterwards became Vicar of Bradford, a very large parish in Yorkshire. After some years however he resigned this office, and retired to Torqnay in Devonshire.

As a clergyman, Dr. Scoresby is stated to have "combined what may perbape be considered extreme evangelical views with the most abounding charity and liberality to those who differed from him. His 'Discourses to Seamen' evince the earnestness with which he laboured for the good of the service in which he had passed his earlier years." He took also enlightened and enlarged views of pnblic education, which while vicar of Bradford he labonred zealously to realise.

But of all the very varions subjects to which Dr. Scoresby directed bis attention, practical magnetism and its relation to navigation appear to have heen most actively pnrsned by him through his life. The increasing quantity of iron introduced into the eqnipment and construction of ships, and the recent construction of the entire hull of that metal, were watched by him with nnceasing care; and all the resources of his cultivated mind were at length applied to the most important of all subjects of this class—the influence of the iron of ships upon their compasses, and the requisite correction of the indications of the latter. He had published various papers on magnetism in the 'Philosophical Transactions,' the 'Transactions of the Royal Society of Edinburgh,' the 'Reports of the British Association,' the 'Edinbnrgh Philosophical Journal,' and the two journals which eucceeded it. The snbstance of these, or of many of them, he now made public, in an improved form, in his 'Magnetical Investigations.' Part i. 'Comprising investigatione on the principles affecting the capacity and retentiveness of steel for the magnetic condition; with the development of processes for determining the quality and degree of bardness of steel.' London, 1839; 92 pages, 2 plates. Part ii. 'Comprising investigations concerning tbe laws or principles affecting the power of magnetic steel-plates or bars in combination, as well as singly, nnder varions conditions as to mass, hardness, qnality, form, etc., as also concerning the comparative powers of cast-iron.' London, 1843; 280 pages, 2 plates. Vol. ii., part iii., 'Investigations, with illnstrative experiments, on the nature and phenomena of magnetic induction, and the mutual influencss of magnetical hodies.' London, 1852; 463 pages.

To the section of Mathematics and Physics of the meeting of the British Association at Glasgow in 1855, he communicated a summary of his matured views, and of the evidence in their favour which had occnrred since their original promnlgation, entitled 'Elucidations, by Facts and Experiments, of the Magnetism of Iron ships and its changes.' In this he recalled attention to his plan of a *compass aloft*, as affording a simple and effective mode of ascertaining the direction of a ship's course, stating that it had not only been extensively adopted by some of our first firms interested in the building and property of iron ships, but had received the particular sanction and commendation of Mr. Airy, the astronomer-royal, and of Lieutenant M. F. Manry, the American hydrographer; "that is, as being recommended by both these gentlemen for adoption for determining safe compass guidance, or the correction of adjusted compasses whenever they might be fonnd to be in error." In the further prosecution of his researches on this snbject, and with the view to determine various questione in magnetic science, Dr. Scoresby nndertook in his age a voyage to Australia in the Royal Charter. He was received at Melbourne with great distinction, almost with enthusiasm, and was granted the honorary degree of M.A. hy tbe new university of that city. He returned in 1856, but with his constitution much enfeebled by the arduons lahours to which he had subjected himself during the voyage; and after a lingering illness he died at Torquay, on the 21st of March 1857, aged sixty-seven, and leaving a widow.

Three principal scientific works of Dr. Scoresby have heen described above. The following enumeration will render the acconnt of his separate publications nearly complete. 'Memorial of an Affectionate and Dutiful Son, Frederic R. H. S., who fell asleep in Jesns, December 31, 1834, aged 16 years.'—'Discourses to Seamen: consisting of Fifteen Sermons, preached in the Mariner's Church, Liverpool, treating for the most part generally on snbjects of Christian Practice and Doctrine.'—'Jehovah glorified in his Works: a Sermon preached in St. James' Episcopal Chapel, Edinburgh, August 4, 1850, on occasion of the Meeting of the British Association.'—'Memorials of the Sea:' 1, 'Sabbaths in the Arctic Regions;' 2, 'The Mary Russel.' Of both these two editions have appeared. 3, 'My Father: being Records of the Adventurous Life of the late William Scoresby, Esq., of Whitby,' 12mo, Lond., 1851, pp. viii. and 232. 4, 'The Franklin Expedition;' stating his views on its probable conrse and fate, and on the measures of search for it.

'Zoistic Magnetism.' The contents of this work on a peculiar subject are thus stated by the author himself: "Original Researches in Mesmeric Phenomena, with the view of eliciting the scientific principles of this mysterious agency, and in which experiments are described, eliciting strong electric or magno-electric conditions, with the intercepting of the mesmeric infinence by electrics, and the nentralising of the effects of substances having an ungehial influence on the subject, by the same process as was fonnd to neutralise the electricity of sealing-wax, &c., as acting on the electroscope."

Dr. Scoresby had prepared for pnblication prior to his decease, a work fully detailing the results of his most recent iuvestigations in nautical magnetism. As ho contemplated, while commemorating his father, a continuation of the series of 'Memorials of the Sea,' in which the story of his own life should be told, it is not improbable that this also may find a place in the work, which had not appeared in April, 1858.

SCORZONERA, a genus of Plants belonging to the natural order *Asteraceæ*. The pappus is feathery, in several rows. Bracts imbricated. Receptacle naked. Achænia neither stalked nor beaked, with a lateral scar.

S. Hispanica, Viper's-Grass, has a cylindrical succulent root, branches monocephalous; leaves amplexicaul, lanceolate, wavy; involucres smooth; flowers yellow. It is found in Spain and the south of Europe. The root is said to be sudorific. It is delicate and eatable, and is supposed to be a specific against viper bites.

S. glastifolia has roots similar in quality.

S. delicosa is cultivated as an esculent at Palermo, and the gummy root of *S. tuberosa* is eaten by the Kalmucks.

SCOTOPHILUS. [CHEIROPTERA.]

SCOTT, DAVID, was born in Edinburgh, October 10, 1806. The son of a landscape engraver, he was brought up to his father's profession; but from childhood he had sketched and drawn incessantly, and at length his father yielded to his desire to become a painter. From the first his ambition was to paint in the 'grand style.' His early pictures were of themes such as the 'Hopes of Early Genius dispelled by Death,' 'Fingal and the Spirit of Lodi,' and 'Lot and his Daughters flying from the Cities of the Plain.' Of a melancholy turn of mind, and of somewhat gloomy theological views, his pictures naturally wore a sombre air, and attracted few admirers beyond the circle of his friends. His 'Lot and his Daughters' was returned from the British Institution as too large; his series of outline etchings, 'Monograms of Man,' met with a slow and unremunerative sale; and it was not till 1831 that he sold his first picture. But he loved labour, and he went on painting subjects with which few could sympathise, in a manner that did little to remove the unattractiveness of the theme. Slowly however he made his way, finding ardent if not numerous admirers; and his progress began to be watched with interest by his fellow-citizens. In 1832 he visited Italy, staying awhile at the Louvre on his way. In Italy of course his chief stay was at Rome, but the amenities of Raffaelle seem rather to have repelled him, his chief attention, characteristically enough, being fixed on Carravaggio. Here however he made the acquaintance of the leading resident artists; he worked hard, and painted much; and his power in painting was evidently enlarged. His style however was not materially changed. He continued to paint in the 'grand style' pictures of heroic size; and even when he stooped to the simpler realities of life, or to such matters as 'Love whetting his Darts,' 'Ariel listening to the Mermaid,' 'Beauty wounded by Love,' the 'Triumph of Love,' and the like, it was very much in the spirit of an ancient Covenanter. The themes he entered upon with more congenial feeling were such as his 'Genius of Discord' (a large work, painted at Rome, but repainted on his return); 'Descent from the Cross;' 'Jane Shore found Dead in the Street;' 'Orestes pursued by Furies;' 'Achilles mourning over the Dead Body of Patroclus;' 'Paracelsus, the Alchemist, in his Lecture-Room;' 'Hope passing over the Horizon of Despair;' 'The Dead rising at the Crucifixion;' 'Peter the Hermit addressing the Crusaders,' and several others, which alike attest his remarkable diligence and his soaring ambition; but which, in their want of power to interest the spectator, and their artistic shortcomings, too clearly show that lofty ambition, strong imagination, and unwearied industry, are insufficient to form a great painter, without living genius, a well-directed purpose, and carefully disciplined technical skill. Mr. Scott had built himself a large studio in Edinburgh, and was full of dreams of future glory, despite the warnings of failing health, when the cartoon competition in connection with the new houses of parliament aroused his feelings to a high pitch of excitement. He prepared and sent in a large cartoon of 'The Defeat of the Spanish Armada,' but it was unnoticed by the judges who awarded the prizes, and the blow fell upon the painter with a severity similar in its intensity to that which the like fate inflicted upon Haydon—whom in his ambitious thoughts, and passion for 'grand art' and huge canvasses, Scott greatly resembled. But Scott painted on; devoting now all his energies to his largest and perhaps, on the whole, best work, 'Vasco da Gama encountered by the Spirit of the Storm in passing the Cape,' now in the hall of the Trinity House, Leith. This work occupied him during the last ten years of his life, and he lived only to complete it, dying on the 5th of March, 1849, in his forty-third year. Some of his great works have been purchased for public institutions in Edinburgh. Scott was a vigorous writer both in prose and verse. His 'Essays on the Characteristics of the Great Masters' excited a good deal of attention when first published in 'Blackwood's Magazine,' 1840; and some of his poetry is contained in the 'Memoir of David Scott, R.S.A., containing his Journal in Italy, Notes on Art, and other Papers,' 8vo, 1850. This 'Memoir' is a warm-hearted tribute to his worth and merits by his brother, Mr. William B. Scott, himself an artist of considerable ability.

SÉBASTIANI, HORACE FRANÇOIS, COUNT, was a native of Corsica, having been born at the hamlet of Porta, near Bastia, on Nov. 11, 1776. His uncle, who was a priest, took charge of his education, and was preparing him for his own profession, when the call to arms, in 1792, induced the lad to exchange his cassock for a uniform. He then became secretary to General Casabianca, after which he joined the army of Italy, in 1796, was noticed by Bonaparte, and was made a chef-de-bataillon after the battle of Arcola. In 1799 he distinguished himself greatly at Verona, for which conduct General Moreau appointed him to a regiment on the field of battle. On the 18th Brumaire, being in garrison at Paris, with his regiment of Dragoons, he assisted in the coup d'état by which Bonaparte became master of France. The First Consul promised to reward this proof of devotedness on the part of his compatriot, and henceforth took charge of his fortune.

After the battle of Marengo (June 14th, 1800) Colonel Sébastiani was appointed commissioner along with Marmont to conduct negotiations preparatory to the armistice of Treviso. In 1802, he was sent to Turkey, Egypt, and Syria, on an important diplomatic mission, which he conducted so skilfully as to obtain the rank of General of Brigade for his address.

In 1804 he was despatched to watch the movements of the Austrian army in Germany, when the reports he addressed to the War Office are said to have partly determined the campaign of 1805. General Sébastiani commanded the vanguard of Murat's cavalry when that brilliant corps entered the Austrian capital. At the battle of Austerlitz he displayed his habitual energy, was badly wounded in a desperate charge, and was raised to a division for his conduct. During the next few years he was employed with much distinction in diplomatic missions; in one of which he lost his first wife, who died in giving birth to a girl, afterwards known as the unfortunate Duchesse de Praslin, murdered by her husband in 1847.

General Sébastiani was one of the many French officers sent to Spain to retrieve the fortunes of the Emperor, in 1809. He crossed the Gaudiana, and defeated the Spaniards at Ciudad-Real, at Santa Cruz, and several other places. In the early part of 1810 he took possession of the provinces of Jaen, Granada, and Malaga, and is accused of having greatly mutilated the Alhambra and other monuments of antiquity, and of ransacking the convents for his own private gain. In the following year, not deeming his services sufficiently appreciated, he returned to France. Napoleon I., who considered the chief talents of this general to be diplomatic rather than military, had determined not to give him a command during the Russian campaign. But the remonstrances of Sébastiani overcame this decision; he was therefore placed in the vanguard of the Grand Army. During the march to Moscow he strongly urged upon the Emperor the prudence of wintering in the province of Lithuania; but this advice was unheeded. General Sébastiani was present at the battles of Smolensko and Moskwa; he was also one of the first to enter the Russian capital, at the head of the 2nd corps. He suffered greatly during the retreat, lost all his artillery, and all his horses perished in the snow.

In 1813, after the battle of Leipzic, at which he was wounded, he contributed to the victory at Hanau, where

Prince Wrede was defeated. Napoleon afterwards gave him the command of the 5th corps, and ordered him to defend the left bank of the Rhine, at Cologne; but he was obliged to fall back into Champagne; where, at the head of three regiments of cavalry of the Imperial Guard, he repeatedly won new honours, particularly at the battles of Arcis-sur-Aube and Saint Dizier.

On the abdication of Napoleon he retired to private life, but during the Hundred Days he became a member of the Chamber of Representatives, and was sent as one of the deputies to wait on the allied sovereigns after the battle of Waterloo. After the return of the Bourbons he spent a few months in England in voluntary exile, though they had not included his name in their list of proscription. In 1819 he was chosen deputy for Corsica, and soon became distinguished as a member of what was termed the liberal opposition in the Chambre des Députés. In 1826 he succeeded General Foy as representative of the department de l'Aisne. After the revolution of 1830, Louis Philippe, in August, appointed him minister of marine, and in the following November, on the retirement of Molé, made him minister for foreign affairs; in which office he continued until 1832. It was during his administration of this office, in September, 1831, that he incurred so much obloquy by his famous announcement from the tribune of the chamber that "order reigns in Warsaw." In 1833 he again filled for a short time the office of minister for foreign affairs, but resigned on the chamber refusing to confirm the treaty he had made with the United States of America, and was appointed ambassador to Naples. In 1835 he was sent ambassador to London, where he was replaced by Guizot in 1840, and on the death of Marshal Maison, he received his bâton de Maréchal after 48 years service. In 1841 he spoke strongly in the chamber in favour of the project for fortifying Paris. Ill health compelled him soon afterwards to retire from public business, and the unfortunate fate of his daughter, the Duchesse de Praslin, darkened the latter years of his life. He died however suddenly while at breakfast, on July 20, 1851. He was buried in the church of the Invalides, and during the funeral some of the hangings caught fire, endangering the whole building, but the fire was fortunately subdued with only the loss of several of the military trophies.

SEBESTEN PLUMS. [CORDIA, *S.* 2; CORDIACEÆ.]

SECALE, a genus of Grasses, to which the cultivated Rye belongs. The flowers are arranged on a spike; the spikelets are 2-flowered, with a long stalked rudiment of a third floret; the glumes are subulate. In other respects this genus strongly resembles *Triticum*, to which the Common Wheat and Couch-Grass belong. [TRITICUM.]

S. cereale, Rye, has the glumes 1-nerved and shorter than the spikelet; the rachis is very tough. This plant is extensively cultivated in Europe, and nowhere has been observed in a truly wild state, away from the possibility of escape from cultivation, being sown by the agency of man. [RYE.]

S. montanum has the rachis hairy, brittle; glumes with a short point; the root fibrous. It is found on the gravelly mountains of Sicily.

S. villosum is also a European species, in which the spicules are 4-flowered, and the glumes have 2 or 3 strong ribs. It is found in France.

SECRETIONS OF PLANTS. [SECRETIONS, VEGETABLE.] Although the term secretion is generally connected with the idea of separating for the purpose of throwing off or getting rid of a product, it is very manifest that such a use of the term would restrict its application to the substances which, amongst animals, are called excretions. It does not appear that any one class of substances can be called excretions more than another in the vegetable kingdom. It is true that a theory of the practice of 'rotation of crops' supposes it to depend on poisonous excretions given off by the roots of one plant which are not poisonous to another. But the facts brought forward to support this theory are doubtful, and other explanations of the necessity of rotation have been given. [ROOT.]

In plants the organs of secretion are simpler than those of animals, as they have no fixed reservoir from which to draw the materials of secretion, as the blood. This function, however, seems to be performed in both plants and animals on the same general plan. It is in both cases in the interior of the cell that the most remarkable instance of the process takes place. In the plant the compounds changed are simpler, whilst the chemical forces in action during secretion are stronger than in animals. All the important secretions of plants are compounds of the four organic elements: carbon, hydrogen, oxygen, and nitrogen. These enter the plant in the form of carbonic acid and ammonia. Out of these compounds the various substances that give the hardness to the wood of plants, the nutritive value to their seeds, roots, and other parts, the colour and scent of their leaves and flowers, with the medicinal virtues of many special plants, are formed. The substances thus produced are easily distinguishable, and may be divided into two great classes.

First, Nutritive or Assimilable Secretions, that is, substances which having been formed in the plant, are used for forming its tissues, and constructing the mass of which it is composed. The principal substances which are thus employed are cellulose, starch, sugar, oil, and protein. The first four are distinguished by containing the elements carbon, hydrogen, and oxygen, whilst the latter contains in addition nitrogen. [CELLULOSE; DEXTRIN, in TISSUES, ORGANIC, *S.* 1; STARCH; SUGAR; OILS; PROTEIN, in TISSUES, ORGANIC, *S.* 1.]

These substances are found universally in the vegetable kingdom. No cell can be formed without one of the ternary compounds, and a portion of the quaternary substance in some form. Hence they are called in relation to the plant Nutritive Secretions. These substances are also easily convertible the one into the other; the sugar may be converted into starch or cellulose, and vice versâ, and thus their powers and properties are essentially connected with the assimilative processes of the plant.

The second class of substances are called Non-Assimilable or Special Secretions of Plants. They are substances which are not found in every part of every plant. When once formed also they are not liable to change, and are certainly never converted into the nutritive secretions; hence they are called non-assimilable. Some of these substances are very generally diffused amongst plants, as chlorophyle, which is the substance which gives the peculiar green to the leaves and other parts of plants. [CHLOROPHYLE, in TISSUES, ORGANIC, *S.* 1.]

These secretions are very numerous, and may be classed under certain general heads.

1. Colouring Matters. To this head may be referred chlorophyle; the colouring principle of the petals of plants seems also to be a modification of this substance. There are however other colouring matters in plants, such as those used by the dyer, and which do not give any colour to the plants in which they exist, which have nevertheless a very definite chemical composition, and by combining with various other substances produce the colours used by the manufacturers of coloured cotton, linen, silk, and woollen cloths of various kinds. These colouring matters would appear to arise from the decomposition of the assimilable secretions, as many of them bear a close relation to both the ternary and quaternary forms of these secretions.

2. Acids. Substances having an acid reaction, and capable of combining with the oxides of the metals, are very common in the vegetable kingdom. The most familiar forms are those which occur in fruits, as the oxalic, citric, malic, and tartaric acids. Oxalic acid is found in the *Oxalis Acetosella*, hence its name, and other forms of *Oxalidaceæ*. It is also found in the *Cactaceæ* and *Polygonaceæ*. In the latter order it exists in the species of *Rheum* (Rhubarb), used for making pies, and also in the Sorrels (*Rumex*). In all these cases it is combined with the oxide of some metal, either potassium or calcium. In sorrel (*Rumex acetosa*) it exists as a quinoxalate or superoxalate of potass, which, when separated, is called Salts of Sorrel. In the *Cactaceæ* it exists as an insoluble oxalate of lime, in the form of raphides. These bodies, which are merely needle-like crystals of this salt, are very common in the vegetable kingdom. Citric Acid is found in the fruits of the order *Aurantiaceæ*, as the lemon, orange, lime, shaddock, &c. It is easily separated from these fruits in a crystalline form. It is soluble in all its combinations with the oxides of the metals, hence it does not occur as oxalic acid in the form of raphides. Tartaric Acid is found in the juice of the grape. Though closely resembling citric acid, it differs in forming an insoluble compound with potass. This compound is the supertartrate of potass, or cream of tartar of the shops. This salt is deposited whenever grape-juice is allowed to stand. It forms the basis of the tartar of wine procured from the lees. This property of tartaric acid makes the juice of the grape the most efficient compound from which to make wine. The juice of fruits containing citric acid, whose salts are soluble, are much less fitted for wine-making. Malic Acid is the acid found in the apple,

and which gives the sour taste to verjuice, as also to the fermented juices of the apple and pear—cider and perry.

The chemist has described a very large number of organic acids as present in plants, and every day is increasing their number. Many of the colouring matters appear to be acids, which assume their particnlar colours by combination with metallic oxides, such as the lecanoric, orsellic, erythric, and parellic acids, obtained from lichens, used in making cudbear and archil. The vegetable alkalies, or alkaloids, are also found in combination with acids; thus, aconitine is found in combination with aconitic acid, morphia with meconic acid, and a variety of others.

The acids generally occur in combination, and sometimes supplant each other. Even mineral acids will sometimes take the place of organic acids; thus sulphuric acid is sometimes found combined with morphia in the place of meconic acid. On the other hand, the metallic oxides will sometimes take the place of the alkaloid, and be found in combination with the organic acid. In the instance however of gallic and tannic acids, there appears to be no combination with alkalies or alkaloids. Tannic acid, formerly called tannine, is found very generally present in the woody parts of plants. It is supposed to result from the decomposition of cellulose. Theoretically, it may easily be formed out of carbonic acid and water. Whether it passes through the stage of cellnlose is doubtful. It is of great nse in the arts, especially in tanning and dyeing, and for these purposes it is obtained from the bark of oak, elm, willow, sumach, and other trees. It exists in the fruits of the *Chrysobalanaceæ*, and the legumes which are called 'divi divi.' The vegetable extracts called catechn, or cutch, and the exudations which are sold by the name of kino consist principally of tannic acid. This acid is converted into gallic acid by oxidation. Such a process takes place dnring the formation of the galls produced by the puncture of insects in the buds of many of the species of *Quercus*, especially *Q. infectoria*. These excrescences are called gall nuts, and from the presence of this acid in them it has been called gallic acid. [GALLS.]

The alkaloids are substances founds in the leaves, fruits, bark, and other parts of plants. They are some of them peculiar to particular species of plants, whilst others are more generally diffused. Many of them possess extraordinary properties in relation to the animal kingdom, prodncing poisonous effects: such are strychnia, from the *Strychnos Nux Vomica;* morphia, from the *Papaver somniferum;* conia, from the *Conium maculatum.* These substances are always found in combination with organic or mineral acids. There is however another class of substances closely resembling these in their composition and action, which do not combine with acids. These are called neutral principles: such is theine, the principle found in tea, coffee, and Paraguay tea; and theobromine, the principle of cocoa.

The volatile oils are another gronp of secretions of great interest. They differ in composition and character from the mixed oils, and do not appear to belong to the assimilable secretions. They are many of them used as perfumes—others as stimulant medicines, and are remarkable for the interesting compounds they can be broken np into by the agency of chemistry. Their investigation is throwing much light on vegetable chemistry. [OILS.]

The resins are a gronp of substances standing in a similar relation to the fixed oils, as the volatile oils. They do not appear to be assimilable, they are only occasionally formed, and present special properties in particular plants. They are often combined with gum, forming the substances called gum-resins, and from this combination it may be supposed they are directly formed from the ternary assimilable secretions. When occurring with gnm, as in the case of the gum-resins of the *Umbelliferæ,* or without gum, as in the resins of the *Coniferæ* and in Myrrh, they are combined with volatile oils, which appears to give them their peculiar odours, flavours, and action. In the *Coniferæ* the volatile oil they are combined with is the same in most species, and is nsed in the arts nnder the name of oil or spirits of turpentine. [CONIFERÆ.] Wax is another snbstance very commonly found in plants, and having relation with the fixed oils. [WAX.] Caoutchouc and Gutta-Percha are also compounds belonging to the non-assimilable gronp of vegetable secretions, and are remarkable for the absence of both oxygen and nitrogen. [CAOUTCHOUC; ISONANDRA, *S.* 2.]

Although the processes by which these products may be gradually elaborated in the vegetable kingdom may be very numerous and much more complicated than any processes with which we are at present acquainted, we can readily explain their formation from the carbonic acid, water, and ammonia, taken up by plants, and the loss of oxygen.

The following tables illustrate this process, with regard to several of the substances mentioned:—

TABLE OF SUBSTANCES FORMED FROM CARBONIC ACID AND WATER, BY THE LOSS OF OXYGEN.

Substance formed.		Carbonic Acid used in eqs.	Water used in eqs.	Oxygen lost in eqs.
Name.	Formula.			
Oxalic Acid (dry) .	C^2, H, O	2	1	1
Gallic Acid . .	C^7, H^3, O^5	7	3	12
Tartaric Acid . .	C^8, H^6, O^{12}	8	6	10
Malic Acid . .	C^8, H^8, O^{10}	8	6	12
Citric Acid . .	C^{12}, H^8, O^{14}	12	8	18
Meconic Acid . .	C^{14}, H^4, O^{14}	14	4	18
Cellulose . . .	C^{12}, H^8, O^8	12	8	24
Starch . . .	C^{12}, H^{10}, O^{10}	12	10	24
Cane Sugar . .	C^{12}, H^{11}, O^{11}	12	11	24

TABLE OF SUBSTANCES FORMED FROM CARBONIC ACID, AMMONIA, AND WATER, BY THE LOSS OF OXYGEN.

Substance formed.		Carbonic Acid used in eqs.	Water used in eqs.	Ammonia used in eqs.	Oxygen lost in eqs.
Name.	Formula.				
Asparagine . .	C^8, N^2, H^{10}, O^8	8	4	2	12
Indigo . .	C^{16}, N, H^6, O^2	16	3	1	33
Nicotine . .	$C^{10}, N, H^8,$	10	8	1	28
Coniine . .	$C^{16}, N, H^{16},$	16	16	1	48
Morphine . .	$C^{35}. N, H^{20}, O^6$	35	17	1	81
Quinine . .	C^{20}, N, H^{12}, O^6	20	9	1	43
Strychnine . .	C^{44}, N^2, H^{22}, O^4	44	16	2	106
Theine . .	C^{16}, N^4, H^{10}, O^4	16	0	6	28
Albumen . .	$C^{216}, N^{27}, H^{169}, O^{68}$	216	88	27	452
Caseine . .	$C^{288}, N^{36}, H^{228}, O^{90}$	288	120	36	612

It should not however be lost sight of that other elements besides the four organic are constantly found present in the secretions of plants. Sulphur and phosphorus are found in fibrine, caseine, and albnmen. The alkalies and alkaline earths are found very commonly associated with all these secretions, and it is very certain that plants will not form their secretions nnless the inorganic elements are present. [SAP; ROOT.]

SEDGE, SEDGES. [CLADIUM, *S.* 1; CYPERACEÆ.]

SEDGLEY. [STAFFORDSHIRE.]

SEINE-MARITIME, a department in France, recently constituted with HAVRE for its chief town, extends along the coast of the English channel from the Seine to the Bresle. It is formed out of the coast portion of Seine-Inférieure, which bounds it on the south. The Bresle separates it from the department of Somme. It is divided into five arrondissements, Havre, Fecamp, Yvetot, Dieppe, and Tréport. Etretat and Criel, a small coast village, west of Tréport, are made chief towns of cantons. The tribunal of commerce of St.-Valery is suppressed, and that of Yvetot transferred to the more important town of Bolbec.

A change has also been made in the limits of Seine-Inférieure, to which that portion of the territory of the department of Eure that lies east of the Seine to the Epte is added. Seine-Inférieure, by this arrangement, has Seine-et-Oise to the south-east; and out of the new territory two new arrondissements, Elbœuf and Gournay, are chiefly formed. At Gournay, the railways authorised to be made from Amiens to Rouen, and from Beauvais to Tréport, through Aumale, are to meet. In the absence of any official return, it is useless to offer any conjecture as to the area or the population of the new department; though these may be very nearly ascertained by consulting the articles EURE and SEINE-INFÉRIEURE, which have been described as they stood previous to the recent alterations.

SELENALDINE. [CHEMISTRY, *S.* 2.]

SENEGUINE. [CHEMISTRY, S. 2.]

SEPARATE PROPERTY. The savings and earnings of a wife may become her separate property *at law;* and she may deal therewith as a *feme sole*, either where an order has been made to that effect under the statute 20 & 21 Vict. c. 85, or a judicial separation has been obtained by the wife. [DIVORCE, S. 2; JUSTICES OF THE PEACE, S. 2.]

SEPARATION, JUDICIAL. Until the statute 20 & 21 Vict. c. 85, divorces *a vinculo*, which put an end to the marriage altogether, were only obtainable by a special Act of Parliament, which the legislature would not pass in favour of a husband, until after a sentence of separation *a mensâ et thoro* in the ecclesiastical court, and would not pass at all if his conduct had not been free from reproach. [DIVORCE.] Either of the spouses could always however obtain on the ground of adultery, cruelty, and certain other causes, a divorce *a mensâ et thoro*.

The remedy now given in such cases by the Court for Divorce and Matrimonial Causes is termed a *judicial separation*. This, like a divorce *a mensâ et thoro*, does not dissolve the marriage; it does not bar the wife of her dower, for instance; it effects only such a separation of the parties as leaves it open to them to come together again. But it relieves the husband from all liability for his wife; and it confers on the wife the right of having and disposing of her own property and earnings, as freely as if she were a *feme sole*.

This kind of separation may be obtained on the ground of adultery or cruelty, or desertion without cause for two years or upwards; but unlike a decree for a divorce, which is absolute and irreversible, a sentence of judicial separation may be reversed at any time afterwards, if obtained in the absence of the defendant, on its appearing that there was reasonable ground for the alleged desertion.

In cases either of divorce or judicial separation, the Court may, if it shall think fit, order that the husband shall secure to the wife such sum as it shall deem reasonable. The allowance which may thus be made to a woman for her support out of the husband's estate, is to be settled at the discretion of the court on consideration of all the circumstances of the case, and to be proportioned to the rank of the parties.

SEPPINGS, SIR ROBERT, F.R.S., the distinguished naval architect, received his education as a shipwright under Sir John Henslow, surveyor of the navy, and continued in connection with the important service of our dock-yards during a period of fifty years. He was the author of many improvements of the first order in our naval architecture, including the system of diagonal bracing and trussing, which he devised while he was master shipwright of Chatham Dockyard. This system formed the subject of two memorable papers in the 'Philosophical Transactions' of the Royal Society, for the years 1814 and 1818, one by Sir R. Seppings in each of those years, and one by the celebrated Dr. T. Young, For. Sec. R. S. [YOUNG, THOMAS] in the former, and which attracted an unusual amount of public attention. The great principle of this method was such an arrangement of the principal timbers as would oppose a powerful mechanical action to every change of position of the ribs and other timbers in every part of the ship, thus firmly compacting together the entire fabric, and preventing that perpetual racking of beams and working of joints which in the ancient system of ship-building, produced hogging, creaking, leakage, and rapid decay; and filling up likewise every vacuity between the timbers, which are occasionally the unavoidable receptacles for foul air, filth, vermin, and various other sources of rottenness and disease. These important improvements, though opposed to the inveterate prejudices of the older shipwrights, a body of men who have not sufficiently valued and understood, in this country at least, the just principles of mechanical action, in the practical operation of ship-building, were universally adopted in the navy under the enlightened administration of Mr. Charles York, and the powerful advocacy of Sir John Barrow in the 'Quarterly Review;' and the merit of their author was acknowledged by his appointment as surveyor of the navy, and by the award of the Copley Medal of the Royal Society, of which he became a Fellow on the 10th of November, 1814.

While the claims of Sir R. Seppings to the invention of the system of diagonal bracing in naval architecture is indubitable, it may not be out of place to record here the following point of information. It can be no derogation to the merits of discoverers or inventors to show that their progress is a portion of the general advance of the human mind. Sir John F. W. Herschel has stated in a letter to Mr. C. R. Weld, Assist. Sec., R.S., inserted in the 'History of the Royal Society' by the latter, that he is "disposed to think that the system of triangular arrangement adopted by Sir W. Herschel in the wood-work of his great telescope, being a perfect system of diagonal bracing," or rather that principle to which the "diagonal bracing" system owes its strength, was original with his father at the time of its construction, that is about the year 1786.

Sir Robert Seppings introduced other improvements into our system of naval architecture. The admiralty presented him with 1000*l.* as a reward for his simple yet most useful invention of an improved block for supporting vessels, by which their keels and lower timbers were much more easily and promptly examined and repaired. It was produced while he filled the office of master-shipwright assistant in Plymouth dockyard, and is described in the 'Transactions of the Society of Arts' vol. xxii. p. 275-292, the Society having awarded him their gold medal for it in the year 1804. His plan for lifting masts out of the steps, which superseded the employment of sheer hulks for that purpose, has been the means of saving much expense and labour. His new mode of framing ships has led to a much more extensive use of short and small timbers, which were formerly of little value; but the most valuable of all the reforms of construction for which the navy of England is indebted to him was the substitution of round for flat sterns, which afford increased strength to the framework of the ship, greater protection against pooping in heavy seas, an almost equal power of anchoring by the stern and by the bow, a more secure and effective position for the rudder, and a stout platform for a powerful battery, embracing a sweep of more than 180°. This capital improvement was strenuously opposed by many distinguished naval officers, who regretted the loss of those magnificent cabins, which were better suited for their purposes of state than of service, but the good sense of less prejudiced judges happily prevailed, and secured for our ships of war an additional claim upon the respect of our enemies. The select committee on finance of the House of Commons on several occasions bore testimony to his official merits, and he received the marked approbation of both houses of parliament.

Foreign nations were not tardy in acknowledging the value of the improvements in ship-building originated by Sir R. Seppings, and their author received many substantial proofs of their sense of his merits; the Emperor Alexander of Russia, and the kings of Denmark and Holland, presented him with memorials of their appreciation of what he had effected. We may safely affirm, that in the national record of the great benefactors of their country, there are few names which will deserve more grateful commemoration than that of the object of this notice. In addition to the papers on the diagonal bracing already alluded to, Sir R. Seppings communicated to the Royal Society a paper 'On a new principle of constructing ships in the mercantile navy,' which was inserted in the 'Philosophical Transactions,' for 1820. Dr. Young's paper, also referred to above, though not communicated to the Royal Society till 1814, had been presented in the form of a report to the Board of Admiralty in 1811. It will be found reprinted in Dr. Peacock's edition of the 'Miscellaneous Works' of Young, (vol. i. p. 535-562) together with the official correspondence relative to it between the latter and Sir J. Barrow. Sir R. Seppings was an honorary member of the Cambridge University Philosophical Society, and a corresponding member of the Philosophical Society of Rotterdam. It had been proposed by the University of Oxford to confer upon him the honorary degree of D.C.L., at the commemoration of 1836, but severe indisposition compelled him to decline it. He died at his house at Taunton in Somersetshire, on the 25th of April 1840, aged seventy-two, leaving several children; his wife's decease had taken place a few years before.

SERICA. [MELOLONTHIDÆ.]

SERICOSTOMA. [PLICIPENNES.]

SERICULUS. [MERULIDÆ.]

SERPENTINE. As a mineral Serpentine occurs, although rarely, in right rectangular prisms. It is usually massive and compact in texture, and of a dark-green or blackish-green colour. It also occurs in fibrous and lamellar varieties. Its hardness is 2·5 to 4, and it may be cut with a knife. Its specific gravity is 2·5 to 2·6. It becomes yellowish-gray on exposure, and feels sometimes a little unctuous. The following varieties are recognised:—

Precious Serpentine.—Purer specimens of a rich oil-green colour, and translucent, breaking with a splintery fracture. It is a beautiful stone when polished. It has the following composition:—

Silica	42·3
Magnesia	44·2
Protoxide of Iron	0·2
Carbonic Acid	0·9
Water	12·4
	100·0

It gives off water when heated; becomes brownish-red before the blow-pipe, but fuses only on the edges.

Common Serpentine.—Opaque, of dark-green shades of colour.

Picrolite, Schiller Asbestus.—A Fibrous Serpentine, of an olive-green colour, constituting seams in Serpentine. The fibres are coarse or fine, and brittle. It resembles some forms of asbestus, but differs in its difficult fusibility. Thomson's *Baltimorite* belongs here.

Marmolite.—A Foliated Serpentine, of greenish-white and light-green shades of colour, and pearly lustre, consisting of thin folia rather easily separable. The folia are brittle, and the variety is thus distinguished from talc and brucite. It has the following composition:—

Silica	40·1
Magnesia	41·4
Protoxide of Iron	2·7
Water	15·7
	99·9

Kerolite.—Near Marmolite, but folia not separable.

Serpentine is a very handsome stone when polished. Beautiful specimens from Cornwall, and other parts of England and Ireland, may be seen in the Museum of Economic Geology, London. When mixed with limestone it constitutes the Verd-Antique Marble. It does not wear well, although at first it receives a fine polish. Chromic iron is usually found disseminated through it. Dr. Jackson of America has shown that Epsom salts or sulphate of magnesia may be profitably manufactured from Serpentine.

(Dana, *Mineralogy*.)

SERRATULA, a genus of Compositous Plants of the order *Cynaraceæ*, and the section *Serratuleæ*. The heads of flowers are diœcious by abortion; the involucre is imbricated, sharp, and unawned; the scales of the receptacle split longitudinally into linear bristles; fruit compressed, not beaked, basal areola oblique; the pappus persistent. There is but one British species of this genus, *S. tinctoria*, the Saw-Wort. (Babington, *Manual of British Botany*.)

SERVIA or SERBIA, a political division recently formed by decree of the emperor of Austria, consisting of portions of South Hungary and Slavonia. It is styled the Woiwodschaft of Servia and Temesvar Banat, and includes the Banat of Temesvar (comprising the counties of Bacz, Bodrogh, Torontal, Temes, and Krasso, in other words, the territories of the Baczka and the Banat), and the Syrmian districts of Ruma and Illok. The emperor is styled Grand-Woiwode, and the actual governor Vice-Woiwode, who resides in Temesvar, and is assisted by a ministerial commission and a native administrative council. The woiwodeschaft is divided into 5 districts. It has an area of 11,528 square miles, drained by the Maros, the Temes, the Theiss, and the Danube. The population amounts to 1,426,221 Serbs, Wallachs, Germans, and Hungarians. [CROATIA; HUNGARY; TEMESVAR.]

SERVITUDE, PENAL. This punishment has come in place of the former punishment by *transportation*, said to have been first inflicted by stat. 39 Eliz. c. 4. The first Act of Parliament on this subject is the 18 Car. II. c. 3, s. 2, enabling the judge of assize to transport certain offenders to *America*, there to remain and not to return.

The 22 Car. II. c. 5, s. 4, gave the judges power, "at their discretion," to grant a reprieve, and to cause felons to be transported beyond the seas, there to remain for the space of seven years; but if the offender refused to be transported, or returned within the time, then he was to be put to execution upon the judgment. The 22 & 23 Car. II. c. 7, s. 4, directed a judgment of transportation to be entered, when the felon elected to be transported, and it authorised the sheriffs to cause offenders to be embarked. It also made a return before the expiration of the sentence, a capital felony. The next statute on the subject was the Act 4 Geo. I. c. 11, "the foundation of the law of transportation," which enacted that, when the Crown should be pleased to extend mercy, upon condition of transportation to any part of *America*, any court, having proper authority to do so, might direct the offender to be transported. The stat. 6 Geo. I. c. 23, again made a person "*at large* in Great Britain, before the expiration of the term" of transportation, liable, on conviction, to suffer death. The 8 Geo. III. c. 15, extended the powers of the judges to make orders for transportation by enabling them to do so out of court; and by the stat. 30 Geo. III. c. 47, the king was empowered to authorise the governors of convict settlements to remit the sentences of transports.

By the stat. 5 Geo. IV. c. 84 (amended by 11 Geo. IV. and 1 Will. IV. c. 39), consolidating the laws on the subject of transportation, the king in council was empowered to appoint places beyond the seas, to which persons under sentence of transportation should be conveyed, the governor or other person to whom they were delivered, or his assignee, having the property in the service of the convicts. The sovereign was also empowered by warrant to appoint places of confinement at home, either on land or on board vessels in the Thames, or other rivers or harbours, for the confinement of male offenders (recently extended by the stat. 16 & 17 Vict. to females) under sentence of death, but reprieved or respited, or under sentence of transportation, there to remain under order of the secretary of state until entitled to their liberty, or removed, or otherwise dealt with. The capital punishment for offenders found unduly at large before the expiration of their sentence was subsequently abolished by 4 & 5 Will. IV. c. 67, which substituted transportation for life, with previous imprisonment not exceeding four years.

New South Wales, Van Dieman's Land, and Norfolk Island, thus became the principal receptacles for convicts. Although the property in the services of these persons was vested in the colonial governor or his assigns, a practice prevailed of granting them, in certain cases and on certain conditions, permission to employ themselves for their own benefit. These permissions were usually called 'tickets of leave.' By the stat. 6 & 7 Vict. c. 7, the legislature, thinking it just that ticket-of-leave convicts should be protected in their persons, and in the possession of such property as they might acquire by their industry, empowered them to hold personal property, and to maintain actions in respect thereof while such tickets remained unrevoked.

The reception of convicts having, however, become distasteful to the inhabitants of the colonies, the stat. 10 & 11 Vict. c. 67, was passed, permitting offenders under sentence of transportation to be removed to any prison or penitentiary in Great Britain; directors of the principal convict prisons being appointed afterwards under the stat. 13 & 14 Vict. c. 39. The difficulty attending the reception by the colonies of transported convicts having increased, the stat. 16 & 17 Vict. c. 99, finally abolished the punishment of transportation *for less than fourteen years*, and substituted penal servitude at home for certain periods, giving the courts power in all cases to substitute such penal servitude for transportation.

Before this last statute was passed, a system had for some time prevailed with respect to well-conducted convicts (who, although sentenced to transportation, had been kept at home), of granting them free pardons, generally at the expiration of half their sentence of transportation. As the continuance of the same system under the last-mentioned statute seemed likely to cause serious evils, but as it was at the same time desirable to encourage good behaviour in convicts, it was determined to try the experiment of retaining some control over them in cases where they were set at liberty before the expiration of their original sentence. With that view the statute empowers the Crown, by order of one of the secretaries of state, to grant any convict a licence or 'ticket of leave,' to be at large during such portion of his term of transportation or imprisonment, and upon such conditions, as may be thought fit, such licence being also revokable at pleasure.

Finally by the stat. 20 & 21 Vict. c. 3, the sentence of *transportation* is entirely abolished, and the sentence of penal servitude substituted; but the statutes which have reference to transportation are to have reference to penal servitude, so that the name alone is changed.

SEXUAL SYSTEM, in Botany, is the name given to the method by which Linnæus arranged the Vegetable Kingdom. In this system plants are divided into twenty-four classes, each of which is distinguished by the number and relative position of the stamens. The following are the classes:—

I. Flowers with Stamens and Pistils.

Class 1. *Monandria;* flowers with 1 stamen.
2. *Diandria* . . . . 2 stamens.
3. *Triandria* . . . . 3 „
4. *Tetrandria* . . . . 4 „
5. *Pentandria* . . . . 5 „
6. *Hexandria* . . . . 6 „
7. *Heptandria* . . . . 7 „
8. *Octandria* . . . . 8 „
9. *Enneandria* . . . . 9 „
10. *Decandria* . . . . 10 „
11. *Dodecandria* . . . 12-19 „
12. *Icosandria* . . . . 20 or more stamens inserted into the calyx.
13. *Polyandria* . . . . 20 or more stamens inserted on the receptacle.
14. *Didynamia* . . . . 4 stamens; 2 long and 2 short.
15. *Tetradynamia* . . . . 6 stamens; 4 long and 2 short. [CRUCIFERÆ.]
16. *Monadelphia;* flowers with the filaments of the stamens united in one set.
17. *Diadelphia;* flowers with the filaments of the stamens united in 2 sets. (In this class the flowers are papilionaceous.)
18. *Polyadelphia;* flowers with the filaments of the stamens united in 3 or more sets.
19. *Syngenesia;* flowers with the anthers of the stamens united. [COMPOSITÆ.]
20. *Gynandria;* flowers with the stamens and pistils combined. [ORCHIDACEÆ.]

II. The Stamens and Pistils on different Flowers.

21. *Monœcia;* flowers with the stamens and pistils on the same individual.
22. *Diœcia;* flowers with the stamens and pistils on different individnals.
23. *Polygamia;* flowers perfect and unisexual, on the same or on different individuals.

III. Fructification concealed.

24. *Cryptogamia.*

It will at once be seen that this system is exceedingly artificial, and that the great object of arrangement and classification in natural history is not attained by it. The effort of the naturalist in all systems shonld be to bring together those objects which most resemble each other, and to separate those which differ. A classification like the above, which takes only one organ or part of an organised being as a means of arrangement, is therefore certain to frustrate the great aim of the systematist. The only gronnd on which artificial classification such as the above can be tolerated is that of convenience in finding out the name of any particular object. It was undoubtedly this that led to the general adoption of the sexual system of Linnæus by botanists. It is now however fast falling into disuse; and our catalogues of plants and annuals of indigenous Floras are written on the plan of the Natnral System.

Linnæus divided the above classes into orders in the same artificial way. The orders in the first thirteen classes were founded on the number of styles or stigmas in each flower. Thus, flowers having one style were placed in the order *Monogynia*, those with two in the order *Digynia*, with three in *Trygynia*, aud so on. Thus the names of the orders are repeated in each of the thirteen classes. In the remaining classes however other points of structure are adopted. In *Didynamia* the orders are two, according as the fruit is 4-lobed or capsnlar. The first order is called *Gymnospermia*, and the second *Angiospermia*. These names were given by Linnæus under the erroneous supposition that the 4-lobed ovary was a series of naked seeds.

The class *Tetradynamia* was divided into two orders, according to the form of the fruit, *Siliculosa* embracing the species with the fruit a silicle, and *Siliquosa* those with a silique.

In the classes *Monadelphia, Diadelphia*, and *Polyadelphia*, the number of the stamens was made the text of the orders, and these were named as the classes. Thus we have the order *Decandria*, class *Monadelphia*, and the order *Decandria*, class *Diadelphia*.

With regard to *Syngenesia* the following plan will afford the best idea of the nature of the orders:—

Order 1. *Polygamia Equalis.*—Florets all hermaphrodites.
Order 2. *Polygamia Superflua.*—Florets of the disc hermaphrodite, those of the ray pistilliferous and fertile.
Order 3. *Polygamia Frustanea.*—Florets of the disc hermaphrodite, those of the ray neuter.
Order 4. *Polygamia Necessaria.*—Florets of the disc staminiferous, those of the ray pistilliferous.
Order 5. *Polygamia Segregata.*—Each floret having a separate involncre.
Order 6. *Monogamia.*—Anthers united, flowers not compound.

This large class thns divided by Linnæus forms the natnral order *Compositæ*, and has been recently snbdivided in a mnch less artificial manner than in the orders above given. [COMPOSITÆ.]

The class *Gynandria* was divided into orders by the number of the stamens. It inclndes the natnral orders *Orchidaceæ* and *Aristolochiaceæ*.

The classes *Monœcia* and *Diœcia* are also formed into orders according to the number of stamens, and the orders are again named as preceding classes. Thus we have order *Diandria*, class *Diœcia*, &c.

The class *Polyœcia* has the following orders:—

Order 1.—*Monœcia.*—Hermaphrodite, staminiferons, and pistilliferous flowers on the same plant.
Order 2. *Diœcia.*—Flowers on two plants.
Order 3. *Triœcia.*—Flowers on three plants.

The *Cryptogamia* were divided into the orders:—

Filices . . . . . Ferns.
Musci . . . . . . Mosses.
Hepaticæ . . . . . Liverworts.
Lichenes . . . . . Lichens.
Algæ . . . . . Sea-Weeds.
Fungi . . . . . . Mushrooms.

For the arrangement of the vegetable kingdom, according to the Natural System, see the articles EXOGENS and ENDOGENS.

SESSIONS. The stat. 12 & 13 Vict., c. 45, has amended the procednre in Courts of Quarter Sessions, by prescribing uniformity of time for giving notices of appeal; by conferring extensive powers of amendment; a large discretion as to costs; and by enabling them to refer matters to arbitration. By the statute 11 & 12 Vict., c. 78, these Courts, in common with the Courts of Oyer and Terminer and Gaol Delivery, are empowered to reserve questions of law for the consideration of the Court of Criminal Appeal; and by the statute 12 & 13 Vict., c. 45, the powers previously given to Judges to order payments by way of reward for the apprehension of certain offenders was extended to these Courts, the compensation to one person in no case to exceed 5*l.* The statute 12 & 13 Vict., c. 18, makes further provision for the holding petty sessions in connties and boroughs, and declares that every sitting and acting of justices, or of a stipendiary magistrate for a city or borough, having a separate commission of the peace, shall be deemed a petty sessions. The fees of justices' clerks in petty sessions are moreover provided for by the 11 & 12 Vict., c. 43, and 14 & 15 Vict., c. 55. See further JUVENILE OFFENDERS, *S.* 2; JUSTICES OF THE PEACE, *S.* 2.

SEYBERITE. [MINERALOGY, *S.* 1.]

SHAKHOVSKY, PRINCE ALEXANDER ALEXANDROVICH, a prolific and popular Russian dramatic anthor, was born in 1777, at a village in the government of Smolensk. He entered the army in 1793, bnt in 1801 obtained the more congenial appointment of one of the directors of the theatre. The war of 1812 recalled him to the army and to the command of a regiment of Cossaks, but after its conclnsion he resumed the duties of management. He retired with a pension in 1818, and died in 1846. During his lifetime Prince Shakhovsky was the most conspicuous of Russian dramatic anthors, and was sometimes styled the Russian Kotzebue. The number of his plays is loosely said to have approached a hundred; many of them were translations and adaptations chiefly from the French. Among them may be found a refashionment of Shakspere's 'Tempest,' and a drama founded on Walter Scott's 'Black Dwarf.' The original play which is considered his best, bears the title of 'Aristophanes,' and is founded on the history of the great Athenian dramatist; another, a comedy, 'What yon don't like don't listen to' ('Ne lyubo ne slushay'), and a third, 'A Lesson to Coquettes,' are also of unusual merit. His vaudevilles and light comedies are considered his most successfnl efforts.

SHAP. [WESTMORELAND.]

SHARPE, DANIEL, F.R.S., at the time of his decease president of the Geological Society of London, was born in London in 1806. His mother who died a few weeks after his birth, was sister to Samuel Rogers the poet. He was educated at Walthamstow, and as a boy early showed a taste for the study of natural history, but he did not commence seriously to work at Geology till after he had been admitted a Fellow of the Geological Society in June, 1829. In that year he gave his first memoir to the society, on a new species of *Ichthyosaurus*, *I. grandipes*, which, however, it afterwards appeared had been previously described by Conybeare, under the name of *I. tenuirostris*.

Throughout the greater part of his life, Mr. Sharpe was actively engaged as a merchant, and his business connection with the wine-growing districts of Portugal occasionally leading him there, in 1832, 1839, 1848, and 1849, he gave to the Geological Society a series of memoirs on the rocks of the neighbourhood of Lisbon and Oporto. The first is a mere sketch of the general arrangement of the tertiary and secondary rocks by a young and intelligent geologist; the second, on the same subject, is fuller and more definite, but not sufficiently complete in the determination of fossils to fix the precise age of the strata described. It contains, however, in an appendix, some observations of great value on the comparative effects of the great earthquake of 1755 on the strata on which Lisbon stands. The destructive effects of this shock were chiefly confined to the area occupied by the soft tertiary beds, while the buildings erected on the more solid Hippurite limestone and chalk escaped entirely. The line of division between the shattered and entire buildings Mr. Sharpe found to correspond precisely with the boundaries of the strata. In his third memoir Mr. Sharpe describes the granitic, gneissic, clay-slate, and coal-bearing rocks of Vallongo near Oporto. The clay state he proved by its fossils to be of Lower Silurian age, and his sections show that the strata bearing anthracitic coal underlie the slate, and rest on gneiss pierced by granite. He thence concluded that the coal is of Lower Silurian age. In the obituary notice of Mr. Sharpe given in the 'Anniversary Proceedings' of the Royal Society for 1856, on which the present article is founded, but with omissions, alterations, and additions, the following just remarks occur on this subject:—"In the present state of knowledge regarding that country, it is impossible to deny that this may be the case, but it must be remembered that the few remains of plants discovered in these strata are considered by palæontologists to present characters indicative of 'carboniferous' age; and even those geologists who most strenuously support the so-called uniformitarian doctrines, incline to attribute the peculiar position of the coal to one of those great inversions of the strata so frequent in highly disturbed districts of all ages, from palæozoic up to tertiary times."

The fourth paper commences with a succinct sketch of the general geology of Portugal, and goes on to define the limits of the secondary rocks north of the Tagus, both by stratigraphical and palæontological evidence. Long before this paper was read, Mr. Sharpe had acquired much critical skill and knowledge as a palæontologist, and on palæontological principles he now established the existence of cretaceous and Jurassic rocks in the country described. The whole formed an excellent sketch of a hitherto undescribed country, and up to this date British geologists are chiefly indebted to these memoirs for the knowledge they possess of a land where the science is almost uncultivated.

Between the years 1842 and 1844 Mr. Sharpe gave four memoirs to the Geological Society, on the Silurian and Old Red-sandstone rocks of Wales and the north of England, territories previously chiefly illustrated by the labours of Professor Sedgwick. The first of these is 'On the Geology of the South of Westmoreland.' Part of this paper describes the range of the Coniston limestone. Mr. Sharpe identified it by its fossils as forming part of the Lower Silurian series, but did not determine its actual horizon. In 1839 Mr. James Garth Marshall, F.G.S., in a paper communicated to the British Association, placed it on the parallel of the Caradoc sandstone, which determination the researches of later geologists have sustained. Mr. Sharpe also pointed out the unconformity of the Upper on the Lower Silurian rocks of the area; and in describing the passage of the Ludlow rocks into the Old Red-sandstone, he correctly infers that the tilestones of South Wales should be withdrawn from the base of the Old Red-sandstone and classified with the Ludlow rocks, to which their fossils unite them. At a later period of the same year he produced a memoir 'On the Bala Limestone, and other portions of the older Palæozoic Rocks of North Wales.' Up to this date it was believed that at Bala and elsewhere there was a great thickness of fossiliferous 'Upper Cambrian rocks' of Sedgwick below the Lower Silurian strata. Mr. Sharpe maintained that this was an error, and that both stratigraphically and by their fossils, the Bala rocks were the equivalents of the Llandeilo flags and Caradoc sandstone. This sagacious determination has since been confirmed by Mr. J. W. Salter, F.G.S., as regards the Caradoc sandstone, the fossils of Bala and the typical Caradoc sandstone of Sir Roderick Murchison in Shropshire being the same.

The more elaborate paper of 1844 is accompanied by a geological map of North Wales, and has been considered less happy. Mr. Sharpe's genius chiefly lay in the palæontological determination of the age of rocks, and, in this case at least, the time he allowed himself to map North Wales was too short for the satisfactory elucidation of the problems he proposed to solve.

Pursuing at intervals these subjects, Mr. Sharpe produced in 1847 an elaborate analysis and comparison of the Silurian fossils of North America, collected by Sir Charles Lyell, with those of Great Britain, and confirmed the views entertained by the American geologist, Mr. Hall, that the American Silurian strata, like the British, consist of two great divisions, namely, upper and lower.

While engaged in these investigations, Mr. Sharpe's attention was drawn to the subject of the slaty cleavage and foliation, which affects the more ancient rocks of Devonshire, Wales, the North of England, the Highlands of Scotland, and Mont Blanc. In 1846, 1848, 1852, and 1854, he produced four memoirs on these subjects, the two first and the last of which are published in the 'Quarterly Journal' of the Geological Society, and the third in the 'Philosophical Transactions' of the Royal Society. These questions had previously been made the subject of special investigation by Professor Sedgwick, Mr. Darwin, and Professor Phillips.

It has been said, that from imperfect data Mr. Sharpe generalised too largely; and though this may be the case, an attentive perusal of the memoir of 1846 proves that in some important points he materially advanced the subject at that date in the direction to which the labours of Mr. H. C. Sorby, F.G.S., have since tended. He attributes the cleavage of rocks, and consequent distortion of fossils, to pressure perpendicular to the planes of cleavage, and asserts that rocks are expanded along the cleavage planes in the direction of the dip of the cleavage. In the communication of 1848, the doctrine that pressure is the cause of cleavage is still more distinctly insisted on, and remarkable instances are given, in which pebbles were observed which appeared to have been compressed and elongated in the planes of cleavage. He also recognises the fact, since so beautifully explained by Mr. Sorby, in the 'New Edinburgh Philosophical Journal,' that the fine particles composing the slaty rocks are arranged lengthwise in the direction of the cleavage planes, and he attributes bends in the cleavage in its passage from one bed to another, to beds of different lithological character offering different degrees of resistance to pressure. The idea that cleavage may be due to crystalline action he altogether repudiates. It must be admitted, however, that no adequate investigation has yet been instituted of the relations of crystallisation to the greater structures of rocks. We are as yet uninformed whether there are or are not jointed structures on the great scale, resulting from the coincidence of crystalline planes over comparatively large areas, as some of the phenomena exhibited by the sub-crystalline limestones and by certain serpentines, tend to indicate. The two last of the series of Mr. Sharpe's papers on these subjects, published in 1852 and 1854, describe respectively the cleaved and foliated rocks of Scotland and Mont Blanc, and are chiefly devoted to the development of his theory of the great 'cylinders' or arches, in which he asserted that the laminæ of cleaved and foliated rocks lie. In these memoirs he made no advance beyond his previous ideas, for he attributed the formation of cleavage and foliation to the same cause; and though he indicated the fact, he gave no explanation of the reason of the occurrence of planes of cleavage and foliation in arched lines, a subject that has since in part been acutely treated of by Mr. Sorby, and of which the full explanation seems not far distant. In the paper on Mont Blanc however Mr. Sharpe explains and corrects for the first time, we believe, the remarkable error of Saussure, in representing the cleavage of slates, wherever they occur in the Alps, almost invariably as stratification; having mistaken the planes of cleavage for those of bedding, and regarded the latter as a series of parallel joints. But while showing that this systematic error runs throughout the whole of Saussure's volumes, he shows also that Saussure's observations, even when his conclusions are erroneous, are always accurate and instructive. He was led into the error from observing the analogy between the foliation of the schists and the cleavage of the slates, an analogy on which Mr. C. Darwin afterwards founded the correct conclusion that the foliation has no reference to stratification; other English geologists however as Mr. Sharpe points out "after correctly distinguishing cleavage planes from stratification, still continued to class the foliation of crystalline rocks with the latter instead of the former; thus proposing to unite two phenomena of totally different origin, while they separated those which are really analogous, and probably due to one and the same cause."

Besides these memoirs Mr. Sharpe contributed to the Geological Society various papers on special subjects, 'On the Quartz Rocks of Macculloch's Map of Scotland,' 'On the Southern Borders of the Highlands of Scotland,' and various palæontological communications; 'On the genus Trematis,' 'On Tylostoma, a new genus of Gasteropods from the Cretaceous beds of Portugal,' 'On the genus Nerinea,' and a note on the fossils of Boulonnais, appended to a paper by Mr. Godwin Austen on that district. He also furnished several parts of a monograph to the splendid publications of the Palæontographical Society, 'On the Fossil Remains of the Mollusca found in the Chalk Formation of England,' and on this important work he was still engaged when he met with the accident that caused his untimely death.

"Such is a brief outline of some of the scientific labours of Daniel Sharpe—a man whose mind alike powerful, active, and well cultivated, urged him successfully to grasp and make his own a wider range of subjects than many geologists dare to attempt. Neither should it be forgotten that all the while he was unceasingly engaged in mercantile pursuits, and it was only during brief intervals of leisure when more imperative labours were over, that he accomplished what many would consider sufficient work for their lives. And it is not in geology alone that he is known and appreciated, philologists and ethnologists equally esteemed him. With marvellous versatility of talent he grappled with the ancient Lycian inscriptions, brought home by Fellows, Forbes, and Spratt, and revealed the secrets of an unknown tongue written in an unknown character. In debate he was clear, keen, severely critical, and at times somewhat sarcastic, occasionally alarming to an opponent unaccustomed to his style; but those who knew him best were well aware that an unvarying fund of kindly good humour lay beneath, and that if he hit his adversary hard, no man than himself more rejoiced in a harder blow in return." His private life is stated to have been full of unostentatious benevolence.

Mr. Sharpe became a Fellow of the Royal Society on June 6th, 1850; he was also a Fellow of the Linnæan, Zoological, and Geological societies. In 1853 he became treasurer of the Geological Society; and on the retirement of Mr. W. J. Hamilton, in official course in 1856, was elected its president, being, as was remarked at the time, the first person actually engaged in commercial pursuits in the city of London, who had been selected for the chair. This honourable position in the world of science however he occupied three months only; for on the 20th of May in the same year, while riding near Norwood, he was thrown from his horse, and sustained a fracture of the skull. In a few days he so far recovered as to be able to recognise the relations who were admitted to his chamber. He had actually recommenced the study of his fossils, and his numerous friends rejoiced in the prospect of his speedy restoration; when a sudden relapse succeeded, and he died May 31, 1856.

(*Proceedings of the Royal Society*, 1856; *Anniversary Address of the President of the Geological Society*, 1857; *Anniversary Proceedings of the Linnæan Society*, 1857.)

SHEE, SIR MARTIN ARCHER, President of the Royal Academy, was born on the 23rd of December, 1770, in Dublin, where his father (the descendant of an old Irish family) was a merchant. His father having, after considerable hesitation, yielded to his desire to adopt painting as his profession, he was entered, while little more than a child, as a student in the Dublin Society. Here, before he was twelve years old, he had carried off the three chief prizes for figure, landscape, and flower drawing. His father's death threw the youthful artist on his own resources, but he had prosecuted his studies to such purpose, that at the age of sixteen he is said to have found ample occupation in Dublin as a portrait-painter, and his lively and polished manners gave him ready access to the best society of the Irish capital.

Anxious however to acquire a wider reputation, he, in 1788, came to London. Here he found in Edmund Burke a kind friend and adviser. Burke introduced him to Sir Joshua Reynolds, who treated him with much cordiality. Mr. Shee now entered as a student at the Royal Academy, and in 1789 became for the first time a contributor to the exhibition, sending a 'Portrait of a Gentleman,' and a 'Head of an Old Man.' Though he did not become a popular portrait-painter, nor, for some years at least, obtain many sitters from among the aristocracy or beauty of the land, Shee made his way steadily into a good and tolerably lucrative practice, towards which his geniality of manners rendered him valuable service. In 1798 he was elected an Associate of the Royal Academy, and he now deemed his position sufficiently secure to venture on taking the house in Cavendish-square, which Romney (whose successor he aspired to become) had built for himself when in the height of his celebrity. In this house Shee continued to reside until failing health compelled him to abandon his profession and remove to Brighton, some half a century later. This change of residence was attended with an improvement in his professional standing. He had painted a good many portraits of the leading actors, and of noted politicians, and other celebrities, which had attracted attention at the exhibition, and sitters readily followed him to his fashionable house. That he was fast making his way was sufficiently shown by his election as Academician in 1800, only two years after his election as Associate: his presentation picture was a 'Belisarius.'

From this time his career was marked by few changes or vicissitudes. Like most of the English painters of the time, during the short lull in the war between France and England he went to Paris to examine the art-treasures which Bonaparte had collected in the Louvre; but besides that, his biographers find little to notice until he appeared before the public in the character of a poet, by the publication, in 1805, of his 'Rhymes on Art, or the Remonstrance of a Painter,' a work which its author described as "a poem on painting, in which, more particularly, the early progress of the student is attempted to be illustrated and encouraged." A second part of it appeared in 1809. Byron praised the poem, and it was a good deal read and quoted at the time; and painters still occasionally garnish their literary essays with a stanza from it; but its vitality has long since departed, though it has an easy flow of rhyme, and is not without more substantial merit, and the notes are occasionally valuable. Again—on the occasion of a collection of the works of Sir Joshua Reynolds being exhibited at the British Institution, and a 'commemoration dinner' in honour of Sir Joshua being given by the directors of the institution in May 1803, at Willis's Rooms, the prince regent presiding—Mr. Shee invoked the muse, and published, in 1814, a small volume of poetry entitled 'The Commemoration of Sir Joshua Reynolds, and other Poems.' His next appearance as an author was under, to himself, more exciting circumstances. He had written a tragedy called 'Alasco,' the principal character of which he deemed to be particularly suited to the histrionic powers of his friend Kemble; who agreed to act it. But it happened to be the first tragedy which fell under the hands of Colman, the new licenser of plays, and he regarding himself as charged with the conservation of the political as well as the moral purity of the play-going public, sternly refused to permit it to be performed so long as it contained certain bits of declamation about liberty, and denunciations of despotism, as well as one or two expletives. To the expurgation of these the author as resolutely refused to submit, and appealed to the Lord Chamberlain himself against the decision of his deputy. But the chamberlain (the Duke of Montrose) declining to examine that on which his deputy had "reported," replied, with some characteristic dislocation of grammar, "I do conclude, that at this time, without considerable omissions, the tragedy should not be acted." Shee however was not to be so silenced, and resolved to shame his censors by printing his tragedy, though it was not allowed to be performed. It accordingly appeared in 1824, with a preface in which the facts were set forth with considerable warmth, while all the prohibited passages were printed in italics. The tragedy itself is forgotten now, but it will be referred to by writers of literary and political history for illustrations of what was prohibited as politically dangerous in London so late as 1824. The censor certainly did his work carefully. Treason is seen to lurk sometimes in single words—often in single lines, such as—

"Or question the high privilege of oppression."

Even the mention of—

"Some slanderous tool of state,
Some taunting, dull, unmanner'd deputy,"

is thought to bode mischief, and is expunged accordingly. This was Shee's latest appearance as a poet, but once later he tried his hand as a novelist.

Literature however was bnt his amusement. During all these years he had been steadily making his way to a foremost place among the fashionable portrait-painters of his day. The mantle of Reynolds had not fallen on his successor, bnt Lawrence's easy gracefulness of style concealed his deficiencies from the eyes of his contemporaries, and he reigned in undispnted supremacy. But Lawrence conld not alone supply the demands of the titled and wealthy claimants for the immortality of portraiture; and though among the political and literary celebrities Phillips perhaps was most in repnte, his gay colour and polished manners undoubtedly rendered Shee second favonrite with lords and ladies. On the death of Lawrence in 1830, he naturally aspired therefore to succeed him not only as a fashionable portrait painter, bnt also as president of the Royal Academy. Wilkie became his opponent, but though of course there conld be no comparison between the artistic power of the two men, the academicians felt that Shee's fluency of speech and courtly address were of far more conseqnence in the academic chair than more eminent artistic abilities with reserved manners and a falteriug tongue. Shee was elected president by a large majority, and soon afterwards received the honour of knighthood. He is said to have filled all the duties of his office with zeal and ability, and his official eloquence on those pnblic occasions which called it forth was much admired. He continued to paint till 1845, in which year he exhibited for the last time five pictnres; bnt his powers had been for some years evidently failing. He now, on the ground of inability to discharge its dnties, resigned the presidency, bnt at the unanimous reqnest of the academicians he was induced to withdraw his resignation, and he continned to hold the office till his death, which occurred on the 13th of August 1850, in his eightieth year.

Sir Martin Archer Shee will not rank among the great portrait painters of the English school. He is deficient in depth and force, in intellectual expression and in characterisation. Bnt his colonr is often pleasing though too florid, and his figures have an air of ease and refinement; and his pencil has undonbtedly preserved the best portraits of many of the more eminent of his contemporaries. He occasionally painted historical figures and fancy snbjects, but none of them won mnch attention. He was an accomplished gentleman rather than a great painter.

SHEEPSHANKS, REV. RICHARD, M.A., F.R.S., F.R.A.S., was born at Leeds, July 30th, 1794. His father was engaged in the cloth manufacture, and destined his son for the same pursuit. At the age of fifteen however, and after an ordinary school edncation, the son discovered his own preference for a learned professiou, and the father accordingly placed him under the care of the Rev. James Tate, M.A., the master of the Grammar-school of Richmond in Yorkshire, well known as one of the most successful teachers of his day, and subsequently as an editor of Horace. Here he remained nntil 1812, when he was removed to Trinity College, Cambridge. He took his degree with honours in 1816, obtained a fellowship in the next year, and proceeded to stndy for the bar, to which he was called abont 1822. A weakness of sight, to which he was always snbject, is supposed to have been the principal cause of his not practising law; but it must be added that his share of his father's property placed him in easy circumstances, independently of his fellowship, and his taste for science had become very decided. He took orders abont 1824, and soon began to devote himself entirely to astronomy. He became a fellow of the Royal Astronomical Society in 1824, and was elected into the Royal Society on the 1st of April 1830. Of the former he was always one of the most active of the executive body. His leisure, and his desire to help the young astronomer so long as he wanted advice and guidance, gave a peculiar value to his services, and a peculiar ntility to his career.

Mr. Sheepshanks resided in London till about 1842, when he removed to Reading, where he died of apoplexy, August 4th, 1855. There is mnch reason to suppose that his life was shortened by his laborious exertions in the restoration of the standard scale of linear measure. "Though an ardent politician of the school of opinion which had to struggle for existence during the first half of his life, bnt gradually became victorious in the second, he never took any pnblic part in a political question, except that of the Reform Bill. He was one of the Boundary Commissioners appointed in 1831 to fix the boundaries of the boroughs under the new system of representation." His reading in politics and history is stated to have been extensive; and he was especially partial to military matters, with which he was very well acquainted, both ancient and modern tactics having formed a portion, and no inconsiderable portion, of his studies. To this must be added literature and poetry, to which he was much attached. He never abandoned classical reading, and those who knew him best were often surprised at the extent to which he had cultivated modern literature.

But his subject was astronomy, and his especial part of that snbject was the 'astronomical instrument.' His reputation among astronomers on this point, and the articles which he contributed to the 'Penny Cyclopædia,' have indnced an expression of regret that he did not draw up a full treatise on a matter which he had so completely fathomed.

Mr. Sheepshanks was engaged in active efforts on several special occasions, to which we make brief allusion. In 1828 he joined Mr. Airy, now Astronomer-royal, in the pendulum operations in Cornwall, and suggested some of the most important plans of operation. In 1828 and 1829 he was active in the establishment of the Cambridge Observatory. In 1832 he was consulted on the part of the admiralty with reference to the edition then preparing of Groombridge's Circumpolar Catalogue: the resnlt was the publication of that work in a mnch more efficient and more creditable form than it would otherwise have appeared in. In 1832 he also interfered in a matter to which, connected as it is with personal differences, we can only here allnde, as eliciting much information on the snbject of equatorial instruments in general, a result which is entirely due to the part taken by Mr. Sheepshanks. In 1838 he was engaged in the chronometric determination of the longitudes of Antwerp and Brussels; in 1844 in those of Valentia and Kingstown in Ireland, and Liverpool. In 1843 and 1844 the subject of the Liverpool Observatory led him into a controversy, his pamphlets on which will be useful study to those who are interested in astronomical instruments. He was always an active member of the Board of Visitors of the Royal Observatory at Greenwich.

Mr. Sheepshanks was a member of both the commissions (of 1838 and 1843) for the restoration of the standards of measure and weight, destroyed by fire in 1834. The standard of measure was placed in the hands of Francis Baily [Baily, Francis, *S.* 1], at whose death Mr. Sheepshanks volunteered (November 30th 1844) to continue the restoration. This matter occupied him closely during the last eleven years of his life. It would not be possible to give any detailed account of the operation, a full history of which is expected from Mr. Airy. It need only be said, that after a thorough examination of the process, beginning with the very construction of thermometers,—a point which gave no small tronble,—results were obtained which were embodied in a bill (18 & 19 Vict. cap. lxxii.) which received the royal assent on the 30th of July, 1855, the day following that on which Mr. Sheepshanks was struck by the shock which ended his life. The nnmber of recorded micrometer observations is just five hnndred short of ninety thousand. He had given a succinct bnt very satisfactory account of the operations for the production and verification of the new standard, in the Report of the Commissioners, for March 28, 1854, which was presented to Parliament.

It has been recorded on adequate authority that Mr. Sheepshanks was especially distinguished by the integrity of his mind, and by his ntter renunciation of self in all his pursuits. He did not court fame, it was enough for him that there was a useful object which could be advanced by the help of his time, his thonghts, and his purse. His consideration for others was made manifest by his active kindness to those with whom he was engaged, and no less by his ready appreciation of the merits of those against whom he had to contend in defence of truth and justice, as they appeared to his mind.

(*Proceedings of the Royal Society*, 1855; *Report of the Council to the Thirty-sixth Annual Meeting of the Royal Astronomical Society*, 1856.)

SHEFFORD. [Bedfordshire.]

SHEIL, RICHARD LALOR, the son of Mr. Edward Sheil, a merchant of Cadiz, was born in Dublin in the year 1793. His father was a Roman Catholic, and he was educated in that religion at the Jesuit College of Stonyhurst, Lancashire, whence he was removed at the usual age to Trinity College, Dublin, where he graduated with distinction. He next proceeded to London, and entered himself at Lincoln's Inn to study for the English bar, which had been recently opened to Roman Catholics; but the ruin of his father's means through a disastrous partnership caused a change in his destination, and he returned to Ireland, where he was called to the bar in 1814. He defrayed the expenses of his years of study by the successful tragedy of 'Adelaide' in which Miss O'Neill performed, and by those of the 'Apostate,' 'Bellamira,' 'Evadne,' and 'The Huguenot.' About the same time he also contributed some 'Sketches of the Irish Bar' to the 'New Monthly Magazine,' then edited by Mr. T. Campbell. It appears however that although Mr. Sheil gained credit as a writer and a speaker, he never heartily devoted himself to a deep study of so dry a subject as the law, and that his professional income in consequence was not large. He was not a lawyer but an orator by nature, and he found the platform a more congenial stage for the display of his talents than the law courts of Dublin. As a Roman Catholic too he laboured under the civil disabilities which, though modified from what they had been, still shut the doors of the House of Commons against himself and his co-religionists. It is not surprising therefore that he turned his attention to political and religious agitation. In 1822 he became an active member of the Catholic Association; and three years later was chosen in conjunction with the late Mr. Daniel O'Connell to plead at the bar of the House of Lords against the bill introduced for its suppression. The bill however passed; but it only served to inflame his religious zeal and to rouse his oratorical powers to such a pitch of vehement invective against the government, that a prosecution was commenced against him for seditious language. The illness of Lord Liverpool however transferred the premiership to the hands of Mr. Canning, who wisely ordered the prosecution to be abandoned. In 1828 Mr. Sheil took an active part in procuring the return of Mr. O'Connell to parliament as member for the county of Clare, and also addressed the great meeting held at Penenden Heath for the purpose of resisting the Roman Catholic Emancipation Bill. In 1829, soon after the passing of the Relief Act, Mr. Sheil was returned to parliament for the since disfranchised borough of Milborne Port, by the influence of the late Marquis of Anglesea, who, while holding the lord lieutenancy of Ireland, had noticed his career, and who thus turned the restless agitator into a peaceful citizen and a useful legislator. Here his oratorical powers were appreciated, and he soon became one of the most popular and attractive speakers in the House of Commons, though the matter of his speeches never rose to a level with the brilliancy of illustration and flow of impassioned declamation with which they were adorned. In 1830 he was again returned for Milborne Port, and in 1831 for the county of Louth. After the passing of the Reform Act, which gave much dissatisfaction in Ireland, Mr. O'Connell commenced agitating for repeal, in which Mr. Sheil at first refused to join, but subsequently consented, considering, as his biographer, Mr. T. M'Cullagh asserts, that it "was in point of fact but short-hand for just and equal government in Ireland." In December 1832 for the first reformed parliament he was chosen to represent the county of Tipperary, where he had acquired some extensive landed influence by his second marriage with the widow of Mr. E. Power of Gurteen, on which occasion he adopted that lady's maiden name of Lalor. In 1834 the Grey ministry introduced an Irish Coercion Bill, which was strongly opposed by most of the Irish members, among whom was Mr. Shiel, but a report became current that several of them had expressed a wish that it should be carried, "or there would be no living in Ireland." A great outcry was raised of "Who is the traitor?" and on Lord Althorp being appealed to, he replied that he had no personal knowledge of any such expression, but had heard it, and though he could not give up the names, he would tell any member who asked whether he was one. On Mr. Sheil making the inquiry, he replied he was one who had been mentioned. Mr. Sheil denied it at once: a parliamentary committee was appointed, and Mr. E. Hill, who appeared before the committee to support the allegation, confessed that he believed that he had been misinformed. In the same year Mr. Shiel was a party to the "Lichfield House Compact," a term applied from a phrase of his own, in which he hoped "that no minor differences would mar their compact and cordial alliance." In 1838 he was offered office by the Melbourne administration; at first the clerkship of the ordnance was spoken of, but ultimately he became one of the commissioners of Greenwich Hospital, and never again advocated repeal. In 1839 he was made vice-president of the Board of Trade; and was also sworn a member of the Privy Council, being, we believe, the first Roman Catholic on whom that honour had been conferred since the reign of James II. In June 1841 he was appointed judge-advocate-general, when he resigned the seat for Tipperary for that of the borough of Dungarvan; but he held office only till the following September, when his party were superseded in office by the late Sir Robert Peel. On the advent of Lord John Russell to power in 1846, Mr. Sheil was appointed to the mastership of the Mint, which he filled until November 1850, when he accepted the post of British minister at the court of Tuscany. His health however had been failing for some time, and he had rarely spoken in the House of Commons for the two or three years immediately preceding his retirement from parliamentary life. Although the appointment to Florence could be regarded by himself and his friends as nothing less than expatriation and an extinction of what might have been a growing reputation, yet he submitted not so much with a feeling of philosophic indifference as in a joyous spirit, as though he felt that his diplomatic post would prove a great promotion and a dignified retirement. The melancholy death of his stepson, by his own hand, which happened in the following April, gave a shock to his feeble constitution from which he never entirely recovered, and an attack of gout in the stomach brought his life to a close at Florence on the 23rd of May 1851, in the fifty-ninth year of his age. His younger brother, Sir Justin Sheil, K.C.B., for some time held the post of envoy extraordinary and minister plenipotentiary at the court of Persia. (*Memoirs of the Right. Hon. Richard Lalor Sheil*, by W. T. M'Cullagh.)

SHELBURNE. [Nova Scotia.]

SHELLEY, MARY WOLLSTONECRAFT, daughter of William Godwin and wife of Percy Bysshe Shelley, was born in 1798. In 1816, while in Italy, she wrote her powerful and striking romance of 'Frankenstein,' which commanded an extensive popularity in England, and is still a favourite with the admirers of the wild and wonderful, while the extremely ingenious and consistent development of the character of the monster excites and sustains a human interest amidst all its improbabilities. Though her success was great in this her first effort, it did not induce Mrs. Shelley to resume her pen for some time. She devoted herself to promoting the comfort and guarding the health of her husband with affectionate solicitude, which he gratefully acknowledged and repaid. Just previous to his unfortunate death however she had finished 'Valperga,' a novel, afterwards printed in 3 vols., for which Shelley says in one of his last letters that she had been offered 400*l.*, which he designed for the relief of the necessities of his father-in-law, W. Godwin. After her husband's death she published 'Falkland,' 'The Last Man,' and 'The Fortunes of Perkin Warbeck,' each in three volumes. She also wrote 'Rambles in Germany and Italy,' an account of her journeys with her husband. In 1839 she published an edition of his poetical works, with a few biographical notes added, in which the more offensive passages of 'Queen Mab' are omitted; and in 1840 a selection from his letters and a few specimens of his prose writings. In all these she pays a most affectionate tribute to his goodness of heart and the other amiable qualities which she states invariably secured him the love of all who knew him. She died in London, on the 1st of February 1851.

SHEPHARDITE. [Mineralogy, *S.* 1.]

SHERBROOKE. [Canada, *S.* 2.]

SHIPPING. [Trade, Shipping, &c., *S.* 2.]

SHIPS. Nearly all the statutes mentioned under this head [Ships, v. xxi. p. 397] have been repealed (17 & 18 Vict. c. 120). The law relating to shipping, to the contracts arising from the employment of ships, and to the mutual duties and obligations of owners, masters, passengers, and seamen, remains, nevertheless, almost unaffected; the provisions of the repealed statutes being, in principle, though not always in detail, re-enacted by the statutes about to be mentioned.

The most important of these is the Merchant Shipping Act, 1854, which is amended by stat. 18 & 19 Vict. c. 91; the next in importance, the Passengers' Act, 18 & 19 Vict. c. 119. The Act relating to bills of lading, and that conferring admiralty jurisdiction on the County Courts, have been already referred to. [LADING, BILL OF, *S.* 2; COUNTY COURTS, *S.* 2.] It would be quite impossible in this place to give any detail of the provisions of these Acts, which constitute complete codes in themselves, and which must be referred to by every one who wishes to know anything of the subjects to which they relate.

It is necessary to mention here, however, the statutes which have repealed the Navigation Acts, whereby, it was said, "the constant increase of English shipping and seamen was not only encouraged, but rendered unavoidably necessary."

These Acts were by various statutes maintained down to a recent period; their leading feature being to secure the exclusive trading by which it was thought British shipping and navigation were encouraged. The first step in favour of free trade was effected by the statute 12 & 13 Vict. c. 29, by which the exclusive privileges of British ships were limited in effect to the coasting trade of the United Kingdom, the trade with the Isle of Man and Channel Islands, and the coasting trade of the colonies. But that Act has been almost entirely repealed by the statute 16 & 17 Vict. c. 107, by which the entire trade has been thrown open to vessels of all nations.

The Board of Trade exercises a general superintendence over all matters relating to merchant ships and seamen, and the carrying into execution the statutes in force relating to them. For that purpose it requires various kinds of returns as to trade and navigation, and originates inquiries and considers reports made to it by its inspectors and other officers. It exercises a partial control over local marine boards, and may lay down rules as to the conduct of examinations, and the qualification of applicants for the posts of masters and mates of passenger-ships. It grants licences to persons to engage or supply seamen or apprentices for merchant ships; adjudicates on claims for seamen's wages, investigates cases of alleged incompetency and misconduct in master mariners; and appoints officers to report on the condition and efficiency of steam-vessels and their machinery. These and its other duties, and the mode in which they are exercised, are defined in the Merchant Shipping Act, and other statutes above referred to.

SHIPSTON ON STOUR. [WORCESTERSHIRE.]

SHIPWRECKS AND LIFE-BOATS. That wrecks are numerous, is a fact well-known to a seafaring nation like ours; that they must necessarily be considerable in number, regard being had to the perils of the deep, will of course be admitted; but that nothing can be done to lessen their frequency, would be a hopeless theory of which we ought to be ashamed. Supposing for the sake of fixing the ideas, that some wrecks are occasioned by a want of scientific knowledge of winds, waves, currents, whirlpools, shoals, reefs, and sunken rocks, on the part of meteorologists and hydrographers; that others are caused by the incompetency of captains and mates; that others again result from the insubordination, carelessness, ignorance, or obstinate fatalism of seamen; that a fourth group are due to the deficiency of lighthouses, beacons, and buoys; and that the remainder arise from want of ready assistance to ships which, though placed in peril on shoals or near rocks, might yet be saved if aid were at hand on the beach or the cliff—who shall say that these evils are incurable? who can put a limit to the improvements which might be wrought?

A dismal story, indeed, does the 'Wreck-chart of the British Islands' tell, as published by the Admiralty, and afterwards in the Life-Boat Journal. It may be designated a truly distressing map. Every wreck on our coasts has its little black mark; and the aggregate of such black marks reveals the number of wrecks in one year. Knowing that a black spot ● indicates a vessel wrecked, and that + indicates a vessel so seriously damaged as to need to discharge cargo, we look eagerly for the relative numbers of these little spots and stars; and it is saddening to see how numerous are the fatal black signs. At some places the wrecks are numerous because the coast is dangerous; at others, because the congregating of ships is very great.

And if it be asked, "What ratio did 1857 bear to previous years, in respect to these calamities?" it is encouraging to know that on the whole it was favourable, fewer lives were lost and more were saved, than usual; yet still our coasts saw no fewer than 1143 wrecks of ships. The lives lost numbered 532 (in 1854 they amounted to 1540), and the number saved was 1668, of which 399 were by life-boats, 512 by luggers, coast-guard boats, &c., 507 by assistance from shore with ropes, mortar-apparatus, &c., 243 by ships' own boats, and steam-vessels, and 8 by individual exertion of a meritorious character. All these wrecks, be it remembered, happened on our own coasts—on the coasts of the most busy maritime islands in the world; where, if there be liability of disaster through the vast congregation of shipping, there ought, on the other hand, to be a supply of invention and good sense sufficient to check, in some degree, such disasters. In examining the details of the chart, it will be seen that, as usual, the line of coast between Dungeness and the Pentland Frith is the most fatal, and that the mouth of the Tyne takes the unenvied precedence of all other places, in the number of black dots and stars opposite to its name; next come the mouth of the Tees and the mouth of the Wear. These three rivers may be taken as the representatives of the district whence three million tons of coal are brought by sea to London yearly, employing the services of several thousand collier ships, which sail to and fro, and add to the otherwise busy commercial trade of the Northumbrian and Durham ports. The mouth of the Humber, the Suffolk coast between Yarmouth and Southwold, the intricate sandy shoals off the mouth of the Thames, the Goodwin Sands, the Scilly Islands, Barnstaple Bay, and Liverpool, are the portions of the English coast which present, in the next degree, the most numerous indications of ship-losses. The Welsh coast is thickly strewn, especially Glamorgan, Pembroke, and Anglesea. Scotland, except in and near the Frith of Forth, presents no large numbers; the western coast is, indeed, remarkably free, due probably to the less exposure to the winds which tend to drive ships ashore on our eastern seaboard. Ireland presents a tolerably equable distribution along the east and south coasts: less on the northern and western.

The annual report states that the year 1857 was a favourable one with respect to shipwrecks, yet 437 vessels were totally lost, and 706 damaged. Of these, 890 were registered British ships; 33 were registered in British colonies; 213 were foreign vessels; and 7 were not known: the total amount of the tonnage of these ships was 218,570, and they were manned by 9819 sailors. Of the total wrecks, 53 were by collision, owing, in many cases, as the report states, to "bad look-out," "neglect to show light," "neglect of the rule of the road," &c.; and cases of collision continue to increase. One prominent cause of collision is stated to be the difficulty of making out the direction in which a ship is standing by the showing of a single light, and a coloured one at the bow is recommended. The total estimated loss occasioned by these wrecks was 519,301*l.*, and the amount insured was 473,135*l.* The Board of Trade institute inquiries into the causes of the wreck in many cases, and during the year the certificates of several of the captains and mates of the wrecked vessels were cancelled or suspended for drunkenness, carelessness, and incapacity.

Many inquiries into the causes of shipwreck have been instituted; and especially one by a Committee of the House of Commons, whence a voluminous report resulted. But public attention was perhaps more fully drawn to the subject by the Duke of Northumberland, who, in 1850, offered a premium for the best model of a life-boat. The examiners by whom the award was made, prepared an interesting Report on the whole subject, which his Grace caused to be printed for distribution in any and all quarters where it might render most service. This Report caused increased attention to be paid to the means for preventing shipwreck, or to assist the sufferers if prevention were impossible. The Duke has caused many life-boats to be placed on the Northumbrian coast, which course of proceeding has acted as an incentive to others. The Report, and the circumstances attending it, also led to the starting of a small periodical * by a Society which has laboured since 1824 in the same benevolent cause. This Society, by means of a subscribed fund, has sought to assist in the establishing of life-boats and rocket-mortars at all the dangerous parts of our coast; to induce the formation of Local Committees at the chief

* 'The Life-Boat; or, Journal of the Shipwreck Institution.' Published by C. Knight, 90, Fleet-street; and to be had at the office of the Institution, 14, John-street, Adelphi.

ports for a similar purpose; to maintain a correspondence, beneficial to all parties, with these Local Committees; to reward persons who render assistance to distressed ships or mariners; and to encourage the invention of new or improved boats, buoys, belts, rocket apparatus, and other means for saving life. To further this end, as just observed, the Society commenced a little work, in Numbers at twopence each, which, at intervals, gives an epitome of all that is worth knowing on this matter.

A deserved meed of praise was given by a Quarterly reviewer to the Duke of Northumberland, in that he has established, at his own cost, at the principal stations off the coast of his native county, "life-boats of an improved construction, and supplied with all the necessary apparatus and appendages—a piece of munificence which has acted most favourably in stimulating the humanity and activity of the neighbouring peasantry, and from which the tourist, without being unseasonably sentimental, may derive his full share of satisfaction. The grave-yards which surround the striking ruins and picturesque churches 'of mountainous Northumberland,' are full of the mournful records of youth cut off in its bloom, and manhood in its prime, by the tempestuous waves. Each stone has its own sad tale—of brothers found locked in each other's embrace—of a father who perished in a vain attempt to save his son—of whole families, united in industry and affection, and undivided in death, swallowed up in the little craft that constituted the whole of their worldly wealth. He must be 'duller than Lethe's dull weed' whose heart does not swell as he reads the simple tale of their struggles and their fate, and whose eye does not glisten when he hears of the munificence which has done all that on that dangerous coast can be done to avert such catastrophes in future."—'Quarterly Review,' No. 194. It is too much, however, to say that *all* has been done that can be done; this is to put a limit to man's ingenuity and forethought, which we should be sorry to admit until the desired end has been more fully attained.

As an example—not of the means for preventing shipwrecks, or for saving the lives of those who may be endangered by wreck—but for rendering aid to the poor fellows who may have lost all but life by such calamities, the "Shipwrecked Fishermen and Mariners' Royal Benevolent Society" deserves a word of notice. The scheme was formed at Bath in 1839 by Mr. Rye, who was impressed with the importance of affording relief to the widows and orphans of fishermen and mariners who might be drowned, and of assisting with clothes, food, and money, those who might be cast ashore from a wreck—alive, it is true, but deprived at once of all the necessaries of life. Aided by Sir Jahleel Brenton, at that time Governor of Greenwich Hospital, Mr. Rye succeeded in establishing a society, and in collecting a respectable sum as a first subscription. On the 8th of May, in that same year, three fishing-boats were lost in Mount's Bay, involving the death of 20 persons, and the sudden impoverishing of 7 aged persons, 12 widows, and 35 children. A sum of money contributed to the bereaved survivors served to bring the usefulness of the Society into notice. The Society progressed steadily. Between the years 1839 and 1854, it afforded relief to 30,000 shipwrecked persons, and to more than 14,000 widows, children, and dependants of fishermen and mariners, who had been drowned. The aid is not wholly eleemosynary: it partakes in some degree of the character of a provident fund. Primarily, the Society "boards, lodges, and conveys to their homes all destitute shipwrecked persons to whatever country they may belong, through the instrumentality of the agents of the Society;" but aid beyond this limit depends upon membership. All fishermen and mariners may become members by the payment of *2s. 6d.* per annum. The Society affords temporary assistance to the widows, parents, and children of all such members as may have been drowned: and gives a gratuity to such members as, without losing life, lose or damage their apparel or boats by wreck or similar calamity. The longer the period during which a fisherman or mariner has been a member of the Society, the larger is the allowance to his widow and children in the event of his death by wreck or drowning. Every institution which fosters habits of provident forethought is worthy of respect and support; and the Society now under notice does this by the system just described. As to the purely charitable part of the plan, it ranks with a multitude of other praiseworthy modes of helping those who *cannot* help themselves.

It was found, however, in the course of years, that two societies—bearing the titles "National Shipwreck Institution," and "Shipwrecked Fishermen and Mariners' Royal Benevolent Society,"—were liable to be confused in the public mind; and a union or amalgamation became desirable. Accordingly, in the early part of 1855, the latter-named society transferred to the former nine life-boats, eight boat-houses, and five life-boat carriages; in order that one society might have the sole management of the life-boat department of those benevolent schemes; while the other might continue to attend to the wants of shipwrecked mariners, or their widows and children. The "National Shipwreck Institution" at the same time changed its name to the "National Life-Boat Institution," to define more clearly the objects aimed at.

That there is a positive amount of good work rendered by the Life-Boat Institution is made manifest by the simple fact, that in 1857 alone the life-boats belonging to, or in connection with, the Institution, were the means of saving the lives of 399 persons, all of whom would probably have been lost but for such aid. The following is a list of the lives saved, for which rewards were given by the Society:—

	Lives Saved.		Lives Saved.		Lives Saved.
1824	124	1836	225	1848	123
1825	211	1837	272	1849	209
1826	175	1838	456	1850	470
1827	183	1839	279	1851	230
1828	301	1840	353	1852	773
1829	463	1841	128	1853	678
1830	372	1842	278	1854	355
1831	287	1843	238	1855	408
1832	310	1844	193	1856	473
1833	449	1845	235	1857	374
1834	214	1846	134		
1835	364	1847	157	Total	. 10,475

It may not be that these lives were all saved by the instrumentality of the Society: indeed such was not the case. In many instances the saving of life by the life-boats or other means did not involve any extraordinary risk, or the exercise of any remarkable skill or bravery, and it is only to such cases, whether performed by persons connected with the Society or strangers, that the rewards are distributed; and the list, therefore, only includes the cases of lives saved from shipwreck on our coast, in which the Society gave honorary or pecuniary rewards.

The life-boats belonging to, or in connection with, the Institution, in March, 1858, were no less than 70 in number, and there are 75 others provided from various sources, and not in connection with the Society. Considering that the boats usually cost from 150*l.* to 200*l.* each, the boat-carriages about an equal sum, and the boat-houses about 100*l.*, it will be seen that the amount of money thus sunk is something considerable. Northumberland, Suffolk, and Anglesea are the three counties most liberally provided. These boats, on an average, appear to be about 30 feet long by 8 feet broad, 3½ feet deep, weight 40 cwt., and are rowed by 8, 10 or 12 oars.

The life-boats above adverted to, are purposely so constructed as to brave the peculiar dangers of a coast where shipwrecks are liable. Seventy years ago the construction of such boats began to attract attention; and in 1789 Mr. Greathead, of South Shields, constructed what may be deemed the original of all the life-boats since made. Cork was largely used in Greathead's boat to render it more buoyant; and since his time air-tight cases, formed of india-rubber cloth, have been a favourite feature in many of the inventions. When the Duke of Northumberland offered the prize in 1850, no fewer than 280 plans and models were sent in, exemplifying numerous modes of combining buoyancy with stability in boats. About 50 of the best of these models were placed in the Hyde-Park Exhibition. The prize was given to Mr. Beeching, of Yarmouth, as the constructor of the boat which seemed to combine the greatest number of good qualities. Since that time a boat, invented by Mr. Peake, of her Majesty's Dockyard at Woolwich, has been more frequently adopted as a model than any other.

A boat being the first requisite for such service, there are numerous fittings necessary to render it workable: there must be a boat-house, in which to keep it sheltered from the weather when out of use; and a carriage whereon to wheel it to the part of the coast most adjacent to the wrecked or stranded ship. Moreover, there must be a crew of trusty men, able and willing to brave a raging sea, strong and resolute to pull the oar under any stress of weather; and there must be a master or coxswain exercising sufficient control to command the men, and direct their energies in a proper channel. It is in this direction, quite as much as in the provision of life-boats and buoys, that the Life-Boat Institution has rendered service. A system of payment, partly in the nature of a salary, partly as a reward, is adopted, such as may induce steady men to render aid; and the local committees assist in collecting the means whereby the outlay is to be defrayed, and in laying down the rules which are to govern the movements of the life-boat corps.

The exact mode in which a life-boat renders its useful service must depend, of course, on many contingencies of winds, waves, shoals, reefs, rocks, &c. The following is an example:—On the 2nd of May, 1855, in early morn, the beachmen at Ramsgate heard alarms given, and saw signal-rockets fired on board the light-vessels moored off the Goodwin Sands, indicating that a vessel was in danger or distress in that perilous region. The Ramsgate life-boat (the property of the Ramsgate Harbour Commissioners) was speedily manned and equipped, and taken in tow by the Samson steam-tug against a rough wind and tide. The hapless ship was seen from the steamer with signals of distress flying, and apparently high and dry on the further edge of the Goodwin; the tide being low at the time, and a heavy sea on the edge of the sand. At a particular point the life-boat left the steam-tug, and steered towards the stranded vessel; but it was speedily found that the depth of water around the vessel was too small to permit a close approach by the boat. The men, therefore, waited until the in-coming tide favoured them a little; they went on; they ran on shore among the breakers; and the master and four of the crew, jumping overboard into the surf, waded to the ship, which they reached in an exhausted state. The ship was the Queen of the Teign, bound from Antwerp to Liverpool with a valuable cargo, of sugar, bark, and seeds. When the crew of the ship saw the exertions of those who had undertaken to aid them, they descended from their vessel into a boat, jumped on the lee-side of the sand, and thence got into the life-boat. As soon as the tide had risen sufficiently to allow the steamer to approach, a line was thrown on board her; and a communication being thus established, she was enabled to lay out an anchor to leeward, and subsequently to get her own large tow-rope fast to the vessel. By these means the vessel was hove off from her dangerous position, and taken, in a leaky state, with four feet water in her hold, into Ramsgate Harbour.

Another example is worth noticing, as showing the recklessness of crews, and the probability that such recklessness frequently occasions loss of ships. On October 7th, 1854, signals of distress were observed in the direction of the Holm Sand, off the Suffolk coast, during a strong easterly gale. The Pakefield life-boat immediately put off, towed by the Lowestoft steam-tug. Finding that it could not reach the vessel to leeward, the boat weathered the sand, and then observed the sea breaking heavily over the ship, a Norwegian brig, of 180 tons. With some difficulty the boatmen succeeded in getting on board, where they found a crew of eight men, *all drunk;* the besotted seamen, though in imminent peril of being drowned, and without the possibility of seeing their vessel got off, obstinately refused to leave. The boatmen, finding persuasion to be useless, and knowing that the life-boat itself was in a perilous position on the verge of the shoal, with the waves constantly breaking over it, returned to Lowestoft Harbour. At daybreak on the next morning, another crew from Pakefield manned the life-boat, and succeeded in reaching the vessel, where the crew, sobered during the night, were glad to avail themselves of this second offer to aid them. They were all brought safely to land.

No part of our maritime system has, in recent years, attracted more attention than that which has just been illustrated—the personal character and conduct of the men employed. Who can tell the amount of misery which one hour of inebriety, one display of incompetency, may produce? The ship may be all that human art can effect, in strength and efficiency; the fittings and stores may be all that could be needed; the provisions may be good in kind, and ample in quantity—and yet one slight manifestation of indiscretion or of unskilfulness, may give room for a catastrophe which will plunge scores or hundreds of human beings into a watery grave. This matter was taken up by the Legislature many years ago; but it is now treated in a more direct way by the system established in virtue of a statute presently to be noticed.

The life-boats of which we have spoken, are not the only means necessary for affording aid to stranded or wrecked ships. There are times when other aid is needed; when a ship is in distress so near the shore as to be within reach of a rope, if means were at hand to throw it—while, perhaps, no boats are near the spot fitted to render the required service. The name of Captain Manby is intimately associated with the history of this part of the subject. Captain Manby's ingenuity was excited by a terribly distressing scene which he witnessed in 1807; when the Snipe, a gun-brig, was lost off Yarmouth; when sixty-seven persons were drowned within sixty yards of the beach, after remaining five or six hours on the wreck, without a possibility of receiving assistance. Long before this, he had thought on the subject. He had, in 1783, thrown a line, by means of a small mortar, over Downham Church, in Norfolk; and it struck him that he might, by the same means, throw a line over a stranded vessel. During many subsequent years he made repeated experiments; his main difficulty consisted in securing the shot to the rope; iron chains were liable to break on the discharge; but at length he found that stout strips of closely-plaited raw hide would answer the purpose. In 1792 the Society of Arts gave a premium of fifty guineas to Lieutenant Bell for "a plan for throwing a rope on shore by means of a shell from a mortar on board a vessel in distress;" but Captain Manby was the first to put in practice a really available plan.

Let us see what is the end to be attained, that we may understand the mode of attaining it. A ship is stranded near the shore, say two or three hundred yards off, where no boat, perhaps, is available. What are the crew to do? Sailors, unfortunately for themselves, are in too few cases swimmers; and even a swimmer has a poor chance for his life in such weather and such a sea as usually accompany these strandings of ships. The men generally cling to their vessel as long as her timbers will hold together, rather than strike out and endeavour to swim to shore. In such case their safety mainly depends on the establishment of some communication with the shore. Such communication was the object of Captain Manby's attention. On February 12th, 1808, a brig ran aground within a hundred and fifty yards of the Yarmouth coast; the crew lashed themselves to the rigging, and bore up against a furious storm as best they might—hoping almost against hope. All attempts to send off a boat to them failed. At length Captain Manby brought his mortar down from his residence to the coast, and succeeded in throwing a line over the ship, by which all the poor fellows were saved. Having thus given practical proof of what could be effected, Manby was instrumental in causing many mortars to be so applied on the coast. He frequently tried to obtain some recognition of his services from the Government; and in this matter he was more fortunate than many useful discoverers. He was unquestionably the means whereby the attention of the Legislature was drawn to the subject of wrecks and life-saving apparatus; and when he died at a venerable age in 1854, he left behind him a name worthy of the gratitude of society.

It is believed that more than one thousand lives have been saved by means of the ropes thrown out to stranded ships, through the agency of mortar-rockets. There are 198 places on the shores of the United Kingdom, where such apparatus is kept, mostly under the charge of the Coast Guard, who, from the peculiar nature of their other duties, are well adapted for this kind of service.

The articles transmitted to the Paris Exhibition of 1855, by the Life-Boat Institution, may be taken as a test of the present state of the arts applied to this kind of construction; for it is to be supposed that the institution would be conversant with the latest practicable improvements. The first was a model life-boat and carriage, as now adopted by the Institution, and stationed on many parts of our coasts; the boat, invented by Mr. Peake, of Woolwich Dockyard, and made by Messrs. Forrestt, of Limehouse, is 30 feet long, 7½ feet wide, and 3¾ feet deep; it is considered to possess, in a high degree, seven qualities required in a life-boat—lateral stability, speed against a heavy sea, facility in launching and beaching, quick self-discharge of water, the power of self-righting if upset, great strength, and stowage-room for a number of passengers. Another specimen, was the life-boat which gained for Mr. Beeching, of Yarmouth, the Northumberland prize; it is a little longer and wider than Mr. Peake's, but not quite so deep. A third was Mr. Palmer's life-boat, employed for many years by the Society, and stationed at many points on the coast of France. A fourth was Mr. Ward Jackson's life-boat, such as is stationed at the West Hartlepool Docks. Besides these boats there were several minor articles, such as travelling life-buoys, to be used with the rocket and mortar apparatus; cork life-belts and life-buoys; and so forth.

We have now to notice the recent law concerning shipwrecks. The year 1854 gave strength to the cause, by bringing the power of the government to bear upon it—not that such strengthening is necessarily a result; for the 'right man' is not always in the 'right place,' nor do the government departments always do the right thing at the right time; but it seems especially fitting that the legislature, and through it the executive, should have a voice in the shipping economy of a maritime nation. Mr. Cardwell brought in and carried a Bill "To Amend and Consolidate the Acts relating to Merchant Shipping;" it constitutes the Act 17 & 18 Vict. cap. 104, and received the royal assent August 10, 1854. The statute is of great length, and relates to eleven different topics, bearing upon the well-being of sailors and their ships,—the relation of the Board of Trade to the Commercial Marine; the ownership, measurement, and register of British merchant ships; the qualifications of masters and seamen; the precautions for safety on ship-board; the arrangements concerning pilots; the management and tolls of lighthouses; the constitution of the Mercantile Marine Fund; the laws relating to wrecks, casualties, and salvage; the liabilities of ship-owners; legal course of procedure in the event of misdemeanor; and miscellaneous details. Inspectors of merchant ships, and investigators in respect to wrecks and accidents, are to be appointed by the Board of Trade; new examinations for masters and mates are to be organised, separating foreign-going ships from home-trade passenger ships; the Board is empowered to suspend certificates to masters and mates, in case of misconduct or inefficiency; naval courts are to be instituted abroad or on the high seas, in correspondence with the Board, to inquire into cases of wreck or abandonment of ships; the number and size of the boats to accompany all trading ships are denoted; every ship carrying more than ten passengers must be provided with a life-boat, or an ordinary boat rendered buoyant, and with two life-buoys—the boat and buoys being always kept ready for use; lights and fog-signals are to be used, such as may be suggested by the Admiralty; iron steamers must have water-tight compartments, and safety-valves beyond the control of the engineer; sea-going ships must be provided with fire-engines and hose, signal-guns, and ammunition for firing signals of distress.

Besides the provision for preventing wreck, the Act contains many clauses, applying to cases in which wreck may unhappily have occurred. As these arrangements are somewhat peculiar, it may be well to notice them a little closely. All matters relating to wreck are placed under the general superintendence of the Board of Trade, by whom 'Receivers of Wreck' are to be appointed. These receivers will have the chief command and authority over all persons present at any wreck, or similar casualty, and power to issue such directions as may seem expedient for the preservation of life and property, or for the prevention of plunder and disorder. Whenever a ship is stranded, or otherwise in distress on British shores, bystanders are to be encouraged to render assistance, by having a pecuniary interest in the preservation of life or property. If services so rendered shall be instrumental towards the object in view, the persons shall have a claim on the owner of the ship for a "reasonable amount of salvage." Numerous directions are given for ascertaining what would be a "reasonable amount" in each case; for enforcing the claim of the salvor against the distrainer; for disposing of an unclaimed wreck; and for adding to the salvor's reward out of the Mercantile Marine Fund, in cases where life has been preserved, and where the wrecked ship is insufficient in value to pay the salvage awarded. The Mercantile Marine Fund here adverted to is made up in a curious way; it consists of certain fees received by the Board of Trade for examinations and registries connected with merchant-ships; lighthouse dues accruing by virtue of certain sections of the Act; rates accruing from lastage and ballastage in the Thames; and fees derived through the Receivers of Wreck. The fund, kept with her Majesty's Paymaster-General, is employed in payment of the salaries of examiners, surveyors, receivers, &c.; expenses in regard to lighthouses, buoys, beacons, lastage, ballastage, life-boats, &c.; and rewards to persons who assist in saving wrecked ships, or crews, or passengers.

In pursuance of the powers conferred by the statute above sketched, the Board of Trade proceeded, early in 1855, to give effect to its provisions. Among other steps, the Board addressed a Circular to all the Life-boat Committees throughout the United Kingdom. Considering that in 1854 no fewer than 1540 persons perished from wrecks on our own coasts, it is not too much to say that a wide field is yet open to the exertions of individual humanity and bravery. Doubtless, many of those persons might have been rescued had there been life-boats and willing aiders at the places where the calamities occurred. The principle intended by the Act, and entrusted to the Board of Trade for realisation, is not to supersede local exertion, but to support it—to "help those who will help themselves." A preparatory Circular was addressed to the several Life-boat Committees in September 1854, and this was followed by another in February 1855. The Circular dwelt strongly on the fact that the Board would insist on evidence of local activity before sanctioning grants out of the Mercantile Marine Fund. "In the wealthier and more populous portions of the kingdom, my Lords anticipate that the public spirit of the neighbourhood will supersede the necessity of recurrence to this Board for aid. In cases where a necessity for such assistance exists, the assistance contemplated by the Board of Trade will be confined to assisting towards the manning and exercise of boats, and towards defraying expenses connected with actual service rendered in saving, or endeavouring to save, life from shipwreck. The construction and maintenance of boats and boat-houses will, my Lords anticipate, be provided for as heretofore by funds voluntarily raised. My Lords have entered into correspondence with the National Life-boat Institution, which offers many advantages to local Committees in correspondence with it, and they propose also to communicate from time to time with any Local Committee which may desire to address their communications directly to this department."

The principal arrangements marked out in the Circular may be condensed as follows. Every Life-boat Committee must have as one of its members an officer of the Coast-guard, or of the Customs, or some official person connected with the Board of Trade. The Local Committee must be provided with a boat and boat-house satisfactory to the Board. The boats, houses, and gear, must be kept in efficient repair, and accessible to the Inspector appointed by the Board. Each boat must have a coxswain, and a crew at least one-half more than is necessary to man the boat; permanent, if possible. The coxswain is to receive a small salary, and he, as well as the crew, are to receive certain specified rewards as payments for each time of exercising (once a quarter at the least), each time of launching to assist a wreck, and each time of undergoing special danger or fatigue. In the event of the death of any of the crew while on service, the Board will contribute towards a fund for the widow. All the payments are in the first instance to be made by the Local Committees, but to be repaid by the Board of Trade when satisfactorily tested. Signal rockets and mortar apparatus on the coast are to remain under the charge of the coast-guard.

The Life-boat Institution, to further the object held in view by the Board of Trade, also issued a Circular to the Local Life-boat Committees, containing advice and suggestions couched in more familiar language than a Government department is accustomed to employ. One extract will suffice to explain in some degree the mode in which men are induced to tender their services in the hazardous duty of manning a life-boat. Speaking of the remuneration promised by the Board of Trade, the Circular says:—"The scale of payment for services in saving life is greater than has ever before been paid, and is calculated to give every encouragement to seamen who engage in such an honourable and humane, yet often perilous, service. They conceive that the chief point in connection with it, which will call for the attention of the Local Committees, will be to exercise a careful and wise discretion in recommending the higher awards for extraordinary services; taking care never to do so but for those of a really distinguished character. The quarterly exercise of the life-boat should never be omitted. If, as may happen in the summer months, rough weather does not occur, the crew may still, with advantage, be exercised in rowing together, and the sound and tight condition of the boat herself, and the perfectness of her gear and fittings ascertained; and if, from any cause, the greater part of her ordinary crew are absent, she had nevertheless better be taken afloat by any other of the seamen of the port who may be obtained, but always, if possible, in charge of the permanent coxswain of the boat. The salary of the coxswain is double that which has previously been paid by this institution. In return, it will be expected that they shall devote the more time and attention to preserving the boats and their appurtenances under their care in a constant state of efficiency, and ready for instant service. With regard to the hire of horses or steam-tugs, and the payment of persons to assist in launching and hauling up life-boats, the attention of the Local Committees will here also be chiefly required to check undue charges and to avoid incurring such expenses, except when necessary. It is thought, also, that they may do much good by endeavouring at all times to encourage public spirit, and other disinterested motives, in those who are called upon to assist on such occasions, and, as far as possible, to divest such services of a mercenary character." Under this Act, in 1857, the Board of Trade paid a total sum of 5020*l.* for rewards, pensions, &c., and for maintaining the Rocket and Mortar Apparatus.

SHIRE. See County Courts, *S.* 2, p. 158. Hundred Courts and Courts Leet have long been almost entirely obsolete, and the County Court statutes accordingly contain provisions for the surrender of such courts by the lords thereof to the Crown. It does not appear, however, that any surrenders have yet been made.

SHOVELER. [Ducks.]

SHRIMP, FRESH-WATER. [Gammarus.]

SICILY. The island has been described in vol. xxi., but it is now divided into seven provinces, the area, subdivisions, and population of which, according to the latest returns, are as follows:—

Provinces.	Area in Square Miles.	Districts.	Communes.	Population in 1851.
Palermo . .	1984	4	72	514,717
Messina . . .	1386	4	116	349,484
Catania .	1761	2	81	379,991
Girgenti . . .	1375	3	45	245,974
Noto . . .	1482	3	41	237,814
Trapani . . .	1358	3	21	182,809
Caltanisella .	1190	3	31	180,791
Total . .	10,536	22	407	2,091,580

SILICA. [Silicium.]

SILURIAN SYSTEM. The following list of fossils, found in this system, is given by Professor Phillips:—

Amorphozoa.

	Species.		Species.
Acanthospongia (?)	1	*Cnemidium*	1
Choria	2		

Foraminifera.

	Species.
Endothyra	1

Zoophyta. (*Zoantharia* of Edwards.)

	Species.		Species.
Aceroplaria	1	*Goniophyllum*	2
Alveolites	4	*Halysites*	1
Arachnophyllum	1	*Heliolites*	10
Aulacophyllum	1	*Petraia*	7
Aulopora	3	*Pyrilonema*	1
Chætites	4	*Protovirgularia*	1
Cladocora	1	*Sarcinula*	1
Clisiophyllum	1	*Stenopora*	1
Cœnites	5	*Strephodes*	5
Cyathaxonia	1	*Stromatopora*	2
Cyathophyllum	5	*Strombodes*	2
Cystiphyllum	4	*Syringopora*	5
Diphyphyllum	1	*Thecia*	2
Favosites	7	*Zaphrentes*	2
Fistulipora	1		

Alcyonaria.

	Species.		Species.
Didymograpsus	3	*Graptolithus*	12
Diplograpsus	10	*Rastrites*	1
Gorgonia	4	*Retiolites*	1

Hydroidia.

	Species.
Oldhamia	2

Echinodermata.

Crinoidea.

	Species.		Species.
Actinocrinus	4	*Marsupiocrinus*	1
Crotalocrinus	1	*Perischocrinus*	2
Cyathocrinus	3	*Sagenocrinus*	2
Eucalyptocrinus	3	*Sasocrinus*	1
Glyptocrinus	1	*Tetrameroorinus*	1
Ichthyocrinus	1	*Tetragonis*	1

Cystidoidea.

	Species.		Species.
Agelacrinites	1	*Echinosphærites*	4
Apiocystites	1	*Hemicosmites*	2
Caryocystites	5	*Prunocystites*	1
Echinencrinus	2	*Pseudocrinites*	4

Asteroidea.

	Species.		Species.
Lepidaster	1	*Uraster*	4
Prolaster	1		

Echinoidea.

	Species.
Palæchinus	1

Articulata.

Annelida.

	Species.		Species.
Aphredita	1	*Nereites*	3
Cornulites	1	*Serpulites*	4
Cropopodia	2	*Spirorbis*	1
Lumbricaria	2	*Tentaculites*	3
Myrianites	1	*Trachyderma*	3
Murestites	1		

Crustacea.

Entomostraca.—Trilobitidæ.

	Species.		Species.
Acidaspis	10	*Harpes*	2
Æglina	2	*Homalonotus*	5
Agnostus	4	*Illænus*	8
Amphion	1	*Lichas*	9
Ampyx	5	*Ogygia*	2
Asaphus	7	*Olenus*	4
Bronteus	2	*Paradoxides*	1
Calymene	6	*Phacops*	15
Cheirurus	4	*Proëtus*	3
Conocephalus	1	*Remoplourides*	7
Cybele	2	*Sphærexochus*	1
Cyphaspis	1	*Staurocephalus*	2
Cyphoniscus	1	*Stygina*	2
Deiphon	1	*Tiresias*	1
Eccooptocheile	1	*Trinucleus*	5
Encrinurius	4		

Other *Entomostraca.*

	Species.		Species.
Beyrichia	3	*Eurpyterus*	2
Ceratrocaris	3	*Hymenocaris*	1
Cythere	1	*Leptocheles*	3
Dithyrocaris	1	*Pterygotus*	1

Bryozoa.

	Species.		Species.
Cellepora	1	*Heteropora*	1
Cercopora	5	*Intricaria*	1
Dicistopora	2	*Oldhamia*	—
Discopora	3	*Polypora*	1
Escharina	1	*Ptilodictya*	5
Fenestella	6	*Retepora*	1
Glauconone	1		

Brachiopoda.

	Species.		Species.
Athyris	6	*Chonetes*	1
Atrypa	9	*Crania*	3

Cyrtia	1	*Pentamerus*	8
Discina	12	*Retzia*	3
Leptæna	42	*Rhynconella*	26
Lingula	16	*Siphonotreta*	2
Obolus	2	*Spirifera*	5
Orthis	45	*Trematis*	1
Orthisina	2		

LAMELLIBRANCHIATA.

Monomyariæ.

	Species.		Species.
Ambonychia	7	*Posidonomya*	1
Avicula	16	*Pterinea*	10
Inoceramus	2		

DIMYARIA.

	Species.		Species.
Anodontopsis	7	*Modiola*	6
Aria	12	*Modiolopses*	8
Cardiola	3	*Mytilus*	7
Cleidophorus	7	*Nucula*	13
Conocardium	3	*Orthonota*	3
Cypricardia	3	*Psammobia*	1
Dolabra	2	*Sanguinolites*	10
Grammysia	4	*Telluria*	1
Leptodomus	2		

PTEROPODA.

	Species.		Species.
Cornularia	3	*Pterotheca*	2
Ecculiomphalus	3	*Theca*	3

GASTEROPODA.

	Species.		Species.
Capulus	2	*Natica*	1
Euomphalus	16	*Nerita*	1
Helminthochiton	1	*Paletta*	1
Holopla	2	*Pharsanella*	1
Holoppella	9	*Pleurotomaria*	10
Loxonema	2	*Raphistoma*	2
Maclurea	2	*Trochus*	8
Macrochalus	1	*Turbo*	10
Murchisonia	14	*Turritella*	4

HETEROPODA.

	Species.
Bellerophon	13

CEPHALOPODA.

	Species.		Species.
Actinoceras	3	*Orthoceras*	54
Cyrtoceras	3	*Phragmoceras*	10
Litrutes	11		

FISHES.

	Species.		Species.
Onchus	2	*Sphagodus*	1
Plectrodus	3	*Thelodus*	1

Of the above list, 496 were found in the Upper Silurian; 485 in the Lower Silurian; and 19 in the Cambrian.

SILVER. The ores from which the silver of commerce is mostly obtained are the Vitreous Silver, Brittle or Black Silver-Ore, Red Silver-Ore, and Horn Silver, in addition to Native Silver. Besides these, silver is obtained in large quantities from galena (lead-ore), and from different ores of copper; and some galenas are so rich in silver that the lead is neglected for the more precious metal. This metal occurs in rocks of various ages, in gneiss, and allied rocks, in porphyry, trap, sandstone, limestone, and shales; and the sandstone and shales may be as recent as the middle secondary, as is the case in Prussia. The silver-ores are associated often with ores of lead, zinc, copper, cobalt, and antimony, and the usual gangue is calc spar or quartz, with frequently fluor spar, pearl spar, or heavy spar.

The Silver of South America is derived principally from the Horn Silver and Brittle Silver-Ores, including Arseniuretted Silver-Ore, Vitreous Silver-Ore, and Native Silver. Those of Mexico are of nearly the same character. Besides, there are earthy ores called Colorados, and in Peru Pacos, which are mostly earthy oxide of iron, with a little disseminated silver; they are found near the surface, where the rock has undergone partial decomposition. The sulphurets of lead, iron, and copper, of the mining regions, generally contain silver, and are also worked. (Dana.)

The principal mines of silver in Europe are those of Spain, of Kongsberg in Norway, of Saxony, the Hartz, Austria, and Russia.

In England, argentiferous galena is worked for its silver. Forty thousand tons of this ore were reduced in 1837, which contained upon an average about six ounces of silver in a ton of lead.

The annual product of the several countries of Europe is thus estimated by Dana in his 'Manual of Mineralogy:'—

	Pounds Troy.
British Isles	7500
France	4150
Austria	63,000
Sweden and Norway	13,000
Spain	130,000
Saxony, the Hartz, and other parts of Germany	78,500
Belgium	440
Piedmont, Switzerland, and Saxony	1560

making in all 298,150 troy pounds, or about 4,500,000 dollars annually. With the sum from Russia, about 730,000 dollars, it becomes 5,230,000 dollars a year. This is small compared with the amount from America, which at the beginning of the present century equalled 2,100,000 pounds, or $31\frac{1}{2}$ millions of dollars, nearly six times the above sum; and it is probable that these mines will again yield this amount when properly worked. The whole sum from Russia, Europe, and America, makes nearly 2,000,000 pounds avoirdupois.

SIMCOE. [CANADA, *S.* 2.]

SIMETHIS, a genus of Plants belonging to the natural order *Liliaceæ*, and the tribe *Anthericeæ*. The parts of the perianth are six, spreading, deciduous; the stamens are attached to the base of the perianth; the filaments bearded; the anthers incumbent; the capsules are 3-celled, and each cell contains two seeds.

S. bicolor is a recent addition to the British Flora. It is a native of the South of Europe, and is found on sandy heaths near the sea-shore. In England it was first found at Bournemouth, in Dorsetshire. It has also been found at Derrynane, Kerry, in Ireland. This plant has linear leaves, flat, or a little keeled upwards. The flowers are panicled, the petals are purple without, and white within. In Hooker and Arnott's 'British Flora' it is suggested that this plant may have been introduced with trees from France.

SIMIADÆ. In the list of the specimens of *Mammalia* published by Dr. J. E. Gray, we find almost a complete representation of this family. They are as follows:—

SIMIADÆ.

The Chimpanzee (*Troglodytes niger*, Geoff.; *Homo Troglodytes*, Linn.). West Africa. [CHIMPANZEE.]

The Orang-Outan, or Pongo (*Simia Satyrus*, Linn.; *S. Wurmbii*, Kuhl; *S. Agrias*, Schreb.). Borneo. [ORANG-UTAN.]

The Siamang (*Siamanga Syndactyla; Simia Syndactyla*, Raffles, Horsf.). Java.

The Hoolock (*Hylobates Hoolock*, Martin; *Simia Hoolock*, Harlan). [HYLOBATES.]

The Oungka (*H. agilis*, F. Cuv.; *Simia Lar.*, Vigors and Horsfield; *Pithecus agilis*, Desm.). Himalaya and Malacca.

The Gibbon (*H. Lar.; Homo Lar*, Linn.; *S. longimana*, Schreb.). Malacca.

The Silvery Gibbon, or Wou-Wou (*H. leuciscus*, Kuhl; *Simia leucisca*, Schreb.). Malacca.

The Kalasie (*Presbytes rubicunda*). Borneo.

The Simpal (*P. melalophos; Simia melalophos*, Raffles). Sumatra.

The Tianac (*P. flavimana; Semnopithecus flavimanus*, I. Geoff.). Sumatra.

The Rufous Presbytis (*P. nobilis*, Gray; *Semnopithecus melalophos*, Desm.). Himalaya.

The Lutung (*P. Pyrrhus*). Java.

The Chingkau (*P. cristata; Simia cristata*, Raffles). Java and Sumatra.

The Dusky Presbytis (*P. obscura*). Singapore.

The Negro Presbytis (*P. maura; Simia maura*, Schreb.). China.

The Hooded Presbytis (*P. Johnii; Simia Johnii*, Fischer). India, Madras.

The Hoonuman (*P. entellus*). Bombay and Nepaul.

The Nestor (*P. cephalopterus; Cercopithecus cephalopterus*, Zimm.). Ceylon.

Pennant's Colobus (*Colobus Pennantii*, Waterh.). Fernando Po.

The Red and Black Colobus (*C. rufoniger*, Ogilby, Martin). Fernando Po.

Temminck's Colobus (*C. Temminckii*, Desm.). West Africa, Gambia.

The Black Colobus (*C. Satanas*, Waterh.). Fernando Po.

The King Monkey (*C. polycomos*, Geoff.; *Simia polycomos*, Schreb.). Fernando Po.

The Guereza (*C. guereza*, Ruppell). Abyssinia.

The Vervet (*Cercopithecus pygerythrus*, F. Cuv.). Cape of Good Hope.

The Grivet, or Tota (*C. engythithia; Simia engythithia*, Herm.). Abyssinia.

The Callithrix (*C. sabæus*. Erxl.; *Simia sabæa*, Linn.). West Africa.

The Talapoin (*C. Talapoin*, Erxl.; *Simia Talapoin*, Schreb.). West Africa.

The Mona (*C. mona*, Erxl.; *Simia mona*, Schreb.). West Africa, Guinea.

Burnett's Mona (*C. Burnettii*, Gray). Fernando Po.

The Red-Eared Monkey (*C. erythrotis*, Waterh.). Fernando Po.

The Hocheur (*C. nictitans*, Erxl.; *Simia nictitans*, Linnæus). Fernando Po.

The Diana (*C. Diana*, Erxl.; *Simia Diana*, Linn.). West Africa.

The Bearded Monkey (*C. Pogonias*, Bennett). Fernando Po.

The Patas (*C. ruber*, Kuhl.; *Simia rubra*, Gmel.). Africa, Senegal.

The White-Collared Mangabey (*Cercocebus collaris; Cercopithecus Æthiops*, Kuhl.). Africa.

The White-Crowned Mangabey (*C. Æthiops; Simia Æthiops*, Linn.). Africa.

The Sooty Mangabey (*C. fuliginosus*, Geoff.; *Cercopithecus fuliginosus*, Kuhl.). Africa.

The Zati, or Capped Macaque (*Macacus radiatus*, Desm.). India.

The Munga, or Bonnet-Macaque (*M. Sinicus*, Desm.; *Simia Sinica*, Linn.). India.

The Bruh (*M. nemestrinus*, Desm.; *Simia nemestrina*, Linnæus). Sumatra.

The Macaque (*M. cynomolgus*, Desm.; *Simia cynomolgos*, Linn.). India, Sumatra.

The Rhesus (*M. Rhesus*, Desm.; *Simia Rhesus*, Audeb.). India, Bengal.

The Oinops (*M. Oinops*). Nepaul.

The Brilliant Macaque (*M. Speciosus*, F. Cuv.). Japan.

The Magot (*M. Inuus*, F. Cuv.; *Simia Inuus, S. vulgaris*, and *S. Sylvanus*, Linn.). Gibraltar Rock, Stora, North Africa.

The Black Macaque (*M. niger*, Bennett; *Cynocephalus niger*, Desm.). Philippines.

The Wanderoo (*S. veter; Simia Silenus*, and *S. Veter*, Linnæus). Ceylon, China, India.

The Gelada (*Gelada Ruppellii*). Abyssinia.

The Tartarin (*Cynocephalus Hamadryas*, Latr.; *Simia Hamadryas*, Linn.). Abyssinia.

The Chacma (*C. porcarius*, Desm.; *Simia porcaria*, Bodd). South Africa.

The Baboon (*C. babouin*, Desm.; *Simia cynocephalus*, Fischer). West Africa.

The Papion (*C. Sphinx*, Latr.; *Simia Sphinx*, Linn.). Guinea.

The Mandrill (*Papio Maimon*, Latr.; *Simia Maimon*, and *S. Mormon*, Linn.). Africa.

The Drill (*P. leucophæa*). Africa.

Cebidæ.

The Chameck (*Ateles Chameck; Simia Chameck*, Humb.). Guiana.

The Black Spider Monkey (*A. ater*, F. Cuv.). Brazils.

The Coaita (*A. Paniscus*, Geoff.; *Simia Paniscus*, Linn.). Brazils.

The Marimonda (*A. Belzebuth*, Geoff.). Brazils.

The Chuva (*A. marginatus*, Kuhl.). Brazils.

The Five-Fingered Miriki (*Brachyteles arachnoides; Simia arachnoides*, Humb.). Tropical America.

The Black-Foreheaded Miriki (*B. frontatus*). Tropical America.

The Miriki (*B. hypoxanthus*). Tropical America.

The Caparro, or Negro Monkey (*Lagothrix Humboldtii*, Geoff.). Brazils.

The Araguato, or Brown Howler (*Mycetes ursinus*). Guiana, Brazils.

The Golden Howler (*M. Seniculus*, Kuhl.; *Simia Seniculus*, Linn.). Royal Monkey, Penn. (*Alouate*, Ruff.). Brazils.

The Caraya, or Black Howler (*M. Caraya; Simia Caraya*, Humb.). Brazils.

The Guariba, or Yellow-Handed Howler (*M. Beelzebul; Simia Beelzebul*, Linn.). Brazils.

The Tufted Capuchin (*Cebus cirrifer*, Geoff.). Brazils.

The Kaite, or Horned Capuchin (*C. Fatuellus*, Erxl.). Brazils.

The Capuchin (*C. Apella*, Erxl.; *Simia Apella*, Linn.). Brazils.

The Hierang, or Yellow-Chested Capuchin (*C. xanthosternon*). Brazils.

The Sai, or Weeper (*C. Capucinus*, Erxl.; *Simia Capucina*, Linn.). Brazils.

The White-Headed Sapajou (*C. hypoleucus*, Geoff.). America.

The Yellow Sapajou (*C. gracilis*, Spix). Brazils.

The Golden-Handed Sapajou (*C. chrysopus*, F. Cuv.). Brazils.

The Tee-Tee (*Callithrix sciureus*, Kuhl.; *Simia sciurea*, Linnæus). Brazils.

The Sahuassu, or Masked Tee-Tee (*C. personatus*, Kuhl.). Brazils.

The Oiabassu, or White-Handed Tee-Tee (*C. Moloch*, Geoff.). Brazils.

The Collared Tee-Tee (*C. torquatus*, Hoffm.). Guiana, Brazils.

The Cuxio, or Bearded Saki (*Brachyurus Satanas; Cebus Satanas*, Hoffm.). Guiana.

The Yarke (*Pithecia irrorata*, Gray). Brazils.

The Black Yarke (*P. leucocephala*, Geoff.). Brazils.

The Whiskered Yarke (*P. pogonias*, Gray). Brazils.

The Douroucouli (*Nyctipithecus trivirgatus*, Gray). Brazils.

The Vitoe (*N. felinus*, Spix). Brazils.

The Marmoset (*Jacchus vulgaris*, Geoff.). Brazils.

The Gnick-Gnick, or Black-Eared Marmoset (*J. penicillatus*, Geoff.). Brazils.

The White-Eared Marmoset (*J. auritus*, Geoff.). Brazils.

The Tamarin (*J. Midas; Simia Midas*, Linn.). Brazils.

The Black Tamarin (*J. Tamarin; Cebus Tamarin*, Link.). Brazils.

The White-Whiskered Tamarin (*J. labiatus*, Desm.). Brazils.

The Marikina (*J. Rosalia; Simia Rosalia*, Linn.). Brazils.

The Pinche (*J. Œdipus*, Desm.; *Simia Œdipus*, Linn.). Brazils.

The following forms of *Simiadæ* and *Cebidæ* were existing in the Gardens of the Zoological Society, Regent's Park, between the years 1847 and 1852:—

Simiadæ.

Simia Satyrus, Hylobates Hoolook, Semnopithecus Guletta, Cercopithecus nictitans, C. petamista, C. melanogenys, C. cephus, C. albopilaris, C. Campbellii, C. Pluto, C. Mona, C. Pygerythrus, C. Sabæus, C. cynosurus, C. callithricus, C. Talaponi, C. niger, Cercocebus fuliginosus, C. Æthiops, Macacus sinicus, M. pileatus, M. cynomolgus, M. erythræus, M. nemæstrinus, M. Silenus, M. niger, Inuus sylvanus, Cynocephalus Hamadryas, C. Sphinx, C. Babouin, C. Porcarius, C. leucophæus, C. Mormon.

Cebidæ.

Ateles Chamek, A. paniscus, A. ater, A. Beelzebuth, A. marginatus; Pithecia chiropotes; Lagothrix Humboldtii; Brachyurus Ouakari; Saimiri sciureus; Callithrix torquatus; Nyctipithecus trivirgatus; Cebus apella, C. capucinus, C. cirrifer, C. xanthosternum, C. hypoleucus; Hapale Jacchus, H. aurita, H. penicillata, H. (Midas) Œdipus, H. (Midas) rufimanus, H. (Midas) Tamarin.

SINAPOLINE. [Chemistry, *S.* 2.]

SINNAMINE. [Chemistry, *S.* 2.]

SIPHONOSTOMES. [SUCTORIAL CRUSTACEANS.]

SIPUNCULOIDEA, an order of Echinodermatous Animals, embracing the families *Sipunculidæ, Priapulidæ*, and *Thalassemadæ*. This order is thus defined: The cutaneous envelope is coriaceous, and free from calcareous corpuscles; there is no calcareous ring about the œsophagus; the body is cylindrical; the digestive canal usually asymmetrical.

1. The *Sipunculidæ* (Syphon-Worms) have a retractile proboscis, at the base of which is placed the vent, and round the extremity of which there is a circle of tentacles. This family embraces the genera *Syrinx, Sipunculus*, and *Phascolosoma*.

Syrinx (Bohadsch) has a cylindrical proboscis shorter than the body, having a circle of short-fingered tentacles around its tip. In his 'History of British Star-Fishes,' Forbes refers three British species of *Sipunculus* of other authors to this genus—*S. nudus, S. papillosus*, and *S. Harveii*.

Sipunculus (Linnæus) has a cylindrical proboscis about as long as the body, and a circle of simple linear tentacles around its tip. The following are British species of this genus:—*S. Bernhardus, S. Johnstoni, S. saccatus, S. tenuicinctus, S. Forbesii, S. granulosus, S. punctatissimus*, and *S. Pallasii*.

2. The *Priapulidæ* (Tailed-Worms) have a retractile proboscis with no tentacles, and the vent at the end of a long thread-like tail.

Priapulus (Lamarck) has the body truncated behind, and the tail much branched and pointed.

The only British species is *P. caudatus*, which is only rarely taken.

3. The *Thalassemadæ* (Spoon-Worms) have a body oval or oblong, a proboscis with a long fleshy appendage; vent at posterior extremity, tentacles none.

Thalassema (Cuvier) has a cylindrical body rounded and smooth behind; the proboscis retractile, short, furnished at one side with a long fleshy furrowed simple sheath, which is not retractile. *T. Neptuni* is a British species.

Echiurus (Cuvier) has a cylindrical body, set at its hinder extremity with circles of bony points, and a proboscis as in *Thalassema*. [ECHINODERMATA; THALASSEMA.] *E. oxyurus* is a British species.

(*Manual of Natural History;* Gosse, *Marine Zoology;* Forbes, *British Star-Fishes*.)

SISMONDINE. [MINERALOGY, *S.* 1.]

SISTOVA, a town in Bulgaria, is situated on a height above the right bank of the Danube, 37 miles above Rustschuk, and 25 miles below Nikopoli, and has about 21,000 inhabitants. The town is defended by a citadel, and inclosed by a dry ditch and palisade. The houses are low and ill-built. The mosques, of which there are eight, are the only buildings worth notice. Sistova is a place of considerable commerce, and is looked upon by the Bulgarians as their proper capital. In ordinary times it has a good trade in corn, hides, leather, foreign manufactures, and colonial produce. The Turks and Austrians concluded a peace at Sistova in 1791.

SISYMBRIUM. [IRIDACEÆ.]

SIVATHERIUM (from Siva, an Indian deity), a genus of extinct animals belonging to the family of *Elephantidæ*. The remains of species of this remarkable genus were found by Dr. Falconer and Colonel Cantley in the valley of Mackanda, in the Sewalik Hills of the Himalaya.

Two species of this genus, *S. giganteum* and *S. Perimense*, have been described. A cranium, lower jaw and teeth, and bones of the extremities of *S. giganteum* are now in the British Museum. The skull of this animal is nearly as long as that of the Elephant, the neck was shorter and stronger than in the Giraffe. The posterior portion of the skull is greatly developed, and formed of cellular cavities, as in the Elephant. "The face is short, and the nasal bones are remarkable for the manner in which they are prolonged into a pointed arch above the external nostrils, indicating a trunk, or proboscis. The very inclined direction of the front of the face in relation to the triturating surface of the teeth, imparts a physiognomy altogether peculiar. Two horns arise from the brow between the orbits, and diverge from each other, and it is probable that the posterior protuberances of the forehead also supported a pair of short massive horns." (Mantell.)

When living, the Sivatherium must have resembled an immense Gnu, or Antelope, with a short thick head surmounted with two pairs of horns. The front pair of these horns were small, whilst those behind were probably palmated. The eyes were small, and it had a nasal proboscis, an organ unknown amongst the *Ruminantia*.

(Mantell, *Petrefactions and their Teachings; Journal of the Asiatic Society*.

SKATES. [RAIIDÆ, *S.* 2; SKATE.]

SKENEA, a genus of Gasteropodous *Mollusca*, named after Dr. Skene. The shell is very small, flat, and with few whorls. It is deeply umbilicated; the mouth is entire, circular, not quite connected with the body whorl; operculum rather spiral. The animal is nearly like that of *Rissoa*, and has large eyes. The species are few, and are found generally on the roots of *Corallina officinalis*.

SKIBBEREEN, County Cork, Ireland, a market-town and the seat of a Poor-Law Union, is situated on the river Ilan, in 51° 34′ N. lat., 9° 16′ W. long., distant by road 52 miles S.W. from Cork, and 210 miles S.W. from Dublin. The population in 1851 was 3856. Skibbereen Poor-Law Union comprises 23 electoral divisions, with an area of 115,024 acres, and a population in 1851 of 38,059. The town contains a parish church, chapels for Roman Catholics and Wesleyan Methodists, two National schools, a court-house, market-house, dispensary, bridewell, and Union workhouse. In the town are flour-mills and a brewery. Quarter and petty sessions are held. There are six yearly fairs, at which large quantities of yarns and coarse linens are sold.

SKULLCAP. [SCUTELLARIA, *S.* 1.]

SLATE. *Drawing slate* is a finer and more compact variety than the common slate, of bluish and purplish shades of colour. The best slates come from Spain, Italy, and France. A good quality is quarried in Maine and Vermont, United States.

Novaculite, Hone-Slate, or *Whet-Stone*, is a fine grained slate, containing considerable quartz, though the grains of this mineral are not perceptible. It occurs of light and dark shades of colour, and compact texture.

Argillite is a general term given to argillaceous or clay-slate rocks. Many shales or argillites crumble easily, and are unfit for any purpose in the arts, except to furnish a clayey soil.

Alum Shale is any slaty rock which contains decomposing pyrites, and thus will afford alum or sulphate of alumina on lixiviation.

Bituminous Shale is a dark coloured slaty rock containing some bitumen, and giving off a bituminous odour.

Plumbaginous Schist is a clay slate containing plumbago or graphite, and leaving traces like black lead.

The *Pipestone* of the North American Indians was in part a red claystone or compacted clay from the Coteau de Prairies. It has been named *Catlinite*. A similar material, now accumulating, occurs on the north shore of Lake Superior, at Nepigon Bay. Another variety of pipestone is a dark grayish compact argillite; it is used by the Indians of the north-west coast of America. (Dana.)

SLEEMAN, SIR WILLIAM HENRY, K.C.B., the son of Philip Sleeman, Esq., was born at Stratton, Cornwall, in 1788. In 1808, he became a cadet in the East India Company's service at Bengal. He served in the Nepaulese war of 1812 with distinction; and at its conclusion being laid up with an illness which disqualified him for active employment, he spent fifteen months at the College of Fort William, during which time he made himself master of the history and language of the natives, and prepared himself for a career of future usefulness. In 1816 he commended himself to Lord Moira (afterwards Marquis of Hastings), then Governor-General of India, by conducting an inquiry into the claims arising out of the war in Nepaul, and in 1820 was appointed agent in the Saugur and Nerbudda districts. Here he employed his energies in the extinction of the atrocious systems of Thuggee and Dacoity, on which he wrote several able pamphlets; he at the same time produced a larger work, entitled 'Military Discipline in our Indian Army.' In 1842 he was commissioned by Lord Ellenborough to report on the condition of Bundelcund; and in 1849 he was promoted to the Residency at Lucknow, by Lord Dalhousie, who employed him in preparing for the reduction of Oude under British laws. As a proof of the necessity for adopting stringent measures, it should be mentioned that while resident at Lucknow, he intercepted a letter sent from the King of Persia to the King of Oude, in which the former spoke hopefully of a Persian invasion of India, and promised in that event to secure to him his throne, on condition of betraying the English into his hands. He also wrote a 'Treatise on Political Economy,' and a 'Review and Analysis of the Peculiar Doctrines of the System of Political Economy founded by Ricardo.' His most popular works, however, are his 'Diary in Oude' (1852), and his 'Rambles and Recollections of an Indian Officer' (1843), a work which has been pronounced by competent authorities to be the best adapted of all existing treatises on British India, to give an Englishman a faithful picture of the actual state of the religious, moral, and social condition of the natives of that country. He lived to see his measures with regard to Oude carried into effect by his successor, Sir James Outram, and to hear of the proclamation of Lord Dalhousie, announcing the actual annexation of that rich and important district. His health gave way towards the close of 1855, and he died at sea on his return to England, February 10, 1856, a few days after having been created a Knight Commander of the Bath, at the special request of Lord Dalhousie, to mark his distinguished services in the cause of religion and humanity by the suppression of Thuggee.

SLOUGH. [BUCKINGHAMSHIRE.]

SMELT. [SALMONIDÆ.]

SMILACIN. [CHEMISTRY, *S.* 1.]

SMITH, JAMES, the great propagator of the system of deep ploughing and thorough draining, was born at Glasgow on the 3rd of January 1789. His father had been in business at Glasgow, in which he acquired some property, but died when his son was only two months old, leaving him in the charge of his mother, who was a daughter of Mr. Buchanan, of Carston in Stirling. After her husband's death Mrs. Smith resided with her brother, who was the manager of an extensive cotton manufactory at Deanston, a few miles from Stirling. James Smith received his early education at home, completing it at the University of Glasgow. On leaving the university he returned to his uncle, who had by this time removed to the Catrine Works in Ayrshire, where, in order to attain a thorough knowledge of the trade, he worked through the various grades, labouring with persevering industry for twelve hours a day, with such good effect that at eighteen he was entrusted with the entire management of the works at Deanston, into which he subsequently introduced many improvements for promoting the health of the labourers that were noticed with approval by Mr. Chadwick in his 'Report on the Sanitary Condition of the Labouring Population of Great Britain,' published in 1841.

But Mr. Smith's attention had been early given to agricultural processes, and his intimate acquaintance with manufacturing machinery was made available in gratifying his predilection. The Dalkeith Farmers' Club having offered a prize of 500*l.* for a reaping-machine, Mr. Smith produced one, which, though it was not successful in obtaining the prize, was so ingenious that he was encouraged to prepare another in 1813. For this, though an accident prevented his gaining the prize, he received presents from several Scottish agricultural societies, and a gold medal from the Agricultural Society of St. Petersburg. He had the management of his uncle's farm, and many of his experiments were eminently successful; but he could not obtain his uncle's consent to carry out a full development of his theories. In 1823 however he became possessed of the farm of Deanston, about 200 acres of extremely poor land, having a soil not averaging more than four inches in depth, formed chiefly of the débris of the old red sandstone, with a subsoil partly of sandy clay and partly of a compact soil with stones, and the whole interspersed with boulder stones, producing little but rushes in the watery hollows and broom on the dryer portions. The whole of this he intersected with drains, laid at distances of 21 feet and at a depth of 30 inches. This, and a subsoil plough to stir the ground deeply without bringing the subsoil to the surface, produced an effect on the crops that proved the soundness of his theory. In 1831 he published a pamphlet on 'Thorough Draining and Deep Ploughing,' which excited immediate attention among his more immediate neighbours, but it was several years before its merits were generally acknowledged and the practice it recommended was adopted.

In 1846 Mr. Smith was appointed one of a commission to inquire into the health and sanitary condition of our manufacturing towns. One of his recommendations was the removal of the sewage for agricultural purposes: there are many difficulties to be overcome in effecting this, and Mr. Smith gave much attention to plans for overcoming them, propounding several means of singular mechanical ingenuity combined with simplicity. After considerable opposition an act of parliament was passed enabling municipalities to adopt his scheme where circumstances admitted of it. He also suggested several valuable improvements to the Agricultural Society of Ireland, of which he was an esteemed member, as he was also of the Glasgow Philosophical Society, to whose 'Transactions' he was an occasional and valuable contributor. In political economy Mr. Smith was a follower of Adam Smith, and of course opposed to protection, holding that free competition was the great spur to improvement. After a life of almost incessant activity, he died on the 10th of June 1850, somewhat suddenly, having retired to bed on the 9th apparently suffering nothing but an accustomed feebleness, and being found dead in the morning.

SMITH, JAMES and HORACE, were the sons of Robert Smith, of London, an eminent legal practitioner and Solicitor to the Ordnance. James Smith was born Feb. 10, 1775, in London, where also Horace Smith was born in 1780. James Smith, after receiving a good education in the school of the Rev. Mr. Burford, at Chigwell, in Essex, was articled to his father, and in due time was taken into partnership. He eventually succeeded his father in the business and in the appointment of Solicitor to the Ordnance. Horace Smith became by profession a stockbroker.

The first literary productions of the two brothers were gratuitous contributions to 'The Pic-Nic,' a periodical started by Colonel Greville, in 1802. 'The Pic-Nic' was soon merged in 'The Cabinet,' which maintained a struggling existence till July, 1803, when it was discontinued. When the 'London Review' was started by Cumberland, the dramatist, on the principle of each writer affixing his name to his criticism, James Smith wrote one of the articles, but the 'London Review' was unprofitable, and was soon discontinued. James and Horace Smith wrote several of the prefaces to a new edition of 'Bell's British Theatre,' which was published about this time under the sanction of Cumberland's name. They were also contributors from 1807 to 1810 to the 'Monthly Mirror,' in which periodical originally appeared the poetical imitations entitled 'Horace in London,' which were subsequently published in a small volume. Horace Smith wrote several of these parodies, but the larger number was written by James Smith.

The celebrity, however, which the two brothers enjoyed arose chiefly from the 'Rejected Addresses,' a small volume which was published on the opening of the new Drury Lane Theatre, in October 1812. The committee of management had issued an advertisement requesting that addresses, one of which should be spoken on the first night, might be sent in by way of competition. As all the addresses sent in, except one, were to be rejected, Mr. Ward, secretary to the theatre, casually started the idea of publishing a series of supposed 'Rejected Addresses.' This was just six weeks before the opening of the theatre. The brothers eagerly adopted the suggestion, and having immediately settled what authors each should imitate, Horace left London on a visit to Cheltenham, and James remained at home. Horace having executed his portion of the task returned to London a few days before the opening of the theatre. Each then submitted his productions to the other; a few verbal alterations were made, a few lines were added, and the little book was immediately printed and published. It was received by the public with enthusiastic delight. As the 'Rejected Addresses' are humorous imitations mostly of authors well known, and as the work is still in circulation, it is perhaps worth while to mention that the imitations of Wordsworth ('Baby's Debut'), Cobbett ('Hampshire Farmer's Address'), Southey ('The Rebuilding'), Coleridge ('Playhouse Musings'), and Crabbe ('The Theatre'), are by James Smith, as well as the songs styled 'Drury Lane Hustings,' the 'Theatrical Alarm Bell' (an imitation of the editor of the 'Morning Post'), and the travesties 'Macbeth,' 'George Barnwell,' and 'The Stranger.' The rest of the imitations are by Horace Smith. The copyright, which was originally offered to Mr. Murray for 20*l.*, was purchased by him in 1819, after the sixteenth edition, for 131*l.*

Besides a great number of amusing trifles which James Smith contributed to the periodical literature of the day, he was a gratuitous contributor to the earlier series of theatrical entertainments entitled 'At Home,' in which the elder Charles Mathews displayed his extraordinary powers of humorous imitation. Subsequently, for the 'Country Cousins,' the 'Trips to Paris,' 'Air-Ballooning,' and the 'Trip to America,' he received from Mr. Mathews altogether 1000*l.* "You are the only man in London," said Mathews to James Smith, "who can write what I want, good nonsense."

The brothers were both admired for their conversational powers. James Smith especially had a large circle of acquaintance, and went much into society. Though he was always a man of temperate habits, he became in middle life subject to attacks of gout, which increased in frequency and severity till he gradually lost the use of his limbs, and could only move himself by the aid of crutches. He died in London, December 24, 1839. In early and middle life he was distinguished for manly beauty both of figure and face. He was never married.

Horace Smith contributed numerous pieces of poetry, half playful, half sentimental, to the 'New Monthly Magazine,' while it was under the editorship of Thomas Campbell, the poet. He was also the author of about twenty novels, of about three volumes each, the greater part of which seem to have been little known except to the regular novel readers of the circulating libraries. 'Gaieties and Gravities,' published in 1825, was one of the earliest of his novels. 'Love and Mesmerism,' 1845, was the latest. In the intermediate twenty years he gave to the public 'Bramhletye House,' 'Tor Hill,' 'Reuben Apsley,' 'Zillah,' 'New Forest,' 'Walter Colyton,' 'Jane Lomax,' 'The Moneyed Man,' 'Adam Brown,' 'Arthur Arundel,' and others. Horace Smith died July 12, 1849, at Tunbridge Wells. He was a widower, and left two daughters.

(*Memoirs, Letters, and Comic Miscellanies in Prose and Verse*, by the late James Smith, Esq., one of the authors of the 'Rejected Addresses,' edited by his brother, Horace Smith, Esq., 2 vols., cr. 8vo, 1840.)

SMITH, JOHN PYE, D.D., LL.D., one of the most learned ministers and theological tutors of the Independent or Congregationalist denomination, was born at Sheffield, May 25, 1774. In his early years he was employed in the shop of his father, who carried on a respectable bookselling establishment in Sheffield; but always a diligent student, and becoming strongly impressed with religious feelings, he became desirous of engaging in the Christian ministry. He accordingly left business, and in his twenty-second year entered the Independent Academy at Rotherham. Here he devoted himself zealously to the studies of the place, and such was the character he attained for ability and learning that, on a vacancy taking place in Homerton Theological Academy, Mr. Smith was chosen in 1800 to occupy the post of classical tutor in that seminary. At Homerton he subsequently formed a church, of which he became pastor, and which increased so largely in numbers as to require a separate chapel. In 1807 he received the diploma of D.D. from Yale College, Newhaven, Connecticut. In 1813 Dr. Pye Smith gave up the situation of resident classical tutor, retaining at the request of the directors the post of divinity tutor. In 1835 he received the diploma of LL.D. from Marischal College, Aberdeen. Dr. Smith became again in 1843 the resident tutor at Homerton, which office he filled till the breaking up of the establishment in 1850, when New College, St. John's Wood, was formed from the junction of Homerton, Highbury, and Coward Colleges. Dr. Pye Smith, who had been for many years afflicted with deafness, then retired from active duty, and his friends and admirers testified their regard for his character by raising a sum of 3000*l.*, to provide an annuity for him while he lived, the interest to be afterwards devoted to the foundation of a Smith scholarship in New College. Dr. Pye Smith died on February 5, 1851, in his seventy-seventh year. Dr. Pye Smith was held in unusual regard by all who knew him, as much for the singular simplicity, zeal, and benevolence of his character, as for his earnestness and devotion in his official duties, and his extensive erudition. He had been twice married.

Dr. Smith was a man of untiring industry, as well as of very unusual acquirements. He published numerous works on theology and on science, especially the science of geology. His great work was 'The Scripture Testimony to the Messiah,' 2 vols., 1818 and 1821. The remarkable range of reading which this work displayed, and particularly its familiarity with recent German theological literature, then a rare attainment with English divines, and especially with those of the Nonconformist body, attracted great attention to the work, and though some of the positions of the author were regarded as questionable by many theologians who agreed with him in his general theological views, it at once took a high place, and eventually came to be pretty generally regarded as a standard work on the subject of the divinity of Christ, and as perhaps the most important work of the kind on the orthodox side of the question. In subsequent editions the work was in parts considerably enlarged, and in some respects modified; and in its final shape it may be regarded as embodying almost the whole of the erudition on the important subject of which it treats. The fourth edition was published in 1847. Among his other works, several of which were of a controversial character, may be enumerated—'The Adoration of our Lord Jesus Christ vindicated from the Charge of Idolatry, a Sermon,' 1811. 'Four Discourses on the Sacrifice and Priesthood of Jesus Christ,' third edition, 1827. 'On the Personality and Divinity of the Holy Spirit, a Sermon,' 1831. 'The Mosaic account of the Creation and the Deluge, illustrated by the Discoveries of Modern Science,' 1837. 'On the Relation between the Holy Scriptures and some parts of Geological Science,' fourth edition, 1848. Dr. Pye Smith was a Fellow of the Royal Society and of the Geological Society, and took a deep interest in the philanthropic and religious movements of the day.

SMITH, JOSEPH, founder of the religious body commonly known as Mormons, but called by their founder and by themselves 'The Church of Jesus Christ of Latter Day Saints.'

Whether regarded as a religious, political, social, or intellectual phenomenon, the rise and progress of Mormonism is one of the most remarkable movements of modern times; and a calm survey of its origin and development, made with a view to arrive at a true knowledge of the facts, and, as far as practicable, a clear understanding of its inner spirit—to comprehend, that is, alike the system and its effects, the character of its founders, and its influence on its disciples—could not but be serviceable as well as interesting. Such a survey we cannot of course attempt here. What will be attempted in the present article will be to give a brief notice of the founder of Mormonism, and of the system as he left it. Its subsequent development and present state will be noticed under UTAH, *S.* 2.

Joseph Smith left behind him an autobiography; and a strange book purporting to be written by his mother has been published, under the title of 'Biographical Sketches of Joseph Smith, the Prophet, and his Progenitors for many Generations, by Lucy Smith, Mother of the Prophet.' Of these, as well as the notices of him by his adherents and opponents who profess to have obtained their information respecting him at first hand, we have made use; but we prefer to let the Prophet in a measure tell his own story as we find it in a short sketch of himself and his system, which he supplied a few months before his death to Mr. Daniel Rupp for that gentleman's 'Original History of the Religious Denominations at present existing in the United States,' 8vo, Philadelphia, 1844, and which may consequently be taken as an authentic representation, as far as it goes, of what Smith himself wished to be believed. He says:—

"I was born in the town of Sharon, Windsor County, Vermont, on the 23rd of December, 1805. When ten years old, my parents removed to Palmyra, New York, where we resided about four years, and from thence we removed to the town (township) of Manchester, a distance of six miles. My father was a farmer, and taught me the art of husbandry. When about fourteen years of age, I began to reflect upon the importance of being prepared for a future state; and upon inquiring the plan of salvation, I found that there was a great clash in religious sentiment. . . . . Considering that all could not be right, and that God could not be the author of so much confusion, I determined to investigate the subject more fully. . . . . Believing the word of God, I had confidence in the declaration of James, 'If any man lack wisdom let him ask of God, who giveth to all men liberally and upbraideth not, and it shall be given him.'

"I retired to a secret place in a grove, and began to call upon the Lord. While fervently engaged in supplication my mind was taken away from the objects with which I was surrounded, and I was enrapt in a heavenly vision, and saw two glorious personages, who exactly resembled each other in feature and likeness, surrounded with a brilliant light which eclipsed the sun at noonday. They told me that all the religious sects were believing in incorrect doctrines, and that none of them was acknowledged of God as his Church and Kingdom. And I was expressly commanded to 'go not after them,' at the same time receiving a promise that the fulness of the Gospel should at some future time be made known to me."

This "fulness of the Gospel," was that revealed in the Book of Mormon; and as his account of the discovery of the book and its contents is really the point on which our estimate both of the man and the doctrine must to a great extent turn, it will be best given in his own words and without abridgment. He says:—"On the evening of the 21st of September, A.D. 1823, while I was praying unto God and endeavouring to exercise faith in the precious promises of Scripture, on a sudden a light like that of day, only of a far purer and more glorious appearance and brightness, burst into the room; indeed, the first sight was as though the house was filled with consuming fire. The appearance produced a shock that affected the whole body. In a moment a personage stood before me surrounded with a glory yet greater than that with which I was already surrounded. The messenger proclaimed himself to be an angel of God, sent to bring the joyful tidings, that the covenant which God made with ancient Israel was at hand to be fulfilled; that the preparatory work for the second coming of the Messiah was speedily to commence; that the time was at hand for the Gospel in all its fulness to be preached in power unto all nations, that a people might be prepared for the Millenial reign.

"I was informed also concerning the aboriginal inhabitants of this country (America) and shown who they were, and from whence they came;—a brief sketch of their origin, progress, civilisation, laws, governments, of their righteousness and iniquity, and the blessings of God being finally withdrawn from them as a people, was made known unto me. I also was told where there were deposited some plates, on which was engraven an abridgment of the records of the ancient prophets that had existed on this continent. The angel appeared to me three times the same night, and unfolded the same things. After having received many visits from the angels of God, unfolding the majesty and glory of the events that should transpire in the last days, on the morning of the 22nd of September, 1827, the angel of the Lord delivered the records into my hands.

"These records were engraven on plates which had the appearance of gold; each plate was six inches wide and eight inches long, and not quite so thick as common tin. They were filled with engravings in Egyptian characters, and bound together in a volume, as the leaves of a book, with three rings running through the whole. The volume was something near six inches in thickness, a part of which was sealed. The characters on the unsealed part were small and beautifully engraved. The whole book exhibited many marks of antiquity in its construction, and much skill in the art of engraving. With the records was found a curious instrument which the ancients called 'Urim and Thummim,' which consisted of two transparent stones set in the rim on a bow fastened to a breastplate. Through the medium of the Urim and Thummim I translated the record by the gift and power of God.

"In this important and interesting book the history of ancient America is unfolded from its first settlement by a colony that came from the tower of Babel, at the confusion of languages, to the beginning of the 5th century of the Christian era.

"We are informed by these records, that America, in ancient times, has been inhabited by two distinct races of people. The first were called Jaredites, and came directly from the tower of Babel. The second race came directly from the city of Jerusalem, about 600 years before Christ. They were principally Israelites of the descendants of Joseph. The Jaredites were destroyed about the time that the Israelites came from Jerusalem, who succeeded them in the inheritance of the country. The principal nation of the second race fell in battle towards the close of the 4th century. This book also tells us that our Saviour made his appearance upon this continent after his resurrection; that they had apostles, prophets, pastors, teachers, and evangelists; the same order, the same priesthood, the same ordinances, gifts, powers, and blessing as was enjoyed on the eastern continent; that the people were cut off in consequence of their transgressions; that the last of the prophets who existed among them was commanded to write an abridgment of their prophecies, history, &c., and to hide it up in the earth, and that it should come forth and be united with the Bible, for the accomplishment of the purposes of God in the last days. For a more particular account I would refer to the Book of Mormon."

We must here for a while interrupt the Prophet's narrative. It will have been noticed that the account of his early life, and of his proceedings between the first appearance of the angel and the discovery of the plates, is remarkably vague. His education had evidently been of the rudest kind. From various accounts, including those of his mother, it would seem that he used to assist his father in his business, but that he was of an unsettled disposition, and probably spent a good deal of time in wandering about the country. It is stated also, that he for some time got a living by trying for mineral veins by a divining-rod, and some affirm that, like Sidrophel, he used "the devil's looking-glass—a stone," and was consulted as to the discovery of hidden treasures, whence he had come to be commonly known as the "money-digger;" and on one occasion he had been, at the instigation of a disappointed client, imprisoned as a vagabond. He is also stated to have carried off and married a Miss Hales, during the interval between the first angelic visitation and the discovery of the plates of Nephi.

As to the Book of Mormon itself, the authorship has been claimed for one Solomon Spalding, a presbyterian preacher, who having fallen into poverty composed a religious romance, entitled 'The Manuscript Found,' which professed to be a narrative of the migration of the Lost Tribes of Israel from Jerusalem to America, and their subsequent adventures on that continent, in the hope of obtaining enough from its publication to release him from his difficulties. The work was written, but he could not find a publisher for it, and some ten years after his death, the manuscript was carried by his widow into New York, where it was stolen by or somehow got into the hands of Smith, or Rigdon (an early associate in his proceedings). The statement is supported by affidavits made by Spalding's daughter, his brother, one Henry Lake, and some other persons, who declare that they had heard him read portions of the work which were substantially the same as parts of the Book of Mormon. The story is incoherent in its details and the authenticity of the affidavits does not seem clear; but the work itself appears to agree pretty well with such an origin, supposing, that is, that the presbyterian preacher, as might well have been the case, was a rude-minded uneducated man, sufficiently familiar with the Old Testament to find no difficulty in clothing his story in its language, and making use of the easily-obtained information respecting the ruins of ancient "towns and temples," which have been discovered in various parts of America, as a ground-work for his narrative. The book itself is (even now that its grosser grammatical errors are said to have been expunged) a singularly ill-written one, and how any decently-educated man could have written it as a book to be read for amusement would be inconceivable, were it not that experience teaches us that authors are by no means unfrequently mistaken in that respect. At the same time there is certainly nothing in the book to contradict the supposition that it is the work of Smith himself—for as to its being a divine revelation, the most cursory examination of the book will be enough to convince an educated man of the utter improbability of that, if its possibility were otherwise conceivable. Be the author who he may, Smith having obtained the book—whether from Solomon Spalding's travelling chest, his own brain, or the stone-box which the angel discovered to him—thought it behoved him to make his treasure known. At first he told the members of his own and his father's household, and, more fortunate than Mahomet, found little difficulty in persuading them of the truth of his mission and the reality of the gift. But he says:—"As soon as the news of this discovery was made known, false reports, misrepresentation, and slander flew, as on the wings of the wind, in every direction. My house was frequently beset by mobs and evil-designing persons; several times I was shot at, and very narrowly escaped; and every device was made use of to get the plates away from me; but the power and blessing of God attended me, and several began to believe my testimony."

Among those whom he told of the discovery was a farmer named Martin Harris, whom he persuaded to convert his stock into money in order to assist in printing the book. But Harris wanted to consult some scholar, and Smith was induced to entrust him with a copy of a portion of one of the golden plates to carry to New York. Harris took the copy to Dr. Anthon, who according to the triumphant declaration of the Mormonites, was unable to make out the characters, which he described to be "reformed Egyptian"—and this is one of "the proofs" cited by Mormonite teachers of the authenticity of the book. But Dr. Anthon's own account is very different. He says that he at first supposed the paper to be a hoax, and gave little heed to it; but on hearing the man's story, he assured him that the work was an imposture, and strongly advised him not to have anything to do with it. The paper itself he thus describes (and it is the only description of the 'Book of Mormon' which has been published):—"The paper was, in fact, a singular scrawl. It consisted of all kinds of crooked characters, disposed in columns, and had evidently been prepared by some person who had before him, at the time, a book containing various alphabets. Greek and Hebrew letters, crosses and flourishes, Roman letters inverted or placed sideways, were arranged in perpendicular columns, and the whole ended in a rude delineation of a circle divided into various compartments, decked with various strange marks, and evidently copied after the Mexican calendar, given by Humboldt, but copied in such a way as not to betray the source whence it was derived." ('Letter to Mr. Howe,' February 17, 1834.)

Mrs. Lucy Smith (the Prophet's mother) tells an odd rambling story about the first translation made from the plates having been entrusted to this Harris, and stolen from him by his wife. Smith, she says, was, after long repentance, assured by the angel of forgiveness for his negligence, but at the same time informed that Satan would cause the stolen work to be interpolated and altered; and in order to avoid the mischief that would else arise from these machinations, he was directed to make another translation—not as the first was to have been—from the original book, but from an abridgment of it. Harris, though despite of Dr. Anthon's advice he did sell his goods as a contribution towards Smith's outlay, afterwards apostatised, and one might fancy from Mrs. Smith's story that he had in his possession some version of the revelation differing from that eventually published, but it is possible that she might have written with some reference to the Spalding story.

No sooner was the discovery published, than great curiosity was manifested by the faithful as well as by unbelievers, to obtain a sight of the marvellous plates, and the Prophet and his mother gave a minute account of the shifts to which he was driven to conceal them. At length it was revealed to him that the desired sight should be vouchsafed to three witnesses—whose 'testimony' is prefixed to every printed copy of the 'Book of Mormon.' These witnesses aver in their strange language—"that an angel of God came down from Heaven, and he brought and lay before our eyes, that we beheld and saw the plates, and the engravings thereon." This is sufficiently vague, and it is noteworthy that the more detailed account of this transaction by the Prophet's mother, has just the same vagueness as to what manner of vision this was. But a more specific testimony was given by eight other witnesses, to whom Smith was permitted to show the plates. Mrs. Smith says that these eight men went with Joseph into a secret place "where the family were in the habit of offering up their secret devotions to God. They went to this place because it had been revealed to Joseph that the plates would be carried by one of the ancient Nephites. Here it was that these eight witnesses, whose names are recorded in the Book of Mormon, looked upon them and handled them." The witnesses themselves say—"We have seen and hefted, and know of a surety that the said Smith has got the plates of which we have spoken." Of these eight witnesses three were members of Smith's own family. After these witnesses had seen the plates, Mrs. Smith tells us, "The angel again made his appearance to Joseph, at which time Joseph delivered up the plates into the angel's hands;" and Joseph himself says, "He (the angel) has them in his charge to this day." It is needless to remark that this disposes of any demand on the part of the sceptic to see the original plates, and gets rid of many awkward inquiries; nor need we add that it is a story quite satisfactory to Mormon 'saints'—but how far it is likely to satisfy the outside world the reader will judge for himself. We have, at the risk of being tedious, related these particulars, because they concern the very foundations of the system. To satisfy the curious we may mention that Smith carried on the process of translating the plates by retiring behind a screen where he read the plates through the "curious instrument called the Urim and Thummim," and was thus enabled to translate them, while a 'scribe' outside the screen wrote as he dictated.

The 'Book of Mormon' was published in 1830. In the previous year Smith and Oliver Cowdery, the scribe, had been baptised by an angel, and power given them to baptise others. Smith himself may now carry on the narrative:—'On the 6th April 1830, 'The Church of Jesus Christ of Latter Day Saints' was first organised, in the town of Manchester, Ontario county, state of New York. Some few were called and ordained by the spirit of revelation and prophecy, and began to preach as the spirit gave them utterance, and though weak, yet were they strengthened by the power of God; and many were brought to repentance, were immersed in the water, and were filled with the Holy Ghost by the laying on of hands. They saw visions and prophesied, devils were cast out, and the sick healed by the laying on of hands. From that time the work rolled forth with astonishing rapidity, and churches were soon formed in the states of New York, Pennsylvania, Ohio, Indiana, Illinois, and Missouri. In the last-named state a considerable settlement was formed in Jackson county; numbers joined the church, and we were increasing rapidly; we made large purchases of land, our farms teemed with plenty, and peace and happiness were enjoyed in our domestic circle and throughout our neighbourhood; but as we could not associate with our neighbours—who were many of them of the basest of men, and had fled from the face of civilised society to the frontier country to escape the hands of justice—in their midnight revels, their sabbath-breaking, horse-racing, they commenced at first to ridicule, then to persecute, and finally an organised mob assembled and burned our houses, tarred and feathered and whipped many of our brethren [Smith himself was tarred and feathered], and finally drove them from their habitations; these, houseless and homeless, contrary to law, justice, and humanity, had to wander on the bleak prairies till the children left their blood on the prairie. This took place in the month of November (1833)." The government, he says, winked at these proceedings, and "the result was, that a great many of them died; many children were left orphans; wives, widows; and husbands, widowers. Our farms were taken possession of by the mob, many thousands of cattle, sheep, horses, and hogs were taken, and our household goods, store goods, and printing-presses were broken, taken, or otherwise destroyed." These outrageous proceedings were the result of the reports which had spread abroad of the scandalous practices of the Mormonites—practices almost perfectly analogous to those formerly charged upon the Anabaptists and other new sects, and in all probability with no more foundation in truth. Driven from Jackson, the Mormonites settled in Clay county, where they remained three years, when being again threatened with violence, they removed to Caldwell and Davies counties. Here their numbers rapidly increased. They formed three extensive settlements, established a bank, and appeared to be in a most flourishing condition. But again various troubles fell upon them. The bank failed, and Smith was obliged to conceal himself. Their old persecutors roused the popular feeling against them, and finally, by "an extraordinary order," issued by the governor of Missouri, in the summer of 1838, they were violently ejected from their homes, plundered of their goods, and subjected, the women especially, to the most frightful atrocities.

Being thus expelled from Missouri, they settled in Illinois, where they were at first treated with great kindness. An admirable site having been purchased by them on the Mississippi, at the head of the Des Moines Rapids, they "in the fall of 1839" laid the foundation of their famous city of Nauvoo, or 'the Beautiful,' for which the state legislature granted them in December 1840 a charter of incorporation with unusual privileges. Smith dwells with great delight on this city, which he had seen rise up under his presidency from a wild tract to be a place of "1500 well-built houses, and more than 15,000 inhabitants," all looking to him for temporal as well as spiritual guidance. Among the chief things which he describes as provided for, was "the University of Nauvoo, where all the arts and sciences will grow with the growth, and strengthen with the strength of this beloved city of the saints of the last days." But the grand feature of the city was the great temple, which Smith thus describes:—"The temple of God, now in the course of erection, being already raised one story, and which is 120 feet by 80 feet, of stone with polished pilasters, of an entire new order of architecture, will be a splendid house for the worship of God, as well as unique wonder of the world, it being built by the direct revelation of Jesus Christ for the salvation of the living and the dead."

The progress of Nauvoo was even more rapid than that of any of the preceding places. Converts flocked in from foreign countries as well as from different parts of America; the people were peaceful and industrious, the land was fertile, and the settlement was eminently prosperous. Dangers of various kinds beset Smith, but he escaped from them all. He had in 1841 been arrested on a charge of sedition, &c., but being carried before the authorities of Nauvoo, he was set at liberty. Again, he was charged with shooting at the ex-governor of Missouri, and he deemed it prudent to conceal himself for a time, bnt eventually surrendered, and being able to prove that he was "some hundreds of miles distant" from the scene of the attack, he was acquitted. Among his followers too there were occasional symptoms of disaffection, but they never extended widely, and were easily suppressed. With the 'gentiles' settled in Nauvoo, and whom he could not keep out, he had more trouble; and, as might have been anticipated, the reports which had led to the expulsion of the Mormons from their former cities followed them here, and suspicion and hatred gathered about them. But Smith from the foundation of Nauvoo had been making provision against this danger. He had procured the insertion of a provision in the city charter empowering the formation of an independent civic militia, which he at once organised, and of which he constituted himself 'lieutenant-general.' He also set about consolidating his spiritual as well as civic government, and he made careful provision for an ample succession of hardy and zealons missionaries. The Book of Mormon was an historical revelation: the doctrine and discipline of the church were to be enunciated in subsequent revelations as circumstances called them forth. The first point was his own acceptance as "prophet, seer, and revelator." In other words, this "church of the latter days" was to be a theocracy, with himself as its head and inspired legislator—at once the Moses and Aaron of this new house of Israel. Nor in this capacity was he ever found wanting. He was always ready in the moment of difficnlty with the needful revelation. In this manner he successively defined his own position, provided for his requirements, established his 'orders' of apostles, elders, priests, &c., in the church, and regulated all ceremonies, as well as defined its creed. These later revelations will all be found in the 'Doctrines and Covenants of the Church of Jesus Christ of Latter-Day Saints, selected from the Revelations of God, by Joseph Smith, President,' of which there have been nnmerous editions published. But, whatever was Smith's power over his followers, he was sadly deficieut in wariness in his dealings with the outer world. Again and again he suffered himself to come into contact with the civil anthority of the state; and his impnnity led him, notwithstanding the terrible lessons he had already received, to defy the storm that was plainly gathering aronnd him. So little did he heed the danger, that in prospect of the presidential election of 1844 he published his own 'Views of Government,' a sort of social scheme, in which "honesty and love," so that all might form a brotherhood, were declared to be the motive forces of jnst government: and he was actnally put in nomination for the presidency.

But he did not live to the day of election. The storm that had been so long gathering, burst before then and swept him away in its fury. The 'gentile' residents in Nauvoo, snpported as it would appear by some of the dissatisfied among the saints, had established an opposition newspaper, 'The Expositor,' which, growing more and more bold, ventnred at length to denounce the morals of the prophet as well as his system of government. The city council now interfered and condemned the newspaper to silence; npon which a mob assemhled, hroke into the office and destroyed the presses. The proprietors charged some of the Mormon leaders with inciting the mob to this act, and they were formally arrested, but immediately set at liberty by the public prosecutor entering a *nolle prosequi*, a practice said to have become usual when a 'saint' was charged with any offence. The injnred parties now carried their complaints before the governor of Illinois, who, having been long waiting, as is said, for a legal opportunity to crush the power of Smith, readily granted a warrant for his apprehension, Jnne 24, 1844, on a charge of treason and sedition. Smith's first impulse was to put Nauvoo into a state of defence, and his militia was drawn out. But on the approach of the state troops, he offered, in order to avoid bloodshed, to surrender on condition that Governor Ford wonld guarantee his safety till his trial could take place. This was agreed to, and Joseph Smith, his brother Hyram, and some other of the leadiug members of the council were carried prisoners to Carthage jail. A guard small in number and purposely choseu, as is affirmed, from among Smith's declared enemie was set over them; but, on the 27th of June, a mob of about 200 armed ruffians broke into the jail, and firing in at the door of the room in which the brothers were confined, shot Hyram dead at once. Joseph Smith attempted to escape by the window, bnt was knocked down, carried out, and shot. His dying exclamation is said to have been "O Lord my God." His body was given up to his friends, and buried with great solemnity.

Perhaps the death of Smith at that time did more than any other event could have done, to confirm and consolidate the Mormon church. Smith himself, it is evident, was becoming intoxicated with power and prosperity. He is said to have given way to lust and intemperance, and though the statement is warmly denied, there appears to be truth in the report, though the extent has been no doubt greatly magnified. There is every reason to believe that he was beginning to disgust even his followers, when his murder banished all feelings but those of pity and reverence. Thenceforth, he was thought of only as the glorified prophet and martyr; and his followers braced their nerves to endurance by the remembrance of their master's fate and example. In Nauvoo itself the impression produced by the event was most profound. At first the popular cry was only for revenge, but their leaders exhorted them to forbearance, and succeeded in their exhortations. They then proceeded to elect a successor to Smith. Three candidates put forward their claims to the prophet's place. The choice of the council fell on Brigham Young, who, as soon as he was installed, took measures to remove his people far beyond the farthest settlements of his countrymen, convinced now that only in a country far distant from societies living nnder the established forms, could the vision of the Prophet stand a chance of realisation. The only stipulation made with their enemies was that they should be unmolested till they could finish and dedicate their beautiful temple; and as soon as that was accomplished, September 1846, the last band of the brethren departed from the land of their hopes to seek a new land of promise.

Shortly before Smith's death he estimated his followers at npwards of 150,000, and declared that they were to be found among almost every civilised people on the face of the earth. Probably he exaggerated alike the number and the diffusion of his disciples, but that their nnmber was very great, and that they were very widely spread, there can be little douht. To what extent, if any, they have since increased, we need not now stay to inquire. Their present condition will be more properly noticed in another article [UTAH, *S.* 2]. It only remains now to state their doctrines as enanciated by Smith, and this will be best done in the creed which he forwarded a few months before his death for publication in Rupp's work, quoted above:—

"We believe in God the Eternal Father, and his Son Jesus Christ, and in the Holy Ghost.

"We helieve that men will be punished for their own sins, and not for Adam's transgression.

"We believe that through the atonement of Christ all men may be saved, by obedience to the laws and ordinances of the Gospel.

"We believe that these ordinances are—1st, Faith in the Lord Jesus Christ; 2nd, Repentance; 3rd, Baptism by immersion for the remission of sins; 4th, Laying on of hands for the gift of the Holy Spirit.

"We believe that a man must be called of God by 'prophecy, and by laying on of hands' by those who are in authority, to preach the Gospel and administer the ordinances thereof.

"We believe in the same organisation that existed in the primitive church, namely, apostles, prophets, pastors, teachers, evangelists, &c.

"We believe in the gift of tongues, prophecy, revelation, visions, healing, interpretation of tongues, &c.

"We believe the Bible to be the Word of God, so far as it is translated correctly; we also believe the Book of Mormon to be the Word of God.

"We believe all that God has revealed, all that he does now reveal; and we believe that he will yet reveal many great and important things pertaining to the kingdom of God.

"We believe in the literal gathering of Israel, and in the restoration of the Ten Tribes; that Zion will be established npon this (the Western) continent. That Christ will reign personally npon the earth; and that the earth will be renewed and receive its paradisal glory.

"We claim the privilege of worshipping Almighty God according to the dictates of our conscience, unmolested, and allow all men the same privilege, let them worship how, where, or what they may.

"We believe in being subject to kings, presidents, rulers, and magistrates; in obeying, honouring, and sustaining the law.

"We believe in being honest, true, chaste, benevolent, virtuous, and in doing good to all men: indeed we may say that we follow the admonition of Paul, 'We believe all things,' we 'hope all things,' we have endured very many things, and hope to be able to endure all things. If there is anything virtuous, lovely, or of good report, or praiseworthy, we seek thereafter."

In this creed it will be seen that there is no reference to what is now commonly regarded as the characteristic feature of the Mormon system—polygamy, nor has it been mentioned in connection with Smith himself. There is no doubt that during the last year of Smith's life this was one of the charges brought against the Mormonites, but the doctrine of a plurality of wives was never openly taught until after his death, and if he proclaimed it at all, he confined the revelation to the initiated. He is said however to have "sealed" to himself "plural wives," as the Mormons express it, about two years before his death; and the privilege may have been accorded to some of the chief of his followers. But the doctrine in its present form is one of the 'developments' of the system.

SMITH, ADMIRAL SIR SIDNEY, was born at Westminster in 1765, and in his twelfth year was sent as a midshipman on board the Sandwich, Lord Rodney. At the age of sixteen he was made lieutenant, and at nineteen post-captain. War having broken out between Russia and Sweden, he obtained permission to offer himself as a volunteer to the latter power, in whose service he showed so much courage and skill as to lead to his investment with the order of the sword. On the surrender of Toulon to Lord Hood, August 1793, Captain Smith, being in the south of Europe unemployed, hastened thither, and offered his services, which were accepted; and on the evacuation of the city in the following December, the destruction of the French ships of war, which could not be removed, and that of the powder magazines, arsenal, and stores, was entrusted to him. On his return to England he was appointed to the command of the Diamond, with a small flotilla, charged to cruize in the Channel. He succeeded in considerably annoying the enemy, but in attempting to cut out a ship at Havre he was made prisoner.

After a confinement of over two years, Captain Smith, by the assistance of a French officer named Philippeaux, made his escape and reached England in safety. Appointed to the command of the Tigre, 80 guns, and a small squadron, Sir Sidney proceeded to Constantinople, and thence to Acre, which, as the key of Syria, was then closely invested by Bonaparte at the head of 10,000 men. Sir Sidney, with admirable decision and promptitude, brought two of his largest ships close in shore and landed a party of sailors and marines, at the same time sending his friend Colonel Philippeaux, who was a skilful engineer, to assist in directing the fortifications; Bonaparte made several desperate assaults upon the place, but was on each occasion repulsed with heavy loss, and ultimately was compelled to raise the siege and retreat in disorder. This successful resistance was attributed in no small degree to the gallantry and energy of Sir Sidney Smith. In the events which followed Bonaparte's departure from Egypt, Sir Sidney took an active part, and when General Kleber on whom the command of the French army had devolved, offered to evacuate Egypt, Sir Sidney, though without instructions, confirmed the treaty which he made with the Turkish commander to that effect at El-Arish, January 24, 1800. The English ministry however disavowed his procedure, and Sir Sidney continued to participate in the measures adopted for the expulsion of the French. In the battle of Alexandria, in which Abercrombie was killed, Smith received a severe wound. On his return to England, the 'Hero of Acre,' as he was popularly designated, was received with great enthusiasm, and among other marks of public approval, had the freedom of the city of London voted him along with the present of a valuable sword.

In 1802 he was elected M.P. for Rochester, and during the brief peace took part in the debates; but on the renewal of war he was appointed to the Antelope, 50 guns, with command of a flying squadron, at the head of which he displayed his wonted activity. In 1804 he was made colonel of marines; in 1805 rear-admiral of the blue; and in 1806 he proceeded to the Mediterranean in the Pompey, 80 guns, with a small squadron to harass the French in Naples. He took Capri, succeeded in twice throwing succours into Gaeta, landed his sailors, and battered the fortresses of the French, and renewed, on a smaller scale, his Acre tactics, inflicting at various parts of the coast severe losses upon the troops of Massena. He was not able however to save Gaeta. As long as he was there the garrison was firm, but soon after his departure for Palermo the governor surrendered. In the following year Admiral Smith was ordered, under Admiral Duckworth, to the Dardanelles, and there he destroyed a Turkish squadron of one line-of-battle ship, four frigates, four corvettes, two brigs, and two gun-boats. In 1810 he was made vice-admiral: in 1812 he was appointed second in command of the Mediterranean fleet, and remained stationed in comparative inactivity off Toulon to the end of the war, when he was created K.C.B., and received a pension of 1000*l*. for his distinguished services. In 1821 he rose to the rank of full admiral, and in 1830 succeeded King William IV. as lieutenant-general of marines. He died May 26, 1841, at Paris, where, in consequence of pecuniary difficulties arising out of unsuccessful trading speculations, he had been for some years a resident.

SMYTH, WILLIAM, was born at Liverpool in 1766, and was educated at Peterhouse, Cambridge, where he graduated B.A., and 8th Wrangler in 1797, and M.A. in 1790. His father, who was a banker, having become embarrassed in consequence of the war between England and France in 1793, he was compelled to look around for means of maintaining himself, and accepted the office of tutor to Thomas, the eldest son of R. B. Sheridan. Of his connection with these two celebrated characters Mr. Smyth has left an interesting little 'Memoir,' printed not for sale in 1840. Mr. Smyth had accompanied his pupil to Cambridge, and from that time it became his settled residence. In 1806 he published a small volume of poetry, 'English Lyrics,' of which a fifth edition was issued in 1850. In 1809 he was appointed Professor of Modern History, which secured him a moderate competence, as the salary is 400*l*. a year. He commenced his lectures the same year, of which the first series comprised the period from the irruption of the northern nations into the dominions of the empire, to the English revolution of 1688; the second series extended from that period to the close of the American war; the third series commenced in 1810, comprised a history of the French revolution from the accession of Louis XVI. to the close of the Constituent Assembly; and the fourth continued it down to the fall of Robespierre. To these he added in 1832, 1835, and 1837, Supplementary Lectures, containing reflections and observations on the events of that revolution, and in 1836 two others on America. The whole were published in 1840, and have been since reprinted in Bohn's Historical Library in 1854-5. These lectures were popular during their delivery, and are well adapted for the purpose intended, namely, that of exciting attention to the study of history, rather than as satisfying all the requirements of the student; nevertheless they contain a useful commentary on the events: the first two series, though the briefest, being perhaps the best. In 1840 was also printed, for private circulation, what is called an 'Occasional Lecture.' It is a pleasant little pamphlet, occasioned by the desire of a lady to hear a lecture, of which it takes the form. It is an eulogium on woman, displaying considerable humour, with much varied reading, and is dated 1814. In 1845 he published his last work, 'Evidences of Christianity,' and on June 24th, 1849, he died at Norwich, after having worthily occupied his professorial chair for forty years. In 1851 a painted window by Warrington, representing the 'Adoration of the Magi,' was erected by some of his friends to his memory in the north aisle of Norwich Cathedral.

SNAKE-FISH. [CEPOLA.]
SNETTISHAM. [NORFOLK.]
SNOW-BERRY. [CHIOCOCCA, *S.* 2.]
SNOW-BUNTING. [EMBERIZIDÆ, *S.* 2.]
SNOWDROP. [GALANTHUS.]
SODA-ALUM. [MINERALOGY, *S.* 1.]
SOLANINA. [CHEMISTRY, *S.* 1.]

SOLASTERIÆ, or SOLASTERINÆ, a sub-family of *Asteriadæ*, including those forms of Star-Fishes which have two ranges of suckers in each avenue. There are two British genera, *Cribella* and *Solaster*.

Cribella has only a few rays covered with spine-bearing warts; the intermediate spaces porous; the avenues bordered by two sets of spines.

There are two species which are not uncommon on the shores of the British Islands, *C. oculata* and *C. rosea.*

Solaster (Forbes) has many rays studded over with bundles of spines; the avenues bordered by three sets of spines.

S. papposa, the Rosy Sun-Star, is common on the eastern coasts of Great Britain, where, on account of the number of its rays, it is called Ten-Fingers. It is of a deep red or orange colour. Another British species is *S. endeca.*

SOLDANELLA, a genus of plants belonging to the natural order *Primulaceæ*. Some of the species are slightly purgative.

SOLIHULL. [WARWICKSHIRE.]

SOLITARY BIRD. [DODO.]

SOLOMON'S SEAL, the common name of the species of *Polygonatum*, a genus of Plants belonging to the natural order *Liliaceæ*, and the sub-order *Asparageæ.*

Polygonatum has the perianth tubular, 6-toothed, tardily deciduous; the ovary 3-celled: cells 2-ovuled; the stigma blunt, trigonous; berry with 1-seeded cells; the flowers not jointed to pedicel. There are three British species.

P. verticillatum has linear-lanceolate whorled leaves, with an erect angular stem. It is a rare plant in Great Britain.

P. officinale, Solomon's Seal, has leaves ovate-oblong, half-clasping, glabrous, stem angular: peduncles 1-2-flowered; filaments glabrous. It is the *Convallaria Polygonatum* of Linnæus, and has been confounded with the following. It is only found in Scotland.

P. multiflorum has leaves ovate-oblong, half-clasping, glabrous, alternate; stem round; peduncles one- or many-flowered; filaments downy. This plant is the common species known by the name of Solomon's Seal.

SOMERVILLITE. [MINERALOGY, *S.* 1.]

SOMMITE. [NEPHELINE.]

SOPHIA, a city in Bulgaria in European Turkey, situated on the route from Constantinople to Belgrade, about midway between Nissa and Philippopoli, near the point indicated by 42° 37′ N. lat., 22° 27′ E. long., in a wide plain bounded by high ramifications of the Balkan, and traversed by the Isca, a feeder of the Danube, and has about 10,000 inhabitants, the greater part of whom are Christians. It is a large place, and has a beautiful appearance from a distance, but the streets are narrow, tortuous, dirty, and lined by high mud walls, which here and there inclose good houses, but in general the houses are poorly built. It has a great number of mosques and Christian churches, which are the principal buildings in the city; there are also a large and well-frequented bazaar, public baths (which are supplied from a hot-spring), and khans. The chief industrial products are—knitted-stockings, for which Sophia is celebrated, broad-cloth, some silk-stuffs, leather, and tobacco. Sophia was formerly the residence of a pasha and capital of an eyalet of the same name, but the eyalet is now named from its capital, Nissa, called by the Turks Nish. It gives title to a Greek archbishop and to a Catholic bishop. There are hot-springs in the environs. Sophia is a place of considerable commerce. It was founded by the emperor Justinian on the site of the ancient *Sardica*. The only remains of antiquity are the ruins of the church founded by Justinian. Sardica is famous for the council held in it A.D. 347, which confirmed the decree of the Pope acquitting St. Athanasius of the charges brought against him at the council of Antioch. The council of Sardica also passed twenty canons, one of which permits a bishop condemned by a provincial council to appeal to the Pope. The Arian bishops, to the number of about eighty, withdrew from the council of Sardica to the town of Philippopolis, and held what they called the council of Sardica, in which they pronounced sentence of excommunication against Osius, St. Athanasius, and the Pope. (*Frontier Lands of the Christian and Turk; L'Art de Vérifier les Dates.*)

SORDAWALITE. [MINERALOGY, *S.* 1.]

SOREL. [CANADA, *S.* 2.]

SORREL, WOOD. [OXALIS.]

SOULIÉ, MELCHIOR-FRÉDÉRIC, one of the most fertile writers of the French Romantic school, was the son of a teacher of philosophy at Toulouse, and was born at Foix, in the department of the Ariège, December 23, 1800. In 1808, his father having obtained employment at Nantes, Frédéric Soulié commenced his studies at the Lycée of that city; and afterwards completed them at Poitiers, Paris, and Rennes, so migratory was his early life. In 1820 he accompanied his father to Laval, where the elder Soulié had received an appointment in a public office, and in this office the future novelist laboured also assiduously for several years. The object of his father had been to prepare him for the bar, and young Soulié having spent several years in the study of law, was admitted an avocat, and waited for his briefs like other barristers. But his inclinations were for literature; he wrote pretty verses for his amusement, his letters already displayed an elegant style, and a vein of exquisite pathos, if not of deep reflection, pervaded all he produced. About the year 1825 his father's desultory life brought the family once more to Paris; when the young poet published a volume of fugitive pieces under the title of 'Amours Françaises.' The book did not sell; but several of the poems it contained have since been well spoken of. Frédéric Soulié at once took his resolution, and unwilling to trust for his maintenance to literature alone, sought for and accepted a situation as foreman to an upholsterer. In this laborious employment he passed ten hours a day, and at night be devoted one or two more to the production of his first drama, 'Romeo et Juliette.' This play, though founded on the tragedy of Shakspere, which consequently afforded its adapter nearly all his materials, took him three years to prepare. Nearly another year was spent in vain endeavours to obtain from the managers permission to read it; at last he was fortunate enough to secure the intervention of Jules Janin, who had read and admired some of his poems, and Soulié's drama was represented with some éclat at the theatre in 1828. From that day he took his place as a man of letters. In 1829 he produced at the Odéon his 'Christine à Fontainebleau,' but it failed; and in 1830 he began to write critical articles for the 'Mercure,' the 'Figaro,' and the 'Voleur,' in all of which his genial spirit sought consolation for his own failure, by his cordial panegyrics of other dramatists. His 'Lusigny,' which was produced at the Théâtre Français in 1831 with better success, was followed in 1832 by his 'Clotilde,' the triumph of which, both on the stage and in the drawing-room, was absolute.

Shortly after his 'Clotilde,' which established his reputation as a dramatic writer, Frédéric Soulié began to contribute a series of romances in the shape of feuilletons to the newspapers. In this new and lucrative class of literature, he became and continued for twelve years, 1833-45, the most popular of French romancists. The 'Deux Cadavres' was published in this form in 1833; the 'Vicomte de Beziers' in 1834; the 'Comte de Toulouse' in 1835; the 'Comte de Foix' in 1836; 'Un Été à Meudon' and 'Deux Séjours: Provence et Paris' in 1837; 'L'homme de Lettres,' in 1838. In this manner upwards of thirty fictions, some of them of considerable length, were produced. In 1842 appeared his 'Mémoires du Diable,' the sale of which was immense. It was the universal popularity of this novel which stimulated Eugène Sue to undertake his 'Mystères de Paris.' Soon after this the success of Sue and Dumas in the same class of writing somewhat obscured the fame of Frédéric Soulié, who witnessed their sudden popularity without jealousy. But he never gave up his connection with the newspapers, whose proprietors to the last paid him liberally for his works. In 1846 he bought an estate at Bièvre, where he died September 22, 1847.

SOULT, NICOLAS JEAN-DE-DIEU, MARÊCHAL DUC DE DALMATIE, was born at Saint Amand-du-Tarn, on the 29th of March 1769, or, according to some biographers, in 1765. He was the son of a notary, but not being inclined to follow his father's calling, and having made, it is said, but little progress at college, it was considered best to devote him to a military life, for which he manifested more inclination. Consequently he was allowed to enlist as a private in the regiment of the Royale-Infanterie, on the 15th of April 1785. So slow was his early advancement, that six years after, in 1791, he had reached no higher grade than that of sergeant. In that year he was noticed by old Marshal Luckner, who appointed him to discipline a regiment of volunteers of the Upper Rhine, giving him a commission of sub-lieutenant for that service. The great war shortly after opened new paths to talent, and men of true capacity and courage were no longer prevented by court favour to high birth and family interest, from ascending by degrees to the highest ranks for which nature had fitted them.

On the 29th of March 1793, Lieutenant Soult obtained credit for his conduct at the combat of Oberfelsheim, under General Custine. In November 1793, Hoche placed him on the staff of the army of La Moselle, when, as captain, Soult led the attack of the left at the battle of Weissenberg, and repulsed a body of Austrians. His next service was in the Palatinate under General Lefebvre, who entrusted him with the post of chief of the staff in the vanguard of his army. In 1794 Soult was created colonel, and was one of the most distinguished officers present at the great battle of Flenrus, June 26. He displayed great skill by his dispositions in this action, and in the very crisis of it, when General Marceau, deserted by his troops, had resigned himself to despair, Soult arrested the panic, and restored the battle. For this feat of arms he was promoted to a brigade, October 11, 1794, in the division of General Harty, and assisted at the blockade of Luxemburg. At the battle of Altenkirchen, in 1796, he commanded the attack of the left against the Austrians, who were entirely defeated. Shortly after this victory, being detached with 500 horse to cover the left of the army at Herborn, he was suddenly hemmed in by the enemy's cavalry, amounting, it is said, to 4000; he repulsed seven charges without his ranks being broken; and at length drew off his troop without the loss of a single soldier. This brilliant retreat covered him with honour, and has always been cited among the most memorable actions of the war. His excellent manœuvres at the battle of Friedberg, in 1796, contributed most effectually to its success. At this epoch, and during the whole period of the Revolution, Soult was a constant frequenter of the clubs, a flatterer of the men then in power, and no voice more loudly denounced the 'ancien régime;' conduct which was not forgotten in after days.

In 1799 he joined the army on the Upper Rhine, under Jourdan, and at the head of the vanguard of the left wing was present and acted with distinguished bravery and ability at the battle of Stockach, March 25. Though the battle was eventually won, after a fierce struggle, by the Archduke Charles and the Austrians, such was the opinion entertained of Soult's skilful conduct, that the Directory promoted him to a division on April 21st, whilst Jourdan, the commander-in-chief, lost credit and command by the same action. Soon after, he found himself under the orders of Massena, who, besides his own army in the Alps, had lately succeeded to the command of that on the Rhine, after Jourdan's disgrace. Under that able general he took part in the battle of Zurich, June 4, 1799, when the Austrians were defeated, and France preserved from invasion. In 1800, when Massena shut himself up in the walls of Genoa, General Soult was one of the most active of its defenders during the siege, distinguishing himself highly in the numerous skirmishes which took place beneath its walls. He was wounded and taken prisoner in one of these sorties, but recovered his liberty after Napoleon's victory of Marengo.

After the battle of Marengo, June 14, 1800, the military command of Piedmont was conferred upon General Soult; who was next despatched with a corps of 15,000 men to occupy the peninsula of Otranto; but after the peace of Amiens, he was superseded in this government by General Saint-Cyr. Soult returned to France during the suspension of hostilities, and though, for some unexplained cause, he was not personally a favourite with Bonaparte, on the recommendation of Massena he became one of the four colonels of the Consular Guard. The rupture between England and France soon followed, and it was General Soult who organised the vast armament collected on the heights of Boulogne, known as the Army of England. Meanwhile, the French Empire had been formed, and so assiduous had been the court paid by Soult to the First Consul during the short period of transition, that although he had served neither in the first campaigns in Italy, 1796-97, nor in that of Egypt, 1798-99, nor even yet fought under Napoleon, nor commanded an army in the field, his name was included in the list of French marshals created at the coronation.

In the campaign of 1805 Marshal Soult obtained still greater distinction; his services at the battle of Austerlitz, December 2, being so efficient, that Napoleon thanked him on the battle-ground, before his whole staff, calling him one of the first of living strategists. Thenceforward, and until the end of the war, he ranked as one of the leading generals of France, to whom the greatest undertakings might be committed when Napoleon himself was elsewhere. With the same success, he took part in the campaigns of 1806 and 1807. After the battle of Jena, October 14, 1806, he defeated Marshal Kalkreuth, captured Magdeburg, and put to flight the Prussian General Blücher, and the Russian General Lestocq. Again he signalised himself at the battle of Eylau, February 8, 1807, and captured Königsberg the same year. He had now been fifteen years in constant service in the field, and had fought under the ablest and most experienced commanders, with all of whom he had enjoyed the same confidence. He had now fully acquired the confidence of Napoleon himself, who for the rest of his career treated Soult as his lieutenant, by honouring him with the chief command he had to bestow after the one he filled in his own person.

When the ambition of the French Emperor had turned towards Spain, Marshal Soult was appointed to command the 2nd corps, with which he was despatched, in November 1808, to attack Belveder's corps of 20,000 men, at Burgos. In this battle, fought on the 10th of November, the Spanish army was defeated, although one of Soult's divisions alone (Maison's) was engaged. Madrid having surrendered to the French, after its fall Napoleon marched against the British army under Sir John Moore, then on its way from Portugal. Marshal Soult was at first directed upon Sahagun; but Sir John Moore, seeing the risk to which he was exposed of being intercepted and hemmed in, lost no time in commencing his retreat upon Corunna. Napoleon was averse to dilatory war, and was moreover unwilling to fatigue the troops under his command unnecessarily; he therefore recalled the marshal, with injunctions to pursue Sir John, and "drive the English into the sea." At the same time Marshal Ney was commanded to support the operation with the 6th corps. Some French generals, and other military historians, with the anxiety so common with them to explain away any failure of the French arms, have, on this occasion severely censured Marshal Soult for inactivity and negligence, "in halting at every defile to collect the sick and loiterers, by which the almost total destruction of the British army," according to them, was prevented. On the other hand, the marshal always expressed his astonishment at the skilful retreat of his enemies. At length, on the 16th of January, 1809, the British army, having approached Corunna, the place intended for their embarcation, made a stand, and a bloody engagement ensued. In this action Sir John Moore was mortally wounded, but the French met with a decisive repulse. [Moore, Sir John.] The British troops effected their passage to their ships unmolested by the French, and it was not until the 20th that the Spanish governor capitulated.

Soon after, Marshal Soult entered the Portuguese territory with the 2nd and the 8th corps; and having defeated the Portuguese troops under Romana, he appeared before Oporto, which was carried by storm on the 29th of March, 1809. Instead of marching at once upon Lisbon, the marshal lingered at Oporto, where he is said to have conceived the plan of making himself king of Portugal, and to have postponed the interests of his imperial master, whilst indulging this intrigue.

Meanwhile, Wellington had landed, collected his forces, and made his preparations; on the 8th of May he reached Coimbra with the English army, whilst Beresford at the head of the Portuguese troops was advancing towards Chaves and Amarante to turn the French army. After passing the Douro with his usual boldness and promptitude, Wellington fell upon the marshal, drove him from his position, and captured his sick, his baggage, and almost all his guns. Soult then retreated upon Galicia, with a loss upon his route of 2000 men; whence, after leaving Ney, with his single corps, to defend that province, he continued his retreat to Zamora. The retreat was conducted in a manner creditable to his military talent, but he suffered his troops to commit atrocities on the helpless peasantry which have left an ineffaceable stain on his memory.

After the battle of Talavera, July 28, 1809, Soult was appointed to replace Marshal Jourdan as Major-general of the army in Spain, the chief command being nominally left in the hands of King Joseph, a man without any capacity for war, but faithful and devoted to his brother's plans. On the 19th of November, 1809, he won the battle of Ocana, and soon after resolved upon an expedition into Andalusia, one of the richest provinces in Spain. Accordingly, in January 1810, he collected a strong army, consisting of four corps, and taking his way through Andujar and Seville, appeared before Cadiz on the 5th of February; but was disappointed of taking the place. Soon after this check, King Joseph returned to Madrid, leaving the marshal in command of the Army of the South, consisting of the 1st, 4th, and 5th corps. The year 1810 was almost entirely occupied by the marshal in establishing his position in Andalusia; but the wide cantonments over which his troops were dispersed, constantly exposed them to loss in petty skirmishes with the enemy, who, supported by the strong fortress of Badajoz to fall back upon, had a great advantage over him. In the beginning of 1811, Napoleon, who felt the urgent necessity of supporting Massena in Portugal, ordered Soult to besiege Badajoz. The marshal obeyed; but although he captured the place on the 11th of March, 1811, the Prince of Essling, unable to penetrate the strong lines of Torres Vedras, had fonnd it necessary to abandon Portugal.

The departure of Massena having relieved the English army from one of their most formidable opponents, Lord Wellington determined to recapture Badajoz, for which purpose he despatched Beresford to invest it. The siege was opened on the 7th of May, 1811; Soult came to its relief, and on the 16th had to fight the battle of Albuera, in which —though by means of his great superiority in numbers he inflicted great loss upon Beresford's army—he was thoroughly defeated. The fall of Badajoz now appeared inevitable, when Napoleon, apprised of Soult's recent defeat, ordered Marshal Marmont, who had superseded Massena in the command of the army of Portugal, to push forward to his support. This movement rendered it necessary for Wellington to raise the siege on the 16th of June. However, in the following spring, encouraged by the capture of Ciudad Rodrigo, Wellington laid siege a second time to the fort of Badajoz, and—though not without terrible loss—the place was carried on the 6th of April, 1812. Soult was in consequence compelled to retreat from Seville, his rear-guard being severely cut up at Villa Garcia.

The subsequent defeat of Marmont at the battle of Salamanca (July 22, 1812), and the surrender of Madrid to the British general, compelled Joseph Bonaparte to withdraw behind the Tagus with his army, and Marshal Soult received orders to join him. Accordingly, to his deep regret, he marched out of Andalusia, and on the 10th of November took the command of the three combined French armies stationed on the Tormes. This junction of forces was too powerful to be attacked; Lord Wellington therefore fell back upon Ciudad Rodrigo, with a heavy loss of troops on his route, and went into winter quarters. After his departure from the rich province of Andalusia, which he had occupied for nearly three years, the strongest charges were brought against Marshal Soult for the cruel extortions levied on the people by himself and his agents, and his shameless and unbridled robbery of pictures and articles of value. The reports of military men of every army engaged in the Peninsular war have fully corroborated the charges; while the enormous wealth which he ostentationsly displayed after the peace seemed to indicate that he did not feel the disgrace his atrocious conduct had drawn down upon his name. For a few months during the year 1813 Soult was employed in the German campaign, having been summoned by Napoleon to take the command of his guard, after the death of Marshal Bessières at Weissenfels.

But the disastrous defeat of Marshal Jourdan at Vitoria, on the 21st of June, 1813, having threatened, not only the loss of Spain, after an occupation of five years, bnt the security of the French soil, Napoleon was once more compelled to employ Soult in the Peninsula, though it was not without some sense of shame that he sent him there. Accordingly, in July, Soult returned to Spain as commander-in-chief of the French armies. Then followed the most arduons period in his career; and although—overmatched by the genius of Wellington—nearly every enterprise was a failure, and every battle a defeat, we cannot refuse to Soult the credit due to resolute perseverance and dauntless bravery. The fall of Pampeluna, the battles of San Marcial and Soranren, succeeded, in all of which the marshal was worsted; then he took np a strong position on the banks of the Bidassoa, but was driven from it by the leader before whom so many marshals had succumbed. The losses of Napoleon in Champagne required some relief, and thousands of Soult's veterans were drafted off; his German troops deserted him. Still, wherever the ground enabled him to defend himself the marshal formed a new position. First, he fortified himself on the Nivelle; driven from that river, he took up a new position on the Nive, whence his impetuous enemy dislodged him; bnt, without being depressed, he offered the English battle at St. Pierre, and was again defeated. Wellington had at last entered the French territory in the south, whilst in the north Napoleon was falling back before the allied armies. But even then he did not despair. A truce of a few weeks was forced npon the opposing armies after November, when both sought winter quarters. But early in February 1814 the war was renewed. The battle on the Adour, the battle of Orthes, the battle of Tarbes, succeeded each other, and were lost by the marshal. To complete his embarrassment, he had been informed of the surrender of Bordeaux to the Bourbons, and the subsequent capitulation of Paris. Yet, even when the three allied armies were in possession of the capital, when Lyon had submitted, when so many marshals and generals were deserting Napoleon at Fontainebleau, he fell back upon Toulouse, and formed that admirable position which not even the impetuous valour of British troops could force without a carnage so fearful as almost to balance their own victory. The loss of the French was however more than commensurate, and their defeat was complete. This was Soult's last and the greatest of his battles; it was fought with consummate skill, April 10, 1814, eleven days after the fall of Paris: Soult evacuated Toulouse on the 11th.

On the escape of Napoleon from Elba, Soult, who had attached himself to the restored king, and who was then in office as minister of war, published an order of the day, March 8, 1815, calling on the army "to rally round their legitimate and well-beloved sovereign, and resist the adventurer, who wanted to seize again that usurped power of which he had made so pernicious a use." But on the 25th of March he saw the emperor at the Tuileries, was easily reconciled to him, and accepted the post of quarter-master-general to the army preparing to open the campaign. In this quality he was present at the battle of Waterloo, on the 18th of June 1815. Soult was banished from France in July; but in 1819 he was once more permitted to return, and his baton was restored to him. Charles X. showed him great favour throughout his reign: he created him a peer on the 5th of November 1827. During the reign of Louis-Philippe he was made Minister of War, Ambassador Extraordinary to Queen Victoria's court at her coronation, and on two occasions President of the Council, or prime minister. Whilst filling this office for the second time, in September 1847, he wrote to the king requesting leave to resign. His request was granted; but in order to mark his appreciation of the services of the marshal, Louis-Philippe re-established in his favonr the ancient but disused dignity of Marshal-General of France, which had not been borne by any subject since the death of Marshal Turenne. From that time the marshal went to live in retirement, to which he confined himself more closely still after the revolution of February 1848. His health and strength had long been severely shaken; the marshal grew worse during the year 1851, and breathed his last at the castle of Soult-Berg, on the 26th of November in that year. After his death his splendid gallery of Spanish pictures *collected* by him during his Spanish campaigns was sold by auction, and realised a very large sum: several of the best of these pictures are now in the Imperial Galleries of France. The 'Mémoires du Maréchal General Soult, duc de Dalmatie, publiés par son fils. 1ère partie. Histoire des Guerres de la Révolution,' appeared in three vols. 8vo, with an Atlas, Paris, 1854.

SOUR-SOP. [ANONACEÆ.]

SOUTH AUSTRALIA. Under this head, in Supplement 1, an account of the geographical features of the colony was given. It has risen since into greater importance, and is better known. We therefore add the following particulars:—

The climate of South Australia is one of the finest in the world, resembling that of the south of Italy. The atmosphere is generally clear and elastic, and the sky remarkable for the variety and brilliancy of its colours. There are no prevalent diseases. On entering the country some are attacked with dysentery, which with a little care may be avoided. Adelaide has been occasionally visited with influenza; and at particular seasons there are some cases of ophthalmia, which is rather a swelling of the eyelids, caused by a small insect. The seasons are divided into dry and wet. The dry season begins at the end of August and continues to the end of March. In December and January, corresponding in temperature to our June and July, the heat is very great, and the ground so arid that the least breeze raises clouds of dust. Occasionally in summer a hot wind from the north blows over the plains, and compels all to seek shelter from the close and dusty atmosphere; but it seldom lasts many hours before it is succeeded by a cooling breeze from the south-west. The thermometer ranges as high as 115° Fahr. Its highest range in 1852 was 105°; its lowest, 44°; the average was 67°. The temperature is subject to sudden and very extraordinary changes; but these do not in general affect the health injuriously, neither do they occasion much inconvenience. During the wet season, from the end of March to August, it rains frequently and sometimes very heavily. During this period the earth is covered with the richest verdure, and the weather is so genial that the approach of summer is scarcely perceptible. In summer the grass is speedily parched, and frequently becomes so dry as to break when trampled on; but the ground is as rapidly clothed with fresh pasture by the showers which fall at no great intervals. The long droughts, with which New South Wales is periodically visited, are not known in the settled parts of South Australia. During the rainy season the wind blows from the west or south-west, and frequently in hard gales. In the dry season northern and north-eastern winds prevail. No fall of snow has been experienced, and in the Mount Barker district, the coldest part of the colony, the frost has only in rare instances been of such force as to form a thin crust of ice. The lowest temperature for the year is about 37°.

During the rainy or cold season a great number of whales visit the coasts of the colony, and are chased by British, American, and French vessels. The black whale is most frequent, but the sperm-whale also occurs. The native animals are—the kangaroo, the wallobi, a smaller species of the same genus, the wombat, the opossum, and the dingo, or Australian dog. Porcupines, although unknown on the mainland, are found in considerable numbers on Kangaroo Island. For several years locusts have appeared in great numbers, and caused much damage to gardens and young crops in the district around Adelaide. Birds are numerous, and distinguished by their beauty. The emu, several kinds of parrakeets and cockatoos, partridges, and quails are common. The most common sea-fowl are—pelicans, black-swans, wild-ducks, divers, waders, cormorants, and Cape pigeons. Several kinds of fish are taken in the sea, as salmon, snappers, porpoises, and large and small sharks. There are several kinds of snakes and lizards: among the latter the iguana, which is eaten; among shell-fish, oysters and periwinkles are plentiful.

The colonists have imported horses from Tasmania and New South Wales, and ponies from the island of Timor in the Indian Archipelago; cattle and sheep from the Cape, Tasmania, New South Wales, and Victoria; hogs from New Zealand. Fowls are common, both the common species and the larger one from the countries of the Malays. The kangaroo-dog is a valuable cross-breed of the bull-dog and greyhound, and is used for chasing the emus and kangaroos.

The woods of South Australia contain many large trees, of which the stringy bark, the blue, white and peppermint gum-trees, different species of the Eucalyptus, are the most useful, their timber serving for building and fencing, for the construction of carts and ploughs, and the manufacture of agricultural implements; but timber for finer purposes is imported from New South Wales and New Zealand. All kinds of grain are successfully cultivated: maize grows well, and also potatoes. Melons, water-melons, pumpkins, and cucumbers attain an uncommon size, as do also cauliflowers. Onions are cultivated to a great extent in Kangaroo Island. No edible fruit is indigenous, except some berries, which are eaten by the natives. Fruit-trees have been extensively introduced. At Adelaide a prize was awarded in 1851 for a collection of sixty varieties of apples grown about ten miles from the city. The peach grows luxuriantly. Oranges and lemons, olives and mulberries, are cultivated to some extent. Every approved variety of grape is grown.

South Australia is rich in minerals. Iron-ore is found in many places, especially in the deserts. Copper-ore is very widely distributed in great abundance, and of the richest quality. Lead also exists in considerable quantity, and some gold has been found. Salt occurs in many places. Twelve copper-mines were in operation in 1851. These are —the Burra-Burra mine, 90 miles N. by E. from Adelaide; the Kapunda and North Kapunda mines, 50 miles N.N.E.; Karkulto mines, 76 miles N. by W.; Worthing mine, 14 miles S.S.W.; Perseverance mine, 12 miles N.E. by E., where parties were engaged digging for gold on licences; Tungkillo, or Reedy Creek mine, 35 miles E.N.E.; the Consolidated mines in Barossa and Lynedoch Valley, 38 miles E. by N.; the Kanmantoo, Bremer, Wheal Mary, Wheal Maria, and Wheal Friendship mines, all in a group about 25 miles E.S.E. from Adelaide. The ore of the Burra-Burra mine is peculiarly rich. It contains 75 per cent. of metal, in the form of a pure oxide requiring no flux to smelt it, the heat of a blacksmith's forge sufficing to run the metal. The lode is 17 feet wide, of great extent, and is quarried like stone, in masses. The mine yields annually about 20,000 tons of copper ore, valued at 20*l.* per ton. The lead-mines are Glen Osmond and Wheal Watkins mines, about six miles south from Adelaide, and the Wheal Gawler and Yattagolinga mines, the first two yielding 75 per cent. of metal.

The natives of South Australia, like those of New South Wales, belong to that race which is called Negro Australian. They have not yet attained an equal degree of civilisation with the native population of the eastern coast, but measures have been adopted for their improvement with some degree of success. There are schools at Adelaide and Port Lincoln for the education of the children. Connected with the latter is a training institution under the superintendence of Archdeacon Hale, in which the youths, after leaving school, are kept separate from the tribe, and instructed in the Christian religion and in some industrial pursuit. A number of youths are employed on stockholders' stations along the Murray. Though it appears certain that all the natives of the southern and eastern coast of Australia speak the same language, a marked difference exists in the dialects spoken in different parts. Various dialects are used within the territories of South Australia: one is spoken by the few isolated families which live in the districts west of 136° E. long.; another by the tribes inhabiting the vicinity of Adelaide; and the tribes along the banks of the Murray below the junction of the Darling, have been found to use four different dialects, three of which were unintelligible to natives from the neighbourhood of Lake Victoria. The tribes within the settled parts of the colony are generally peaceable and inoffensive.

The settled parts of the colony have been distributed into the counties of Frome, Burra, Stanley, Gawler, Light, Eyre, Adelaide, Sturt, Hindmarsh, Grey, Robe, Russell, all lying to the eastward of the gulfs of Spencer and St. Vincent; and the county of Flinders on the south-west shore of Spencer Gulf. A township has been laid out at Port Wakefield, at the head of the gulf of St. Vincent, where a considerable quantity of copper from the Burra-Burra mines has been shipped for Swansea. Roads and bridges have been liberally provided for as settlements have been formed.

The population of South Australia in 1854 was 97,387. The government of the colony is vested in a lieutenant-governor, an executive council, and a legislative council. The executive council consists of the governor, the colonial secretary, the advocate-general, and the surveyor-general. The legislative council, which was instituted in 1851, in terms of an Act of the Imperial Parliament, passed in August, 1850, consists of 24 members, 8 of whom are nominated by the crown, and 16 are elected by 10*l.* householders and the possessors of freehold property of the value of 100*l.* sterling, in the 16 districts into which the colony is divided for the purposes of the Act. The main source of revenue is the customs, the greater part of which is derived from the duties of 1*s.* per gallon on wines, and 10*s.* per gallon on spirits. There are no differential duties between British and foreign goods; but an 'ad valorem' duty of five per cent., or an equivalent rated duty, is charged on all imports except wines and spirits. The general colonial revenue in 1852 was 102,325*l.*, the expenditure was 88,238*l.*; for 1855 the revenue had risen to 504,250*l.*, and the expenditure to 810,327*l.*, no less than 173,376*l.* having been expended during the year on streets, roads, and harbours. The land fund revenue realised 233,745*l.* for 171,610 acres of land. The total exports in 1852, exclusive of bullion and coin, amounted to 736,267*l.*; the imports were 538,973*l.* In 1854 the imports amounted to 2,054,458*l.*, but decreased considerably in 1855; while the exports had increased from 823,104*l.* in 1854 to 839,915*l.* in 1855, exclusive of gold, which in 1854 amounted to nearly half a million. The staples of the exports are wool and copper.

For the promotion of education in the colony, an inspector of schools has been appointed. Schoolmasters obtain an annual grant of 20*l.* for the first 20 scholars, and 1*l.* for each additional scholar, the aid however in no case rising above 40*l.* per annum. The number of day schools receiving government aid in January, 1853, was 69, with about 3300 scholars. The amount paid to teachers during the year was about 3100*l.*

In 1850 there were about 150 places of worship in the colony. The ministers of religion were 17 of the Church of England, under the superintendence of the Bishop of Adelaide; 11 of the Roman Catholic Church, under the Roman Catholic Bishop of Adelaide; 2 of the Church of Scotland; 2 of the Free Church of Scotland (which in 1857 had increased to 7); 1 of the Scotch United Presbyterians; 6 Wesleyan Methodist ministers, besides many local preachers; 2 Primitive Methodist missionaries, and several local preachers; 15 Independent, 8 Baptist, 6 German Lutheran, 1 German Independent, 3 Christian, and 2 Bible Christian ministers. The New Church, the Quakers, and Jews, have each a place of worship in Adelaide.

Adelaide, now an episcopal city, and the seat of Government and the capital of the colony, is situated chiefly on the left bank of the river Torrens, in 34° 56′ S. lat., 128° 30′ E. long. That part of the city which stands on the left bank of the river is called South Adelaide, and is the seat of Government and of the commerce of the town; North Adelaide, on the right bank, is much smaller, but more pleasantly situated. The two divisions are connected by four neat wooden bridges; and a public demesne, averaging half a mile in width, surrounds the whole city. This, known as the Park-lands, is to be converted into a series of public gardens. Adelaide was founded in 1836, and it has made remarkable progress in the 21 years which have elapsed since that time. North Adelaide stands on a gentle slope; in 1852 it contained one public square, 27 streets, and occupied an area of 350 acres; while South Adelaide occupied an area of 750 acres, contained 5 large public squares, and 30 principal streets, which intersect each other at right angles. The streets are wide, but ill paved or unpaved, and are only lighted by lamps in front of the public-houses, every keeper of which, by the terms of his licence, is bound to keep one burning from sunset to sunrise. The site of South Adelaide is flat, and in 1852 was without drainage. The public improvements and sanitary arrangements are under the management of a Board of Commissioners, who, between January, 1850, and September, 1851, expended upwards of 20,000*l.* in forming and repairing streets, erecting public buildings, and otherwise improving the city. Among the public buildings are the Supreme Court-House, a large stone building, the Resident Magistrate's Court, Police Court and offices, the Bishop's palace, a lunatic asylum, an hospital, military barracks, police barracks, and a large jail erected at a cost of 36,000*l.* The post-office is a large and handsome building. An Assay-office was established at Adelaide in 1852 for receiving and assaying gold, chiefly from the Mount Alexander diggings. The total amount of gold deposited in it from February 12 to September 10 was 292,243 ounces, of the value, at the assay price of 3*l.* 11*s.* per ounce, of upwards of 1,000,000*l.* Trinity Church is the temporary cathedral of the diocese of Adelaide. The Roman Catholics have a cathedral dedicated to St. Francis Xavier. A very fine chapel in the Gothic style has been erected by the Wesleyan Methodists, at a cost of about 6000*l.* Besides these, the places of worship in Adelaide are, four for the Church of England; one each for the Church of Scotland, the Free Church, and the United Presbyterian Church; five for Baptists; three each for the Wesleyan Methodists, Primitive Methodists, and Independents; two for Roman Catholics; two for German Evangelical Lutherans; and one each for German Evangelical Independents, Christians, Bible Christians, Quakers, Swedenborgians, and Jews. No burial-ground is permitted to be attached to any church or chapel in the city, but a large cemetery is provided to the west of it. Among the educational institutes of the city are, the Church of England College of St. Peter, a spacious and very handsome edifice, and a training institute for native aborigines. There are three banks, for one of which, the Bank of Australasia, a handsome stone building was erected in 1851, at an expense of 9081*l.*: the amount of money in the Adelaide Savings Bank in 1850 was 11,772*l.* 1*s.* 11*d.* The South Australian Agricultural and Horticultural Society holds an annual show of fruits, garden and field produce, and colonial manufactures. A Chamber of Commerce was established in July, 1850. The South Australian Library and Mechanics' Institute is open daily from noon till ten o'clock, P.M. There are several building societies and various benevolent associations. The cattle-market is outside the city, and the cattle sold there are only permitted to be slaughtered in the city slaughter-house, a spacious and convenient building on the left bank of the Torrens, half a mile below the city.

Port Adelaide, at the mouth of the river Torrens, and on the shore of the Gulf of St. Vincent, about eight miles from Adelaide city, is a capacious harbour, well situated in respect to the prevailing winds; but the great expense and delay in the transport of merchandise between the city and the port are considerable drawbacks to the prosperity of the place. The usual mode of conveying goods is by bullocks and horses. In 1850 an Act was passed by the local council for the construction of a railway from the city to Port Adelaide Creek, which has been completed. A steam-tug is employed to assist vessels in entering the harbour. By an Act passed in 1845, the port was made free to the ships of all nations. Port Adelaide contains extensive and substantial warehouses, built of stone, wharfs alongside which ships can lie to load and unload, a custom-house, a patent slip on which vessels of 1000 tons burden can be raised, a wet dock, a church, a Presbyterian chapel, a theatre, and numerous shops.

The population of Adelaide, Port Adelaide, and Albert Town, which together form one municipality, was 14,577 at the end of the year 1850; since that time it has considerably increased. *Albert Town* is a small straggling village, about a mile from the port, and is chiefly occupied by persons connected with the shipping. Between Albert Town and Adelaide are several other villages, the principal of which is *Hindmarsh*, where there is a steam-flour-mill, the largest brewery in the colony, and many good shops. Within a range of about 5 miles from the city are 11 villages, which may be considered as suburbs of Adelaide: some of them contain excellent residences. In Adelaide county there are about 40 more villages, some of which are inhabited solely by German immigrants, who have erected their houses in their own country fashion. The diocese of Adelaide, to which Bishop Short was appointed in 1847, extends over the two colonies of South Australia and Western Australia; the chapter comprises a dean, two archdeacons, two canons, and twelve clergymen.

The Burra-Burra and other copper mines in South Australia, and the export trade in wool, have rendered Adelaide and its port very flourishing. In August, 1852, gold was discovered at Echunga, 23 miles S.E., and subsequently on Field river, about the same distance S. from Adelaide. A considerable number of diggers were attracted to the spot, and a large amount of gold has been obtained, but not in quantities at all equal to the other Australian gold fields.

SOUTH MOLTON. [DEVONSHIRE.]

SOUTHERNWOOD. [ARTEMISIA.]

SOUTHEY, CAROLINE ANNE, (better known as *Caroline Bowles*), the second wife of Robert Southey, was the only child of Captain Charles Bowles, of Buckland, near Lymington, Hampshire, where she was born December 6, 1787, and where she spent the whole of her days, with the exception of the four years of her married life. Her early days spent in the comparative solitude of a retired village of the New Forest, and a feeble state of health, induced a morbid shrinking from society, which she never in later life endeavoured to shake off, even when her poems had made her name widely known, and her friendship eagerly sought after. Miss Bowles first appeared before the public as an authoress in 1820, when her poem 'Ellen Fitz-Arthur' was published, but without her name. Indeed it was not till many years later that any of her works were issued with her name, though their authorship was no secret in literary circles. In 1822 she published 'The Widow's Tale, and other Poems;' in 1826 'Solitary Hours' (prose and verse); and in 1829, in two volumes, 'Chapters on Churchyards,' which had already appeared in 'Blackwood's Magazine,' where they had excited much interest. In June 1839, as already mentioned, Miss Bowles was married at Boldre Church, in the New Forest, to Robert Southey. Some twenty years before, and whilst they were quite unknown to each other, a literary correspondence had commenced between them, and it was continued with little interruption, their mutual respect gradually strengthening into warm friendship. Their marriage was a melancholy one, at least for the lady. Southey's mental faculties were already beginning to fail, and they soon gave way altogether. But she never permitted a murmur to escape her at her heavy lot. During his few remaining years she ministered to him with unwearying devotion, and her devotedness deserved a somewhat different notice than the ungenerous reference made to it in Mr. Cuthbert Southey's life of his father. She survived her husband somewhat over ten years, but her health had entirely broken down under her affliction, and her last years were years of constant suffering. She found at first occupation in completing a poem on Robin Hood, commenced by Southey, which she published in 1847, and afterwards in collecting her husband's letters, which have since been edited by Mr. Warter. The poetry of Caroline Bowles is of a kind that will always give pleasure to persons of a reflective turn of mind, but is scarcely fitted for continuous popularity. It is tender, graceful, and, though somewhat melancholy, pervaded by a fine moral tone; but it is diffuse, and wanting in strength of thought and passion.

SOUVESTRE, EMILE, one of the most able writers of the modern French school, was born at Morlaix, in Brittany, on the 15th of April 1806. His father was an engineer officer employed in repairing the roads and bridges of his district. Educated at the college of Pontivy until he had reached the age of seventeen, he began to evince a decided taste for literature. But his father's death in 1823 induced him to select the bar as his profession. He therefore studied the law, and in 1827 was formally received as an advocate at Rennes. He soon however grew weary of waiting for practice, and proceeded to Paris, with a strong determination of setting up as an author. His first efforts in this way were not encouraging. Having written a drama, the 'Siege of Missolonghi,' it remained unnoticed at the theatres until M. Alexandre Duval, a Breton like himself, and already known as a successful dramatist, supported him with his interest. After this his tragedy was read, accepted at the Théatre Français, and put into the prompter's hands. But then came the 'censure' with its pruning knife, and such was the mutilation of his piece, as to scare the very managers who had before applauded it. Thus disappointed of his hopes, he returned to his family, and being left without resources, accepted a situation as shopman with M. Mellinet, a bookseller at Nantes. In this situation he was living when the July revolution of 1830, and the fall of Charles X., gave so much stimulus to the young generation.

He began in 1830 to write for the provincial press, and in 1832 was appointed managing editor to a liberal journal published at Brest. Whilst living with M. Mellinet, Emile Souvestre was frequently noticed by the customers who frequented the library, for his unobtrusive good sense, and one of these, the deputy Luminais, a gentleman devoted to the reform of national education, conceived a friendship for him. The deputy soon perceived that Emile Souvestre felt an unusual interest in the same object, and having founded a school at Nantes, for the illustration of his new plan, he entrusted the management of it to young Souvestre, and another youthful reformer, M. Papot, under whom its success was from the first decided. In 1835 M. Souvestre was made régent de rhétorique at the college of Malhouse, in Alsace; he did not however continue many months in this situation.

For several years he had been quietly collecting materials to produce a work on his own province, to which he was extremely attached. This he did in 1836, under the title of 'Les Derniers Bretons,' a book which at once established his name. It is one of the best descriptions of Brittany, full of vivid yet unexaggerated painting, and affords a just idea of the customs, manners, and literature of the 'Wales of France.' His 'Echelle des Femmes' appeared at the same time, and was likewise successful. Encouraged by this change of fortune, Emile Souvestre returned to Paris to fix himself there. He was then thirty, and his future lot was decided.

For the next twelve years, 1836-48, he took a prominent part in the 'rédaction' of the 'Révue de Paris,' and the 'Révue des Deux Mondes;' he also contributed many notices and feuilletons to the 'Temps,' the 'National,' the 'Siècle,' and the 'Journal du Commerce.' His style is very pleasing; his matter thoughtful and instructive. His articles, tales, and books have none of the levity, or persiflage, so lamentably common in too many of his countrymen in the present day; they may be taken up with full reliance on their taste and tendency. Among his numerous writings may be cited: his 'Voyage dans le Finistère,' 'La Maison Rouge,' 'Le Mat de Cocagne,' 'Pierre et Jean,' and 'Les Confessions d'un Ouvrier.' This last especially is a work of incontestable value, full of maxims of the soundest character, especially as relates to the industrious classes. He has also produced several successful dramatic pieces, amongst others: 'Le Filleul de tout le Monde,' 'Le Riche et le Pauvre,' 'Henri Hamelin,' 'Ainée et Cadette,' 'L'Oncle Baptiste,' 'Maitresse et Fiancée;' and 'Un Enfant de Paris.' He is also the author of a good history of the Revolution of 1848.

In 1848, Emile Souvestre, who never lost sight of the principle of educational reform, was appointed by M. Carnot, then minister of public instruction, a lecturer in one of the schools established for the civil service. He likewise gave gratuitous lectures in the evenings to large audiences, consisting of working men and their families. These lectures were well calculated to produce a beneficial effect, and were always crowded.

In 1853 he spent the summer months in lecturing in the principal towns in Switzerland. These lectures were also very successful. He seemed to have found a new vocation, and had begun to diffuse new and more rational ideas among a class, who do not always think for themselves, when his health gave way, and death put an end to his useful labours, on the 5th of July 1854. Having married a second time, he left behind him a widow and three daughters.

SOWERBY, GEORGE BRETTINGHAM, second son of James Sowerby, one of a numerous family distinguished as naturalists, or natural history artists, was born at Lambeth on the 12th of August 1788, and died on the 26th of July 1854. He studied natural history with more success than his elder brother, perhaps on account of his not being so good an artist. In early life he was attached to the study of Entomology, and assisted his father in those departments of his labours where a knowledge of insects was required. On marrying however he gave up his Entomology, and commenced business as a dealer in natural history objects, and visited the Continent of Europe for the purpose of obtaining specimens. He bought the celebrated Tankerville collection of shells, for which he gave six thousand pounds. He also bought several other large collections. His knowledge of the forms of shells was very extensive, and he projected and published a great work entitled 'The Genera of recent and Fossil Shells.' This was published from 1820 to 1824. His father and brother executed the drawings and engravings, and he drew up the descriptions. His papers on various species of Mollusca are very numerous, and were published in the 'Zoological Journal,' the 'Proceedings of the Zoological Society,' the 'Magazine of Natural History,' and the 'Reports of the British Association.' A list of these papers, upwards of forty in number, is given in Agassiz's and Strickland's 'Bibliography of Zoology,' published by the Ray Society. Besides these papers and the work on the genera of shells he published several other independent works; amongst these should be mentioned the Catalogue of the collection of the late Earl of Tankerville, 'Species Conchyliorum, or concise original Descriptions and Observations of all the Species of recent Shells with their Varieties,' London, 1830. 'Conchological Illustrations, or coloured figures of all the hitherto unfigured recent Shells, with their Varieties,' London, 1832-45. 'Thesaurus Conchyliorum, or Figures and Descriptions of Shells,' London, 1842. He was a Fellow of the Linnæan Society.

SOWERBY, CHARLES EDWARD, third son of James Sowerby, was born on Feb. 1st, 1795, and died in June 1842. He assisted first his father and afterwards his brother James de Carle in their natural history publications till 1831, when the copyright of 'English Botany' falling to his share, he commenced the publication of a second edition on small paper, with large additions. This work has been reprinted by his son, John Edward Sowerby.

SPAIN. Since our previous account very material alterations have taken place, which we shall briefly indicate. The first is the sub-division of the old provinces for administrative purposes, which we subjoin, with the population in 1849, the latest return available; but by a return not yet published, the total population it seems amounts to about 17,000,000.

Area and Population of Political Divisions.

Old Provinces.	Modern Provinces.	Area in Sq. Miles.	Population in 1849.
Aragon	Zaragoza	5,254	350,000
	Huesca	5,052	247,105
	Teruel	4,404	250,000
		14,710	847,105

	Canary Islands	3,340	257,719

Commerce and Manufactures.—Spain, from the extent of its coast-line, its large ports of Cadiz, Cartagena, and Ferrol, the number of its smaller barbours, its geograpbical position, and its abundance of natural productions, possesses very great commercial advantages, but those advantages have been diminished, and in a great measure destroyed, by the restrictive laws of the government. Smuggling to an enormous extent is carried on almost everywbere along the coast, especially at and near Gibraltar, and also from France, across the Pyrenees, and from Portugal across the frontier. The articles smuggled through Gibraltar consist of cottons, linens, muslins, tbread, stockings, and the like, and tobacco to a large amount. The total imports into Spain during the year 1849 amounted to 587,171,795 reals (about 6,160,000*l.*). Of course these are the registered imports. The amount of goods smuggled into the country cannot be estimated. The exports during the same year amounted to 478,162,822 reals (about 5,000,000*l.*). The imports consist of colonial produce, dried fish and salted provisions, cotton and woollen goods, cutlery, glass, butter, and cheese. The exports consist of wool, wine, brandy, oil, fruits, chestnuts and nuts, cork, quicksilver, iron, silver, lead, and salt, witb a small quantity of silk and manufactured goods. Of late years a large amount of wheat and flour has been exported from the northern provinces, cbiefly to Cuba and Brazil. The manufacturing industry, formerly considerable, has greatly declined; and the grape-vine disease (*oidium*) has very materially lessened their manufacture and exportation of wine. The government has still manufactures of tobacco, saltpetre, gunpowder, cannon, fire-arms, and porcelain, but they are all in a decayed state except the manufactory of cigars at Sevilla. Other manufactures are silks, coarse cottons and woollens, and leather. Cutlery and iron-ware are made to some amount in the Basque Provinces and Asturias.

Roads, Canals, and Railways.—The public roads in Spain, except those around the capital and the royal road from Madrid through Leon to Oviedo and the coast, are amongst the worst in Europe. The only canal of importance is the Imperial Canal, commenced by Charles V., extending along the southern bank of the Ebro. There are three or four small canals in the Castillas and in Murcia. The railways completed in January 1858, are—from Barcelona to Arenis del Mar, 23 miles; from Barcelona to Granollers, 19 miles; from Barcelona to Martorell, about 20 miles; from Barcelona to Tarrasa, 22 miles; from Valencia to Alcudia, 39 miles; from Valencia to Grao, 3 miles; from Madrid to Albacete, 173 miles; Reinosa to Alar del Rey, 32 miles.

Revenue.—The budget proposed for 1857 amounted to 20,030,000*l.*; the ordinary receipts were estimated at 17,400,000*l.*, leaving a deficiency to be supplied of 2,630,000*l.* The amount of the public debt in November 1856 was 141,200,000*l.*, on which the interest payable was 2,277,000*l.*, in addition to a loan for 3,330,000*l.* recently contracted for. The army and navy are given under Military and Naval Forces, *S.* 2.

Religion and Education.—The established religion is the Roman Catholic, and no other is allowed in the Spanish dominions. The crown presents the archbishops and bishops, who are confirmed by the Pope. The wealth of the church was at one time immense. After the revolution of 1836-7, the monastic orders were suppressed, and the convents and the lands belonging to them were sold; but the convents of nuns were suffered to remain till the death of the then occupants. A law was passed in 1855 for the sale of the whole of the church-property, and its conversion to secular uses; which law was revoked, at least so far as the property unsold, in 1857; and an indemnity to the clergy of upwards of 2,500,000*l.* has been introduced to the Cortes, but has not yet (May, 1858) been adopted.

Education is very little diffused. The lower classes receive little or no instruction, except in the principal cities, where infant-schools have of late years been established. The children of the upper classes are mostly educated in France and other countries. The universities, formerly numerous and of great reputation, are now reduced to about 14, and those are attended by only a comparatively small number of students in theology, law, and medicine. There are, however, several academies and literary societies in Madrid, Cadiz, Sevilla, and other large cities.

History.—After the queen-mother, Christina, had been appointed queen-regent (Reina Gobernadora), Don Carlos, the brother of Fernando VII., laid claim to the throne on the ground that by the Salic law females were declared ineligible. A civil war ensued, which lasted till September, 1840, when the partisans of Don Carlos were finally defeated, and the sovereignty of Isabella established. Early in 1854, in consequence of the arbitrary and unconstitutional measures of the Spanish government, insurrectionary movements occurred in Barcelona and other places. On the 22nd of February the whole kingdom was declared in a state of siege. On the 15th of Jnly the city and garrison of Barcelona issned a 'pronunciamento' (a pnblic declaration) against the government. This was followed, Jnly 17, by an insnrrection in Madrid. The streets were barricaded, and the people fought against the soldiers till July 19, when the ministry fled, the soldiers gave np the contest, and a National Jnnta was established. Espartero was reinstated in power; the constitntional government was re-established; and the qneen-mother was banished from the kingdom, August 28, 1854. In Jnne, 1856, a revolution took place, and General O'Donnell became dictator, suppressing all opposition by force of arms. He was succeeded by Marshal Narvaez in October. Narvaez was dismissed in the following year, and was succeeded by M. Isturitz, as prime minister, bnt the government is yet in a very nnsettled state.

SPECIES OF PLANTS. All the individnal forms of plants, as well as animals, that occur on the globe, may be collected into gronps resembling each other, and these gronps are called species. A species has been defined to be "a combination of individuals alike in all their parts;" "a systematic combination of homogeneous individuals;" "a collection of individnals which will breed together and prodnce fertile offspring." De Candolle says, a species is "a collection of all the individuals which resemble each other more than they resemble anything else, which can by mutual fecnndation produce fertile individuals; and which reproduce themselves, by generation, in such a manner that we may from analogy suppose them all sprung from one single individnal." However clear such a definition may be, it would assist a botanist only in a very limited degree in determining whether a new plant shonld be looked npon as a new species. If there were perfect structnral identity between two individuals of the same species, or if we conld ascertain, on the physiological ground, that the individnals after fecnndation reproduced similar individuals, it would then be a more easy task. But perfect stroctnral identity does not exist, and the physiological test cannot be always applied, and hence the difficnlty of determining what is really a species. From this some have gone so far as to deny the existence of species altogether, and assert that the supposed distinctions between plants are altogether arbitrary and imaginary. This notion is however altogether upset by the well-known fact of plants maintaining for centnries the same structural characters.

However mnch it may be regretted, on acconnt of the vexations multiplication of species, that some fixed rules cannot be laid down for their formation, it does not appear at present that anything more than general rules can be given, and that mnch mnst depend on the judgment and experience of the observer.

As a general rule species are not distinguished by differences in the internal organisation, snch differences being left for the higher divisions into genera, orders, and classes; bnt by those superficial and external differences which are independent of internal structure. Of these may be named dnration, dimension, snrface, form, division, nnmerical proportion, and colonr. The valne of each of these points varies according to circumstances, and in proportion to the knowledge of the observer will be the skill with which he selects them for distinguishing species. The duration of a plant is a point of great importance, as in no instance do we find, nnless from change of climate, plants of the same species differing in being annual, biennial, &c. Dimension is rarely of any importance, and should only be taken into consideration in extreme cases. Differences of surfaces, depending on structnral pecnliarities, are of importance; smoothness, roughness from tubercles, and the existence of stinging hairs and prickles, are points of value. The presence or absence of lymphatic hairs on the surface of leaves is a point that may mostly be disregarded; they are of more importance on other parts. The form of parts is only of importance when it is the consequence of anatomical differences, tbat is to say, the arrangement of the veins, &c. The division of organs is not of much importance where it depends on the degree of the laceration of the parenchyma. The nnion or non-union of contignous organs, as the parts of the calyx, corolla, &c., is of the greatest value, being mostly uniform in all the individuals of the same species. The nnmerical proportion of the parts of a plant is of valne in proportion to the small number of parts or organs; the greater the nnmber, the more subject it is to variation. Differences in colonr, odonr, or taste, are little to be relied on.

Those departures from identity of structnre, which are considered insnfficient to constitute a species, are called Varieties, and the points of strncture that should constitute a species or variety is freqnently a matter of difference, and it is no nnfrequent thing for one autbor to reduce the species of another to mere varieties. Thns, Borrer has made 71 species of *Salix*, bnt Kocb has reduced them to 29, and nnmerous examples could be cited. A careful attention to the influence of climate, soil, elevation, &c., on species, wonld save much trouble and vexation on this point. De Candolle has elegantly summed np the influence of these agents on plants:—"Let us snppose," he says, "what really happens, that the seeds of plants are scattered at hazard over the snrface of the earth; or, to speak more correctly, by causes that have no necessary connection with the existence of those plants; such seeds will find themselves in an infinite variety of sitnations; some which have fallen in soil that is too tenacious or too loose, too dry or too wet, too hot or too cold, do not grow, and are soon destroyed. But between these extremes some will encceed, although it may be nnder very different circumstances. Thus, for instance, if the place has not light enough, the plant will be half blanched, which will be indicated by its paleness and feebleness, or by being spotted, or by the diminution or even loss of its hairs; if the light is too bright, the plant will he stronger, smaller, more deeply coloured, harder, and more velvety than nsnal. Temperature also exercises some influence, though in a less degree; in a cold climate the same plants are smaller and weaker than ordinary, the colonr of the flowers and fruit is paler, the wood worse ripened, their leaves more decidnous, their fruit often abortive, and the sap destined to nourisb lt throwing itself into the neighbouring parts, sometimes changes tbeir appearance. In a hot climate plants become larger, prodnce more wood, and their leaves have brighter colours and a higher flavour. In the same climate humidity canses the appearance of differences without end; plants that grow in water lose all their hairs, their leaves become divided into capillary segments so as to look like hairy roots, their stems and flower-stalks lengthen to reach the snrface of the water, and these different effects are fnrtber variable as the water is still or agitated, clear or turbid, pure or mixed with heterogeneons substances; the varieties of *Ranunculus aquatilis* offer a remarkable example of this. If, on the other hand, a plant accustomed to water is found to live in a drier soil, it becomes covered with hairs, remains smaller than usnal, and acquires greater hardness. In air rarified like that of mountains, plants are generally found smaller and more stunted than usual, while their flowers are larger than npon the plains. The influence of soil is not less manifest: if it is tenscious, the roots, which penetrate it with difficnlty, are small, hard, and clustered; if it is very sandy, the roots become large, fleshy, and fnlly formed; if it contains a great quantity of carbon, the colonrs of the flower are often altered, as those of the *Hydrangia* into blue, and of the Pink into violet; if it is charged with salt, or if the plant is within the reach of salt, even brongbt through the atmosphere, we nsnally find the leaves more fleshy and more glancous, as in *Lotus corniculatus*. All these different circumstances, combined witb each other in nature, are fertile causes of varieties, which are still further multiplied by cultivation."

SPONTINI, GASPARD, a celebrated Italian dramatic composer, was born at Jesi, in the Roman States, in the year 1778. After stndying the principles of music under Padre Martini at Bologna, he entered, at the age of thirteen, the Conservatory of La Pietà at Naples, then a music school of great renown. At seventeen he composed his first opera, 'I Puntigli delle Donne,' which spread his name over Italy, and led to the favourable reception of a long series of dramatic productions. He visited Paris in 1804, and from that time became much connected witb the mnsic of the French opera; his principal works, 'La Vestale,' 'Olympia,' and 'Fernand Cortez,' having been composed for and produced at the Académie Royale de Musique. Of these works 'La Vestale' acquired the greatest celebrity. Having been adapted both to the Italian and the German stage, it was performed in every great musical theatre in Europe, and for a time had almost as much popularity as the works of Rossini himself. Spontini passed many years of the latter period of his life at Berlin, as director of music at the Prussian court, and held this office at the time of his death, January 21, 1851.

STAINDROP. [DURHAM.]

STALEYBRIDGE, Lancashire, a market-town in the parish of Ashton-under-Line, is situated chiefly on the right bank of the river Tame, in 53° 30′ N. lat., 2° 4′ W. long., distant 8 miles E. by N. from Manchester, 185 miles N.W. by N. from London by road, and 192 miles by the London and North-Western railway viâ Trent Valley. The population of the town in 1851 was 20,760. The living is a perpetual curacy in the archdeaconry and diocese of Manchester. Staleybridge owes its importance chiefly to the cotton manufacture. Woollen-cloth is manufactured to some extent; there are also brass and iron foundries, machine-making factories, brickfields, collieries, stone-quarries, and corn-mills. The parochial chapel is an octagonal structure occupying an elevated site, and there are three district churches, chapels for Wesleyan, Primitive, New Connexion and Association Methodists, and for Independents, Baptists, and Roman Catholics; National, British, and Roman Catholic Schools; a mechanics institute, and a savings bank. Saturday is the market-day; fairs are held on Easter Monday and November 5th.

STAMP ACTS. See 17 & 18 Vict., c. 83; 18 & 19 Vict., c. 36; 18 & 19 Vict., c. 82; 18 & 19 Vict. c. 27; 18 & 19 Vict., c. 78; and 19 & 20 Vict., c. 81.

STAMP-DUTIES. That the relaxing of a heavy tax, while it confers great advantages on the public, does not always involve a loss of revenue, has been strikingly shown in the example of the postage rates, as well as in many others, of which the Stamp Duties form one. In 1850 and 1854 great alterations and reductions were made by the 13 & 14 Vict., cap. 97, the 16 & 17 Vict., caps. 59 & 60, and the 17 & 18 Vict., cap. 83. That the acts were altogether a great boon to professional men and to the public is a point upon which there are not two opinions. The effect upon the revenue will be seen from the following figures:—

In the year ending Jan. 5, 1850, the sum produced by the Stamp Duties was .	£6,867,548
In the year ending March 31, 1858 . .	7,372,209

It must, however, be taken into account that the Succession Duty on real estates was passed in 1853. But in 1852 the stamp duties amounted to 6,761,634*l.*; and the penny receipt duty has come into operation since.

In pointing out the difference between the former and the new duties, the *ad valorem* duties first claim attention.

Conveyance Duties upon the Sale of Property.—These duties show a considerable reduction in all purchases for sums not exceeding 200,000*l.* The highest *ad valorem* duty under the late law was 1000*l.*, there being no increase on sums exceeding 100,000*l.*; the duty is now one uniform rate of 10*s.* per cent., without limit; which, speaking in general terms, may be said to be about half the amount of the former duty on sums from 500*l.* to 100,000*l.* That duty was not a uniform per centage, as at present, but a fixed amount on all sums between those specified in the scale, being somewhat more or less than 1*l.* per cent. as the purchase money approximated to the higher or lower amount in each step; on the mean sum it was precisely that rate. But on sums under 500*l.* the rate was, for the most part, much higher, being as much as 5*l.* per cent. on the mean sum under 20*l.*; 3*l.* per cent. on that under 50*l.*, and 1*l.* 10*s.* under 150*l.* On purchases of small properties, therefore, the advantage is very great; and, referring to these, the justice and propriety of the new scale of duties will be more apparent. In giving a comparative statement of the two duties a difficulty arises from the difference in the language of the two acts imposing them, in expressing the turning point; in the new act the words "exceeding" and "not exceeding" being substituted for "amounting to" and "not amounting to."

The omission to charge the *ad valorem* duty on conveyances where the consideration was stock, whether in the funds, or of any company, is supplied.

The following comparative table will exhibit at a glance the difference between the old and the new duties in all cases of sales for sums not exceeding 1000*l.*

	£		£	New Duties. £	s.	d.	Old Duties. £	s.	d.
		Not amounting to .	20 ...	0	2	6	0	10	0
Amounting to	20	and not exceeding	25 ...	0	2	6	1	0	0
Exceeding .	25	and not amounting to	50 ...	0	5	0	1	0	0
Amounting to	50	and not exceeding	50 ...	0	5	0	1	0	0
Exceeding .	50	„ „	75 ...	0	7	6	1	10	0
„	75	„ „	100 ...	0	10	0	1	10	0
„	100	„ „	125 ...	0	12	6	1	10	0
„ .	125	and not amounting to	150 ...	0	15	0	1	10	0
Amounting to	150	and not exceeding	150 ..	0	15	0	2	0	0
Exceeding .	150	„ „	175 ...	0	17	6	2	0	0
„	175	„ „	200 ...	1	0	0	2	0	0
„	200	„ „	225 ...	1	2	6	2	0	0
„	225	„ „	250 ...	1	5	0	2	0	0

Amounting to	750	and not exceeding	800 ...	4	0	0	9	0	0
Exceeding .	800	„ „	900 ...	4	10	0	9	0	0
„	900	and not amounting to	1000 ...	5	0	0	9	0	0
Amounting to	1000		...	5	0	0	12	0	0

Bonds and Mortgages.—These duties are also charged at one uniform rate throughout, viz., 2*s.* 6*d.* for every 100*l.*, and any portion of 100*l.*, except that on sums not exceeding 300*l.* the duty is imposed by fifties, so as to charge only 1*s.* 3*d.* on the fraction over 50*l.*; thus favouring minor transactions, instead of the more important ones as under the old system. The repealed duty was unjust and wholly indefensible upon principle; as will be perceived when it is stated that the duty on the mean sums in the scale, from not exceeding 50*l.* to not exceeding 20,000*l.* gradually diminished from 4*l.* per cent. to 2*s.* 3*d.*; that the highest duty being 25*l.*, the rate on 40,000*l.* was 1*s.* 3*d.* per cent., and that this rate proportionately diminished with the increase in the amount of money secured.

The following is a comparison of old and new duties on bonds and mortgages for sums not exceeding 20,000*l.*:—

	£		£	New Duties. £	s.	d.	Old Duties. £	s.	d.
		Not exceeding .	50 ...	0	1	3	1	0	0
Exceeding .	50	and not exceeding	100 ...	0	2	6	1	10	0
„	100	„ „	150 ...	0	3	9	2	0	0
„	150	„ „	200 ...	0	5	0	2	0	0
„	200	„ „	250 ...	0	6	3	3	0	0
„	250	„ „	300 ...	0	7	6	3	0	0
„	300	„ „	400 ...	0	10	0	4	0	0
„	400	„ „	500 ...	0	12	6	4	0	0
„	500	„ „	600 ...	0	15	0	5	0	0
„	600	„ „	700 ...	0	17	6	5	0	0
„	700	„ „	800 ...	1	0	0	5	0	0
„	800	„ „	900 ...	1	2	6	5	0	0
„	900	„ „	1000 ...	1	5	0	5	0	0

And proceeding upwards to £20,000 by thousands, dropping the intermediate hundreds, the comparison will be as follows, viz.:—

	£	New Duties. £	s.	d.	Old Duties. £	s.	d.		£	New Duties. £	s.	d.	Old Duties. £	s.	d.
On	2,000 ...	2	10	0	3	0	0	On	12,000 ...	15	0	0	15	0	0
„	3,000 ..	3	15	0	7	0	0	„	13,000 ...	16	5	0	15	0	0
„	4,000 ...	5	0	0	8	0	0	„	14,000 ...	17	10	0	15	0	0
„	5,000 ...	6	5	0	9	0	0	„	15,000 ...	18	15	0	15	0	0
„	6,000 ...	7	10	0	12	0	0	„	16,000 ...	20	0	0	20	0	0
„	7,000 ...	8	15	0	12	0	0	„	17,000 ...	21	5	0	20	0	0
„	8,000 ...	10	0	0	12	0	0	„	18,000 ...	22	10	0	20	0	0
„	9,000 ...	11	5	0	12	0	0	„	19,000 ...	23	15	0	20	0	0
„	10,000 ...	12	10	0	12	0	0	„	20,000 ...	25	0	0	25	0	0
„	11,000 ...	13	15	0	15	0	0								

At this point the old duties stopped, there being no increase beyond 25*l.* whatever might have been the amount of money secured; but the new duties continue on, *ad infinitum*, at the rate of 1*l.* 5*s.* for every additional 1000*l.*, and in proportion for less than 1000*l.*

A mortgage, or (as in Scotland) a bond without penalty, for securing money to become due, without limit, is available as a security for such an amount, only, as the duty thereon extends to cover. In other such cases of bonds the duty is charged on the amount of the penalty.

A mortgage for securing money by way of rent-charge or annuity is chargeable with *ad valorem* duty on the money advanced. The case of an advance of money under the private Drainage Act (12 & 13 Vict. c. 100) is referred to in the work of a writer on the stamp laws (supplement to Tilsley's Treatise on the Stamp Laws, p. 26) as an instance in which this will apply.

The *ad valorem* duties on annuity bonds are somewhat varied. Where the annuity does not exceed 100*l.*, relief, to some extent, is given; above that amount there is an increase, which is greater as advance is made upwards. The new duty is 2*l.* for every 100*l.* and any fraction of 100*l.* per annum; the former duty was not a per centage, but, as in other cases, according to a scale, but not extending beyond 2000*l.* a year. The present duty is not limited.

A valuable alteration is made in the duty on bonds given for any other purpose than as a security for money, where the penalty is of comparatively small amount. Under the old law the duty in every such case was 1*l.* 15*s.*, or some other fixed sum; it is now the same duty as would be payable on a bond given for securing money to the same amount as the penalty, where such latter duty is less than the fixed sum. Bonds given as a collateral or additional security for money are likewise charged with *ad valorem* duty where it would be less than the fixed duty of 1*l.* or 1*l.* 15*s.* respectively.

Leases.—Under this head the equity of the new system, by comparison with the old, will perhaps be more striking than under any other. The present rate of duty on the rent is 10*s.* per cent.; imposed thus, viz., where the yearly rent exceeds 100*l.*, then for every 50*l.* and any fraction of 50*l.*—5*s.*; but upon rents of lower amount than 50*l.* the proportionate duty is charged in smaller steps, involving a less amount of duty for any fraction; thus, again, having favourable regard to matters of comparatively small value, and reversing the former principle. The repealed duties on leases, computed on the mean sums in the scale, were as follows, viz. 10*l.* per cent. on rents under 20*l.*; 5*l.* per cent. on rents under 100*l.*; 1*l.* 6*s.* 8*d.* on rents under 200*l.*; and gradually decreasing to 13*s.* 4*d.* on rents under 1000*l.*; the maximum duty on a rent of 1000*l.* or upwards being 10*l.* only. Relief for the most part to the agricultural interest no doubt prompted the adoption of so liberal a measure, but it will be found, perhaps, more extensively advantageous to the owners and occupiers of property in large towns.

A lease of minerals reserving a portion of the produce, by reference to an annual maximum or minimum amount, is to be charged with duty on such amount; and where the fine or rent consists of corn, &c., the duty is charged on the value, to be ascertained where there is no special contract by the returns published under the Tithe Commutation Act, or, in Scotland, the fiars prices of the county.

Assignments and surrenders of leases (not upon sale or mortgage) are to pay the same *ad valorem* duty, if not exceeding 1*l.* 15*s.*, as the lease itself would be liable to.

The duties on leases in Ireland are to be the same as in England.

Settlement of Money.—All the advantage afforded by the new Act in respect of the *ad valorem* settlement duties is on sums not exceeding 600*l.* The new duty is 5*s.* for every 100*l.* unlimited, and any fraction of 100*l.* The lowest duty under the former law was 1*l.* 15*s.*, which extended to cover any amount under 1000*l.*, and the highest, 25*l.*, for all sums amounting to 20,000*l.* or upwards; being 7*s.* per cent. on the mean sum under 1000*l.*, and averaging less than 2*s.* 6*d.* on the mean sums above 1000*l.* and under 20,000*l.* Thus the order of taxation is again rightly reversed.

These are the *ad valorem* duties affected by the new Act; and they may be said to be the only ones connected with the transfer of property by way of sale or security. Reference will now be made to other alterations which afford almost uniform relief.

Transfer of Mortgage.—This is an important branch of conveyancing; but it appears from the work of the writer already referred to, that it is one that has been more perplexed than any other by the Stamp Duties; and the result of various modern decisions, although tending to quiet doubts previously existing, was to inflict an amount of charge not considered to have been intended by the legislature. The shifting of a mortgage security from one to another is always a cause of vexation to the debtor; but to the poor man it is a matter of serious moment. Independently of professional charges for investigating the title, and for preparing the conveyance, the stamp duty was, of itself, an intolerable burden. The lowest *ad valorem* mortgage duty, oppressive as it was, amounted only to 1*l.*; but the lowest duty on a simple transfer of mortgage was 1*l.* 15*s.*; and as in every instance a new covenant was, as a matter of course, contained in it, a further duty of 1*l.* 15*s.* became, under a recent authority, chargeable; making 3*l.* 10*s.* (besides a third stamp of 1*l.* 15*s.* for the duty on a lease for a year, of which hereafter, where that attached) upon every transfer of mortgage, whether the money secured was under 100*l.* or above 20,000*l.* This is now remedied. The maximum duty on a transfer of mortgage is 1*l.* 15*s.*; and where, if the transaction was a mortgage, instead of a transfer, the *ad valorem* duty would be less than 1*l.* 15*s.*, then such *ad valorem* duty only is to be charged. Thus, for example, on a transfer of a mortgage for 100*l.*, the stamp duty, instead of 3*l.* 10*s.* as the lowest amount, as heretofore, is now only 2*s.* 6*d.* By this alteration every transfer of mortgage is relieved from one stamp of 1*l.* 15*s.*; and on all transfers where the money secured does not exceed 1400*l.* further proportionate relief is given. Where, on a transfer, further money was advanced, the *ad valorem* duty on such further advance was payable in lieu of one of the duties of 1*l.* 15*s.*; now, in such a case, the new *ad valorem* duty is all that is chargeable.

Further Assurance and further Security.—These instruments, which before were charged with 1*l.* 15*s.* in all cases, are now charged with that amount as a maximum; the *ad valorem* duty being payable where less than 1*l.* 15*s.*

Further Advance.—Besides the duty on the further money lent, 1*l.* 15*s.* was necessary if the deed contained any additional security, by covenant or otherwise, for the original sum. Now, merely the *ad valorem* duty on the further advance is requisite.

Bargain and Sale (or Lease) for a Year.—Whilst the cumbrous mode of conveyance of freehold property by actual lease and release gave rise to two deeds, there was certainly no inconsistency in imposing a stamp duty upon each of them; but when, by modern enactments, that system was superseded, and one of the instruments ceased to have, in fact, any existence at all, it may be said to be somewhat inconsistent, as it was felt to be exceedingly inconvenient in practice, to encumber the other deed with the duties on both; but so it was; the release, or grant which had a new conveyancing principle given to it, was charged with the duty before payable on the bargain and sale, or lease, for a year, as well as that which was properly its own. These duties are now swept away entirely. Under the title *Conveyance* certain additional duties were imposed on a feoffment and bargain and sale enrolled as an equivalent for the duty on a lease for a year; these are, of course, also repealed.

Progressive Duties.—A vast improvement will be effected in conveyancing when any system can be established which shall materially curtail instruments in their verbosity. Something has been attempted by the legislature in this way, but without, at present, producing in general practice any alteration. The great length to which a deed may extend is by no means an indication of the value of the subject-matter: and it is sufficiently oppressive that, to effect a transaction of perhaps minor importance, and of unavoidable necessity, an instrument of considerable length must be created, swelling the professional charges to an inordinate amount; but the burden is increased by stamp duties imposed, without regard to value, upon every certain quantity of words made use of. The late progressive duties were 1*l.* or 1*l.* 5*s.* on every 1080 words (15 folios) after the first 1080. The new duty, which is charged in the same manner, is a relief in all cases; the maximum is 10*s.*; but where the primary duty is of less amount the progressive duty is not to exceed it. Similar reduced duties under the head Schedule, are also imposed on papers referred to in certain instruments as part thereof but not annexed. A provision is contained in the Act (section 11) that progressive duties shall not be, or be deemed to have been, chargeable on any instrument in respect of *any other instrument*, liable to stamp duty, and duly stamped, incorporated with or referred to in it; so that an old document, duly stamped *per se*, may be made to form a portion of a new one without being taken into account in calculating the progressive duty on the latter.

Duplicates and Counterparts.—In the case of settlements of money and a few other instances where *ad valorem* duties were payable, duplicates were expressly charged with the same duties as the original instruments; and counterparts became also liable, in some cases, to the like duties; but, in general, they may be stated to have been subject to a duty of 1*l.* 15*s.* except as to leases, the counterparts or duplicates of which, where the duty on the original exceeded 1*l.*, were charged with 30*s.* These duties are now reduced to 5*s.* as a maximum, with progressive duties of 2*s.* 6*d.*; the same duty, including the progressive duty, as the original, being imposed where such duty exclusive of progressive duty is less than 5*s.*

Memorial.—The duty on a memorial for registering a deed is reduced from 10*s.* to 2*s.* 6*d.*

Copyhold.—In all cases of sale and mortgage of copyhold property the instruments charged with *ad valorem* duty are, of course, liable only to the new duties; but there is one instance in which a reduction is made where the instrument was not subject to *ad valorem* duty. In the case of an admittance the instrument was charged with 1*l.*; or, where the yearly value did not exceed 1*l.*, with 5*s.* By the new Act these duties are reduced to 2*s.* 6*d.* where the admittance proceeds upon a sale or mortgage. In all other cases the duty on an admittance remains as before.

Covenant.—A particular duty is now for the first time charged on a deed of covenant. It was, it seems, apprehended that where the *ad valorem* bond duty was considerable, a practice might be resorted to of executing a covenant, as a security, which would be liable only as a common deed to 1*l.* 15*s.*, in lieu of giving a bond; it was therefore thought proper to impose the same *ad valorem* duty on a deed of covenant as on a bond, where it exceeded 1*l.* 15*s.* But relief is given in the case of a separate deed of covenant, executed on the sale or mortgage of any lands, for title, &c. by imposing 10*s.*; or less, where the duty on the conveyance is less.

Agreement.—The duty of 2*s.* 6*d.* on an ordinary agreement remains as before, except that this amount is sufficient for any quantity of words less than 30 folios, instead of merely a quantity not exceeding 15 folios. But in lieu of the leap from 2*s.* 6*d.* to 1*l.* 15*s.* in any excess of the latter quantity, and of 1*l.* 5*s.* for every additional quantity of 15 folios, the duty is now 2*s.* 6*d.* for every such further quantity.

The advantage of this may be illustrated by the following example: suppose a contract for the performance of any work according to plans and specifications, the words and figures amounting altogether to 100 folios, the duty under the old law would have been 1*l.* 15*s.*, and five times 1*l.* 5*s.* for five entire quantities of 15 folios after the first, making altogether 8*l.* By the new law the duty imposed is six times 2*s.* 6*d.*, making only 15*s.*

Charter, Precept, Resignation, and Seisin.—The duties on certain instruments in Scotland under these heads, are reduced from 9*s.* to 5*s.*

Warrant of Attorney.—The duties on securities of this description are as before, the same as on bonds, with a reduction of the duty on a warrant of attorney given as a collateral security, from 1*l.* to 5*s.*, where the duty on the principal instrument exceeds that amount; and also, where it is given for money exceeding 200*l.* for which the person giving it is under arrest. A warrant of attorney given for any other purpose than as a security for the payment of money or the transfer of stock is charged with 1*l.* 15*s.*, which is an increase, the former duty in such case being 1*l.* only.

The foregoing are all the cases in which the duties have been altered by the new act; but there are some material provisions which it will be proper to glance at.

All the provisions of former Acts relating to Stamp Duties are kept in force, including exemptions.

Certain agreements for letting lands in Ireland which were charged with *ad valorem* duties as leases, but which, if in England would have been subject only to the duty of 2*s.* 6*d.* as agreements, are to be deemed to have been liable to the latter duty.

Any person receiving money for stamp duty (including legacy duty) and not applying it, is to be accountable to the Crown by summary process.

Transfers of mortgages, further charges, and further securities executed before the 11th October, 1850, are not to be deemed to be liable to the additional duties already pointed out and attaching by reason of the decisions alluded to, but, in this respect, are to be put upon the same footing as those executed subsequently.

The terms on which instruments may be stamped after execution are materially varied. The penalty, in ordinary cases payable on stamping an instrument executed before the passing of the Act is 5*l.*; upon payment of which and the duty, the stamp may be affixed. By the new Act the penalty is 10*l.*; and where the duty required exceeds 10*l.*, then, further interest at 5*l.* per cent. per annum on the duty, calculated from the date or first execution of the instrument; but no amount of interest beyond that of the duty is to be paid by way of penalty. In lieu of a receipt for the duty and penalty as formerly, a stamp denoting the payment of the penalty is to be impressed. One advantage to the party is however given. Under the old law, if an instrument was stamped, but with an insufficient amount, the whole duty was to be paid without regard to what had been already paid besides the penalty; but now, the deficient duty only is required.

Where instruments are executed abroad, the commissioners are empowered to stamp them without penalty at any time within two months after they are received in this kingdom.

Until this Act there existed no power to determine what stamp duty was payable in any case, so as to assure parties that the stamp on an instrument was sufficient. The Commissioners are now invested with a power to adjudicate in all such cases, and to certify by means of a particular stamp, that any instrument is duly stamped, and so to preclude all question upon the point. The fee for obtaining this adjudication is 10*s.* An appeal is given to the Court of Exchequer.

The duties in Great Britain and Ireland are now assimilated, but it appears that a deed liable to Irish duty could not be stamped in London; and *vice versâ*; this is now permitted.

By the Act of the 12 & 13 Vict. c. 80, the discount of 7*l.* 10*s.* per cent. allowed on the purchase of receipt stamps, was taken away; by the act now under consideration it is restored.

Licences to insure against fire both in Great Britain and Ireland are necessary before any such insurance can be made; they were all formerly required to be obtained annually, but by the 5 & 6 Vict. c. 79, such licences in Great Britain were to be permanent; the same provision is by the recent Act made as to Ireland.

One or two examples have been already given of the benefit to be derived from the new scale of duties in particular transactions of small value; it will be well to furnish an instance or two more.

Take the case of a sale of freehold property for 150*l.*, the conveyance consisting of 40 folios, that is one entire quantity of 15 folios after the first, and requiring, therefore, one progressive duty. Under the old law the duties would be as follows:—

	£	s.	d.			
Ad valorem duty	2	0	0			
Ditto in lieu of a lease for a year	1	15	0			
Progressive duty	1	0	0			
Total				4	15	0
Under the new Act the duties are:						
Ad valorem duty	0	15	0			
Progressive duty	0	10	0			
Total				1	5	0

Again, take a mortgage of a freehold estate for the same sum. The duties were the same in amount as on a sale, viz.:—

	£	s.	d.			
Ad valorem duty	2	0	0			
Progressive duty	1	0	0			
Lease for a year duty . .	1	15	0			
				4	15	0
They are now—						
Ad valorem duty	0	3	9			
Progressive duty	0	3	9			
				0	7	6

The great feature of the 16 & 17 Vict. cap. 59, was the reduction of receipt stamps for all sums amounting to 40*s.* and upwards to an uniform rate of 1*d.* The stamp may be either impressed or affixed, but must be cancelled by the signature, and a penalty of 10*l.* is imposed for neglecting or refusing to give such a stamp with a receipt. The other provisions were—that indentures or covenants for an apprentice, clerk, &c., where no money was paid, was fixed at 2*s.* 6*d.*; debentures or certificates for drawbacks or bounties, 1*s.* if not exceeding 10*l.*, 2*s.* 6*d.* above 10*l.* and not exceeding 50*l.*, and 5*s.* if above 50*l.*; drafts or orders for payment of money on demand, 1*d.* (bankers' cheques and letters of credit sent abroad were exempt by this Act; but now, May 1858, a bill is passing through Parliament, by which all bankers' cheques are to bear a penny stamp); policies of assurance, 6*d.* on every 50*l.* up to 500*l.*, 1s. for every additional 100*l.* up to 1000*l.*, and 10*s.* for every additional 1000*l.* (the fractional parts in each case carry the additional stamp). By cap. 63 the stamp on articles of attorney's clerk was reduced from 120*l.* to 80*l.*; attorneys' and conveyancers' certificates were lowered; and also the conveyance duties on feu-rents in Scotland.

The 17 & 18 Vict. c. 83, is for altering certain Stamp Duties, the effect of which is sufficiently shown by the new scale given in the schedule, which we subjoin. It is only necessary further to give the more material enactments not indicated in the schedule. By § 4, bills purporting to be drawn abroad are to be so deemed, though drawn in the United Kingdom, and are chargeable with duty accordingly; and the holder of a bill drawn out of the United Kingdom (§ 5) is to affix an adhesive stamp of the proper amount before negotiating it, and the neglect to do so, or to cancel the stamp, incurs a penalty of 50*l.* Bills purporting to be drawn in sets (§ 6) must be so drawn under a penalty of 100*l.* Unstamped drafts on bankers (§ 7) are not to be circulated beyond fifteen miles from the place where payable, under a penalty of 50*l.*; but drafts (§ 8) lawfully issued unstamped, may be circulated at any distance by affixing and cancelling the proper stamp. Stamps (§ 10) denoting the duty of one penny may be used for receipts or drafts without regard to their special appropriation. All bills, drafts, and notes (§ 12), except Bank of England notes, are rendered liable to the stamp duty. The exemption from the stamp duty (§ 13) of letters acknowledging the receipts of bills, promissory notes, &c., is repealed; but receipts for money paid to the Crown are still exempted. The stamp duty on pawnbrokers' licences in Dublin (§ 20) is reduced from 15*l.* to 7*l.* 10*s.* Instruments liable to stamp duty (§ 27) are to be admitted in evidence in any criminal proceeding although they be not stamped.

Schedule.—Inland bill of exchange, draft, or order for the payment to the bearer, or to order, at any time otherwise than on demand, of any sum of money.

	£	£	s.	d.

„ 50	75	2	5	0	4	10	0
„ 75	100	3	0	0	6	0	0
And where the same shall exceed £100, then for every £50, and also for every fractional part of £50		1	10	0	3	0	0

And where any such lease or tack as aforesaid shall be granted in consideration of a fine, premium, or grassum, and also of a yearly rent, such lease or tack shall be chargeable also, in respect of such fine, premium, or grassum, with the *ad valorem* stamp duties granted under the head or title of "conveyance" in the schedule annexed to the Act passed in the 13 & 14 Vict., c. 97.

Exemption.—Any lease made in pursuance of the Trinity College, Dublin, Leasing and Perpetuity Act, 1851.

Conveyance of any kind or description whatsoever in England or Ireland, and charter, disposition, or contract containing the first original constitution of feu and ground annual rights in Scotland (not being a lease or tack for years), in consideration of an annual sum payable in perpetuity or for any indefinite period, whether fee farm or other rent, feu duty, ground annual, or otherwise. The same duties as on a lease or tack for a term exceeding 100 years, at a yearly rent equal to such annual sum.

Exemptions.—Any lease or tack for a life or lives not exceeding three, or for a term of years determinable with a life or lives not exceeding three, by whomsoever granted; and any grant in fee simple or in perpetuity, made in Ireland, in pursuance of the Renewable Leasehold Conversion Act, or in pursuance of the Trinity College (Dublin) Leasing and Perpetuity Act, 1851; all which said leases or tacks and grants respectively shall be chargeable with the stamp duties to which the same were subject and liable before the passing of the Act 16 & 17 Vict. c. 63.

Every such lease or tack, and every such conveyance, charter, disposition, or contract as aforesaid hereby charged with duty, and the duplicate or counterpart thereof respectively, shall be chargeable with the respective stamp duties granted and made payable under the several heads or titles of "Duplicate or Counterpart," and "Progressive Duty," in the schedule annexed to the 13 & 14 Vict. c. 97.

License to demise copyhold lands, tenements, or hereditaments, or the memorandum thereof if granted out of court, and the copy of court roll of any such licence if granted in court:

Where the clear yearly value of the estate to be demised shall be expressed in such licence and shall not exceed 75*l.* The same duty as on a lease at a yearly rent equal to such yearly value, under the Act of the 13 & 14 Vict. c. 97.

And in all other cases . . . . . . 10*s.*

STANDARD MEASURE, WEIGHT, &c. The imperial standard yard, and standard pound troy having been destroyed in the fire at the Houses of Parliament in 1834, and doubts moreover existing as to the accuracy of the methods which had been provided by the act 5 Geo. IV. c. 74, for ascertaining the standard, scientific men have constructed a new standard yard and pound, which have been recently legalised. These standards, copies of which have been deposited in various places, now constitute the standard of measure and weight of the United Kingdom; 18 & 19 Vict. c. 72.

STANLEY, REV. EDWARD, D.D., Bishop of Norwich, was born in London on the 1st of January 1779. He was the second son and seventh child of Sir John Thomas Stanley, Bart., of Alderley Park, Cheshire, by Mary, daughter and heiress of Hugh Owen, Esq. of Penrhos in Anglesea. His elder brother, who inherited the baronetcy on his father's death, was raised to the peerage in 1839 by the title of Baron Stanley of Alderley. In his boyhood the future bishop had a passion for the sea and would have preferred the navy to any other profession. Being destined for the Church however he was sent, in 1798, after a desultory education at various schools, to St. John's College, Cambridge; and here in 1802, he graduated B.A. and was 16th Wrangler of his year. He took the degree of M.A. in 1805. In that year,—having meanwhile travelled on the Continent and having had for some time the curacy of Wendlesham, in Surrey—he was presented by his father to the family living of Alderley. In 1810 he married Catherine, eldest daughter of the Rev. Oswald Leycester, rector of Stoke-upon-Trent, Shropshire. He continued rector of Alderley for the period of thirty-two years (1805-37) during which he discharged his duties in a manner so conscientious and so thorough as to gain the affection of all his parishioners in an unusual degree. He worked assiduously among the population of his parish—which amounted to about 1300; and, besides performing his purely clerical duties, he did everything in his power, by encouraging schools and the like, to promote the intellectual and secular welfare of his parishioners. For the use of the young in his parish he prepared 'A series of Questions on the Bible' which was published in 1815. Inheriting Whig principles from his family, he was noted at this time for great liberality and toleration in his ecclesiastical opinions; though the zeal and the warm-heartedness of his Christianity were unquestioned. It was perhaps his slight interest in matters of purely theological controversy that inclined him at this time to the quiet pursuit of natural history. Using the opportunities afforded him by his position as the clergyman of a rural parish, he gratified his tastes in this direction by becoming acquainted with the geology, the mineralogy, the botany, the entomology, and the ornithology of his parish. He became a contributor on topics of natural history, and on kindred topics, to 'Blackwood's Magazine' and to the 'British Magazine;' and one of his articles in 'Blackwood,' entitled 'An Adventure on the Alps in the Mauvais Pas' is supposed to have suggested to Scott the opening scene in his 'Anne of Geierstein.' The department of natural history which he principally cultivated was ornithology; and in 1835 he published under the auspices of the Society for Promoting Christian Knowledge, his well-known work in two volumes entitled 'A Familiar History of Birds, their Nature, Habits, and Instincts.' He had already lectured on subjects of natural history to one or two Mechanics' Institutions in the north of England, and in 1836 he was Vice-President of the British Association. He was also a Fellow of the Royal Society and President of the Linnæan Society.

Though never obtruding his politics on his parishioners, he had taken part on the liberal side on some of the questions of the day relating to the Church. In 1829 he had published 'A Few Words in favour of our Roman Catholic Brethren,' advocating Roman Catholic Emancipation. In 1835 he published 'A Few Notes on Religion and Education in Ireland.' The spirit shown in these pamphlets, taken along with his excellent character, and his family-connections, recommended him to the Whig government as a suitable man for a vacant bishopric; and accordingly, on the vacation of the see of Norwich by the death of Bishop Bathurst in 1837, Lord Melbourne offered the bishopric to Dr. Stanley. It was with much reluctance that he quitted the parish where he had laboured so long to accept this preferment; with which was conjoined the appointment of Clerk of the Closet of the Chapel Royal. Having accepted the office, however, he set himself with great zeal and punctuality to its duties. Seldom has there been a more hardworking bishop, or one more sanguine in all schemes of improvement. He abandoned his pursuit of natural history and devoted himself exclusively to diocesan business. As the previous bishop had lived to the age of ninety-three, there were necessarily great abuses in the diocese—abuses of non-residence, and the like. These Bishop Stanley set himself to reform with a boldness, which, though successful in the end, aroused much bad feeling against him. As in the House of Lords and elsewhere, where public questions were discussed, he always took what was called "The Liberal side," he was accused of latitudinarianism. In the sense of deviation from any of the standards of the Church the charge was untrue; and nothing but the tolerance of his disposition in all non-essential matters gave any colour to it. Beloved by all who knew him, and with the reputation of being one of the most kindly, sanguine, and hospitable men in the Church, he lived till 1849, when he died unexpectedly on the 6th of September at Brahan Castle in Ross-shire, Scotland, where he was then on a visit. He left five children—three sons and two daughters. His eldest son, OWEN STANLEY, entered the navy, where he rose to the rank of captain. He was a man of very considerable scientific attainments, and was regarded as an officer of unusual promise. He had been engaged on a survey of a portion of the coast of Australia, which he had just completed, when he died somewhat suddenly in 1849, his death being apparently hastened by the labours of the survey. Bishop Stanley's youngest son, Charles Edward, is in the Royal Engineers; his second son, the Rev. Arthur Penrhyn Stanley, is Regius Professor of Ecclesiastical History at Oxford, and the foregoing particulars have been derived from a memoir prefixed by him to a collection of his father's "Addresses and Charges" published in 1851. Of the bishop's writings his 'History of Birds' is the most important: it has passed through several editions. Among his various pamphlets and sermons may be noted his 'Heads for the Arrangement of Local Information in every Department of Parochial and Rural Interest,' published in 1848.

STANNARY COURTS. The jurisdiction of the Stannary Courts has been extended, and their procedure amended and improved by the statute 18 & 19 Vict. c. 32.

STARCH. [TISSUES, ORGANIC, *S.* 1.]

STATUTE OF FRAUDS. The enactments of this statute have been extended by the Mercantile Law Amendment Act, 1856, and the law as to guarantees considerably improved. The alterations thus effected are, however, so entirely technical that the reader can only be referred to them.

STATUTE OF LIMITATIONS. The Mercantile Law Amendment Act, 1856, has removed some of the anomalies which have arisen upon these statutes, but any explanation of the different provisions of this Act would be too technical in its nature, and require too much space to be given here. It may be enough to state, that the general effect of all the enactments of the statute is to remove certain nice legal distinctions and difficulties, which formerly in many cases served only to defeat the ends of justice.

STEFFENS, HEINRICH, was born at Stavanger in Norway on May 2, 1773. His parents removed in 1779 to Helsingör, where he received his early education, and in 1787 he was taken to Copenhagen, as his early-displayed piety and eloquence seemed to point out divinity as his proper study, though he had already acquired a great fondness for natural history. In 1790 he was entered at the University of Copenhagen, where he so distinguished himself that he received in 1794 a travelling prize. He spent the summer of that year at Bergen in Norway, and in the autumn while proceeding to Germany he suffered shipwreck at the mouth of the Elbe, saving only his life, and that with difficulty. After residing about a year in Hamburg, he removed to Kiel, where in 1796 he gave lectures in natural history, and acted as private tutor. He however felt a want of a fundamental principle in natural science, and, repairing to Jena, imagined that he found in the theories of Schelling what he needed. He was intrusted with the revision of Schelling's writings on natural philosophy in 1800, and became one of the warmest supporters of the doctrines of Schelling's school (then in its most flourishing state), at least so far as they were restricted to natural philosophy. After having been created adjunct to the professor of philosophy in the University of Jena, he repaired to Freiberg, where he was instructed by and acquired the friendship of Werner. While here he wrote his 'Geognostisch-Geologischen Aufsätze' (' Geognostic-Geological

Essays'), not published till 1810, which he expanded in 1811-19 into three volumes of a 'Handbuch der Oryktognosie.' On returning to Denmark in 1802, he excited considerable attention by his lectures; but as he experienced some coldness from influential persons, he accepted in 1804 a call from the University of Halle to become professor there, and while there published (in 1806) his 'Grundzüge der philosophischen Naturwissenschaft' ('Fundamental Features of Philosophical Natural Science'). The years 1807-9 he spent with his friends in Holstein. He then returned to Halle, and took an extremely active part, not unattended with danger, in the secret preparations of the Prussian patriots to cast off the French yoke, which they felt to be alike burdensome and disgraceful. When the time for action arrived, Steffens joined the Prussian forces as a volunteer, and by his enthusiastic addresses roused and supported the energy of his comrades, with whom he continued till the entry into Paris in 1813. After this he returned to Breslau, where he had been created professor of physics and of natural history. These offices he held till 1831, when he removed in a similar capacity to the University of Berlin, in which city he died on February 13, 1845. While in Breslau he wrote, in connection with what may be called his professional pursuits, his 'Anthropologie,' published in 1822, in which he strove to elucidate on philosophical principles the existence of mankind in connection with the universe. This subject he continued in his 'Polemische Blättern zur Beförderung der speculativen Physik' ('Polemical Leaves for the advancement of Speculative Physics'), in two parts, issued in 1825 and 1835; but these works rather represent the philosophy of the Schelling school than add to our knowledge by any new facts. The intellectual activity and mental riches of Steffens however were not confined to one branch of knowledge, and he frequently and successfully appealed to the present thoughts and feelings of his fellow-countrymen. To this description of works belong his essay 'Ueber die Idee der Universitäten' ('On the Ideas of the Universities'), 1809; 'Die gegenwärtige Zeit, und wie sie geworden' ('The present Time, and how it became'), 1817; and 'Ueber geheime Verbindungen auf Universitäten' ('On the secret Societies of the Universities'), in 1835. His disinclination also to the attempted church union in Prussia rendered him at first the leader of a considerable number of dissenters from that union, and at length involved him in many controversies, which ultimately occasioned the production of his work 'Von der falschen Theologie und dem wahren Glauben' ('On the false Theology and the true Faith'), in 1824, of which more than one edition has been called for. In 1831 he published 'Wie ich wieder Lutheraner wurdé und was mir das Lutherthum ist' ('How I became again a Lutheran, and what Lutheranism is to me'), which is a personal confession of faith, certainly of the Pietist class, but it is of a far higher character of thought than that of most of the works of that sect, and appears to be the result of an inward struggle against the modern system of absolutism, which principle he defines as a positive surrender of the belief in the personality of the Deity. In 1827 also he struck into a new line: he began a series of novels, of which the first 'Die Familien Walseth und Leith,' in three volumes, was followed in 1828 by 'Die vier Norweger,' in six volumes, and that by 'Malcolm' in two. These novels contain many references to himself both in the incidents and opinions, but they also contain well-defined pictures of the peculiarities of national character, narratives of the historical events of the period, with lively and correct descriptions of scenery, especially that of his native country in 'The Four Norwegians,' and all are penetrated with a deep-lying religious feeling, which give them a peculiar character. In the last years of his life he occupied himself with writing a detailed autobiography, 'Was ich erlebte,' published in ten volumes, from 1840 to 1845. It is perhaps too minute, but contains many interesting facts, and a fragment of it has been translated into English under the title of 'Adventures on the Road to Paris,' an account of the advance of the allied armies in 1813. Since his death some posthumous works have been published, 'Nachgelassene Schriften,' with a preface by Schelling.

STELLITE. [ZEOLITES.]

STEPHENS, JAMES FRANCIS, a distinguished British entomologist, was born at Shoreham, Sussex, on the 16th of September 1792. He was for many years a clerk in the Admiralty Office in Somerset House. Whilst holding this position he devoted his leisure hours to the study of natural history, and was a remarkable example of the knowledge that may be gained by the cultivation of the small portion of time allotted for rest in a government office. In the course of a long life he made one of the most complete collections of British insects extant. This collection was the admiration of foreigners and the constant resort of the British entomologist. Mr. Stephens's taste for entomology led early to his employment in the British Museum, where he assisted Dr. Leach in commencing the present collection of insects in that institution. The literature of entomology is largely indebted for his contributions. In 1829 he commenced the publication of his 'Illustrations of British Entomology,' which was produced in parts and completed in 10 vols. This is one of the largest and most comprehensive works on British entomology, and must secure for its author a lasting name amongst the cultivators of the natural history of his own country. In addition to this splendid work, he published several papers on entomological subjects, which appeared in the 'Transactions of the Entomological Society.' He also was engaged at the time of his death in writing a catalogue of the British *Lepidoptera* in the collections of the British Museum. He also published separately 'The Systematic Catalogue of British Insects,' and 'A Manual of the British Coleoptera.' Although distinguished as an entomologist, he took an interest in all branches of natural history, and was the author of a continuation of Shaw's 'Zoology' comprising an account of the Birds, published in 1827. He was a fellow of the Linnæan Society, and president of the Entomological Society. He died on the 22nd of December 1852, at his house in Kennington, after a few days' illness, of inflammation of the lungs.

STEPHENSON, GEORGE, the inventor of the locomotive steam-engine, was the son of Robert Stephenson and Mabel Carr, and was born June 9th, 1781, at Wylam, a village in Northumberland, where his father was employed as fireman at a colliery; he afterwards removed to Dewley Burn in the same county, where George's first employment was to herd cows, occupying his leisure in modelling clay engines, and even constructing a miniature windmill. He soon began to be employed about the colliery, during which time he displayed a great affection for birds and animals, particularly rabbits, of which he acquired the reputation of having a fine breed. At fourteen years of age he was appointed assistant-fireman to his father, who soon after removed to another colliery at Jolly's Close, where George, then only fifteen, was engaged as fireman to an engine in the neighbourhood. Ambitious of becoming an efficient workman, he strove to attain a thorough knowledge of the engine, and he succeeded so well that at seventeen he was promoted to be a 'plugman,' whose duty it was to see that the engine was in proper working condition, and that the pumps drew water effectually; repairing such accidental defects as might occur. To do this well required an intimate knowledge of construction, and at his leisure hours he would take the machinery to pieces, that he might the better understand it. His father, who had six children, of whom George was the second, had been unable to give them any education, though by example a sound foundation of good principles and morals had been laid, and at eighteen, whilst employed for twelve hours a day in his labours, and earning only twelve shillings a week, George Stephenson commenced a course of self-culture. He attended a small night-school at Walbottle, where in a year he learnt to read, and to write his own name, for which instruction he paid threepence a week. He next, in 1799, placed himself under a Scotchman named Robertson, at Newburn, who for fourpence a week taught him arithmetic, which he acquired with remarkable facility. At twenty he had been advanced to the superior office of brakesman, with increased wages, to which he added, in his leisure hours, by learning to make and mend shoes. At that time he was a big raw-boned fellow, fond of displaying his strength and activity at the village feasts, but remarkable for his temperance, sobriety, industry, and good-temper, yet on one occasion he fought a bully who would have oppressed him, and his victory on that occasion secured him ever after from a repetition of the offence.

When by the most rigid economy Stephenson had saved sufficient money to furnish a small home, he determined to settle, and on the 28th of November 1802 he married Fanny Henderson, with whom he removed to Willington, where he had been appointed brakesman to the engine employed for lifting the ballast brought by the return collier ships to Newcastle. In his new abode at the Ballast Hills, he continued to occupy himself with mechanical experiments, expending much time and great ingenuity in a fruitless effort to obtain perpetual motion; until an accident having obliged him to repair his own clock, he became the general clock-cleaner and mender for the neighbourhood, thus improving his own mechanical skill whilst adding to his income. On the 16th of December 1803 his only child Robert was born, and soon after he removed to Killingworth, where his wife died. In 1804 he was engaged to superintend the working of one of Boulton and Watt's engines at Montrose; but after continuing there a year—during which time he saved about 28*l.*, a considerable sum in his circumstances, and during a period of war-prices of provisions—he returned to Killingworth to find his father in extreme distress, having been accidentally scalded and blinded by a discharge of steam, let in upon him while repairing an engine. Stephenson paid his father's debts at the expense of more than half his savings, and settled his parents in a cottage, where they lived during many years entirely supported by him. He was immediately re-engaged in his old position at Killingworth, but being drawn for the militia, the obtaining a substitute absorbed the remainder of the produce of his economy, and he seriously contemplated emigrating to America, whither his wife's sister and her husband went; but he could not raise money enough to accompany them. He therefore continued his various labours, attending the engine, mending clocks, making and mending shoes, and studying mechanics. His acquired knowledge and mechanical skill enabled him to suggest improvements to his employers, and in 1810 a new engine in the neighbourhood having failed in its work, Stephenson was called in to mend it, which he did most effectually. He received for this job a present of 10*l.*, and was promoted to the post of engineman at good wages. Whilst thus engaged he formed an intimacy with a farmer named Wigham, at Long Benton, whose son John proved of great assistance to him, by increasing his acquaintance with arithmetic, and with some of the principles of mechanics and chemistry; and in 1812 his merit was so far recognised that he was appointed engineer of the colliery, at a salary of 100*l.* a year. He was now elevated above the rank of a mere artisan, but he was not less busy. He projected and carried out many improvements, and among others constructed at the coal-loading place at Willington, the first self-acting incline used in that district, by which the descending laden waggons on the tram-road were made to draw up the empty waggons.

The most important epoch of Stephenson's life was now approaching. Many attempts had been made to construct a locomotive steam-engine, and some had attained a certain degree of success, but none had succeeded in uniting economy with efficiency. Mr. Stephenson carefully examined all within his reach, and at length declared his conviction that he could make a better than any yet produced. He communicated his proposal to his employers: one of them was Lord Ravensworth, who, after giving him a patient hearing, commissioned him to make a trial of his skill. His object at first was only to make an engine for the colliery tramways, but even thus early he told his friends "that there was no limit to the speed of such an engine, if the works could be made to stand it." The difficulties he encountered were great; the engine was built in the workshops at West Moor, Killingworth; the chief workman was the colliery blacksmith, tools had to be made, and everything rested upon the designer of the machine. In ten months it was completed, and on July 25, 1814, it was placed on the railway, and was decidedly successful, drawing eight loaded carriages, weighing thirty tons, at the rate of four miles an hour. It was however a cumbrous affair, and he speedily saw in how many parts it could be improved. Accordingly, in February 1815, he took out a patent for a locomotive, and in the same year constructed an engine, which (with certain mechanical improvements, that, though conceived by him to be necessary, could not be supplied by the manufactories at that time,) may be considered as the model of all that have been since produced.

From Mr. Stephenson's connection with collieries he could scarcely avoid having his attention painfully excited, by the frequent explosions arising from fire-damp, and in 1814 one of the collieries under his care having taken fire, he, at great risk of his life, and with the assistance of the workmen, who trusted to his knowledge and skill, succeeded in extinguishing it by bricking up the passage where the foul air was accumulated. The constant danger from the use of exposed candles in coal-mines was so well known, that many inventors had attempted to produce lamps to meet the difficulty; and as early as 1813 a safety-lamp was invented by Dr. Clanny, but it was found to be unmanageable. Sir Humphry Davy was invited to attempt something; for which purpose he visited Newcastle in August 1815, and on November 9 of that year he read a paper on the construction of his lamp before the Royal Society of London. Mr. Stephenson was at the same time occupied on the same subject. In August he made a drawing for a lamp, which on October 21, 1815, had been made and tested; a second and a third were made, for the purpose of increasing the amount of light; and on November 30, of that year, before he could by any possibility have heard of Davy's invention, his third lamp was finished and tried in Killingworth pit, where it was found thoroughly effective, and has ever since been in use. A controversy has arisen, into which we shall not enter, as to priority of invention. There is, however, every reason to believe that Stephenson invented his lamp long before and had tried it a few days previous to Davy having announced his discovery; and the natural conclusion is, that, urged by the want of a safety-lamp, and reasoning from the same facts, the inventors arrived at the results independently of each other; for the two lamps, although different in construction, are founded upon identical principles, but arrived at by different trains of thought.

We cannot attempt to trace all the improvements in details which Mr. Stephenson introduced in the locomotive, but he very early perceived that, for its proper working, the railway required equal attention, and that a firm bed and a regular level were essential requisites. Very little attention had hitherto been paid to this, and the tramroads were carelessly laid out and not kept in good repair. In 1816 therefore he took out a patent for an improved form of rail and chair, and for further improvements in the locomotive engine, one of which was placing it on springs, and they were attended with marked success.

The construction of railroads had for some time occupied much of the public attention. In 1819 the owners of Hetton Colliery, desiring to turn their tramroad into a railway, employed Mr. Stephenson in its construction. The length was about eight miles, and being over a hilly country, he took advantage of the heights to form self-acting inclines, the locomotive working on the level part; and on the 18th of November 1822 it was opened for traffic. He was next employed to construct the Stockton and Darlington line, for which an act of parliament was obtained by Mr. Pease in 1820, to be worked "with men and horses, or otherwise." The proprietors had agreed, on his recommendation, to make the line as a railroad and not as a tramroad, with stationary engines for the steep gradients, but horse-power was to be used for the levels, for Mr. Stephenson's confident anticipations of the success of his locomotive engines were still regarded with suspicion. He began the work in May 1822, but in 1823 an amended Act being procured for working the line with locomotives, Mr. Stephenson was appointed resident engineer at a salary of 300*l.* per annum, and upon that appointment he removed to Darlington. The line was opened in September, 1825, and an engine driven by Mr. Stephenson himself drew a load of ninety tons at the rate of upwards of eight miles an hour. It proved highly remunerative, for besides a far larger amount of goods traffic than had been calculated on, a passenger traffic arose that had been wholly unthought of; the passengers however were for a time conveyed in carriages drawn by a horse at a speed of ten miles an hour. It may be mentioned, that this railway has created the town and port of Middlesborough-on-Tees, then the site of a farm, but now containing 15,000 inhabitants.

In 1824, while the Darlington line was in progress, Mr. Stephenson, feeling the difficulty he had experienced in constructing his engines in a blacksmith's shop, proposed to Mr. Pease of Darlington, his firm friend and great patron, the establishment of an engine-factory at Newcastle. The proposal was adopted, and for a considerable time it was the only manufactory for locomotives in the kingdom. It is now increased to an enormous extent, and has been the training-school, whence has issued a vast number of skilled workmen and eminent practical engineers.

In 1824 the project of a railway or tramroad between Liverpool and Manchester began to be agitated. Increased facility of communication was imperatively required, but there was much controversy as to the means. At length a railway was decided on, Mr. Stephenson was employed to conduct the survey, and application was made to Parliament for an Act. A strong opposition was raised both within the House of Commons and without. Landowners drove the engineers off their grounds, and before the Committee the most absurd objections were urged against the whole scheme, the idea of any quick transit being a subject for especial ridicule. The Bill was however carried on a second application, and Mr. Stephenson was appointed principal engineer. The work was commenced in June 1826, and after struggling through many difficulties—one, and not the least, being the carrying the railway over Chat Moss—it was opened on Sept. 15, 1830. During its progress eminent engineers had reported against locomotives being worked on the line, recommending horse-traction; but at length Mr. Stephenson prevailed on the Directors to offer a prize for a locomotive engine, conforming to certain conditions, which was done, and the prize of 500*l.* was won by the Rocket engine, in the construction of which he had availed himself of the assistance of his son Robert.

From this moment his fortune was made. Employment of a most remunerative character poured in from all sides. Railways were projected in every direction, and he became the chief engineer of several of them. With these he was incessantly engaged till 1840, when he resigned most of them, and settled at Tapton in Derbyshire, where he commenced a fresh pursuit in working the Clay Cross collieries. At this time he took much interest in the well-doing of the Mechanics' Institutes in his neighbourhood, and on more than one occasion related to them the circumstances of his own career, as an encouragement to the members to adopt a course of steady and persevering industry. His interest in railway extension however continued unabated, and he took an active part, either as engineer, chairman, or shareholder, in the Whitehaven and Maryport, the Yarmouth and Norwich, and the Newcastle and Edinburgh East Coast Line, with which the stupendous work of the High Level Bridge at Newcastle (designed by his son), is connected; he was one of the committee of management, but he did not live to see it completed. He was also employed in Belgium, and he travelled into Spain to inspect a proposed line from the Pyrenees to Madrid, but the project was fruitless. On his return from Spain in 1845 he relinquished still more his attention to railway matters, and occupied himself almost entirely with his collieries and lime-works, with the cultivation of his farm and gardens, and indulged in his old fancy for keeping birds and animals. With the exception of promoting the Ambergate and Manchester Railway, inventing a new self-acting break, of attending the ceremony of opening the Trent Valley Railway (when Sir Robert Peel made a speech complimentary to him), and of being considerably troubled by applications for assistance and advice from projectors and inventors of all kinds, to whom however he was invariably attentive and kind, he passed the remainder of his days in ease and peace. He, however, continued to take great interest in the Institution of Mechanical Engineers of Birmingham, which he had founded, and was President of. He died after a short illness on August 12, 1848, leaving a name rendered illustrious by the patient perseverance of a high-minded industry, and the widely-developed productions of a remarkable genius. A valuable biography of this eminent man has been written by Mr. S. Smiles, to which we are indebted for many of the facts in this notice.

STEREOSCOPE, from στερεός (solid) and σκοπος (a view, or σκοπεω to view), an instrument by which two pictures of any object, taken from different points of view, are seen as a single picture of that object, having the natural appearance of relief or solidity.

The fact that we see with two eyes, yet that only a single representation of the object is presented to the mind, must of course have very early forced itself on the consideration of men of attentive and reflective habits. And it could not fail to be observed that the appearance which an object—a statue or a vase for instance—presents when looked at steadily, and with only one eye, is different from that which it presents if it be then looked at, without changing the position or moving the head, by the other eye alone. Accordingly we find in some of the earlier as well as the later Greek writers on natural philosophy, references more or less full and direct to the subject, and speculations as to the cause. Euclid showed by means of a sphere that each eye sees a dissimilar representation of an object; and Galen some centuries later endeavoured to explain the matter, by stating that the dissimilar pictures are not seen at the same instant but successively, and that these rapidly succeeding pictures produce on the mind the impression which is conceived of the object. At the end of the 15th century, Lionardo da Vinci, and in the 16th and following centuries, Baptista Porta and Aguilonius wrote on the subject of vision as produced by dissimilar pictures seen by each eye; but down to our own time natural philosophers have been almost universally content to adopt the opinion that we see with only one eye at a time. The whole question of vision by one and by two eyes, or of monocular and binocular vision, was re-opened by Mr. Wheatstone—to whom the world is indebted for the application of electricity to telegraphic purposes—in a paper entitled 'Contributions to the Physiology of Vision: Part I. On some Remarkable and hitherto Unobserved Phenomena of Binocular Vision,' read before the Royal Society, June 21st, 1838, and again, before the British Association at Newcastle, in the following August, and printed in the 'Philosophical Transactions' a few months later.

In this paper Mr. Wheatstone argued that the appearance of relief and solidity which we obtain in looking at objects in nature, arises from there being a dissimilar picture of the object projected simultaneously on the retina of each eye, the optic axes of which are not parallel; whereas in viewing a pictorial representation two similar pictures are projected on the retinæ, and hence the resultant flatness. It is not necessary to enter further upon his views, nor upon the theory of vision generally, as the subject has already been treated of fully under the head SIGHT, vol. xxi., p. 504-6. Mr. Wheatstone sought to elucidate and confirm his theory by an ingenious instrument which he exhibited when he read his paper, and which he called the Stereoscope. This instrument, now known as the Reflecting Stereoscope, consists of two plane mirrors, fixed with their backs to each other at an angle of 90 degrees. These mirrors (or polished glass prisms) are supported on a central stand, which is fixed in a mahogany frame, and two arms, which slide on the frame, support the two pictures (which have been taken from dissimilar points of view) in the same horizontal line, parallel to each other and at equal distances, one on each side of the mirrors. The observer, by placing his eyes as close as he can to the mirrors, the angle of which must coincide with the middle line of his face and forehead, sees the two dissimilar pictures united, so as to give the appearance of the object represented, not as it is seen depicted on a plane surface, but with all the solidity of the object itself. The reflecting stereoscope excited great interest among scientific men when first exhibited, but the pictures prepared for it were almost exclusively dissimilar outlines of various geometrical solids—photography not being then in existence—and by those who did not employ it for a purely scientific purpose it soon came to be regarded as merely an ingenious and somewhat cumbrous as well as expensive optical toy. For most purposes it has been superseded by the more convenient refracting stereoscope; but it possesses some advantages, among others that of exhibiting photographs of any size.

For the Refracting Stereoscope we are indebted to the inventor of another very beautiful contrivance, the Kaleidoscope [KALEIDOSCOPE, *S.* 1, p. 133]. Sir David Brewster having taken certain objections to the theory of Mr. Wheatstone, prosecuted an elaborate series of experiments with a view to the establishment of what he regarded as the more correct theory of binocular vision; and some of these experiments led him to construct the instrument which, in the form it ultimately assumed, he called the Lenticular Stereoscope. He early exhibited his instrument in his classes at St. Andrew's but he first fully explained his views on binocular vision, and made public his invention, in a paper 'On the Law of Visible Position in Single and Binocular Vision, and on the Representation of Solid Figures by the union of Dissimilar Plane Figures on the Retinæ,' which he communicated to the Royal Society of Edinburgh in January 1843. He further explained and defended his views in many subsequent papers, which, like the former, appeared in the 'Edinburgh Transactions' of that and following years. Of these very valuable contributions to the science of optics it is unnecessary to speak further here, and into the controversy which arose between the author and Mr. Wheatstone on their theories of binocular vision, and their respective claims as the inventors of the stereoscope, we shall not enter: the opinions of Sir David Brewster, in their matured and digested form, will be found amply set forth in his work 'The Stereoscope,' (8vo, 1856); those of Mr. Wheatstone must be sought in the paper already referred to, and in another which formed the Bakerian Lecture of the Royal Society for 1852, being 'Part II. of Contributions to the Physiology of Vision, and on Binocular Vision.'

The Lenticular Stereoscope of Sir David Brewster, as described by himself, "consists of a pyramidal box of wood or metal, or any other opaque material, blackened on the inside, and having a lid for the admission of light when the pictures are opaque. The box is open below, in order to let the light pass through the pictures when they are transparent. Another lid is sometimes added, so as to open externally on the bottom of the box, for the purpose of exhibiting dissolving views in the stereoscope. The bottom of the box is generally covered with ground-glass, the surface of which ought to be very fine, or very fine-grained paper may be used. The top of the box consists of two portions, in one of which is the right eye-tube containing a semi-lens, or quarter-lens, and in the other the left eye-tube, also containing a semi-lens or quarter-lens. These two portions may be advantageously made to approach or recede, in order to suit eyes at different distances from one another; and the tubes containing the lenses should draw out, in order to suit long and short-sighted eyes." The two dissimilar pictures (which for convenience are mounted on a thick card, forming the universally known 'slide') are placed in a groove in the bottom of the box, when, on looking through the eye-tubes, they are seen united into a single picture, and the object or objects, if a proper amount of light is obtained, stand out with an almost magical appearance of relief and solidity. The employment of photography for the stereographs has wonderfully extended the range of the instrument, and now, what might have been confined to the study of the natural philosopher as an extremely ingenious piece of scientific apparatus, or have found a somewhat larger though less important circle of admirers as an elegant toy, has become one of the most widely known and universally popular means of social amusement, and, rightly used, an extremely valuable means of instruction.

In describing the instrument, it was said that each of the eye-pieces contained a semi-lens. It is by means of these semi-lenses that the stereoscopic effect is produced, though they do not themselves produce that effect. What they accomplish is the transference of the two dissimilar pictures or stereographs to a middle point. The union of these two pictures, or their superposition on that middle point, produces the stereoscopic effect. The semi-lenses are the two halves of a convex lens, so placed that the edge or thin part of each is turned inwards—the opposite direction that is, to that which it held in its original position. How this acts may be understood by a very simple experiment. If any small object as a coin or medal be laid on a piece of white paper and looked at with the right eye only, through a convex lens, the right half of which is covered by an opaque substance, the coin will be seen some distance on the left of its true position—supposing, that is, that the eye be held close to the lens, and the proper focal distance be chosen. On turning the lens so that the left half is covered, and looking through the uncovered half with the left eye only, the coin will appear a like distance on the right side of its true position. Just so the half lenses in the eye pieces of the stereoscope—which are placed $2\frac{1}{2}$ inches apart, corresponding to the distance between the eyes—make the two pictures in the instrument to approach and become superimposed on each other. But as the pictures are slightly dissimilar, having been taken from points of view correspondent to those of the right and the left eye respectively—and as, consequently, that portion of the right side of all solid objects which the right eye sees is represented in one picture, and that portion of the left side which the left eye sees, in the other, as well as the front which is common to both eyes, it follows that when these pictures are superimposed, the resultant single picture includes all that each eye sees, and therefore has all the apparent roundness, solidity, and relief which the original presented when looked at with both eyes: an effect aided it must be confessed by the isolation of the pictures in the chamber of the stereoscope. Various modifications have been made in the instrument—as the employment of larger lenses, the changing its frame from a pyramidal to an oblong form, &c.—but the principle is the same in all, and some of the changes are certainly not improvements.

From what has been said, an attentive reader will have no doubt drawn the inference that the truthfulness of the stereoscopic picture must depend mainly on the character of the dissimilar pictures or stereographs. This is most certainly the case, though too often overlooked or insufficiently regarded by those who take stereoscopic pictures. Stereographic portraits are usually taken with cameras contrived for the purpose. In order to take stereographs of landscapes, buildings, statuary, &c., the ordinary landscape camera is employed; the camera being removed, after the first picture is taken, to a position parallel to that just occupied, and at an equal distance from the principal object, but more or less distant from the first position in proportion to the distance from the object to be represented. The stereoscopic angle, as it is called, has been laid down by high authority at 1 in 25 for objects 50 feet or more distant, some have even recommended that the camera should be removed to a distance of 4 feet, in order to take views of an object only 20 feet distance. But the effect of such an arrangement is obviously to make one picture represent much more of the right side, the other more of the left side of an object falling within the field of vision, than could be seen by a person standing, say midway, between the two positions. And the two pictures so taken must, when united in the stereoscope, present an exaggerated and therefore untrue representation. In fact there will be, what is so commonly seen in the stereoscope, an unnatural appearance of separation between the chief object and the accessories. You see round the figure in fact, just as in life you see round a statuette or small model, and hence there arises that detached model-like appearance which is often, and very properly, objected to stereoscopic representations. What the stereoscope ought to show is, the representation of an object or objects in nearly the same relative solidity, relief, and separation as the reality possesses; and that is what the stereoscope would exhibit if the stereographs were taken, as they ought to be, and as the most successful (though not the most popular) are taken, from positions little if at all exceeding that of the eyes apart. The great importance of strict accuracy in views of countries beyond the reach of the ordinary traveller, of antiquities, objects of special scientific interest, &c., will be at once acknowledged; and the value of the stereoscope for affording such representations in their greatest attainable perfection is daily becoming more apparent. It will be enough to allude, as illustrating this, to the recently published views in Egypt, in which the antiquities and the scenery of that country are almost literally brought home to those who cannot go to them; and to the very remarkable series of stereographs of the Peak of Teneriffe, published by Mr. Piazzi Smyth, in his recent work, 'Teneriffe, an Astronomer's Experiment,' which gives us almost the very cone itself, in some of its most striking and characteristic phases, to gaze upon and to study.

STERLING, JOHN, was born at Kaimes Castle, in the island of Bute, Scotland, on the 20th of July 1806. Both his parents were Irish by birth, though of Scottish descent; and his father, Edward Sterling (afterwards well known as a leading writer in, and editor of, the 'Times' newspaper, but then pursuing the occupation of a gentleman-farmer, after having been educated for the Irish bar, and having served for some time as a captain in the army) had rented Kaimes Castle a short time before his son's birth. John was the second child of seven, five of whom died while he was still a youth, leaving only himself and an elder brother. In 1809, the family removed to Llanblethian, in Glamorganshire, Wales; and here John Sterling received his first school-education. His father about this time began to contribute to the 'Times' as an occasional correspondent; and the interest he thus took in politics, led him, on the peace of 1814, to remove again with his family to Paris. Driven from Paris by the return of Napoleon from Elba, and the resumption of the war, the family in 1815 settled in London, where gradually the father rose to his eminent position in the world of politics and journalism. He was destined to outlive his son.

After having been at various schools in or near London, Sterling was sent to the University of Glasgow; whence, after a brief stay, he was removed in 1824 to Trinity College, Cambridge. Here Julius Hare, afterwards Archdeacon of Lewes, was his tutor, and here he formed the acquaintance of various young men afterwards distinguished, including Frederick Maurice, Richard Trench, Spedding, J. M. Kemble, Venables, Charles Buller, and Monckton Milnes. In the Union Debating Club of Cambridge, of which these and others were members, Sterling was one of the chief speakers; and it was here perhaps that he first exhibited the qualities of intellect and character which made him afterwards socially celebrated. From Trinity College, Sterling removed, along with his friend Maurice, to Trinity Hall, with an intention of studying law; but in 1827 he left Cambridge altogether.

without taking his degree. In 1828 the 'Athenæum,' then recently started by Mr. Silk Buckingham, was purchased by Sterling, or at his instance, and he and Maurice conducted it and wrote in it for some time. The speculation however in their hands did not answer commercially, and the journal was sold to its present proprietor. Sterling, to whom it was not absolutely necessary that he should engage in any employment for his living, continued to reside in London, the centre of a circle of ardent and thoughtful young men, including not only his college friends, but such additions as John Stuart Mill. An eager radicalism of opinion was then Sterling's characteristic. It was about the year 1828 that he first became acquainted with Coleridge, then living his recluse life at Highgate; and Coleridge's influence on Sterling was great and enduring. It was evident in a three volume novel, entitled 'Arthur Coningsby,' which he wrote in 1829-30, but which was not published till a year or two later. In November 1830 he married; and shortly after, being in ill-health, he and his wife went to the West India island of St. Vincent, where a valuable sugar estate had been bequeathed to him, his elder brother, and a cousin, by one of his mother's uncles. He stayed about fifteen months in St. Vincent, returning to England in August 1832. In the spring of 1833 his novel was published, but obtained little recognition except among the few. Chancing in that year to meet again his tutor, the Rev. Julius Hare, at Bonn, the effect of their conversation on Sterling's mind, then vibrating under the prior influence of Coleridge, was that he resolved to take holy orders in the English Church. He was ordained deacon at Chichester, on Trinity Sunday, 1834, and immediately became curate of Hurstmonceaux in Sussex, where his friend was rector.

Sterling retained his curacy only eight months, resigning it in February 1835, on account of delicate health. It is not improbable that at the same time there was a change, or a tendency to change, in his opinions. From this time, at all events, there was a gradual divergence in his views from the fixed creed of the Church of England, though his relations to many of its most excellent members continued to be as intimate and affectionate as ever. It was in 1835 that he first became acquainted with Mr. Carlyle, then recently settled in London; and it seems evident that gradually the influence of Mr. Carlyle modified the results of that of Coleridge. "Coleridge," says Mr. Carlyle himself, in his memoir of Sterling, "was now dead, not long since; nor was his name henceforth much heard in Sterling's circle; though, on occasion, for a year or two to come, he would still assert his transcendant admiration, especially if Maurice were by to help. But he was getting into German, into various inquiries and sources of knowledge new to him, and his admirations and notions on many things were silently and rapidly modifying themselves." Literature was thenceforward Sterling's chief occupation; though, from all the accounts that remain of him, what he accomplished and has left behind him in literature gives but a faint idea of the influence he exerted in intellectual society, and especially in that of London, by his frankness and powers of talk. Very few men had so many friends or was so loved by them. It was unfortunate for them and him that his extremely precarious health caused him every now and then to absent himsel ffrom London and seek a warmer climate. In 1836 he went to the south of France; and in the following year he went to Madeira. While at Madeira he wrote much, and sent some contributions, in prose and verse, to 'Blackwood's Magazine.' In the spring of 1838 he returned to England, and for a time he resided on the southern sea coast, making frequent visits to London. He began to write for the 'Westminster Review,' then under the charge of Mr. John Stuart Mill; he was also busy privately with various compositions in prose and verse. It was at this time too that, in order to secure Sterling's meeting with as many of his friends as possible on his flying visits to London, the famous so-called "Sterling Club" was formed. A list of the members of this club is given in Mr. Carlyle's 'Life of Sterling,' at page 208.

Part of the years 1838 and 1839 were spent by Sterling in Italy; and on his return he took up his abode in Clifton. It was while residing here that he published under the general title of 'Poems, by John Sterling' (Moxon, 1839), a collection of his metrical effusions up to that time. The two next years were spent in migrations from place to place, including a second visit to Madeira, on account of health. In 1841, while living at Falmouth, he published 'The Election: a Poem, in Seven Books'—a poem of English life and society. He was then engaged on what he intended to be his best work—'Strafford, a Tragedy,' which however was not published till 1843. This year, 1843 (he had again been absent in Italy in the interim), was one of calamity to him and his. His wife died in April, and his own always feeble health was rendered more precarious than ever by the accidental bursting of a blood-vessel. Sterling retired to Ventnor in the Isle of Wight in June 1843, where his last labours were on a poem on the subject of 'Cœur de Lion,' still unpublished. Here he sank gradually, and on the 18th of September 1844, he died at the age of thirty-eight. A collection of his 'Essays and Tales' from the 'Athenæum,' 'Blackwood,' and other periodicals, was edited in two volumes, with a memoir prefixed, by Archdeacon Hare, in 1848; the well-known 'Life of Sterling' by Mr. Carlyle, representing the man less in his ecclesiastical than in his general human relations, appeared in 1851; and in the same year 'Twelve Letters by John Sterling' were edited by his relative Mr. Coningham of Brighton.

STERNBERGITE. [MINERALOGY, *S.* 1.]

STEVENSON, ROBERT, the celebrated engineer of the Bell Rock Lighthouse, was born at Glasgow on June 8, 1772. His education was conducted under the care of his mother (his father having died when he was young), and when completed he was placed with Mr. Thomas Smith, of Edinburgh, who had projected the mode of improving the illumination of lighthouses by the substitution of oil lamps with parabolic mirrors for the open coal-fires. When that gentleman was appointed engineer to the Northern Lighthouse Commissioners, Stevenson became his assistant; and when only nineteen had the superintendence of the construction of the lighthouse on the island of Little Cumbray, in the Frith of Clyde, between the southern point of the isle of Bute and Kilbride on the coast of Ayr. In 1797, having a short time previously succeeded Mr. Smith as engineer to the Northern Lighthouse Commissioners, he made his first tour of inspection, and afterwards introduced a still greater improvement in the illumination of lighthouses by means of the catoptric principle, and by adopting various means to distinguish one lighthouse from another. In 1807, an Act having been obtained in the previous year, he commenced the construction of the Bell Rock Lighthouse, on a rock in the North Sea, a few miles off Arbroath in Forfarshire, on which the light was exhibited for the first time on Feb. 1, 1811. The rock being extremely small, and almost entirely covered, even at low-water, except in spring-tides, offered great obstacles to the construction, but they were successfully overcome, and an account of the details of the erection and structure, illustrated with plates, was published at Edinburgh in 1824. A controversy has arisen as to the originality of Mr. Stevenson's plans, into which we cannot enter, but it is certain that much of the merit arises from the mechanical means adopted to secure a firm and enduring foundation, and this was undoubtedly done by Mr. Stevenson. In 1814, on another tour of inspection, Sir Walter Scott was a companion of the engineer and commissioners in the voyage, which afforded many materials for descriptions in Scott's poem of 'The Lord of the Isles,' and in the novel of 'The Pirate.' Mr. Stevenson held the situation of engineer till 1842, during which time he erected no fewer than 23 lighthouses. He was also employed in numerous engineering works in various parts of the United Kingdom, but chiefly in Scotland, in connection with the improvement of rivers and harbours, and the erection of piers and bridges, into which latter class of works he introduced some new principles of construction. He likewise surveyed a line of railway between Edinburgh and Glasgow, which, though not adopted, was admitted to be extremely clever. He was employed to report on other lines of railway, and he suggested the use of malleable iron rails instead of the cast-iron rails and tramplates previously in use. In 1828 he became a member of the Institution of Civil Engineers, and while he lived was looked upon as an authority of great weight on all questions connected with the improvements of ports, harbours, and rivers. He died on July 12, 1850, when the Commissioners of Northern Lighthouses passed a resolution acknowledging his great services and merits. He left sons, whom he had brought up to his own profession, who worthily sustain the reputation of their father.

STILBENE. [CHEMISTRY, *S.* 2.]

STILBITE. [ZEOLITES.]

STILPNOMELAN. [MINERALOGY, *S.* 1.]

STOCK-DOVE (*Columba Œnas*). [COLUMBIDÆ.]

STOCKS. [MATHIOLA.]

STOCKS, JOHN E., M.D., was born in 1822. He was educated for the medical profession at University College, London. Here he distinguished himself in his classes, and especially attached himself to the study of botany. He obtained an appointment in the East India Company's service, and soon distinguished himself for his acquaintance with plants. He was sent to Sinde and Beloochistan to report on their vegetable riches, and returned laden with specimens and information. He came back to England about the year 1854, intending to work up his numerous materials for publication. His health however failed him, and after having deposited his collections at Kew, he retired to Dottingham, near Hull, where he died in September 1854.

STOCKTON. [CALIFORNIA, S. 2.]

STODDART, SIR JOHN, KNIGHT, was born in 1773 in the parish of St. James's, Westminster, but his father, who was a lieutenant in the navy, residing in Wiltshire, he received his early education in the grammar-school at Salisbury under Dr. Skinner. His proficiency in Greek at this school occasioned his being sent to the University of Oxford, where he was entered at Christchurch College in 1790, and graduated as B.A. in 1794. He at first studied divinity, but feeling an inclination for the law he proceeded B.C.L. in 1798, and D.C.L. in 1801. In the meantime he had not neglected general literature, and in 1796 and 1798 he had published translations of Schiller's two dramas of 'Fiesco' and 'Don Carlos,' in conjunction with Dr. Noehden, but to which only their initials appeared on the title-page. At this period he took a favourable view of the French revolution, and in 1797 published a translation from the French, entitled, 'The Five Men; or a View of the Proceedings and Principles of the Executive Directory of France, with the Lives of the present Members.' In 1801 he was admitted a member of the College of Advocates, and published 'Remarks on Local Scenery and Manners in Scotland, during the years 1799 and 1800,' in 2 vols. 4to. In 1808, on the recommendation of Sir William Scott, he was appointed king's advocate and admiralty advocate in Malta, in which situation he remained nearly four years, when he returned to England, and resumed his practice in the courts of Doctors' Commons. In 1810 he commenced writing on political subjects in the 'Times' newspaper, his contributions being marked J. S., and this led to his becoming the political editor in 1812. His writings in this paper were distinguished by great energy, the possession of much varied knowledge, a clear style, with a power of fulmination, too often founded on mere prejudice, that occasioned his receiving the sobriquet of Dr. Slop, and as such he was burlesqued by George Cruikshank in the parodies and satires published by Hone. Dr. Stoddart is said to have taken Burke as his model, but he failed in reaching to any greater similarity than that arising from their dislike to the course taken by the French revolution, which, in the doctor's case, displayed itself in his rancorous denunciations of Bonaparte and his policy. He held this important post till the close of 1816, when, in consequence, it is said, of the disapproval of the proprietors of the continued violence of his attacks on the now imprisoned emperor, his connection with the 'Times' was dissolved, and in 1817 he started an opposition paper called 'The New Times.' It was unsuccessful, and in a short time he left it, retired to private life, and to his practice as an advocate. In 1826 he was appointed chief-justice and judge of the Vice-Admiralty Court of Malta, being knighted at the same time, and in that office he distinguished himself by the able and conscientious manner in which he discharged his duties, until his return to England in 1839. From that time till his death he led a private life, in which he was much and widely esteemed; but occasionally published pamphlets on legal subjects, and took considerable interest in the reform of the law, being one of the earliest members of the Law Amendment Society. He also wrote 'An Introduction to General History,' and a 'Universal Grammar; or Science of Language,' which were printed in the 'Encyclopædia Metropolitana,' but have likewise appeared as separate works. A 'Statistical, Administrative, and Commercial Chart of the United Kingdom, compiled from parliamentary and other authentic documents,' was another of his productions. He died at Brompton-square, near London, on February 16, 1856; and on the first meeting of the Law Amendment Society after his death, Lord Brougham pronounced a warm eulogium on his memory.

STRANGFORD, PERCY CLINTON SYDNEY SMYTHE, SIXTH VISCOUNT, was born in 1780, and graduated in 1800 at Trinity College, Dublin, obtaining the gold medal and other honorary distinctions. He entered the diplomatic service early. Before he was of age he had gained a high reputation by his contributions to the 'Poetic Register.' In 1801 he succeeded to his father's Irish peerage, and became secretary of legation at Lisbon. Here his love of language and poetry led him to master the Portuguese language, and to translate the poems of Camoens, to which he prefixed the life of that poet. This translation is highly praised by both Lord Byron and Thomas Moore, and attained considerable popularity, several editions having been called for. He became afterwards British envoy at Lisbon, and accompanied the court and royal family of Portugal to Brazil. In 1817 he became ambassador at Stockholm, from whence he was transferred in 1820 to the Sublime Porte, and to St. Petersburg in 1825. In 1828 he was sent on a special mission to the Brazils. He was created a D.C.L. of Oxford in 1834, at the installation of the Duke of Wellington, with whom he had been associated as co-plenipotentiary at the Congress of Verona. He was made in 1825 a Knight Grand Cross of the Hanoverian Guelphic Order, and raised to the peerage of England as Lord Penshurst. Lord Strangford was an ardent lover and patron of literature and the fine arts, an active member and vice-president of the Society of Antiquaries, and a frequent contributor, under the initials of P. C. S. S., to the 'Gentleman's Magazine' and 'Notes and Queries.' He was collecting materials for the biography of his ancestor Endymion Porter, to whom Milton has addressed a sonnet, when he was carried off by a short illness, May 29, 1855.

STRATFORD. [ESSEX.]

STRAWBERRY-TREE. [ARBUTUS.]

STREPTOSTACHYS. [GRAMINACEÆ.]

STRICKLAND, HUGH EDWIN, was the grandson of Sir George Strickland on his father's side, and of the celebrated Dr. Edmund Cartwright on his mother's side. He was born at Righton, in the East Riding of Yorkshire, on the 2nd of March 1811. After receiving a careful private education he was placed as a pupil with Dr. Arnold, then living at Laleham, previous to his appointment as head-master at Rugby. After leaving Laleham Mr. Strickland was entered at Oriel College, Oxford. Here the taste which he had acquired in the country for natural history became systematically directed towards geology under the teaching of Dr. Buckland. On leaving Oxford he went to reside with his father at Tewkesbury, and here he studied with great diligence the geology of the Cotswold Hills, and of the great valley of the Severn. Although distinguished as a naturalist, one of his earliest literary productions discovered a taste similar to that of his maternal grandfather. This contribution consisted of the description of a new wind-gauge in the 'Mechanic's Magazine,' for 1825. His papers on the geology of his native district were mostly published in the Proceedings and Transactions of the Geological Society, of which he was an early and active member. The following are the titles of some of these papers:—'Description of a Series of coloured Sections of the Cuttings on the Birmingham and Gloucester Railway.' 'On the Occurrence of the Bristol Bone Bed in the Lower Lias near Tewkesbury.' 'On certain Impressions on the Surface of the Lias Bone Bed in Gloucestershire.' 'Notes of a Section of Leckhampton Hill.' 'On the Elevatory Forces which raised the Malvern Hills.' 'Memoir of the Geology of the Vale of Evesham.' In conjunction with Sir Roderick Murchison he also worked at the geology of the district in which he lived. Thus in the fifth volume of the 'Geological Transactions' a conjoint paper appeared 'On the New Red Sandstone System in Gloucestershire, Worcestershire, and Warwickshire.' They also published a separate work, entitled 'Outline of the Geology of the neighbourhood of Cheltenham.'

In 1835, in company with Mr. Hamilton, he made a journey to Asia Minor. During his travels he made notes, generally on natural history, but more especially on the zoology of the districts through which he passed. In the 'Geological Transactions' he published the following papers, 'On the Geology of the Thracian Bosphorus.' 'On the Geology of the neighbourhood of Smyrna.' 'On the Geology of the Island of Zante.' 'On Currents of Sea-Water running into the Land in Cephalonia.' 'A general Sketch of the Geology of the Western Part of Asia Minor.'

On the failure of the health of Dr. Buckland, Mr. Strickland was appointed reader in geology in the University of Oxford. This post he held at the time of his death in 1853. As a zoologist Mr. Strickland was best known as an ornithologist. He was thoroughly acquainted with the birds inhabiting Great Britain, and gradually extended his knowledge of the forms of these animals. His papers on the classification and description of birds are very numerous. Amongst these the following were published in the 'Proceedings of the Zoological Society:' 'Descriptions of New Species of Birds from West Africa.' 'Notes on a certain Species of Birds from Malacca.' Many other papers on birds were published by him in the 'Annals and Magazine of Natural History,' in Jardine's 'Contributions to Ornithology,' and in other works.

Whilst at Oxford his attention had often been directed to the head and foot of the Dodo, the only existing remains of a bird that had ceased to exist within a comparatively recent period. These remains had occupied the attention of naturalists, and many conjectures had been made as to the exact nature of this bird. Mr. Strickland expended a large amount of time and labour in getting together all the facts that existed with regard to the history and disappearance of this bird [DODO, vol. ix. pp. 47-55], and published a volume on the subject, entitled 'The Dodo and its Kindred, or the History and Affinities of the Dodo, Solitaire, and other extinct Birds,' London, 4to, 1848. This work contained copies from drawings of this bird, and a discussion on its zoological affinities, and the conclusion of the author that it belonged to the family of *Columbidæ* or *Doves*. In the soundness of this conclusion most naturalists now agree. During his life Mr. Strickland was engaged in preparing a large work on the synonymy of the family of birds, one volume of which has been published since his death.

Mr. Strickland, during his geological studies, had his attention necessarily drawn to the family of Mollusca, and numerous papers on the recent and extinct forms of the Mollusca attest his knowledge of this department of natural history. With his great knowledge of the detailed facts of the natural history sciences it is not matter of surprise that he took a deep interest in classification. He proposed at one of the meetings of the British Association for the Advancement of Science the appointment of a committee for the purpose of reforming the nomenclature of natural history. He was the author of the report issued by this committee, and which has been extremely useful in establishing clear rules for the nomenclature of zoology.

He was one of the original founders and a member of the council of the Ray Society. He was mainly instrumental in inducing this society to undertake the publication of Professor Agassiz's 'Bibliographia Zoologiæ et Geologiæ.' This work he undertook to edit and see through the press, and had completed the third volume at the time of his decease. The original list of works in this book was increased by Mr. Strickland at least one third. His own publications, the list of which was published in the fourth volume and after his death, amounted to eighty-six. He was cut off in the midst of his labours and usefulness. He had been attending the meeting of the British Association for the Advancement of Science held in the year 1853 at Hull. He wished to inspect the cuttings of the Gainsborough and Retford Railway, and whilst thus engaged, note-book in hand, at the Clarborough Tunnel, on that line, he was run over by a passenger train, and killed on the spot, September 14, 1853. He was married in 1845 to the second daughter of Sir William Jardine, Bart., but left no children.

STRONTIA, the name of an Earth, composed of Oxygen and the metal Strontium. Neither strontium nor its oxide is found pure in nature. The Salts of Strontia have a high specific gravity, varying from 3·6 to 4·0. In this respect they resemble Baryta. Two are found in the form of minerals.

Celestine — Sulphate of Strontia — occurs in modified rhombic prisms. Crystals sometimes flattened, often long and slender. Massive varieties:—Columnar or fibrous, forming layers half an inch or more thick, with a pearly lustre; rarely granular. Colour generally a tinge of blue, but sometimes clear white. Lustre vitreous, or a little pearly; transparent to translucent. Hardness 3·0 to 3·5. Specific gravity 3·9 to 4·0. Very brittle. It contains—Sulphuric Acid, 43·6; Strontia, 56·4. Decrepitates before the blow-pipe, and on charcoal fuses rather easily to a milk-white alkaline globule, tinging the flame red. Phosphoresces when heated.

It resembles heavy spar, but is distinguished by its specific characters and behaviour under the blow-pipe. It is distinguished from the carbonate by not effervescing with acids. It is found in the United States of America. Sicily affords very splendid crystallisations associated with sulphur.

The pale sky-blue tint so common with the mineral, gave origin to the name Celestine.

Celestine is used in the arts for making the nitrate of strontia, which is employed for producing a red colour in fireworks. Celestine is changed to sulphuret of strontium by heating with charcoal, and then by means of nitric acid the nitrate is obtained.

Strontianite—Carbonate of Strontia—occurs in modified rhombic prisms. It occurs also fibrous and granular, and sometimes in globular shapes with a radiated structure within.

The colour is usually a light tinge of green; also white, gray, and yellowish-brown. Lustre vitreous, or somewhat resinous. Transparent to translucent. Hardness 3·5 to 4. Specific gravity 3·6 to 3·72. The analysis gives—Strontia, 70·1; Carbonic Acid, 29·9. It fuses before the blow-pipe on thin edges, tinging the flame red; becomes alkaline in a strong heat; effervesces with the acids.

Its effervescence with acids distinguishes it from minerals that are not carbonates; the colour of the flame before the blow-pipe, from witherite; and this character and the fusibility, although difficult, from calcspar. Calcspar sometimes reddens the flame, but not so deeply.

Strontianite occurs in limestone at Scoharie, New York, in crystals, and also fibrous and massive. Strontian in Argyleshire was the first locality known, and gave the name to the mineral and the earth strontia. It occurs there with galena in stellated and fibrous groups and in crystals. It is also used for making nitrate of strontia.

(Dana, *Manual of Mineralogy*.)

STURGEON, WILLIAM, distinguished as an electrician, was born at Whittington, in the county of Lancaster, in 1783. His parents were in humble circumstances, and he was at first apprenticed to a shoemaker; he subsequently entered the militia, and afterwards the Royal Artillery as a private soldier. It was whilst thus engaged that his taste for scientific pursuits commenced, and he employed his leisure hours in making experiments more especially in electricity. He appreciated the discoveries of Oersted, Faraday, Arago, and Ampère, in the newly-created sciences of magneto-electricity and electro-magnetism, and was soon enabled to suggest a modification of Ampère's rotatory cylinders. In 1824 he began to publish the result of his researches, and in that year four papers by him on electricity were printed in the 'Philosophical Magazine.' In 1825 he presented a paper to the Society of Arts which was published in their 'Transactions,' describing a complete set of electro-magnetic apparatus of a novel kind. This apparatus was remarkable for attaining a larger amount of power in a smaller bulk than had been hitherto attained by any other arrangement. For this invention he obtained the large silver medal of the Society of Arts and a purse of thirty guineas.

Soon after the invention of the electro-magnetic machine, Mr. Sturgeon drew attention to the powerful effects to be obtained from the use of soft iron in the construction of the electro-magnetic apparatus. The soft iron horse-shoe magnet has entered more or less into the construction of all electro-magnetic machines since that time. Mr. Sturgeon subsequently directed his attention to the construction of plates for the various kinds of galvanic batteries. In his 'Experimental Researches in Electro-Magnetism, Galvanism,' &c., he first drew attention to the superiority of amalgamated plates of rolled zinc over the unprepared cast zinc before generally used. His method of dipping the zinc plates in acid, and afterwards in mercury, is employed to this day in the majority of galvanic machines. He subsequently suggested many modifications in the forms of machines which are now in daily use, and his name is inseparably connected with the mechanical application of the principles that had been worked out by Oersted, Faraday, and Ampère, since the beginning of the present century. Mr. Sturgeon for some years occupied the chair of Experimental Philosophy in the Hon. East India Company's Military Academy at Addiscombe. During the latter part of his life he filled the office of Lecturer on Science at the Royal Victoria Gallery of Practical Science at Manchester. He died at Manchester in the month of December, 1850.

STURM, JACQUES CHARLES FRANÇOIS, the discoverer of the celebrated theorem which bears his name, was born at Geneva in September, 1803, of a family which had quitted Strasbourg in the middle of the last century. After completing his school education and his classical studies at the college with remarkable success, he became in his fifteenth year a student of the university of his native city, where he made rapid progress in the study of mathematics and philosophy. The sudden death of his father, leaving his mother and four children, of whom Charles was the eldest, without any adequate maintenance, compelled him, before the close of his seventeenth year, to resort to private tuition for the support of himself and his family, and three years afterwards he was recommended as tutor to the son of Madame de Stäel. At the close of the year 1823 he accompanied his pupil to Paris; and though he shortly afterwards returned to Geneva, he found no sufficient occupation there, and he finally resolved, in company with his intimate friend and school-fellow, M. Colladon—the present distinguished professor of physics at Geneva—to seek his fortune in the French metropolis. Sturm had already become favourably known to mathematicians by several articles in the 'Annales des Mathématiques' of M. Gergonne, published at Nîmes, on different branches of analysis and geometry, and the strong recommendations which he and his companion bore with them from Lhuillier, and the kind offices of M. Gerono, an eminent teacher of mathematics at Paris, made them known to Ampère, Fourier, Arago, and other eminent members of the Institute of Sciences, who recommended them to pupils as a means of support. Sturm afterwards obtained employment upon the 'Bulletin Universel,' under Baron de Férussac, and was in fact a subordinate in the office of that journal when he published his theorem. The joint labours of Sturm and his friend were shortly after rewarded by a distinction of no ordinary importance, when the Academy of Sciences of the Institute awarded to them, on June 11th, 1827, the great prize of mathematics proposed for the best essay on the compression of liquids. Their memoir was inserted in the 'Mémoires par divers Savants' ('Savants Étrangers'), vol. v., published, agreeably to the very inconvenient usage of the Academy, eleven years afterwards, in 1838.

The determination of the number of real roots of a numerical equation which are included between given limits, is a problem which had occupied the attention of the greatest analysts of the past age—of Warang, of Lagrange, and more especially of Fourier, who of all other analysts had made the nearest approaches to its practical, though he had failed in its theoretical, solution. The attention of Sturm had been for some time directed to this class of researches, which he pursued with remarkable continuity and diligence, encouraged, as he himself assures us, by the instructions and advice of this eminent master. The result was the discovery of the theorem which will be for ever associated with his name, and which conquered the difficulty that had embarrassed all his predecessors, and thus permanently extended the dominion of analysis. [STURM'S THEOREM.]

The memoir which contained this important theorem was presented to the Academy on the 23rd of May, 1829, supplementary papers being read at the two following meetings; and rapidly conducted its author to fortune and public bonours. His connection with the 'Bulletin Universel' enabled him to give an immediate account of his method to the world ('Bull. Univ. des Sciences Math. Phys. et Chim.,' vol. xi. p. 419, art. 271, 272, 273). The paper itself was not published till the year 1835, in the 'Mémoires des Savants Étrangers,' vol. vi., where it appears without a date.

In the course of a few years he was chosen a member of the principal scientific societies of Europe: he was elected a member of the Academy as the successor of Ampère in 1836: in the same year he was made Professor of Mathematics, upon the special recommendation of Arago, at the Collège Rollin, répétiteur at the École Polytechnique in 1838, and in 1840 he was appointed to succeed Poisson in the chair of Mechanics in the same school. In 1840 also, he was elected a foreign member of the Royal Society of London, and received the Copley Medal, "for his valuable mathematical labours in the solution of a problem which has baffled some of the greatest mathematicians that the world has produced." The first announcement of the theorem in the English language was not made until 1835, when Professor J. R. Young, of Belfast, inserted the substance of Sturm's memoir in his work entitled 'The General Theory and Solution of Algebraical Equations,' published in that year. The first intimation of it had reached him in the month of May, when his own work was in great part printed, and disregarding a disparaging comment of Lacroix, he thought the discovery of sufficient importance to justify the destruction of many pages of his manuscript prepared for the printer, and the suspension of the work until the volume of the 'Savants Étrangers' should be published. This he received in July, and his own work was published in August. To the appreciation and zeal of this analyst, whose recognition and promulgation of the value of Sturm's labours were thus both immediate and simultaneous, British mathematicians, as well as M. Sturm himself, were greatly indebted. In the preface to his 'Mathematical Dissertations' (one of which is devoted to the theorem) dated November 25, 1840—only five days before the presentation of the Copley medal—he adverts to Sturm's discovery as at that time exciting considerable interest among analysts, as well in this country as on the continent; and he then expresses his own estimation of it in the following terms: "I believe that I have already contributed somewhat to extend the knowledge of this important theorem among British analysts; and although it has been since disparaged and undervalued in certain quarters, I have always entertained the conviction that it must eventually supersede every other method at present known for effecting the complete analysis of a numerical equation." In Professor Young's subsequent introductory volume on 'The Analysis and Solution of Cubic and Biquadratic Equations,' published at the beginning of 1842, he invited the attention of the young analyst to Sturm's method; and the second edition of his former work on equations,—entitled 'The Theory and Solution of Algebraical Equations of the Higher Orders,'—which appeared early in the following year, is chiefly devoted to the analysis and developments of that method and the previous theories of Budan and Fourier.

In France it was not without some difficulty that the substantial rewards of his scientific achievements were obtained; he was a foreigner, and naturally placed at a disadvantage in a contest with native competitors. It is right to notice this both for the honour of France and as a proof of the very high reputation which Sturm had attained. The subsequent memoirs of Sturm, whether first presented to the academy or not, were chiefly printed in the journal of M. Liouville. Two of these memoirs, relating to the discussion of differential and partial differential equations, such as present themselves so commonly in the solution of the more important problems of mathematical physics, possessed a merit so extraordinary that M. Liouville—a most competent judge—declared, at a time when he was himself a competitor with Sturm for a place in the Academy, that "impartial posterity would place them by the side of the finest memoirs of Lagrange."

The first of these two memoirs was presented in 1833 to the concours for the great prize of mathematics, to be awarded by the Academy in 1834 for the most important discovery in that science made known within the preceding three years. The academy conferred the prize on Sturm—not for the memoir which he had submitted to the judgment of the commission, but for that which contained his celebrated theorem and which had been presented in 1829. Other memoirs relate to optics, mechanics, pure analysis, and analytical geometry, and embrace the most difficult questions which have been treated in those several branches of science. One of the latest of these was a communication to the academy on the theory of vision, and is remarkable both for the geometrical and analytical elegance with which many questions subsidiary to the theory are treated in it. It confirms generally,—with one important exception relating to the asserted muscularity of the crystalline lens and the changes attributed to its action,—the views of the late Dr. Thomas Young [YOUNG, THOMAS] in his well-known memoir on this subject: Dr. Young himself, it must be remembered, once relinquished his belief in the muscularity of the lens, though he finally resumed it.

Sturm visited England in 1841, and gave the mathematicians with whom he conversed a high impression, as well of the extent of his knowledge as of his inventive power.

The health of M. Sturm, which had previously been remarkably vigorous, began to decline in 1851, probably in consequence of his laborious public employments and the unremitting severity of his studies. He died on the 18th of December 1855, to the deep regret of a large circle of friends and pupils, to whom he appears to have been singularly endeared by the modesty, truthfulness, and simplicity of his character.

STURMIA, a genus of plants belonging to the natural order *Orchidaceæ* and the tribe *Malaxideæ*. It has a patent perianth; lip anterior, erect or oblique, entire, dilated, much larger than the sepals; stigma roundish; rostellum obsolete, but with an appendage consisting of two tubercles; anthers terminal, deciduous, moveable like a lid, with two distinct cells; column elongated; germen on a twisted stalk.

S. Loeselii has the leaves oblong-lanceolate; stem triangular; lip obovate, longer than the petals; flowers from 6 to 12, in a lax spike, yellowish in colour; the sepals lanceolate; petals linear; the hybernaculum is large, ovate, inclosed in the whitish sheaths of the decayed leaves. It is the *Liparis* of some authors. It is found in spongy bogs in Norfolk, Suffolk, and Cambridgeshire, but is very rare.

SUBERYLE. [CHEMISTRY, *S.* 2.]

SUCCESSION DUTIES. For many years persons succeeding to personal property (including leaseholds), whether they took by will as executors or legatees, or merely as administrators or next of kin, were charged with *Legacy Duties*, which were payable over and above the stamp duty, then and still levied in the first instance, on the grant of probate or letters of administration, according to the estimated sworn value of the personal property of the deceased. The legacy duty was chargeable after the estate of the deceased had been realised and administered, on the property distributed among the legatees or next of kin, as the case might be; and varied in amount, according to the consanguinity of the next of kin, or the absence of any relationship between the legatee and the testator. The exemption of real estate from this species of taxation, long complained of as creating an undue preference in favour of the holders of landed property, has at last been removed. By the Succession Duties Act, 1853, duties are imposed on every succession to property, whether real or personal, according to the value and the relationship of the parties to the predecessor. Where the successor is the lineal issue or lineal ancestor of the predecessor, 1*l.* per cent.; where a brother or sister, or a descendant of a brother or sister, 3*l.* per cent.; where a brother or sister of the father or mother, or a descendant of the brother or sister of the father or mother of the predecessor, 5*l.* per cent.; where a brother or sister of the grandfather or grandmother, or a descendant of the brother or sister of the grandfather or grandmother of the predecessor, 6*l.* per cent.; and where the successor is in any other degree of collateral consanguinity to the predecessor, or is a stranger in blood to him, 10*l.* per cent. The value of the succession, if it be to real property, is ascertained by considering the interest of the successor as of the value of an annuity equal to the annual value of the property, estimated as the Act directs; and the duty may be paid by eight equal half-yearly instalments, or at once, according to the wish of the party liable thereto.

SUE, EUGÈNE, the popular romancist, was born at Paris Dec. 10, 1804. His ancestors, who came from Lacolme, near Cannes, in the south of France, settled in the French capital at the beginning of the 18th century, and having adopted the medical profession, produced three generations of respectable physicians, two of whom became celebrated, and enjoyed a very extensive practice. Joseph Sue, his grandfather, and Jean-Joseph Sue, his father, are both mentioned with honourable distinction in the national biographies of France. The latter, who had been principal physician to the Hôpital de la Maison du Roi, and anatomical lecturer to the École Royale des Beaux Arts, during the reign of Louis XVI., was one of the household physicians to Napoleon I.; and the future author of the 'Wandering Jew' was held at the font by the Empress Josephine and her son Eugène Beauharnais, from whom he derives his Christian name.

Dr. Sue, having but two children—a son and a daughter—was desirous of bringing up his son to his own profession, and Eugène in consequence studied medicine at the hospitals as well as at the schools of Paris; and, thanks to his father's position and influence, was enabled at the age of twenty to enter a company of the Royal Body Guards as aide-major. He was soon after transferred to the staff of the French army preparing to enter Spain under the Duke of Angoulême. In this campaign he was present at the siege of Cadiz and at the Trocadero in 1823. In 1825 he quitted the land for the sea service, visited America, Asia, and the coast of the Mediterranean, during which excursions he obtained that knowledge of ocean scenes and sailor life which he has since described with indisputable power in his earlier tales. He was present in 1828 at the battle of Navarino, on board of the line-of-battle ship le Breslau. In 1829 his father died at the age of sixty-nine, leaving to his son an unincumbered estate of 40,000 francs (1600*l.*) a year, besides a splendid museum of anatomy, valued at several thousands more, bequeathed to the nation. Eugène Sue, at this time in his twenty-sixth year, renounced the profession by which his family had acquired so much distinction, and to which he owed his fortune. His taste inclining to art, he became a painter, and in that vocation entered the studio of Gudin. About the same period he felt an ambition to signalise himself in literature, and this was gratified by the insertion of some slight articles in the journal recently established by Emile de Girardin—'Le Voleur.' Encouraged by this success, he began to write tales descriptive of sea adventures, publishing in quick succession, 'Plick et Plock,' 'Atar-Gull,' and 'la Salamandre.' The two former were rejected by the trade, he therefore published them at his own risk. In 1832 he had already become popular both with publishers and their subscribers. But it would be quite a mistake to suppose that he was an advocate of the July revolution—no man at that time could repudiate it more; wherever he went he was loud in denouncing it. His father's name and his private fortune gave him access to the best company; he selected the highest for his cultivation, and lived among the old families of the Faubourg Saint-Germain.

Sue was one of the first to try his skill in framing those historical romances which the genius of Sir Walter Scott had rendered so universally popular. A new market had been opened for the purchase of his, and similar fictions—the newspaper feuilletons. Thus his 'Latréaumont,' his 'Jean Cavalier,' his 'Commandeur' were published, and devoured from day to day by the public. His name had become a magnetic charm in the estimation of those speculators who had once rejected his manuscript. It was presumed that so popular a name was a guarantee for success in literary enterprises; and acting on this presumption, he was engaged at very high terms, having a reputation for concocting vivid scenes of naval adventure, to write a 'History of the French Navy.' But the speculator in this instance was disappointed: the public bought the first volume on account of the name, and refused to buy all the other volumes on account of the work. From 1832 to 1840, Eugène Sue had confined himself to that class of fictions in which he had attempted to emulate, if not to rival, Fenimore Cooper in sea adventures, and Sir Walter Scott in historical delineations. But at this period the novels of Balzac in France, and those of Charles Dickens in England, had created a taste for the novel of real life, or as the French call it, le Roman de Mœurs. He therefore resolved to adopt the new style, and to this change we owe 'Arthur,' the 'Hôtel Lambert,' and 'Mathilde,' published in 1841 and 1842. Making allowance for those licences in morality which are too frequently found in the current French fictions as well as dramas, there is a skill in the combination of the plot, and a power of description in the incidents, in 'Mathilde,' which his earlier tales did not prepare the reader for. The highest critical authorities have admitted that it exhibits more than one of the qualities of a superior novel. It was in this work that Eugène Sue first started that idea of the moral Howard, going about succouring the poor, redressing wrongs, and chastising the wicked, which he developed afterwards in the 'Mysteries of Paris' and the 'Wandering Jew.' These two novels originally appeared in the 'Journal des Debats' and the 'Constitutionnel,' occupying by their great length nearly three years in the course of publication. Including the interval between the conclusion of the former and the first appearance of the latter, the whole of the four years from 1842 to 1846 was taken up with these baleful writings, and the ferment and agitation of the public fancy was excited to the highest degree, without respite or relaxation. The original terms proposed and accepted for each of these fictions, was 100,000 francs (4000*l.*); but it is understood that they were purposely extended and developed, on account of their unexampled success, and much larger sums allowed for them to the anthor. They were afterwards repnblished in volnmes, going through many editions, and being translate l into most living languages. 'Martin, l'Enfant Tronvé,' appeared in 1846 in the columns of the 'Constitntionnel,' and 'Les Sept Péchés Capitaux' in the same paper in 1847-48. Perhaps the most serious censure passed on his writings was that passed on this last hy the anthor himself when he said in bravado, "that he wonld show the fair side of all these sins;" for the work, which consists of seven separate tales, is nothing else hnt an apology for each and all of them. The first of these tales—'Pride'—is perhaps the masterpiece of Eugène Sne; the second tale—'Envy'—contains one very dramatic scene; hut his 'Avarice,' his 'Sloth,' &c., are unworthy of his reputation.

The 'Mystères du Peuple,' pnblished in 1852, is the last fiction of any note produced hy the pen of this voluminous writer. It is intended as an exposure of all the misery and injnstice to which the common people of every country have heen reduced in all the ages of the world. After the Revolntion of Feh. 1848, Sue, who had ahandoned his early conservative priuciples for extreme democratic and socialistic ones, was elected a representative of the Assemhlée Nationale; hnt after the election of Napoleon III. he took no part in politics. He died on Ang. 3, 1857.

SURGERY. Some references which have been made in other parts of this work will here be made good.

Anus, Diseases of. One of the most freqnent diseases of this part of the hody is that which is commonly known by the name of Fistula, or *Fistula in Ano*. This disease consists of a fistula or sinus by the side of the rectum. It sometimes opens externally, without communicating with the bowel, and is then termed blind external fistnla. It more frequently communicates with the howel, withont opening externally, and is then called blind internal fistnla. Usually, however, these sinnses have an opening internally and externally, and the disease then constitntes complete fistula. In this latter form pus, flatus, and fæculent matter, are discharged from the openiugs. It is accompanied by heat of the parts, great discomfort, and sometimes pain and spasm of the sphincter muscles. It is sometimes attended with acnte inflammatory symptoms, and the general health suffers.

When this kind of ahscess occurs, the healing is prevented hy three circumstances:—1. The fistnlous condition of the cavity. 2. The presence of foreign matters. 3. The frequent motion of the part by the action of the neighbonring muscles.

This disease originates most frequently in the interior of the bowel hy a small ulcer, which, extending, at last prodnces a second opening. It is often found in persons lahouring nnder pnlmonary consumption, and its persistence and inconvenience are increased by the constant cough which accompanies that disease.

The treatment of fistnla is simple, and nsually very successful. By laying open the whole of the sinns and dividing the sphincter, the two main ohstacles to the cure of this disease are removed. The mode of operating in this case is simple. A grooved probe is introduced into the external opening until it passes out at the internal opening. A probe-pointed histoury is then introduced along the groove, and the sinus is laid open through its whole length. Usnally no important vessels are divided in this operation, so that all that is necessary after is to introdnce a slight dressing of lint. An opiate should he given after the operation.

Hæmorrhoids or Piles consist in an enlarged condition of the veins snpplying the anus and rectnm. This disease is divided into two kinds, external and internal. It seldom occurs before puherty, and is more common in females than males, and in the rich and luxurions, than in the poor and hard-worked. This arises from the fact that whatever tends to determine hlood to the lower part of the rectum, and to retard the retnrn of hlood from that part, favours piles. Thus they come on in pregnant females, in persons tronhled with hahitual constipation, abdominal tumours, obstructions in the portal system of veins, and in those who lead sedentary lives or who feed too well.

External piles consist of a congeries of varicose or enlarged veins, which are surronnded by a condensed and enlarged connective tissue, and are covered partly hy mncous membrane and partly hy loose rugous integument. The parts are sometimes inflamed, at other times free from any capillary derangement. The mncous or rugous surface occasionally becomes ulcerated. It is nnder these circumstances that the coats of one or more of the veins give way, and they bleed to a greater or less extent. When this does not take place they do not hleed. These two states are called respectively *bleeding* and *blind* piles.

The treatment of this form of piles may be either palliative or radical. The radical cure consists in removing the parts either hy the scissors or bistoury, and leaving them to heal in the ordinary way, or a ligature may he passed round the enlarged vessels, and the strangulated part left to slough off. When this operation is not thonght desirable, mnch may be done to relieve the enlargement and pain of piles by a palliative treatment. Whatever will remove the loading of the vessels in the lower part of the bowels will relieve them. Thus parturition removes them when caused by pregnancy. If the part is inflamed, rest, purgatives, poultices, and anodyne applications may be had recourse to. Astringent applications comhined with opium may be applied, as gallic and tannic acids. The purgatives most to be recommended are castor oil, or an electuary with the confection of senna, sulphur, and cream of tartar. In cases where the liver is affected, the state of this organ shonld be especially attended to.

Internal piles, are of three kinds: 1. Varicose veins surronnded hy enlarged connective tissue, and covered by mncous membrane, and bleeding or hlind. 2. Tumours of the nature of sarcoma. 3. A congeries of blood-vessels resemhling erectile tissue, and occuring in the submucous connective tissue. This last form is the most common. They may protrude from the anus or not. When they do not, they descend occasionally when the howels are acted on, and become very trouhlesome till they are returned. If not replaced they hecome constricted and inflamed or bleed. In these cases hleeding nsually occurs when the bowels are acted on. When the tnmours are replaced, no great inconvenience occurs. If, however, the bleeding continues, the patient becomes pale, thin, and weak; noises in the ears, giddiness, and palpitation of the heart come on, in fact all the symptoms of anæmia set in.

The treatment in this case may be either palliative or radical. Freqnently the latter conrse should at once be had recourse to. The internal tumours are seldom of a kind to allow of removal hy the knife, and ligature is hy far the safest process. When the base of the tnmour is small, it may he pulled down hy a tenacnlum and a single ligature placed round it; hnt when the hase is broad, a needle with two ligatures is passed directly through the tumour, and a ligature is tied ronnd each half of the tnmour. This operation is very painful and difficult, and wherever circumstances will admit is greatly facilitated hy the use of chloroform. After the operation opiates should be given.

Nitric acid has heen recently recommended in these cases, but nnless the tnmours are small, and the cases slight, this remedy is liahle to fail, and after the infliction of much pain the operation must he had recourse to.

Should the palliative treatment be had recourse to, all those points to which refereuce has been made under the head of external piles, mnst be attended to. Astringent remedies and opiates must be injected into the bowels. The bowels mnst be regulated, the liver looked to, and when the hæmorrhage is considerahle, gallic and tannic acids, with acetate of lead, mnst he given internally.

Prolapsus Ani is a very frequent and troublesome affection of the lower howels. In consequence of relaxation the rectnm passes down, and becoming everted protrudes itself beyond the anus. This protrusion may he either *partial* or *complete*. It is called complete when the entire bowel comes down, and partial when the mncous coat alone descends. The latter is the most frequent, and sometimes accompanies internal piles. Children and old persons are more liahle to the complete form. The qnantity of bowel or memhrane which passes down varies in size, from a mere annular enlargement to a tnmour as large as a child's head. It is sometimes accompanied with inflammation, and the mucous membrane throws off a coloured discharge. Great pain and uneasiness are often felt, and general languor and debility are present.

The treatment is either palliative or radical. When this disease depends on general constitutional weakness, tonics, change of air, and a proper regimen, will restore the patient to health. The bowel should always be returned as speedily as possible, and this may be done by proper pressure after lubricating the parts. When they are inflamed, leeches should be applied and rest secured before attempting reduction.

The radical cure is effected by removing one or more of the redundant folds of the mucous membrane by the knife or ligature. The cicatrix thus formed contracts and sustains the replaced parts, or the bowel may be left intact, and a portion of the redundant external integument may be removed, which by its subsequent contraction prevents the painful protrusion.

Imperforate Anus. Children are occasionally born without an anal orifice. Three forms of this malformation are described: 1. The rectum may be fully developed, and have its orifice closed by an external membrane, or a septum may be developed at some distance from the orifice. In the treatment of this form of imperforate anus, nothing more is required than an incision through the occluding membrane. 2. The rectum terminates at some distance from the perineum, and there is a mere depression where the anal orifice ought to be. This is the most common form. It requires a more serious operation than the last. The meconium should be allowed to accumulate, and pressure being made on the abdomen, an incision must be made down to the bowel, and a passage thus established. 3. In this form the rectum is very deficient or altogether absent. An operation like the last may be performed, and failing this, an attempt may be made to form what is called an *artificial anus.* This operation is performed not only for imperforate anus, but in cases where, from tumours, or the impaction of foreign matters, the fæcal matter does not find its way to the anal orifice. The sigmoid flexure of the colon is the part which is preferred for this operation. It may be reached from before or behind. The former is the easiest operation ; the latter is the most convenient position for the new opening to the patient. In performing the latter operation, an incision is made midway between the last false rib and the crest of the ileum. The colon is then secured, an incision made into it, and the edges of the bowel brought in contact with the external wound by means of ligatures. This operation, has been successfully performed in cases of non-malignant tumours and other causes of the impaction of the lower bowel. In children with imperforate anus, however, it seldom succeeds, as other malformations often exist which speedily terminate the life of the patient.

Aorta, Diseases of. [Arteries, Diseases of.]

Arteries, Diseases of. Besides aneurism the arteries are subject to other diseases. [Aneurism.] The arterial tissues are liable to inflammation, which may be acute or chronic.

Acute Arteritis, is either limited to a particular spot, or it spreads along the course of the artery. When limited, this disease arises from external injury, and is a common result of wounds and ligatures. In the milder forms, this inflammation is attended with the exudation of a plastic matter, which fills up the artery and leads to its obliteration, a result which is sought for in the application of a ligature to arteries. The inflammation may, however, proceed to suppuration and ulceration, when the coats of the artery are opened and hæmorrhage is the result. In every instance of ligature such a result is carefully to be avoided. A still more intense form of inflammation may occur, and the result will be the death of the part and gangrene—a result which sometimes follows wounds involving the destruction of the arterial tissue. It may also come on from a ligature being applied too tightly. In the treatment of such cases the ordinary remedies for inflammation should be applied. Cooling applications should be made to the part, and rest, and an antiphlogistic regimen enjoined.

The spreading form of arteritis occurs in middle age in persons of broken constitution. It is seldom confined to one vessel, but affects the arteries of a whole limb. The tracks of the inflamed arteries are painful to the touch, there is slight induration of the affected arteries, the pulse is feeble and has a peculiar thrilling stroke. The surrounding textures are not often involved in the disease. The pulse in the affected arteries is feeble, has a thrilling stroke, and gradually diminishes till it finally ceases. The tissues surrounding the arteries are seldom affected with the inflammation, and the skin is not altered, except that it is pale.

The effects on the arterial coats are the production of turgescence, and a loss of the smoothness of the internal coat. There is a tendency of the blood to coagulate and become adherent in the inflamed vessel, and ultimately the canal becomes blocked up. In proportion as these changes are extensive, will be the general local mischief. The temperature and sensation of the part are diminished, and gangrene, unless the disease is arrested, sets in.

The treatment consists in the employment of antiphlogistic measures. Leeches may be applied to the part, and calomel and opium given internally. The employment of stimulants, both internally and externally, should be avoided.

Chronic Arteritis is of more frequent occurrence than acute, and is a state of the artery in which abnormal deposits are formed in the coats of the artery, and which frequently lead to the more serious derangements of the arteries. This disease is not to be detected by any symptoms during life, but is recognised after death by its effects on the arteries. The artery may be affected in spots or throughout its whole extent. The internal coat of the artery is enlarged and is less smooth and serous on its surface. Between the internal and middle coat there is a deposit of a soft, cheesy-looking, granular matter, either in points or patches. This deposit is usually called *atheromatous.* Under the microscope it is found to consist of fatty granules and molecules, which are frequently associated with crystals of cholesterine. The middle coat of the artery is frequently altered in its character, presenting a thin yellow opaque appearance. From this cause the elasticity of the artery is much impaired, its cohesion is diminished, it easily stretches, and is apt to tear. It is in this condition that dilatation of the artery, or true aneurism, takes place. It may also become the seat of ulceration, or it may tear at once, thus leading directly or indirectly to dangerous hæmorrhages. Although these changes are supposed to take place as the result of inflammation, there is no reason to believe that they may not go on quietly without inflammation. It is not improbable that the changes which thus go on in the artery are identical with those which produce fatty degeneration in the other tissues of the body. When this change takes place in the small arteries of the brain, it not unfrequently leads to an attack of apoplexy, from the rupture of the vessel and the effusion of blood upon the brain.

Calcareous deposits between the inner and middle coats of the artery may take place in the same way as the fatty deposits. In this manner the artery becomes ossified. In this case the arteries become hard and non-elastic, the internal coat is dry and shrivelled in appearance, and atheromatous deposits are found mingled with the calcareous.

The treatment of these forms of arterial disease, where they are suspected to exist, should consist in removing all causes that can contribute to hasten the changing condition of the arteries, and to prevent that action which may facilitate the enlargement, or endanger the bursting of the arteries.

Vascular or Erectile Tumour. This is a form of disease of the arterial tissue, sometimes called *Aneurism by Anastomosis.* There are three varieties: 1. The capillaries of the integument may become dilated so as to produce a discoloured elevation of the skin, more or less depressed. These tumours bleed copiously on the slightest abrasion, or from ulceration. It is commonly called *Nævus.* 2. The veins and arteries may be enlarged in the sub-cutaneous areolar tissue, producing a dark livid tumour of the skin. Copious hæmorrhage occurs from any rupture of the skin, but this may be generally arrested by pressure. Such tumours may occur under the mucous membrane, and are exemplified in those forms of hæmorrhoids which are situated partly within and partly without the verge of the anus. 3. The true erectile tumour which is composed of dilated blood-vessels, which are closely crowded together, and open into each other at many points. "These openings may be of secondary formation ; the result of close apposition in the dilated vessels. Or more probably they are primary; the structure consisting of a network of dilated capillaries ; the openings of communication being the ordinary and original inosculations, and what were intervascular spaces being now condensed into mere fibrous bands. The whole constitutes a vascular network of great capacity and activity of circulation, supplied, for reception of the returned blood, with large and tortuous veins, whose lining membrane is plainly continuous with that of the abnormal vascular cells. Also in the neighbourhood are to be found the feeding arteries; originally, perhaps, twigs, now enlarged to trunks pulsating strongly, and obviously carrying on a plentiful and active supply." (Miller, 'Practice of Surgery.') Such is the nature of those tumours which partake of the character of true erectile tissue. Like this tissue also, these tumours become enlarged and diminished in size, according to the sluggishness or activity of the blood circulating through them. They are compressible, elastic, and of a reddish hue. They are usually subcutaneous, but they are also submucous. The most common situations are beneath the integuments of the face, head, neck, back, and buttocks. The tumour pulsates synchronously with the heart, and may be considerably diminished in size by pressure, but resumes its usual condition when the pressure is withdrawn. On auscultation, a beat is heard, dull and rough, sometimes accompanied by a vibratory thrill.

Ulceration is likely to occur in these tumours, and lead either to great hæmorrhage or their cure.

Erectile tumour may be treated in three different ways:—

1. The tumour may be removed. This is always better done by the ligature than by the knife.

2. The tumour may be starved by diminishing the arterial supply. This is done, as in cases of true aneurism, by the application of a ligature to the artery or arteries which supply the tumour with blood.

3. The structure of the tumour may be changed. This may be effected in various ways; as by pressure, the introduction of a needle, the application of caustic potash, nitric acid, or other agent. A hot needle may be run through, or a wire connected with the poles of a galvanic battery may be passed through the tumour. All these plans have been found to succeed with small erectile tumours.

Varix of the Arteries.—A tortuous and dilated condition of the arteries frequently comes on in the smaller arteries, and produces a painful tumour. It may be removed in the same manner as varicose veins.

Arteriotomy is the term applied to the opening of an artery for the purpose of drawing blood, as phlebotomy is applied to the same operation in a vein. When it is thought desirable to take blood in large quantity and with much rapidity, it is better taken from an artery than from a vein. This operation however is more difficult to perform, and may be attended with ulterior consequences. Hence phlebotomy or venæsection is always preferred, except under urgent circumstances, as the means of drawing blood from the system. When arteriotomy is performed for the sake of blood-letting, one of the superficial anterior branches of the temporal artery is generally selected. In this position the wound is easily healed afterwards by pressure. The accidental wounding of an artery, as is sometimes the case in bleeding from the veins at the bend of the arm, may lead to false aneurism and the necessity of placing a ligature round the wounded artery. Sometimes false aneurism follows arteriotomy in the temporal artery, and in this case it becomes necessary to ligature the arteries on each side of the wound. Sometimes on removing the compress after arteriotomy, an ulcer is found to be formed. If the ulceration spreads, the vessel may be opened and hæmorrhage occur. In this case also the artery must be tied.

Bladder, Diseases of.—The bladder, like every other organ of the body, is liable to inflammation. This disease is called *Cystitis*. When present there is pain and tenderness in the region of the bladder, also in the region of the perineum and sacrum, and along the urethra. The urine is voided very frequently with great pain and straining. The urine passed is clouded with mucus, and afterwards contains pus often mixed with blood. These local symptoms are accompanied with general fever. The inflammation may extend from the bladder to the peritoneum.

This disease may come on after the operations of lithotomy or lithotripsy, or other direct injury. It may be the result of specific inflammation of the urethra, extending to the bladder, or it may come on from irritating medicines acting on the bladder, as cantharides.

In its treatment antiphlogistic remedies of an active kind are needed, such as bleeding generally and locally, antimony, calomel, and opium. Opium should be given by the mouth and per anum for the purpose of relieving the pain. The bowels should be opened by enemata and gentle purgatives; the recumbent position must be absolutely enjoined.

Cystitis may become chronic, or a chronic inflammation of the bladder may be produced by irritation in neighbouring organs, as in the urethra, rectum, or kidneys. There is pain in the bladder, frequent micturition, and mucus in the urine. The mucous membrane of the bladder may ulcerate, and then the urine is mixed with blood and pus. The ulceration may extend through the bladder to the surrounding organs. In the treatment of this disease, the obvious cause must be removed. Opium for the pain, a generous diet, astringent infusions, as of buchu, and mineral acids, are principally recommended. Iron is sometimes of great use, also copaiba. Counter-irritation on the hypogastrium, or over the sacrum, should not be neglected. In very chronic cases it has been recommended to wash out the bladder with warm water by means of a double catheter. Lallemand recommends the direct application of the nitrate of silver.

Irritable Bladder.—A state of the bladder is recognised in which there is no inflammatory action, but in which the symptoms resemble those of cystitis. There is frequent micturition, uneasiness in and about the region of the bladder. The urine is mostly limpid and clear. This state depends on some derangement of the kidneys or general health, or it may come on from piles, stone in the bladder, or thread-worms.

In treating this state the great thing to be done is the removal of any observed cause. Where it comes on in a generally decayed state of the health, the treatment must be directed to this condition of the system.

Hæmaturia.—Blood in the urine may present itself when the kidneys, bladder, or urethra are affected. When it arises from the kidneys the blood presents itself in the form of small tubular cysts, produced in the tubules of the kidneys. When the bladder is the seat of stone, cystitis, or malignant tumours, bloody urine may make its appearance. When the hæmorrhage proceeds from the urethra, the blood passes away independent of the urine. In these cases the cause of the hæmaturia must be treated.

Incontinence of Urine or Enuresis. This disease presents itself in two classes of cases, in children, and in adults. The first is a very common and troublesome disease. The urine is usually passed voluntarily during the day, but in the night it passes away involuntarily. Although frequently treated as though it were a bad habit, it is the result of a morbid state of the system, which must be removed, and the will should only be called into exercise to assist a judicious system of treatment. All causes of general debility should be removed. Sea air, cold sea-bathing, with the administration of iron, especially the tincture of the sesquichloride, are the most appropriate remedies for the want of tone of the nervous system which accompanies this disease. Strychnia has been recommended. The child should not lie on its back, and it should be awakened in the night, at stated intervals, to pass the urine voluntarily. Mechanical remedies are to be condemned.

In the incontinence of adults, either the urine passes away from previous retention, or, as happens in aged people, the bladder loses its tone, and both its expulsive and retentive powers are feeble or gone. In the first case the catheter must be employed to empty the bladder, and the retention treated. In the other case, tonics and other remedies necessary for the debilitated state of the system must be employed. Generally, however, little can be done, and cleanliness and the use of urinals are the only means left.

Retention of Urine. This arises from various causes, and the treatment must vary accordingly. The symptoms in all cases are, an inability to evacuate the urine, whilst the desire to do so is constant and frequently accompanied with pain, straining, and distress. The bladder is distinctly felt to be distended above the pubes, there is dullness on percussion there, and pressure produces great pain. Sickness is frequently present, the pulse becomes rapid, the skin hot, and at last symptoms of the absorption of the urine present themselves, and unless relieved, the patient dies from the blood becoming poisoned by the urea of the urine. All these symptoms are removed by the removal of the urine. This may frequently be done by the catheter, but the disease can only be cured by the removal of the cause.

The following are enumerated as causes of this disease. Stricture of the urethra. Inflammation of the urethra. Irritation and spasm of the neck of the bladder. Priapism. Abscess in the perineum. Abscess in the pelvis. Calculus in the urethra. Injury of the perineum. Paralysis. Diseased prostate. Blood in the bladder. Malignant disease of the bladder or urethra. Imperforate urethra. In each of these cases a special treatment is necessary, but in all it should be remembered that fatal results will occur unless the distended viscus is emptied of its contents. It often happens that for this purpose the catheter cannot be passed into the urethra; under these circumstances the only means left is to puncture the bladder. This operation may be performed from the perineum, the rectum, and the pubes. In puncturing the bladder from the perineum an operation is performed similar to that for lithotomy. [LITHOTOMY.] When this operation is deemed unadvisable, the bladder may be reached from the rectum and punctured here. It is only when these two methods are found to be impracticable that puncturing the bladder through the parietes of the abdomen in the region of the pubes is had recourse to. These operations are not often performed: "but any one of them is much preferable at any time to postponement of relief, and consequent disaster by extravasation; and all, too, are preferable to pushing a metallic catheter by sheer force through an impassably strictured urethra." (Miller.)

Diseases of the Prostate. The prostate gland is liable to the various diseases of other parts of the urinary organ. It may be inflamed, or abscess may occur in it, or it may be subject to malignant disease. It is, however, most liable to *enlargement* or hypertrophy, which is one of the most troublesome and frequent diseases to which old age is liable.

Enlargement of the prostate is of two kinds. One is the result of inflammatory action, and the other is an enlargement independent of that process. The first is only temporary, and may be frequently speedily removed by treatment. It is the result of stricture, gleet, affection of the rectum, or injury to the perineum in riding. Leeches, purgatives, the recumbent position, and counterirritants, are the proper treatment. The second form of enlarged prostate is more difficult to manage. It is one of the consequences of increasing age. The enlargement in these cases may be partial or general. One of the most painful consequences of either is a difficulty in passing the water. This comes on gradually, and is also attended with difficulty in emptying the rectum, as this organ is pressed on by the distended prostate. As the tumour enlarges the calls to empty the bladder are more frequent, and the act is less perfectly accomplished, and a portion of residuary urine remains in the bladder behind the enlargement. Under these circumstances the bladder becomes irritable, and chronic cystitis is established. The symptoms of this disease are then added to those of the enlarged prostate.

There is no cure for this state of things, and the treatment is consequently palliative. Much, however, may be done for the comfort of the patient. All excess and imprudence in diet and exercise must be avoided. The recumbent position must be maintained as much as possible. The bowels regulated by enemata and gentle aperients. Opium, iron, mineral acids, and buchu, may be given according to circumstances. In order to prevent distension the catheter must be had recourse to, and the water drawn off occasionally.

BREAST, DISEASES OF. The mammary gland, especially in the female, is liable to various diseases, requiring the attention of the medical man.

Irritable Mamma. In both married and unmarried females the breast is liable to irritation from sympathy with other parts of the system. In these cases there is often great pain and uneasiness in the breast, and the whole system suffers more or less. There is no inflammation, and no swelling or external alteration of the mamma. The pain is sometimes intermittent or periodic, similar to neuralgia. When the general health is affected this must be attended to. Opium and hemlock may be employed internally, and nitrate of silver, belladonna, and aconite, have been recommended externally.

Mammitis. Inflammation, acute and chronic, of the substance of the mamma is not an unfrequent disease. It comes on from exposure to cold or a blow, or during the period of lactation. The pain is intense; the breasts are swollen, and tender to the touch. From the first there is a tendency to suppuration. The secretion of milk is perverted and arrested. In the treatment leeches and warm fomentations and poultices should be applied to the breast. The bowels should be kept open, and the fever subdued. When matter forms it should be early evacuated. A chronic inflammation is sometimes observed. When this is the case stimulant applications to the breast will be found useful. Where this is attended with abscess it should be opened, so as to give free exit to the pus, and pressure applied.

Tumours of the Breast. The breast is subject to various kinds of partial and general enlargement. The "chronic mammary tumour" of Sir Astley Cooper consists of a partial hypertrophy of the gland. Enlargement of the whole gland also frequently takes place. These enlargements may be got rid of by pressure and treatment of the general health. The lactiferous ducts are sometimes blocked up, so as to produce distension, and an enlargement called *lacteal tumour*. Puncturing the enlarged tube and keeping it open will cure this form of tumour. The breast is also liable to fatty tumours, fibrous tumours, cystic sarcoma, hydatids, and malignant tumours. In many of these cases it becomes necessary to remove the breast. This is done in the following manner: "The patient having been placed recumbent, and duly anæsthetized, the arm on the affected side is raised and held by an assistant, so as to stretch the pectoralis major and facilitate incision. The knife is entered in the axillary aspect of the tumour in a line with the mammilla, and is moved in a semi-elliptical direction towards the opposite point; a similar proceeding is adopted—above or below, as the case may be—to complete the ellipse, and the size of this space necessarily varies according to the extent to which the integument seems to be involved, and according to the natural laxity of the parts. It is a fault to take away an undue amount of sound textures, so that difficulty is experienced in effecting and maintaining apposition of the wound; but it is a worse error to leave tainted parts, whereby reproduction of the disease cannot fail speedily to ensue. It is well to make the lower incision first, otherwise its course and position are apt to be uncertain under the irrigation of blood. Then on each aspect the knife is sloped through the subcutaneous part; and regular dissection is proceeded with from the axilla downwards, dividing the principal vessels and nerves at once, and so rendering the subsequent steps of the operation comparatively bloodless and free from pain. The diseased mass, with its border of comparatively sound tissue, in the case of malignant tumour, having been removed, is carefully examined on every aspect by both sight and touch; and, if need be, the knife is re-applied where thorough removal is not assuredly apparent. The vessels having been secured, the wound is brought together and treated in the ordinary way."

Much has been recently said of the removal of malignant tumours, especially of the breast, by means of escharotics. It is always difficult to decide exactly as to whether a tumour is malignant; and from all that has hitherto been made known of these formations, it would appear that, if they are cured by general or local treatment, the inference is that they were not malignant. With regard to general treatment, the evidence is very decisive that we possess no internal remedy that has any known influence over the progress of those tumours which are truly malignant. A recent American writer has professed to remove cancerous ulcers by a general and local treatment, which has been witnessed and reported on in this country. The cases referred to were treated at the Middlesex Hospital. The general treatment consisted in the administration of iodide of arsenic and the *Sanguinaria Canadensis.* The local treatment consisted in the application of the Sanguinaria and chloride of zinc. The method employed was to make a decoction of the sanguinaria, and, with an equal quantity of the chloride of zinc, to make the whole into a paste with common flour. This paste was applied directly to ulcerated cancers; and, where the skin was unbroken, nitric acid was first employed to produce an eschar. After this process incisions were made into the tumour, and the paste was inserted into the incisions on pieces of calico. This was continued from two to seven weeks, till the whole depth of the tumour was penetrated and removed. When this was effected the application of the paste was discontinued, and the wound allowed to get well. The Sanguinaria seems to exert no effect in this treatment, and its consideration may be altogether set aside. The following passage concludes the report of the surgical staff of the Middlesex Hospital on this mode of treating malignant tumours:—

"The last peculiarity of this treatment is the practice of incisions; and we are of opinion that this is its only but its very great merit. The Sanguinaria is inert; the chloride of zinc paste was known before; but the incisions constitute a new feature in the treatment of cancerous tumours for which we find no parallel in the writings of the past, or in the practice of present surgeons. Cancer in its constitutional nature remains as ruthless and as unassailable as ever."

SUZAMNITE. [Mineralogy, *S.* 1.]

SWEDEN. In 1839, to which date the population was given in the previous article, it amounted to 3,109,772. The following table shows the increase, and also the läns or provinces into which Sweden is divided:—

Läns.	Area in Square Miles.	Population, December 31, 1855.
Malmö	1,774	268,664
Christianstads	2,421	196,121
Halmstads	1,892	110,815
Carlscrona	1,130	111,239
Wexiö	3,771	143,707
Jönköpings	4,274	166,462
Calmar	4,240	212,565
Linköpings	4,236	230,601
Mariestads	3,301	209,236
Wenerborgs	5,015	254,544
Göteborgs	1,883	195,792
Wisby	1,222	46,985
Stockholms	2,899	117,193
Upsala	2,059	90,828
Westerås	2,650	98,941
Nyköpings	2,497	123,689
Örebro	3,250	142,863
Carlstads	6,916	232,521
Falun	12,209	158,755
Gefleborgs	7,529	126,368
Hernösands	9,461	110,148
Ostersunds	19,053	55,988
Umeå	29,258	79,515
Piteå	32,893	60,108
Total	165,833	3,543,648

This area, increased by 3548 square miles of water not included in the läns, and the population column by 97,952, the number of the inhabitants of Stockholm, the capital of the kingdom, gives the total area 169,381 square miles, and the total population 3,641,600.

Manufactures.—The industrial products of Sweden comprise vast quantities of linen, which is manufactured in almost every house, woollen-cloth and other stuffs, refined sugar, tobacco, paper, leather, glass, some calicoes and other cotton goods, cotton twist, silks, china-ware, cast-iron, sail-cloth, soap, spirits, beer, &c. Ship-building is carried on to some extent in most of the harbours of the Baltic.

Internal Commerce.—The internal commerce in corn, salt, and manufactured goods, especially the linens of Wenerborgs-Län, which are carried to the most remote parts of the country, is very considerable. This commerce is facilitated by the excellent roads, and in winter by the whole country being covered with snow for four or five months, which renders the conveyance of goods in sledges easy and expeditious. In summer a like advantage is derived from the navigation of the sea, which washes most of the provinces. The Trolhättan Canal is navigated by a great number of barges, which bring down to Göteborgs, for export, large quantities of iron and steel, and timber in planks and boards; and they carry into the interior corn, whiskey, salt, herrings, sugar, butter, fish, wine, and some other articles. Large barges ply also on the other canals, conveying heavy goods of different descriptions, such as bar-iron, alum, corn, salt, herrings and strömings, whiskey, bricks, and tiles. A railway has been commenced, of which a portion, from Örebro to Arboga, with a branch from Dylta to Nora, was open in 1858. It is intended ultimately to connect the Wener lake with the Malar lake, and thence with Stockholm, Arboga being a great entrepôt for iron.

Navigation and Foreign Commerce.—The Swedes are much given to a sea-faring life. Their vessels visit most of the countries contiguous to the Atlantic, and they are also employed in the carrying-trade between other countries, especially in the Mediterranean and on the coasts of South America. The mercantile navy at the end of 1855 numbered 2874 vessels (carrying together 126,236 lasts), exclusive of those carrying less than ten lasts; and 131 steamers. The total number of foreign (including Norwegian) ships that entered Swedish ports in 1855 amounted to 6733, carrying 200,880 lasts; the departures numbered 10,565 vessels, measuring 428,384 lasts. The imports were valued at 56,561,000 crowns; the exports at 63,898,000 crowns. The foreign trade extends to most countries in Europe and America. The chief imports are brought from the following countries, which are named in order of the values:—The Hanse Towns, Great Britain, Brazil, Norway, Russia, Denmark, United States, East Indies and Australia, Prussia, and the West Indies. The best customers for Swedish exports are Great Britain, Denmark, the Hanse Towns, France, Prussia, United States, Russia, and Portugal.

The principal articles of export from Sweden are iron and timber. Norway takes a considerable quantity of iron, and sends fish in return. Stockholm receives from Finland three-fourths of the fire-wood which it consumes, the northern provinces not being able to supply the article either so cheap or so good. Finland also exports to Stockholm meat, butter, cheese, bacon, flour, hides, pitch, and tar. Other articles of export are copper, cobalt, alum, tar, pitch, hemp, oil, paper, tree-bark, tobacco and snuff, bricks, furs, some linens, vessels, and some minor articles. The chief articles of import are: sugar, coffee, salt-fish, hides, cotton-twist, cotton in wool, woollen stuffs, linens, cottons, wine and brandy, wool, dye-stuffs, raisins, almonds, pepper, cinnamon, arrack and rum, butter, bacon, tobacco, soap, train-oil, ginger, lacquered ware, tea, tallow, potashes, and oil.

Education.—Sweden has two universities, Upsala and Lund. The average annual attendance at the former is about 1000 students; at the latter, between 400 and 500. There are besides, 12 gymnasia for higher instruction, preparatory to the universities; 41 lardoms skola, or grammar schools, and 40 apologist schools, where the common branches are taught, with, in some instances, French and German. For elementary education, the law of 1842 commanded the erection of a school in each commune or parish. Owing to the sparseness of the population this was found to be in many instances impracticable; in such cases however the communes are divided into districts, each of which is visited in turn by ambulatory schoolmasters. Schoolmasters are trained by government and paid by the communes in kind. In 1850 there were 2107 stationary and 1351 ambulatory schoolmasters. Of the masters, 218 were clergymen and 690 church clerks. In that year, 143,526 children were receiving instruction in the stationary schools, 126,178 in ambulatory schools, 128,996 were instructed at home, 6223 in the secondary schools above named, and 17,465 in private schools, making a total of 422,388 altogether under instruction. It is a general practice in Sweden for parents, especially those who live in the country, to instruct their children in the long winter evenings.

Finance, &c.—The income of the state has been calculated for 1856 and 1857 at 14,358,300 crowns; and the expenditure at 12,876,920 crowns; but in the budget proposed for 1858, 1859, and 1860, the receipts are set down at 25,427,500 crowns, and the expenditure at 24,217,000 crowns. These sums are for Sweden independent of Norway. The strength of the army and navy are stated under Military and Naval Forces, *S.* 2. The present king, Oscar I., succeeded his father in March, 1844.

SYCAMORE-FIG. [Ficus.]

SYLVIADÆ. The following is a list of the British species of this family, as given in Yarrell's 'British Birds':—

Accentor alpinus, Alpine Accentor.

A. modularis, the Hedge Accentor, or Hedge-Warbler.

Erythaca rubecula, the Redbreast, or Robin. [Erythaca, S. 2.]

Phœnicura Suecica, the Blue-Throated Warbler. [Blue-Breast.]

P. ruticilla, the Redstart. [Warblers.]

P. tithys, the Black Redstart.

Saxicola rubicola, the Stonechat. [Warblers.]

S. rubetra, the Whinchat. [Whinchat.]

S. œnanthe, the Wheatear. [Wheatear.]

Salicaria locustella, the Grasshopper Warbler.

S. phragmites, the Sedge Warbler. [Salicaria, S. 2.]

S. luscinoides, Savi's Warbler. [Salicaria, S. 2.]

S. arundinacea, the Reed Warbler. [Salicaria, S. 2.]

Philomela luscinia, the Nightingale. [Nightingale.]

Curruca atricapilla, the Black-Cap Warbler. [Black-Cap.]

C. hortensis, the Garden Warbler.

C. cinerea, the Common Whitethroat. [Whitethroat.]

C. sylviella, the Lesser Whitethroat.

Sylvia sylvicola, the Wood Warbler.

S. Trochilus, the Willow-Warbler.

S. hippolais, the Chiff-Chaff.

Melizophilus Dartfordiensis, the Dartford Warbler.

Regulus cristatus, Golden-Crested Regulus. [Regulus, S. 2.]

R. ignicapillus, Fire-Crested Regulus. [Regulus, S. 2.]

R. modestus, Dalmatian Regulus. [Regulus, S. 2.]

(Yarrell, *History of British Birds.*)

SYMONDS, REAR-ADMIRAL SIR WILLIAM, C.B., F.R.S., Surveyor of the Navy, was born on the 24th of September 1782, entered the navy at an early age, and during the early part of his career was much engaged in active service on the coasts of France and Spain, and in the West Indies. But his reputation chiefly rests upon his skill as a naval architect. Notwithstanding the innovation in established usage which had been made by the genius and vigour of Seppings [Seppings, Sir Robert, S. 2] destroying the force of those prescriptive restraints which had so long trammelled the older ship-wrights, enterprise in naval architecture was still checked by the custom of building ships of certain dimensions, which had been officially established, and a restriction with respect to tonnage was always imposed on constructors. It remained for Commander Symonds to procure the removal of this restriction. He was first allowed, but under, it is said, a very unusual and restrictive penalty, to construct a corvette, the Columbine. To her he was appointed, December 4, 1826, and so great was the success which attended him in the experimental cruises he made during the next twelve months, that he was advanced, as a reward, to post-rank, by a commission bearing date December 5, 1827. In these cruises the sailing qualities of Captain Symonds's ship were compared with those of other ships constructed respectively by Sir Robert Seppings, the School of Naval Architecture, and Captain Hayes. And although no fact directly conducive to improvement in naval architecture was established by these and subsequent trials, it was found that great superiority in cruising was exhibited by the Columbine, and the zeal and devotion of Captain Symonds were farther rewarded. At the beginning of 1831, by the munificence of the late (fourth) Duke of Portland, he was enabled to build, as an improvement upon the Columbine, the 10-gun brig Pantaloon, the triumph of which vessel led to the construction, under his superintendence, of the Vernon 50, Vestal 26, Snake 16, and other ships. Improved velocity and greater stability, obtained by great breadth of beam, and diminution of breadth immediately below the water-line, were the characteristics of these new vessels. The restriction arising from the prescribed limit of tonnage was first broken through in the case of the Vernon, which Captain Symonds was allowed to construct free from that impediment. And, even whilst she was upon the stocks, she was considered to present such excellent qualities, that it was deemed Captain Symonds had already given sufficient proof of his skill in naval architecture to be entitled to the highest post and responsibilty in that profession. In 1832 on the 9th of June, he was offered, and accepted, the office of Surveyor of the Navy, in succession to Sir Robert Seppings. This appointment was associated with the entire removal of restriction as to the amount of tonnage in ships of the navy. Captain Symonds therefore had liberty for the exercise of judgment and talent in designing ships, which had not been granted to the commissioners or surveyors of the navy before; so that he might at once build ships on the best conditions of excellence that both science and practice had yet indicated. This freedom from conditions in determining the dimensions of ships, was taken ample advantage of by him; having a great principle to bring out in practice, he applied it with a decision, which, in a short time, altered the general character of no inconsiderable part of our navy. He had the merit of having boldly taken the lead in a path which future constructors, intending to carry on improvements in our ships, may pursue with the highest advantage. Considerable difference of opinion exists as to the value of the totality of qualities possessed by Captain Symonds's ships; but it was remarked in 1849, two years after he had retired from office, that of the 180 vessels of different kinds, built during the period of sixteen years, for which he was surveyor of the navy, and all upon the same principles of construction, as already noticed, and as originally adopted in the Pantaloon, none had foundered.

Captain Symonds received the honour of knighthood in 1836. He had received the thanks of the Admiralty in 1830 for a memoir containing 'Sailing Directions for the Adriatic Sea;' and again, in 1837, for "the valuable qualities of his several ships, and for improvements introduced by him into the navy;" he was elected a Fellow of the Royal Society on June 4th, 1835, and nominated a C.B. of the Civil division in 1848. In 1854 he became a Rear-Admiral on the retired list. He died, March 30, 1856, on his voyage from Malta to Marseille.

(O'Byrne, *Naval Biographical Dictionary*; Fincham, *History of Naval Architecture, &c.*)

SYNÆTHERES. [Porcupines.]

SYNAPTÆ, a family of *Echinodermata*, belonging to the order *Holothuriadæ*. It is characterised in this order by the absence of suckers. It is represented in the British seas by the genus *Chirodota*, which has a cylindrical and vermiform body, elongated tentacula, digitate at their extremities.

C. digitata has a vermiform body, white with orange spots, the tentacula long, pedunculated, digitate. This animal was first found by Montagu on the shores of South Devon. It is very rare. Professor E. Forbes, in his 'History of British Star-Fishes,' says that he never had seen a living specimen.

SYNAPTASE. [Chemistry, S. 2.]

SYNGNATHIDÆ, a family of Fishes, embracing, according to some authors, the Pipe-Fishes, the Sea-Horses, and the Winged Sea-Horses. These forms are sometimes assigned to distinct families, as in the following definitions:—

Syngnathidæ, Pipe-Fishes.—Body prolonged, slender, linear, or angulated; snout greatly prolonged, cylindrical; mouth terminal, vertical. Ventral fins absent; caudal fin wanting in some.

Hippocampidæ, Sea-Horses.—Head and body compressed; snout narrow, tubular; mouth terminal. Pectorals small; dorsal single; caudal fin wanting.

Pegasidæ, Winged Sea-Horses.—Body broad, depressed; snout suddenly contracted, narrow, somewhat protractile; mouth terminal, beneath. Pectorals generally large; caudal fin small.

They all agree in having the endo-skeleton partially ossified; exo-skeleton ganoid; gills tufted (hence the group is named *Lophobranchia*), in the opercular aperture being small, and the swimming-bladder without an air-duct. We shall illustrate this family by a short description of the British species:—

Syngnathus has the body elongated, slender, covered with a series of indurated plates arranged in parallel lines. Head long; both jaws produced, united, tubular. No ventral fins.

In certain of the species the males are furnished with an elongated pouch under the tail; these are called marsupial, and include the British species *S. Acus* and *S. Typhle*.

S. Acus, the Great Pipe-Fish, is one of the most common forms of the genus. It is found on many parts of the coast, sometimes at low-water amongst sea-weeds; at other times in deep water. The most curious feature in the economy of this fish is the fact that the roe is transferred from the belly of the female to the pouch of the male.

S. Typhle (Linnæus), the Deep-Nosed Pipe-Fish, Lesser Pipe-Fish, or Shorter Pipe-Fish; *Acus Aristotelis* and *Typhle antiquorum* of Willughby. This fish is distinguished from the last by the more compressed form of the jaws. From the British species it is distinguished by the possession on the part of the male of a pouch for the reception of the ova. The habits of this fish resemble those of the last.

S. æquoreus, the Æquoreal Pipe-Fish. This fish has no subcaudal pouch. It is comparatively rare on the British coast.

S. anguineus, the Snake Pipe-Fish. Although this and the preceding species possess no subcaudal pouch, the ova after exclusion from the female are carried by the male in separate hemispheric depressions on the external surface of the abdomen.

S. ophidion, the Straight-Nosed Pipe-Fish, is known by its straight nose. It is about nine inches in length.

S. lumbriciformis, the Worm Pipe-Fish, is the smallest of the British species. It has been taken on various parts of the coast. It does not exceed five inches in length. The young of this species have been observed to undergo a curious metamorphosis. On their escape from the egg the tail is covered with a fin-like membrane, and it also possesses pectoral fins. During their growth the caudal membrane and pectoral fins are absorbed.

Hippocampus.—The jaws are united and tubular, the mouth placed at the end. The body compressed, short, and deep. The whole length of the body and tail divided by longitudinal and transverse ridges, with tubercular points at the angles of intersection; both sexes have pectoral and dorsal fins; the females only have an anal fin; neither has ventral or caudal fins.

H. brevirostris, the Sea-Horse, or Short-Nosed Hippocampus, is occasionally met with on the British coasts. The habits of these creatures are very singular. When swimming about they maintain a vertical position, but the tail is ready to grasp whatever meets it in the water. It quickly entwines in any direction round weeds or other objects, and when fixed the animal intently watches surrounding objects, and darts at its prey with great dexterity. When two are together they often twist their tails together. Their eyes move independently of each other, as in the chameleon.

Pegasus has a snout as in the previous genera, but the mouth is under it, and moveable. Two distinct ventral fins behind the pectoral, which are often large, hence the name of *Pegasus*, or Flying Horse. The species are found in Indian Seas.

T

TAHITI. [Otaheite.]

TALFOURD, SIR THOMAS NOON, Knt., was born January 26, 1795, at Doxey, a suburb of the town of Stafford, where his mother was then on a visit. His birth was premature. His father was a brewer at Reading in Berkshire. His mother was a daughter of Thomas Noon, minister of a congregation of Independents in that town, to which sect his father also belonged. Thomas Noon Talfourd was educated at the grammar-school of Reading, under Dr. Valpy, for whom he always entertained an affectionate respect. In the year 1813 he was placed for legal instruction under Mr. Chitty, the special pleader, and in 1817 commenced practice as a special pleader on his own account. During many years of the earlier part of his residence in London his income was derived chiefly from his literary labours, as a contributor to the 'London Magazine,' the 'New Monthly Magazine,' and other periodicals. He was called to the bar by the authorities of the Middle Temple, February 9, 1821, and in 1822 he married the daughter of John Towell Rutt, Esq., of Clapton, near London, the editor of Dr. Priestley's works. He soon afterwards joined the Oxford Circuit. By steady application, rather than by any peculiar aptitude or liking for the law, he gradually rose in his profession. He was a fluent speaker, distinguished by feeling and fancy, more than by argumentative powers. After about ten years practice he applied for a silk gown, but his claim of the dignity of Queen's counsel was deferred till his patience was exhausted, and he therefore, in Hilary Term, 1833, assumed the coif, and became Mr. Serjeant Talfourd. He was also for some years Recorder of Banbury.

At the general election in 1835 Mr. Serjeant Talfourd was returned to parliament as one of the members for the borough of Reading, Mr. Fyshe Palmer, the previous liberal member, having retired. In 1837 Mr. Palmer again came forward, and was returned with Mr. Talfourd. At the next election two conservatives were returned, and Mr. Talfourd was out of parliament from 1841 to 1847, when he was again returned for Reading, and retained his seat till July 1849, when he vacated it on his being appointed successor to Mr. Justice Coltman in the Court of Common Pleas, on which occasion he also received the honour of knighthood. As a member of the legislature Mr. Serjeant Talfourd may be said to have added two valuable enactments to the statutes of the realm—the Custody of Infants Act (2 & 3 Vict., c. 54), and the Copyright Act, which he first introduced in 1837, but which was strongly opposed, and was not passed into a law till 1842 (5 Vict., c. 45), when he was not a member of parliament, and then in a modified form.

During all this period of legal and parliamentary activity Mr. Talfourd continued his labours in literature. He was for several years law-reporter of circuit cases for the 'Times' newspaper, and he continued to contribute to the 'New Monthly Magazine,' and also to the 'Retrospective Review,' the 'Edinburgh Review,' the 'Quarterly Review,' and the 'Law Magazine,' to which last he furnished in January, 1846, an able article 'On the Principle of Advocacy in the Practice of the Bar.' In 1835, he printed for private circulation two editions of his tragedy of 'Ion.' On the 26th of May, 1836, the tragedy was acted for the benefit of his friend Mr. Macready, at Covent Garden Theatre, and at the same time was published. It was afterwards acted with success at the Haymarket Theatre, and elsewhere. The tragedies of the Greek dramatists were occasionally performed by the scholars at Dr. Valpy's school in Reading, and there Mr. Talfourd acquired his taste for dramatic literature. The first two privately printed editions of his tragedy of 'Ion' were dedicated to his venerable master, who, however, died before it was acted, and then a 'Notice of the late Dr. Valpy' was "prefixed instead of Dedication to the first published Edition of Ion." The title is borrowed from the 'Ἴων' of Euripides, which also suggested the leading incident of a foundling youth educated in a temple, and assisting in its services, but nothing more. His next tragedy, 'The Athenian Captive,' was published in 1838, and was performed in the same year at the Haymarket Theatre with moderate success. This tragedy was succeeded by that of 'Glencoe, or the Fate of the Macdonalds,' first represented at the Haymarket, May 23, 1840. 'The Castilian,' an Historical Tragedy, in Five Acts, was published in 1853, but was not acted. In none of these tragedies does he display much of what may be properly called dramatic skill, nor does he excite that kind or degree of interest which arises from distinctness and discrimination of character, depth of emotion, and truthfulness of thought and expression. They may be rather regarded as dramas of poetic sentiment and description. The blank verse is smooth, graceful, and "in linked sweetness long drawn out," bnt all the individnals use indiscriminately the same elaborate form of expression, and the meaning is not unfreqnently rendered obscure by the redundancy of the diction.

In 1837 Mr. Talfourd published the 'Letters of Charles Lamb, with a Sketch of his Life,' 8vo. In 1848, after the death of Lamb's sister, he published 'Final Memorials of Charles Lamb, consisting of Letters,' &c. 2 vols. 8vo, a domestic tragedy of the most affecting interest, which had been long known to a few friends, bnt was not till then disclosed to the pnblic. [LAMB, CHARLES.] On the 20th of June, 1844, he was created a Doctor of Civil Law by the University of Oxford. In 1845 he published 'Vacation Rambles and Thoughts, comprising the Recollections of Three Continental Tours in the Vacations of 1841, 1842, and 1843,' 2 vols. 8vo, and in 1854, a 'Snpplement to the Vacation Rambles, consisting of Recollections of a Tour through France to Italy, and Homeward by Switzerland, in the Vacation of 1846,' fcap 8vo. The journeys were all rapidly made, and the information which the volumes contain is very scanty. Some of his speeches as an advocate and also as a member of parliament were published in a separate form. He was an eloquent speaker, and had extraordinary command of language, but his style was too florid to be very effective. His repntation is that of a sound lawyer for deciding cases, at the same time that his persevering labour, great practice, and love of justice, made him respected both as an advocate and a judge. In his private character he was amiable and social in an eminent degree, and he had a large circle of friends, chiefly literary and legal.

The death of Mr. Justice Talfourd occnrred on the 13th of March, 1854. He had opened the assizes at Stafford on Saturday the 11th, and on Monday morning, while delivering his charge to the grand jury, and commenting on the increase of crime and its causes, he was observed to be much excited. Suddenly his face became flushed, his head bent forward, and his body swayed on one side. He was immediately borne ont of court to the jndge's chambers, where it was found that he had ceased to live. He was bnried in the cemetery at Norwood, near London. He left issne three sons and two daughters. In 1855 the members of the Oxford Circuit placed a bnst of him, sculptured by Longh, in the Crown Court at Stafford. It is an excellent likeness.
